"Step after step the ladder is ascended."—GEORGE HERBERT, *Jacula Prudentum*.

THE TROPICAL AGRICULTURIST:

A

MONTHLY RECORD OF INFORMATION

FOR

PLANTERS

OF

Tea, Coffee, Cacao, Cinchona, Sugar, Rubber, Tobacco, Palms, Spices, Rice,

AND OTHER PRODUCTS,

SUITED FOR CULTIVATION IN THE TROPICS.

[ISSUED ON OR ABOUT THE 1ST OF EACH MONTH.]

COMPILED BY

A. M. & J. FERGUSON,

of the "Ceylon Observer," &c.

"It is both the duty and interest of every owner and cultivator of the soil to study the best means of rendering that soil subservient to his own and the general wants of the community; and he who introduces, beneficially, a new and useful *Seed*, *Plant*, or *Shrub* into his district, is a blessing and an honour to his country."—SIR J. SINCLAIR.

A. M. & J. FERGUSON: COLOMBO, CEYLON.

The "TROPICAL AGRICULTURIST" can be obtained from, or advertisements for it sent to, the following agents:—

London:—Messrs. TRÜBNER & Co., 57 & 59, Ludgate Hill; JOHN HADDON & Co., 3, Bouverie St., Fleet St.; GEO. STREET & Co., 30, Cornhill; F. ALGAR, 11 and 12, Clement's Lane, Lombard St.; BATES, HENDY & Co., 37, Walbrook; COWIE & Co., 17, Gresham St.; GORDON & GOTCH, St. Bride St., Ludgate Circus; CALRE, SON & PLATT, 85, Gracechurch St.; W. MDCCCLXXXVII.

PRINTED AT THE "CEYLON OBSERVER" PRESS: COLOMBO, CEYLON: 1887.

TO OUR READERS.

In closing the Sixth Volume of the "Tropical Agriculturist," we have but to repeat what we have said on similar previous occasions, in directing attention to the large amount of useful information afforded, and to the great variety of topics treated in our pages. From month to month, we have endeavoured to lay before our readers the latest results of practical experience and scientific teaching in all that concerns tropical agriculture; and our ambition has been to make this periodical not only indispensable to the planter, but of service to business men and capitalists, never forgetting that agriculture trenches upon every department of human knowledge, besides being the basis of personal and communal wealth.

While directing our attention chiefly to the products prominently mentioned on our title-page, we have never omitted to notice minor industries likely to fit in with tropical conditions; and our readers have an ample guarantee in the pages before them, that, in the future, no pains will be spared to bring together all available information both from the West and East, the same being examined in the light of the teachings of commonsense as well as of prolonged tropical experience in this, the leading Crown and Planting Colony of the British Empire.

The official Reports on the Royal Botanic and Economic Gardens in Ceylon are republished in full in the present volume, and throughout our pages will be found reviews of, and extracts from, the Reports of other Botanic Gardens situated in or near the tropics. We are ready to give copious extracts from, if not to reprint *in extenso*, the Reports of all other sub-tropical Public Botanic Gardens which may reach us. Most of these Reports we already receive and utilize as above-mentioned for the benefit of our planting readers.

A full and accurate Index affords the means of ready reference to every subject treated in this, the sixth volume, which we now place in our subscribers' hands, in full confidence that it will be received with an amount of approval, at least equal to that which has been so kindly extended to its predecessors.

We are convinced that no more suitable or useful gift can be made to the tropical planter or agriculturist, whether he be about to enter on his career, or with many years of experience behind him, than the half-dozen volumes of our periodical which we have now made available. They are full of information bearing on every department and relating to nearly every product within the scope of sub-tropical industry.

In conclusion, we have to tender our thanks to readers and contributors, and our wish that all friends may continue to write instructively and to read with approval; for then, indeed, must the "Tropical Agriculturist" continue to do well.

A. M. & J. FERGUSON.

Colombo: 7th June 1887.

INDEX.

A.

CEYLON AS A PLANTING FIELD OF ENTERPRIZE FOR YOUTH.

It is curious to note, how, during the course of a long connection with Ceylon, it has been found necessary at almost recurrent periods to vary the advice to be given to parents seeking a field in which their sons may commence life. "What shall we do with our boys?" is a question constantly heard in England from parents and guardians. Only a short time back, we were obliged to tell such that this colony presented no opening; that the market for young men was overstocked; and we had to instance to them the numerous cases of sad distress which were witnessed among us. We do not say that we should be altogether justified in changing the tone of that advice even now as regards those who may desire to select Ceylon solely with a view of obtaining employment. It will be some time yet, we fear, before the demand for young Europeans at a rate of pay commensurate with their wishes, and even needs, can render it desirable that any considerable influx of such men should be counselled. But there is another class for whom, perhaps, the condition of affairs in Ceylon and the prospects it opens out, will shortly offer a singularly eligible opportunity. We feel, therefore, that we may well direct the attention of parents in England to the opening this island is now developing for their sons, who may have the prospect before them of ultimately being able to invest capital.

Some years have passed since we were able to make a recommendation of such a character, and there is no doubt that instances of ill-success during the prevalence of the depression which has throughout those years characterized our planting industries have given this colony a bad name at home. Parents who some ten years back looked to a start in Ceylon as ensuring to their sons a prosperous future, have long ceased to regard the island in such a light, and have preferred to send them even to the distant farming lands of Manitoba and British Columbia rather than here. We have been so repeatedly appealed to for our opinion on the subject of this island as affording an opening for the start in life of British youth, and have for so long a time past deprecated its selection, that it is doubly a pleasure for us now to feel justified in improving the position in this respect that it has lately occupied.

We may feel confident, however, that the distrust we have above alluded to will not suddenly be removed. It has been engendered by conditions which have unfortunately been too long existent to justify any hope that it can be so: nor have we failed, when personal reference has been made, to insist on the desirability of further waiting before sending out young men with the object of future investment in Ceylon planting pursuits. A great responsibility necessarily rests upon those who tender advice upon which the life of a youth just entering upon manhood may be ultimately wrecked. We have felt this responsibility often weigh heavily upon ourselves, and have constantly refrained even when of late we had felt almost justified in endorsing the desire of many friends to send out young men to begin life as planters among us. That hesitation, we now feel assured, need no longer be felt. We are satisfied that the improvement in our planting prospects has every chance of being permanent and progressive, and under that impression we desire no longer to tell our friends in England to wait, but, on the contrary, to assure them that the present time affords opportunities for their sons, of which they will do well to avail themselves.

It is in a transition time, indeed, that such opportunities have a specially favourable character. One or two thousand pounds sterling judiciously invested within the next few years, will, we believe go as far as double the amount will do later on in the history of our tea-industry. We cannot and ought not to forget the lessons of the past, how land rose to a price at which, although it was eagerly bought, it could offer no prospect of remunerative cultivation. It was the eager, the almost insane, rush after land when selling at such rates that contributed greatly to intensify the distress which was afterwards experienced when bad seasons, and that fell enemy of our coffee trees, the leaf disease, afflicted us. We desire therefore never again to witness such a mania for speculation in land as we saw during the years 1872, on at intervals, to 1878. But we feel that if this is to be avoided, young men possessing capital must begin their career here before increasing scarcity of land brings about any chance of a recurrence of what took place during those years. A youth coming out now might well serve an apprenticeship to planting in all its branches including of course, tea preparation, for a term of say three years. The rule of thumb no longer applies to estate cultivation in Ceylon. It has become a science, one that requires to be studied before success can be hoped for. An aspirant for that success should, while learning the methods which alone can ensure it, make himself acquainted not alone with the routine of tea cultvation and preparation, but with those peculiarities of soil and situation, knowledge as to which can alone fit him to select judiciously for his operations where experience has prepared him to undertake them. With the reservation, therefore, that in all cases this preliminary training should be submitted to before investing, we feel that we can, with sincerity, recommend fathers and guardians once again to regard Ceylon favourably as affording the prospect of a successful career to English youths.

"THE CEYLON DIRECTORY AND HANDBOOK."

THE CHANGE IN THE COLONY IN EIGHT YEARS.

(Communicated.)

The Ceylon Directory for 1885-86 duly reached me, and I must really add my testimony to the many complimentary remarks on its usefulness, already published by you. In my library I have the guides and directories of almost all our colonies, but none of them can compare, in the smallest degree, with the Ceylon one, which is not only a Directory but contains a general outline of the history of the whole country and an immense amount of information of various other kinds. Comparing the present volume with that of 1876-78, which I brought home with me, when I left Ceylon, I find the new one larger and more complete, and in every way better, although, at the time the other one was published, I thought it could not be more complete than it was. In some respects the matter which is contained in the new directory, is not pleasant reading: for, on turning up the list of estates in the old district, in which I lived so long, I find several estates abandoned; one of the best ones, now in the hands of a native, has been abandoned to the extent of more than one-third of its acreage; and another, which, in my day, had over 200 acres of coffee, now only

returns a few acres of cardamoms; the group of estates which had the character of being the best in the district has dropped from 750 acres cultivated to 520, whilst one estate, which was considered a second-rate one in my time, has added 50 acres to its cultivated area, and as I was told the other day by one who ought to know, is far the most valuable estate in the district, thanks to good management. The ups and downs of these estates I suppose are on a par with those of other districts, and it is interesting to read the information and to try to account for the difference between then and now, whether bad management, short funds or worn-out soil has most to answer for. Although many old names are wiped out of the list of the estates, they are not singular in this respect, for on reference to the list of Colombo firms I find no less than twelve well-known and well-to-do ones have been withdrawn.

But these drawbacks do not appear to have interfered with domestic arrangements, for I find that the population of the island has gone up 300,000 and this in spite of a decrease of Tamil immigrants from 164,000 in 1876 to 45,000 in 1885. All the centres of population appear to be adding to the number of their inhabitants in a most marked manner, except poor Galle, which has dropped from 47,000 to 33,000.* Under the heading "Occupations of the People," I find only 2,719 returned as coffee-pickers, and yet, ten years ago, that number would have been attached to the mills of one firm alone in Colombo—but coffee was King then. In the class called "landed proprietors," there are entered 452 males and 1,525 females. This seems strange to me, but not more strange than the fact that, in the commercial class, there appears under "tavalam *men*," one *female*, and that there are 47 female barbers in the island. Woman suffrage will soon follow this, I fear!! Reading a dictionary or a Directory is supposed to be dry work—but, to any one, at all interested in Ceylon, the reading of the "Ceylon Handbook and Directory for 1885-86" will be not only agreeable, but entertaining and instructive.

COSMOPOLITE.

"THE CEYLON TEA PLANTER'S CATECHISM,"

Ought to be the title of the information collected under the auspices of the Maskeliya Planters' Association when the same is republished in a complete form with the questions and answers duly following each other. Today we find room for the very full summary sent us by special arrangement with the Sub-Committee through the Honorary Secretary, Mr. Welldon. We think that the thanks of their brother-planters not only in Maskeliya, but throughout the island have been earned by the Sub-Committee for the considerable amount of useful practical information brought together in a concise form in their summarizing Report. Could a better illustration be afforded of the untiring, almost insatiable craving of the Ceylon planter for "more light" in reference to every branch and detail of his profession? Here we have a body of men in one district,—and that not the largest or most important in the island,—and although they have had several gentlemen of experience to lecture before them, though they have had all the essays locally published and all the practical books, we and others have been able to introduce from India—from Money's prize essay to Dowling's "Notes"; from the Vade Mecum to Brace's papers in our Handbooks for 1874-5—yet, they are not content. They resolve to get at the diverse opinions of the men of most repute in different parts of the island, as cultivators and makers of tea. They form a Sub-Committee: draw up a series of questions: have the same printed and circulated; and the result does not disappoint them. The typical Ceylon planter is as ready to give as to receive information, and although the Maskeliya catechism was laughed at in some quarters, the result has fully justified the trouble taken, as our columns testify today. The names of the gentlemen who have furnished answers based on their own experience—apart from Mr. Barber's special report—afford ample guarantee for information of very considerable practical value, representing too a variety of districts at different elevations and with differing conditions. Now it is this spirit of enterprise and restless enquiry among our planters that have justly earned for Ceylon her high reputation in connection with the agricultural industries carried on within the island. There is nothing like it, at least in Northern India; and if so much has been done here almost at the very outset of the enterprise to examine, check, simplify and improve all the details of the cultivation and management of the tea-bush, and the preparation of the leaf, how much more may we not look for as time rolls on? In Tea Machinery alone, how much of invention and improvement is likely to be due to Ceylon planters. Full credit is given in the Report before us, as to the—in some respects—unequalled position attained by Jackson as a machinist, whether in his Rollers, Driers, or Sieves, and if this leading patentee succeeds with the Witherer he is now said to be busy on, at home, he will indeed have furnished a series of machines of unique importance in the Tea-planting world. But it is undoubtedly encouraging to learn how Ceylon planters and colonists are following hard on the men of many years of Indian experience: Barber's Roller is an illustration, though it is said to owe much, very much, to Thompson's "Challenge"; more local is Frater's Uva Roller *par excellence;* and now we have Kerr's improved roller, costing no more than R350; while just as we write we hear that under Davidson's and Law's patent, a very serviceable Roller nearly all in hard wood, jarrah perhaps—will be offered for as low as price as R250, guaranteed to do all that is required on a small garden and to give the utmost satisfaction in the quality of its work. What Fairweather and Megginson have done in the improvement of Withering arrangements is duly noticed; and there are several other suggestions both as regards appliances, and the several modes of plucking and manufacture which are certain to arrest attention and to be subjected to the test of experience, or to searching criticism.

One result mentioned is rather startling in the high amount named for the cost of erection and fitting up of a suitable Tea Factory, for a plantation of 200 acres, namely R12,000 to R15,000. This, however, is likely to be modified as time runs on. But what are we to say to the force of 300 coolies required to work 200 acres of tea? At this rate for the 150,000 acres likely to be under tea before 1886 closes, we shall have to provide a force of 225,000 coolies. Altogether therefore in Ceylon, over 300,000 labourers will be required on the plantations for tea, cacao, coffee, cinchona, &c. and even with all the assistance that Sinhalese may give, our draft on Southern India must be greatly increased. We have no doubt however, that it will meet with a full response in due season.

Altogether, it is very satisfactory to learn that the Maskeliya Sub-Committee arrive at the conclusion that careful planters under average cir-

* The limits of the town have been circumscribed. —ED.

cumstances as regards climate, soil, jat of tea, &c., in Ceylon, ought to turn out their tea at not more than 24 cents per lb. This is enough to warn our Indian and even China competitors of what they have to expect. "No more planting"—ought to be the cry in both Northern and Southern India—"until we are better able to judge what the 150,000 to 250,000 acres of tea in Ceylon are really going to do." But, whoever yet took warning after this fashion? Nevertheless, we may, with the Maskeliya Report before us, well believe that in the coming tea struggle, Ceylon will hold her own, and that if we are to see the "survival of the fittest," the position of our little island ought to be well in front.

TEA PREPARATION IN CEYLON.

RESULT OF ENQUIRY BY SUB-COMMITTEE OF MASKELIYA PLANTERS' ASSOCIATION.

ANSWERS TO QUESTIONS BY SOME 16 PRACTICAL PLANTERS.

PAPER BY MR. BARBER.

QUESTIONS ON TEA CULTIVATION.

We have seen the questions on tea manufacture sent out by the Maskeliya Planters' Association, and we would ask any of our readers who receive them to reply to them, as we feel that the answers of the 100 tea manufacturers to whom the questions have been sent, carefully collated, will be an extremely important addition to our information on tea, and will probably be a means of still further improving manufacture and raising the repute of Ceylon produce in the London Market. As the report will be published, each of those who reply will benefit by the information obtained from the replies of the others. So we hope no one will refuse to assist as far as he is able. Every effort has been made by the Committee to save those applied to trouble, even to supplying stamped directed wrappers for the return of the paper. It is by such means as this that District Associations really do good, and the Maskeliya Association has always been well to the front. These questions are a continuation of the work commenced by the Dimbula Association, and we hope the Dikoya Association will not be behind in this kind of work.

The questions are as follows:—

PLUCKING.

1.—Defining fine plucking—leaving the bud leaf and ¾ of the next leaf and plucking including the tip 2¾ leaves—and coarse plucking—leaving 1 proper leaf, ½ the second and ¾ of the next, *i.e.*, plucking including the tip 2¾ and a half leaf—which do you consider most trying to the tea tree?

2.—If by the latter method 500 lb. tea per acre was obtained, about how much per acre do you think could be obtained by the former—other circumstances being equal—and what would be probable difference per lb. in value of the tea made?

3.—Off old and young bushes should bangy below pruning level be plucked, should the flower be pulled off?

4.—How do you pluck first four rounds after pruning?—and do you pluck high class and inferior jat the same way?

5.—Do you use cutty sacks or baskets for pluckers?

WITHERING.

6.—Do you sift green leaf?—What kind of sifter do you use?

7.—Do you take off water from wet leaf before putting it out to wither?—and if so, how?

8.—Do you advise hard withering or if anything slightly under-withering?

9.—Is natural withering better than sun or artificial withering?—and of the latter which do you prefer?

10.—Is a draught of air and much light good for withering?

11.—What kind of withering tats are best?—For 1 lb leaf how much room is required?

ROLLING.

12.—What roller do you recommend for a small garden?—How many lb. withered leaf will it do per hour and how much at a fill?—what horsepower is required to drive it and what is cost?

13.—(Same question for large gardens.)

14.—Do you recommend hard or light rolling?—and your reasons?

15.—If hand-rolling what is task per cooly?—and do you prefer plain or grooved table?

16.—Do you sift rolled leaf?—when and through what sieve?

17.—Do you roll twice?—if so how long?—and hard or lightly?

FERMENTATION.

18.—What is best temperature for fermenting?—how do you ferment and how long? Do you encourage or by turning stop heating during fermentation?

19.—Does roll ferment or oxidize?—how do you account for change of color?

20.—Can you advise any plan to assist fermentation or mention anything that should be avoided?

21.—How can flavor or strength be increased?

FIRING.

22.—*Chulas*—Wood supply being near what is task of charcoal per diem from dry wood?—from green wood?

23.—To 1 lb. tea how much charcoal is used?

24.—What kind of chula do you use, and have you a grating?—do you replenish charcoal from an oven?

25.—To each tray how much roll is put and how long taken to fire off?

26.—Do you fire tea quite crisp or take off a little sooner?

27.—What effect has leaving tea in tray all night over embers?

28.—Before packing do you finaly fire?—and how? and do you bulk after or before this?—If by machine, at what temperature?

29.—*Firing Machines*—Which one do you prefer?—can you suggest any improvement?

30.—At what temperature do you fire?—How much roll to a tray and how much tea per hour?—how long do you take firing each tray?—what does fuel cost per lb. tea?

SIFTING.

31.—What sieves do you use?—How do you sift or what machine is best?—What grades of teas do you make?

COST OF WORKING.

32.—Where are tea requisites of best quality obtained cheapest?

33.—What machinery, what number of coolies are required for an estate of 200 acres giving 100 lb. tea per acre?

34.—What should be cost per lb. made tea on this estate thus distributed:—

Superintendence
Plucking
Manufacture—withering, firing, sifting
Packing (final for "boxes lead")
Transport to Colombo
Cultivation, weeding, pruning, manufacturing, field, &c.?

35.—What would be approximate cost of erecting factory and machinery for the above estate?

CULTIVATION.

36.—Would you use water-wheel, turbine or engine?—what is cost of fuel per lb. made tea for the last?

37.—For withering-shed should you put iron or wood roof?

38.—What effects have you seen from manuring, digging, burying prunings, and would you do it before or after pruning?

39.—What month do you prune?—or how do you prune?—and do you treat high-class and inferior jat the same?—do you prune whole estate at once or half at one time and the rest 6 months later?

GENERAL.

40.—Do you know any invention not generally used? that if used would save labor, such as utilizing coffee machinery for tea sifting, breaking, &c.,—and can you

suggest any method that will enable us to make better teas and get higher prices?

41.—Would you eradicate really bad jât plants and trees?

42.—What do you consider the best shape and material for a cheap external withering-shed or sheds? Will yield from inferior jât at high elevation be less than yield from high class jât.

From which can best tea be made.

ANSWERS.

Report of Sub-Committee of Maskeliya Planters' Association on Tea Manufacture.

The Sub-Committe have drawn up this Report from the replies of Messrs. Jas. Taylor, T. J. Grigg, W. Turing Mackenzie, J. Roydon Hughes, H. Deane, J. N. Campbell, T. Dickson, F. L. Clements, W. Cameron, W. Raffin, Giles F. Walker, W. B. Hope, A. Cantlay, T. W. B. Crowther, S. G. Tench, R. Webster and R. Maclure, and some which were unfortunately not signed. The Committee thank these gentlemen for replying to the questions and also Messrs. Blacklaw, Cantlay, J. Ferguson and Rutherford for assistanee rendered. The Sub-Committee regret that delay in the publication of their Report has in some respects lessened its value.

Questions 1-2. The definition of fine plucking given was not universally accepted. The Committee consider the majority of the replies sent in, advise that the method of fine plucking, as defined, should be adopted four or five months after pruning in order to get the highest return per acre combined with a good average price. The replies lead them to think fine plucking as defined by Mr. Taylor (an extract from whose reply is annexed) is decidedly more trying to the bush than medium plucking, as the shoots are removed before the bush benefits by them; the difference per acre in return is put at about 150 lb. per acre in favor of medium plucking the first year, later on perhaps more; the difference of price from 2d to 3d per lb. in favor of fine plucking, the cost of the latter system of plucking being much more expensive, perhaps double. All replies agree that before fine plucking can be safely adopted the bushes must have a good plucking surface and that on no account should it be commenced until the fourth or fifth month after pruning.

(Extract referred to.)

Question not intelligible.—If the bushes be allowed to get a good start after the pruning by leaving three or more leaves on all primary shoots, there is no apparent harm from finer plucking, that is, plucking the same leaves and leaving a leaf, the same as in coarser plucking, but doing it at an earlier stage of growth. Nevertheless it is reasonable to suppose that the finer plucking must be more exhausting to both tree and soil, yield being the same. There is practically no difference in quantity and the difference in value is fully ninepence per lb. in favor of the finer plucking which costs about twice as much for plucking or nearly so.

3. Bangy leaf below pruning level at the sides of young bushes should not be plucked, but where the bushes are old and cover the ground, this is not so important. It is not generally considered necessary to search for bangy in the centre of the tree below plucking level; a few replies however state that if bangy in the centre is plucked close during drought the yield when rain comes on will be greatly increased: to pull off seed and flower though beneficial is practically impossible.

4. After pruning it is advised that for three rounds 5 to 6 inches of primary shoots above pruning level should be left, or 3 full leaves, perhaps more after a heavy pruning; after third round all primary shoots may be plucked. On secondary shoots it is at first well to leave 2½ leaves including the bud leaf. Inferior jâts should be kept lower, some however say prune lower and pluck the same; the general opinion is that if thus carefully plucked after pruning, the bush will better stand hard plucking later on.

5. Baskets are unanimously recommended. For steep faces or when plucking new flush after pruning, cutty-sacks may be used with advantage if the leaf is continually turned out.

6. In a few cases leaf is sifted through ¾ inch mesh. The sieve can easily be attached to the waterwheel, and we are surprised it is not oftener done as it certainly improves the wither and fermentation and takes off some water from the leaf and bruises it very little.

7. By spreading wet leaf thick in the sun and turning it frequently or by continual turning without sun, water can be partially taken off.

8. Hard withering is almost unanimously advised. Mr. Taylor's remarks are:—"As hard as possible to allow the rolling to be properly done, so that no yellowish or unsquashed patches of leaf may be found in outturn from the tea-pot, and so that the depth of color in the liquor be not reduced. With under-withering, rolling will also be imperfect as the mass of leaf is too soft and slushy and slips about without the tissue being perfectly squashed; and depths of color of liquor will also in that way be reduced. Besides a lot of water must be evaporated from the leaf in withering or else juice will drop from the machine during rolling."

9. Natural withering is undoubtedly the best, but rather than keep leaf over till the second day it is advisable to utilize sun or artificial heat in moderation (*i.e.* Chula or Sirocco heat). At high elevations this is often absolutely necessary. Sun withering is preferable to artificial. The result of much heat in artificial withering is bad fermentation. It is advised by some that after sun or artificial withering, leaf should be allowed to cool before rolling. Artificial withering is apt to dry the leaf.

10. Plenty of air and light are necessary for withering purposes but whether the air should be damp or dry is disputed. The direct rays of the sun should always be excluded. The cold at high elevations retards withering. Mr. Taylor considers it a question whether light, except for the heat connected with it, is not a disadvantage.

11. Messrs. Fairweather's or Megginson's system of Tats is recommended: one pound of green leaf thin spread covers 6 sq. ft. Leaf withers best on boards.

12. For small gardens Jackson's hand-roller worked by power is highly recommended It takes 45 to 50 lb. withered leaf at a fill, rolls it in 40 minutes, requires 1 to 1½ horse power; costs R550 without power fittings. This refers to the old hand roller. In the new one there is no movement of the bottom tray and it is similar in action to Kerr's old roller which is also recommended in some papers. Jackson's Universal rolls 120 lb. withered leaf in 1 hour, in two fills; costs £85 stg f. o. b. in England; requires 2 horse power. For a large garden where there is plenty of power, Jackson's Excelsior is unanimously recommended. It takes 300 lb withered leaf at a fill, rolls it in 40 minutes, requires 4 horse power; price £138 stg. in Colombo. Barber's Blackstone rollers have the advantage of doing much work in a short time and require little power; there are two of them, the "Standard" takes 100 lb withered leaf at a fill, requires 20 minutes to complete the roll, which equals 300 lb withered leaf per hour; cost R900 in Colombo. Opinions on this subject expressed now will prob-

ably be obsolete in a few months as improvements and new inventions are announced, among which may be mentioned Kerr's new roller and Frater's. In none of the papers is the Challenge referred to, but we have heard it well spoken of. The price of all rolling machines is still exorbitant, but we hope competition will before long lead to considerable reduction.

14. Hard rolling and plenty of it, is generally recommended for giving strength and body to the tea, but not for appearance, which, however, is not so much considered at home at present. Hard-rolled tea will show little tip: for a hard roll a hard wither is necessary, and for a hard wither a hard roll is necessary. As the object of rolling is to break the sap cells of the leaf, the length and hardness of the roll depends to a certain extent upon the weather and the quality of the leaf. It is advisable not to put great pressure on at the commencement of the roll as it prevents an even twist, but weight should be added later on. For fancy teas light or hand rolling is preferable.

15. Task for handrolling is 35 to 40 lb. green leaf; a plain table is generally recommended.

16. Roll is generally sifted during fermentation through a No. 4; some prefer to sift immediately rolling is completed: some about one hour after; some at the end of the fermentation.

17. A second rolling of about 10 minutes or more, and a hard one is generally recommended; the time when this rolling is done varies as the above-mentioned sifting is always done first. Second rolling is said to improve the twist.

18. Fermentation is generally done by spreading the roll about 3 inches deep on a table, turning it every ½ hour, temperature 75 to 90. 1½ to 4½ hours seems to be the minimum and maximum time for leaving the ferment. In some cases baskets are used, and the roll is kept in a cool place. Turning the roll prevents it heating and gives an even ferment. The process is supposed by some to be oxidization: only a few replied to this question. In answer to No. 18, Mr. Taylor says:—"I do not think that temperature at least within range of climate here, has very much to do with it, though I think it has a little. My time is usually two-and-a-half hours, and three hours for first roll of the day, I spread loosely to ferment in flat trays about two or three inches deep for two hours, turning it at the end of one hour; at the end of two hours I put it into a deep basket, still loosely, to ferment the rest of the time. It gets a little warm during the process, but my turning of it is to let air get more evenly at it and to break small lumps."

20. It is considered advisable to avoid great heat during fermentation as it dries the roll, also cold draughts which blacken it. Roll should not be pressed down: free access to the atmosphere should be allowed and all balls very carefully broken up. Fermentation of fine leaf is quicker than that of coarse. A hard even wither followed by hard and long rolling of good leaf give a good fermentation. A damp cloth spread over the roll in dry weather is said to hasten the fermentation.

21. A few say that light rolling improves flavor at the expense of strength. Strength is obtained by fine plucking, hard withering and rolling. It is mentioned that tea from a new clearing gives stronger liquor than that from bushes on old land. Strength and flavour depend much on soil, the jât and the altitude, and brisk firing and as little exposure to the air as possible is recommended. Mr. Taylor deprecates long fermentation as he considers it a sign of deficient rolling, and states that for tea fermented for only one hour, he has obtained a 2s average, but he considers his present ferment better.

22-3. Average task for charcoal is 80 lb. or by contract 75 lb. From coffee stumps 60 lb. per cooly has been obtained. To one pound of tea, one to three lb. charcoal is used, according as rolls can be fired consecutively or not.

24. Chulas 2 ft. 5 in. wide at top, 13 in. at bottom, 2 ft. 6 in. or 3 ft. high are usual. Replenishing from oven optional: without gratings preferred. Brick is better material than stone for building them.

25. To each tray 3 to 4 lb. of roll is put which is fired in from 35 to 45 minutes; the former preferable. Roll is generally fired quite crisp, some take it a little sooner, some take it off when ¾ dry, empty contents of three trays into one, fire over milder fires or leave over the embers at night. Unless carefully watched coolies are inclined to leave too much to the dying embers to perform. Properly carried out this system tends however to ensure the drying being perfect and is said to develop aroma. The trays should be covered to keep out rats or anything falling on the tea. If roll is taken off before it is quite crisp, thorough final firing is required it not put over the embers as aforesaid.

28. Final firing by Sirocco or Victoria is done at 150 to 200° putting 5 to 6 lb. per tray. Final firing over chulas is done over slow fires, taking ¼ to ½ hour to each tray, 5 to 6 lb. per tray; firing before bulking is perhaps preferable to bulking before firing, as the latter is apt to falsify the bulking; but in the majority of instances the former system is adopted. A piece of cloth spread over the tray and under the tea is a safeguard against burning when chulas are used.

29. The Sirocco is certainly the firing machine generally preferred. Jackson's Venetian and Victoria are well spoken of. No. 3 Sirocco fires at 240 to 280° F., 11 to 14 lb. roll, 20 to 25 min. per tray, 55 to 65 lb. tea per hour. By using coffee stumps carried when knocking off work, cost of fuel has been reduced to less than 1-6th cent per lb. tea made. Jackson's Victoria at 280° F. has fired 240 lb. tea per hour, and cost of fuel for rolling, firing and sorting was about ¼ cent per lb. tea. No. 1 Sirocco at temperature 300° F. 4½ lb. per tray, has fired 35 lb. tea per hour, 18 min. per tray, cost of fuel 1-5th cent per lb. tea. Since this information was received great improvements have been made to the Sirocco.

31. Sifting by hand Nos. 14 or 12, 10 and 8 are used for 3 grades; 12 and 7 for 2 grades are recommended; dust being taken out through No. 30. Gore's Sifter with patent mesh for taking out flat leaf. No. 8 and 12 sieves have sifted over 200 lb. bulk per hour. Bailey & Thomson's Sifters and Jackson's Eureka are well spoken of.

33. Machinery required for 200-acre garden yielding 400 lb. tea per acre.—The following machinery advised:—

Jackson's Excelsior with hand Jackson in case of accidents; or

Barber's Big Roller with a Venetian Drier and improved T Sirocco; or

Two Improved T Siroccos, price each £95 f.o.b. Liverpool; or

A Victoria and No. 1 Sirocco, a Tea Sifter, a a Jonas' or Jackson's Cutter.

It is recommended to use the old pulper-sifter for a roll-sifter and attach green leaf sifter for the water-wheel.

300 coolies will be required for an estate as above described.

34. Cost of manufacture per lb. made tea including superintendence 5c; plucking 12c; manu-

facture 3c; packing 3c; transport 1c=24 cents per lb. in Colombo.

35. Approximate cost of machinery and factory for estate as above described is from R12,000 to R15,000.

36. Water-power is best where possible. Turbine is advised; a water-wheel being a less steady power and requiring more water; the former is, however, most likely to get out of order. Cost of fuel for engine per lb. tea is ¼ cent.

38. Digging is highly recommended. The effect of castor-cake manure in one case good; in another it did not improve the quality or price of tea. Cattle manure has undoubtedly shown good results; also burying green prunings and applying other bulky manure. In very dry weather it is advised not to manure; about a month or two before or during pruning are the times preferred. Manure increases strength.

39. Two papers advise pruning all the year round to keep the labour occupied and never to have a large lot of inferior tea all at once. A few recommend pruning half from June to Sept. and half from Nov. to Jan. The majority advise from June to Sept. and get over it as quick as possible. Indigenous and hybrid can be pruned the same; bad jât hybrid is pruned after the style of China or at any rate lower and more severely than good jât. Pruning at two seasons keeps labour employed. To prune or dig in very dry weather is not advisable.

40. To be careful in every detail is the only way to make good tea. Good soil and jât help greatly, and good leaf and hard withering and rolling are advised by all. In time the whole process may be done mechanically, and at any rate great improvements in machinery may be effected.

41. When a supply has been put in and has well started near a bad jât plant in young tea, take out the bad jât, but not before; as it is difficult to grow supplies. In old tea do the best possible with the bad jât.

42. An oblong wooden building of jungle timber, boarded floor, thatched or wooden roof with plenty of light and air make the best withering shed.

43-4. One paper says in a very wet climate a medium jât will flush better than a high jât, but the majority prefer the latter. The highest class hybrid and indigenous will not yield so well, and bad jât teas will yield 100 to 200 lb. per acre less and value per lb. will be 2d to 3d less. The appearance of the bush alters with soil. In bad soil no jât will appear good.

The Sub-Committee are of opinion the falling-off in the quality of tea complained of is not owing to any weakness or disease of the tea bush and must be sought for from other causes, perhaps the recent fall in price has caused this complaint to be exaggerated.

C. E. WELLDON, Honry. Secretary.

(Mr. Barber's paper.)

BLACKSTONE, 4th Jan. 1886.

1, 2, 4.—There is but one mode of plucking that can be safely recommended for the good of the bush, as for the quality of the tea to be manufactured: an entire leaf with the bud and stem attached to it, with the best part of the leaf below it, but without the stem attached—all taken at one nip. This can be done with safety at all times of the year; except soon after pruning, when the newly-grown shoots are being nipped. Calling these shoots primaries or primary shoots here for the sake of distinction, I will recommend that for the first four rounds or so, while still plucking the primaries, that they be nipped still more sparingly, a leaf with the bud and stem attached to it being all that should be taken; an entire leaf being thus left to develop at the end of the shoot, the next flush will be retarded somewhat, and the bush in the meantimes will mature, a condition to be observed if we aim at securing quality. At this early season of the year, instead of displaying an eagerness to fall with unsparing hands on the green stalks and leaves just shooting, and glutting our withering racks and machinery with vast quantities of insipid vegetable matter, which no art or skill can convert into good tea, as turned out later in the season,—if we exercise a little forbearance, and permit the bush to grow and gradually mature, taking meanwhile just enough to keep it in shape and form, we shall be speedily compensated for the apparent loss, with an ample yield of more matured leaf, without any very appreciable reduction of quantity in yield at the end, and we shall be the better enabled to maintain unimpaired the prestige we have won for quality in Ceylon.

3. Bangy leaves below pruning level should not be plucked, I think. A vigorous shoot is not commonly found ending in a bangy terminal, where the field is duly attended to, at the regular intervals. Twigs with unsufficient supply of sap are generally not worth attention. Flowers may with advantage be pulled off when flowering, and seeding are due to a change of season or inferiority of jât. Where however the cause is to be found in poverty of soil, something more than taking away the flowers will be found necessary to be done at once, viz., manuring. When due to age of bush a treatment more heroic will have to be prescribed, viz., the knife. In some instances trees badly planted with the tap-root bent or injured also speedily run into seed.

5. Cutty sacks for plucking should not be tolerated for a moment; their use would lead to the bruising, crushing and heating of the leaf in the field.

6. I do not sift green leaf; as I sift the green "roll" I am inclined to think that the pekoes would be less liable to be broken if rolled along with the souchong.

7. I do not remove water from wet leaves before spreading to wither. I do not say it should not be done.

8. I do not advocate either under-withering or hard-withering, though it may be safer to incline towards the latter than to the former. 30 to 35 per cent for wither is a sufficient average.

9. Natural withering is better than sun or artificial withering especially for flavour. Sunning is preferable to artificial withering.

10. Light and air are among the acknowledged agents in natural withering; a draught is no disadvantage if it does not blow away the leaf.

11. The withering tats I use are similar to Mr. Fairweather's, only a little more primitive in the details and perhaps a trifle less expensive. I believe his arrangement with the wire to guide the web a better plan than mine, but in principle they are much the same. For both serving and discharging they afford greater facilities than any other withering arrangements I know of, while they have the merit of being the least expensive at the same time.

12, 13. The "Blackstone" roller, of course; as for its merits—well! are they not chronicled in the columns of the local papers? I should wish to be spared discussing rollers in this paper under the circumstances.

14. When the souchong leaf has acquired the necessary twist for a marketable tea, and the juice is readily expressed on the roll being grasped by the hand, it is time to stop rolling. Hard and light rolling being relative terms may be differently understood according to the apprehension of different individuals, but if we go by the above tests anything under it would not ferment properly, while rolling beyond it would, to my mind, be barren of profitable results. The disadvantages would be the following:—Discoloration of tip, breaking of tip, risk of getting the coarse and unwithered leaf broken up and mixed with the broken pekoe; waste of time and energy; fuel where an engine is used, and water in the case of a water-wheel being used; extra wear and tear of machinery. Where, however, early plucking is resorted

to, that is to say, within the week, the mixing up of the grades would not matter much, as the souchong itself will command an extreme price; so that we should not be in a hurry to jump to conclusions and generalize from the success of one or two estates. Among the believers in hard-rolling there are some I am aware, whose opinions are entitled to great weight. It is nevertheless, a creed that cannot be followed by one and all, indiscriminately.

15. Forty lb: is a good task for hand-rolling; a plain table is preferable to a grooved table. Rolling being a process of gradual compression and bruising combined, there should be no endeavour to hasten the progress of work by corrugating or flirting the table; as it may result in the tea getting broken up, before getting flaccid enough to be rolled, especially when found underwithered, during the wet season. The table should be not only flat but sufficiently high to prevent too much weight being put on the leaf during the process at the start.

16. I sift about 40 to 45 per cent of pekoe out of "roll" after fermentation by means of a simple sifter with No. 3. Sieve, designed by me and manufactured by Messrs. McIlwraith Walker & Sons, at a cost of R80. It takes two minutes, driven by power, to work off a 100 lb. roll. It is not patented and may be had from Messrs. W. H. Davies & Co., Colombo.

17. I re-roll for about three or four minutes, the souchong only just before firing.

18. Fermentation should be carried out in a cool room not exposed to the wind; especially the dry N. E. wind. It is a good plan to turn the "roll" over occasionally. I do not encourage heating during fermentation; on the contrary I check it. The roll is spread about two inches thick on tables for about three hours. If leaf be found to overfermented, and cannot be fired off speedily for want of chulas or *firing* machinery, adequate to the demand at the moment, the leaf should be thinned out at once.

19. Whether oxidation or fermentation be the correct word to be used for the purpose of expressing the chemical change the roll has to undergo before firing, can hardly be said to be of any practical use to us without being prepared to carry the investigation further with the assistance of scientific men. As fermentation includes oxidation I see no reason why we should change this now familiar word into one less comprehensive and probably less applicable. The first chemical change that the bruised leaf undergoes when exposed to the action of the air at a certain temperature is oxidation. We cannot say we stop at this, before the leaf undergoes fermentation. Fermentation, according to M. Pasteur, is said to be essentially the life history of certain microbes, the germs of which are to be found in the air everywhere and always. According to the suitability of any organic matter for the development of any particular variety of these microbes, a particular kind of fermentation will result. There are, it is said, innumerable species of microbes each of which starts its characteristic fermentation. It exists for a while, during which it produces a certain chemical change, by which the organic matter is rendered fit for the growth and development of another species, which in turn gives place to a succeeding variety, and so on, till all fermentation ceases. What we have now to ascertain with the aid of science, is what that particular stage or kind of fermentation is which conduces most to the development of the qualities we desiderate in tea. It is possible, I believe, for a competent chemist both to define this particular stage and to help the planter with simple means by which to ascertain the right fermentation since every kind of fermentation (every stage according to advocates of this theory) can be ascertained by means of chemical tests and the microscope.

20. Heaping up leaf.—Putting roll thickly in baskets, appears to help fermentation. But the safest mode, I think, is to spread on tables.

21. Flavour to begin with, is due distinctly to altitude; care in the details of manufacture, a good wither and full fermentation will secure flavour, as far as it can go on any given estate. But strength is a matter outside the factory. I have said before, the art of good tea making begins in the field. I do not believe that we can obtain more strength from tea leaves, by passing them through "rollers" and firing machines than there is to be found chemically in the leaf itself; briefly we cannot get more out of a roller than we put into it. But we can get far less, by neglecting the cardinal rules of tea-making. It is by careful selection of our jât of tea, attention to the soil, a rational mode of pruning, maturing our bushes, and regular plucking, instead of waiting till the leaves get bangy, that we should hope to secure strength. The student who pursues his investigations exclusively in the factory is apt to gradually nurse himself into the pleasant delusion that good tea like good wine needs no bush.

I pass over questions intended for those who use "chulas."

28. Before packing I first bulk and then re-fire at a thermal heat, not exceeding 180 for Broken Pekoe, 200 for Pekoe and 240° for Souchong.

29. I have no fault to find with the Sirocco. I think it can hold its own a good while yet.

30. In firing I keep to the instructions.

31. The sieves I use are 14 and 10 for Broken Pekoe, that is 10 for Broken Pekoe out of "dhool-ghoorie" (the 40 per cent sifted out from "roll") and 14 for Broken Pekoe left in the bulk. No. 9 for Pekoe, and Nos. 7 and 6 for breaking and sifting Souchong.

38. Manuring has a marvellous effect on tea.

39. I prune at both monsoons to find work for the coolies all the year round.

40. I have answered this already partly.

41. I cannot recommend the eradication of bad jât plants and bushes now; as if followed, it may lead to the denuding of much of the present planted area of Ceylon. The result may prove disastrous to the prosperity of the colony.

42. For external withering sheds I would recommend the use of round timber "jungle sticks" and shingled roof with jute nailed on the sides to keep off the wind. I have two such here. Hundred feet by twelve or fourteen is a good size, with jute stretched on either side on rollers and laths. Ten lengths of jute on each side giving 4,500 square feet of withering area or a total of 9,000 square feet for the room. Such a building should cost no more than R150. Boarding the floor of same R112; rollers and laths for the jute R30. The total, exclusive of jute, within R300.

J. H. BARBER.

"W. M. L." ON COFFEE IN THE PAST AND TEA IN THE PRESENT IN CEYLON.

LONDON, April 30th, 1886.

Many of those who have lost their money in the struggle to keep the coffee plant going in Ceylon must have read with deep interest, perhaps even with a melancholy satisfaction, the account given in your columns by Mr. Blacklaw of the dying out of the once flourishing coffee estates in Rio districts. The similarity of the fate of these coffee districts to that of the estates of Ceylon, though apparently without the intervention of that arch dsetroyer, Hemileia Vastatrix, raises the question, (one now purely of speculative interest to the Ceylon planters) how long even under the most favourable circumstances could coffee cultivation in extended areas as practised in Brazil, Ceylon and Java be expected to flourish?

Strange it is that this question, twenty years ago of most vital practical importance to all engaged in the cultivation of coffee in Ceylon, should even at that date have received little or no attention. The coffee estates had so far borne regular crops, were still bearing them, and "next year" almost invariably was promising a bumper.

What more could hopeful man require? Why seek to peer into the certainly uncertain future?

Between the years of 1860 and 1870 one word of warning, and one only, came to the ears of the writer. It came from one who had never seen Ceylon, from a gentleman in London of very wide experience and learning, noted both in financial and philosophical circles. His son was proposing to join a flourishing Ceylon business. But the father put an unhesitating veto on the proposal on the ground of the uncertainty of the future of coffee cultivation.

Now on what grounds had this gentleman, so early as 1866, formed so strong an opinion as to the probable doom of Ceylon coffee that on his faith therein he should be guided as to his son's career?

Can you, sir, from the fulness of your stores of information in regard to the history of the coffee plant and its cultivation, say on what grounds such an opinion may have been formed at the date named? and how it came that in spite of such causes of mistrust the feeling in Ceylon was then and continued for some years later one of serene confidence in the future.*

It was not till about 1871 that the first cries of warning were heard within the household of Ceylon itself. About that date Dr. Thwaites of Peradeniya made public his fears that Hemileia Vastatrix would in time be the death of the coffee enterprise, and among planters about the same date Mr. William Mackenzie stepped forward as the prophet of the doom to come. Almost with tears in his eyes he confided to the writer the depth of his fears, especially as to all coffee north of Kandy. We were inclined to laugh at the time, but the sad truth has even exceeded in its misery these first gloomy forebodings of evils.

As has been said above, the question of the permanence of *coffee* is for Ceylon now only of speculative interest. All practical interest, for the future centres in *tea*. How lies the matter with that plant? Are there instances in history of large contiguous areas being planted with the shrub, to such an extent as will surely soon be the case in Ceylon? and if so, how long did the cultivation flourish? One naturally turns to China for a reply, but it must be remembered that, in regard to consoling information derived from that empire if such be forthcoming, the plant grown there differs much in habit and in hardihood from the Assam plant grown in Ceylon. Whether any reliable data as to the permanence of the Assam plant are to be obtained except from the Indian estates the writer knows not. He only ventures to bring this matter forward as subject for inquiry that may prove useful in guiding future operations in the direction of extending tea cultivation in Ceylon.

A matter of more immediate and present importance to the tea planters is the course of prices in Mincing Lane. It is pretty clear that the high prices ruling for the good Ceylon teas last year are, like high prices for so many other kinds of goods, a thing of the past. The net result of the praiseworthy efforts of Ceylon planters will be, as was foreseen, that the British consumer will at the same price as before, if not at a lower one, drink a much better tea than he has been accustomed to drink.

The fall in the better classes of tea has been very great during the last three months, and it is difficult to see how, as the weight of good tea from Ceylon rapidly increases (as needs it must), the continuance of the fall is to be arrested.

Within a few days the great Exhibition of the year will be opened in great pomp by Her Majesty —a recent visit showed something like a state of chaos in the Ceylon Court. But there were many willing hands at work, Messrs. Saunders and Davidson with several native attendants, Dr. Trimen, Mr. Smither, Messrs. Shand and Whitham, all under the command of Mr. Commissioner Birch, and no doubt by the 4th proximo, some sort of order will have been evolved.

The Kandy Tea House is approaching completion, and will no doubt be very pretty. Unfortunately it stands crouched between much higher buildings, and its goodly proportions will be dwarfed by those of its great ugly neighbours. After the opening it will be more easy to speak of the merits of the various exhibits from Ceylon.

The Government of India has spared no effort and no expense to make a grand Show, and with the vast resources at its command, it can hardly be but that poor little Ceylon, India's neighbour at Kensington as in the East, will be in some sort eclipsed. It may be hoped, however, that in the economical products Ceylon may, in spite of all, hold her own.

CEYLON UPCOUNTRY PLANTING REPORT.

CROTON OIL TREES AS A CATTLE FENCE—THE FUTURE OF COFFEE—KERR'S ROLLERS.

May 24th, 1886.

Yet another use for the CROTON. A man tells me that he has discovered that it is a perfect fence, once it is grown up and bearing, for all kinds of wandering cattle. They take kindly to eating the seed, and when they once do that, they never come back again! For years he has been worried with trespassing buffaloes; has tried both mild and drastic measures with the view to mitigate the evil, and had given up all hope of any really effectual relief until he saw a buffalo stiff on its back, and some of his seed-bearing croton plants pretty well eaten into. He calculates that that dead buffalo with its hoofs turned up to the sky had been browsing thereon. The owner of the brute mourns over it a great deal more than the planter does. To have crotons growing about anywhere within the reach of cattle or horses is rather dangerous. I know of a planter who lost his horse, by its eating a mouthful of croton seed, which it snatched off a tree in passing. It made the misfortune all the worse to bear that he had sold the horse, and the animal was to have left the estate that day for its new owner.

As to Coffee, I see, that the black-bug is again appearing on it, and this too on the best trees which had been left with the hope of getting a little therefrom. Ah! it's a heart-break. I like your cheery cry, Mr. Editor, that those who keep up their coffee will in due time be rewarded! Yet I know of some coffee which has been pampered and petted, treated in season and out of season in the most handsome manner, and *that* almost up till now, and when you look at the results,—well, you want a lot of faith to believe in that bright future. I suppose we will be trying to grow it by-and-bye as an ornamental shrub, a sort of thing to point out to a visitor from home, a plant with a history.

* 1886 was the black year of Overend-Gurney's downfall and Ceylon suffered terribly in the re-action, money being so scarce that it was said scarcely £1,000 could be raised in the Fort of Colombo on the best estate security at that time available. There was also a great outcry then about the heavy rate of expenditure on estates. The only other possible reason we could suggest is that the philosophic-financier had formed a well-grounded objection to a colony dependent on one staple, and to the turning of the Ceylon forests into fields with one product.—ED.

I hear rather good accounts of Kerr's Rollers. The hitch in the manufacture has been got over and the difficulties which until lately existed in getting a machine have been altogether removed. The price too is moderate (R350) and in the hands of the new manufacturers there should be no delay in placing them on the market. A rival engineer who saw one lately had only one fault to find with them—they were too cheap. That, as I take it, is not likely to prove a fault in the eyes of intending purchasers, and if that really be the only objection, I should say that Mr. Kerr has a chance before him of making up in some measure for the worry he had in connection with his first roller. I understand that a charge of 100 lb. of withered leaf can be rolled off by coolies in 40 to 50 minutes or by water-wheel in half-an-hour.

PEPPERCORN.

NEW MARKETS FOR CEYLON TEA.

What Mr. Rutherford mentions in his letter (page 18) about "Rings" in New York buying up Indian teas and reshipping them to sell in London at a profit, was experienced also in the more distant Melbourne market to the natural disgust of the Calcutta Syndicate. We quite agree that the best means of checkmating such operations on the part of "Rings" or merchants opposed to a change in the present course of trade, would be to get at the country retailers or the consumers and to show them how they can obtain equally cheap teas of far better quality than the "posts and rail" stuff now seen in "the bush" in Australia, or the adulterated green teas of Japan chiefly used in America. Mr. C. M. Henry who knows a good deal about the tea business in Victoria, shewed very clearly in the letter we published in our issue of the 25th inst. how this can best be done in the Southern Colonies. If a Tea Syndicate can be formed under the auspices of the Ceylon Planters' Association, and a reliable as well as smart man of business acquainted with the Australian tea trade employed to travel through the Colonies—the country towns especially—no doubt a considerable impression would be made, and a new demand created for wholesome good tea. Perhaps this work could best be done in conjunction with the Calcutta Syndicate and their Melbourne Agents, and as to this the Planters' Association will do well to inquire. We call attention to what our Tasmanian correspondent has to say today about small boxes.

In reference to the United States and Canada, we feel sure that no better means of checking and overcoming the opposition can be found than through the employment of Mr. J. L. Shand as lecturer and reporter. America is the country of "Rings" *par excellence*. The latest development is that which renders cattle-raising in the far West unprofitable, because all the Chicago "beef buyers" have established a "Ring" not to compete with each other for the cattle sent for sale there. New York is especially the head and centre of the trade in Japan and China teas. All are distributed from that trading capital, save what San Francisco gets by sea to distribute through California and along the North Pacific Coast. Now to defeat the New York "Ring," we must get at the tea-retailers in the surrounding States and their distributing towns, and not only at the retailers, but at the heads of families and we know of no better means of reaching the American intelligence than by lectures such as Mr. Shand could so well arrange for and deliver. Mr. Rutherford is right in referring the organisation of this matter as a duty incumbent on the Planters' Association and we hope that an early opportunity will be taken of considering it. We found the greatest possible interest taken in Toronto in our Ceylon tea industry and Alderman Lobb of that city—a leading resident—was prepared to become agent for Ceylon teas and to do his best to promote their acceptance and consumption throughout the Dominion. At that time (April 1884) the tea market in London was too good—and the Ceylon supply too limited—to make "new markets" an object of much practical interest. The case now is rather different and just as we lectured in Toronto with the result of interesting a circle of well-known citizens there, so should we like to see Mr. J. L. Shand discoursing on the merits of Ceylon teas (with, if possible, practical illustrations for matter-of-fact householders and housewives) in the towns of New England and at any rate the Northern division of the Central and Western States. It is perhaps too much to expect that the people of the Southern States from New Orleans to St. Louis and from Richmond to Kansas should give up their favorite coffee. But among the numerous town and agricultural population, West and North of Washington, New York and Boston, we feel confident that there is the grandest opening for the introduction of the wholesome, superior teas of India and Ceylon that can be found anywhere on the world's surface. The entire population of Australasia is not equal to that of one of the rising American States, and moreover, the surplus population of Europe keeps pouring into the region we refer to, going to swell the host of coffee drinkers although many of them have been accustomed in the (still) United Kingdom to drink nothing but tea. We travelled across from Yokohama to San Francisco, with a gentleman who was pointed out to be the largest buyer (and best judge of) Japan teas for the American market, and he freely confessed to the artificial facing and adulteration of their green teas, saying tea-drinkers would have them so prepared to their taste. But there is a vast proportion of the people who have no such taste and who therefore do not drink tea at all in America, because they cannot get that quality to which they have been accustomed in Ireland, England and Scotland. With such Mr. Shand should find little difficulty in persuading them to become not only drinkers but upholders of the good qualities of our teas, so soon as they learned where they were to be obtained; and so by degrees we should have also the bad taste for the adulterated green teas of Japan superseded even among native-born Americans.

THE TESTING OF KEROSENE OIL.

A correspondent writes:—"Having heard of kerosene lamps exploding in tea houses and also that there is a tremendous amount of bad oil being sold, I write to enquire if Government tests all the oils that arrive, and if so whether by the open or close test. I send you a little information on the subject as unhappily very little is known about it. In Ceylon, it seems, kerosene or refined petroleum is the principal product of the distillation of petroleum, crude American yielding 50 to 70 per cent of its weight. A similar product is obtained from bituminous shale in the south of Scotland. Good lamp oil should have a tolerably high boiling point, being neither too viscous nor too volatile. In addition to the density, the temperature at which kerosene commences to give off

inflammable vapour is important and was made the standard of test in both the Petroleum Acts of 1871 and 1879 and was called the oil flashing point. The 1871 act adopted the open test which was found inaccurate, while the 1879 Act describes the close test so minutely that it is practical and workable.

"Cold kerosene oil of good quality will not take fire when a light is applied nor will the superincumbent vapour inflame. The flashing point by the 1871 Act was limited to not less than 100° F. whereas the 1879 Act shows and has fixed it at not less than 73° F. D. 22.7 C. Now the burning point may be 10° or 20° higher and the two must not be confounded, as oils when spilled will ignite instantly on the approach of a flame when heated a degree or two above their flashing point. Now experiment shows that an oil flashing at 86° by open test and burning at 107° can be made to flash at 100° by removing 6 to 7 per cent by distillation, on the other hand a small admixture of Naphtha will reduce them greatly. *Water-white oil* is the best brand I know of, it has a flashing point of 140° F. and over, accompanied by a low specific gravity. The partial exhaustion of the U. S. supply has necessitated a larger use of Canadian oil, which is heavier, hence the greater density of that recently imported. The heavier and more viscous oils require a more loosely woven wick for their satisfactory consumption. The N. Y. Produce Exchange has adopted the test and limit as described in Act of 1879 for export oil test to England."

IN SEARCH OF A HOME IN TASMANIA.

(*By "Old Colonist," F. R. C. I.*)

THE FRUITFUL DISTRICT OF FRANKLIN—THE GRAND HUON ROAD—GREAT EUCALYPTS AND PINES—A COACH AND FIVE SPANKERS—THE LAND AND THE PEOPLE—FRANKLIN TOWNSHIP—IN THE FIELDS: THE ODOUR OF OLD FAVORITES—ORCHARDS AT £100 PER ACRE—A JAM FACTORY—THE FIRST SHIPMENT OF CEYLON TEA TO HOBART.

"Whatever fruits in different climes are found,
That proudly rise, or humbly court the ground;
Whatever blooms in torrid tracts appear,
Whose bright succession decks the varied year;
Whatever sweets salute the Northern sky
With vernal lives that blossom but to die:—
These here disporting own the kindred soil,
Nor ask luxuriance from the planter's toil."

No one is supposed to have seen Tasmania who has not visited the fruitful district of Franklin. One might as well talk of having seen Ceylon without having done Dimbula. Franklin—named after the celebrated Sir John—lies S. W. from Hobart, 60 miles by water or 30 by land, and is famous for its fruits and valuable forests. The climate is decidedly damp, the yearly rainfall being 39 inches against 19 at the Botanical Gardens, Hobart. The soil as a rule is very good, but the lay of the land being rugged and rocky, it is reckoned unfit for general agriculture. Admirably adapted for fruit-growing however, and as yet, free from codlin moth.

The magnificent road leading to Franklin—for the Huon—is one of the chief lions of the south-side of the island. "Have you seen the Huon Road?" is the usual query put to the new-comer by fair Hobartina, when she makes her formal call. A certain element of danger seems necessary to give zest to the enjoyment of travelling. The Huon Road has not so many awkward zig-zags as the old Ramboda Pass, but more break-neck gullies, and pleasant surprizes in the shape of lovely peeps by the wayside. A rattling good coach leaves Hobart every morning drawn by five spanking horses. Mr. Froude, in his "Oceana" expresses his disappointment with Melbourne horses, thinks them decidedly "a scratch lot" and surmises that the best may be away in Hobart with their owners during the hot season. But the fact is, it takes the eye a little time to become accustomed to the Australian horse: he is less compact and graceful than the English or Arab horse, but has many good qualities, and there can be no question that the gum-sucker is an admirable whip. Talk of horses and you at once rouse the dormant enthusiasm of young Tasmania, and rise in his estimation. To thoroughly enjoy a ride like this, one would certainly require a driver in whom they could place implicit confidence. The first few miles of the road are well-known to all who have done Mount Wellington, and is daily being traversed by picnic parties, whose destination may be the fern tree bowers. A charming view of Hobart and the Derwent is obtained as we ascend the hill. On the right, some hundred feet below, is the romantic cascade hollow, in which is pointed out that excellent institution "The Training School" for boys, so admirably managed by Mr. Longmore an indefatigable young Aberdonian, and born manager of boys. A little further up the hollow is the Cascade Brewery, an institution which if less admirable, is probably quite as much appreciated. We soon arrive at the finger-post pointing towards Wellington's pinnacle, and pass in succession fern-tree bower, and fern-tree inn, and onwards we go at the rate of 9 or 10 miles an hour, now holding in our breath as the horses turn the awkwardly acute angles, and cannot help thinking how a little bridging would have saved much road-making, and the nerves of many an old gent. These deep dark gullies are no doubt very pretty, and very interesting, but I doubt if the best way to enjoy them is riding in a coach and five and, I confess, I breathe much more freely when we get upon a tolerably straight bit of road, from whence we can have peeps of the distant channels. A fine view of Adventure Bay (where Cook landed) is to be had from here.

The little clearings themselves are not encouraging examples of the petit culture. Fruit, potatoes and grain are grown in a half-hearted sort of way, amongst the dead gum trees, which like gaunt skeletons extend their bleached arms from a height of 250 feet and upwards; their colossal trunks measuring from 50 to 80 feet round. What pigmies men look while perched on a scaffold ringing one of these gigantic denizens! The *Eucalytus amygdalina* may indeed be allowed to rank amongst the largest trees in the world: the celebrated Lady Franklin's tree is 107 feet in circumference at four feet from the ground, and other trees are pointed out with boles capable of holding a party of 15 or 20, and Sir John is remembered to have once attended service held in the bole of one of those trees! The most valuable tree, however, in this part of the world is the Huon pine, *Dacrydium Franklini*, which is restricted to this island, and most abundant in this locality. An extensive trade is now carried on in this fine wood, used for boat-building, house furniture, and anything for which oak is used in England; it is very durable, and in the hands of the cabinet-maker takes on a beautiful polish. I am afraid to trust myself to express exactly what I think of the unmitigated vandalism which destroys those fine trees for the purpose of dibbling a few potatoes or scratching in a few grains of oat-seed; and yet the poor immigrant—driven back from the agricultural land—is not to blame, but no language is strong enough or gibbeting bad enough for the men who have idiotically

bartered away the millions of acres of purely agricultural land in this island. For the vulgar cry in England of restoring the land to the people, I have no sympathy. Landed, or any other property honestly acquired, must be respected, but to speak of '*confiscation*' as applied to the recovery of the agricultural lands of Tasmania is a contemptible misuse of language. The shady transactions by which these lands were alienated will not bear light, and the sooner light is brought forcibly to bear upon them the better. A thousand pities that a valuable island like this was not retained as a Crown Colony, or united to Victoria until able to walk circumspectly alone.

Near the 24th mile-post from Hobart we reach the Huon,—a dark and dismal-looking water, crossed here by a fine bridge, at one end of which is a good hospitable little hotel, and here roads branch off to Port Cygnet on the one hand, and up the riverside to Victoria on the other. A pleasant drive of seven miles more brings us to Franklin, the principal township of the locality, situated on the banks of the black sluggish river. Franklin is by no means a cheerful spot, showing but few signs of life, and, like too many other townships of Tasmania, seems to have begun to decay ere it reached a tithe of the dimensions anticipated by the sanguine surveyor who traced its stately streets on paper. There are two comfortable hotels—where much hospitality is received at very little cost—which is more than one can say at most places, two unattractive little churches, two miscellaneous (very) stores where haberdashery and honey, silk sashes and soft soap, gold bracelets and galvanized iron barrows may be bought at the same counter; but the general aspect of the place is not inviting, and I am soon fain to seek the suburb of the village in hopes of finding something more attractive, nor was I disappointed. The climb up a rough lane was both exhilarating and inspiring. Surprised and delighted, I was too, to see so many of the Old World favourites growing wild around me. The air was laden with the scent of white clover; soon it changed, for the white gown-like flowers on which I trod, were nothing else than *camomile*, (the veritable *camowyne* o' my dear auld mither); and yonder feathery bush is *Southernwood*, to be sure; *lost Mercy*, too, like dockens, and mint, horehound, thyme and marjoram, all wasting their fragrance on this desert air; while the bells o' bonnie blue, deck the dykes and the whins and sweet briar still struggle for the mastery:—

> "And golden rods, and tansy running high,
> That o'er the pale top smiles on passer-by;
> Flowers in my time, that everyone would praise
> Though thrown, like weeds, from gardens now-a-days."

All this is very delightful and unexpected. It is only when I come to the more prosaic orchard that my feelings of dismay and disappointment return. Coffee in its darkest days was never so rudely treated as these poor fruit trees, which seem so willing to do their best, and yet few things more amuse me than the conceit of the crude cultivators. The cooly used to say: "Tamil teriyadu oonum teriyadu," meaning, I daresay, that the man who knows not Tamil, knows nothing. The Tasman is equally decided in his opinion that the new-comer must necessarily be an ignoramus. Armed with an introduction to an orchardist who had advertised his garden for sale, I proceeded at once to critically inspect his property, but it was easy to see that if I did not overvalue his practical cultivation, he did not overestimate my experience; if I made awkward allusions to surface weeds, grass, yellow leaves, dead tips and fallen apples, he was ready to overawe me with dissertations on the mysteries of budding and grafting; and while I attempted to make commonplace remarks on the hopeless state of the strawberry beds, or jungle of rasps and brambles, he spoke eloquently of the delicious flavour, and the tons per acre, "them paddocks" produced. But to business, "What is your lowest figure for cash down?" "£100 per acre" "£100! Why I could buy virgin forest for £2 per acre." "Yes and it would cost you £90 to clear out them stones and roots." But I do not consider it necessary to clear out stones and roots for the purpose of fruit growing. A look of withering scorn was the reply to this, enough to daunt the boldest V. A. and no further attempt at business was made, though—as I have often said of the Ceylon planter of 1873-4—it would be very interesting to ascertain upon what basis he framed his valuation.

I observe that in most cases the cultivation of small fruits is being abandoned here, the price (3s 1d per lb.) realised at the Jam Factory being insufficient to pay for the gathering; the great staple being now apples, the crops of which are quite as heavy as in the best parts of the Derwent Valley, and as yet they are free from the codlin moth, which the orchardists confidently attribute to their wet climate; but as I have seen the ruinous effects of this pest in districts of the island where the rainfall exceeds even that of Franklin, I hope there is something else to account for this immunity.

Being now in the neighbourhood of what is stated to be the principal Jam Factory of Tasmania I had a desire to inspect the establishment. "You need not trouble yourself," said my friend the apple planter, "strangers are not admitted," and on knocking at the gates the manager frankly told me "it was against their rules." However, after eyeing me from head to foot, and satisfying himself I did not look like one of those newspaper-writing-fellows, he admitted me. I feel now almost sorry he did, for I do not like to seem ungrateful or to betray confidence, but one has a duty towards their neighbours at large, and *Jam* is a very important article on the breakfast table of the Anglo-Indian. *I am not* satisfied with this Jam Factory. To speak plainly, it is no factory at all. Merely a *receiving house*, and a very dirty one. The immense quantities of small fruit smell like a pulp heap, as they are pitched into large casks, and the only curing they got here, is a bit of burning brimstone, the fumes of which are blown into the bung hole! This may for a time effectually prevent decomposition or the growth of fungi, and if anyone thinks that it sufficiently preserves the colour, flavour, and wholesomeness of the fruit, he is at liberty to do so. In this state it is shipped to Melbourne in order to save the heavy protection duties imposed by our big sister, and best customer, Victoria. In Melbourne, the mess is boiled with sundry additions, duly labelled and sent out to the world as "*Finest Tasmanian Jam:*" *Try it*,—and compare with Moir or Keillor. I have no object in advertising either, but the comparison may be interesting as showing the difference between *Free Trade Jam* and *Reciprocity Jam*.

THE FIRST SHIPMENT OF CEYLON TEA reached Hobart a fortnight ago and has all been sold at 1s 3d (in bond). There is no mark on the chests, not even the weight, and the quality is rather a dusty P. S. though it liquors better than the atrocious stuff in common use here, which reminds one of *ship* or Waverley Hotel tea. If the people here excel in anything it is in tea drinking! I have never seen anything approaching to it. It's tea to breakfast, dinner and supper. Tea when

you call at any hour of the day or night and when friends take a walk for a couple of miles or so, they almost invariably carry the everlasting tea-kettle. I should think 10 lb. per caput per annum would scarcely suffice here. The Chinese have the trade simply because they take the trouble to get the tea up in nice little boxes to suit the market. The Ceylon chests were all said to be 95 lb. though really 92 was the weight of the one I purchased. Few families care to take 90 lb. at once and to break up and divide, costs money. Mind you, labour is labour in a colony where the poorest creature will rather go to the invalid hospital than take less than 6s 6d for 8 hours' dawdling.

BRITISH NORTH BORNEO.

The *British North Borneo Herald* for 1st May has reached us, and proves an interesting number as our extracts show. The chief paper is on "the Climate of British North Borneo," a Report by J. H. Walker, Esq., M.D., Principal Medical Officer. This is an instructive and business-like account, though with the comparatively short experience and insufficient meteorological and other data, the conclusions drawn can only be provisional. We read :—

The climate of British North Borneo is noticeable for nothing more than for its equability and the absence of extremes. The Temperature, Rainfall, Winds, Natural Phenomena generally and the diseases are, for a tropical country, of the most mild and temperate types.

MONSOONS AND WINDS.—The Monsoons are the North-East and the South-West. The North-East Monsoon commences about the middle of October and continues till about the middle of April. The South-West Monsoon lasts from about the middle of April till the middle of October.

RAINFALL, &c.—The Annual Rainfall near the coast, according to the records kept has during the last seven years ranged from 156·9 to 101·26 inches and has averaged 124 34. The true Wet season occurs in the North-East Monsoon and includes the months of November, December and January, and generally part of either October or February or both. The true Dry season immediately follows this true wet season and includes March and April and generally the whole of May and part of February.

TEMPERATURE.—The temperature recorded at the coast has ranged between the extremes of 67·5 and 94·5. Until within the last few months however these records have been taken from thermometers kept in the shade of a verandah—with the exception of Kudat where there was a thermometer shade two years since, and little or no inferences can be drawn from the records there as the meteorological station is on a sandy plain, the temperature of which is several degrees above that of the country generally. Judging from the results of the observations at Sandakan since the proper shade was erected I think the minimum records fairly well represent the truth, while the maximum records are from two to three degrees over the true "temperature in the shade."

The absence of Tornadoes, Cyclones, and Earthquakes is to be noted. The only indication of the existence at the present day of volcanic action is the report of a hot spring in an island near the Coast. In some individual parts the South-west monsoon is by far the most unhealthy, and this is especially noticable at Kudat and Silam, where during the South-west monsoon fever is prevalent and rather severe, while during the North-east it is mild and at Kudat now almost absent. At these stations the evil influence in the South-west monsoon is undoubtedly the stronger winds which, blowing over the whole of Borneo, reach these places laden with the impurities collected from swamps, &c., in their passage; while Sandakan is protected from this influence by the purifying effects of the bay, over which the South west winds have to sweep for a distance of some fifteen miles before reaching the town, and consequently at that station there are no clearly defined healthy and unhealthy seasons as at the two others mentioned.

The CHIEF DISEASES to be considered under this head are Fever, Beriberi and Dysentery. In addition to these a few lines will be given to Anæmia and Sunstroke. *Beriberi* occupies a far more important position in the list of diseases of Borneo than would be gathered from the small proportion it forms in the table in the appendix (only 1·75 per cent of the diseases treated); partly on account of the high rate of mortality it gives and partly on account of the extent to which it has already interfered with planting. It has broken out in each of the plantations opened in the rivers in Sandakan Bay and has claimed its quota of victims not only in these—Sigaliud, Domoondong, Suanlamba and to a less extent Sapagaya—but also in the native village of Malapi, at the Birds-nest caves at Gomantou, among some of the parties of Dyaks collecting produce on the upper waters of the Segama and to some extent on the island of Banguey. This disease generally appears almost in the form of an epidemic and is generally closely restricted both to the locality and the race among whom it first appears. The cases enumerated in the appendix were chiefly drawn from the various rivers in the bay (patients sent to Sandakan for treatment,) but include also a few sporadic cases that appeared in the low-lying ground in Sandakan, and a few cases in the commencement of the recent outbreak in the old gaol here. The cause of this obscure disease is as yet uncertain; some ascribe it to the food, more especially to bad rice and fish, and there is no doubt that a generous diet has a strong curative influence on the disease; but on the whole, from its many analogies with Malarial fever and the strict localisation of the disease, I am more inclined to the view that is due to a specific maisma or exhalation from the soil. There are two distinct forms of the disease, and I think it not improbable that these may ultimately prove to be distinct diseases.

The Indian races on the whole stand the climate well. The Sikhs and Bengalees have attacks of fever, colic, constipation and occasionally slight dysentery, but there have been but few deaths among them; one or two from fever, one from heart disease, one from opium smoking, one from chronic neglected dysentery and one sudden death, cause unknown. The Klings are also fairly healthy here but like others have occasional attacks of fever and in two cases Beri-beri. The Sinhalese who were brought here for the survey department suffered severely from fever and its results. The Chinese are the only race that can be said to be decidedly unhealthy in this climate and even of them this can be said only of those fresh from China and sent to work in the jungle before they are acclimatized. Men such as those contribute more than half of all the deaths registered in Sandakan, succumbing chiefly to Fever, Beri-beri and Anæmia with ulcers. The Dyaks from Sarawak have excellent health in British North Borneo.

SANITARIA.—In the future when the country gets opened up there will be comparatively little difficulty in forming Sanitary stations on the hills near the West Coast. Probably the best site will be found on some of the spurs of Kinabalu, such as that described by St. John on the West-North-West spur, where, at an elevation of some 5,000 to 6,000 feet, on a good site to which a road could easily be made, is be found good water and an average temperature of 75° at midday, 63° at sunset, and 56° at sunrise. At Bodc Silam also on the East Coast it is possible that a site may be found at an elevation of some 2,000 feet, but this would probably prove much less satisfactory, not only on account of the smaller elevation, but also because from the isolated nature of the hill there would probably be difficulties about road, water-supply and shelter from the wind. 2.—At present, in default of such sanitaria, I find the short sea voyage from this to Singapore and back has a most powerful recuperative effect in convalescence from sickness. The voyage to Hongkong is not found so satisfactory in such cases, as the transition of climate is so rapid, and, though

the distant effects may be good, the immediate effect is to stir up any seeds of fever and other disease that may be latent in the system and cause an outburst of the disease.

We make further extracts as follows :—

COUNT GELOES D'ELSLOO, the first Netherlander to take up land in British North Borneo, described in the Java papers as "The land of promise," left Sandakan for Singapore on the night of the 3rd April by the S. S. "Banca." Count Geloes, who was the Governor's guest during his short stay, appeared much pleased and somewhat surprised at the liberal lines on which the Government of this territory is carried on as compared with the Dutch regime in the magnificient Netherlands Possesions in these seas. He was more amused than pleased with the freedom of intercourse existing between the Europeans and the Chinese, Sulus, Malays and other nationalities. The Count obtained on favourable terms the lease for 999 years of 26,000 acres of land in the vicinity of the Ranow river in Marudu Bay, making, with the 4,000 acres already taken up by his agent Mr. Persyn, a total acreage of 30,000 acres. He also made certain propositions, which have been forwarded for the consideration of the Court of Directors, for the concession of Mineral right on the Segama river.

TOBACCO IN NORTH BORNEO.—The Dutch Count Geloes d'Elsloo visited the Suan Lambar Estate of the Chinese Sabah Land Farming Company, and is said to have formed a high opinion of the *quality* of the tobacco. It appears that *one* leaf of tobacco from the Banguey Estate had found its way to Java, which did not stand the burning test, whereas the Suan Lambar tobacco was demonstrated to burn beautifully. Surely it must be to the advantage of Planters that their numbers in this country should be increased, with the result of better communication, cheaper supply of labour, attaps, and so forth, and it is difficult to understand how the solitary bad leaf found its way to Java. On the 13th April the Chinese Sabah Land Farming Company had ready packed 110 bales of 117 pounds of tobacco each, and are only waiting for mats to pack the remainder of their crop of about 430 pikuls. It seems that a large quantity of the mats procured by the Manager had been destroyed by rats. We learn that the German Borneo Company, Banguey, have 50 bales of tobacco ready for shipment by the S. S. "Paknam" in about a fortnight's time.

TIMBER IN NORTH BORNEO.—Mr. E. E. Abrahamson has converted his business as a Timber Merchant into a Company under the style of E. E. Abrahamson & Co. The principal works of the Company at present are on the right bank of the Dumoundong river in Sandakan Bay, an hour and a half by steam launch from Sandakan, where permission to fell over 100 acres of Government Forest land has been acquired. A visit to the locality would well repay any person who has not had previous experience of the way in which heavy timber is brought out of the jungle with a motive power of Chinese and Malay coolies only. Billian of excellent quality abounds, also large quantities of Sirayah (cedar) and some Camphor. About 30 rough tracks have been made up the small valleys separating the undulating slopes and on these are laid crossways from side to side wooden spars, at distances of three to four feet, on which a sledge made of billian, and kept well greased with tallow by men running alongside, is hauled by Chinese or Malay coolies. On this sledge heavy logs of billian 30 to 40 feet long are transported to the river, where they are made up in rafts with light timber to float them off to the ship. At the present time some 1,000 tons of wood are ready for shipment including one raft of 400 tons of Sirayah. The timber is as a rule squared by Chinese at so much a foot, the Malays not being handy with the large squaring axes. About 60 to 70 Brunei Malays are engaged on monthly wages and on piece work in one part of the ground and in another about 30 Chinese, who work entirely on contract, providing their own tools, rope and other requisite appliances. On the score of cost Mr. Abrahamson says there is little to choose between the Malay and Chinese coolies.

GOLD IN NORTH BORNEO.—Mr. H. Walker returned from the Segama on the 9th April with Mr. Ah Chee, leaving Captain Beeston to prosecute his researches further up the river, where he will be accompanied by Mr. Callaghan of Silam. It appears that Captain Beeston is of opinion that the alluvial below Sabandar Pungut's Campong is not rich enough to pay working, but above that the river working will pay Chinese and Malays well for some time to come, its richness improving as the river is ascended. The gold is confined to the bed of the stream, being continually washed down from the sources or the upper waters, so that in all probability the ground will take a long time to work out. Mr. Ah Chee appears much pleased with what he saw and intends to commence operations at once.

NEW PRODUCTS.—Referring to the paragraph in our last issue to the effect that the Government had allowed a grant of $1,000 for the purpose of encouraging the planting of gambier and pepper we are informed that the Chinese of Kudat have promised to contribute a like sum for the said purpose. Resident Davies must feel gratified at this proof of the confidence placed in him by the Chinese community.

WE hear that sport is good round Kudat just at present. On the 11th of April, Mr. G. L. Davies shot a large boar, his head being 22 inches long. On the 13th April Messrs. Davies, and Wheatley were out again, when the former's dogs brought a fine young Buck across the road within 20 yards of them. The deer fell with an express bullet placed just behind his shoulder by Mr. Davies, and with another shot in the stomach from Mr. Wheatley. On the same evening a native also shot a fine young Buck.

WE hear that the results of the Tawaran expedition have even exceeded the expectations formed by the Resident Mr. G. L. Davies, and that fifty-two villages have tendered their allegiance to the Government, and agreed to give up head-hunting. To show that they really mean it, they have already sent in part of the Poll Tax, which would be due from them in about one month's time.

GAYA Sago Factory has been shewing greater activity during the past quarter. 500 piculs of Sago Flour having been shipped to Singapore. A change of management has recently taken place which will probably act beneficially.

BUKIT MINDALONG.—Would not this fine mountain be a good point at which to form a Sanitarium, if one is ever contemplated, lying, as it does, an easy distance from the Coast, on the true right bank of the river Sayap, an affluent of the Tampassuk in the true right bank of the latter,—easily approached up the levell Tampassuk valley, and offering any elevation up to 8,000 and 10,000 feet? The word "Sayap," it may be added, is Illanun for the pointed, plaited-straw hat, worn by the Dusuns, and is synonymous with the Bajau "Sadok," the Brunel "Sirahun," and the Dusun "Siong." The Sayap valley owes its designation to a lofty, peaked mountain at its head.

IN CONSEQUENCE of the expedition against Penassan and Sirambutan, some fifty four villagers have signified their wish to come under the flag of the Company. The country may be said to be quieted down up to the banks of Kinabalu. This is a gratifying result to have been achieved with so little bloodshed, and it is to be hoped the head-hunting Hydra has been scotched, if not altogether killed.

The Hon. Ralph Abercromby travelling round the world, gives his impressions of North Borneo, and states among other things :—

There is not the slightest doubt that the soil and climate of British North Borneo are eminently suited to the culture of valuable big leaf tobacco. Two plantations are already started in Banguey and the first samples are now ready for market.

On the whole Sandakan seemed to be a very little hotter than Singapore, damper but not so hot as Colombo, much less baking than Port Louis in Mauritius, and greatly less trying than Sava in Fiji.

A well-known Ceylon Colonist Mr. L. B. von Donop, was acting for Colonial Secretary during the absence of Mr. Malcolm Brown and we read

the Governor has been pleased to appoint Mr. John Robertson of the Land Office to act as Superintendent of Public Works during the absence on leave of Mr. J. Sampson.

CINCHONA CULTIVATION AND SYNTHETICAL MANUFACTURE OF QUININE.

We are indebted to the correspondent who writes to us as follows—and we feel sure he is right in his conclusions on the subject :—

"The enclosed advertisement appears in the last *Lancet*. If quinine can be produced by synthesis it will be a bad look-out for cinchona growers :—

'Synthetical Manufacture of Quinine.—A Syndicate is now being formed for the above purpose. Capital £50,000. As the medical profession are almost the sole users, it is proposed to confine the interest to them—Particulars by post (stamp), M.D., 50A. Lincoln's-inn-fields.'

We are certainly living in wonderful times, and the progress of science will before long alter the interests of many industries. I always thought the chemists would have a shot at the artificial manufacture of quinine, and perhaps their efforts have had some effect in keeping down the price of the article. The former high price no doubt set many minds thinking how it would be done, but I doubt the feasibility of the proposal as all efforts hitherto to produce expensive alkaloids artificially have ended in failure in a commercial point of view. What has been the result of the artificial production of indigo !"

The marvellous cheapening of quinine by the successful cultivation of cinchona in the East operates against the usual inducement to manufacture by chemists, and, as our correspondent says, the "synthetical manufacture," long ago announced, of other products, Indigo for example, has not so far been very successful.

THE GOVERNMENT ENTERPRISE IN JAVA.

REPORT FOR THE 1ST QUARTER OF 1886.

(Translated for the "Ceylon Observer.")

During the month of January and the half of February there was comparatively very little rain ; the second half of the quarter was, on the contrary, very rainy. The planting out in the field was carried on uninterruptedly during this quarter. The young plantations thrive generally very well and rapidly develop, which is to be attributed to the selection of fine robust plants. At Nagrak the young plantations were subjected to an attack of grasshoppers(locusts ?) which caused some damage. The results of the harvest of 1885 was despatched to Batavia at the end of January. It amounted to 432,718 half-kilograms of bark packed in 1,008 chests and 2,026 bales. The harvest of 1886 is as yet very small, chiefly in consequence of the continued damp state of the weather, which in many establishments stopped the gathering. On the whole the quantity collected has been about 40,000 half-kilograms, almost exclusively obtained by the extremely necessary thinning-out of the closely growing ledgerianas and succirubras of which 9,794 half-kilograms were sent to Batavia by the end of March.

For the purpose of securing further data respecting the influence which the succirubra stem exercises on the graft of ledgeriana upon it, samples of bark from grafted branches from well-known and repeatedly examined parent trees have been transmitted to chemical examination. From these analyses it seems evident that in opposition to former opinions, the succirubra stem acts beneficially on the ledgeriana grafted on it as shown by the quantity less or more of cinchonidine which is found in the bark of the ledgeriana, and which is not to be discovered in the parent ledger trees. The conclusion appears unquestionable, that the yield of cinchonidine increases with the age of the tree, whatever may be the issue of future experience. It remains still to be ascertained whether or not the succirubra stem affects the higher parts of the ledgeriana grafted on it ; and if it does so, to what extent ? Even should the results cause no small degree of disappointment, still the analyses show plainly that the graft plantations of Tirtasari will yield a very valuable produce of ledgeriana bark, and that there does not exist the smallest reason for relaxing in the application of the system of grafting on a large scale, or even for placing any limits to it. The original ledgerianas, and the graft and cutting plantations at Tirtasari produced during the last quarter such a trifling quantity of seed, that up to the present time, it had not been possible to hold any public sale of cinchona seed. (Signed) VAN ROMUNDE,

Director of the Government Cinchona Enterprise.

Bandoeng, 6th April 1886.

* Schilfers, the common meaning is scales (schilferen, to scale off); but I have no means of ascertaining its application to cinchona bark.

† Reep, is a strip, or a band of cloth torn off, and Reep-bast, I presume, is a strip of bark off the tree in contradistinction to what is shaved off, but I do not like to make a guess at the application of the word.—*Translator.*

LOWCOUNTRY PLANTING REPORT.

(*From an Old Hand.*)

MONSOON—COCONUT PLANTING—THE COPRA TRADE.

Hapitigam Korale, 25th May 1886.

The Monsoon opened here on the 17th, and it has dribbled daily evei since, with very little wind, except one fierce squall on the 23rd, that lasted only a few minutes, but quite long enough to tear forest trees up by the roots, and scatter large limbs of jak and other fruit trees in all directions.

This is the proper season to plant Coconuts, but most of the clearings in this part are somewhat behind, and in some cases the proper time may slip away and leave some of us up a tree. In my own case I was a trifle late, but I am getting on with lining and holing about 20 acres of new clearing as fast as the rainy weather will permit.

Within the past ten or twelve years, a vast improvement has taken place in the management of Coconut property in this district. A clean estate was then the exception, it is now the rule.

There are still a few, who stand true to old ideas; for instance, there are a few acres of the best soil in my neighbourhood, that about fifteen years ago was given out to goiyas and planted. When they had taken all they could from it, the land was left without another cent being expended, the lantana rushed up, and in a couple of years not one coconut plant remained. At the end of seven years it was again cleared, again cropped by goiyas, and again it ran precisely the same course. It has this season been taken in hand a third time, and it remains to be seen whether it will be better cared for on this occasion, than on the former attempts at cultivation.

On the other hand there appears to me to be more energy and liberality in some cases than knowledge of the plant and its requirements. My idea of Coconut Cultivation can be conveyed in two words, *manure* and *plough*, and those two operations should be modified according to the character and quality of the soil.

Within the past few years a revolution has taken place in the Copra Trade, the local oil mills cannot compete with the export prices, and have had to close up, but the export trade requires a better article than the smoked and less than half dried commodity, that satisfied the local trade. The copra dealers that used to compete keenly for the estate crops have not readily accommodated themselves to the new development, and, in consequence, they are not so prompt to purchase crops, and nuts accumulate so as to induce proprietors seriously to consider the expedience of drying their own copra, and such among them as have any constructive talent are using it in the invention of drying houses to render themselves independent of weather and enable them to turn out a good clean well-dried product that will take the top of market. I had occasion many years ago to test the difference between thoroughly dry copra and that taken to market by native dealers, and found that thorough drying brought 1 cwt. to 95 lb to say nothing of the discolouring of the resulting oil by smoking the copra, to save it from too rapid deterioration, before it could be sold in its less than half dry state. In those days, copra rose and fell in price, according to the supply and the wants of the mill and chekku owners, but there was no distinction of qualities. The rise of the export trade has done much to remedy this state of things, and the planter has now the chance of being rewarded for careful preparation, and more or less perfect drying apparatus will soon be made on most estates.

JAVA AND CEYLON.

Some idea of the difference between Java and Ceylon in planting enterprise may be gathered from the following particulars taken from a Batavia newspaper. At a meeting of the Planters' Association of Sukabumie held at that station on the 22nd April Mr. G. F. Mundt, a planter, set forth his experiences during a recent tour in Ceylon as regards plantation matters there. He spoke in high praise of the excellence of the roads in that country which taken on the whole, is unsuitable for the cultivation of the soil. On railways in Ceylon there is heavy traffic even in small produce articles in consequence of the low freights. The rapid progress and widespread destructiveness of the coffee disease were mainly ascribed by him to the unfavourable and stony nature of the soil and the gross carelessness shown in laying out estates. What struck him particularly was the rapidity with which in Ceylon substitutes were found for the declining coffee growing industry. The light pressure of taxation there has thus made it possible for planters to do what is beyond the reach of their fellows in Java. Abroad, people have been astonished at the enormous quantities of cinchona bark unexpectedly thrown upon the market from Ceylon all at once. The explanation must be sought for in the hasty planting of cinchona often between standing coffee trees, or their stumps and in equally hasty cropping, so that bark is actually shaved off from small trees barely a few feet high from below in consequence of eagerness to make money and take advantage of a rising market. At the outset, the favourite varieties were those styled *Officinalis* and *Succirubra*, but latterly great activity has been shewn in carefully laying out *Ledgeriana* estates with plants raised from seeds procured in Java, which found their way to Ceylon in spite of the hindrances laid in the way of their export from fear of competition abroad. In Ceylon, tea cultivation has been taken in hand with not less thorough-goingness and energy. Within the five years since that form of cultivation was undertaken, six hundred thousand rupees worth of tea seeds were bought in India. This branch of planting industry also has been carried on with an overhaste natural under the circumstances. Deep loosening of the soil, terracing, &c., were neglected. Tea also has been often planted among coffee and occasionally among cinchona as well. Plucking operations too quickly begun and too often repeated cannot have a favourable effect on the life of the plants. In spite of these drawbacks, the area under tea increased last year from 13,500 to fully 100,000 acres. Mr. Mundt held that reports from Ceylon bearing upon estimates of crops are sometimes misleading from a desire to influence capitalists. In his opinion the 80 millions of pounds of produce expected to be gathered in within the next few years may be safely reduced to 25 millions, that estimate being high enough for all practical purposes. There was also every prospect of tea in the long run feeling the harmful effects of the washing away of the thin layer of culturable soil loosened by weeding. Generally speaking Mr. Mundt felt no alarm at the prospect of Ceylon competition with Java, so far as regards planting enterprise, but as regards fiscal burdens and means of transport and the silver difficulty the balance of advantages was on the side of Ceylon from hardly any taxation at all falling on estates. He concluded his observations by noticing cocoa cultivation in Ceylon which yielded 100,000 hundred weights in 1885. This form of enterprise also bore the mark of the same eagerness for speedy profits in order soon to return to Britain with a fortune, which characterised Ceylon planters generally, and has been all along a source of harm. Sometimes in this way shade trees were cut down to secure a larger outturn of cocoa with the result that insect pests grew rife and the trees had to be replanted.—*Straits Times.*

[Some of Mr. Mundt's figures, if correctly reported, are very wonderful, like the 100,000 cwt. of cocoa: we have not got to 10,000 yet; and who estimated 80 million lb. of tea? In taking 25 millions as the estimate for a few years hence, Mr. Mundt is merely following the "Ceylon Directory." We put the export for 1887-8 at 20, and for 1888-9 at 30 millions lb. Mr. Mundt is too hasty in condemning the Ceylon modes of planting, though his criticism on a few points is deserved—ED.]

"MARKET GARDENERS" upcountry in Ceylon ought to be encouraged by the advertisement which appears regarding the requirements of the Military Commissariat for Colombo and Mount Lavinia. Were the railway running into Uva, there would not be the slightest difficulty in receiving a perennial supply of vegetables of all descriptions and of cheap, good fruit in abundance. But Nuwara Eliya and Dimbula can do a good deal.

JAPAN TEA.—The *Japan Herald* translates the following from the *Bukka Shimpo*:—"If the price of the first tea of this year be compared with that of last year there is a difference of some $30. The cause of this difference is the earliness of warm weather and tea leaves coming out very early in various districts, especially at Suruga province. The amount of the new tea transported to Yokohama, before the 24th instant, when the American mail left with the first teas, reached 15,000 catties, and until the *Kiyogawa-maru* entered the port with new tea, the price was about $70. But just before the American mail left foreign merchants offered low prices, and holders afterwards agreed to sell. Indeed the first price, is not a real price at all, and it is usual at the time of the second mail for the price to fall to about $40. Now in this year the first tea showed the second price, on account of the great amount transported to Yokohama at the time when the first mail left. Therefore in this year there may not be any great difference of price at the time of the second mail.

COFFEE IN UVA IN THE OLD DAYS.—A correspondent writes as follows:—* * * Referring back to old memories which Mr. Irvine's letter has "brought to mind," the finest native coffee in all Uva was grown in the villages behind Ella and about Leangawelle. (By the way, how few Europeans of today have seen the site of the old Ella Fort and the grave of a European officer who died at his post, name lost and unknown.) This coffee weighed much heavier than any other coffee in Uva or in Ceylon: the traders who bought the coffee by measure and sold it by weight made at least 10 lb. on every cwt. as compared with ordinary native coffee. I recollect well the wild coffee trees in the strips of jungle, now the outlying fields of Broughton estate; these trees were upwards of 20 feet high and were fully 5 inches in diameter at the bottom and tapered like a fishing rod, the villagers used them for rafters. These trees were not indigenous; the seed had been carried by wild animals from the villages and where the forest shade was not too dense the whole ground was carpeted with coffee seedlings. When coffee stumps or plants were required for planting, the coolies sent for plants were simply told to go and bring a thousand plants which they easily got, not in the villages but in the forest. * * *—*Cor.*

Correspondence.

To the Editor of the "Ceylon Observer."

NEW TEA MARKETS.

Madulkelle, 20th May 1886.

Sir,—Mr. Scovell has certainly opened up a subject which deserves the attention and support of all tea planters. But while I agree with him that it is highly important for us to endeavour to find fresh outlets for our teas, yet it is my firm belief we could do more in a given time but perhaps at a greater cost by endeavouring to cut down retail dealers' profits and so lower retail prices. If all grades of tea were lowered in (retail) price at least from 4d to 6d per lb. I scarcely think there can be a doubt but that the general consumption would largely increase—so largely indeed that I think all our tea would be absorbed for a few years at least, and this would give us time to attend to new markets also. I do not think Ceylon planters can hope to carry out this sort of work alone; the co-operation of India must be sought and if possible obtained; for the opposing interests at home are wealthy and influential. But there is another factor in the future which tea planters ought most carefully to watch, namely the price of silver and exchange. If, by any tinkering legislation at home to give silver a fictitious and high value, exchange is caused to rise against us; a very severe blow will be dealt at our industry, and not ours only but against all India; and there does seem to be a "reasonable prospect" of some legislation of that kind being proposed.

Will not Mr. Scovell himself initiate a movement in the matter, through the Association or otherwise?—Yours truly, A. M. W.

NEW MARKETS FOR TEA—AUSTRALIA.

Goatfell, 21st May 1886.

Dear Sir,—With the view of supporting Mr. Scovell's suggestions with regard to the immediate necessity for some efforts being made to increase the demand for what is now our staple product, I beg to offer a few remarks. The subject has been mooted in your columns before, and a little has been done towards making known the existence and quality of Ceylon tea far and wide, but our efforts seem rather to have slackened of late, while as yet but very poor results have been attained.

The passage from Messrs. Gow, Wilson & Stanton's review quoted by Mr. Scovell will commend itself to all who are in any degree interested in the matter; and the question only remains as to what are the most likely means to ensure the placing of our teas before the consumer. Mr. Scovell says the existing channels are capable of expansion, and this is doubtless true; but at the same time there are obstacles, in the shape of trade interests and inordinate profits, to be removed before those channels will yield the required expansion. I believe that in Australia there is a market for Ceylon tea capable of very considerable development if properly worked up; but it must not be left to the mere efforts of individuals struggling to earn a livelihood in pushing an article, almost, if not quite unknown, and this in the face of a well-established trade in the Chinese rival. Doubtless the Melbourne Exhibition did much to make Ceylon and Ceylon tea known to many in the Colonies; but out of the many there are probably very few indeed, who have either seen or heard of Ceylon tea since. Sometime in 1881; I think it was, Mr. Poett wrote to your columns and pointed out a means of bringing Ceylon tea before the Australian public which I quite agreed with at the time, and still think is the most feasible method of securing the desired result; viz., to establish travelling agents to sell our tea all through the country, the more directly to consumers the better. To carry out this plan, capital would be required in order to sustain the risks attendant upon an undertaking of this nature at the outset.

Tea is looked upon by travellers as one of the most paying commissions in their line of business, and it is not to be wondered at, when the retailers consider 9d per lb as no more than a fair profit. This is one reason why our teas do not fetch their value in Melbourne, for with China tea procurable at prices from 6d to 1s, and the low duty of 3d per lb, the selling price to consumers is easily fixed so as to allow the handsome margin I have quoted. Dealers will not buy Ceylon tea at its value, when in order to secure this high profit, they would have to raise the price at least 6d per lb to the consumer, who would not give it. But place Ceylon tea of average quality before the consumer, and he will give 2s per lb. for it and want the same article next time. It cannot be done through the dealers, as the trade is deeply interested in China tea and simply pooh-pooh anything else. I took samples of good Ceylon Pekoe Souchong to two dealers in a town in Victoria, both doing a very considerable business and making tea a speciality. One said the tea was undrinkable, and the other valued it at 1s 8d. I sold the bulk of it at 1s 5d at auction. The man who condemned it was very largely interested in China tea, and I am inclined to think his palate was rather in sympathy with his interests.

An accredited representative with the ability to lecture through the country would no doubt achieve a great deal, and by making Ceylon known as a field for the investment of capital, he might be the means of bringing about such commercial relations as would inevitably secure the diverting of a portion, at least, of our produce to the Melbourne mart. The population of the Colonies is not large, comparatively, although it is rapidly extending; but it is an eminently tea-drinking population, and it is certainly worth while making some effort to establish a demand for our teas in view of the vast amount of competition which will be erelong, and is even now, beginning to be felt in its effects upon our industry.

Since writing the above I have seen "A. M. W.'s" letter; and as our ideas seem to be coincident as regards the retailers' profits, I feel all the more justified in putting in my word. There is another point which I will just touch upon. I don't think there is much to be gained by a wholesale vilification of China tea especially in the colonies. Ceylon tea will easily make its way upon its own merits, but it is calculated to engender needless hostility to decry indiscriminately a commodity, the trade in which, affects such large and important interests.—I remain, sir, yours truly,

CHAS. M. HENRY.

LIBERIAN COFFEE.

Mahaoya Valley, 22nd May 1886.

Dear Sir,—I send dimensions taken of three Liberian coffee trees growing in the above valley between 6 and 7 years old, and would like to learn if there are

any finer specimens to be seen elsewhere :

	Feet	inches.
1st tree measured :—		
Height	16	8
Circumference ..	27	6
2nd tree :—		
Height	15	6
Circumference ..	28	6
3rd tree topped at ..	10	
Circumference ..	33	

—Yours truly, VISITOR.

NEW TEA MARKETS.

Colombo, 26th May 1886.

SIR,—Mr. Scovell has the interests of Ceylon Tea thoroughly at heart when he advocates extended markets for this product.

Mr. Scovell's scheme of a combination to ship at a loss, so as to establish a market in America, in the hope of ultimate gain, is not so easy of realization in its dual aspect, as it is in its first stage, viz., that of shipping at a loss.

From the experience gained by the Syndicate formed for pushing the sale of Indian teas in America it would seem they were perfectly successful in shipping at a loss, but lamentably failed in their endeavours to establish a market. Our American cousins in the tea trade formed a "Ring," bought up all the Syndicate shipments as they arrived, and quietly re-shipped them to London, thus preventing their being sold in America, and frustrating the designs of the Syndicate. It is not the prejudice of the people in favor of China and Japan teas that we have to overcome so much as the determined struggle the merchants interested in China and Japan teas make to keep us out of their field.

Now, this will not be overcome simply by placing large quantities of tea in the open market for sale, as it will be bought up by those opposed to its introduction, but it is more likely to be so by sending small consignments well distributed, thus getting in the thin end of the wedge. It will be well to recall the method by which our teas were introduced so successfully into Great Britain, which was by the distribution by Ceylon planters among their friends, of small packages of Ceylon teas. Their friends soon learned to appreciate the good qualities of the tea and demanded Ceylon tea from their grocers, who in self-defence were bound to keep the article. From family to family the knowledge of the excellence of the tea spread, and the trade generally (after a good deal of prejudice) was compelled to satisfy the demands of consumers. It is thus seen that the public first discovered the good quality of Ceylon tea, and that the grower is not indebted for its introduction either to the London sale room or to the London broker. The sale of Ceylon tea must be introduced in a somewhat similar manner into America, but it is obvious that exactly the same lines cannot be followed as the grower is not so intimately connected with that country.

Although I hold that it is more within the province of the trader or merchant than of the grower to introduce and establish himself in a new field, still, under the special circumstances of our product, the question arises whether it is not rather a subject for combined action than individual effort and one which the Ceylon Planters' Association might well take up in the interests of what will undoubtedly become in a year or two the staple product of Ceylon.

I am, therefore, strongly of opinion that at one of the early Committee-meetings of the Association this question should be prominently brought forward for discussion, so that by unity of action some defined plan may be formulated which would ensure the introduction of our teas into America, where, although the development of consumption might be slower than it was in England, still when once established, it should go on increasing and eventually assume very large proportions.—Yours faithfully,

H. K. RUTHERFORD.

NEW MARKETS FOR CEYLON TEAS.

Kandaloya, Nawalapitiya, 28th May 1886.

SIR,—With regard to the opening up of fresh markets for Ceylon tea, Messrs. Scovell and Rutherford are at one on the point of *combination*, although the latter gentleman is not sanguine of America absorbing much of our produce. There is an old saying that we should "look at home afore looking out o' window"; and, looking at home, I maintain that we have not tapped the home market. With the exception of families who have friends in Ceylon, and are supplied by them direct, the proportion of people at home who knew the taste of Ceylon tea is infinitesimal.

Whenever I send tea home, my friends invariably write "We would always drink Ceylon tea if we could get it." When the Ceylon Tea and Coffee Agency first started, I sent them a list of addresses of friends at home. These religiously dealt with the Agency so long as they could: but latterly the tea supplied has been so inferior in quality that my friends have been obliged to provide themselves elsewhere.

No doubt there is scope for the Planters' Association to move in the matter: but in the meantime I would venture to suggest that private enterprize might do a great deal on the lines laid down in some letters which I wrote, and which appeared in your columns, so far back as 1881.*

Let proprietors of estates *combine* and form a Company to start a "Ceylon Tea Refreshment Room and Retail Agency" in some central part of London. I believe that many coffee-houses pay satisfactory dividends. Why should not a Tea House do so also? While, in addition to paying on its own merits, it would serve as a depôt for the retail sale of produce *shipped to it direct from the gardens of the shareholders*, and would introduce Pure Ceylon Tea to multitudes to whom it was only a name before.—Yours faithfully,

W. TURING MACKENZIE.

* We (ED. *T. A.*) append a few extracts from the letters referred to :—

(Addressed to Indian Tea Gazette, 23rd Oct. 1880.)

Your address to English housewives in your issue of 1st September has suggested to me a plan by which our Indian and Ceylon teas might be brought more prominently before the tea-drinking public. I don't know if the plan is at all feasible, but here it is, in a very crude form to establish in some central part of London, an Indian and Ceylon Tea Refreshment Room (on the same principle as the teatollers' coffee-houses) at which a cup of Indian or Ceylon tea and a sandwich or bit of bread and butter could be always obtained. We all know what a refeshing thing a cup of tea is, to men whose brains or eyes are tired with much reading or writing; and I doubt not that many a jaded clerk would often turn in for a cup of tea, not to mention ladies out shopping who frequently don't care to go to regular eating-houses. The same place could be a depôt for the sale of tea, and if only people at home who are interested in tea, would combine to carry out such an idea, I have little fear that in time it would pay well, both directly as a Tea Refreshment Room, and indirectly, by introducing to the public pure Indian tea. If found to pay well in London, similar establishments could be started in other large towns. The *sine qua non* of success is that tea must be sold on the spot, so that if a man liked a cup of tea, he could

buy some of the same at once to take home: after he has drunk a pound or so of Indian or Ceylon tea, he will never go back to the China.

(*To Ceylon Observer, 16th May 1881.*)

I was afraid that my proposal to establish in London a Tea Room and Agency had quite fallen to the ground. I see however that Sir Wm. Gregory comments favorably on my letter; and as you yourself have taken the matter up, I begin to hope that something may yet come of it. I feel convinced that such an establishment would be the best advertisement that our tea planters could have; and as a considerable portion of our planting community is now interested in tea, it would only seem natural for the Planters' Association to move in the matter. Wants of funds, of course, would be the serious difficulty; but surely the numerous gentlemen now engaged in tea-planting could, if united, command sufficient influence to start a company for the purpose of establishing a Tea Room and Agency in London, with a view to stimulating a demand for our teas. It may be said by some that we have no tea should a large demand arise, and what is the use of creating a demand before we have the supply to meet it? But if we wait to create a demand until we have a large stock of tea, the market will be glutted, and prices ruinously low. Clearly therefore the sooner a start is made the better. Apart from the benefit of the tea rooms as an advertisement, the Agency would be most advantageous to planters, who by shipping direct could realize a decent profit themselves, while they could put their teas in the market cheaper than if they went through the broker's hands, in fact the planter would sell at a low retail price, and the consumer would get a good genuine article at a cheap figure.

(*To "Ceylon Observer," 4th June 1881.*)

Your extract from the *Home and Colonial Mail* in your issue of the 28th ultimo shows that what the Ceylon tea planters ought to do in London, viz., establish agency for the sale of their teas has already been done in Dublin by an energetic Indian Tea Company with respect to its own produce, and that the venture has been attended with success. If nothing better can be done, by all means form a tea syndicate to be affiliated with the Indian syndicate; but I maintain that by the establishment of such an agency as I advocate a great deal better can be done than affiliation with a syndicate whose power is necessarily handicapped by having to find markets for and dispose of such large quantities. Another point in our favour is that Ceylon tea is more readily appreciated than Indian which, though as good, takes longer than ours to accustom itself to the palates of people who have been in the habit of drinking China tea. Of course the whole secret of success would lie in advertising, and this should be done not only at home, but in the local papers here, with, at the foot of each advertisement, a "*note*" to European residents in Ceylon: "Please cut" this out and enclose it in your next home letter! Say 100 only responded to this and each house used 2 lb. of tea a week, there are 10,000 lb. per annum disposed of at once.

MARKS OF CEYLON TEAS IN MINCING LANE.

Matale, 29th May, 1886.

DEAR SIR,—In the list of tea sales published in your paper from time to time I have frequently noticed very large breaks sold under the mark of Highlands. Can you or any of your correspondents inform me of the whereabouts of this estate? It is remarkable that an estate putting in breaks into Mincing Lane of over 100 chests at a time should be so little known. Highlands estate does not seem even to be mentioned in the Ceylon Directory. Tea on this side flushing well.—Yours faithfully,

INQUIRER.

[We take "Highlands," "Oya" and some others to be Colombo marks, put on by buyers of tea in small parcels at local sales in making up big breaks. —ED.]

CEYLON TEA IN WESTERN AUSTRALIA.

29th May 1886.

DEAR SIR,—Should you think these few lines worth a corner in your valuable paper please insert them. Feeling deeply interested in the welfare of K. C. B. (alas! a title soon to be erased), and particularly after persuing a letter of Mr. Henry's in the *Observer* of the 25th, induces me to pen a few lines, endorsing his sentiments with regard to Australia being a good market for Ceylon teas. I have as a *bait* sent a few pounds of good tea to Western Australia, and I am glad to say, it has been *much* appreciated; and by the last mail I heard from a friend, and quote his words merely to show there is a demand for it:—"If anyone would let me know what they would sell tea a pound for and would send it over, I could guarantee them ready sales, as people here are paying 2s 9d for real *trash*. I have spoken to several of the merchants, and they are ready to buy at high prices. Mr. ——— should send his tea here, to pay well." I have also forwarded samples to a friend in Melbourne and am waiting the results. I think the above will show Ceylon teas will sell in Australia. K. C. B.

PRESERVING FISH IN A FRESH STATE by means of a mixture of salt and boracic acid, forms the subject of a paper which has been sent to us by the Madras Government. Deputy Surgeon-General G. Bidie, M.B., C.I.E., ever on the watch for improving the resources of the country, was struck with the abundance and cheapness of large sardines at Tellicherry and desirous that a cheap means of preserving the harvest of the sea and distributing it inland in a fresh state should be discovered. He found what he wanted in a series of articles in the *Scotsman* on a chemical powder, the constituents of which we have indicated, by means of which herrings sent from Norway in a fresh state were underselling English herrings in the English market. There should be two pounds of salt to one of the acid, and the fish should be packed between layers of the mixture. The full details appear on page 22.

OF THE BECHE-DE-MER fishing in Torres Straits Mr. Douglas reports that it is passing into the hands of South Sea Islanders who "will require pretty close watching." He believes that "there is not much margin of profit in it, unless very cheap labour can be obtained. This, however, is secured in the native inhabitants of the islands in the Straits, who are glad enough to work for small wages in order to earn what is called their 'tucker,'" He estimates that there are 500 men and boys employed, of whom probably a third, though possibly a half, come from the mainland of Australia, and he has reason to "believe that there has been a good deal of quiet kidnapping." In one case especially he ascertained that a lot of mere children had been purchased from their relatives on the Jardine and Batavia rivers. They were subsequently brought from Darnley to Thursday Island, in order to be entered on shipping articles, but it was so evidently a case which required his intervention, that Mr. Douglas "caused them to be taken back to their own people at the expense of their so-called employers." This action had a beneficial effect in checking the employment of mere children, and also established more friendly relations with the native inhabitants of the mainland. Port Kennedy, the seat of Government on Thursday Island, is a progressive place. The revenue collected in 1885 amounted to £12,553; and the exports of pearl shells were valued at £86,990, while the beche-de-mer sent away was worth £7,383.—*Australasian.*

IMPORTS OF AMERICAN COFFEES FOR FISCAL YEAR 1885.

The first quarterly report of the Bureau of Statistics of the Treasury department has just been issued, and it gives in detail the imports into the United States from all the countries south of us for the fiscal year ended June 30, 1885. From the statistics given we compile some statements that will be of interest to all dealers in coffee.

The following table shows the imports of coffee, by pounds, into this country for the fiscal year 1885, from the principal coffee producing countries of America, compared with the imports of the two preceding years:—

Countries	1885.	1884.	1883.
Brazil	406,714,346	347,873,001	315,465,986
Mexico	10,041,421	9,975,466	17,020,669
Central American States	36,811,072	31,827,573	22,449,112
Hayti	19,034,988	16,825,183	22,527,950
Dutch West Indies.	322,620	1,221,858	3.442,467
British West Indies	3,896,698	5,205,957	2,888,404
United States of Columbia	4,608,889	8,817,733	6,956,008
Venezeuela	53,506,130	53,363,495	43,369,170
Porto Rico	4,864,188	217,827	80,286
Total	539,800,352	474,288,093	491,974,968

It will be noted that the imports for 1885 are some 65,000,000 larger than for 1884, and nearly 50,000,000 pounds more than for 1883. The imports from Brazil are very large—nearly 60,000,000 pounds in excess of last year. Outside of Brazil the increase is something over 5,000,000 pounds. The Central American states and Venezuela still continue to furnish large supplies, while Mexico does not loom to the front with the bigness of a few years ago.

It has frequently been said that low prices would decrease the cultivation of coffee, but no evidence has yet been produced that there is any decrease in coffee culture. On the contrary, there appears to be an increase. —*St. Louis Grocer.*

SEEDTIME AND HARVEST.

[Not poetry, but a good deal of common sense for cultivators of the soil.—ED.]

The sowing time and reaping are surely linked together,
The issue often pending on the rain and clime, and whether
The tiller has attended to his duties with the soil
By making a good seed-bed, not thinking of the toil.

***

Economy of labour is good enough 'tis true
To warrant an endeavour to limit it all through;
If while the work we spare thus we do not touch our purse,
And show our progress downward from bad right on to worse.

***

Temptations most alluring assail the planter's heart
To well reduce the labour and try by scheming part,
To make secure his profits without the toil or care,
Which trouble those who patiently and well the soil prepare.

***

But since the world began it has been thus decreed
That from the sweat of brow no tiller can be freed,
For without fit preparation the soil can never do
The will of those who work it, or cheer them fully through.

***

Then with good will bestow ye that daily meed of toil,
Which surely will reward you with an abundant spoil,
In sowing time be thorough that in reaping time you may
Rejoice in full and plenty and make a good display.

***

Resist the wily tempter who whispers "never mind,
The soil is there and seed too, so in good time I'll find
A crop all ripe to garner whether I work or play."
Beware! or lessened profits will chill you with dismay.
—*Planter and Farmer.*

COFFEE-TEA.

(TO THE EDITOR OF THE "ADELAIDE OBSERVER.")

Sir,—The following extract from the "Chemistry of Common Life," by Professor Johnston, is, I think, of sufficient interest to warrant me in asking you to publish it.—I am, Sir, &c., CONRAD N. WORNUM.

"Attention has been drawn to the use of the leaf of the coffee-tree as a substitute for that of the tea-tree. In 1845 Professor Blume, of Leyden, who had travelled much in Java, made known in Holland that this leaf was so used in the Eastern Archipelago, and recommended it for trial in Europe. Subsequently it was known in this country by Professor Brande; and at the Great Exhibition, in 1851, Dr. Gardiner showed specimens of prepared coffee-leaves, announcing at the same time that they contained theine, and suggesting that they should be substituted for our ordinary tea. These, along with other circumstances, have drawn the attention of Eastern merchants to the subject; and it appears from various communications which have been made public that the use of coffee-leaves in this way is an old practice in the Eastern Archipelago. In the Dutch island of Sumatra especially, prepared coffee-leaves form the only beverage of the whole population, and from their nutritive qualities have become an important necessary of life. The leaves are roasted over a clear, smokeless bamboo fire till they become of a brownish-buff colour. They are then separated from the twigs, the bark of which, after a second roasting, is rubbed off and used along with the leaves. In this state they have an extremely fragrant odour, resembling that of a mixture of tea and coffee. When immersed in boiling water they give a clear brown infusion, which, with sugar and cream, forms an agreeable beverage. Mr. Ward, many years settled at Pedang, in Sumatra, thus narrates his experience in regard to the use of the coffee-leaf in that island:—'The natives have a prejudice against the use of water as a beverage, asserting that it does not quench thirst or afford the strength and support the coffee-leaf does. With a little boiled rice and infusion of the coffee-leaf, a man will support the labours of the field in rice-planting for days and weeks successively, up to the knees in mud, under a burning sun or drenching rain, which he could not do by the use of simple water, or by the aid of spirituous or fermented liquors. I have had the opportunity of observing for twenty years the comparative use of the coffee-leaf in one class of natives, and of spirituous liquors in another, the native Sumatrans using the former, and the natives of British India settled here the latter; and I find that while the former expose themselves with impunity to every degree of heat, cold, and wet, the latter can endure neither wet nor cold for even a short period without danger to their health. Engaged myself in agriculture, and being in consequence much exposed to the weather, I was induced several years ago. from and an occasional use of the coffee-leaf, to adopt it as a daily beverage, and my constant practice has been to take two cups of a strong infusion with milk in the evening as a restorative after the business of the day. I find from it immediate relief from hunger and fatigue. The bodily strength is increased, and the mind left for the evening clear and in full possession of its faculties. On its first use, and when the leaf has not been sufficiently roasted, it is said to produce vigilance; but I am inclined to think that where this is the case, it is rather by adding strength and activity to the mental faculties than by inducing nervous excitement. I do not recollect this effect on myself except once, and that was when the leaf was insufficiently roasted. As a beverage the natives universally prefer the leaf to the berry, giving as a reason that it contains none of the bitter principle, and is more nutritious. In the lowlands coffee is not planted for the berry, not being sufficiently productive, but for the leaf the people plant it round their houses for their own use. It is an undoubted fact that everywhere they prefer the leaf to the berry.' (*Pharmaceutical Journal*, vol. xiii., p. 208).

"He adds further that while the culture of the coffee-plant for its fruit is limited to particular soils and more elevated climates, it may be grown for the leaf wherever, within the tropics, the soil is sufficiently fertile.

This is a very important fact, and, should the leaf come into general use, will no doubt lead to the introduction of new forms of husbandry in many tropical regions, from which the coffee-tree, as a profitable article of culture, has been hitherto excluded. At present the price of the prepared leaves in Sumatra is about 1½d. a pound, and they may be packed, if good quality, for the European market for 2d. a pound. In regard to the constituents of the dried coffee-leaf, the agreeable aroma emitted shows that, like Chinese tea, it contains a volatile oil, which will probably act upon the system like the similar oils of tea and coffee. It has been proved also to contain theine to the extent of about 1½ per cent (Stenhouse), and an astringent acid closely resembling that which is found in Paraguay tea. Both of these are present in it in larger proportion than in the coffee-bean, and hence, probably, the reason why the leaf is preferred to the bean by the natives of Sumatra. These, with about 13 per cent of glutin and some gum, are all the important ingredients yet found in the leaf. But the presence of these substances proves it to be so similar to the tea leaf in composition as to lead to the belief that it may be successfully substituted in common use for the Chinese tea. And this conclusion is supported by the wakefulness which is said to be produced by the infusion of coffee-leaves, by the bodily refreshment it is found to yield, by the directly nutritive power which the leaves possess, and by the general favour they have found in the estimation of the people of Sumatra. To boiling water the dried coffee-leaves yield about 39 per cent of their weight—as much as is taken up by water from the most soluble varieties of the coffee-bean, and more than is yielded by average Chinese tea. In this property, therefore, the leaf of the coffee-tree is also equal to the bean."

ANNUAL STATEMENT OF THE COFFEE TRADE OF THE UNITED STATES.

The more prominent features of the coffee trade of the United States during 1885, have been, first, a further increase in consumption as compared with previous years; second, an extremely low range of values throughout the year; and, third, the change that has become established in the methods of conducting business, more particularly with respect to the product of Brazil, which constitutes the bulk of our supply. Increased consumption has been due partly to the growth of population, but unquestionably the most important element has been the increasing popularity of coffee as a beverage among all classes, while its relative cheapness to consumers as a food staple has not been without its influence. The extent to which roasted coffee is now prepared and distributed has had much to do with its increased popularity. So long has this preliminary preparation had to be accomplished in the kitchen, the loss and labor that was entailed deterred many from its use. A lack of care or experience in this important process was apt to cause waste, in addition to the ununiform and imperfect results obtained, but this has been entirely obviated by the erection of large roasting establishments throughout the country, where, with the aid of improved machinery, and by the utilization of many ingenious inventions this labor is all performed perfectly and satisfactorily, and consumers are enabled to obtain from retailers an article that is thoroughly prepared for cooking. This fact, together with the relatively low prices that have been established during the past two years, has made coffee peculiarly the poor man's diet, and greatly popularized and extended its use with all classes. The extent to which low prices have influenced consumption may be readily appreciated from the fact that the average price of Rio during the year under review is the lowest since 1852. The changed methods of doing business relate to the manner of importation and sale. Jobbers and roasters now supply their wants chiefly by purchases made direct in Rio, that is, instead of coffee being imported here for sale, its sale has been accomplished in most instances before it is shipped, and the sea coast ports have become clearing-houses, and distributing centres, rather than marts where actual merchandize is bought and sold. The net results of low prices and new methods of business have been narrow profits to importers and dealers and a year of trade that, while in no sense disastrous has not proved one of singular prosperity to those engaged therein. These features have not been confined, however, to the coffee trade alone, but have characterised, to a greater or less extent, the operations of the year in almost every department of commercial activity and may be readily traced to the natural development of the tendencies of the times, after experiencing a long period of trade depression and the practice of close economy. The existing condition of affairs has resulted from keen competition, a radical improvement in the methods of transportation by water, as well as on land, increased facilities for rapid communication with all parts of the world, the abundance and cheapness of money, the closer relations existing between buyer and seller, and a consequent disposition to trade upon a narrower margin of profit. The fact that the yearly average price for fair to prime Rio is the lowest since 1852, is the best proof of its relative cheapness during the year, but the very narrow fluctuations of the market have been of still greater importance in restricting the opportunities for obtaining more than a living profit.

Consumption east of the Rocky Mountains has increased in comparison with 1884, 11,855 tons, or 5·3 per cent, which although not as great an increase as shown the year previous, nevertheless means about one-half pound more for every man, woman and child of our population, which is a very considerable expansion, considering the relative proportion of this population that are not coffee drinkers. This brings the per capita consumption of the country up to about 9·31 pounds, against 7·61 pounds in 1879. While the United States, as a whole, is one of the largest consumers of coffee in the world, its population is not so universally addicted to its use as Holland, where the per capita consumption is about 21 pounds or in Denmark and Belgium, where it amounts to about 13½ pounds, but with these exceptions we are the largest individual consumers of the beverage. In this connection it is worthy of remark that Great Britain shows a steady decrease within the past few years, the quantity imported last year, which amounted to only 41,000 tons, being less than one-half what it was four years previously.

The total importations of all kinds of coffee have been 16,938 tons in excess of the previous year, that the stocks carried over January, 1, 1886, were 1,785 tons less than at the corresponding date in 1885, and that there was exported 3,700 tons more than during 1884, thereby resulting in an increased consumption of 11,855 tons. Brazil has been the most important source of supply, the United States absorbing by far the largest proportion of the product of that empire, and the direct importations from there forming about 73 per cent of the total quantity of all kinds imported. The total importation of Brazil coffee last year from all sources was 3,180,343 bags, against 2,787,111 bags in 1884, an increase of 393,232 bags. There has been a slight falling-off in the importation from Venezuela and the United States of Columbia which amount to only 417,632 bags, against 462,040 the year previous. This has been due to the political disturbances in the latter states, which prevailed from March to September, and in some unexplained way led to the disappearance of over 40,000 bags that was expected from that source. The direct receipts from Java and Sumatra show a considerable decrease compared with last year owing to smaller crops in those islands, but the deficiency has been more than made up by increased importations from Macassar, which, although inferior in quality and price, has no doubt been readily consumed by an unsuspecting public as "old Government Java." There has been an increase in the receipts of Mexican, which are nearly double those of last year, and would seem to point to increased cultivation. These grades are of excellent quality and appearance, but in the hands of the distributer they lose their identity and find their way into consumption in the various mixtures that are sold to the public under other names. In addition to 43,753 packages received at New York, about 32,500 packages were imported at New Orleans and Galveston. The

importation of Mocha is about the same as last year, but the 18,000 bales received at all the ports is but a small percentage of the Mocha consumed, Santos Pea Berry and other similar appearing beans being used by mixers to supplement the supply of genuine Mocha. There has been a considerable increase in the importations from Holland, which are nominally brought over as the product of the East Indies, but the mixing proclivities of Dutch coffee traders are too well known to make the identity of these grades in any sense sure. — *New York Shipping List.*

PRESERVATION OF FRESH FISH.

In my official report on the town of Tellicherry recorded in G. O., Financial Department, No. 166 M., of 20th February 1886, it was mentioned that "at the time of my visit fresh sardines of large size were being sold at the rate of 100 for quarter of an anna." It was further remarked that "as this fish is so abundant at certain seasons and so cheap, it seems a great pity that it could not be cured in large quantities so as to keep good for some time for the benefit of the inland population." At other places on the coast I was also much struck with the rich harvest of the sea both as to numbers and variety, and the subject of the more general utilization of fresh fish has at intervals occupied my thoughts ever since. It was, therefore, with much satisfaction that I noticed in recent issues of *The Weekly Scotsman* a series of papers by so distinguished an authority as Professor Cossar Ewart on the preservation of fish, and, as one of these is calculated to be of some use now or hereafter in the way of increasing the food supplies of the rural population of Southern India, I take the liberty, and have now the honor, to submit it to the Right Honorable the Governor in Council with the suggestion that it might advantageously be republished in the District Gazette of Malabar and perhaps also in the Gazettes of some other maritime districts on the East Coast. Professor Ewart's attention was directed to the subject by the discovery that through the use of a "chemical powder" in preserving her fish, Norway was driving indigenous fresh herrings out of the English market, as many as 30,000 barrels having been sent across during the present winter and sold at prices so low as to defy all local competition, and in a state which led the consumers to believe that they were eating absolutely newly caught fish. Before giving the extract from the Professor's paper, I would express a hope that its perusal may induce some enterprizing firms on the West Coast of Madras to try the experiment of sending fish, prepared with the "chemical powder," by rail into the interior, where no doubt they would find a ready market. There is apparently no reason why stations all along the line, such as Coimbatore, Salem, Trichinopoly and Bangalore, and even places on the north-west line, should not be thus supplied with some of the admirable species which at certain seasons are so plentiful off the Malabar ports. I am not in a position to discuss the commercial aspects of the proposal, but *primâ facie* it seems likely to be remunerative. At present the Madras Railway carries fresh fish at reduced rates, and if the traffic were increased it is probable that a further reduction would be made. It may be also anticipated that with an increased demand more extensive and skilled means of capture, and more speedy delivery at the curing stations, would follow. In a European climate the "chemical powder" is said to keep fresh fish perfectly good for several weeks, and if in India it would perform the same office for one week or even three or four days, the gain to the country would be very great. The preservative is a mixture of common salt and boracic acid, and the latter can be bought in England for less than six pence a pound. The following are Professor Cossar Ewart's remarks on the subject, including instructions as to the application of the powder:—

THE PRESERVATION OF FRESH FISH.

The "chemical powder" used by the Norwegians for preserving herring is a mixture of boracic acid and common salt. From our greatest authority in antiseptics I have learnt that boracic acid has been in use in Norway for at least fourteen years "for the preservation of articles of food, &c." Those acquainted with Norway can well understand how necessary it is for the farmers and others who live far removed from the towns—by the margins of the long winding fords, or on the slopes of the great mountains—to provide themselves with various kinds of pickling agents. It seems boracic acid, after a long trial, has proved a most valuable preservative, chiefly because it keeps fish and other food stuffs in a perfectly fresh condition for several weeks, and, without being hurtful, it often tends to improve the flavor.

Recently, a mixture of boracic acid and salt has been used with so great success for preserving herring in a fresh condition that it is now possible for Norwegian herring to compete successfully with absolutely fresh herring in the English market. Thousands of people in England have consumed Norwegian herring a week or more after their capture, believing they were fresh from Yarmouth or some of the great Scottish fishing stations. I need not say that herring rapidly become unfit for food when taken out of the water. In summer they are often useless twenty-four hours after they are captured, and in winter the process of disintegration is not long delayed. What is true of herring is to a great extent true of other fish. Often in summer the fish landed at Newhaven (from fishing boats becalmed at sea) is all but putrid, and were it thoroughly inspected, as it doubtless should be, it would often be at once condemned as unfit for food. It is, as already pointed out, this extreme perishableness that necessitates the rapid dispatch of fresh fish, and affords an excuse for the high rates charged for carriage. Hence the boracic acid will be welcomed as a great boon if it preserves fish in a fresh condition for several weeks. On learning some time ago that the Norwegians were sending us herring preserved in a chemical powder, I succeeded in getting a sample and had it at once analyzed. After an elaborate examination, Dr. Atkinson, Assistant to the Professor of Materia Medica in the University, reported that the substance submitted to him was a very pure preparation of boracic acid. Mr. David Murray, of Anstruther, who takes a keen and practical interest in all question relating to the fish trade, was good enough to pickle several samples of herring according to the Norwegian plan. Some of these samples I have examined with the most satisfactory results. Herring pickled on the 19th January are as fresh and sweet to-day as they were when introduced into the mixture, and when cooked they can scarcely be distinguished from herring only a few hours out of the water. I understand that equally good results have been obtained by Mr. M'Combie, of Peterhead, with haddocks.

Let us now indicate how the boracic acid should be applied. For preserving herring, the best plan seems to be to make a mixture of powdered boracic acid and fine salt, taking two pounds of salt to every pound of boracic acid. This mixture having been made, the fresh herrings should be arranged in layers in a barrel, in exactly the same way as cured herring are packed, and each tier covered with a thin layer of the mixture. When the barrel is full it should be tightened down in the ordinary way, and then "pickled" with a weak solution of pure boracic acid. For treating a barrel of herrings in this manner, 2½ lb. of acid and 5 lb. of salt are required for spreading on the tiers of herrings during packing, and about 10 ounces of pure acid for dissolving in the fresh water used for pickling. After further experiments it may be found advisable to alter somewhat the proportions here given. The barrels when packed should be kept in a cool place where there is a nearly constant temperature. The expense of pickling a barrel of herrings (a barrel holds from 800 to 1,000 herrings) in this way need not be great, for boracic acid can be purchased under 6*d.* per pound. A barrel of herring, which cost originally 8*s.*, might be preserved in boracic acid and delivered in London for 14*s.*; this is supposing the pickling to cost 3*s.*,

and the carriage 3*s*. If sold for 20*s*. (*i.e.*, three or four for 1*d*.), a considerable margin would be left for profits to the curers and others.

In addition to preserving fish, boracic acid might be of use for preserving fishermen's bait. Often the fishermen (or more often the fisherwomen, at considerable expenditure of time and money, bait their lines in vain. All arrangements are made for a night's fishing, when a change of weather prevents the boats reaching the fishing ground. Before another night arrives the bait has usually lost its catching powers, and the tedious process of baiting the lines has to be repeated. Whether boracic acid will preserve bait the fishermen only can settle. If at Anstruther, or some other fishing station, two or three fishermen use bait which has been preserved for some days in an equal mixture of salt and boracic, and compare its catching power with fresh bait, they will be able to ascertain whether this preservative will in any way lessen their labors. The United States fishermen often have wonderful success when they use frozen herring as bait; the herring are usually frozen and exported from Labrador.

It may be hoped this system of treating fresh fish will be useful. It ought at least to enable our curers to compete with Norway, for in addition to other advantages they have better material to work with, our herring being undoubtedly superior to those taken around the Scandinavian coast; even the Norwegians prefer Scotch-cured herring to their own. Further, if curers preserve herring with boracic acid they will to a great extent be independent of the Railway Companies, it will no longer be necessary to dispatch fish by express trains, and pay for their carriage two or even three times their value. Whether the herring take a day or a week to reach London, Manchester, and other large towns will make no differece, and in many instances curers may with advantage forward parcels of fish by the ordinary coasting steamers. The saving made by sending fish by sea will be evident when it is stated it would probably cost less to send a barrel of herrings twice round the world by steamer than to send it once from St. Andrews to London by rail We must, however, not expect too much from boracic acid. Something more will be required before the fishery industry recovers from its present state of collapse, and begins to assume the importance it deserves. The consideration of a more thorough system of reaping and distributing the harvest of the sea will be better reserved for another communication.

TEA CULTURE IN NATAL.

Sir,—In my previous letters respecting the above, dated Oct. 10, 1884, and Aug. 28, 1885, which you kindly published, I endeavoured to convey to your readers that a profitable and pleasant industry, requiring but small capital to commence with, was open to those anxious to benefit themselves and relieve the congestion of population in this country, whereby others would be also benefited.

At the Colonial and Indian Exhibition your readers have an opportunity of seeing the exhibits of Natal tea, and assuring themselves that tea of really superior quality is grown and manufactured in South Africa, a fact that I have heard many question.

The *Natal Mercury* of March 23 has the following:—"Up to date Mr. J. L. Hulett has manufactured this season 28,500 lb. of tea. His estimate for the season was 35,000 lb., which he will be able to secure now without much difficulty." "Messrs. Lyle and Reynolds, Kirkby Vale estate, have secured over 5,000 lb. tea this season, but they anticipate getting 10,000 lb. altogether before the present season closes." These paragraphs refer only to two estates. The oldest, Mr. Hulett's, commenced with the planting of half-an-acre, Nov., 1877; 5½ acres planted out Nov., 1880; 26 acres Nov., 1881; 18 acres 1882.

Now that the industry is assured, extensive planting is going on throughout the coast lands of the colony. Mr. Hulett kindly volunteers any information required to beginners on the spot, or to correspondents. I am also open to afford all information at my disposal, and desire to state that the tea-growers in Natal have all had to grope their way without special training. I have heard it suggested that with the cultivation of Indian and Ceylon teas increasing, that over-production is sure to be the result in the course of a few years. I put the question to a practical man some few weeks back, and he replied thus: China teas year by year decrease in strength and value, owing to overcropping and the natural exhaustion of the soil. The demand for good tea is ever-increasing, and to keep up the standard of quality, increased quantities of Indian teas have to be mixed with those from China for retail trade. In other words, China at present supplies bulk, and India and Ceylon quality or strength. The sample of tea enclosed, of Mr. Hulett's, has just been valued at 2*s*. 7*d*. in bulk, and partakes of the full character of Indian and Ceylon teas in liquoring and appearance.—MORTON GREEN.

[Having submitted the inclosed sample to a firm of high standing, we have received the following report as to its quality and value: "It is very like a Ceylon tea, has a very pretty leaf, but not much of a liquor, and would be almost sure to find a market in England. If it was printed as a Ceylon tea no doubt it would fetch 1*s*. 3*d*. to 1*s*. 4*d*., but being a new tea people would not care about giving more than 1*s*. to 1*s* 2*d*., as they would not know how it would do for bulking purposes. The infusion is good, but inclined to be greenish."—ED.]—*Field*.

PEPPER.—Discussing the future prospects of pepper generally, the *Grocer* says:—"High as prices may be considered in London, they are looked upon as being very moderate or low in Singapore and Penang, and it has been reported that shipments from thence have in consequence been stopped. Be that as it may, the arrivals from the East are certain to be later than usual, having only lately begun,-whereas in other years at this time they have been near at hand; and besides that, heavier stocks were also already in warehouse. The bulk of the supply of black pepper may consist of Penang descriptions, or it may not, and the answer to this question will decide whether or not the season's shipments to this port will be large, restricted, or small. Advices from Eastern India are silent on that point, and it is of course impossible to predict whether the market will go higher or lower. Home buyers naturally would prefer to see the value further decline, as it enables them to get rid of a larger quantity of stuff and that too at a better profit. At the same time the exporters are much freer purchasers when prices tend more in their favour; and although their being so increases the competition between one branch of the trade and another, it helps to quickly absorb the supplies on offer, and make the necessity for liberal importations to this country all the greater. It thus appears that the tendency of the market is as much dependent on the largeness or smallness of the demand for export in the spring or autumn, as it is on the scantiness or abundance of the whole season's supply, and until the one or the other of these probabilities develop themselves into living facts, it is mere coquetting with the question to say what will be the prevailing condition of the pepper market during the next six months. There are, nevertheless, one or two things of which we may be sure, and the first is, that speculators for a rise—should there be any persons so foolish or misguided—will not have much scope for operating as they wish, as with Singapore white pepper of fair merchantable quality at 10¾d. to 11d., and black at 6¾d. per lb., there is but little room for a fresh advance, unless the enquiry is very strong or the consignments hither extremely light. Another circumstance which ought not to be lost sight of is, that while the supply of pepper in general does not appreciably augment, the consumption and deliveries at the leading depots are gradually extending, and may at no distant day assume bigger proportions that any dealer or exporter ever supposed."—*Home and Colonial Mail*.

A JUDICAL SLAVE AUCTION was held at Limeira, Sao Paulo, a few days since, which was largely attended. The bidding on some slaves went up as high as 1,600$, notwithstanding the maximum valuation in the Saraiva-Cotegipe compact is 900 $. It would seem that the planters have little fear of an immediate collapse of "the foundation of our society."—*Rio News.*

A SUCCESSFUL FRUIT-GROWER in the Rockhampton district gives us a chapter from the dark side of his experience as follows: "I see some one signing himself 'C. M. H.' fancies that the scale is the orange grower's worst enemy. I guess if he had to fight the orange moth as we have had to do it this season he would alter his opinion. On the evening of April 15th I. and T. caught 356, and during the fortnight, from the 10th to the 24th of April, we got 2,333. For three weeks we had to work almost all night at them, and we still have to patrol every night, and after all our work I believe that to estimate the portion of the crop thus destroyed at eleven-twelfths is very moderate. Out of the large quantities of guavas on our trees we gathered only seven sound ones, for the grubs and flying foxes got the rest." Fruit-growing in some parts of Queensland at any rate is not all "beer and skittles." Daylight marauders are bad enough, but these "night birds" are evils magnified, and "hanging is too good for them," especially the flying foxes.—*Planter and Farmer.*

THE FRUIT TRADE WITH NOVA SCOTIA.—Our contemporary, the *Colonies and India*, says:—"Very few consumers know that the nice rosylooking apples which they see in the fruiterers' shops come from Nova Scotia, or that there is exported from that province to this country something like 100,000 barrels out of an annual average production, say, of 200,000 barrels. It is only in late years that the people of the valley have awakened to the remarkable adaptability of their lands to apple culture. Cheap railway and ocean communication and the opening of the English markets a few years ago inaugurated, however, a new era. In 1871 the acreage of the valley devoted to Apple culture was 5,152; in 1881 it had increased to 8,500. To-day it is over 10,000 acres. When the next census is taken there is reason to believe it will be 16,000 acres; while the acreage of the province, which to-day is about 25,000 acres, will then at least be 30,000 acres. Nova Scotia's great advantages as a fruit producing country are these:—1st, its nearness to Europe and consequent short land and ocean carriage and cheap freights; 2nd, the generally acknowledged fact that her Apples, as a rule, have better keeping qualities than the same Apples grown on any other part of the continent, so that if properly handled the risk of loss from decay and overripeness is reduced to a minimum.—*Gardeners' Chronicle.*

TOMATOES IN POTS.—The great demand that has arisen for tomatoes has led many to give up other crops and to concentrate their energies on the production of tomatoes, which never seem sufficiently plentiful. With such a strong-rooting plant as the tomato, there is little difficulty about growing it, the main question being how to get a maximum weight of crop from a given space. We find confining the roots to a limited area, and cutting off all side shoots, so as to make regular cordons of each plant, to produce the best results. For main crops under glass, we sow in January in heat, and grow the young plants on by giving them successive shifts until they are in 8 in. pots, which are allowed to get rather full of roots. This induces free flowering, and then they are set on boxes filled with good rich soil, and allowed to root through into it. By keeping the soil moist by frequent applications of water, a very heavy crop may thus be produced in any position under glass exposed fully to sunlight. As regards varieties, I find a good selection of the old smooth red kind to be very prolific, and not easily excelled for general use; but all have their special merits. The main point is to prevent excessive leaf production by timely attention to pinching out the side shoots directly they are visible, and only leaving large and healthy foliage on the main stem. It is sheer waste of force to let a crowd of shoots grow and then cut them off. Preserve the foliage on the main stem intact, and do not let any other be produced. Plenty of fruit will set on the leading shoot for any one plant to swell off to full size.—HANTS. —*Field.*

PLANT LIFE is invigorated by the mechanical condition of the soil as certainly as by its fertilising properties. Unless the pores of mother earth are kept open above and below for air to rush in and water to move downwards healthy vegetation need not be expected. Both air and water should be able to permeate the soil freely to ensure good vegetable growth. —*Planter and Farmer.*

A BILL has been introduced into the Sao Paulo provincial assembly by Visconde de Vinhal for the repeal of the law imposing a tax of 2,000$ on all slaves imported into that province. According to the *Diario Mercantil* the reason for this is to be found in the fact that some 40 or 50 slaves have been brought into Sao Paulo from Bahia and are for sale. When this hard-fisted Paulista gets down to Rio, he will probably ask the imperial assembly to repeal the Rio Branco law and the anti-slave trade law of 1831, so that Brazil can return once more to unrestricted traffic in human flesh and blood.—*Rio News.*

COPALCHI BARK.(*Croton niveus*, Jacq.,) forms the subject of a note by M. E. Schmidt (*Repertoire*, April, p. 157). According to the author its first appearance in European commerce was in 1817, when it was brought to Hamburg under the name of Trinidad or Cuba cascarilla. He finds in the bark a bitter principle, soluble both in water and alcohol, also a resin. The aqueous infusion of the bark has a yellowish and the alcoholic a brown colour. A careful description of the physical and microscopical characters of the bark is also given, such as will serve to identify the article examined for future reference.—*Pharmaceutical Journal.*

THE WEATHER AND FEVER.—Mr. C. E. Paget, medical officer of health for the Westmoreland Combined Sanitary District, has published a detailed review of the prevalence of "fever" in the borough of Kendal. He compares it with the average rainfall, barometer records, and temperature. The records of only a few years are available, so the results may need revision, but it seems that excessive falls of rain have been followed with an increase of enteric fever; sudden falls of the barometer, especially when accompanied by heavy rain, have a similar effect; and a rise or fall of the mean annual temperature generally corresponds with an increase or decrease in the mortality from the disease. The *Lancet* points out that heavy rainfall forces the air from sewers to escape from every available outlet; reduced atmospheric pressure sucks the air from sewers and from soil alike; so that it is possible that the apparent relation between disease and the weather may have a simple explanation.—*Chemist and Druggist.*

DESICCATED COCOANUT.—Messrs. Linton, Hubbard & Co., Red Lion Square, London, are bringing out, by means of a new patent and improved process, the article known as "desiccated cocoanut," so largely used by biscuit manufacturers, confectioners, pastry-cooks, and now slowly gaining hold with the English house-wife for puddings, cakes, tarts, &c. Hitherto this has been imported by this country from the United States, but the American goods are found frequently to be adulterated with starch, topioca, Indian corn-meal, and even with "terra alba" or pulverised soap-stone. Messrs. Linton, Hubbard & Co., who do a large business in goods of this description, have therefore determined to make desiccated cocoanut and "Noix de coco" themselves, and to produce none but the purest goods. We are confident that by this enterprize they will command the general approval of the English consumer of these productions, and they also deserve the thanks of the public for introducing what is a new industry in this country, as they are the only manufacturers of these goods outside the United States. We have examined their samples, and find them much whiter and brighter than the American product. They are, moreover, fresher, and retain the full flavour better after baking. With sugar, and spread on tarts and buns, desiccated cocoanut is a delicious substitute for peel or almonds; and as such its use is likely to spread very considerably when it has been properly brought before the attention of the trade. Messrs. Linton, Hubbard & Co.'s productions cannot be too highly commended, and we wish their enterprize all the success that such energy deserves. —*British Trade Journal.*

CURING OF TOBACCO.

At the close of Mr. Jackson's very interesting article on this subject he takes exception to my recommendation as to allowing the plants to lie a short time on the ground before removal to the drying-shed. He also appears to deny the necessity of any fermentative action at all. In my own practice I found it useful to let the plants lie for an hour or two, for this reason—that the leaves, especially the lower ones, which stand out from the stem, are succulent and brittle to handle when freshly cut, and so liable to become bruised or broken when placed on the cart or wheelbarrow. When slightly wilted this does not occur. In one of the notices which I have read this is carried to excess, as the crop is directed to be laid in heaps at once, under cover, and kept there for some time; this is there called "the first sweating." I made some experiments in this direction, but found the process did not suit our climate. From the various accounts I have read it is evident that there are "more ways than one" in "killing the cat." The artificial heating process for producing the fashionable yellow colour is new to me; but, in fact, the same thing is effected in my simple way under the ripening vine leaves in a warm September. In none of the descriptions I have read can I find anything like perfect information as to the physicial changes which take place in the plant between the cutting of the crop at the beginning, and the "perfect cure" at the end. I have watched these closely, and will try to describe them. There are, in fact, two yellows concerned, which seem to be confused together in the description. A plant in proper condition for harvesting will have the lower leaf perhaps quite yellow, and the next ones, counting upwards, more or less tinged, the topmost ones remaining without apparent change. When such a plant is hung up as I have directed the whole plant will turn yellow in a few days—sometimes in forty-eight hours. Now this is yellow No. 1, and is, in fact, the "sere and yellow leaf" of normal, seasonal decadence, in which life still faintly lingers. After this, and extending over a much longer interval, comes the next grand change—the change from life to death. Then appears yellow No 2: that is the tint of tobacco-paper, minus the ripening or ferment, which is the result of any tight packing. I use the term "yellow" here, but, in fact, you can never tell what colour, differing somewhat in which individual plant, will turn up. I am familiar with every gradation, from true yellow, through varying shades of chestnut-brown to nearly black. Another example of yellow Tobacco making was described a year or two since in an admirable article in the *Times* by Mr. Hamilton Lang. Here the changes I have described seem to have been effected in the full sun. I tried this system also, but found it impracticable in our uncertain climate. I believe, however, that the colour of the ultimate product is due to soil and conditions of cultivation. This would appear from Mr. Jackson's quoted pamphlet to be either virgin or unmanured soil, and in my remarks on this subject I deprecated the use of manure as likely to encourage a rank vegetation antagonistic to the development of the aromatic and other organic products peculiar to the plant.

The phenomenon of colour is a very curious and interesting subject, and well worth investigation. I have seen a beautiful bale of yellow from China, and the Japanese I am told will produce any colour to order, from plain black shag to imperial Lebanon. Why is Turkish yellow as gold, and Latakaia as black as your hat? In all the processes I have read of, and they are many, a fermentative process is indicated, notably so in Mr. H. Lang's article, where it is described as going on for several months. Doubtless the treatment varies in different countries, and according to the purpose to which the article is destined, whether for cigars or cut Tobacco for instance. In the former instance I believe the material takes a heat after its formation into cigars. I think if Mr. Jackson were to take a pipe before and after a ripening or fermentative process he would find the difference very remarkable indeed.

Finally, the subject is new to us here in England and we should be cautious in criticising each other's work. I have only had it in hand four or five years and I begin to suspect that neither I nor anybody else "knows everything."—R. T. CLARKE.—*Gardeners' Chronicle.*

DELI TOBACCO PLANTATIONS.

Deli tobacco owes its good quality mainly to the seasonable rainfall. The soil is not so good as in Java, but there, the weather has to be struggled against, whereas planters in Deli do not trouble themselves about it. Tho longest drought lasts generally 20 to 25 days at the outset of the planting season. It is by no means easy to get nowadays suitable land sure to yield satisfactory results as is too evident from the heavy losses suffered by growers from neglect, wastefulness or ignorance, owing to most of them lacking experience. A few lucky enough to pitch upon good land at the start gained enormous profits. Others took up land at a venture, only to abandon it on finding that they could never make the enterprize pay. All the land fit for tobacco growing has been taken up throughout Deli and Serdang. Even land formerly abandoned has been again brought under cultivation generally with success. The terms for leasing are 75 years at a quit rent amounting to one guilder per bouw, besides the purchase money which varies from 2 to 6 dollars per bouw. Seeking and demarcating land is no trifling matter owing to difficulties arising from jungle swarming with leeches, ants, &c. Should the land prove to be of doubtful quality the safest course is to be always prepared for failure at a slight loss rather than to sink capital sure to be gone beyond recovery in that case. Tobacco is grown by means of Chinese coolies from Penang or Singapore. To bring out singkehs or coolies direct from China costs $50 each. Experienced coolies may be had for $30 each. Large companies always work with singkehs. Pioneers and small land owners get on better with the other class of coolies from their being cheaper, more fully acquainted with the details of cultivation, and standing the climate better. Planters deserving of confidence say that singkehs are preferable chiefly from their being less troublesome to manage. On starting an estate 60 to 100 Chinese are engaged. In clearing, roadmaking, and housebuilding operations 100 Chinese are made use of on a plantation of large size together with 30 to 40 Javanese. The wage of the latter is from 6 to 8 dollars a month. They have to work 10 hours per day and set their hands to anything handy besides the planting of tobacco. Felling jungle is undertaken by Malays and Battaks, the Chinese bearing part of the expense. After it is over, burning the felled timber, &c., is set about when the dry season sets in, generally in December. In January the Chinese set to work planting, fifteen thousand plants being set out on the average every season. They receive 5 to 8 dollars per 1,000 plants delivered into the storehouses according to quality. These houses are built of jungle timber and roofed with thatch. To every 10 Chinese, there is usually one storehouse 150 feet long, 60 broad, and 30 high. In Deli sometimes the yield becomes higher than usual when the plants admit of a second cut. The planters being almost the owners of their holdings, can manage better than their fellows on Government land in Java, besides having Chinese labourers who are simply invaluable when compared with Javanese. Safety of life and property is sufficiently ensured. The Chinese are generally well treated. Most of the difficulties with them arise out of ignorance of their language. There is medical aid at hand on every estate. I never saw any Deli planter ill-treating his coolies. The planters are first-rate fellows, hardy, muscular, hospitable, open hearted, and helpful. On the East Coast, the most unbounded hospitality is met with. Visitors are welcomed everywhere and readily supplied with information. The planters being good-humoured and enterprizing get on very well with one

another. They do not foolishly compete with each other, but help one another as much as possible. Owing to the bad weather, I was prevented from seeing the wonderful work wrought by the Deli Company, whose successful operations are borne witness to by the large dividends distributed. Other estates held either individually, or on the joint stock principle are also doing well. One remarkable characteristic that strikes the eye in Deli is the total absence of lavish display of any kind. Dwelling houses and tobacco sheds are fitted up simply just enough to meet practical requirements. Land after being cropped once is allowed to lie fallow for several years. Sorting operations are carried through by Chinese only who do the work very quickly, it being greatly facilitated by the circumstance that the rains which usually fall at the season make the tobacco pliant and easy to handle. Everything seems to work together to render the country fit for tobacco growing. However brilliantly successful many planters have been in Deli, I would not advise any one to go there at a venture trusting to luck, from the slender chances of his doing well in that quarter. There are more applicants for employment than there are situations available. I met with many young men tramping through the country vainly seeking for something to do. Generally speaking, the assistants there are of a superior stamp to those in Java from their being men of a determined and fearless cast of mind. Many of them are highly educated and they comprise a great number of foreigners. Living in Deli is not cheap. Servants in particular are expensive there. Matters however in this respect show signs of improvement. The Deli Company keeps a store of its own where ordinary food supplies are obtainable by its employees at low rates. In conclusion, I heartily wish that the planters may do well and may be amply rewarded for their toilsome exertions to develop the resources of the country.—*Samarang Locomotief.*

ROCKHAMPTON BOTANIC GARDENS.

THE ROSE.

Most people are fond of a good rose, but only a few take the trouble to grow plants so as to get blossoms worth looking at. Numbers of plants are annually put in the ground something after this fashion. They are bought from some nurseryman, and a small hole is dug, very likely about a foot square. Into this the plant is put, the soil filled in and watered. Possibly the plants thus dealt with are watered every day. A good deal of the soil in town, which has not been previously drained, when holed in this way will hold the water until it is dried out by evaporation. I have seen holes two feet deep that have been full of water for months at a time. Is it any wonder then that so many plants die. A most amusing thing is that when all has been done inadvertently that could be reasonably expected to try and kill the plants, the climate of Queensland gets the blame and hard words are used by the would-be rose grower.

My experience is, there is a great number of varieties of roses that can be grown here to prefection, if the ground has been properly prepared, and this is requisite in any country. Almost any good soil will suit roses. Experienced growers prefer a rather strong loam, but very good roses are produced here on a light sandy loam. Whatever the soil may be, it is indispensable that it be trenched and drained, and if bones are available a layer should be put in the bottom of each trench, and plenty of rotten manure spread on the surface, well dug in, and forked over two or three times to thoroughly mix it with the soil. Roses should always be grown in a bed or border by themselves, unless in cases where ground has been prepared for fruit trees. For three or four years they will do very well in the spaces between the trees if the ground is specially manured for them. When the ground has been prepared the next thing is planting. If a border, the climbing and tall-growing varieties should be set at the back, and the dwarf varieties in front. The climbers can be either trained as pillars, or on a trellis. If in a bed, put all the tall sorts in the centre.

Now, about the varieties to plant in this district. The nurserymen are offering from two to three hundred varieties in their catalogues for this year, so that it is easy to get a large collection if anyone wishes it. For my own part, I prefer a dozen or two of well-defined varieties, well cultivated, to having a larger number not skillfully and properly taken care of. For the benefit of those who may contemplate planting I will give the names of a few varieties which have done well in our gardens:—Acidal, Adam, Aimee Vibert, Baronne Hallez, Beauty of Waltham, Celine Forestier, Charles Lefebre, Cloth of Gold, Comtesse de Bertha Cramoisie Superieure, Devoniensis, Eclair de Jupiter, Gloire de Dijon, Glorie de Lyons, Victor Verdier, Paul Neron, Triomphe de Lyons, Souvenier de Dr. Gommes, Lyonaise, Dr. Ardre, Robin Hood, Lord Raglan, Marie Guillot, Madam Moreau, Marechal, Neil, Solffateur, White Banksian, Yellow Banksian, Souvenier de la Malmaison, Souvenier de un Ani, Gloire de Ducher, Madam de Vatry, Acturios, Amelia Hoste, Duke of Connaught, Mrs. Baker, President Thiers. Most of the above varieties are free growers, and are of easy cultivation.

Those who wish to propagate any favourite variety have three methods open to them; first, budding, which is very little practised in this country, and is rather a difficult operation to be performed by amateurs. I don't think it is necessary to describe how it should be done. Second, by cuttings which is easy if the season is a good one, and the cuttiugs are put in during the month of July. The cuttings should be made of well matured wood of the last season's growth, cut off square just below one of the eyes. Six inches is quite long enough for rose cuttings, and a very small portion should be left above the surface. The bed is best made of nice sandy loam, and shaded slightly. Thirdly, comes the easiest plan I can recommend, which is layering. All that is necessary is to carefully bend down the branches, and make a small hole three or four inches deep beneath where the middle of the branch touches the ground. Bend the branch until it is well down on the bottom of the hole. Cut it half through with a sharp knife; fill in soil; cut the point of the branch off to within a few inches of the ground; water occasionally, and the following Autumn the plants can be taken up, and put in a nursery bed, or planted out permanently. If the season is good layering can be done at any time from March to the beginning of August. It is very little use trying to propagate roses or anything else in such a season as the present unless there is a good supply of lagoon water to be had. It is not easy in an article like this to explain how roses ought to be pruned as this needs to be done according to the strength of the growth of the different varieties. As a general rule it is safe to cut back all tall straight growing varieties to one third of the season's growth. Those that form compact heads do best by cutting off the ends of the branches so as to make the head as symmetrical as possible, and removing all dead and useless brush out of the centre. Climbing roses require different pruning to all other varieties. They require stakes or trellising to support them. Train in the young shoots as they grow, in the spring. Take the shoots off the trellis or stake, and shorten them by about one-fourth of their length; cut off all dry or weak branches, and tie them up again neatly. I have found that from the middle of July to the middle of August is the best time to prune most varieties.—J. S. EDGAR.—*Rockhampton Bulletin.*

TEA.

We took occasion, some months ago, in commenting on the relief afforded to Java tea in the Netherlands budget, to remark that Chinese statesmen also would do well to realize the fact that Indian tea is a sufficiently dangerous competitor on its merits, without being helped by a handicap on its rivals. There

is no doubt that one reason of the rapid increase of production of India is the absolute freedom from impost, and Holland is wise in giving the nascent industry in Java similar encouragement. China tea is handicapped in two ways. SIR ROBERT HART has lately pointed out that the imperfect preparation of the leaf places it at a disadvantage with the produce of its rivals, which it will feel more keenly as the shipments from India and Ceylon augment still further in quantity; and—supplementing this argument—there has lately appeared, in the columns of our Shanghai contemporary, a series of letters insisting that heavy taxation is a still more serious factor in the case. It is beyond question that China tea might be very much improved if the same care were given to its manufacture as is given in India, Ceylon, and Java; still, though the export figures have lately become stationary; the taste for it is not dying out; England and America will still buy it at the same relative value as that from other countries; "but buyers "naturally look for the best value, and that can un- "doubtedly be better found in the duty-free produce "of other countries." The import duty of sixpence a pound which it encounters in England is no doubt in itself a heavy burden, and we have more than once suggested that there is room for grave remonstrance against the incidence of a tax which amounts to nearly a hundred per cent. on the cheaper teas, and only five-and-twenty on the dearer. It might perhaps be argued that, from this point of view—the China teas being the cheapest in the market—it constitutes an indirect handicap on the latter against their dearer rivals. There is however, here, no direct disadvantage. The sixpenny duty falls on all teas alike—whether from India, Ceylon, Java, China, or Japan. Where the shoe really pinches is at home. In India and Ceylon there is no tax at all; in Japan the duties amount only to about one dollar a picul; while China tea starts with a handicap of from 30 to 40 per cent. in the race. In the Hunan and Hupeh provinces, it. appears that local duties are exacted ranging from Tls. 5.22 to Tls. 5.38 per picul—nearly, in fact, doubling the export duty; while the districts which feed Kiukiang have to pay from Tls. 4.41 to Tls. 5.74, and Green Teas of Chekeang from Tls. 4.05 to Tls. 5.17. The legitimate export duty of Haekwan Tls. 2.50 per picul constitutes, of course, the larger portion of these amounts, and that is probably the only portion which subserves imperial purposes; lekin—ranging from about a tael and a half in the majority of cases, to H. K. Tls. 2.50 on one district of Kiangsi—comes next, and various petty local taxes go to make up the total.

It may well be asked, how can China tea be expected to hold its own, under such conditions, against absolutely untaxed rivals? The policy of remitting direct taxation, in faith that compensation will be found in a consequent increase of general prosperity is, as we remarked on a former occasion, as opposite as possible to the principles of Chinese Government; and even if Peking statesmen could be brought to see that China tea, weighted by lekin and local taxation and subject to a heavy export duty besides, is unwisely handicapped, the bare idea of relieving it of all the various squeezes which go to fill the pockets and coffers of the local officials would be sufficient to produce a rebellion in Mandarindom. Either by direct remission, however, or by a more gradual process of evaporation, it seems clear that a great portion of these taxes are certain to pass from them. If the trade is not relieved from their pressure, it will be gradually killed by increasing competition. "England," to quote the concluding words of the writer whose statistics we have taken, "will be virtu- "ally "independant of China in a few years, owing "to the rapidly increasing production of India and "Ceylon. The United States, another large customer, "promises to be chiefly supplied from Japan. Can "China afford to lose the two best customers she "has? She can only retain them by a great effort. "First, by making tea duty-free; second, by improving "the article itself."

We remarked, in a recent article on the same subject, that the Chinese are indebted to SIR ROBERT HART for having impressed it upon their attention. They will be still more indebted to him if he will return to the attack with improved statistics and with the additional weapon which the above arguments furnish. We pointed out that the figures quoted by him for India and Ceylon, produce were—unless a clerical error could be suspected—very far below the mark; and his representations could obviously not be expected to have the weight they deserve, so long as they fail to indicate the real extent of the competition. A quarter of a century ago, China had nearly a monopoly of supply to the tea markets of the world. The demand for tea has since then very greatly increased but, though the value of her tea has fallen heavily, her export stands nearly where it did; while an additional supply of 115,000,000 lbs. has grown up from India, Ceylon, Java, and Japan. The 260,000,000 lbs. sent forth by China still give her an immense preponderance; but the fact has to be faced that they constitute now only two-thirds instead of, as they once did, nine-tenths of the world's supply, Hitherto, as we have said, increasing demand has kept pace with the increasing supply from other quarters, but that supply threatens to increase so rapidly within a very easily measurable period, that keen competition must ensue in which the heavily taxed and less carefully prepared China tea is sure to suffer. Already the increase of export which might have been looked for under fair conditions has been stopped; in one case, even, the current would seem to have turned—the export of green, which in 1874-5 reached 31,000,000 lbs., against 19,500,000 lbs. from Japan—having fallen this season to about 28,000,000 lbs., against 38,000,000 lbs. from Japan! Let the Inspector-General of Customs, we repeat, return to the attack with greater vigour, improved statistics and greater breadth of argument than before. There is here, as his commentator points out, no question of conceding anything for the benefit of foreigners. It is one of importance to the Chinese themselves. If the duties are not reduced, they must be prepared to stand by and see the tea trade go to other countries which have a more intelligent fiscal policy. "China will then grow merely for its own wants, and the districts "which have profited by supplying foreign markets "will become impoverished; while a speedy reduction would again give life and importance to the trade." The prospect may seem remote; 260,000.000 lbs. is a great figure to overtake; but the tendency is distinctly in that direction, unless Chinese statesman and Chinese growers agree to mend their ways —*L. & C. Express.*

THE VALUE OF THE EUCALYPTS AS TIMBER TREES.

By D. Howitz, Forest Conservator.

The Eucalypts, or Gum-trees as they have been called, have of late years attracted a great deal of attention on account of their healthy properties, but their value as timber trees has hitherto not penetrated to the great markets. There have been several reasons for this, the distance from far-off Australia, their native place, the difficulty of transport to the shipping place, the peculiarities of the wood, which as a rule is very heavy and hard, and last, but not least, that people have not known the quality of these timber trees, nor quite understood how to treat them. There is as yet a large field open for experience with these trees, but as it is likely that they will play a prominent part in the near future, it may not be without interest to know a little of their general character and utilization.

The first objection, *viz.*, the distance to the great markets, will in a few years be somewhat modified by the introduction of the more valuable Eucalypts on a large scale into the countries around the Mediterranean, and particularly in the colony of Algiers, where the cultivation of these valuable trees is being executed at a great rate. As the Eucalypt timber gets more known, the demand for the more valuable

kinds and dimensions will also cause a brisker trade in Australia, and thereby lessen the freight and the cost as better means of obtaining these dimensions are discovered.

Foremost amongst the Eucalypts, of which a couple of hundred species are known in Australia, the great home for the whole Myrtle family, stands the Jarrah tree (*E. Marginata*) of Western Australia, where it is found on the ironstone ranges along the cost. The exact extent of the vast forest containing Jarrah timber cannot be exactly ascertained, as this tree gradually gives room for other trees, but Baron von Müller, the celebrated botanist, maintains that the belt stretches from the Collie River as the southern boundary as far as the Hershel ranges in a width of varying size. The wood is brownish, and if taken from dense forest of a straight and even texture, hard, resinous, closely grained, and particularly from rocky ground of an oily appearance. It receives a fine finish and polish, and shipbuilders prefer it to teak and oak. This wood is exceedingly durable, but its chief virtue consists in the now recognized fact that it resists the attack of the "teredo navalis" as well as that of other insects destructive to timber in exposed positions. It is therefore extremely well suited for piles, wharves, railway sleepers, and telegraph poles, and as it also resists the attack of fungi or rot caused by putrid water, it should find a prominent place as wood pavement. In Australia it is a common theory that vessels built of this wood do not require copperplating, a fact only mentioned to show that it resists animal or organic parasitical life. India has already during several decades been monopolizing this tree for railway sleepers, and a great export trade has long taken place from Perth to various places in India. On the south-eastern part of Australia is found a congener, called the Bastard Jarrah (*E. botryoides*), which resembles the Jarrah, but its wood is not so durable or oily and does not resist the attacks of insects so well. The Bastard Jarrah is found in Gippsland, in the colony of Victoria, where it forms fine forests. It grows taller and furnishes straighter and larger dimensions than the Jarrah, and though not so durable as that tree is still a most valuable timber tree. In Western Australia there were about thirty saw-mills in 1882, and most of these were only employed on the Jarrah for sleeper-cutting.

The next in rank should be the Red Gum (*E. rostrata*), on account of its durability when used for underground work. This tree is a native of Southern Australia, where it is found on river flats, in swamps, and on the plains. The wood is reddish, resinous, hard, works well, and receives a high degree of polish. Ship-builders utilize it extensively for all purposes where strength and hardness are required. If used for planks the wood should be steamed before use. This tree is being cultivated largely in Algiers, and it will not be many years before its presence there will make itself felt on the flats at Lacalle, and near Bona, where this tree seems to prosper and grow exceedingly well, but no information is as yet to hand about its timber value. For railway sleepers it is extremely well suited, and even in very awkward positions it has been known to last for upwards of 23 years before showing signs of decay. Also for wood pavement this timber should be utilized; and as it resists the attacks of insects nearly as well as the Jarrah, it should take a prominent place in importation for that purpose. To this class belong also the so-called "Flooded Gums" of South Australia and New South Wales, but as transport to the seaports is difficult, and they do not play a very prominent part, they are only mentioned here.

There are many more valuable Eucalypts, but I will not weary the reader with their names and descriptions, and only remark that amongst them are found the hardest and most durable woods known, for experience has shown that some of them are practically everlasting as fencing posts and sleepers, wear and tear, of course excepted. The large giant tree, the stringybark (*E. obliqua*), furnishes immense dimensions of a light fissile wood, useful for shingles, rails, &c., and when it becomes more known, perhaps some more paying use might be found for it, while some of the mahogany Eucalypts furnish beautiful wood for cabinet-making and ornamental work. With the present facilities for transport it is a curious fact that these timber trees are so little known in the timber market, where they ought to take a very prominent place, and it is also curious that the greatest part of these woods are exported to India and to America, while Europe knows little or nothing about them. The most practical way to test the value of these timber trees would most likely be to form a company of timber merchants to deal with the matter, and then, after having communicated with the various agent-generals in London to send a practical man out to make himself acquainted with the various places and to form business acquaintance with the saw-mill owners, so as to secure a supply of good timber to throw on the market. I have no doubt that the public would back such an effort, and I feel sure that the Australian colonies would, singly and collectively, do their utmost to aid the success of the undertaking, whereby everybody would be a gainer.

The next important Eucalypt should be the Karri of Western Australia (*E. diversicolor*, Müeller) on account of the large dimensions of a straight even-grained timber which it furnishes. This timber is much sought for masts and ship-building, and is not so heavy as the before mentioned, but of a lighter and more elastic character. The tree is of a rapid growth and reaches a great height and considerable girth. In the valleys and on the flats in South-west Australia colossal Karries are found, frequently reaching a height of 300 to 400 feet and a girth of 40 to 50 feet about 6 feet from the ground, but it is rarely found except in mixture with other Eucalypts. Most important is also the so-called Ironbark tree (*E. Leucoxylon*) found mostly in Southern Australia, although it does not furnish such large dimensions as the above named. The wood of this tree is close grained, firm, and of remarkable elasticity and durability. Carpenters, ship-builders, and wheel-wrights use it, and for treenails, rudder stocks, belaying pins, blocks, &c., as well as for wheels, spokes, &c., it cannot be surpassed. There are already several saw-mills at work, and there is room for many more, as the supply is very great. For axe handles and handles in general it excels the hickory (*Carya alba*) both as regards durability and elasticity, and as this valuable tree prefers a rocky, stony ground it will most likely be cultivated to a very large extent on the otherwise useless ranges. This tree has received some attention in Algiers, whence it may confidently be expected that a good supply will be obtained before many years. The Ironbarks of New South Wales and Queensland furnish also most valuable timber of this kind, and will, no doubt, be cultivated largely as soon as the demand for them arises; but the ignorance of the European market with regard to them has caused them to be but little appreciated as yet, and consequently the forests have not been properly protected.—*Timber Trades Journal.*

TEA IN JAPAN.

Through the courtesy of Messrs. J. M. Robertson & Co. we have been enabled to inspect several models of Japanese tea machinery and implements which have been procured by Mr. Drummond Deane and which are to be eventually presented to the Colombo Museum. These miniature models are very neatly executed in the material from which the originals are made. the basket-work and sieves been really pretty specimens of workmanship, and are worthy the inspection of those who take an interest in knowing how the Japanese manipulate their produce. It may also be of interest to give some information as to the whole course of tea cultivation and manufacture in Japan. The plantations are opened in similar localities to those we have in Ceylon, the only difference apparently being that on steep land the slope is cut into terraces to prevent wash. A gently undulating country is pre-

ferred to steep land, and great attention is paid to complete drainage. It is when we come to the planting of the tea bushes that the custom in Japan differs so much from what we have been accustomed to. The seed is planted in circles of about two feet diameter and about five feet apart. As many as thirty seeds are at first sown round each circle. The circle of seed developes into one thick bush, and here a difficulty presents itself which we avoid by our single plant system. The plants in the circle develop into different classes of bushes, so that it often happens that several varieties of plant are growing also, and consequently the leaf gets mixed together. Plucking commences in the third year, and the bush is considered at its best from the fifth to the tenth year, after which it may require manure. The bushes are topped at a height of from three to four feet. There are not more than three rounds of plucking in the year; and each lasts about twenty days or a month, the first beginning at the end of April or the beginning of May, the second in June or July, and the third (which is not always available) later on in the year. This work is done principally by women and girls, and seems to be done very roughly, as whole shoots and long stems are frequently met with in the basket. Quoting from Mr. H. Gribble's "Preparation of Japan Tea" a publication by the Asiatic Society of Japan, "as a rule the tea belongs to very small proprietors, who fire their few catties a day, generally in the entrance of their own apartments, and then sell the fired leaf to larger dealers, who as principals or go-betweens, mix their various purchases together and then send 20 or more boxes of similar tea for sale at the treaty ports. But the process of preparing the green leaf is the same whether done in a small shanty or the godowns of a well-to-do merchant." This is done by steaming it for about half-a-minute in a wooden tray with brass wire bottom, placed in the mouth of an iron cauldron set in plaster, over a wood fire and covered over with a lid. The workman takes a look at the leaves and stirs them before removal, and the moist leaves, with their natural oil brought to the surface are thrown on a wooden table for a few minutes and then fired. "A box-shaped wooden frame, about four feet long by 2½ feet broad, coated with plaster forms the oven. Charcoal (well covered with charcoal ash) is alight at the bottom of the oven, and about a foot and a half above the charcoal rests the wooden frame with tough Japanese paper stretched across it." Six-and-a-half lbs. of steamed leaf is reduced by firing to about one-and-a-half. "At first he throws up the soft, moist leaves in quick succession and keeps the whole mass moving without any attempt at rolling or twisting; gradually the leaves assume a darker color, and gradually he works them up into balls, rolling the balls between his hands, separating the leaves again, rolling them on the hot surface of the paper, and finally does so with considerable strength and pressure, occasionally resting one elbow on the edge of the tray and rolling the tea between the palms of both hands with all his might. After some hours' work (depending upon the quality of the tea) the leaves have all become separately twisted, and have changed their color to dark olive purple. They are now crisp, long, thin, wiry spills, and in the case of the best leaf look more like slender tooth-picks than the leaves of a shrub. When finished the tea is strewed on a similar firing tray, but at a lower temperature (about 100°), and is then allowed to dry until it becomes quite brittle. The heat is then further reduced to about 95° and the tea left for four to six hours, even longer, if it is intended to keep it in stock for many months. Tea well fired in this manner and afterwards packed in earthenware jars will keep for a whole year without spoiling." From this description our readers will see that, though steaming is substituted for withering, and a great saving in time is thereby effected, still the process as detailed above is one that requires considerable time and trouble; and to such as it is, must be added "sorting" by hand trays; "sifting" through sieves suspended from the ceiling; and finally "hand picking" by which stalks and refuse are separated and removed. After this, the tea is collected and taken to the treaty ports to be finally manipulated and forwarded to America and Canada, which constitute its principle markets. "There are two systems of final-firing Japan tea—pan-firing and basket-firing. Pan-firing is done in rows of iron pans (21 inches in diameter by 13 inches deep) set in brick work and heated by charcoal." About 5 lb. weight is put into each pan, and stirred until sufficiently done; then it undergoes a second stirring in a cold pan and is sifted to remove the dust, being packed into the lead-lined chests while still warm. The hot firing may take from 40 to 65 minutes and the cold-pan stirring from 25 to 60 minutes. If coloring matter has to be added it is thrown in during the firing process, and is absorbed by the tea. The American demand for colored tea is becoming less every year, and in all probability will fade away altogether before long. Allusion is here made to a matter of which we have heard before "the remanufacture in London or New York of teas shipped from the East, a process for which merchants here are not responsible." Then we have to learn how basket-firing is effected. "Basket-firing consists in simply refiring the tea without any of the stirring process as gone through in the pans. A bamboo basket, shaped like a dice box, but open at the ends, is placed over a large iron brazier containing lighted charcoal (well covered with ashes), and the tea is strewed about an inch in thickness, on a close-woven bamboo tray which fits the neck of the dice box. The baskets are occasionally removed from the brazier and the tea turned over by hand in order that all may be equally fired. They are carefully replaced on the brazier without allowing any dust or leaves to fall through the tray on to the charcoal, and in the course of 40 to 60 minutes the tea is ready for packing."

The foregoing description relates to the manufacture of ordinary Japan tea, known as Japan green tea, and in which, as our readers will no doubt note, fermentation takes no part, but in the making of Japan Congous fermentation has to occur. Hitherto the financial result of Japan-made Congous has not been a success, but, as the demand for green teas is year by year less than the supply, and American and Canada are the only markets for it, it is felt that by making black teas instead of green an outlet would be found in Europe and Australia. The greater part of the Congou made in Japan is shipped to England, where it is mixed with Indan teas, the former most effectually toning the latter, and thus forming an excellent combination. To make the black or Congou the leaf is "spread out on bamboo or straw mats in a sunny place till it is quite soft. In wet weather, or when it is cold, the leaf may be rendered sufficiently pliable by wilting on iron plates or ordinary firing pans over charcoal fires. Steaming, as in the green tea process, must be avoided, as it takes too much vitality out of what is naturally a weak tea." The rolling is done by hand: "each cooly takes a double handful and rolls, as a baker kneads dough, for thirty minutes, after which it is packed tightly in large round baskets and covered over with a cloth for an hour or so to allow it to ferment, at the expiration of which time it attains a reddish brown tint. To assist the process of fermentation the basket containing the rolled leaf should be placed in the firing-room. The leaf is then tipped out on the rolling-table, well shaken out and rolled for fifteen minutes more and fired on iron gauze sieves or drum baskets, over charcoal fires. The first mentioned process takes 45 minutes and the drum baskets seventy-five." Sifting and sorting are much about the same in making both green and black teas: in the latter case, the larger leaf is broken by the hand, and the bulk is finally reduced to 5 sizes—large and small congou, large and small pekoe, and dust. The models we have had the pleasure of inspecting fully illustrate every implement that is used in the manufacture as above described even to the box and brush for the paste used in papering the boxes. Miniature boxes ready for shipment are also included with a remarkable sample of tea in one of them. It is not probable that our planters can learn much, if anything, from the Japanese that would be of advant-

age to them in Ceylon, though the "withering" by steam is a hint which might be taken so far as experiments are concerned. But in regard to native holdings of very small extent the relation of the Japanese method of curing is especially of interest, showing as it does what can be done on a small scale and with inexpensive tools, though, as we have already stated we believe the general custom here will be for the natives to sell the green leaf as picked from the bushes to small manufacturers much as they have been accustomed to do with their coffee in past days. Mr. Drummond Deane has done a service to the island by introducing his Japanese tea boxes, and his models of implements used in Japan may be regarded as an interesting addition to our store of a material for a general knowledge of the tea interest and cultivation throughout the world.—Local "Times."

A PLEA FOR THE PRACTICE OF HYBRIDISATION OF PLANTS.

BY JAMES PINK, ESQ., F. R. H. S., BRISBANE BOTANICAL GARDENS.

THE produce of vegetation as found in its primitive state conduces little in a direct manner to the maintenance of civilized man, and it is not until it has been improved by culture that it is really of any value to the world in general. This beneficial result has been brought about by the practice of the arts of cultivation and hybridisation. In this short paper I intend to deal with the latter of these, viz:—hybridisation, including cross-fertilisation.

It may be fairly assumed that in the origin of vegetation distinct species only were in existence, all other forms being merely varieties of such species; and this opinion is confirmed by the fact that, even at the present day, botanists are unable to define what strictly constitutes a species.

It is only within a comparatively recent date that the organs of fructification of flowers have been thoroughly understood, although the ancients appear to have had certain ideas as to the sexuality of flowers. Empodocles and Anaxagoras in the fifth century before the Christian era, claim for vegetables the same sexuality as animals; and Herodotus states that the Greek cultivators of the date, Phœnix dactylifera, brought the flowers from the male plants and attached them to the fruit-bearing trees, that the produce might attain maturity. Yet it was not till 1787 that any great improvements had been effected in varieties of fruit and vegetables. In that year, Thomas Andrew Knight, President of the Royal Horticultural Society of England, commenced his experiments in hybridisation, which he carried on uninterruptedly for forty years, since which time the general appearance of our cultivated plants has very much changed. It matters not whether we look to the useful or to the ornamental department of the vegetable kingdom—at the beautiful flowers that adorn our gardens and add a charm to our daily lives; or to the more useful, the fruits and vegetables that supply our wants. In each department is the thought and skill of man apparent, as year by year new forms of beauty are added to our already large list of flowers, and new and improved varieties to our stock of fruits and vegetables. For years past both the Queensland Acclimatisation Society and the officers of the Brisbane Botanic Gardens have searched the world for fruits and plants of economic value; and with great success as the garden and orchard throughout the colony testify. But here the matter has ended; with the exception of one solitary instance—so far as I am aware—no endeavour has been made to improve such plants by raising indigenous hybrids, for it is only by such means that plants can be really acclimatised. Some one has truly said that plants like men thrive best on their native soil. The one exception to which I referred is that of our President, Dr. Bancroft, who has succeeded in raising a new and indigenous variety of grape by hybridising or crossing the Isabel with the Sweetwater, the former being the mother and the Sweetwater the father of the new variety. This was done as an experiment, and no great result could be expected of it. To have raised a really improved and invaluable hybrid I would have suggested the crossing of the Muskat of Alexandria with the Isabel. This cross would probably result in a distinct break in our varieties of grapes, and by such means we might obtain a hybrid possessing the hardness and productiveness of the Isabel with the large and delicious fruit of the Muscat.

The art of practical hybridisation is very simple in itself, but it is absolutely necessary for the operator to have a knowledge of the various parts of the flower, and especially of the functions of the organs of fructification. A typical perfectly formed flower is composed of a calyx, corolla, stamens, and pistil. It is with the two latter essential organs that the hybridist has to deal. The pistil is the central organ of the flower and is divided into three parts, the ovary, style, and stigma. The ovary is that part of the pistil which is to contain the future seed. The stigma is the moist, spungy surface destined to receive the pollen-grains by which the ovules are fertilised, and the style is the column supporting the stigma, through which the pollen-tubes pass to the ovary. A stamen consists of a stalk called a filament and the anther containing the pollen-grains. It is by conveying the pollen-grains from the anthers of the flowers of one distinct species or variety to the stigma of the flower of another species or variety that the practical process of hybridisation is effected. Hybridisation is one of the most interesting departments in the whole field of horticulture, and one which from its simplicity can be carried to a successful issue by anyone especially after having once seen the operation performed. Morning and evening, in fine weather, are the best times for effecting the process.

It will be well to glance for a moment at what other countries have effected by hybridisation. Take America, as an example and where America has led surely Australia can follow, and in her turn raise hybrid fruit of her own, better adapted to her climate than imported kinds.

America in the early days of her history did exactly as we are doing, that is, introduced all her fruits from the Old World, with various results. The apple as introduced from Europe would not thrive, neither is it indigenous to America, and early writers say that nearly all the varieties had degenerated to the normal state of "crabs." As soon, however, as Knight had promulgated his theory of crossing and hybridising, through the agency of the Royal Horticultural Society, the Americans, ever ready at grasping improved ideas, at once commenced experiments in raising new varieties of apples by means of artificial hybridisation. The result is that at the present day America has the finest collection of apples of any country in the world, and these all raised on her own soil. So local are many of these varieties, that they will not thrive out of the State in which they were raised. As with apples so with grapes. The early American colonist, crossed the European varieties with the native grapes *Vitis labrusca*. This latter unfortunately gives to all the American varieties a slightly "foxy" flavour, but it also gives them a strong constitution and large productive powers, and California is to-day reaping the benefit of the exertions of her early settlers, in both grapes and apples. To improve our own grape I think we could not do better than follow the example of America, and cross the best European or American varieties with one our native kinds, as a basis for further hybrids. I have been informed by several gentlemen that there is growing around Cooktown one of the tuberous-rooted varieties of grape. I have never seen this plant, but I very much wish to do so, for if it is only half as good as the description given me—which I have no reason to doubt—here is the very thing to our hands: a plant with a fleshy tuberous root, and consequently capable of withstanding any amount of drought, nature having adapted it to the position it occupies, and from which an endless variety of Australian hybrids might be raised perfectly suited to our climate.

I am quite aware that there have been in the past tens of thousands of chance seedling fruits such as oranges and peaches raised in this colony, yet we never get a peach equal to the original varieties as grown in Europe, in consequence of all the European kinds degenerating when imported here. The cause of the lack of improvement in these seedlings is that they have been raised from seed produced from flowers left to fertilise themselves, or to chance fertilisation by insect agency, instead of by judicious hybridisation.

Hybridisation and cross breeding of plants have now become a science of which the results in either fruit or flowers are made an almost absolute certainty. The hybridist should have a clear conception of what he wishes to obtain, and then operate on the two varieties possessing the desired qualities that he wishes to concentrate in one. For instance, take two varieties of oranges or peaches as the case may be. One is very hardy and productive variety that can be always depended on for a crop but its fruit is of inferior quality. Another variety may be of weakly constitution and a shy bearer, but its fruit is superb. and we think if the robust hardy variety would only produce fruit equal to the weakly kind what a grand thing it would be. That can never be; but there is no reason why a hybrid should not be raised, a distinct cross between the two, combining the hardiness and productiveness of the one with the superior quality of the other. To accomplish this flowers of the robust variety should be fertilised with pollen from the flowers of the weaker kinds. thus making the strong-constitutioned plant the seed bearer. If this were properly carried out the result would be a certainty; the hybrid seedling possessing the strength of the mother plant with high qualities of the male parent. It is rare that the progeny of two distinct varieties represent the parents in a perfectly intermediate degree but the general habit is usually that of the mother or seed-bearing-parent. No absolute principle can be laid down on this point, but as a rule the strongest constitution should be made the seed-bearer. Dropping from the useful to the ornamental, there is another wide field open to the labours of the hybridist. There is not a flower of any standard growing in our gardens that has not been more or less civilised or improved by this art. All our hybrid perpetual roses originated in a cross between *Rosa damascena* and the prepetual *chinensis*, and from this group all our hybrid Noisettes, and Tea and scented roses have been raised. Again, it is now difficult to realize that one of the commonest and showiest flowers grown here (the geranium) is the result of a simple cross of a variety growing wild in S. Africa with the small, flowered and sweetly-scented, foliaged *G. citriodora*. But so it is, and still new varieties are being added—the result of artificial fertilisation. It has long been considered an undeniable fact, that distinct species will not cross. It has always been a stock argument that no one has ever yet succeeded in crossing the apple with the pear; the gooseberry with the currant; or the raspberry with the strawberry. Last season this fallacy was swept away by Mr. Culverwell (*Gardeners' Chronicle*, Vol. XIX., No. 490), who succeeded in crossing the gooseberry with the black currant and raised seedlings the result of the cross; and also in raising hybrids from crossing the strawberry with the raspberry. The successes have opened up to scientists a vista of unlimited possibilities, and the full effects of which on our orchards and gardens it is impossible at present to anticipate.—*Planter and Farmer*.

CINNAMONUM OBTUSIFOLIUM.—Mr. Peal writes that *Cinnamonum obtusifolium* is wrongly named, the leaves being fairly *acute*, unless bitten off by insects. which is commonly the case, and this may have given rise to the idea that they are *obtuse*.—*Indian Forester*.

LIME is helpful to the soil by hastening the decomposition of the organic matter, and liberating the fertilising elements contained therein. Lime should not be too frequently applied to land, and is always better when mixed with some other good fertiliser which it can assist. Many have proved the great value of lime to mix with weeds, leaves, or decaying vegetable matter of all descriptions, for it hurries on decomposition and prepares the compost for immediate usefulness. The old farming proverb is a true one:—

"Lime and lime without manure
Makes both soil and farmer poor."

Another axiom equally sound is—

"To well manure and dress with lime
Will surely give good crops in time."

—*Planter and Farmer*.

IT appears from Mr. D. C. Robbins's 'Review of the Drug Trade of New York for the year 1885,' that the total import of drugs and chemicals into that port during the twelve months was valued at 46,075,063 dollars, showing a decrease of nearly 6,000,000 dollars as compared with the previous year, the falling-off being manifest in respect to both dutiable and non-dutiable goods. The import of cinchona bark, however, showed an increase for the first time in five years—from 2,588,307 pounds in 1884 to 3,559,691 pounds in 1885; whilst that of quinine also rose from 1,263,732 ounces to 1,390,691 ounces. Opium is another drug which shows a marked alteration in the figures, since although the increased import of medicinal opium only about compensates for the increase in population. the imposition of a duty of ten dollars per pound on opium prepared for smoking has practically transferred the manufacture required for home purposes from India to the States, crude opium being now largely imported for the purpose. —*Pharmaceutical Journal*.

COCAINE.—Mr. Wm. Copeland, M.R.C.S., Darlington, relates in the *Lancet* his personal experience of cocaine as an anæsthetic in an operation for cataract. He is in his 70th year. Dr. Bell Taylor, of Nottingham, performed the operation. He says:—"The solution of cocaine was applied to my eye three times at intervals of five minutes before the operation, and each step of the operation was explained to me by Dr. Taylor as it was successively accomplished; the preliminary incision was completed without pain, as was also the excision of a small portion of the iris made in the upward direction—a satisfactory answer, it appears to me, to the query. Does cocaine affect deep-seated parts? I can truthfully affirm that the whole affair was painless, that the cataract was removed without pain, that I have had very little pain or discomfort since, and can now. little more than a fortnight after the operation, see objects distinctly, make out words of small print, and am improving every day. You have had satisfactory evidence of the value of cocaine before, but I venture to think none so conclusive as this which I have now to offer."—*Chemist and Druggist*.

THE GROUND NUT TRADE AT PONDICHERRY.—The ground nut trade continues unsteady; notwithstanding prices keep within the neighbourhood of R14 per French candy of 529 lb. Up to date shipments approximate to about 2,00,000 bags, or to one-fourth or one-fifth of the probable total crop available for export. The prices in Marseilles are stationary, and show no signs of advance, while freights have gone up from 32-7 to 36-6 within the last month or six weeks. A fall, however, is expected on the setting in of the south-west monsoon; meanwhile Pondicherry is filled to overflowing, and storage is getting scarcer every day. Penruti, the principal district market for the nuts, is crammed, and large quantities are reported from the surrounding villages. Cuddalore loaded a steamer with about 30,000 bags last month, and Messrs. Parry & Co. are now said to be buying 50,000 bags more for export, but the facilities for shipping seem to be greatly inferior to those of the French port. Until within the last fortnight or so the railway ran an average of three special "nut" trains daily into Pondicherry for five or six weeks; just now the receipts are very irregular, a better price being demanded, which buyers are not disposed to consent to. Judging from the shipments already gone forward, and the enormous stocks on hand and to come forward, the ground nut season of the present year is likely to be a late one.—*Madras Mail*.

DOCTORING PLANTS—AMMONIA.—In cold bleak spring weather, such as characterised the present year, many crops—*e.g.*, French beans, come up yellow, weak, and miserable. It is usual to root them up and re-sow. I prefer another course. I wait until the weather becomes warm and settled and then give them a dose of the "doctor," which is prepared as follows:—Take 1 lb. of the strongest spirits of ammonia, price 9d., and mix it in a quart bottle with a pint of rain water. To eight gallons of ordinary water add two fluid ounces of the solution of ammonia, and then well water the plants with this weak solution. The result is surprising. Two waterings will restore the plants to an exuberant vigour with dark emerald leathery foliage.—W. M.—*Journal of Horticulture.*

THE SUCCESSFUL INTRODUCTION INTO India of the tubers of the *Arracacha* esculent of South America. W. T. Thiselton-Dyer, Esq., Director, Royal Gardens, Kew, to the Under Secretary of State for India, dated Kew, 4th January 1886. In 1882, it was ascertained that the *Arracacha* was naturalized on the hills in Jamaica, and Mr. Morris, the Director of Public Gardens and Plantations in the Colony, stated that he believed it, "to be a most valuable food-plant," and that for his own part he not merely liked it but found it to become more palatable and desirable the longer it was used. He added—"If the natives of India take to it as an article of food, I can conceive nothing more likely to flourish in the hill districts, and to afford, with little labour, the means of sustaining life under adverse circumstances." A supply of tubers received at Kew from Jamaica was sent in 1883 to Saharunpore, Ootacamund and Ceylon, and in 1884 to Calcutta, for Darjeeling. Mr. Lawson, Director of Government Cinchona Plantations, Parks and Gardens Nilgiris, reported in 1884 that plants had been raised from the tubers sent from Kew. The result in the other two botanical establishments in India has not reached us. From Ceylon Dr. Trimen has recently reported that he has raised the *Arracacha* from seed obtained direct from Jamaica. He appears to have obtained the tubers without difficulty and in abundance. As a matter of taste, he has a less favorable opinion of them than Mr. Morris. But the point to which I wish to draw your attention is that the introduction of the esculent into India is accomplished, and that its further diffusion need present no difficulty.

COCA IN FATIGUE.—Dr. E. R. Palmer, of Louisville, gives in the *American Practitioner* an account of a very remarkable experiment made with Fraser's wine of coca. He visited a seven-day "go-as-you-please" pedestrian match on the sixth day, and found that a girl of 17, who had completed 247 miles, had abandoned the contest, but had been persuaded to resume it on a written contract to pay her $100 extra if she completed 350 miles in seven days. She was walking with evident pain and weariness, gait unsteady, eyes sunken and surrounded by broad dark rims. She had nearly 103 miles to complete in 36 hours to save her distance. At the doctor's suggestion Fraser's wine of coca was given, under his own supervision. She drank a large sherry-glass-full at once, and another in 20 minutes. At 30 minutes after the first dose her step was quick and elastic, head up, and she declared that she felt like a new woman. In 10 hours she consumed a pint of the wine, and walked 48 miles, then slept for 2½ hours, walked 3 miles, and slept again for about 6 hours. She then walked for 8½ hours, with an hour's rest for food, covering 31 miles. At this period she was the freshest of all the competitors, and her time the best, barring the spurts of a professional runner. At the 339th mile she had a fall which rendered her insensible, but she returned to the contest, and completed the 350 miles, with 1½ minutes to spare. The wine of coca was given freely whenever she called for it; it did not interfere with her digestion. During two days after the contest the wine was administered regularly. It was then withdrawn, when the pulse somewhat increased with slight irregularity, which soon disappeared. Dr. Palmer says the wine of the U.S. Pharmacopœia is inelegant and possessed of all the nauseal properties of the fluid extract from which it is prepared. He implies that these can and should be removed. He says, "To my mind the experiment was both striking and conclusive, in every way favourable to the vaunted efficacy of the coca wine in physical fatigue."—*Chemist and Druggist.*

THE SOUTH MYSORE PLANTERS' ASSOCIATION ANNUAL REPORT.—New Products.—It is most agreeable to us to record that Mr. Cameron, the obliging and talented Superintendent of the Government Horticultural Gardens, has signified his readiness to afford both friendly and official assistance in all matters connected with facilitating the introduction of new staple products, and we cannot but hope that this offer may lead to the happiest of results in Mysore, in the same way as has resulted in Ceylon, Jamaica, and other Crown colonies. Coffee Adulteration.—It is a matter of supreme importance to all planters, and one which should not be lost sight of in the future, but should be regarded as one of the most baneful influence hitherto unceasingly at work to frustrate the endeavour of the producer to bring within the reach of the consumer a genuine and nutritious article. We must trust to time and future exertions to induce the general public to insist on having a pure article supplied for their daily wants. Holding as we do this opinion, it is gratifying to note that a Company has been started for the sale of the whole bean, and we venture to regard this as an indication of a growing desire on the part of Loudon merchants interested in the welfare of coffee to leave no means untried which are in any way calculated to revive the efforts which were so strenuously made some time ago by some of the leading brokers to check the sale of spurious admixtures.—*Madras Mail.*

THE EFFECT OF THE GERMAN SUGAR BOUNTIES on the consumption of Sugar was thus noticed by Mr. Mundella in an interview with sugar refiners:—

Mr. Mundella: Why, with the German consumption not more than 12lb. per head, an English, what, ("67lb.") 73lb. this last year. It is the most marvellous thing in the world. Then, as Mr. McLean said, there is no depression in the sugar trade—in the demand for sugar. The demand for sugar increases by leaps and bounds. I have an interesting little book here, published by a Professor of Political Economy (Wm. Graham Sumner) at Yale College, and he says, speaking of this system of bounty and drawback, having seen it in his own country, he says: "Germany has an excise tax upon beetroot sugar, but allows a drawback on it when exported which is greater than the tax. This acts as a bounty paid by the German tax-payer on the exportation. Consequently, beetroot sugar has appeared even in our market. The cheap market for it, however, is England." He goes on to say: "So that the consequence is that the sugar, which is 9 cents a pound in Germany, and 7 cents a pound here, is 5 cents a pound in England; and that the annual consumption of sugar per head in the three countries is as follows: "England 67½lb." (now 73lb), "United States, 51lb., and Germany, 12lb.;" and he concludes: "I sometimes find it difficult to make people understand the difference between wanting an 'industry' and wanting goods, but this case ought to make that distinction clear." He concludes: "Obviously, the Germans have the industry and the Englishmen have the sugar." Well now, that is a fact. The evidence that has come before me is indisputable. In consequence of the great cheapness of sugar in our market there is a growth of subsidiary trades, not merely in London here, but in many of our provincial towns; for instance, in some of our iron districts there are large confectionary establishments, and sweet biscuits, and trades of that kind, which, I am quite satisfied that the evidence cannot be doubted, is employing a vast many more men than we could hope to employ by the refinery trade. So that is our compensation, to say nothing about the cheapness with which our people get the sugar. I believe it is computed that they have given us £34,000,000 sterling, in one way and another, by their folly.

This is the truth. The Germans have injured the West India planters and the sugar refiners, but they have given the English people cheap sugar.

CEYLON TEAS IN THE HOME AND LOCAL MARKETS.

HOW INFERIOR TEAS AND STRANGE MARKS ARE ACCOUNTED FOR; AND HOW TO IMPROVE OUR TEAS.

(Communicated.)

Our attention has been drawn to some complaints which recently appeared in one of the London tea brokers' circulars, that a large break of inferior Ceylon tea was offered for sale in London under the new estate name. It appears to us that the broker who made the marks knew very little of what is going on here in the way of local tea sales. The explanation given to us how so large a break as about 300 chests could be offered in one sale, is very simple; they were, we are told, the aggregate purchases of a local buyer, who, to prevent inquisitive and impertinent outsiders from following and criticising his operations, erased the estate names of his purchases, and put his own mark on the packages. It is said, this practice is being generally adopted by local tea buyers, and it accounts for the disappearance, from the London sales list, of the names of many estates, known to produce large quantities of tea.

The local sales, as our readers are aware, include a very large number of small quantities, often single packages of broken tea, broken mixed, red leaf, dust and fannings: the buyers of these little lots probably make much larger profits out of their purchases than they do out those of the better descriptions. These small lots, we are also told, are added together and bulked in London, and thus large breaks are made which the trade largely bid for. What therefore is the use of London brokers complaining of parcels of inferior tea being offered for sale?

It is well known that every estate has a portion more or less of what is called inferior tea. When the proprietors can obtain for it, prices which more than cover cost of manufacture, &c., is it to be expected that they will throw it away to meet the views of those who write about what they can scarcely be expected to understand? It is suggested we should sell all our inferior rubbish to the natives; now these, we have no doubt, have a great and growing capacity for imbibing a lot of inferior tea, but they can scarcely swallow the quantities that are being rapidly produced. What then is to be done with this tea, but to follow John Chinaman's example? There is a great outcry at present amongst unthinking critics, regarding the falling-off in the quality of some of the Ceylon teas; but it is asked, reasonably enough, who are the sufferers by this?—not the brokers, nor the buyers who get tea very cheap, nor the consumers who evidently drink what they like, but the estate proprietors. Is it to be supposed, we are asked, that their own interests are not sufficiently strong to induce them to make and ship the best tea their circumstances will permit? We shall be having London brokers very soon recommending proprietors to make nothing but broken pekoes, with a bright coppery infused leaf and pungent liquor, just as we remember coffee planters were formerly advised to grow nothing but peaberry and first size, and to sell all their triage to natives! It must be admitted that the Ceylon planter as a rule knows very well what he is about, and is quite able to look after his own interests.

A manager of an estate wrote to his principal:—"For goodness sake don't write to me any more of the Colombo opinions, regarding the withering and fermenting of our teas; by endeavouring to follow them, I have overwithered and overfermented my tea, and I have now been taught by Mr. Gow the folly of adopting the opinions of the people who absolutely know nothing about the subject." May not this be the case with London brokers? That the quality of the tea from some of the older estates where the names can be followed has deteriorated, admits of no doubt whatever. The explanation offered is, that, in the majority of cases, it is only temporary! Until every planter acquires Mr. Gow's method of making good tea out of inferior leaf, there will be a recurring period of inferior quality after pruning, and this will be intensified and prolonged if the weather after pruning sets in dry.

Apart from this cause of inferiority now, much of it is attributable to the large and rapidly increasing quantity of young tea made by superintendents who have neither appliances nor the requisite knowledge for making good tea. The art of tea-making is not acquired in a day. So London brokers must make up their minds that for a good many years to come they will have to sell a good lot of inferior tea from Ceylon.

In order to baffle the idle curiosity of those who, having no concern in the matter, make invidious comparison of the teas made on various estates, it is reported that proprietors are shipping all lots of inferior tea which they may have under initials, reserving the estate's name for all good qualities. As all teas are sold on their merits, no advantage is obtained by putting estate names on the cases, except in those instances where the average prices have generally been high; buyers are induced to look at lots of these, which they would otherwise pass by.

As germane to this subject we may mention that we have been shown some samples of tea recently made on Mr. Gow's system; as far as we can judge they are very fine, a great contrast, we are informed, to the last month's tea from the same estate. These samples are valued at an average of 85 cents per lb. against 57 cents, the last sale price.

Why, then, should proprietors grope any longer in the dark? May not much of the inferiority complained of be owing to inexperienced planters trying to make teas on the advice of empirics?

THE WHOLESALE TEA TRADE.

As all matters relating to the tea trade are important to our readers, we give some particulars of the annual meeting of the Wholesale Tea Dealers' Association, which took place on Friday last, at the London Commercial Sale Rooms, Mincing Lane.

After the notice convening the meeting had been read, the secretary read the following report:—

Your committee have again the pleasure of presenting their annual report and statement of accounts made up to the 31st March last. The meetings of the committee have been as numerous as usual, and the subjects which have engaged their attention varied in character, the following being some of the most important affecting the interest of the wholesale tea trade. An action at law was brought against a wholesale tea dealer to recover warrants in his possession, which, although paid for, were said to be held as a lien for an unpaid account. Three or four witnesses were examined in court, but they failed to furnish any evidence of the custom of the trade, and in order that no doubt might exist in future on this point, a circular letter was addressed to the trade, and the Association have sufficient replies to enable any member to give satisfactory and complete evidence as to the custom of the trade. Serious complaints were made respecting unreasonable delays in the delivery of weight-notes, and the subject was brought under the notice of the selling brokers, who at once met the case in a fair spirit and a marked improvement has since taken place. The weighing of Indian teas upon the average net weight principle was found

work with some injustice to the recipients of single packages, and a representation was made to the Customs' authorities which resulted in the amended regulation of November 9th last. It provides that if the variation in the test packages exceeds 2 lb., the whole parcel must be weighed gross and tare as formerly. Your committee would be glad to receive the opinion of the members generally upon the working of this amended regulation, as two or three cases of gross irregularity have recently been reported. An improved method of sampling tea has been adopted at Butler's Wharf, by which a return of fair value is guaranteed, and by the introduction of the principle of payment by stamps the dealers' returns are rendered unnecessary. This, it is confidently believed, will relieve the dealers from some trouble, and no inconsiderable risk of robbery; at the same time, purchasers will, in all cases receive returns, nearly, if not more, than equivalent in value to the sample drawn. It is hoped other warehouse proprietors will see their way to adopt a similar course in this respect. The charges for sampling and carding tea at the bonded warehouses have for a long time been considered exorbitant, and your committee, after making repeated applications to the proprietors for redress, have at last the pleasure to state that these rates were reduced on February 1st, the former by about 30 per cent. and the latter 50 per cent. This the members will no doubt consider a satisfactory step. There is, however, a matter in respect to the varying rates of insurance for teas lying at the docks and warehouses which is engaging the attention of your Committee, who expected the warehouse proprietors whould have met the case liberally. Two or three, however, have arranged either to pay or allow the amount paid for insurance, and negotiations are pending which will, it is hoped, result in the trade being placed in a position to be independent of warehouses where no allowance is made. The thanks of the Committee are again due to Messrs. Francis Peek, Winch & Co. for the use of their room for meetings' and in conclusion your Committee would acknowledge the continued confidence and valuable support of the members, upon whose assistance they rely to successfully carry on the important work of protecting and advancing their interests.—Signed on behalf of the Committee, Charles Hilhouse, Chairman.

The Chairman moved—"That the report and statement of accounts be adopted, printed, and circulated amongst the members." He said he thought the report, as a whole, must be deemed satisfactory, inasmuch as one or two causes of complaint had been met. One regarded the facilitating of the delivery of weight-notes, and the other—which was still more important—affected the trade in the reduction of charges both for sampling and carding tea at the bonded warehouses. There was a further reference in the report to a matter at present in embryo—a matter which must be pushed forward with considerable energy and determination on the part of the trade, inasmuch as it was of the most vital importance to the wholesale man and to the dealer in the country—that was the question of sampling. There were very few days in the week in which some of them did not receive some notice as to the quantity or quality of tea in chests forwarded to their customers. The plan that had been adopted at one wharf of making payments by stamps had inaugurated a principle which had occupied the attention of the trade for some years, and they hoped that the system at Butler's Wharf would be permanently adopted at all warehouses. It would improve the returns, and insure the recipient of the tea that quality which he had a right to expect. With regard to insurance, it was a very broad and difficult question, but it was withiu the knowledge of the trade that the rates of insurance had been considerably enhanced lately, and the committee thought they had a very fair claim on the dock companies, looking to the charges that the trade was subjected to. The committee, therefore, asked that the trade might be met to a certain extent in the extra payment. The proprietors of one warehouse had altogether agreed to pay the extra charge, and from the proprietors of another a satisfactory answer had been received; but with regard to some of the larger warehouses—those belonging to the East and West India Docks and general warehouses—the committee had not made the progress they had hoped for. They were still, however, having interviews with gentlemen interested, and he hoped that before long they would be able to get those gentlemen to see the force of the reasons actuating them. In reference to the accommodation for the bonding of tea the committee felt that, with the large increase in the importation of tea which had taken place in the last twenty-five or thirty years, since the abolition of the charter, there was not sufficient accommodation for the trade, and an application had been made to the Customs to sanction an increase of bonding facilities, which they did not seem at present inclined to grant. They had referred the Committee to the Treasury, and a deputation would very shortly wait upon one of the Lords of the Treasury on the subject, because the Committee felt that if they could get more bonded warehouse included in the Customs bond they would be able to bring more power to bear on the warehouses, which at present had a control over tea which amounted almost to a monopoly. If there were other warehouses to which preference might be given, an outside force might be brought to bear on the companies, so that the trade would have a chance of carrying its point. He hoped the members of the trade would consider the report satisfactory.

Mr. Worthington seconded the motion, which was agreed to.

Mr. Pearse proposed Mr. Jones seconded, and it was resolved:—"That the members of the Committee and the Honorary Treasurer be re-elected for the ensuing year; and further, that the thanks of this meeting be tendered to them for their efficient services."

On the proposition of Mr. Peek, seconded by Mr. S. Edwards, it was resolved:—"That inasmuch as the importation of tea has increased nearly 100 per cent since the present bonded wharves and warehouses were licensed by the Customs authorities, and as the limitation of bonding accommodation has tended to combination and exorbitant rates to wholesale dealers, this meeting requests the Committee to take such steps as may be necessary to secure additional bonding facilities."

Mr. S. Edwards moved—"That the experiment of having sample returns placed by warehouse proprietors in the packages in their keeping, selected from standard qualities, having proved to be practicable and an act of justice to buyers, this meeting requests the Committee to urge the general acceptance of this principle."

This was seconded by Mr. Lowcock, and agreed to.

The Secretary, referring to the recent fire at Hay's Wharf, said he visited the premises the day before that meeting. The system that had been adopted where tea was stored three packages on one making a pile of four packages, and the water came through from the upper floor, was this—they treated the top and bottom packages as damaged and the two intervening ones as sound hence in the lists exhibited in the warehouse, the numbers ran irregularly. The proprietors of the wharf informed him that if any dealer wished to have the teas inspected he could send down, and the tea should be laid out for inspection without any expence to the dealer. It was impossible for them to tell with certainty in all cases which packages were damaged and which were not, and it was very desirable in the interests of the wholesale dealers that the teas should be inspected before they were sent away from the wharf, since the liability of the warehousekeepers ceased upon the teas leaving the bonding warehouse. He had a list, made up to 11 o'clock that morning, of the teas destroyed by the fire, and a long list of those damaged by water, but the proprietors of the wharf had not yet been able to furnish a complete list of all teas burnt, or damaged by water or smoke.

Mr. Harrison asked what assurance dealers would have that teas not included in the list really were

not damaged. Damage by smoke would probably not be detected except by tasting.

The Chairman observed that teas would become affected by remaining long in the atmosphere of the wharf.

Mr. Peek said the water ran down the sides of the packages, and, therefore, those besides the two at the top and bottom must be more or less affected. He thought all the packages in the warehouse destroyed ought to have been handed over to the insurance offices as salvage, and that a claim ought to have been made on all of them.

The Chairman said that that was the only safe plan.

The discussion was continued by Mr. Pearse, Mr. Worthington, Mr. Harrison, and the Chairman.

The Secretary and Mr. Peek suggested that the proprietors of the wharf should be asked to give a list of all teas lying on April 21st in the building destroyed, and on the west of it. The Secretary promised to forward copies to all members of the Association.—*H. & C. Mail.*

TEA COMPANIES REPORT.

DARJEELING COMPANY, LIMITED.

Nominal capital £250,000, in 12,500 shares of £20 each; paid-up capital £135,420, in 6,771 shares of £20 each. Directors: John Farley Leith, Esq., Q. C., Chairman; Sir George Macleay, K. C. M. G.; William Sangster, Esq.; James Percy Leith, Esq.; Henry Smith, Esq. Calcutta Agents; Messrs, Begg, Dunlop and Co. General Manager; William Roberts, Esq.

The following is the report of the directors, to be made to the members at the twenty-first annual ordinary meeting, to be held on May 10th.

The directors beg to present their annual report and several accounts for the consideration and approval of the members of the Darjeeling Company, Limited.

The directors are pleased to be able to state that the gross profit derived from the operations of 1885 amounts to £14,253, which is an increase of £2,429 over the gross profit realized in 1884, and after setting apart a sufficient sum to meet the payments of commissions on profits and income-tax, the sum of £12,249 16s 6d will remain as net profits.

The directors accordingly have the pleasure to recommend to the members of the company the declaration of a dividend at the rate of eight per cent, clear of Income Tax, (which is one per cent above the dividend paid this time last year), and to carry the residue, say £1,416, to the credit of the reserve fund, which will then amount to £5,384 13s 2d of undivided profits.

The crop of 1885 amounted to 511,037 lb. of tea, showing a considerable increase of 37,831 lb. over the crop of 1884; and the average price per lb. was 1s 5·72d against 1s 5·41d in 1884; thus clearly indicating that the increased quantity of tea made in 1885 did not in any way reduce the high standard of quality that has been maintained for some years past. The proceeds of the sales amount to £37,195 19s 10d, being an increase of £3,219 19s 7d over 1884.

There was a further decline in the rates of exchange between India and London during the year 1885, and consequently the difference between these rates and the par rate of two shillings per rupee on the amount of drafts (£17,000) negotiated by our Calcutta agents was £4,330 10d, showing an increase of £1,037 1s 11d, over 1884, when drafts to the extent of £16,500 were drawn.

Thus the proceeds of the crop of tea, and the difference in the rates of exchange, amount to £41,526 8d; and adding to this the sum of £64 12s 5d, realized by the sale of teas in small boxes in 1884, the total receipts amount to £41,590 13s 1d, being £4,268 4d, above the sum realized in 1884 under similar headings.

Comparing the debit side of this profit and loss account for 1885 with that for 1884, it will be found that the expenditure at Darjeeling was £1,315 2s 7d in excess of that in 1884.

Miscellaneous expenditure was £57 5s 7d less than in 1884.

Insurance and charges on tea show a large increase of £581 13s 1d over 1884, caused by the extra charges on the increased quantity of tea manufactured and sold, and by largely enhanced rates levied for warehousing and working teas in London.

Thus the total expenditure in 1885 was £27,337 8s 8d being £1,839 10s 1d more than in 1884, and the gross profit in 1885 was £14,253; against gross profit in 1884; £11,824; increase in 1885, £2,429.

The usual comparative statements for the past three years are now recorded:—

TOTAL OUT-TURN OF TEA AND COST AT PLANTATION.

	Acres.	lb.	lb. per acre.	R.
In 1883 ...	1,562 ...	473,810	at 303 ...	182,965
In 1884 ...	1.586 ...	473,206	at 298 ...	174,932
In 1885 ...	1,661 —	511,037	at 307 ...	188,082

GROSS EXPENDITURE AND COST PER LB. OF TEA, AFTER DEDUCTING THE DIFFERENCE IN THE RATES OF EXCHANGE.

In 1883,	£25,461 ...	cost per lb.	1s 7d
In 1884,	£23,856 ...	„	1s 18d
In 1885,	£25,010 ...	„	0s 91d

ACCOUNT SALES WEIGHTS OF TEA, AVERAGE PRICES AND PROCEEDS.

In 1883,	463,631 lb.	at 1s 6·59d,	£5,927
In 1884,	468.239	„ at 1s 5·41d,	£33,975
In 1885,	503,754	„ at 1s 5 72d,	£37,195

The directors have recommended a dividend at the rate of 8 per cent, the members will be asked to confirm the same resolution, making it payable on and after May 10th, clear of income-tax.

From 1883 crop of tea, at 7½ per cent
„ 1884 „ 7 „
„ 1885 „ 8 „

The amount to the credit of this fund on 31st December 1884 was		£3,275	0 11
From profit and loss account, 1884		693	7 9
		£3,968	8 8
From profit and loss account, 1885		1,416	4 6
Total		£5,384	13 2

This reserve fund has been found most useful in the financial arrangements of the company, more particularly as there is no other working capital available.

The following are the estimates prepared by the manager at Darjeeling, showing the probable quantity of tea that will be made during season 1886, and the expenditure at Darjeeling for cultivating and maintaining the several plantations in a high state of efficiency, and for gathering, manufacturing and packing the crop of tea.

ESTIMATED CROP OF TEA AND EXPENDITURE IN 1886.

	lb.	R.
Ambotia Plantation	208,000	58,372
Ging do.	140,000	47,669
Tukdah do.	112,000	37,720
Phoobsering do.	72,000	25,004
Sudder Charges	—	12,827
Totals	532,000	181,292

These estimates compare favourably with the actual results of the previous season, viz.:—Crop of 1886, estimated 532,000 lb; outlay, 1886, estimated R181,292. Crop of 1885, actual 511,037 lb; outlay, 1885, actual R188,083. Increase, 1886, estimated 20,963 lb; outlay decrease, estimated R6,791.

Sir George Macleay retires by rotation on this occasion from the direction and, being eligible, he offers himself for re-election as a director of the company.

Mr. John W. Roberts, the auditor of the company, begs to offer himself for re-election for the ensuing year.—*H. and C. Mail.*

HARD FOR THE PRODUCER OF SUGAR, TEA, COFFEE, COCOA, &c.

From the *Home and Colonial Mail*, April 30th.

The totals given by Sir William Harcourt in his Budget speech lead to the inference that commercial operations during the first quarter of the present year have been more satisfactory than usual. The *Grocer* takes exception to this view, and, while admitting that the volume of business passing through the grocers' hand has been large, is considerate enough to admit that the continuous decline in prices has been very unfavourable to importers and producers. Undoubtedly this is so, as producers know to their cost. The following figures show that the consumption of many articles of food and manufacture that are entirely "duty free" has increased in an astonishing degree within the last fifteen years:—

			1870.	1873.	1876.
Tea	...	lb.	140,986.000	162,344,100	185,698,000
Coffee	...	cwt.	1,605.730	1,683,700	1,341,38
Cocoa	...	lb.	14,793.000	19,661,250	20,382.300
Sugar	...	tons	721,800	833,500	779.360
			1879.	1882.	1885.
Tea	...	lb.	184,510,300	211,080.300	212,375,300
Coffee	...	cwt.	1,617,380	1,358.960	1,035,600
Cocoa	...	lb.	26,344,760	18,990.400	23,419,400
Sugar	...	tons	885,660	1,128 727	1,236 000

With the exception of coffee, which has given place to tea and cocoa, there is a marked increase in quantities, but much of the increase in the quantities consumed has been due to their extraordinary cheapness as to the abundance and freedom with which they have been offered on the different markets. Nearly all kinds of produce have been declining in value since the begining of January last, and amongst others, sugar, coffee, cocoa, tea.

The losses in the tea trade during the past two or three months on sales by auction "without reserve," especially where the parcels on offer have been in "second hands;" and Indian teas, for example, have lately been disposed of in London at a decline of 8d to 1s 2d per lb., from the cost prices in Calcutta in November and December last. Similar instances of an alarming depreciation in the value of produce could be mentioned as having taken place of late.

A further illustration of the lowness of prices, and the disparity existing between them and those towards the end of April in 1870 is afforded by the following statement of the quotations for some of the leading articles of produce, viz:—

SUGAR.

MR. SHAND ON CEYLON PRODUCTS AT THE COLONIES AND INDIAN EXHIBITION.

Planters' Association of Ceylon,
Kandy, 27th May 1886.

To the Editors, Ceylon Observer.

SIRS,—I beg to enclose for publication copy of letter received from Mr. Shand on the subject of the Colonial and Indian Exhibition.—I am, sirs, yours faithfully, A. PHILIP, Secy.

Ceylon Commission, Colonial and Indian Exhibition, South Kensington, S. W., London, 7th May 1886.

The Secretary, Planters' Association of Ceylon, Kandy.

DEAR SIR,—Your letter of 15th March, which seems to have lain in Colombo for some time, reached at last safely.

Since I last wrote to you we have had a very busy time unpacking and arranging, and though I was not quite ready on the 4th, and it will be some days still before I get our exhibits entirely in order. With the assistance of Mr. Whitham I was able to place our collection fairly before the public. You will, of course, have detailed accounts of the opening ceremony, which was grand and impressive, and Ceylon was fortunate in the position of the seats which were alloted to it and a very liberal allowance of tickets for the Exhibition ceremony was placed at the disposal of myself and others by Mr. Birch for Ceylon friends.

Our three tea cases are arranged along the wall and contain samples of commercial teas from thirty-six (36) different estates; we had not enough to fill these up sent specially so we had to make a selection from the teas of other estates which had enough to show in these cases. Above those cases are Mr. Ferguson's photographs with drawings of tea, coffee, cocoa and cardamoms which I received from Dr. Trimen, and we have also thirty (30) bottles of fancy teas for show on one of our auxiliary stands, while Messrs. Henry S. King & Co. have 343 bottles in the tea trophy opposite one of the Ceylon tea rooms and adjoining the Indian trophies, which is a larger number than Assam or any other Indian districts show.

Our Cardamom case contains eighteen specimens of cardamoms from different estates, and we have filled up the vacant corners with mace and nutmegs from Roseneath, and two samples of vanilla.

The Cocoa case contains twelve (12) samples of cocoa, the corners being filled up with six specimens of Liberian coffee.

Cinchona bark and sections of trees are not things which one can make a pretty show of, but we have made a trophy showing off the splendid section of trees chiefly from Glenlyon, and the magnificent quills from Stair, Glenyon, and other estates and with sections of own space occupied by coffee barrels it has been pronounced by many connected with Ceylon a very effective Show; the rest of our coffee barrels are shown in a pile and show off very well too. I must mention that the show cases and the coffee barrels are very much admired and certainly exhibit their contents to great advantage. I have had a case made for cinchona shavings and pieces which contains the collections from Yarrow, St. Leonards and Mr. Lane's and the Lanka Company.

I have also had a couple of additional stands made for showing off our fancy teas, the samples of coffee for which there are no barrels, Mr. Borron's collection of anatto and Mr. Dickson's collection from Lebanon, and peppers, cotton and other things which we have no special room for. There was a tremendous rush to get things at all in order for the opening, but when I next write I hope to be able to tell you that everything, as far as arrangement goes, has been finished.

The pamphlet is in Messrs. H. S. King & Co.'s hands and the colored paintings were submitted to me yesterday. I do not like them and do not consider them natural, nor does the artist, who says they could be better done if the photographs were departed from altogether, but as what I presume we desire is a faithful representation rather than a work of fancy I have declined to agree to this.

The Ceylon tea room, adjoining my office, in Kandyan palace style, is much admired and frequented, but this is only the third day after opening and there are details which are not yet quite satisfactory but which we shall, I hope, soon adjust. A great many people connected with Ceylon have visited the Exhibition already and they have all expressed satisfaction with our space and arrangements.

I have not yet been able to shake down in my office so I must ask you to excuse this letter which I cannot close without recording the valuable co-operation I have received from Mr. Harry Whitham and also the assistance I have received from Messrs. Birch Davidson, and Goodwin, (Messrs. Henry S. King & Co.) who have all helped me in many ways.—I remain, faithfully yours, (Signed) J. L. SHAND.

P.S.—Messrs. Gow, Wilson and Stanton have supplied us with two large diagrams illustrative of the progress of Ceylon tea which have been placed one adjoining our tea-cases and one close to the tea trophy.—(Initialed) J.L.S.

TOBACCO CULTIVATION IN CEYLON.

The fact that Parliament has decided under certain fixed restrictions to once again permit the cultivation of tobacco within the British Isles is evidence of the extension of the demand for the fragrant weed. In spite of all that has been urged against its use, there seems to be no chance of a diminution. No doubt—as is the case with most of the other gifts of Nature—it is the abuse, *i.e.*, the inordinate use of tobacco, which is injurious, and probably as long as the world lasts, some indulgence in "the weed" will continue. There is no room for doubting that the supply of genuine Havana and Manilla tobacco is no longer sufficient to meet the tastes of the many thousands who restrict their smoking to the product of Cuba and the Philippines. But the expense of the superior Havana tobacco, compels men of moderate means to forego its enjoyment, and, as the result we find the growths of many other countries possessing a place in the tobacconists' shops in London which has hitherto been wanting to them. We may naturally ask why our island tobacco should not compete successfully with these—why it is that among the varieties now offered to the patronage of English smokers Ceylon tobacco finds hardly a place?

There is no cultivation, perhaps, the resulting qualities of which are more dependent upon peculiarities of soil than tobacco. The finest seed, if deposited in unsuitable soils grows up coarse and rank, its leaf departing in a special degree from the original type. But good authorities regard as certain that in Ceylon there are certain localities as well fitted to the growth of the finer descriptions of tobacco as are the West Indies. It only needs that those should be sought out with the same care, and with the same scientific discrimination, as have been given to other forms of cultivation in this island. We have learned from experience how varied are the capabilities of the soil of Ceylon, which in years past had been condemned as suited to scarcely more than a single product for the hill-country and one or two for the plains; and the results which have arisen out of that experience should certainly lead us to extend the information we possess in respect of the growth of tobacco. Such extension can only be gained by full enquiry, and it may be hoped that Dr. Trimen, when he returns, may be enabled to prosecute it. An industry which has for so many years afforded occupation to a large body of native cultivators in Ceylon should not be allowed to lag behind for want of the research for which the means exist ready to our hands.

Among the exhibits forwarded to the exhibition at Kensington from this island was a considerable quantity of the coarse Jaffna tobacco, which was labelled as for "chewing" purposes only. We are told that when the case containing it was opened, the remark was made:—"Oh! this is only that common Jaffna tobacco. It can be put anywhere." It is a pity, we think, that with the capabilities possessed by Ceylon any such remark should be warranted. The coarse and strong tobacco referred to has its market, and an extensive one, among our Indian neighbours, who highly appreciate it, but those who have tried the finer sorts of tobacco which have been successfully grown on our uplands, and especially in the Badulla and Dumbara districts, know how widely the qualities of Ceylon grown tobacco may vary. Mr. J. K. Ingleton, we believe, sent to the Exhibition, samples of his Dumbara cigars, but we do not hear of their being noticed as yet. Experimental shipments of the Central Province growth and the cigars as well as cheroots made of it, have been sold in the London shops under the name of "Lankas." But they did not take the public taste, and we learn from a correspondent that they are now rarely to be seen offered for sale. We are told that this was chiefly due to the appearance of the cheroots. It seems certain that there is a fashion in English smoking circles, and that there are many who dislike to smoke a cigar, however good its flavour,—and that of the Ceylon importation was admitted to be good—because it could be recognized not to be of the Havana type. We are assured that there is a very extensive sale of cigars made in England and on the Continent of Europe, from the Havana leaf, because, although their flavour is poor as compared with genuine foreign cigars, they satisfy the critical eye by their appearance.

Now there are divers and strong reasons why home-made cigars, however fine the leaf from which they are manufactured and however perfect their manipulation in rolling may be, can never aspire to the quality of those prepared in the countries where the leaf is grown. That leaf, after packing and shipment, becomes dry and hard, and it is necessary for its preparation—and especially for the removal of the stronger ribs—to re-steep it in saltpetre and water. This militates against its flavour when soaked, so markedly, that any tyro in the art of smoking can pronounce against the genuineness of it as a foreign cigar. Then, again the spots on the tobacco which are the result of dew falling on the leaf during drying, are lost by the second stripping referred to. We see, consequently, that home-made cigars ought not to be able to compete with those prepared when the tobacco is naturally soft and yielding.

We would urge therefore, that endeavour should be made so to select soils suited to our island growth as should ensure it a fair competition with the West Indian products in flavour, and that, secondly, the dictates of an imperious fashion should be complied with, so as to overcome the dislike to the use of cigars which betray by their appearance that they are not of the coveted growth. Efforts we know have been made in this direction, and successful efforts too, by a gentleman in the Dumbara valley,—but they want further pursuit to ensure such a success as would mean the establishment of a profitable industry of permanent value to the island and to no insignificant number of its people.

PURE JAPAN TEA.

In the articles on "Tea and Tea Customs in Japan," concluded in this issue,* the statement is made that "tea in the West and tea in the far-off East are, two quite different beverages." This is largely due so far as the United States is concerned, to hasty and imperfect preparation for market and the prejudice of consumers. It is thirty years since Japan tea was introduced into this country. The first large cargo of 3,100 half-chests, about 124,000 pounds, was imported by Messrs. A. A. Low & Bro., and consisted entirely of a leaf of a blackish color, in which no coloring matter of any sort was employed. These teas won their way into popular favor because the people objected to the then highly-colored China teas, made so by the use of Prussian blue, gypsum, etc. In 1866-67 the Japanese commenced to adopt the Chinese method and pursued it so diligently that they overdid the matter, the highly colored teas causing a scum to form on the infusion. The trade remonstrated and the abuse was modified, but to this day the bulk of Japan tea sold in the United States is more or less arti

* Republished in full, see pages 40-41.—ED.

ficially colored, it being claimed that the coating of the leaf, to some extent preserves the flavor.

The fact that colored Japan tea retains it flavor more tenaciously than pure tea, or natural leaf, is, we believe, due to the more thorough twisting of the leaf by the manipulation necessary to properly coat it with plumbago or other substance, than to the coloring matter.

Elsewhere Messrs. A. Schilling & Co., Chicago, Ill. agents for the Japan Tea Syndicate, call attention to efforts now being made to place before the trade Japan tea that is free from coloring matter, that is not manipulated by hand, and that is packed in Japan while hot in a patented package and shipped only by direct consignment to merchants in this country.

The nearer the native method of packing Japan tea is followed the better it is for flavor. The large earthenware jar used in the producing country is impracticable for export by reason of its expense and liability to breakage. The next best package is tin, and if the tea is packed therein when hot and sealed it must reach our market in better condition than if sealed in lead-lined chests, which the retailer must open, emptying the contents into a large tin canister, where it is more or less exposed to the air, causing a rapid loss of flavor. If there is no exposure between the packer and the consumer the full flavor of the tea must be preserved.

The use of Prussian blue or gypsum for coloring tea is wholly for the purpose of pleasing the eye of the consumer. The time has come when the use of articles in the preparation of food, requiring explanation or defence, must stop. The use of plumbago, Prussian blue, gypsum, etc., in an article like tea, that must always be judged by its cup quality, and not its appearance in the leaf, is indefensible. Does any one doubt that purer teas mean an increased consumption? Or that a better understanding on the part of consumers of methods of preparation will not tend to popularize the beverage? The country increases its per capita consumption of coffee every year, while that of tea does not increase, but rather diminishes. We therefore welcome any move calculated to raise the standard of the tea supply.—*American Grocer.*

COCOA.—Accounts from Surinam are very favourable respecting the Cocoa-culture; even the young trees, planted only five years ago in the Districts of Surinam and Commewyne on abandoned sugar-fields, have surmounted the many difficulties, and promise a good crop. The one-year-old trees, on the contrary, are in a less favourable condition, owing mainly to insufficient sheltering against the heat of the sun, and are partially lost. Additional plantings of cocoa are constantly being continued. There is great scarcity of available manual labour, and this want is felt most severely in proportion, as the estates are farther from the capital.—*Indian Mercury.*

JAVA PLANTER ARRANGING FOR RETAIL SALES OF QUININE BARK.—A Cinchona planter in Java, of high repute in the course of a business letter, under date 2nd May, writes to us as below: his news will be of interest to "A. M. W." and other Ceylon planters:—"Nobody can tell what will be the future for us, but as a powerful means to keep up prices, we are trying to increase the consumption of quinine by taking the retail-sale of this drug as much as possible in hand ourselves, and for this purpose have got up a Committee. No doubt the necessary funds will be forthcoming, because some trials have given good results. Quinine from the Brunswick manufactory was offered in very beautiful gelatine quills at 155 guilders a kilo, and within a very short time sold out. We, moreover, got sulphate of quinine crystallized in tin-boxes of half a kilo each for 60 guilders, and the Amsterdam manufactory offers quinine in paper parcels of a gram each—very neatly packed, for 100 guilders a kilogram, delivered at Batavia. If there are, perhaps, among your countrymen such that want to escape too high prices from apothecary or druggists, I shall only be too happy to interpret their wishes to the said Committee. You will find more a bout it in ——— ——."

THE DECADENCE AND ADVANCE OF COFFEE CULTURE IN BRAZIL are thus noticed in the *Rio News*:—

The commerce of Santos has been making rapid advances, and as a coffee-shipping port is rapidly overhauling Rio itself. In a few years, fewer perhaps than most men realize, the port of Santos will be even more important than that of Rio in the coffee trade, and a close second in the import trade. The reasons for this are clear. While the coffee-producing areas of Rio and Minas cannot be much further extended and are already showing signs of decline because of the exhaustion of the soil and the character of the country which requires the slave and his hoe for its cultivation, the coffee-producing areas in Sao Paulo are being rapidly extended and still have extensive tracts of arable land yet untouched. In Rio the steep hillsides preclude the use of the plough and cultivator, while in Sao Paulo nearly all the coffee lands can be cultivated with these tools, thus rendering the employment of free labor practicable and profitable. While therefore the coffee product of Rio and Minas must decline with the extinction of slavery, that of Sao Paulo will surely increase. Besides this the speading railway system of Sao Paulo is bringing an enormous section of the Empire into direct communication with Santos, and as the districts within this area become settled with free laborers, and as their industries are developed, their consumption of imported goods will tend to swell the trade of that port. It is clear, therefore, that the future of the city of Santos is most promising, and that no time should be lost in anticipating the needs of a great commercial port.

AGRICULTURE IN JAFFNA.—We are in receipt of a pamphlet containing an essay on agriculture by R. O. D. Asbury, Esq. delivered several years ago before the Jaffna Christian Association. We have perused it with much interest, and have no doubt that a careful study of its pages would repay any one of our numerous gentlemen farmers in Jaffna. Of course none of the ignorant class could profit by it nor would they if they could. After discussing the importance of agriculture and agricultural science, and setting forth its true object, the author discusses at some length the operations of tilling the soil, manuring weeding and watering. In treating of ploughing some very just criticisms are made of the native plough, and such ploughs are recommended for importation as have been since introduced by the Director of Public Instruction. With reference to the yoke, it is suggested that it would be well to adopt the European method of yoking bullocks, viz., by substituting a wooden bow, shaped like the letter U for the wooden pins and rope now in use. We confess to a feeling of surprize that no native, with but a single exception, and that Mr. Asbury himself, has ever tried or even thought of trying such a yoke, its advantages are so manifest. The bullock can then pull naturally and easily with the shoulders and hence can put forth all its strength. The cattle of the country are so weak and puny that some such method of yoking would seem indispensable in order to enable them to do proper work. There are many sensible and practicable hints scattered through the pamplet, on the necessity of knowing the ingredients of the soil in any particular field, so that the crop and the fertilizer may be adapted to its qualities and needs; on the care that should be taken of manure on the rotation of crops; and on many other matters connected with agriculture. Appended to the essay we find a list of topics for future investigation, the following up and discussion of which might be very valuable.—Jaffna "Morning Star."

IN SEARCH OF A HOME IN TASMANIA.

(By "Old Colonist," F. R. C. I.)

"Near yonder copse where once the garden smiled,
And still where many a garden-flower grows wild."

"Is this place in Chancery?" I enquired of the driver of the trap in which I had a few minutes before left Longford railway-station.

"Chancery?" he replied, "I downt knowe what you call chancery, but them places here be all much aloike now, they be different in ould toimes."

I could have guessed as much. The dilapidated gate we had just passed, had evidently in its day no small pretensions to gentility, though now it hangs on one hinge, pulling, in its downward course, the ornamental pillar off the plum. The approach is no longer approachable, the thistle and sweet-briar having taken possession of what had once been the neatly gravelled walk; along which, in brighter days, guests may have been welcomed and children merrily played. The garden, alas! is now a jungle of the most motley description. The once carefully introduced and nurtured European plants, degenerated into weeds of ungainly shape, the strongest crushing down the weak, though all flowering with a brilliancy strangely out of keeping with the sombre surroundings. The great hedge-rows have long ceased to get their annual trimming, and now open at the bottom, branch out at the top into huge gormandizers, heavily laden with haws. The buildings themselves—originally a comfortable compromise between an Indian bungalow with godowns and a Scottish homestead—are now sadly dilapidated. The "stich in time" has evidently been omitted, and there seems a settled air of decay and despair around the gloomy place.

I challenge any living man to say if this is not a faithful picture of the homesteads in this, the oldest, and one of the best agricultural districts of Tasmania. Nor is the cause far to seek. Take one case in point. Mr. M—— came here from India 40 years ago, with a little money, and a nice young family. The Government rule in those days was, *show your money, and we make you a free grant of land, an acre to every pound of capital you possess.* A system which led to very obvious abuses, and old chums still chuckle as they relate how they hoodwinked the officials, by lending to each other for the moment; so that, in the same way that one hat did duty with a dozen planters at the levee in Kandy, £1,000 would secure to many the coveted thousand acres. And the paternal Government in those good old times, not only supplied the land free, but the labour too, or at a merely nominal price, and as the demands of Victoria for all kinds of produce were then all but unlimited, prices rose to a fabulous figure. Under such circumstances, he would indeed be an indifferent farmer who did not rapidly make a fortune.

Mr. M—— was a good farmer, and, moreover, a man of honour, great energy and good taste; his carefully husbanded capital might be looked upon as accumulations of *self-denials.* One great object in his life being to make a fixed and comfortable home for his family, and gain them a better start in life than he himself had. His farm of 600 acres became a model in the district, and the admirably laid out fields still testify to his taste and skill as a practical agriculturist. But, as is too often the case, the sons of this thoughtful and frugal man, grew up with tastes the very antipodes of their father's: never having been accustomed to work, they had no belief in the dignity of labour; never having earned money, they had no compunction in spending. *Horse-racing* was more in their line, and the days of their early manhood were chiefly spent in galloping round the country, settling up for the past or arranging for the coming races. In course of time, the old colonist died—for, even in this best of climates, the best of men do die on reaching the end of their allotted space. The youths now had full swing and indulged their tastes without restraint. The usual result rapidly followed: the money-lender, the foreclosed mortgage, "the worst inn's worst room,"—one such "gentleman" was pointed out to me the other day in the capacity of sub-stableman at a village Drunkerage.

But I beg my readers' pardon, all this I own has got nothing to do with *bona fide* farming and the decline. No, there are other causes for the collapse, the chief of which, is the labour difficulty. Prison labour is no longer available, and no supply as yet to take its place. I note that farmers are advertising for hands at 6s 6d per day to gather potatoes. Meanwhile Victoria much more than supplies all her own requirements, in all kinds of farm produce, and prices are down to a limit that leaves no margin to the cultivator. Such is the present condition of farming here, and I am convinced that things have not yet reached their worst; for ask the price of land and fully 50 per cent more is asked than for similar land in England! The prosperity of the past is not yet sufficiently distant, nor the true cause of the present depression sufficiently realized. And yet, I am no pessimist, I feel assured, indeed, there must be a glorious future for this beautiful island generally, and particularly for this rich agricultural locality, but the conditions are not now present, and probably will not be in our brief time.

Longford lies 113 miles north of Hobart. I have said nothing of the intervening country, the scene of desolation is really too painful to dwell upon. District after district has been cleared of its inhabitants by the remorseless sheep-owner, the frugal little farmer forced into town. Villages extinguished in their infancy and the people compelled to emigrate elsewhere. But there is an agency at work which may in time break down the power—which fostered as it was by corrupt legislation—the people were helpless to resist, and it is wonderful to think of the apparently insignificant agents Providence often employs to work revolutions. We all know what a very minute fungus can do. In this case, the *Rabbit* is the honoured instrument and has already been put in possession of the abandoned fields, the result being that instead of so many sheep to the acre, as estimated by the grasping wool-grower, it is now a case of so many acres to the sheep. This, together with the great fall in wool, has recently brought sheep farmers to their hunkers, whining to Government for help to exterminate "the pest." The only cure, I believe, is *population*, and the ultimate outcome will probably be the breaking up again of the big runs and encouraging the return of the people to a contented country life. I only wish all our "pests" were as curable as the rabbit infliction.

Longford is the largest surviving village in Tasmania, containing a population of 1,286 spread thinly over a level space, sufficient for the site of a mighty city. To the S. W. the "Great Western Mountains" rise abruptly from the plain at a distance of about 15 miles, while in the distant N. E. Ben Lomand raises its blue head 5,000 feet above us. The Arthur's Lake river winds its way sluggishly through the flat fields in which the well-conditioned cattle leisurely browse. An air of extreme stillness pervades the scene as I sit listening to the measured peal of the church-bell, and am reminded that only last week (April 27th) the

remains of a gentleman long connected with Ceylon found a resting-place in yonder churchyard.

Poor *John Frederick Gibbs*! I knew him well. It seems but the other year I met him at 34, Craven Street, London, where for 20 years he had been a valued servant, now being induced—somewhat reluctantly—to try his fortune in Colombo. It seems but yesterday I took him for his first ride into the interior of Ceylon, even into the heart of the distant Morowak Korle, where he first beheld with evident delight the promising young estate into which he had hopefully cast the savings of a lifetime. The Colombo connection was not a success. Rather late in life and feeble in health poor Mr. Gibbs did not transplant kindly, and it must be confessed he was most ungraciously received. A man of scrupulous integrity and systematic industry, he ought to have proved invaluable to his firm, if generously and fairly treated, but this was impossible under the circumstances, he was unequally yoked, and the connection came prematurely to an end. Of the fate of "the wattie" it is needless to write. Opened by that prince of careful planters, Le Cocq, it promised well, but ere it had yet time to give its maiden crop, *Hemileia* overtook it, and—*ruin*, was the word written upon the Abbey Rock. With failing health and, doubtless, depressing spirits, Mr. Gibbs struggled yet a few years in Ceylon. At length, in search of a quiet retreat in a genial climate, he, four years ago, came to Tasmania. Last year he underwent a painful surgical operation, and has since been quite an invalid, frequently suffering much which no medical aid nor circle of sympathizing friends could do much to alleviate. His relief came on 25th April, at the age of 54. Mrs. Gibbs and family of six receive much kindly sympathy in their trouble from the good neighbours amongst whom they are deservedly much esteemed.

I wrote the above before I had seen the following figures, fresh from the hands of the Government Statistician. They are certainly not encouraging reading, and only confirm my growing impression of the country that it is doomed, for a time at least, to suffer seriously from the gross errors of the past, that it is indeed on the verge of disaster. Lovely country, no doubt, but what's the good of ruffles when we want shirts? The area under wheat during the last season, is smaller than it was 50 years ago, when the population was only one-third of what it is now. It is probable that the whole yield of wheat for the last season will fall short of local requirements by 440,000 bushels :—

So far behind the rest of the world is Tasmania, that the wave of depression which years ago overtook all other civilized regions. has only now reached this Ultima Thule. Much of the best capital of the Colony, its bone and sinew, is leaving for more favoured lands, and until property here is re-valued and re-arranged there is little hope for the investment of capital. Indeed, I am more and more convinced that the only thing to save Tasmania from endless trouble, is *to get united to Victoria*. Victoria needs more land. Here is the natural outlet for her superabundant capital and energy. Here is scope for her active agriculturists and a sanatarium for her dust-choked invalids. At present Victoria is only teasing and squeezing the poor silly little sister, by her cruel anti-reciprocity, taxing almost the only thing she (Tasmania) has to sell at 100 per cent A. V. See a case tried last week in Melbourne, where it is decided that par-boiled Tasmania fruit—with or without sugar—is jam, and subject to duty!

Poor misguided Tasmania! with all her expensive paraphernalia of Upper and Lower Houses. Government House and London representatives, too weak to cope with colonies too strong for her own weak and scanty population. The mimicry is as painful to the on-looker as it is costly to the taxpayer.

"THE TEA ROLLER OF THE FUTURE," according to a rumour round the Fort yesterday, is 'Davidson's and Law's"—that is the roller to which we referred as doing its work well on Gikiyanakanda estate. But today we have the following testimony from the purchaser of one of Kerr's "new and improved" rollers :—

"I consider the roller a vast improvement on the old one; it rolls the tea beautifully with as small a percentage of broken leaf as I have seen from *any* machines. I rolled 700 lb. of green leaf to day in five charges, the shortest time was 40 minutes."

The rolling here referred to was done by hand

CORTEX CINCHONÆ.—The direct imports of cinchona barks into France as compared with former years have greatly dwindled, and that country has ceased to be a factor of importance in estimating the situation of the article, while Great Britain has gained in importance as a market, owing to the increased production of quinine bark in Ceylon. The United States are now almost entirely dependent upon London for their requirements. Another factor of importance is found in the increased exports of Java barks, mostly to Holland; the total exports of the island amounting to 1,321,569 lb. 989,158 lb., and 735,381 lb. during the seasons 1884-85, 1883-84, and 1882-83 respectively. An increase in the supplies of better class Columbia bark is anticipated this year, the course of exchange favouring exports from that country. No importance is attached to the rumours recently circulated regarding the discovery of a forest of cinchona trees in the neighbourhood of Rio de Janeiro. It is a fact that some two years ago specimens of bark were brought to Rio by an engineer employed in the construction of a railway in the interior; but upon examination they proved to be devoid of quinine although closely resembling the cinchona bark.—*Chemist & Druggist* for May.

TEA AND TEA CUSTOMS IN JAPAN.

A very interesting historical and descriptive article on the cultivation of tea and on tea customs in Japan, by F. A. Junker von Langegg, appeared in the February number of the *English Illustrated Magazine*. He places the time of the introduction of tea in the first half of the eighth century, A. D., basing it upon the record of a religious festival in 729, at which the Mikado entertained the Buddhist priests with tea, a hitherto unknown beverage from Corea, this country having been for many centuries the high road of Chinese culture to Japan. Plantations were laid out in 815 by order of Saga Tenno, the Mikado. The product was prepared after the Chinese custom by being first steamed, then dried and ground into a fine powder. Subsequently it became almost unknown and was not permanently cultivated until 1199-1210. In 1200, tea seeds were brought from China and planted in the northern province of the island Kiu-Shiu, the climate of which was particularly favorable for the growth of the tea plant. Uji in the province of Yamashiro has since that time been famous for the superior quality of its tea. The growers in that village still show their appreciation of the abbot of the monastery who introduced the plant by annually offering at his shrine the first-gathered tea leaves.

Prior to 1570 it was the custom to immerse the leaves in boiling water, immediately after picking, and, after having dried them in the sun, to make them into powder.

In 1570 a tea merchant invented an apparatus called Hoiro, for drying the leaves, but it was not universally used for "firing" until 1716. Until the year 1700 tea leaves were fired in a pan, which process was called Nabe-iri, "pot roasting."

"The same tea merchant also first distinguished two sorts of tea, the Usu-cha, 'light tea,' and the Koi-cha, 'dark tea. The word 'Usa' in this instance means 'light, thin,' and, although spelled in Japanese like 'Usu, to pound,' is written with a different Chinese character. He likewise was the first who introduced matting covers raised on poles about eight feet high, in order to protect the plantation in winter against hoar frost, and in summer against the sun. Such covers are still universally in use. When riding, in June, the time when the young leaves, which yield the first quality of green tea, are fully developed, the whole country about Uji is under matting, over which the head of the horseman just rises, so that, with the exception of the distant hills and mountains and the roofs of the homesteads, the landscape is hidden from his view.

"In Japan green tea in leaf is universally used. Powdered tea, which at present is most expensive luxury, is reserved for rare ceremonious occasions. Tea is not prepared by making an infusion with boiling water, as is habitual with us, but the boiling water is first carefully cooled in another vessel to 176 deg. F. The leaves are renewed for every infusion, the same never being used for inexhaustible replenishings of the teapot, as is our custom. Tea prepared in the Japanese manner is of the color of pale Sherry or Sauterne, and constitutes a most refreshing, reviving beverage, especially when travelling or when fatigued by exertion. The Japanese, like the Chinese, drink tea without milk or sugar, which, they contend, spoil the delicate aroma; but they recommend the use of both with black and green teas of inferior quality, prepared after the Chinese method, in order to cover their roughness.

"The preparation of good tea is considered by the Japanese almost an art. Persons particularly expert in this accomplishment are called 'Chajin,' lit., 'tea-man.'

"Tea is cultivated in Japan as far as to 40 deg. N. The best tea land is the district of Uji in the province of Yamashiro, after which the plantations of the other provinces rank in the following order:—Those of Omi, Ise, Shimosi, Echiu, Totomi, Kadzusa, Inaba, Suwo, Surugo, Nagato and Musashi on the main island Hon-do, and those of Hizen and Higo on the Island of Kiu-shiu, 'Nine lands.'"

The tea plant must be raised from seeds.

"The first leaves are gathered in the fourth year. The harvest commences in the beginning of the summer, when only the youngest leaves are picked. Thirty days after the first gathering the second takes place. Some tea growers have lately made a third picking, in consequence of the rise in the price of tea, but this proceeding ought to be energetically discountenanced, as it has proved most injurious to the plant."

The success and excellence attained by the Japanese in many undertakings, is ascribed by F A. Junker Von Langegg, to their treatment of details they being, "great in small things." He describes their treatment of tea leaves as carried on at Uji as follows:

The leaves, immediately after having been gathered, are taken to the factory. The tea plant abounds in stipules, and is thus unlike other plants of the order of the Ternstroemiaceæ, which are usually ex-stipulate. Here the stipules are separated by means of a bamboo sieve, and all impurities are removed. This done, the leaves are exposed to the action of steam, by placing them on a bamboo hurdle over water heated to 200 deg. F. in a covered pan. Those intended for tea in leaf are steamed for fifteen seconds, those intended for powdered tea for half-a-minute. After this, they are uncovered, turned and aired by means of fans in the shape of the wellknown palm-fans of the leaf of th *Corypha rotundifolia*. Lam. These fans, which serve for a great many purposes, are called Uchi-wa, and are made of a frame of spilt bamboo covered with paper.

Before the steam has ceased to escape, the leaves are placed in a basket, "the cooler," in which they are continually turned and fanned. The fanning must be particularly attended to, else the leaves would turn yellow and lose their fine aroma.

When perfectly cooled, the leaves are taken to the Hoiro, the apparatus for "firing the tea." The Hoiro proper is merely that portion which contains the fuel, but this term is generall extended to the whole apparatus, in which sense I likewise shall use it in this paper. It is a wooden frame measuring six feet by four, lined with a layer of cement, and covered with an iron grate, a short distance above which a copper-wire net is stretched. On this the desiccator holding the leaves is placed. The desiccator is a box of exactly the same dimensions as the Hoiro proper, formed of a wooden framework and paper.

The fuel, of which twenty-three pounds are used for every firing, consists of equal parts of charcoal of hard and of soft wood. When the fire is quite bright a sufficient quantity of straw is burnt to obtain a layer of ashes in order to prevent the direct action of the radiating heat. During the process of firing, the leaves are continually rolled between the hands until they commence shrivelling and are nearly dry, when they are transferred to a second Hoiro for complete desiccation. In preparing the sort of tea which is known by the name of Giyoku-ro-cha, lit.: "Dew-drop tea," the leaves are steamed but for an instant, and while drying over a slow fire, each single leaf is most carefully rolled betwen the fingers.

The leaves when perfectly dry are removed from the Hoiro, into sieves of copper-wire, in which the petioles, which may have remained attached, are separated by gentle rubbing between the palms of the hands.

After having been winnowed the leaves are assorted into three qualities, and sifted through bamboo sieves, of which there are six different degrees of fineness. Common tea is sifted but once, the better qualities from six to seven times, and the powdered tea even as often as ten times, which expenditure in time and labor renders this kind of tea extremely dear.

The leaves for the powdered tea are likewise desiccated on the Hoiro, but in a somewhat different manner. The apparatus consists merely of the lower box for the fuel, with a grating of bamboo instead of the iron grate and the wire-net on the top. On this is placed a bamboo hurdle covered with a sheet of cardboard of the same size as the Hoiro proper, on which

the leaves are spread. Instead of rolling the leaves between the fingers, they are alternately collected in the middle of the cardboard, and spread out again by means of tiny pincers in order to secure the uniform drying of every single leaf.

The temperature of the room in which the Hoiro is placed, must be very high, and the doors and windows kept closed against the cooler outer air and draught. When the leaves are nearly dry, they are removed from the Hoiro and fanned, then all the faulty ones, and those which had turned yellow, are carefully picked out, and the remaining placed again on the Hoiro until perfectly dry, when they are spread on shelves near the fire and left for some time without being touched. Finally the leaves are sifted through a series of seives from No. 4 to No. 10. The mode of the ultimate picking likewise differs from that employed with the tea in leaf. The leaves are placed in a square dish, spread by means of a feather, and the faulty, ones removed with a pincer. For the first quality of powdered tea even more precautions are taken. The dish remains covered with a sheet of paper, and only those leaves are exposed which are taken up one by one with the pincer.—*American Grocer.*

INSECTICIDES: KEROSENE EMULSIONS.

It cannot be too strongly impressed upon all who use kerosene as an insecticide that it can be considered a safe remedy only when properly emulsified. The formula for the kerosene and soap emulsion, as found most satisfactory by Mr. Hubbard, is as follows:—

Kerosene	2 gals.	=67 per cent.
Common soap or whale oil soap.	½lb.	=33 per cent.
Water	1 gal.	

Heat the solution of soap and add it boiling hot to the kerosene. Churn the mixture by means of a force-pump and spray-nozzle for five or ten minutes. The emulsion, if perfect, forms a cream, which thickens on cooling, and should adhere without oiliness to the surface of glass. Dilute, before using, one part of the emulsion, with nine parts of cold water. The above formula gives 3 gallons of emulsions, and makes, when diluted, 30 gallons of wash.

The kerosene and soap mixture, especially when the latter is warmed, forms upon very moderate agitation, an apparent union; but the mixture is not stable, and separates on standing, or when cooled or diluted by the addition of water. A proper emulsion of kerosene is obtained only upon violent agitation. It is formed not gradually, but suddenly; in short, to use a familiar phrase, "it comes" like butter. The time required in churning depends somewhat upon the violence of the agitation, but still more upon the temperature, which, however, need not be much above blood-heat.

When obtained, an emulsion of kerosene and soap is known by the perfect union of the ingredients and the absence of oiliness, so that the liquid clings to the surface of the glass or metal. It resembles a rich cream, more or less thickened, according to the proportion of soap used in the mixture.—*American Entomologist.*

MONTSERRAT.

"And now, on the leeward bow, another gray mountain island rose. This was Montserrat, which I should have gladly visited, as I had been invited to do; for little Montserrat is just now the scene of a very hopeful and and important experiment. The Messrs. Sturge have established there a large plantation of limes, and a manufactory of lime juice, which promises to be able to supply, in good time, vast quantities of that most useful of all sea medicines * * * * and I for one heartily bid God speed to the enterprize—to any enterprize, indeed, which tends to divert labor and capital from that exclusive sugar-growing, which has been most injurious. I verily believe the bane of the West Indies."—"*At Last,*" *by Rev. Charles Kingsley.*

The little island of Montserrat, considered the most healthy of the Antilles, is situated in 16° 45″ north latitude, and 62° west longitude, and about eight miles in length from north to south, by a breadth of five miles from east to west. This island was discovered in 1493 by Columbus, who gave it the name of Montserrat, after the noted mountain of Montserrat in Catalonia.

The island of Montserrat is composed of a small cluster of volcanic mountain tops, rising out of the Caribbean Sea, to the height of 3,000 feet, the summits being more often concealed by floating clouds. Their steep sides are covered with virgin forest, abounding in graceful cabbage palm—"the glory of the mountains"—exquisite tree ferns and wild bananas, with their magnificent broad leaves, and are intersected by deep rugged gorges, in which the tree fern, banana and mountain palm flourish.

The negroes now form the greater part of the population. They, most of them, own land and cattle or sheep; and cultivate the sugar cane and ground vegetables on their own account, so that their position is far more independent than that of the European peasantry. They are a light hearted, good tempered race; so accustomed to work in gangs that it is almost impossible to get them to do anything alone.

The first lime tree orchards were planted in 1852, by Mr. Burke, an enterprising planter then living in the island, but the speculation was at first by no means profitable, as this is an enterprize that involves a large outlay of capital, which is for a number of years unproductive, and even then only remunerative on a large scale, although the low rate of wages and extent of uncultivated land in a salubrious climate render the island of Montserrat particularly suitable for the purpose.

The lime tree (*Citrus Limetta*), is a member of the orange tribe, which grows wild in many tropical countries but does not flourish even so far North as the Azores. It is a thorny, bushy, evergreen tree, with handsome dark green leaves. These are so fragrant that they are universally used in the West Indies to perfume the water in the finger glasses at dessert. The small white flowers resemble orange blossoms, and the scent is equally delicious. The lime flourishes best in light soil, near the sea, and comes into full bearing about seven years from the planting of the seed.

From the *International Magazine* we learn that the plantations of the Montserrat Company already cover more than 800 acres, and contain 160,000 trees. These are generally planted fifteen feet apart, and the high road passes through them for a distance of more than two miles. No more beautiful sight can be seen than these orchards, when the trees are laden with their bright fruit, and at the same time the air is pervaded by the luscious fragrance of the blossom. The fruit is gathered by the negro women, and they carry it down in baskets on their heads.—*American Grocer.*

FRUIT CULTIVATION IN CEYLON.

Our correspondent, "Oranges and Limes," brings forward a subject which periodically crops up in the public prints, and, receiving no further attention, fades out of sight for a time, until it is again revived by some one who recognizes in it a public want which he imagines could be supplied without very much difficulty. There can be little doubt that Ceylon could supply an abundant variety of tropical fruits, if suitable situation were selected and care were taken in their culture, and we should think their production might be made a fairly profitable one, if undertaken on a large scale, and with a sufficient supply of capital to enable the cultivators to wait, as they would have to do, for 6 or 7 years before receiving any appreciable returns from their investment. We know that orange and lemon and many other kinds of fruits trees begin to give crops in three to four years, but they cannot be considered to be really in bearing in less than double that age. It must not, however, be forgotten that during the time the gardens are growing a very considerable trade might be done in native-grown fruit, from which preserves of various kinds could be manufactured, and sold in the local market as well as exported in large packages to be put up in an attractive form in Europe. This is the course adopted by Messrs. Moir and sons in regard to their marmalade. They prepare it in Spain or Portugal, and forward it to Aberdeen, or some other of their large factories,

where it is put up in the smaller tins with which we are so familiar. We must, however abandon any idea of growing European fruits at Horton Plains or near Nuwara Eliya. There is no doubt that such fruits can be grown, and in fact are grown, near Nuwara Eliya and the higher elevations of the surrounding districts; but they are grown under considerable difficulty, the crops are very uncertain, and the fruit but seldom of any value, wanting as it is in the flavour and piquancy of fruit grown in England. There is much more probability of success as regards European fruits by making arrangements in the Australian colonies for a supply of apples and pears to be sent up by the mail steamers. The "Kaiser-I-Hind" from Australia last week took on a quantity of magnificent pears, one of which shown us was as large as an ordinary Chaumontel grown in Jersey, and in splendid condition; and nothing we can grow in the Island could be expected to compete with such fruit as this. As regards these tropical fruits alone, it would be necessary to have more than one orchard, in which different varieties of fruit could be grown on a soil and in a climate best suited to their respective characteristics. In the lowcountry no doubt a suitable locality might be selected, say at Mahara or Heneratgoda, whilst for oranges of all kinds a very favorable situation would probably be found in the vallies of Kadugannawa, should it be found necessary to go up so high in the hills. For native-grown fruit, suitable more especially for converting into jams and jellies, Kandy would probably be the best possible centre for collecting a large quantity. With agencies in Matale, Gampola and other places, a very considerable trade could be done by agents understanding the people and their language. Suitable sugar could no doubt be obtained in quantity from Baddegama at a comparatively low rate, and its purchase would doubtless give a stimulus to the production of sugar amongst the competitive native growers who do a little in that direction already. Many of our readers will recollect the jams which old "Francis Appu" of Staiuton's Hotel used to retail in pickle bottles, and for which we believe he had a brisk demand. Experiments on a small scale for testing the Colombo market have not been by any means remunerative hitherto; the latest we believe in the way of tomatoes did not by any means prove satisfactory to the enterprizing grower; and in another case within the twelve months, a grower of Malta lemons upcountry failed to obtain a single response to notices and samples sent down. Without pretending to give an opinion upon the suitability of the climate for the preservation of fruit in the shapes of conserves, we would suggest that the headquarters of the enterprize should be Colombo itself, where, in failure of obtaining a market for the fruit, it might be converted into preserves instead. As long as the steamers in harbour, or the ordinary local demand, supplied a market, the produce might be sold in its natural state, and when that demand fell off, say for a day or two, it would be put into the hands of the boiler and confectioner. In addition to anything to which we have already referred, attention might be paid to the manufacture of lime-juice and the different varieties of citric acid and similar preparations, for which there is an immense demand. Pickles again should prove an additional source of income, though possibly the demand would be rather limited.—Local "Times."

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, May 15.—The strength of a horse is in proportion to its health, and the latter depends on its food and stabling. Some cases of blood-poisoning have been reported, and which are traceable to sudden change in diet, and to the drinking of stagnant water. Some farmers conclude, that so long as animal refuse is kept out of the drinking pond, no bad results can ensue. It should never be forgotten, all putrid matters are sources of disease. Insufficient air is a cause of sickness in horses as in human beings. It has been estimated than an ordinary-sized horse, needs 130 cubic yards of air per day. But that it requires 33 cubic yards per hour to get along comfortably in general stable life. The aim then should be to induce a constant supply of fresh, and to expel the viciated air. A high, rather than a low-roofed stable accomplishes that end best.

This being the season for green fodder, the subject naturally suggests itself, how far is such, good for working horses? There cannot be any question about turning them into a meadow there to feed. That plan is excellent only for colts—that rest and liberty develop. M. Gronier held that green forage acted on horses, like mineral waters when employed as medicaments on individuals, A Vichy, Apollonaris, &c. efficacy. Fresh grass, &c., kept away imminent illness, cured existing ones, and discounted convalescence. It forms a kind of annual salad refreshing for animals of an irritable temperament, that have narrow intestines or the system heated from too copious oat rations.

If hay be taken as the standard to test the comparative value of the various green feeding stuffs, there will not be found any very great difference between them, in point of nutritive power. Certainly, some will vary in point of volume, that which implies, not to overload the stomach, but to multiply moderate repasts. The green fodder is most apt to produce flatulency, when after being cut, it has been allowed to lie exposed to the sun, or even some time in the shade under a shed. Many believe that it is good to let the "wild freshness of morning" disappear, before using green food; enable the dew to evaporate, &c. On the contrary, it is more prudent before using to sprinkle faded grass, elover, tares, but above all luzern, which have been exposed to the action of the sun with water. M. Reynal has demonstrated, that fodder rich in sugar, ferments more readily in the digestive organs, in proportion as it has been preliminarily heated.

In spring, stock have a natural longing for fresh food. Occasionally, that desire may even be the symptom of disease; an indication of a morbid condition of the digestive organs. The change of diet will facilitate the falling-off of the old hair; develop transpiration; induce brilliancy of coat and freedom in the intestines. Fresh forage has also the reputation of getting rid of cutaneous affections and thus of purifying the blood Old horses, accustomed to a dry and substantial dietary, do not benefit by a green bill of fare. Animals of a weak constitution ought not to receive green forage.

From experiments tried on cavalry horses at Versailles, it was found that the green forage when coming into flower, was the stage most propitious for consumption. A sharp eye ought to be kept to notice how the change operates on the animals subjected to green soiling. If laxity or weakness appear, the ration of oats should be at once augmented. Never, in the case of working horses diminish the oats, when entering on the green feeding. It costs dearer to feed badly, than to nourish well, and the latter system secures more health and strength that which implies more profit on capital.

The practice is extending in France and Switzerland, to cut or castrate cows, so as to ensure, after a certain age, for a definite period, a uniform yield of milk, simultaneously with the putting up of juicy flesh for the butcher; to transform in a word, the cow into a veritable milk and beef machine. M. Charlier is the great advocate of the new plan of *ovariotomy*, which is effected by a special instrument, and is never attended with danger in the hands of a Vet. The cow will be ill about eight or fourteen days after the operation. During this period, the animal should be kept covered, to guard against cold, and on half-diet, to avoid indigestions. On recovery, the cow will be found less liable to diseases, since gestation and parturition have been rendered impossible.

M. Seippel of Switzerland has adopted ovariotomy, or splaying, executed by the new instrument, since 1885, and with decided success. On twenty cows, he has had a daily yield of 10, and hopes to reach 12, quarts of markedly rich milk. But he has above

all obtained, a quality of meat, tender and succulent, which the butchers have reluctantly admitted, to be equal to the best ox beef. To bring the cows up to the slaughtering standard he had to employ neither a special diet nor extra rations. The cut cows were ever in excellent condition. In ordinary cases, a cow after producing the usual number of calves, only produces beef of a poor quality, which is hard under the tooth, rebel in point of digestion, and devoid of nutritive power, and all this despite their fat appearance. Ovariotomy should be practised when the cow is 5 or 6 years of age; when she can be kept on milking and simultaneously fattening, for eighteen months and then sent to the butcher, with the certainty of proving remunerative.

Dr. Frank was delegated by the Prussian Government to investigate truffle culture. He bore in mind the ideas of Müller and Schlösing as to the role of animalcules in the nutrition of plants and the nutrification of soils. He now shows that in the case of some trees, oak, ash, and pine, the two last especially, their rootlets are composed of bands of microbes, which form a veritable screen, and devour the humus, prepare the food, while forming a "felt" round the interior cellules of the plant. In the case of wheat, the rootlets are capillary fibres, which secrete an acid, to dissolve the mineral matters, in the soils preparatory to their absorption by the plant.

CULTIVATION EXPERIMENTS IN THE ARAKAN HILL TRACTS: NEW PRODUCTS.

Mr. F. C. Fanshawe, acting Deputy Commissioner of the Arakan Hill Tracts, has submitted an interesting report on experimental cultivation of certain economic products in these outlying tracts, but the results obtained by him do not encourage the hope of bringing these remote regions, peopled by ignorant savages, within the pale of civilised cultivation of useful products for the market.

There are two gardens in which these experiments were carried on; one at Paletwa and the other at Kyoukpandaung. A sum of R1,000 was allotted for the year 1884-85, of which R889 were expended. Since the last report was submitted in May 1884, the gardens do not show any marked improvement. The money is chiefly spent on gardeners' wages and cooly hire, as it is found very difficult to keep the gardens free from weeds and grass during the rains, and nearly half the allotment is spent on cooly hire for this purpose.

The Paletwa garden occupies an area of 4½ acres. Its situation is unfavourable, the ground being low and swampy in some parts. The *Tea* plants here are said to be looking healthy, and have been leased out for one year for R100. The *Potatoes* proved a failure; but this was owing chiefly to the seeds having arrived in a bad state; another reason being that they were not planted as they should have been, *i.e.*, in light, sandy soil, and on ridges; but sown on heavy soil, on low ground, and in trenches. In a country possessing a naturally humid climate, with a heavy rainfall, this result was to be expected under the circumstances. Mr Fanshawe, however, is of opinion that the experiment is worth trying again this year. The *Pepper-vine* seems to have done fairly well, and it is intended to plant it extensively on the Burmese method of growing betel-vines. The *Cinnamon* has been a complete success, and "a small forest of them" is said to exist at Kyoukpandaung. The variety of *Caffee* grown was the Liberian, and the plants appear to have done well. The *Arabian coffee* was also tried, but it did not get on well. *Manilla hemp* is said to get on well, and the same is said of the *Betel-vine*. Two *Cocoa* trees have reached the height of 9 and 4 feet respectively, and may be pronounced a success. There are no *Sugar-canes* in the Paletwa garden, but Mr. Fanshawe thinks it would pay to plant them. Among *Fruit*, the *Mango*, the *Plantain*, and the *Pine-upp'e* are mentioned. The last-named is said not to do well. An important feature in the report is the remark about *Khaki cotton*. A little of it is grown for home consumption, but very little is exported. Mr. Fanshawe thinks some seeds might be given to the cultivators as an experiment, as the price is double that of white cotton; and that when the peasants find that it will pay well, they would probably take to cultivating it regularly. The Chief Commissioner has sent seeds to Mr. Fanshawe, and we shall be glad to hear the result of the experiment. There were no new experiments during the year.

Mr. Fanshawe, we regret to see, does not seem to take a hopeful view of the utility of the garden at Paletwa. He says:—

The experimental cultivation in the Arakan Hill Tracts has done little or nothing, I am sorry to say, to induce the peasantry to try new products, and I am afraid that, as long as they live the life that they do at present, they will never attempt anything new. Their staple products are of course rice and seesamum for home consumption, and tobacco and cotton for both home consumption and export. Their time is pretty well taken up in their taungyas and tobacco fields, and the month or two in which they have nothing to do they spend in a series of feasts. The ground used for the cultivation of tobacco could not be used for permanent garden land, as it is all under water during the rains; and if taungyas were cut far from the water, the labour would be immense to keep the ground properly watered during the hot weather, and that is just the time that they are all hard at work cutting their taungyas for planting paddy, &c. They are too lazy and indolent to put themselves out in any way, and as long as they have enough to eat and drink, with a few rupees to spend yearly, they are quite contented. Different kinds of tobacco and cotton they would willingly sow, I think: and if Mr. Bridges supplies seeds next year, as he has very kindly offered to do, I have no doubt that the experiment will be a success.

Even if planters were induced to settle up here, I do not think they would find cultivation profitable, as the great difficulty of course would be cooly labour. The peasantry here simply would not work regularly, and all the labour would have to be imported, and even then I am afraid the coolies would be constantly down with fever, for the first year or two at any rate, and unless they were paid at ruinously high rates, they would desert whenever they got a chance. Burmese peasants are, as a rule, of the stamp Mr. Fanshawe has described, and much cannot be expected of them. With regard to the garden at Kyoukdandaung, which is of more pretensions, it may said that *Tea* and *Cinchona* thrive well, and may be cultivated with success. The tea garden is already assuming fare proportions, and the time is coming when, with a little skilled labour for curing processes, the trees will yield a return which ought to make the garden more than self-supporting. The number of trees and young plants exceeds 12,000, and this number is capable of large extension, so as to form the nucleus of a fairly good tea estate, which would pay well in any part of the country where labour was procurable at ordinary low rates. The fact, too, that there are over 400 cinchona plants at Kyoukpandaung, all doing well, particularly the larger ones, seems to prove that the locality is favourable to the growth of this very important vegetable product.

Potatoes and *Coffee* were failures. *Fruit trees*, such as raspberry and apricot, have done well. *Tobacco* seems to have proved successful, and Mr. Fanshawe has been supplied with seed for extended experiment. The tobacco produced is said to be very good of its kind, and fetches a good price in the local market. Looking at the experiment as a whole, it may be said to have been fairly successful: but in our opinion something more than merely official supervision, such as that exercised by a Deputy Commissioner, is needed to prove to demonstration whether the results obtained cannot be improved upon. The Commissioner, Colonel Sladen, is of the same opinion, as he says:—The experiment need not for the present be repeated until the conditions are more favourable, and we can count upon more skilled supervision. It has, however, been decided to continue the grant of R1,000 for another year. Let us hope that the results of the next year will be more satisfactory.—*Indian Agriculturist.*

TEA WITHERING BY MEANS OF HOT AIR

is advocated by Mr. Percy Swinburne, late of Sylhet, Cachar and Assam, who writes:—

Natural withering, as generally understood, means that the leaf is placed in open or closed houses in which the draught of air may be regulated; while artificial withering includes the use of heated air, or of machinery.

A large proportion of the best tea which is sent to the market is now made from artificially withered leaf, that is to say, from leaf which has been withered by heated air. The lofts of the pucka tea houses are heated by the sun, to a temperature of over 100 degrees, and are often intolerably and suffocatingly warm. In dull and wet weather also, the temperature in these places is still considerably higher than that of the surrounding atmosphere, as they are heated by siroccos or other firing machines, the chimneys of which pass through them.

There has for a long time been a strong prejudice against artificial withering. Closed hot houses were used because the weather so often proved unfavourable, but natural withering, under favourable circumstances, is always supposed to give the best results.

In natural withering, the faster the process the better the result, so we may conclude that perfect withering would consist in removing all superfluous water from the leaf instantaneously, without disturbing the oils, juices &c., while sufficient heat was applied to reduce the fibre to the soft condition required for rolling.

A series of careful experiments have been made in a small house heated by smoke flues, with one maund of leaf spread on about 15 square feet to a pound. It was found still, that the faster the operation the better the result. That the greater the heat the thinner the leaf must be spread, and the more care and nicety required.

The finest tea was made from leaf withered in 3 hours, at a temperature of 140 degrees. The tea was on several occasions carefully assorted, and true samples of the bulk were sent down to Calcutta to be valued, and the quality of the liquor as well as the appearance were pronounced excellent. The average valuations were about 14 annas, and the leaf was good, but not finer than that plucked on most estates in Darjeeling, or Sylhet, or Cachar, being two leaves and a bud. The market at the time was depressed, and the average price of the teas of the districts named was, at that time, between 9 and 10 annas.

In 1883 the entire crop of the Kainagar Estate, Sylhet, just under 900 maunds, was withered in hothouses, heated by smoke flues, and realized 11 annas per lb. average. The houses were "kutcher" ones built of bamboo and plastered ekur. They were 14 feet high in the roof, 7 feet high walls—breadth 20 feet. Two four ,feet wide, passage, and 4 rows of chalnies 3 feet wide. The pipes were 9 inches in diameter, and $\frac{1}{8}$ inch thick and ran along both sides of the house underneath the outer row of chalnies. The heat was much greater near the furnaces than at a distance from them, and the house gets thoroughly heated for a distance of about 15 to 20 feet only from the furnace.

The heat is also uneven. and the greater it is the more difficult it becomes to equalize the withering. The leaf must be thinly spread and carefully watched. One part of the house withers much more quickly than another, and if the leaf is left for an hour only, after it has reached the right stage, much quality is lost.

These houses, defective as they are, are preferred to those of the old style.

When the men have learnt how to arrange the leaf, and work the fires, the rolling can be commenced at 5 a.m. every day in all weathers.

The leaf does not turn red unless it is bruised in some way during the withering process, and its juices become exposed to the air. This may happen from the leaf being gathered up a second time, and removed from one place to another.

If it is once established beyond dispute that the best tea can be made from artificially withered leaf, there should be no difficulty in making a hot chamber in which the leaf could be very thinly spread out, and the heat equalized and regulated, and the moisture removed.

One of the great disadvantages of open houses is, that the damp cold air which checks the withering is admitted, as well as the warm air which favours it. Withered leaf absorbs moisture, and is refreshed by it—as a bouquet of faded flowers is revived by sprinkled water. But when the leaf has withered a second time, it loses its freshness, and when the flowers have again faded, they begin to give out an offensive smell; the first stages of decomposition having set in in both cases. Leaf which has once lost its volatile freshness and delicacy, never recovers it, and can never be converted into fine tea.

The fine qualities in the leaf may be chemically altered in the hot withering process, but they are not lost altogether as is proved by the quality of the tea produced by it.

In the same way, however, as the flavour of the tea is affected by different firing processes, so it is probably also affected by the degree of heat applied in the withering, as well as by the manner in which it is applied.

Good tea can be made of leaf which is carefully withered, rolled, fermented, and finally baked, but, although strong, it is peculiar, and has not the delicate flavour and smell of tea, which is roasted over charcoal in the usual way, and this again is not so aromatic in flavour as that which is dried by the rapid hot-air draught of the "Sirocco."

It would appear that the best withering would be accomplished by a strong draught of moderately warm and quite dry air passing over the whole surface of the leaf.

If the juices can be kept uninjured, the more the leaf is withered, the better the quality of the tea. The presence of water in the rolled leaf appears to affect the fermentation injuriously. It is not accurately known at present what chemical changes take place in the various systems of manufacture, but we know that we are more or less dependent on the weather, and that the changes which take place satisfactorily one day, will not do so on another, under apparently exactly the same condition. Lightly withered leaf makes tea without strength or body, and this is probably due to the presence of too much water in the rolled leaf, which causes an injurious fermentation. On the other hand, over withering or bad withering, by which the juices have been injured or destroyed have the same effect, and produce weak pale liquored tea. As far as we know, the feeling amongst Ceylon Tea Planters is adverse to hot air?—*Planters' Gazette.*

FRUIT-GROWING IN CEYLON.

I noticed in a recent issue of your paper, an article upon fruit-growing for the Colombo market, and, as one who has more than once tried to meet this want, I will relate the chief reasons why hitherto all attempts have been failures. Everyone has noticed how universally unsatisfactory the fruit of Ceylon is, and how the whole might be characterized throughout as inferior. Indeed, it may truly be said that few in Ceylon have ever tasted really good Ceylon ripe fruit, and those who have lived all their lives in the island have never developed the taste.

I once grew some very fine limes, each of them equal in size to three of the usual bazaar specimens, and these I offered for sale in the market, but no one would buy them for more than the usual rate per 1,000 for limes. I now sell them to natives who pay me by the thousand, irrespective of size or quality, and I might almost add the greener the better. Indeed, the more inferior the fruit the better it will pay the producer, for ill weeds grow apace. This is very different to a fruit shop in Europe, where excellence overrules everything; there, if you

observe a particularly fine basket, you may be sure the price will be double or treble that of any ordinary representatives of the same fruit. Here, as I say, a thousand limes, whether large or small, are a thousand limes, and, even though a better price may be obtained for the higher qualities, it is never commensurate with the real intrinsic value—not even weight for weight or measure for measure.

It is difficult to say how this can be remedied; for my part I am most passionately fond of fruit, being practically an abstainer from alcoholic beverages. I have a very great craving for fruit, yet I do not care for the tough pulped oranges with their jackets of Lincoln green with skin upon them that will only come off with the greatest exertion, and, when removed, what remains is but a stringy casement, filled with an acid sweet orange-peel flavor not of any decided lusciousness, making me always think, as I do when I eat tomatoes, "because the doctor says they are good for you." This last opinion is, however, only personal, for many are very fond of tomatoes. To make a long story short, fruit cannot be too good for real enjoyment; the better it is the more pleasure it gives and the more wholesome it is. Indeed, it is like the middy's idea of eggs—"better have one good one than a dozen bad."

To repeat, how it is that good fruit is unprocurable in Colombo? I reply as follows:—

1st.—Those who have never been out of the island cannot appreciate the true value of good fruit, consequently they do not know that there are pines *and* pines, oranges and oranges. Fruit is to them like every other commodity, sold in bulk. 2nd.—Our good European housewife will not go to market herself: consequently the only way she can purchase it is through her appu, and he buys a pine or a dozen oranges or mangoes just as he would buy a bundle of Mauritius grass or straw. Indeed, I may tell the good housewife that I can buy better fish than she gives me in Colombo when I dine with her at Nanuoya, and for not a higher price than she pays her appu or butler, or whatever she calls the supreme being who controls her dinner table.

To return to fruit: if it is required good, it *must* be cultivated, and cultivated fruit cannot be produced in small quantities as cheaply as that which grows like the jungle around it. In time, however, if a market spring up for better kinds, the prices would scarcely be more if the consumption were greater, and this latter would inevitably be the result of really good fruit coming to market. Whoever saw a more disgusting spectacle than the mangoes exposed for sale in the Colombo market? Swedes for sheep and food for pigs in Europe are more attractive. Then take the pines; they are one-fourth of them unfit for human food and should be condemned as such, and I doubt if one-half can be called even wholesome. Now, if it were necessary, owing to some defect on part of the climate, to blame things thus it would be another matter, but fruit ripens as well in Ceylon as elsewhere. Certainly I think the producer very badly protected, for I have sold my fruit to natives for far more than they could grow the same themselves, and they say they have to pluck it green to save it from depredation. Does it not naturally follow that in every probability the bulk of the fruit in the Colombo market is stolen property? For my part. I believe a very large proportion is; but my experience in this case is that "stolen fruit is far from the sweetest." A careful reflection over all I have written will show the number of adverse circumstances against which a grower of superior fruit would have to contend. He would naturally, with European notions, begin, as I did, with quality until he found it was not appreciated, and then he would, as I have done, go in for quantity. The large shipping Companies, such as the P. & O., Messageries and B. I., might do something, for they require a steady supply of fruit, and, if they had it carefully inspecting and rejecting what was not up to the standard, the public would benefit, and they before the public. Of all places where good fruit is appreciated boardship in the tropics comes first. With or without sea sickness, I know nothing more delightful than a good orange or pine-apple, and from time immemorial it has been an understood thing that fruit is beneficial to counteract other influences which without it are prejudicial to health.

To summarize: good and ripe fruit is not obtainable in Ceylon for several reasons. When grown, there is no way of putting it into the hand of the right consumer who will pay its value for it. The natives cannot grow it because depredators would steal it before it was ripe. If placed in the market, the indifferent, though self-interested, appu who caters for his master or mistress will naturally not buy it, as it would cut down the margin of his clippings. If all the large shipping companies would take the matter up, being more particular than they are as regards the quality of their fruit, in no very long time the necessity to produce a better quality would be recognized everywhere, and stolen property of this nature would become less and less in request.

Another point not to be lost sight of is the length of time before most kinds of fruit-trees reach the bearing stage. I know of some of the kinds most in request, besides the plantain, that bear no appreciable quantity of fruit before they are from six to eight years old. Upon an estate I am interested in, in the low-country, orange trees planted seven years ago have only given a partial crop. Limes of the same age gave their first good crop last year. There is no market for my limes, so I have to squeeze them and ship the juice, which in London has fetched one shilling a gallon for unconcentrated, and 3s. for concentrated to a fourth its original bulk. This is scarcely good enough for what it costs. The chief reason why country-grown pines are not so good as those grown in hot-houses in Europe is that no care is taken of them, for I have occasionally tasted this fruit in Ceylon. When carefully tended, they are as rich and full of flavor as could be found on a dinner-table in England.—A BELIEVER IN FRUIT.—Local "Times."

A SOUTH AFRICAN BOX TREE.

In the last number of Hooker's *Icones Plantarum* is figured and described (t. 1518) a new species of Buxus under the name of Buxus Macowani. It is of special interest (says Professor Oliver) as the first representative of the genus in that region, as also in certain structural characteristics, but it is more particularly on account of its possibly furnishing a supply of Box-wood for engraving purposes that we call attention to it, as the supplies of Box-wood from the Black Sea districts is rapidly being exhausted. The following extracts are from the "Report of the Superintendent of Woods and Forests (Cape of Good Hope) for 1884." The Conservator of Forests, King William's Town reports:—

"The coast forests have come into notice during the year by the discovery that the so-called Cape Box is of value for engraving and other purposes for which Box-wood is used. The area of Box-producing forest in the Buffalo River valley is estimated at 15 square miles. Box also occurs in the valley of the Keiskama River, near the coast, but has not as yet been detected west of this in the valleys of the Fish River, Kowie River and Bushman's River."

And again, under "East London Forests:"—

"The event of the year for these forests has been the discovery of the commercial value of Cape Box-wood. This is a small tree like the generality of trees in the East London forests. It is rarely met with over a foot in diameter by 25 of bole, but it is sufficiently abundant to furnish a large supply of wood. Submitted to an expert, it has been declared to be worth about one-penny a cubic inch, if seasoned free from cracks. Cape box (Kafir, Gard-gara) does not appear to coppice, but has a good natural reproduction from seed. The tree was placed on the reserved list a year ago. Previous to that it had been sold at 5s. the waggonload for firewood. See also note by Mr. Jackson on a 'New Box-wood,' *Journ. Soc. Arts*, 1886, p. 465."—*Gardeners' Chronicle.*

PLANT CULTIVATION AND MANURES.

The roots of plants will only absorb from the soil such materials for food as are in a liquid or gaseous form. No matter how richly plants may be supplied with food-substance, they cannot avail themselves of it, or assimilate it into their structure while in a solid condition. Bearing these facts in mind, it is not difficult to understand the great success which has attended the application of Liquid Manure for garden purposes in Flanders, Jersey, and in various parts of our own country, soils that previously were proverbially barren being by this treatment rendered enormously productive.

The late Dr. Voelcker said, "Any one who has passed through Belgium, and examined the nature of the soil, must have been struck with the wonderful change which liquid manure has produced there." The gardener in his practice must, however, alway remember that soils containing a fair proportion of clay, and more especially stiff clay soils, are diametrically opposed in their chemical and physical character to those which are porous and sandy. Generally speaking the retentive and stiff soils contain not only the more common mineral elements which we find in the ashes of plants, such as lime, magnesia, soluble silica, sulphuric acid, &c., in sufficient abundance, but also the more valuable mineral substances, such as phosphoric acid and potash. They, moreover, possess in a high degree the power of absorbing nitric acid, and retaining it for future use; and in addition, under good garden cultivation, the vegetable remains left in such soils, in the shape of roots and leaves from former crops, yield much nitrogenised organic food for succeeding plants. The decided benefit which is usually found by the gardener to result from a liberal dressing of stable-dung is owing to the fact that by the very bulk of the manure the physical and chemical characters of the soil are so altered that in reality the plants feed upon a new and artificially formed soil.

Particular cultures may demand particular manures, but the standard manure, such as well made farm-dung, affords all the ingredients necessary to the development of plants. Such manure contains all the usual elements which enter into the composition of plants, and all the mineral substances which are distributed throughout their tissues; in fact, carbon, hydrogen, nitrogen and oxygen are found therein united with the phosphates, sulphates, and chlorides, &c.

In order to be directly efficacious, every manure must present this mixed composition.

The nitrogen of nitrogenised organic substances only benefits plants when converted into nitric acid, hence no material can act as a powerful fertiliser until it passes into a state of oxidation or decomposition, and the presence of any ingredient which hastens the material applied as manure into that condition, although in itself probably comparatively unnecessary to the plant in that particular soil, yet forms a useful manure. It is in this way we often may explain the great benefits derived from an application of lime, marl or gypsum. Straw, Bracken-Fern, Potato haulms, turf and vegetable refuse, are sometimes mixed with quicklime and earth, to form a compost, in order to facilitate their disintegration and decomposition. The utility of this practice cannot be disputed while confined within reasonable limits, but it is sometimes abused; for it is beyond question that alkaline salts, such as that supplied by lime, mingled indiscriminately with manure, become in reality very mischievous on certain classes of very light soil, where the business is rather to preserve than to destroy the substances that are used as manure. Such soils part too easily with the stores of fertility committed to them; consequently we find soluble plant-food is washed away by the rain, or even evaporated into the air. Mechi aptly remarked that "the best portion of manure is always attempting either to run away, or to fly away;" and time tends to increase this action.

The most suitable manure for the looser and more friable classes of soil, is some substance which will combine intimately with the fertilising materials, and thus husband them securely for future plant use. Thus hungry loose sands are rendered fertile by the application of clayey composts or materials for consolidating the mass, so as to impart a greater resisting power to atmospheric action.

One great objection to the extensive employment of composts, however, is the amount of labour they require in the repeated turnings which are held necessary in their preparation, and in the large quantity of matter which has to be transported.

In order to show why potash, lime, phosphoric acid and nitrogen are the most important elements of plant food, it is necessary to consider the chemical composition of our of various garden productions, and the amount of each constituent they remove from the soil in order to build up their vegetable fabric.

The following table, compiled from various sources, brings before us at a glance the amount of these constituents removed from the land in 1 ton of each crop in a fresh condition as taken from the garden, which of course includes a very large quantity of water.

Amount of Selected Chemical Constituents in Produce Removed from the Land, in Pounds.

In 1 Ton of each :—	Nitrogen.	Phosphoric Acid.	Potash.	Lime
	lb.	lb.	lb.	lb.
Potato tubers	5·6	3·4	12·3	1·5
Carrots	4·5	2·0	6·3	1·8
Parsnips	4·9	4·3	8·1	9·0
White Turnips	4·0	1·1	6·7	1·6
Peas (including pods) ...	64·8	10·3	12·5	5·7
Cabbage (edible portion) ...	6·7	2·9	2·9	5·2
Jerusalem Artichokes ...	5·3	6·7	22·6	1·3
Asparagus	5·0	2·0	0·7	0·5
Onions (bulbs)	5·4	1·6	3·4	1·3
Cucumbers	0·7	2·0	6·7	0·7
Broccoli (heart)	4·4	5·6	10 8	1·1
Cauliflowers (heart) ...	4·6	4·0	5·2	0·5
Spinach	2·5	3 6	4·5	6·0
Radishes	5·0	5·8	3·1	1·4
Kidney Beans (including pods)	61·5	2·3	5·6	1·7
Lettuces	2·5	1·7	8·9	1·2
Celery (stems)	4·5	2·8	5·4	3·1
Beets	4·4	0·7	6·5	0·5
Rhubarb (stalks)	3·1	2·0	5·2	1·6

The true economy of manure can be understood only when we become aquainted, as by the statistics given above, with the special characters of the crops we cultivate; but we not only have to consider the materials required to form a crop, but the power the particular plant we are cultivating has of assimilating the ingredients applied in manure.

For this reason farmyard dung, purchased or home-made, which supplies all the essential elements of plant food, and particularly the constituents shown to be required to such a large extent by the vegetables we cultivate, is so largely used by growers. But on the other hand the immediate return from an application of farmyard manure is much less than from the same amount of plant food applied in well selected artificial manures. We shall hope to continue the subject on a future occasion.—*Gardeners' Chronicle.*

OUR AMERICAN EXCHANGES say that golden millet (*setaria germanica*) is the best of annual grasses for hay, as it yields largely can be cut in six or eight weeks after planting. This is borne out by Queensland experience.—*Planter and Farmer.*

FARMERS should plough their lands a trifle deeper every time they are worked to thereby secure more of its dormant fertility. The deeper the land is ploughed the more productive it will be.—*Planter and Farmer.* [A rule with marked exceptions. In no case should the subsoil be brought to the surface, and ploughing or digging deeper than 18 inches, is generally a mistake.—ED.]

ABOUT HARDINESS.—Many kinds of trees quite hardy after they attain some age are very tender when young, and need protection until they are five or ten years old. It is hardly to be supposed that the growth of the previous season is better fitted to withstand cold on an old tree than on one five years planted. The fact seems to be that most young trees have an excess of plant food. This produces a vigorous though sappy wood, wich does not ripen and cannot resist cold. In a few years the tree becomes partially starved, and grows no more wood than it can ripen. The moral of this experience should be to manure and cultivate young trees somewhat less, and old trees more.—*Southern Planter.*

SILK CULTURE.—There are hundreds of families in Virginia who might add a good many dollars each year to their annual income by engaging in silk culture. Raising a few pounds of cocoons each will not materially interfere with household duties, and how many farmers' wives and daughters would gladly avail themselves of so good an opportunity to add to the family's income if they only knew what silk culture was and how to go about it. To all such, I will say, first purchase yourself a book on silk culture. By following instructions in these books, success is sure to follow. Either of these books can be bought for twenty-five cents. Last summer I bought $1 worth of silk worm eggs. I was so pleased with my success that I am now feeding about 60,000 worms, which I will be spinning in about two weeks from this date. All persons interested are cordially invited to visit my cocoonery, and any information I can give I will cheerfully do so. The time from the hatching to the spinning of the cocoons will vary from thirty to forty days. The food for the silk worm is mulberry, either the white or the common purple mulberry. The latter grows in abundance in the fields and forest of Virginia, and they can also be fed on osage orange—*The Rockingham Register.*—Very Respectfully, *Cross Keys, Va.*, June 15, 1885.—MRS. S. A. CONGER.—*Southern Planter.*

GUTTAPERCHA.—Sir John Kirk, writing in December last, forwarded a sample of native African guttapercha, the produce of a yet unknown tree which he found at Mombasa. From the papers now published, it would appear that after examination of the specimen there remained no doubt that the substance would prove an acceptable addition to the present supplies, its value being about 10*d.* per lb. At the same time Sir John Kirk also forwarded a specimen of some india-rubber taken from plants supplied from Kew Gardens about five years ago, these having flourished and propagated freely at Zanzibar. The report on this specimen valued it, if taken from the trunk of the tree, at about 1*s.* 9*d.* to 2*s.* per lb. As Sir John Hooker, the Director of the Royal Gardens at Kew, remarks, "the attention of Her Majesty's Consular officers in these countries (india-rubber producing states) cannot be too closely addressed to matters of this kind, which are not merely of great scientific interest, but may form the basis of a lucrative and beneficial trade."—*Chamber of Commerce Journal.*

BRAZIL.—Mr Acting-Consul Hampshire, writing on the Trade and Commerce of Santos for the year 1884, refers to the subject of the investment of British capital in that province, and points out that would-be investors should first ascertain from disinterested sources the particulars of the enterprise before accepting all that is stated in the prospectus. "Railways, sugar mills, and gas companies are quite sufficiently developed in the province of Sao Paulo for actual needs. With regard to the first of these, any further augmentation of the present lines that is necessary can be carried out without applying for foreign capital unless the result is of doubtful issue. Only a more diversified agriculture, with an extensive immigration, could warrant any considerable augmentation of the present railway system. Sugar mills are already established in sufficient numbers to provide for local consumption, and present values abroad are far from encouraging any exportations. In some directions there exists a strong feeling in preference of native to foreign undertakings: this, in itself, is a natural and laudable sentiment, but in its application it constitutes, by further development, a possible rock ahead to foreign enterprise, unless the concessions of privileges which have attached to some are clearly irrefragable and safe from any interference or molestation."—*Chamber of Commerce Journal.*

SALT FOR CATTLE IN BURMAH.—We noticed briefly last week the enquiries instituted by the Chief Commissioner of British Burmah concerning the extent to which salt is usually given to cattle in that Province. We print this week the entire correspondence that has passed on the subject, omitting only the detailed replies of cultivators in the seven districts where enquiries were made. It appears that salt *is* given to cattle, and that they not only need it as a salutary diet, but take to it with avidity, thereby proving that it is an essential necessity in the internal economy of cattle. It is a practice that should, we think, be encouraged largely in all districts. From the correspondence before us, it is abundantly clear that salt forms an important element in the diet of oxen, and from the fact that it is administered when the animals are tired and worn out, after a hard day's work, shows the necessity there exists of impressing upon cultivators the wisdom of employing salt more largely than appears to be the case.—*Indian Agriculturist.* [The curious part of the matter is that although the salt duty in Burmah is only one-tenth that of other parts of India, yet the Burmese do not give more salt to their cattle than their neighbours. All, including cattle owners in Ceylon, need to have the benefit of salt given to cattle, pressed them.—ED.]

THE USEFULNESS of the *Sar Kanda*, or *Munj* plant, in the south-east of the Punjab is, according to the author of one of the recent settlement reports of that part of the country, hardly less than that of the bamboo and palm in other localities. The leaves, we are told, are used for thatching houses, the reeds being bound round the edges and across to strengthen the thatch. The reeds are also used for making furniture, such as chairs and stools, and for agricultural implements, such as trays and baskets, and the frame-work of receptacles for chopped straw. The plant, further, often affords the only pasturage available for cattle, and though the dry leaves are said not to be very fattening (a statement which may be readily credited) they suffice to maintain the cattle in condition. The green leaves naturally yield greater nourishment; but these appear only when the plant is fired; and as reeds are seldom produced after the plant has been so treated, the villagers rarely resort to this process, except in the case of inferior plants. But the principal value which munj possesses in the eyes of the cultivator lies in the inexhaustible stores of fibre which it produces for ropes and string, without which no agricultural operations could be carried on, and no comfort would be found in their homes. In the autumn, the view is closed in on every side by the high flowering stems of the p'ant, and then is the chance for the zemindar to lead you a rare dance in search of his fields. Of late years, the villagers have taken to selling the *sar kanda* of their lands, and in many cases a very considerable income is realised from disposing of this natural product.—*Indian Agriculturist.* [All travellers in Northern India are struck with the prevalence of this bamboo-like reed, growing along divisions between lands. It makes splendid thatch for houses, being laid on the roofs thickly in bundles. It also makes nice chairs and small couches. If it would answer in Ceylon; it ought to be of considerable value to farmers and others.—ED.]

STATISTICS OF THE TEA ENTERPRISE:

THE CARD-BOARD TEA ALMANAC.

The Card-board Almanac issued by Barry & Co. of Calcutta, is calculated to be very useful, hung on the wall of an office, showing, as it does, the main facts connected with the great tea industry of China, India and Ceylon. The almanac proper simply gives the days of the week and those of each month, the latter coloured red when Government holidays fall on them. July of all the months is the only one not brightened with a red coloured figure. January, May, June, September, March and August, have each one; February and November two; April and December three each; October is nearly half-red, with fourteen days, twelve of these consecutively from the 2nd to the 13th, and again the 26th and 27th. The total result is that, in addition to the 52 Sundays of the year, the Indian Government and its servants have 28 holidays, for two of the October (Doorga poojah) holidays are Sundays; that is to say, 80 non-working days out of the 365, the working days being, consequently, 285. The figures for tea are given for each month of 1883, 1884 and 1885, a blank column being left to be filled up with similar details. Our readers may care to be reminded that the imports into Britain of Indian tea (Ceylon included) were

1883	.. ..	61,666,000 lb.
1884	.. ..	67,153,000 ,,
1885	.. ..	66,863,000 ,,

There was, therefore, a very material check to previously rapid advancement of production in 1885. But there was no check but a wonderful advance in deliveries in Britain (for export to some extent, but mainly for home consumption), thus:—

1883	.. ..	59,097,000 lb.
1884	.. ..	64,217,000 ,,
1885	.. ..	68,896,000 ,,

An increase of over 9 millions of pounds in 1885 as compared with 1883, and over 4 millions above the deliveries of 1884. The stocks were reduced in proportion, the figures being:—

1883	.. ..	24,116,000 lb.
1884	.. ..	27,076,000 ,,
1885	.. ...	25,780,000 ,,

The highest deliveries of Indian tea which ever occurred were in March 1885, 8,654,000 lb., and in April following 8,704,000 lb., or 17¼ millions in two months. But this was the consequence of a budget scare, and the average for 1885 was somewhat over 5,700,000 monthly. We have good reason to hope that the average for the present year will equal, and, perhaps, exceed 6 millions per month. Lately there has been renewed liveliness in the China enterprise, the wretched peasantry being apparently contented to produce the article at a price which would seem to leave no margin for even the smallest profit. But in the three years in which Indian and Ceylon teas were in such increased demand, there was retrogression in China kinds; the imports having gone down from 160,873,000 lb. in 1883 to 139,940,000 in 1885; the deliveries sinking from 155,820,000 lb. to 151,877,000. The consumption of tea in Great Britain rose rapidly in the 20 years between 1864 and 1885; beginning with 81½ millions and ending with 175¼ millions, a considerably more than doubled consumption in the score of years. In the first year of the series Indian teas constituted only 3 per cent against 97 per cent China: last year the figures were India 39 per cent, to China 61. The rise in the consumption of tea in Britain has been, per head of the population, from 1¼ lb in 1840 to 4⅝ lb in 1885. The probability is that the round 5 lb. *per caput* will be considerably exceeded in 1886. The "district averages" realized in Calcutta, show a steady difference of at least an anna per lb. in favour of the Darjiling and Terai teas, the figures for 1885 being:—

Darjiling and Terai,—	annas 10/10 per lb.
Assam	9/8 ,, ,,
Kachar and Sylhet	9/3 ,, ,,
All other districts ..	9/4 ,, ,,

The area under tea (in all stages, no doubt) are given at

Assam	107,000 acres
Kachar and Sylhet ..	83,000 ,,
Darjiling	53,000 ,,
All other Indian Districts	15,000 ,,
Total for India ..	258,000 ,,
Ceylon	100,000 ,,
Grand total, India and Ceylon	358,000 acres.

If all this area were in bearing at 300 lb. per acre we should get a total "production of 107,400,000 lb." It will be observed that in acreage Ceylon is already on a par with Assam, where the tea enterprise commenced half-a-century ago, only that of course a much larger proportion of our acreage is immature, and some of it,—a good proportion, being not yet exclusively tea. The yields of the various districts in 1885 were:—

Assam	31,209,000 lb.
Kachar and Sylhet ..	19,328,000 ,,
Darjiling	11,346,000 ,,
All other Indian districts	4,526,000 ,,
Ceylon	3,797,000 ,,
Total India and Ceylon ..	70,206,000 lb.

There was a moderate increase in the three years everywhere, but in the case of Ceylon, the produce of 1885 was considerably more than double that of 1883. The estimated average yields per acre were:—

Assam	331 lb.
Kachar and Sylhet ..	263 ,,
Darjiling	214 ,,
Other India districts ..	302 ,,

The Ceylon average figures cannot yet be given, but we think the general anticipation of 400 lb per acre will be more than realized. For estates on virgin forest soil the calculations have been:—700 lb. lowcountry and 500 high, with 300 lb. on old coffee estates, more or less worn. Looking at the record of tea sales in Calcutta, we observe "Nil" against April, and low figures against Feb., March, May and June. The great sales season seems to extend from July of one year to Jan. of the next. The highest number of chests sold in any one month was 64,556 in Nov. 1885; while in London 104,000 were sold in Oct. 1883. The highest average price in Calcutta was 11 annas, 3 pies in June 1885. The lowest was 7 annas, 1 pies in March 1884. Against 371,000 chests sold in Calcutta in 1885, the number in London, including of course the great proportion of those sold in Calcutta, was 813,000.

The Indian Commissariat Department takes about 1,500,000 lb. of Indian tea per annum, at an average price of 7-3 to 7-3 annas per lb. The vast bulk of the Indian teas go to Britain, but we are glad to notice that the exports of Indian tea to Australia is increasing, thus:—

1883	..	699,790 lb.
1884	..	1,029,463 ,,
1885	..	1,939,069 ,,

The exports to the United States, on the other hand, have diminished from 208,000lb. in 1883 to 126,000lb. in 1885. The London and Lancashire Fire Insurance Company insure bungalows and tea factories at rates which differ according as the buildings are *pucka* (permanent and solid,) of brick or stone and iron, or *kutcha* (temporary) slight and combustible; the rates being given at,—

Bungalows and Contents...Pucka....	Premium from	½	% per annum.
Kutcha...	„	1¼	„
Factory Buildings.....Pucka...	„	1½	„
Kutcha...	„	2½	„

Our readers who have effected insurances, may be able to tell us how the above charges compare with those made by the Agencies of Assurance Companies in Ceylon. We learn from the almanac that a Gibbs & Barry Tea Drier, 10′ × 3′ 6″, price f. o. b. £240 to £250 (less 5 p. c.), is capable of "7/8th — drying" 160 lb. to 200 per hour. Nearly one side of the cardboard is covered with a table of equivalents for teas shipped on factory account, freight being taken at £2 5s per ton of 50 cubic feet, with exchange varying from 1s 6d to 1s 10d per rupee. As our readers are aware, exchange is now down considerably below 1s 6d and the signs of the times seem to point down to 1s 3d! In the three years under review exchange began with 1 7 21-32nds; rose in October 1883 to 1 8 1-16, stood between 1 8 and 1/8 5-32nds between March and June 1884 and in 1885 sunk from 1/7 19-32nds to 1/6 5-16th. How low silver may go in 1886, it seems impossible to tell. Tea sold in Calcutta in December 1885 at annas 11/11 per lb. At 1/6¾ per rupee, this was equivalent to nearly 1s 3d per lb.

Our readers will thus see that the Office Wall Almanac which Messrs. Skrine & Co. as the Agents of Messrs. Barry & Co., have sent us is replete with most valuable information regarding the great tea enterprise in which Ceylon is likely erelong to take a foremost position, its acreage already under tea being equal to 2-5ths of the tea area of all India, or 2-7ths of the aggregate tea area of India and Ceylon.

CEYLON UPCOUNTRY PLANTING REPORT.

WEATHER RATHER DRY AGAIN—TIMBER RESERVES AND TIMBER GROWING—GROWING OF FLOWERS.

June 7th, 1886.

The desirability of having timber reserves is too manifest to be questioned: but the difficulty in getting the timber to grow within any kind of a moderate figure is where the pinch comes. What to plant? and how to plant? are ticklish questions; for those who know anything about timber-growing tell us that valuable wood won't grow in waste lands without considerable care. And yet what a diversity of opinion there is about what should be planted. More than a year ago I was encouraged to try the "Wah" tree, which was said to be good wood and was a quick grower. I had this opinion confirmed by a high-class authority, while immediately after another man with a large experience laughed at the idea and gave it as his opinion that perhaps in thirty years or so it might be big enough for cutting for fuel. But as I was committed to a nursery I went on, and as far as I can judge from a year's growth of the planted out plants, I incline to think that the last man has rather understated the length of time required to mature for the furnace, and that half-a-century will be nearer the mark.* In this world of change it is a comfort to have a tree of this kind growing, for you might go home for a trip and stay away for a year or years, feeling quite satisfied that on your return things would be pretty much as you had left them.†

In the search for new products which will be a standby in the day of low prices, for our staples, there has been considerable ingenuity and energy displayed. What to grow which no one else has gone into is, however, the difficulty; for as soon as the rumour is abroad that from such things as pepper, tobacco or limes coin can be landed, there is a rush for them. I had a call the other day from a gentleman representing a Paris firm of perfume manufacturers, who had a whole bundle of suggestions for new industries, the most practical however being the growing of flowers, and the distillation of their essential oils. From among others he specially mentioned the sacred Champak of India (*Micchelia champaca*), the "sapu" of the Sinhalese. For these oils there was a ready market in Europe, and at remunerative prices. The quantity of flowers required to produce a pound weight, was something excessive, or at least it seemed so to me; but it would be pretty much a matter of experiment and a trial on a small scale would not be a costly venture. There was also in India a large market for rose water, it being so much used in native courts, and among the higher castes of the Indian people.

PEPPERCORN.

PROFITABLE COCONUT CULTIVATION IN CEYLON.

(*From an Old and Practical Coconut Planter.*)

HAPITIGAM KORALE, 9th June.

Since the monsoon rains opened on the 17th ultimo we have had few days without more or less, but today has capped all, in heavy squalls and a great fall of rain. This is probably the last effort of the season, and we are likely to have a dry spell now.

I was lucky enough to finish all the planting I can do this season, while the rain lasted, and the gowiyas have very nearly finished their sowings, so that our operations bid fair for success all round. The gowiyas having felled and cleared the land, the owners' work begins, and the following is the cost of my operations:—

Lining per acre	R0·25
Holing „	2·25
Plants „	3·00
Planting and carriage	0·37
	R5·87

Being only five miles from a railway station, I have, on this occasion, cleared R8·50 per acre for firewood for the engines, so that the operations of the season leaves me R2·63 per acre profit.

The gowiyas keep the land in hand for three years; they first sow kurakkan and muneta, and mamottie-weed the land by way of harrowing, then sprigs of sweet-potato vine are put ten or twelve feet apart, and bits of cassava stem five or six feet apart. The grain and pulse first take up the growing, and keep everything else down, while they occupy the ground; when they are

* We received the assurance of Mr. Strong of the Railway that in the lowcountry the "Wah" gave fuel in its fourth year. Of the value of the wood as fuel there is the highest testimony. We have seen the tree growing at 4,500 feet, but generally its range is up to 2,500.—ED.

† Our friend surely draws a conclusion from insufficient experience.—ED.

harvested, in the fourth month after sowing, the cassava gets its innings, and keeps the ground for about a year. The sweet-potatoes come in at the end and continue to be gathered for twelve months or more. Of all those crops, the land share is one-third, and the value may amount to anything between five and thirty rupees, according to the soil and seasons, but, taking the mid term of R15, we have nearly R20 per acre, to the good, at the end of the third year. As soon as the crops are finished, any germs of jungle, that survive in the land, rush up at once, lantana shoots up in all directions, and the seeds of kinds of weeds, common in the vicinity, find their way to the land. All these are easily and cheaply dealt with at first, but if allowed to spread, they soon close in and overtop the plants, and those that are not fairly smothered out, have to maintain a severe struggle for existence, being in no case the fittest to survive. At a cost not averaging more than R5 per acre per annum, a fine field of natural pasture grass may be established, and kept up till the trees come into bearing.

Of 200 plants I put down in May 1879, ten per cent are now in flower, and I have already gathered nuts from the most forward tree.

It appears then, that, though coconuts are not suited to the views of those who think to make rapid fortunes, there is no undertaking in the colony, where so much can be got, for so little outlay, by those who have the patience to *wait*, and there is nothing so suitable for such of the people of the country as have a little capital to invest if they will only do it justice during its early years.

CEYLON HIDES AND HOW TO CURE THEM.

Referring to your editorial on the subject of CEYLON HIDES (page 65), and the poor price which they fetch in the London market, I think you are wrong in supposing that the effect of pasturing on the salt grounds the island would of have an evil effect or otherwise on them. Perhaps the best hides in Australia come from the salt bush country, where water even is brackish—but, at the same time, if any dry salt was put on these hides when drying, it would, to a certain extent, spoil them. In curing hides of all kinds, bullock, sheep, horse, kangaroo, &c., I have been specially successful, and invariably topped the market with any batch that I had sent forward, and my plan of curing was always the same, which, in the case of bullock hides, was as follows :—The hide, as soon as possible after it has been taken off, was spread on a smooth piece of ground and pegged round the edge, driving the peg through the edge of the hide into the ground. The greater the number of pegs, and the tighter the hide was stretched, so much the better. Also the hotter the sun which shone upon it, and the sooner it dried, the better. No salt was required, but no wet or damp had to be allowed to get to it afterwards. I have no doubt, from what I have seen of bullocks in Ceylon, India and Italy, that the secret of the low price for Ceylon hides in London is the curing.

Before KING COFFEE becomes a thing of the past, I wish some planter would try the following remedy, just to satisfy one that no loophole has been left untried to save the annihilation of the old staple. I tried every conceivable method to overcome leaf-disease, in my planting days, but this one I did not try, and, although it may seem a tedious process, still, if it proved successful, no doubt a simpler process might be discovered of applying the remedy. I allude to the "infallible remedy" against the ravages of phylloxera on the vine, discovered by the able Rotland, of the department of Lyons, France. Strange to say, our old friend the blue gum plays an important part in the remedy, and the process consists of inoculating the vine with the pure essence of *eucalyptus globulus*. A broad incision is made through the bark at the neck of the vine, in which a few drops of the essence are deposited by means of a camel's hair brush. The result is that, in about three days, the *phylloxera* entirely disappears, while the vine is not in the least injured by the operation. The incision may be made through any other part of the bark, with equal success, but the result is more speedily attained the nearer it is made to the roots. If the remedy is so successful with *phylloxera*, why should it not be equally so in extirpating *Hemeleia vastatrix*.

COSMOPOLITE.

[The phylloxera is an insect pest, our leaf enemy a fungus like the vine *oidium* : still an experiment is worth making.—ED.]

NORTH BORNEO AND INDIA AT THE COLONIAL AND INDIAN EXHIBITION.

The Exposition made by the youngest of the Britsh colonies—that of North Borneo—though of comparatively limited extent, as might be safely predicted of a colony not yet five years of age, is a very striking example of the utility of the exhibition in making generally known the nature of the productions of the lands under the protection of the British Crown. North Borneo is not altogether unknown to the readers of *The Field*. In the issue for May 3rd and December 20th, 1884, Mr. H. Pryer, the brother of the Resident at Sandakan, described the extensive caves in the limestone rocks at Gormanton forty miles from the coast, which are inhabited by myriads of bats and swallows, whose droppings have produced beds of guano so deep that they are regarded as bottomless. Specimens of this guano have been exhibited by Mr. De Lissa and Mr. Dobson, who estimate its value as being from £5 to £10 per ton, it being excessively rich in phosphates. The caves also furnish a perennial supply of the edible birds' nests so dear to the epicures of the Chinese empire. Among the more striking zoological products of the infant colony is a mounted specimen of the orang-outang, the anthropoid ape of the Eastern Archipelago. This is one of the finest ever seen, and fully bears out the drawings of its prowess in combat with the natives which are given in Wallace's "Malay Archipelago." There is also the skull of a mature specimen that is of unusual size. Among the mineral products of a commercial character that are forwarded from the settlement may be enumerated the trepang, sea slug, or beche-de-mer, so largely used for food by by the Chinese; tortoise-shell, produced by a turtle not unlike the "hawk's-bill" species; and splendid specimens of the mother-of-pearl univalves, mounted as ornaments. The vegetable products are numerous; they comprise very good tobacco, both in leaf and manufactured; and cotton and hemp of excellent quality, the latter exceedingly long in fibre. The coal of North Borneo is abundant, and is found in several places cropping out on the surface; it is exceedingly hard, and resembles anthracite in its fracture, the small pieces that are subjected to the action of the waves on the sea shore being rolled into black pebbles that have a singular appearance.

Amongst the singular objects exhibited in the court is the model of the last piratical proa. This is excessively long and narrow, having an outrigger on each side. It carries an enormous square sail, supported not on a mast, but on a narrow tripod, consisting of three slender spars, two rising from the sides of the proa near the stern, and the other from the bow. With a reaching wind, these craft could make rapid progress through the water, and were admirably adapted to the piratical purposes

of their crews; but the advent of the white man has put a stop to these pursuits, and the flag of the last of the pirate proas of North Borneo ornaments the court of the colony at South Kensington. Ugly-looking creeses or crooked daggers are present in numbers, with dresses and shields and scabbards of the native warriors, ornamented with short fringes of the hair of their victims. There are specimens of the "sumpitan," or blow tube, more than six feet long, and as straight as a gun barrel.

Not the least curious amongst the products of this Eastern land are footballs about seven or eight inches in diameter, made of interlaced cane, so as to present the appearance of open network. These balls are struck only with the foot, and are kept up for a length of time. Of the magnificent timber of the country there are a number of samples varying in hardness and density, from the excessively hard "billian" which is heavier than water, and is procurable in logs 2 ft. 6 in. square and 40 feet long, to the tough "gagil," which though easily worked, has the desirable quality of being ant-proof.

The usual products of the islands of the Eastern Archipelago such as vegetable tallow, gutta percha, lac, &c., are to be found in the small court off this colony but these require no special notice.

The Indian commercial or, as it is called in the catalogue, Imperial Court, is an admirable exposition of the economic resources of the Empire of India, with its population of 250 millions. It is entered through an archway composed exclusively of Indian timber; the table, formed of one complete section of the Andaman redwood tree, shows the gigantic size attained by this valuable timber. At the back of this trophy is a magnificent pair of buffalo horns. A second trophy consists of a platform on the top of a transverse arch formed entirely of bambus, no less than thirty distinct species being employed in its construction. Among the most interesting objects in this court are the four Indian stores, which illustrate, in the most real and truthful manner, the customs of the native trader. The first shows a grain merchant, surrounded by his baskets of produce, which he vends to his customers. Close at hand is a group of women, grinding corn in a hand mill, according to the method which has been in use since the time of the patriarchs. In another store is reproduced a dealer in the culinary vegetables used in the East. A third shows us the fruit-seller, with his wares in circular baskets; but still more indicative of the life in the East is the druggist's store, in which an old herbalist, with his drugs in bags reproduces with the utmost exactitude of a scene familiar to every Indian resident. Opposite to these stores is the model of an Indian fish-wife, surrounded by most admirably modelled and coloured representations of fish; they are so well executed that they appear to have been just taken from the water. The natural history articles in the commercial court are not remarkably numerous, but the collection of Indian game birds, such as the Argus, bustard, &c., from the Indian Museum, may be noticed, as also the plates from "Gould's Birds of Asia," which are hung about the walls.

Amongst the most interesting exhibits, though how it obtained a place in the commercial court is difficult to perceive, is a collection of the earth snakes (Uropeltidæ) of southern India and Ceylon, exhibited by Col. Beddome. These singular reptiles, which are local in their distribution, not extending farther north than 20° north latitude, burrow in the earth and live underground, coming to the surface in wet weather. The earth snakes have pointed heads, well fitted for penetrating the ground. The necks are stout, but the head is not unfrequently found turned to one side, as if it had been partially displaced by the vigorous efforts of the animal to penetrate the soil when in pursuit of the earthworms, which constitute its chief food. The tail is short, and usually cut off at an angle, so as to form a flat terminal plate, admirably adapted to form a *point d'appui* from which the burrowing efforts of the animal can be exerted. These snakes are by no means rare, but are rarely seen, as it is necessary to dig some feet into the earth to obtain them. Those in the court are well shown in long bottles, having been preserved in spirits. On the opposite side of the court is a glass case containing models of snakes in action. These are well shown, the cobras striking and others gliding along or in diverse natural attitudes. The ethnological models in this court are exceedingly numerous, and give a better idea of the various races inhabiting the peninsula of Hindustan than could be acquired by any other means, except visiting the country. Of no less interest is the collection of agricultural implements in the annexe to this court, and the models of agricultural life, such as the representation of a village in Northern India.

The models illustrating farm operations in Bengal, which are all most faithfully represented, should be studied by the aid of the special catalogue. The distinction between the modes of cultivation followed by an agricultural population of many millions, which has remained unchanged for thousands of years, and those pursued in our own country, is most interesting to follow.

Ploughs which only scratch the soil without turning it over are still in use, and improved instruments, such, as are used at the Government experimental farms are rejected by the natives, who prefer to plough the ground over half-a-dozen times with their effete instruments to adopting the more efficacious and improved appliances.—*Field.*

THE ASSAM COMPANY.—The directors of the Assam Company recommend a dividend of 15 per cent., or £3 per share, to be paid on the 1st July to shareholders registered on the 15th June, making, with the interim dividend of 5 per cent paid in January last, a total of 20 per cent for the year. —*Home and Colonial Mail.*

TEA.—At the Liverpool Exhibition a Liverpool firm of tea dealers, Messrs. Roberts, have a tea exhibition. In a Chinese house, with neat lattice work façade, they display samples of almost every known tea, including Indian, Ceylon and even Yerba, tea used by the South Americans, side by side with which are the vessels made from pumpkins, in which the tea is concocted, and the silver pipes through which the liquid is supped. A decided novelty to English consumers are the samples of brick tea. It is not the semi-divided cakes of ordinary pressed tea sometimes sold in England, but large cakes as hard as stones, consumed in Siberia and the North of China, and sometimes passing current as money.—*Home and Colonial Mail.*

COFFEE IN VENEZUELA.—President Crespo's Message to the congress of Venezuela. Speaking of the economic situation of the country the President said:—I regret that our economic situation is not good, owing to causes entirely beyond the control of the Government. Agriculture, which is the main source of our riches, is completely prostrated at present by causes which could not be foreseen, and which threaten to continue; for example, the great and increasing depreciation in the price of coffee, the cultivation of which has long been the support of many of our citizens. We look for alleviation of this unhappy position when the great public works, such as the Port of La Guayra and the great railways now in course of construction, are finished. In the meantime we must have recourse to the most rigid economy, and as in the present state of the country the public cannot stand further taxation, we consider it better to reduce our expenses by at least one-third. There is another circumstance which leads us to this conclusion. The duty upon imported cereals usually yielded 150 to 200 Bolivars per month, but in view of the destruction of our crops by locusts the Government considered it to be advisable to suspend this duty for a season. This has now been in force for five months.—*S. A. Journal.*

TEA-PLANTING AND TRANSPLANTERS.—A tea planter writes and there is much force in what he says :—"I have been thinking a good deal lately about transplanters and am greatly surprised they are not more commonly used. This change in the weather has shown the advantage of them and in one clearing where I put out about 40,000 plants with transplanter I will not lose forty plants, as against 15 to 20 per cent. with hand work in another field. People imagine that the use of transplanters adds to the first year's expenditure greatly. It is the greatest fallacy going, as at a moderate estimate on an average there are 10 per cent of failures and with transplanter there are literally none at all, the extra cost of using them, say R3 per acre, being more than coveed by the saving in supplies, and besides this tea put out with transplanters has a start of at least three months over other tea."

A LESSON IN AN EGG-SHELL.—Five hundred million dozen of eggs are annually consumed in the United States ; their value, at 8d. per dozen, being considerably more than £16,000,000. These figures are to some extent accounted for by the national fondness for pastry, of which Ude declared eggs to be "the great original." One of the best signs of a thriving industry is the little public fuss made about it ; and American poultry-farmers have for a long time been naturally and profitably silent. But a cause of disquietude has at length arisen. No duty is imposed on foreign eggs, and some 16 million dozen of these are annually imported into the United States. The competition is not very severe at present, the foreign supply being less than one-thirtieth of the entire consumption. Still, forewarned is forearmed ; and an American "trade" journal presumably expresses the sentiments of its subscribers when it indignantly asks whether the native egg industry is to be crushed by the rivalry of the "cheap pauper fowls of the Old World." There is perhaps more pique than propriety in this expression, though it suggests obvious matter for reflection on our side of the Atlantic. If we may judge from the innumerable treatises founded upon the problem "How to make poultry pay," poultry seldom does pay in England. In regard to this matter there is a singular if not a painful contrast between English indifference and American enthusiasm. American producers are excited by the fact that a quite insignificant proportion of foreign eggs finds its way into their markets. English should-be producers are in no way disturbed, although every retail shop in the kingdom has practically to rely upon the foreign supply The statistics of these imports tell their own significant story. During the summer months, from fifty to eighty tons of eggs are landed every twenty-four hours on the quays of Harwick. These come almost exclusively from North Italy, by way of the St. Gothard Tunnel. The daily cargoes occasionally amount to as much as 130 tons, representing about 2 millions of eggs, of which London is almost the sole destination. Besides these, from 50 to 60 millions of eggs are sent into England every month from Denmark, Germany, Belgium, and France. The last country does a thriving export trade after supplying the egg-loving Parisians with the 40 million dozen which is their annual consumption. It may be instructive to note some of the points on our coast at which this foreign produce is discharged. Weymouth receives from 3 to 4 millions of eggs per month. Newhaven and Southampton over 8 millions each ; London (port of), 5 millions ; Hartlepool, 8 millions ; Grimsby and Newcastle, 5 millions each Leith, 2 millions. The duty on imported eggs was repealed in 1860.

EXPERIMENTAL TEA A FAILURE.—For many years an experimental farm has been in operation in South Carolina at Government expense, devoted to the attempt to introduce tea culture into this country. It has never met with more than indifferent success. The tea plants would grow well enough, but curing the tea required much labor and skill, and neither could be cheaply obtained near the tea farm. The severe cold this Winter has prematurely stripped the plants of their leaves, and the plantation is now in a more discouraging condition than ever. Commissioner Coleman of the Department of Agriculture thinks the farm had better be abandoned. If more thought had been given the subject the experiment would never have been tried. We cannot compete with China in tea growing, for the reason that wages in that country are only five to ten cents per day. If the Chinese will consent to leave our staple products unmolested with their competition, we can well afford to leave them the monopo of tea-growing. Much of the price we pay for tea goes to middlemen, as the trade in tea has always been enormously profitable.—*American Cultivator.*

CIGARS AND "CIGARS."—What Mr. Sala has to say about the making of Havanna cigars is appetising, what he hints at about the making of cigars which pretend to be from Havanna, but are not, would almost put an end to smoking. "If you offer a Spaniard a cigar—not with the view that he should smoke, but that he should criticise it—he will, after expressing a preliminary wish that you may live a thousand years, produce a sharp penknife and slice the weed through diagonally. Then with a strong magnifying-glass he will scrutinise *las tripas* and tell you as confidently as any Loudon or Linnæus could the precise order of vegetation to which the cigar belongs—whether it is of the superfine vuelta de abajo, the clos vougeot of Nicotia, or of some inferior growth, either from the island of Cuba itself, or from Hayti, or Porto Rico, or Virginia, or Maryland, or the Carolinas, or, haply from the south and east of Europe ; for that vast quantities of Hungarian, Austrian, Sardinian, and Bessarabian tobacco do find their way to Cuba, and come back to us in the guise of prime Havanas—that is certain. A minute investigation of *las tripas* may also lead to the painful disclosure that the cigar is not composed of tobaccoat all.—*Australasian.*

NEW MARKETS FOR CEYLON TEAS.—For the benefit of any of our planters or merchants who wish to do business in a new field, we repeat an extract from a letter addressed to us by Alderman Lobb of Toronto (Lloyd's Ontario Agency) after he had tested samples of Ceylon teas, under date 8th August 1884:—

"I have submitted them (the samples) to some of our leading merchants and they have been very highly approved, some of them remarking, 'they were the finest black teas they ever put the water on.' They are undoubtedly a high grade of teas and could be sold here, if price would not be an obstacle. Having no idea of your valuation I can give no definite opinion, but if any of your friends would like to consign an assorted parcel of, say, 100 half-chests I could test the market here and elsewhere and should hope to make satisfactory returns. I can refer you to the Bank of Montreal here, the Imperial Bank and Messrs. Fra. Peek, Winch & Co. of London, England, whom I represented for nine years. Trusting you are again safe at home much benefitted by your trip, I am &c., J. LOBB."

As already stated, the supply of Ceylon teas in 1884 was so limited in proportion to the good demand for them in London, that no one thought of looking to other fields; but the case may be different now and perhaps Alderman James Lobb of Toronto, may hear from some Ceylon friend with reference to business.

THE ISLAND OF BARBADOS is the most densely populated part of the earth. With an area of 106,600 acres, it contains a population of over 175,000 souls (9 per cent of whom are whites), or an average of 1,054 people to the square mile. The Chinese province of Keang-su, which was at one time imagined to be the most uncomfortably-crowded district under the sun, contains but 850 Celestials to the square mile, while East Flanders, in Belgium the most thickly-populated neighbourhood in Europe, can boast of only 705 inhabitants to the square mile.—*Madras Mail.*

A NEW ELIXIR OF QUININE.—One of the greatest objections to the use of preparations of quinine, especially in the case of children, is the intense bitterness of all its salts, more particularly of the sulphate. A ready and effective means of overcoming this difficulty will be found in a compound wine or elixir of quinine containing glycyrrhizin, the sweet principle of liquorice root In preparing this combination Sherry, Orange or Malaga wine may be used at discretion; the latter is perhaps. the best. Two ounces of dried and decorticated liquorice root, in coarse powder, are macerated for seven days in one pint of Malaga wine. The wine is then filtered, enough fresh wine being poured over the marc to procure a full pint of filtrate. Forty grains of sulphate of quinine and sixty grains of citric acid are then dissolved in two ounces of the filtrate, and added to the bulk. An elixir of this strength, containing one grain of quinine in the table-spoonful, will be found of the most convenient strength for administering to children, and will be pleasantly sweet and almost entirely free from bitterness. If the Malaga wine be good, and of a full alcoholic strength, the preparation will not be found to deposit much on keeping, if at all. —*Burgoyne, Burbidges, Cyriax & Farries' Monthly Export Prices Current.*

THE CHEAPENING OF GRAM.—It appears that in a few localities gram was dearer in 1884 than in 1873, and doubtless this is capable of easy explanation; but generally speaking, the article had declined in price to the consumer, and consequently was not so well worth while growing in the latter as in the earlier year. This is remarkable, for the rupee has declined most seriously in value in gold using countries with which India has an enormous business connection. If the shilling in England were reckoned at its intrinsic value, instead of at a statutory token value, it would now buy only three-fourths of what it would have bought twenty years ago; or, whereas in 1866 it might have bought twelve penny loaves, it would now buy only nine of such loaves. In India the rupee has no statutory value, but it is left to find its own level, and yet, notwithstanding the great decline in its external value, it buys more, or goes farther in regard to gram, than it used to do when exchange was nearly 6d, or 25 per cent. better than it now is. It is, however, the general belief that it costs more to keep horses now than it used to do, or that the rupee does not go so far as it did in filling the gram-bag. —*Madras Mail.*

NOTES ON PRODUCE.—Commenting on the opening of the new season for China teas, the *Grocer* says:—"Wonderful bargains in China teas have been secured under the hammer, and purchasers have been enabled to execute their orders for any description of tea at almost their own prices. How the merchants or consignees here can reconcile this policy of 'smashing' the London market, with their more exalted opinions of the value of the article, in giving at the recent opening of the new season at Hankow rates 10 per cent above those of last year, we cannot tell, but leave it to them to explain, and can only say that by such a contradictory course as this they are multiplying their own risks and spoiling the market for the completion of their regular operations. The mistake of paying high prices at the opening of the Chinese market should always be carefully guarded against, as, to quote the words of advice we used early in March, it causes the shippers there 't form an exaggerated idea as to the true market value of the article, and is greatly to the detriment of the dealers and others here. Purchases for a time go on very briskly, to be followed by considerable shipments to England, when, as fast as the teas arrive, they are probably forced off by auction at rapidly declining rates, and cause a deal of depression to prevail all round.' This is what is likely to happen between now and the end of next July, if holders do not exercise more tact and judgment in buying in one market and selling in another; and what comes of all the complaints or idle boasting about severe losses (?) when they can afford to realize their teas at a material reduction, and thrive without making the smallest gain or profit? Either the reports of higher prices are without real foundation, or the prices themselves are watered down by discounts and allowances which leave them practically at a compartively safe level. If so, it is so much the better for all concerned, whether they are large or small operators in tea, and it is to be hoped that the condition of the trade generally is sounder and more satisfactory than at first sight appears. As, therefore, most circumstances encourage the belief that quotations for China tea in the ensuing season will be very moderate, if not positively low, it is a matter of good augury for the wholesale and retail trade, who will thus be able to supply the consuming public with a serviceable article at a cheap price."—*H. and C. Mail.*

UNIFORMITY IN TEA.—The *Grocer* is publishing a number of letters upon the subject of the want of uniformity in tea. Some of these throw some light upon the blending operations of the grocer. One correspondent writes:—"To show the utter impossibility of any wholesale blender being able to produce suitable blends of teas for all neighbourhoods, it is only necessary to remember the very great difference in the water of different localities. Why, sir, the effect of the water on the same tea on the south side of the Thames is totally different from that produced on the north side; and this I confidently assert after very many years' experience as a tea traveller. Sir, it is not a vital question to me whether I sell my mixers or not; my living in no way depends upon that. All I am desirous of doing is to impress upon every grocer the extreme danger of listening to the advice of those who tell him they can do his business for him better than he himself. No grocer can possibly have the smallest title to the distinction of 'tea dealer' unless he sells an article which, so far as the blending is concerned, is the product of his own skill and judgment." Another says:—"What grocer would ever dream of exposing good tea? My business was not a very extensive one, but in teas my sales were chiefly at 2s 6d and 4s per lb.—at the latter price far in excess of the former. Competition with persons who had tea sent direct from Civil Service stores, and supplied old women in the villages, as well as competition from London wholesale houses who send 20-lb. cads to gentry in the neighbourhood—these never materially affected my sales. My customers returned to the good tea, stating they would rather use less, pay more, and have it good, as one spoonful of 4s went as far as two at 2s 6d of the London teas, besides being excellent in flavour. Now, the grocer must be a dunce at his trade if he cannot mix six pounds of fine Kaisow, six pounds fine Moning, and six pounds good Assam with a pound and half of the finest Pekoe. This mixture I always found to give satisfaction. My friends who sent occasionally for a 20-lb. cad could never understand why they could not get tea like it in the large towns where they lived at 4s—there was so little difference in the 2s 6d and 4s: the same strong capery or Pekoe flavour pervaded both. Too much of either spoils fine China teas."—*Home and Colonial Mail.*

Correspondence.

To the Editor of the "Ceylon Observer."

AN EX-CEYLON PLANTER'S EXPERIENCE OF A HURRICANE IN FIJI.

Taviuni, 3rd April 1886.

DEAR SIR,—On the night of the 3rd March last the most severe hurricane that has been experienced in Fiji for many years past, swept over Taviuni and other islands in the group, doing an enormous amount of damage to property, and the following account from one who went through it, and still survives, may prove of some interest to your readers, especially to those whose inclinations may prompt them to come and settle in Fiji. My only desire is to quit it. In 1881 it was my fortune, or misfortune, to pass through what I thought in my innocence to be a regular proper hurricane, but that was only a gentle zephyr compared with the one of last month. To resume. I was on a visit to my brother at the time, who has charge of the wellknown Alpha tea estate, and was getting quite *au fait* with rolling, withering, firing, etc., and in fact with everything appertaining to tea cultivation.

I beg to state, en parenthesis, that the above is *not* an advertisement, but if there is any tea estate proprietor in your part of the world who wants a manager who can show him an infallible method whereby he can reduce the cost of production to nothing per lb., he can apply to the undersigned.

I can fancy Mr. Editor, your exclaiming "How this fellow *does* blow, why *does not* he tells us about the hurricane?" Well! on the 2nd March, it commenced to blow hard from S.-E. and continued in this direction all day, the wind gradually increasing in violence, until on the morning of the 3rd, it was blowing half a gale. It increased all that day, and at about 2 p. m. my brother informed me that we were in for a regular hurricane. I felt quite cheered at the prospect at 6 p.m. The labour houses, hospital, &c., were all level with the ground, and most of the unfortunate coolies took refuge in the upper floor of the tea house (which was formerly the pulping house when the estate was in coffee), they could not get into the store which was a high double-storied building, as my brother had all the doors and windows battened up early in the afternoon, a vain precaution as events turned out. Our dwelling-house, the walls of which were wattle and daub, lined over, stood it out well until 11-30 p. m. when the first sheet of iron was torn from the roof. The wind all this time was blowing with great fury from S.-S.-E. and S.-E. accompanied by rain. We managed to keep the doors on this side of the house secured, by means of tables, chairs etc., and it took us all our strength to keep same in position. We heard a crash about this time which proceeded from the pantry in the verandah. The walls had given way and the plates, lamps, etc. were having a lively time of it. At about 1-30 a. m. on the morning of the 4th, there was a lull for about one hour. It got quite calm, and I really thought the worst was over. About this time a good many of the labourers who had taken refuge in the Tea house, came and informed us that that house had been blown over, but fortunately for them it fell against the Store which supported it, and they were enabled to make their escape, with the exception of one man who was killed by a beam falling on him and several others were seriously injured. After this short spell, the wind veered round suddenly to N.-W. and recommenced to blow with terrific violence. We saw that the house would not protect us much longer for the sheets of iron were being ripped off one after the other, and the walls looked as if they were going to fall in every moment. It was really hard lines having to leave the house, and I sincerely wished at that moment that we were both in a comfortable bungalow not 100 miles from Gampola town, but there was no help for it, so taking up a blanket we vacated the premises. I had no sooner got outside than off went my hat, and I thought my scalp had gone too, but on passing my hand over my cranium, I found that the few locks of hair which nature has left me, were still there. We managed to stick together although with great difficulty, and after groping our way a short distance from the house, we plumped down on the ground, and drawing the blanket over our heads, we waited as patiently as we could for daylight. How bitterly cold it was to be sure, the covering we had was but a poor protection to the furious blasts of wind which assailed us. I felt sorry for the poor labourers; there were over 100 on the estate and they must have felt the exposure terribly. The principal source of uneasiness to me was the reckless way in which the sheets of iron were flying about. I must confess I did n't half like it, not that I was afraid, but I would gladly have exchanged places with anyone for a short while. We were too near the house to please me. I should have liked to be about 5,000 miles away. Had one of those sheets of iron which were 8 ft. long × 2½ feet wide caught edgeways, it would in all probability have put an end to our career, and this valuable article would have never been written. Many of them were found over 200 yards from the house. At one time, while we were crouching together, I heard a curious clattering sort of a noise which I made sure was caused by a piece of iron coming our way, but which really proceeded from my brother's teeth which were chattering at a fearful rate, only caused by the cold I have to state. I thought daybreak would never come, but it made its appearance at last, and then what a scene of ruin and desolation met the eye! The walls of the house were still standing wonderful to relate, but they collapsed at about 8 o'clock smashing up all the furniture, and in fact everything we possessed; the work of destruction was complete, I can tell you.

We started down the hill that leads from the house to the store when a gust of wind got hold of me, and away I went at a fine pace. I am sure I must have covered 100 yards in not more than 8 or 9 seconds. We found the store and tea-house one mass of ruins, and we had to dig one poor cooly out who had sustained a severe injury to his spine. What a fearful night the poor wretch must have passed! The man that had been killed was only found the next day, he was badly crushed. It is to be hoped he did not suffer much. Most fortunately the machinery was not damaged to any serious extent. The chimney belonging to the Davidson's Sirocco my brother was using was smashed up and the upper part of the Sirocco containing the withering trays was dragged off the lower, or furnace portion, and one of the trays broken, but that damage is easily repaired. The Kinmond's roller escaped. Alpha estate belongs, as I think you know, to Mr. James E. Mason, who is at present in London representing Fiji at the Exhibition there. That gentleman has been most unlucky with his property. When I visited Alpha in 1881, it was one sheet of most magnificent-looking coffee. Leaf-disease soon after made its appearance, and the coffee had to be all pulled up, as the trees would not give any crop. Tea was

substituted and evidently the climate was suitable for it, for it flourished exceedingly when just as everything was progressing so satisfactorily, this hurricane must needs visit the place, doing the damage above recorded.

My brother is very busy getting cooly lines rebuilt, but a month has elapsed already, and it will take another six weeks at least before work can be resumed. It will cost £750 to £1,000 to put up the necessary buildings again. There are about 40 acres of tea 4 years old and 30 acres 2 years old; about 20 per cent of this has suffered severely, and will take some time to recover. There were 15 acres of splendid-looking cardamoms that had a large crop of fruit on them, the whole of which has been totally destroyed. The coconut planters have all sustained an immense amount of damage, and there will be no copra manufactured by them to speak of for the next 18 months at least, and it is not only their coconuts that have suffered. Many of them have lost their fine copra houses, etc., which for convenience of transport were built on the beach by the sea which rose several feet above its normal level, and came inland with an irresistible rush carrying everything before it. It is very hard on these men most of whom have been in the country for many years, and have worked from morning till night trying to make their plantations pay. I have spoken to several old residents of 18 and 20 years, standing, none of whom remember to have seen such a severe hurricane as this. I fear you will deem this letter too long, so I will bring it to a conclusion hoping you will spare me room in your valuable journal for the same. I append some barometrical readings which are reliable. They were taken by the Captain of a steamer who rode out the hurricane in a *sheltered* bay. People have not ceased to talk about the hurricane yet, and I expect it will be a long time before the 3rd March 1886 is forgotten in Fiji. Apologising for the extreme length of this letter, I am, sir, yours faithfully,

——— J. N. O. S.

(Barometer readings referred to.)

1886.		Time.	Bar. Regist.	
March	2	8 a.m.	29·75	
		5 p.m.	29·63	
„	3	7 a.m.	29·57

MR. JOHN HUGHES ON CEYLON PUBLICATIONS AND REPORTS.

London, E.C., 7th May 1886.

GENTLEMEN,—I have great pleasure in acknowledging the receipt of your valuable Ceylon Handbook and Directory for 1885-86, which I found awaiting me on my return from Egypt. It is indeed full of useful information, as all those who have had previous editions can well understand, while those who have never had the advantage of possessing a copy, should certainly lose no time in purchasing one, especially as the book can now be obtained through any of your London Agents.

I suppose no Crown Colony except Ceylon produces such a Directory which from the extensive index appears to furnish information upon every possible subject connected with the planting interests of your beautiful Island.

It always gives me pleasure to refer anyone requiring information respecting Tea, Coffee, Cinchona, or the other numerous productions of Ceylon, to the pages of your Directory. Of course you will have it well represented at the Colonies Exhibition, which I have not yet visited since it was opened, but hope to do so shortly.

I send you a page from this week's *Agricultural Gazette* containing a short paper of mine upon the amount of fat in Fish Guano. It may do for the *T. A.* I have frequently recommended the *Tropical Agriculturist* to persons who come to me for a useful book upon current information respecting Tea, Coffee, Cinchona, Sugar and Tobacco, and I doubt not that you find the circulation increasing. You are aware that it is now taken at the two Agricultural Colleges in this country, namely Cirencester and Downton.—Yours very truly.

JOHN HUGHES.

ORANGES AND CITRONS FOR FLAVOURING PURPOSES.

June 12th.

SIR,—I have pleasure in forwarding American recipe for making the above;

Cut the rind into thin shreds; half fill a wide-mouthed bottle with it, fill up with whisky or brandy. Cork tightly and shake now and then for the first month. This will keep good for months and be better for age. SANITAS.

DAVIDSON'S AND LAW'S TEA ROLLER.—One interested, refering to a paragraph we had a few weeks ago, writes:—"Your mercantile informant would have done well *not* to have made an assertion of the kind he did, as you may be sure that we have carefully taken the opinion of a competent engineer before patenting the machine, and we hope to arrange with Messrs. Walker & Co. for it manufacture, and at all events before any are sold the public will be satisfied that there is no infringement whatever.—It is rolling splendidly now and turning out more tea than we expected."

CHINA *v.* INDIAN TEA came into the opium debate in the House of Commons, the Under-Secretary for India using the following argument:—Not long ago a Government was turned out on the question of raising the duties on alcoholic drinks. There would, therefore, be a touch of Pharisaism in our dealing so drastically with the question of opium as his hon. friend would desire. He would, therefore, make two suggestions to his hon. friend. The first was that he should agitate for the increase of revenue at home from alcohol, and apply that increase to replace the loss occasioned to India by taking away the opium revenue; the second was more practical. The balance of trade as between India and China was against China, owing to the vast quantity of opium going from India to China. As between China and this country the balance was against the latter, owing to the Chinese tea consumed in this country. It had even been said that China paid for her Indian opium with the income derived from Chinese tea sold in this country. His hon. friend then ought to consider that when he drank Chinese tea he was encouraging Chinamen to consume opium—(laughter)—and his suggestion accordingly was that his hon. friend and others should use Indian tea, which he believed was very good, instead of Chinese tea. Even if the Indian tea were not good, his hon. friend should still drink it in the interests of morality—(laughter), and thereby practise a virtue for the benefit of those in whose welfare he was so much interested.—*L. & C. Express.*

TEA: CHINA CONSULAR REPORTS—1885.

Much interesting information on the China tea trade will be found in the following extracts:—

FOOCHOW AND ITS TEA TRADE.

Mr. Consul Sinclair reports as follows:— * *

Exports, of the same denomination as those in 1884, are, outside of tea, altogether the cargoes of Chinese traders engaged in the coasting trade. These cargoes represent a value of 1,548,369 Haikwan taels, and consist principally, of timber, paper, oranges, olives, dried fruit, &c. Tea, the staple article of export, gives employment to some twenty-eight British firms, who engage solely in this trade. Less wild speculation and more sober trading characterises the business of this year. There has been more judgment exhibited in the shipping of cargoes to London; instead of the old system of shipping off in a hurry. and clearing vessels in a heap, by means of combination, the departures have been gradual, so as to avoid too large arrivals at one time in London. The year 1885 has not been unsuccessful to most shippers of tea, and may be counted among the tolerably fair years. In many cases full charges and commissions have been realised, besides a slight profit on merchants' own account. That fortunes can now be made in tea speculation is beyond expectation, considering the low range of prices of the London market for the last few years, and the demand for common and cheap teas. Owing to shortness of supply on the London market, consequent on the large increase of home consumption, Foochow red-leaf teas have fared better than might be expected, looking at the poor class of teas, almost throughout, that were brought down from the tea-growing districts. The teas of both first and second crops were pronounced somewhat badly prepared, owing, it was thought, to the cold and wet weather during the spring months; the musters were generally clean and well fired, and fairly free from dust: they were, for the most part, strong in the cup, with a bright infusion. The most striking characteristics of the crop appeared to be the absence of really fine teas from any of the districts. The Paklings were hardly so well curled as last year's, whilst the Paklums were of similar quality to those of last season, with, perhaps, rather more strength. The other kinds, such as Kaisows, Suey-kuts, Sarynnes, Tong Fong-Tongs, and Yunghows were of poor quality, and were inferior to last year's produce, both in make and liquor. Of Souchongs the general quality of the crop was poor, the liquor being thin, and the leaf showng careless preparation. During the first fortnight on the opening of the market business was steady and active, but without excitement. Prices then commenced to decline on the advent of bad advices from home. Prices have shown considerable fluctation during the year, ranging from 17 to 49 taels and 12 to 32 taels at the opening of the market; and 16½ to 18½ taels and 13 to 20 taels in November. Australians were larger buyers this year than formerly, there being an excess of shipments beyond the wants of the population. Australian business is creating a serious competition to buyers for London, while it has an undoubted tendency to making bargains more difficult for the latter.

The manufacture of brick tea of varieties of tea-dust by Russian merchants only, for export to Siberia, is acquiring considerable importance. The low cost of the dust, the cheapness of manufacture, the low export duties upon it, together with the low import duties in Russia, combine to make this trade a success and a profitable business. The most expensive part of the business is the freight on the bricks by sea to Tientsin and the carriage on camel-back to Kiachta. The Russian merchants' export tea-leaf, but in small quantities, for Russia proper—their chief business being the making of brick tea, their commissions on orders from Russia being large, and no loss is incurred. The brick is so beautifully made, and is so portable, that it has surprised me the British Government does not get its supplies from this port; they would find it less expensive and wholesomer for the army than what is now given the army and the navy. I think a trial should be made, or that a Government agent should be employed on the spot to manufacture the brick tea in the same way that the Russians here and at Haukow do. For the whole year, according to Custom-house returns, the total export of every kind of tea—black, green, brick—is 733,599,66 piculs, at 133⅓, equal to 97,813,238 lb., inclusive of the import to Chinese ports, amounting to 93,581,42 piculs, for foreign export. According to the Chamber of Commerce Market Reports, the shipments from the opening of the market in June to the end of the year come to 80,110,418 lb. as follows:—

	Lb.
To London and Continent of Europe	52,839,309
Australian and New Zealand	21,936,755
United States and Canada	5,334,354

The market opened somewhat later this year, actual buying not commencing till June 19. The delay is specially attributable to the anxiety of the native tea brokers for the establishment of fixed rules in the conduct of the trade in regard to weighing and the date of payment. They had cause of complaint in these respects on the part of a few foreign buyers. After much discussion a set of rules was adopted by mutual consent, and came into operation on June 13. The hope that greater regularity would result from this fresh agreement with the buyers has not been wholly disappointed, and confidence has grown out of the new system between seller and buyer. I am indebted to a commercial friend for the following valuable letter on tea:—

"In reviewing the tea trade of this port for the season 1885-86 there are, I think, several novel features which it might be well to touch upon in the first place.

"1. I would mention the sudden and unexpected termination of the Franco-Chinese war, which upset many calculations; and more especially the reopening of Formosa altered the whole position as regards the trade in Oolongs with the United States, preparations for greatly extending which had been made both here and at Amoy but which were rendered nugatory by this action.

"2. The inconvenience attending the shipping of cargo by the closing of the port and the removal of the anchorage to Sharp Peak; but it is noteworthy that, although there was necessarily much delay, there was not a single accident of any importance, although the risk was greatly increased. It will be in your remembrance that the Pagoda Anchorage was reopened on Sept. 6 last.

"3. The New system of weighing tea, and of the cash payments for same, introduced under the auspices of the Foochow General Chamber of Commerce and the native Tea Guild, the time taken in the settlement of these questions causing great delay in the opening of the market, the teamen refusing to show samples until they were settled. You are aware of the nature of the agreement entered into, and I need not further refer to it beyond saying that the terms agreed upon seemed alike fair to buyer and seller—that experience has proved this, business as a rule progressing smoothly and pleasantly. And I am of opinion that, so long as it is carried out in its integrity, the agreement must continue to exercise a most beneficial effect on the trade of the port.

"4. The agitation in London last spring, caused by the expected increase in the import duty on tea, resulting in enormous duty payments and the consequent reduction in the bonded stock of this article to a very low point.

"5. Another novel feature has been the re-employment of sailing-ships in the carrying trade of tea, no less than five vessels, carrying about 7,000 tons, having been dispatched from this port during this last season. This was brought about by the action of the Conference Lines of steamers preventing competition and fair rates of freight, the average rate per steamer being £3 per ton of 40 feet, while by sailing-ship the rate was only 30s. to 40. per ton of 50 feet, the difference being a heavy percentage on the laying-

down cost of common teas. As far as can be at present ascertained, shipment by sailing-ship have shown a more satisfactory result than by steamer, and it may be predicted that, should the Conference system be continued next season, it will have the effect of still further diverting the carrying trade to sailing-ships. The new season's Congous began to arrive on May 13 last. With the exception of a few Paklins, musters were not shown until June 16, when about 315,000 chests had come to market, the result being that it was impossible to taste and value more than a very small portion of the samples before the opening of the market, which took place on June 19, the following being the quotations for the various districts as compared with the previous season:—

	Season 1885-86. Tls. per picul.			Season 1884-85. Tls. per picul.		
Paklins	11½	to	26	15	to	30
Paklums	17	to	49	20	to	35
Panyongs	12	to	32	15	to	33
Sueykuts	10	to	20	10¾	to	27
Yunghows	12	to	20	10	to	23
Saryunes	9	to	16	10½	to	19½
Scumoos	12	to	34	14	to	35
Tong-foug-tongs...	14½	to	16	10	to	17
Dust & Siftings ...	4	to	9	4	to	7½

Rates of exchange being 3s. 7¼d., against last season's 3s. 9⅝., for four months' sight credits; rates of freight to London, £4 to £3 per ton, or the same as last season; and to Australia 30s. per ton, against £2 and £2 10s. per ton. As regards the quality of the crop, the general impression was that, owing to the unusually wet and cold spring, there was again a scarcity of finest kinds, but that the teas generally were of fair average quality, and possessed considerable strength, the exceptions being those from the Sen Moo, Sar Yune, and Young How districts, which were below the average. For a few days after the opening transactions were not on a large scale, buyers securing their favourite chops of fine and finest teas, while medium Pan youngs were selling cheaply. Dust and siftings were, however, in strong demand at full rates. The "Gleneagles" was despatched for London on June 27, and after this buying became more general, very large transactions taking place for both England and Australia, prices for the lower grades being well supported while the better kinds went in the favour of the buyer. All through July the active demand continued, the low rates of exchange enabling a comparatively high tael cost to be paid; and early in August advices being received that fine and finest kinds had met with a favourable reception, both in England and Australia, the remaining first crop teas were cleared off the market at full rates. With heavy arrivals in London recourse was again largely had to 'public sale without reserve,' with the usual result of low prices and losses to the importer; still buyers on this side being satisfied, that with the increased export to Australia, supplies of Congou could not be in excess of the actual requirements, there was no falling-off in the demand here; and in fact, as the season progressed, rates for common kinds gradually hardened, and in November the highest prices were reached, when low dust realised 5 to 6 taels per picul, and low common Congou 9⅓ to 10½ tales per picul. And it was a matter of surprise to most merchants that, with such quotations, the teamen were unable to bring larger supplies to market; but, juding from the quality of the latest arrivals, it was evident that every available leaf had been collected, some of it being from three to five years old, and it still remains to be seen whether such low quality will be allowed to go into consumption in England. [Three to five years old leaf made into tea! Talk of bangy leaf after this.—ED.]

"The results to the tea men, they having profited by their severe experience of last season, must have been most pleasing, they having secured large profits on their first-crop ventures and a good percentage throughout the season; while so far it is doubtful if the foreign merchant has done more than come out clear. The supply of first-crop Congou was about 30,000 chests less than last year, but the total arrivals for the season were 660,000 chests, as compared with 642,250 chests last season. *Souchongs*, as a rule, could not compare in quality with those of the previous year; but fine and finest kinds found ready sale at very full prices, while the common grades throughout the season have, in sympathy with Congous, brought high rates as compared with taol cost of last season.

"*Oolongs*.—As noticed in the early part of the report, the teamen made preparations for doing an extensive business in these kinds; but the reopening of Formosa upset their calculations, and though the market opened at about last year's rates, the result was a heavy loss to them. And this remark will also apply to the fine strings, which sold cheaply as compared with former years; but the autumn crop being bought at very low rates in the country enabled sellers to recoup themselves. The quality of these teas throughout the season has been most disappointing, besides which there has been a much larger admixture of dust, which is most detrimental to their sale in the great consuming country, namely, the United states; and unless much greater care is taken in their preparation there can be no doubt that this valuable trade will be wholly diverted to Amoy, whose teamen are fully alive to the importance of the question.

"*Scented Teas*.—It would appear as if these teas were going out of consumption in England, for although laid down this season at a fairly moderate cost, the result has been most disastrous to the buyers.

"*Flowery Pekoes* proved to be a fine quality, and found ready sale at extreme tael cost. The circulars issued by the Foochow General Chamber of Commerce furnish you with full and detailed tables of statistics, so that it is unnecessary for me to append them; but you will notice that while to England the export shows a further small decrease, that to Australia and the United States is again larger, while the Russian trade in brick tea continues to increase; but of this we have no particulars beyond those given in the Customs Returns. You will have noticed the continued fall in the value of silver, the latest quotation for four months' sight credits on London being 3s. 3¾d. per dollar. In conclusion, I would draw your attention to the following startling figures as regards the import into, and consumption of tea in, Great Britain. For the eleven months ending Nov. 30, 1885, the total amount of tea delivered was 204,290,693 lb., against, during a similar period in 1882, 192,126,826 lb., or an increase in three years of 12,163,867 lb.; but the deliveries of China Congou alone had fallen from 120,345,012 lbs. for eleven months in 1882 to 111,644,820 lb. in 1885, or a decrease of 8,700,192 lb. The import of China Congous showed a still more alarming decrease, the figures being:—Imported into Great Britain, June 1 to November 30, 1882, 122,214,956 lb., against, for same time in 1885, 98,647,700 lb., or a falling off of 23,567,256 lb; while the consumption of Indian and Ceylon teas for same time were, in 1882 16,040,006 lb., and, in 1885, 63,387,384 lb., or an increase of 17,347,378 lb.

"The sole cause for this enormous decrease in the consumption of China Congous is undoubtedly the continuous falling off in the quality of the tea produced, and this should be a matter for the serious consideration of all concerned in the prosperity of the port; and you, Sir, would be doing a good work—Could you bring these facts home to the officials of this province?" To this highly-interesting and exhaustive letter of my obliging friend on the engrossing subject of tea there can be but little, if anything, to add. More than once has it been brought to the notice of the high officials that so little care is taken by the tea-growers in the upper districts to produce again a fine quality of Congou, as was the case some ten or fifteen years back, and that they should be encouraged to put in fresh tea-shrubs and root out the old ones, and otherwise to be careful in the cultivation and the rearing of the plants. I will again make a fresh endeavour to bring the Viceroy's attention to this important matter, and I hope it may meet with the desired success. But it must be said, on the other

hand, that buyers must expect to pay higher prices than they have lately been doing in this market; there has been so little encouragement on the part of the buyers in this respect, the demand being for cheap and common-class teas to suit the London market.

FREIGHTS IN 1885.

To London and Continent of Europe.—As regards tea, from January 1 up to the opening of the tea market at the end of June, there is nothing of interest to report. The first steamer for London direct left Sharp Peak on June 28. The scale of freights was on the same basis as the previous year, namely, £4 for the first and £3 10s. for the second boat. After these departures the rate was fixed at £3 per ton, at which figure it remained as long as the berth was occupied only by steamers belonging to the regular or Conference lines. At the end of July the British steamer "Ascalon" was advertised to load, when it was decided by the Conference to reduce their rate to £1 10s. per ton to meet the opposition, and, if possible, to prevent other steamers from calling. After the departure of the "Ascalon" the freight was advanced to £3, but was again reduced in the middle of August, as another non-Conference steamer took the berth. These tactics were again repeated at the end of November, since when the normal rate of £3 has been maintained. The feature of the season has been the fact that five sailing-vessels have taken full cargoes from this for London—about 7,000,000 lb., or, say, 10,000 tons of 40 cubic feet—whereas not a single sailing-ship was despatched last year. Many shippers have apparently come to the decision that it is necessary to regulate the arrivals on the home market, and have thus to a certain extent reverted to the old mode of shipment. This has, no doubt, had a beneficial effect on the tea trade of this port by strengthening the London market.

Australian Colonies.—The two principal lines attempted to prevent opposition at the beginning of the season by offering shippers the same inducement as is done by the Conference lines to London, to confine their support exclusively to them, namely, a return of 5 per cent on freight paid. This, however, did not take effect, as a third line entered a strong competition, and freights at the opening of the season were £1 10s. per ton, and have remained at this rate throughout. The first steamer got £2 10s. per ton; second and third, £2; but later in the season the quotation was as low as £1 per ton, consequent on excessive competition.

America.—The trade from this port, being small, is not of great interest to the shipping. Rates have ruled very low; the bulk of shipments have gone to New York, transhipped in London, at the very low rate of £1 10s. under through bill of lading, the competition at other ports having been very keen.

The value of the tea export trade in 1885 may be estimated roughly at $16,000,000, at 3s. 6½d. = £2,833,000.

PAKHOI.

Mr. Consul Allen reports as follows:— * *

EXPORTS.—Exports from Pakhoi may be divided into two classes—those whose final destination is a foreign country, and those which are intended for local consumption. The first class, unfortunately, requires but a very short list. Cassia and aniseed, with the oils extracted from the plants, head the catalogue. Our foreign merchants in Pakhoi are largely interested in these articles, and export considerable quantities to Europe and Bombay. The present export duty on cassia is a little heavy, being six mace on each picul, valued by the Customs authorities at three taels; in other words, 20 per cent., instead of 5 per cent., the estimated tax on each article of export when the Treaty of Tientsin was made. This might, perhaps, be remembered should there be a revision of the tariff at any future time.

TAMSUY AND KELUNG: FORMOSA.

[Formosa is so rich in soil and so genial in climate and the quality of its tea so good, that if good government gives protection to life and property the island may prove a formidable competitor to India and even Ceylon in the produce of tea.—ED.]

Mr. Consul Giles reports as follows:— * * *

The following table shows an enormous increase in the export of tea for 1885 over any previous year:—

	Lb.
1880	12,063,450
1881	12,859,467
1882	12,040,447
1883	13,206,727
1884	13,156,581
1885	16,364,000

The quality of the Formosa tea is steadily improving, and American buyers have written in glowing terms respecting the successful issue of the 1885 crop. There is, in fact, every prospect of the Formosa tea trade expanding before very long to little-dreamt-of proportions.

Since my arrival here in November last I have twice been into the interior to visit the savages. It is a very interesting trip, and the country in which the savages live is beautiful beyond description. At the boundary between Chinese and savage territory there are camps of Chinese soldiers to guard the agriculturists from savage depredations; and on my arrival the petty mandarin in command came to meet me, and disappointed the party very much by saying that no savages had "come out," or would come out for several days, so that we should not be able to see any on that occasion. He then advised us to come again another day, when he promised to send an escort of soldiers with us for safety's sake. An hour after this myself and party (which included Mrs. Giles, the first lady who ever crossed the border) were strolling along in savage territory, accompanied by some half-dozen savages, men and women, who were delighted to see us, partly because we showed no signs of wearing the hated pig-tail, and partly because of sundry strings of beads and other various odds and ends, an earnest of which had already been bestowed upon them. We were of course alone. Our chair-bearers had refused to follow, and wisely so, for it is certain death to any Chinaman who shows his half-shaven head on the wrong side of the line. We had a very pleasant ramble, and hoped at one time to reach a savage "village;" but time was against us, and we were forced to retreat, carrying with us the evident goodwill of our hosts, while they carried away with them other and more tangible spoil. One of them knew a few words of Chinese, but this vocabulary did not run much beyond "Chinaman bad man. You know Chinaman; you good man," &c. They were a pleasant-featured, healthy-looking lot. But they are doomed, and that in the near future. General Liu is carrying on operations against them which can only have one end; he is overwhelming them with numbers. Every now and again he sends in two or three thousand men, who come back minus one or two hundred, killed by the deadly fire of the savage matchlock, and having apparently accomplished nothing. Meanwhile, there are signs that the savage resources are not without a limit. In one direction eight large "villages" have already submitted, and while I write an expedition of no less than 10,000 troops, acting at different points, has been organised by the vigorous official whom even France will have good cause to remember. General Liu has wit enough to see that Formosa, under the civilised rule of China, has a grand future before her. The hills over which the savages are now sparsely scattered would grow thousands of tons of that delicate-flavoured tea over which even now New York purchasers are writing in such hopeful terms. So the savages have to go. They can, if they like, take grants of land, paying no taxes for a certain number of years, and being

all the time taught agriculture free of charge, through an agency specially established for that purpose. But if they do not like, and many prefer the old free jungle life and the excitement of the daily chase, then it becomes a question between their unerring but scattered matchlocks and the bristling breech-loaders of half-drilled Chinese troops. Through part of the territory already recoved the Chinese have constructed a good military road, and before long this is expected to debouch on the east coast, at Soa-bei, where, by the way, there is a fine spring of mineral water, of what value is not known, as none of the water has been subjected to analysis. The authorities are extremely jealous of foreigners visiting these savages. The petty mandarin above mentioned did all he could to prevent my party from advancing, deviating boldly from the truth in order to effect his object. Before long the occasion will hardly arise. Those foreigners who would study the Formosan savage in his native haunts must make haste; there will soon be none left to study.—*London and China Express.*

CULTIVATION OF TOBACCO IN GREAT BRITAIN.

As considerable interest is being taken in this subject at present, it may be interesting to agriculturists to know that about the year 1800 an attempt was made to cultivate Tobacco in Scotland, and it is recorded in the *Statistical Account of Roxburghshire* that "in one season a tenant-farmer in the parish of Crailing (about 6 miles west of Kelso) drew £115 for Tobacco plants, and afterwards grew a crop of between 12 and 13 acres, which he sold upon the ground for £320, but an Act of Parliament intervening, the purchaser was unable to fulfil his bargain, and the farmer was compelled to dispose of his Tobacco to the Government at only 4*d.* per pound, at which rate it brought him only £104." And it is further remarked:—"It appeared from the trials made at that time that Tobacco would thrive well in the southern part of Scotland." It was also grown largely in fields a little to the east of this town (Kelso), part of which is now a cemetery. A road at the west end of the cemetery is still called the "Drying-house" Lane from the fact that the house where the Tobacco was dried stood there. Mr, Brotherston, botanist here, informs us that between twenty and thirty years ago he used to grow regularly in his garden at Ednam (about two miles north-east of Kelso, as much as furnished him with smoking Tobacco; and at the present time we know of its being regularly grown in a nobleman's garden for the purpose of fumigating the greenhouse plants, the sort generally grown being the Virginian, a variety of Nicotiana tabacum, though there are many other sorts in cultivation, one being Nicotiana rustica, the common or green-flowering variety, which is much hardier than Virginica, and, we believe, the first to be cultivated in this country, though the Virginian was introduced fully 130 years earlier. We may say, that for this country the young plants require to be raised in a hot bed, and planted out about the end of May in deeply trenched soil heavily manured. The greatest enemy the plants have to contend with (but only in their young state) is the slug. We have no doubt whatever that Tobacco could in most seasons be profitably grown in this country, provided Government will be somewhat lenient as to the conditions and taxation. If we mistake not, the parliamentary Act referred to was passed almost solely for the benefit of encouraging the growth of Tobacco in the colonies; and surely our colonial friends have had a fair monopoly of its growing, and it is to be hoped that the Government will allow our farmers at home (who may wish to grow it) permission to do so on reasonable and encouraging terms.—LAING & MATHER. Allow me to say a few additional words on the cultivation of yellow Tobacco, which I omitted for the sake of brevity in my last communication. To a certain extent the writer of the pamphlet quoted by me is at one with Colonel Trevor Clarke, "that the colour of the ultimate product is due to soil and conditions of cultivation." Like colonel Clarke, he deprecates the use of farm manures, but strongly advocates the use of prepared fertilisers. Thus he says:—"Eleven years' experience in the use of the Anchor Brand Tobacco Fertiliser, manufactured by the Southern Fertilising Company, Richmond, Virginia, has convinced the writer that it is the planter's best aid in the production of rich, silky, bright yellow Tobacco. Lands capable of producing yellow Tobacco need just such help as is furnished by this fertiliser in hastening the growth and giving size, substance, and early maturity to the plant. From 100 to 300 lb. per acre of the fertiliser may be profitably used." Regarding the black colour of Latakia this is due to a great extent to the system of drying over the smoke of burning Oak-wood, by which it also obtains the smoky flavour characteristic of this Tobacco I am fully aware of the difference in the flavour of Tobaccos that have been fermented and those that have not, or only slightly so and I prefer the later because they are lighter and more fragrant.—John R. Jackson, Museum, Kew.—*Gardeners' Chronicle.*

ON A METHOD OF TRANSMITTING LIVING PLANTS ABROAD.

BY R. LINDSAY, CURATOR, ROYAL BOTANIC GARDEN.

"The method usually adopted in transmitting living plants, particularly where very long journeys have to be undergone, is to pack the plants in Wardian cases, *i.e.*, cases fitted with glass sashes, which, when closed, are nearly air-tight. This is no doubt the best mode of conveying plants safely, provided they are properly attended to on the journey. To do so it is almost necessary for some one who understands the requirements of plant life, to take charge of the case as, when sent without any special attention being paid to them, the results are frequently unsatisfactory. The dangers attending such structures appear to be want of ventilation and shading. The plants contained in them soon become drawn up and weakly in the steamy atmosphere of a close-fitting case, and often arrive at their destination in a dying or dead condition. One of the most successful importations of plants that I recollect of having seen was contained in a small wooden box sent to the Garden from Australia by Baron von Mueller, in 1866. The plants had been over three months on the journey, but were found to be in perfect health on their arrival at the Garden. This result we attributed chiefly to the simple manner in which the case was constructed. It consisted of a rough square wooden box, filled with soil, into which the plants (which had previously been grown in pots) were placed, two narrow strips of wood were nailed on to the sides of the box in an upright position, to which a cross-piece was attached, constituting a handle. The whole was then covered with strong cotton cloth, no glass being used. In vol. viii., p. 482, *Transactions of the Botanical Society*, a description is given of this case by the late Mr. McNab. In July last our associate, Mr. John Buchanan, when returning to Central Africa, being desirous of taking some economic plants out with him to that country, an opportunity was thus afforded of trying an experiment. This was rendered all the more necessary as on previous occasions similar plants sent to Central Africa from the Garden, packed in Wardian cases, although taken every care of on the way out, were found to be mostly dead on their arrival. On this occasion, a case similar to that exhibited was prepared. It is 18 inches long, 12 inches wide, 16 inches deep, has a ridge roof with a handle fastened on the top for carrying. The main difference from an ordinary Wardian case is in the substitution of cotton blinds for glass sashes. The blinds are nailed to the top of the ridge and tied down with cords to the sides of the case, so that they may be easily rolled up or down as required. The advantage of this method is the admission of sufficient light and air to maintain the plants in a healthy condition; the fine meshes of the cloth acts as a shade from strong sunshine, and do not admit so much air as to cause the interior to become quickly dried up. The plants sent on this trial consisted of India-rubbers, several Tea plants, Cinchonas and Ipecachuana. They were all turned out of the pots in which they had been growing previously, the balls of soil slightly reduced, and then

wrapped up tightly amongst sphagnum moss. The plants were then packed in the case firmly, in an upright position, using sphagnum for filling in the interstices. Thin strips of wood were placed across the balls, the ends of which were nailed to a flange inside the case for that purpose, thus preventing the plants from moving, even if the case was turned on end. After being well watered and allowed to settle for a day, the blinds were tied down and the case sent up to London, where Mr. Buchanan took it in charge. He was eighty-two days on the journey out, and in a letter to Mr. Taylor received in December last Mr. Buchanan reports that all the plants arrived in a perfectly healthy condition, except the Cinchonas, and that he had not given up all hope even of them. I may mention that the Cinchonas referred to were not very vigorous plants to begin with; they were the best we had at the time, but were merely young seedlings. It would be well to have this method still further tested, either by having a few plants sent to a distance alone, or at all events in charge of some one less skilful in the management of plants than Mr. Buchanan. For all but very tender plants (where special provision would be required), I think much more favourable results would be attained by the use of a case such as that described, always provided it were placed free from danger of sea water getting through the canvas, than if the usual Wardian case were used." *Edinburgh Botanical.*

FORESTS OF JAPAN.

The area of Japan is about 96,000,000 acres, and the forest area, exclusive of the Loo Choo and the Bonin Islands, is about 29,000,000 acres. The forests are held in nearly equal proportions by Government and by private owners. Forestry has long been made a study in Japan, and it is stated in a recent report of the United States Commissioner of Agriculture that no people are more skilled in grafting and dwarfing trees than the Japanese. The Government Forestry Department is now an important branch of the State. The head office is in the capital, Tokio, but in each of the forty-four *Ken* or States, into which Japan is divided, there is a branch office from which the respective forests and plantations are managed. During the days of the old rulers, each lord had his own forestry laws, all of which were very strict; one of these made it a punishable offence to be found in the forest after nightfall. Since the new *regime* the forestry laws have been consolidated, and their old feudal strictness somewhat abated; but the existing laws are still strict enough to secure the due preservation of the forests. In Tokio there is a Government school of forestry which was established three years ago, and is now attended by 150 pupils. Some of these pupils are preparing themselves for practical work in the State forests; others are the sons of landowners and farmers acquiring a scientific knowledge of arboriculture in order to qualify themselves for the efficient management of their own lands. The curriculum in the forestry school includes botany, the chemistry of the soil, a little natural philosophy, surveying, and the practical work of planting and rearing trees. Illustration is given to the pupils by Japanese officials, who have themselves studied forestry in the schools of Germany. Large plantations have been formed under Government auspices, and every year the area of forest land is being added to—cedars, oaks, spruces, and firs being the trees more generally planted. Within the last few years an important experiment has been made in the introduction into Japan of the seeds of trees and shrubs from other countries. Tea is extensively cultivated, but it was only in 1879 that the first coffee berries were brought from the Sandwich Islands and planted in Japan, and great hopes are entertained of the success of this experiment, from a commercial point of view. The cinchona tree was introduced from India in 1878, but the climate of Japan does not appear to be favourable to it, and in 1880 large importations of forest trees were made from Europe and America, and planted in the experimental gardens of the forestry department at Tokio. Some were failures, and others took favourably to the country—the list including several firs, oaks, and maples, the birch, the German larch, lime, ash, *pinus webbiana*, and other trees, which will in time form an important addition to the timber supply of the country. Extending over 15 degrees of latitude, and with high central ridges of mountains on the larger islands, the climate of Japan differs considerably in the north and south, on the plain and in the mountains, so that the vegetation partakes both of tropical and temperate zone characteristics. The country itself may be divided into five distinct tree regions or zones. In the first the temperature is high, and the forests consists of broad-leaved evergreen trees, then comes the zone of the oak and the beach, and other broad-leaved deciduous trees; next that of the family of cedars, among others the *Thuias* and *Retinosporas* for which the country is remarkable. Higher still is the region of the firs and pines, the conifers including many of the finest specimens of the *Abies veitchii*. Chief, however, among the trees of Japan are the *Cryptomeria japonica* and *Retinospora obtusa*, which attain to a height of about 120 feet, and a girth of 20 feet. The United States Commissioner of Agriculture says, that to those who have only been accustomed to see small dwarf specimens of the Japanese *arbor vitæ* and conifers used for lawn decorations, nothing is more astonishing than the great slabs of wood which such trees supply in their native country. Of such slabs many specimens are seen in Japan, and the ornamental woods are also very numerous. A very useful Japanese hardwood is the *Keyeki*, which has a reddish hue; and there are many varieties of oak. From one of the trees grown in Japan—the *Bronsonetia papyrifera*—the inner bark is taken and manufactured into paper, while from one of the climbing plants the woodmen make their clothing. The wood is steeped in water, then beaten with hammers, and the fibrous mass thus obtained is woven into cloth, which is dyed a deep blue colour. In the way of timber, the Japanese are able to supply the greater part of their own wants, and as the houses are largely built of wood, the quantity required is very considerable. A large quantity of timber is exported to China, and a small quantity is imported from America. In Japan there are large numbers of ponds in which timber is preserved. These are usually constructed near the mouth of a river, and into them fresh and sea water is allowed to flow, in the proportion of six parts salt to four parts fresh. Should there be a larger proportion of salt water, the timber is apt to become black; if a larger proportion of fresh water, the wood is liable to attack from worms. The ponds are about five feet in depth, and by means of canals many of them are often connected. The timber is piled in the form of a cube, and is kept in the pond from two to five years before being used; the trees most frequently treated in this way being the *Retinosporas* and *Cryptomeriæ*; a part of the preserving process being the thorough washing and re-arrangement of the wood twice a year. Some of the ponds are made large enough to contain 10,000 pieces of timber. —*Journal of the Society of Arts.*

VICTORIAN ORANGES.

The value of orange culture in Victoria is annually becoming more distinctly apparent. The quality of the Sydney fruit, upon which we are at present almost entirely dependent, has been deteriorating for some years; while the few of Victorian growth that are occasionally brought to market, testify to its profitableness. One of our correspondents, Mr. Sydney Williams, whose garden is situated to the east of Doncaster, has a small plot of oranges and lemons, that brings him in more profit than an equal area of any other kind of fruit in his extensive garden. Still finer oranges are grown in other districts, especially to the North of the dividing range, whence magnificent specimens have been sent from several parts of

the district; while from the neighbourhood of Swan Hill specimens have been shown in Melbourne surpassing in size and appearance any of the Sydney grown fruit. Therefore, Victorian fruit growers need not fear being starved off the face of the earth by the action of the reciprocity treaty with Tasmania, of which they affect to feel such a dread, while it remains in their power to utilise such a valuable source of profit as that of orange culture, which might be successfully conducted over a large portion of the northern plains, extending from beyond Wangaratta in the east to the extremity of the colony in the west.

The chief inducement to plant orange groves in Victoria, however, independent of Custom duties, is the fact that, the orange groves in New South Wales, at any rate in the neighbourhood of Sydney and Paramatta, the great centre of orange cultivation in that colony are rapidly decaying, owing to bad management, neglect, the use of unsuitable stocks, besides other causes. In a lecture on orange growing delivered in Sydney a short time ago, by Mr. S. W. Pye, it is stated that "orange growing in the county of Cumberland is a very profitable pursuit to those who understand it, but 99 out of every 100 who possess orange orchards know very little from a scientific point of view, *i.e.*, regarding its culture, the failure of crops, and the cause of many diseases affecting the whole of the genus." The great bane of orange culture is disease, and the worse kind is bark disease, which appears to affect the trees in all soils and situations when they are worked upon unsuitable stocks. In a letter to the *Mail*, Mr. Pye states that "an orangery at Lane Cove, 20 years ago contained 2,000 trees; of which 1,998 have since died out from various causes, and the only 2 that remain are Seville orange trees, now 40 years of age. In an orangery at Seven Hills, once the property of the late Mr. Pye, which contained about 1,000 trees, the whole of them, with the exception of 5 Seville orange trees, suffered so much from the rotting of the barks that they had to be destroyed; while the 5 Seville orange trees were in no way affected with the disease."

When the bark disease was causing such havoc among orange trees in Madiera, Portugal and other orange growing countries of Europe, Mr. Charles Moore, Director of the Sydney Botanic Gardens, was despatched by the Government of New South Wales to institute an investigation of its nature and the means to be used for its extirpation. In the report which he gave after his return in the early part of 1868, he showed that working the sweet orange on stocks of the Seville or bitter orange was the only method of preventing the disease. He instances a plantation near Alcira which had been a very fine one; but every tree was either dead or dying, with the exception of a group of a dozen all on the bitter orange, which were entirely unaffected and in fine healthy condition; while some of the surrounding trees which had suffered so severely from the disease were raised from seed, others had been budded, some on citrons, some on lemons, both of which have obtained preference as stocks; but so satisfied was the Spaniard, although singularly adverse to change an old custom, of the value of Seville stocks, that their price had risen to 2s. 6d. each, whereas the other stocks—citrons and lemons—were unsaleable at 6d. each. Culturists are therefore recommended to bear these facts in mind, for undoubtedly the bark disease is the greatest of all drawbacks to successful orange culture. Propagators of oranges appear to pay as little attention to the nature of the stocks they use as the Spaniards paid previous to the appearance of the disease amongst their trees. No one with the knowledge we now possess respecting the universality and the destructive nature of the disease and its cure ought to plant a single tree that he is not sure is on a bitter orange stock; it would be better to buy a few cases of Seville oranges, throw them in rot heap, raise seedlings and wait until they are propagated rather than risk the chance of having the whole or even a portion of his trees affected with disease, and giving out, one after another, as soon as they have arrived at their best.

The immunity from disease exhibited by the Seville orange is probably due to its hardiness, it being able to bear great extremes of both heat and cold with immunity. It is said to be the only variety that thrives and bears fruit in the neighbourhood of Calcutta. While in Italy, in the neighbourhood of Florence, where the cold is so intense that skating is sometimes practised during four months of the year, there are standards in the open air that have attained a height of 15 to 20 feet. It is in favour of seedlings of the Seville orange that they are easy to deal with, either in the nursery or in the transplanting, as they produce much fibre, which enables their removal to be effected with great certainty of success. An instance is given of their facility for being easily shifted, in which, an equal number of plants grafted on the common lemon, and the Seville orange were planted on the same ground by one man, and that, of the former, nearly all died in about six weeks, while the others throve, though another cause might have shared in producing the disastrous result.

In the cultivation of the orange, as in the case of most other fruit trees of somewhat delicate constitution, soil, aspect and shelter are the most important items. It is, however, very accommodating as regards soil, thriving in those of various qualities, disliking only the heaviest clays and such as have become soured through deficiency of drainage; showing that the subsoil is, in most cases, of equal or greater importance than the true soil. With these exceptions, we believe there is very little soil in the northern districts, unless where there is hardly anything but sand, in which the orange would not succeed. It, however, does best in a friable loam mixed with vegetable matter on a porous subsoil; it may be therefore assumed that the Oak Rises on the northern plains would be specially adapted to its requirements. The black and brown soils with clay subsoils, which occur so frequently in the colony, are also suitable if properly drained. It is stated by Mr. Pye, of Parramatta, that "a small proportion of salt in the soil sufficient to render the drainage water slightly brackish has a very beneficial effect upon the growth of the orange." Very light sandy soils are not to be recommended as they require too much manure. There is, at present, a drawback to the use of some of the soils in the northern districts, in the deficiency of moisture, which, however, is certain to be to a large extent remedied erelong; for though the orange invariably succeeds best where artificial water is not required, it cannot thrive on soils that are subject to drought during several months of the year unless water is used; but watering orange is a very particular process, and frequently produces results more injurious than beneficial when applied by the inexperienced. The novice should be therefore, particularly cautious in his first applications of water, and if regular, irrigation is to be practised then drainage is the first process to which the land should be subjected in its preparation. Regarding aspect and shelter the best aspect is north-east on a gentle slope, sheltered from south and westerly winds. In situations liable to be affected with spring frosts, it is not advisable to choose an aspect directly opposite the rising sun, its heat causing a too sudden expansion of the frozen sap, which may produce serious injury to the foliage. Should the situation chosen be a sloping valley, it is not advisable to plant the lower part, as there frosts are most severe; but if it should meet another valley running across its mouth with a good slope, and especially if it contains running water, the cold air would be carried away and no injury might result. The practice of smother burning might be also beneficial in such cases. Shelter from violent winds, from whatever quarter they may come, is absolutely necessary. It may be obtained—naturally—either from the conformation of the ground or from indigenous timber; artificially—from orchards, belts of plantation, high hedges, tall brush fences, or stone wall; of which the first two are decidedly the most efficient.

The site having been chosen, the preparation of the soil may be begun. If drainage is required, that must first of all finished. Early spring is the best season to commence before the drought has rendered the soil difficult to work. The depth to which the soil should be trenched or subsoiled depends to a considerable extent upon its nature. Though the feeding roots of the orange are to be found near the surface, it is nevertheless necessary to break up the soil to a considerable depth, mainly with the object of affording a free descent to water and air. Where a bed of clay underlies the surface soil at a depth of less than 2 feet, it should be dug down to and well broken up with fork or subsoil plough, and if, as is frequently the case, there happens to be a bed of gravel above the clay, a mixture of the two would keep the clay more open, but it should not on any account be brought to the surface. During the summer the soil should be pulverised with the scarifier, and should it be already tolerably friable but not very rich, one or two crops of rape may be sown and partly eaten off by sheep or the whole ploughed down. In the following autumn or winter the land may be ploughed into ridges of a width corresponding with the distance apart the trees are to stand.

The planting of orange trees demands the exercise of the utmost care, combined with a knowledge of the nature and requirements of the plants. To bury the roots deep in the soil is certain to cause either immediate death or permanent decrepitude, for the roots of the orange, at least the true feeding roots, are never found far from the surface, hence they should never be buried under more than a very few inches of soil, the tap roots or fangs, if there are any, being of course accommodated in regard to depth and position to those they previously occupied. The rule should be strictly adhered to not to place the stem at a greater depth in the soil than that which it occupied as a seedling. The graft should on no account be beneath the surface, otherwise it would be liable to take the bark disease.

As the orange is one of, if not the most valuable of fruit trees that can be grown in this climate, so it is deserving of the best kind of treatment. The soil in which it is grown should be kept in an open friable state, in order that the roots may be able to run through it with freedom, while rain and other meteoric influences are also more freely admitted. It should never be allowed to become injuriously dry nor dangerously wet. To prevent the former the soil should be mulched around every tree as soon as planted and continued year after year while the trees exist, for even the largest trees are liable to sustain injury from hot suns if the soil over their roots is not shaded by some means, while water must be applied during drought of extreme severity. With regard to manure, if the soil is of average fertility not much is required until the trees commence to bear beyond what is conveyed in the mulch, for gross growth is rather objectionable in young trees. But as the fruit of the orange contains a considerable proportion of mineral constituents, these must be replaced or reproductiveness will ail. It is found that the ash of the orange contains 36 per cent. of potash, 24 per cent. lime, 11 per cent. soda, 11 per cent. phosphoric acid, 3 per cent. sulphuric acid and 3 per cent. common salt. These figures and names of constituents enable the intelligent cultivator to supply the constituents required in proper quantities, and teach that it is useless to depend upon any one or more substances that do not contain the whole of the constituents the crop demands, for if one constituent alone is absent or even deficient, the full benefit of the others cannot be obtained. A large proportion of the necessary mineral constituents may be derived from the mulch, which must never be removed from the soil, neither is it necessary or advisable to dig it under the surface. Stable manure, which is the substance generally used, contains a large portion, though not all the necessary constituents. The leaves of trees form a still better mulch, containing a greater quantity of mineral constituents, especially potash and lime. In addition to the mineral constituents, nitrogenous substances are also necessary; these are found to some extent in stable dung. Blood, which contains 15 per cent. of nitrogen when dried, is reckoned one of the best of orange manures. Nightsoil, superphosphate and Peruvian guano should be occasionally used. Mr. Pye states that a mixture manufactured by Elliott Bros. from a recipe given by him is by far the cheapest and most valuable manure used; its use increasing the amount of crop six-fold in some instances.

The orange is a tree that requires very little pruning; it has, indeed, been said, "prune not at all," but that principle is only applicable in the case of full grown trees; in that of young trees, especially those that have been worked and transplanted, the well known proverb must be acted upon. It is a not uncommon opinion that the orange tree cannot endure pruning, but that is annually disproved in the immediate neighbourhood of where we write. The trees in the garden of the Horticultural Society having been too closely planted, to prevent them from interlacing and injuring each other, Mr. G. Neilson, curator, annually prunes the branches back to stumps without any evil consequences resulting, the crops being abundant as well as of good size and quality. While young oranges, like other trees, require pruning to some extent, all that is generally necessary is to form them into the proper shape; indeed some young trees form themselves, and therefore need not be pruned. Afterwards all that is required is to prevent any branch from outgrowing the others and to thin out useless spray. It is, perhaps, more important that sufficient space should be allowed for expansion in the case of the orange than in that of any of our ordinary fruit trees. Apple or pear trees when they become overcrowded and interwoven through deficiency of space, may be cut back root and branch and rejuvenated in a year or two; but who would think of planting oranges so that they would require to have half of each destroyed when they were as their best? The case previously referred to merely proves that the orange will endure somewhat severe pruning, when from any mischance it becomes necessary to do so, but it does not prove that trees are the better for it; had those trees been allowed sufficient space for development, and the growth that has been destroyed in the course of the last half dozen years been allowed to remain, they would now have been grand trees, many times larger, finer and more productive than they are at present. The orange, therefore, that is, the ordinary large growing varieties, should not stand less than 30 feet apart. Healthy, well managed trees will occupy that space before very many years; for every orange tree should have a clear space of some feet in width on all sides, otherwise, if the branches become crowded, they dwindle, grow weakly and unfruitful, atmospheric influences are shut out and insect pests increase. It is not to be supposed, however, that the remainder of the ground is to remain unoccupied while the oranges are growing, on the contrary, the more it is cropped, cultivated and manured the better for the soil and ultimately for the oranges. The only precaution necessary is to let nothing interfere with either leaf or root of the oranges. It need hardly be mentioned that the soil must be kept clear of weeds, but, as before mentioned, it should not be dug; the best growers are unwilling to admit the use of any tool that penetrates deeper than the Dutch hoe over the roots, but that must be frequently used; beneath the mulching and over the whole of the roots there should be a layer of dust in summer, except, of course, immediately after watering or rainfall. Irrigating the orange is a practice that requires the utmost nicety in its performance. In dry winters a soaking should be given that will penetrate to the deepest roots, but in summer time great caution must be exercised; in the case of young trees the soil should not be allowed to become dry until they have finished their growth, after which it should remain quite dry to enable them to ripen it. In the case of mature trees, summer irrigation should be avoided as much as possible; as the trees are liable to sustain severe injury from it; only when really necessary to prevent the trees from sustaining injury from drought should the water be applied, and then for only a very short space of time. Irrigating at a time that would cause a second crop to start must be altogether avoided, a second crop being "a calamity."

Under all circumstances oranges are liable to the attacks of scale insects, but, if taken in time, only a

slight amount of injury may result, otherwise they will presently cause the destruction of the trees. The brown scale is more easily destroyed than the white and is less destructive in its nature. Accompanying the scale their exudation forms a nidus for a disgusting black fungus, which does nearly as much harm and has a more disagreeable appearance than the scale themselves. A dusting of fresh slaked lime, applied when the trees are wet, will clear them of both the insects and the blight. The kerosene solution will produce an equal or more immediate effect. Gishurst compound or a strong solution of soft soap will easily destroy the brown scale. Even water alone, if at the temperature of 150 degrees, will clear the trees and cause no injury if applied after the cessation of growth. As previously mentioned, the orange is also subject to the dread bark disease, for which there does not appear to be a remedy, though the disease may be checked, if not quite stopped, if taken in time, and the whole of the diseased bark cut out, the cuts extending clear into the healthy bark. The trees should be, therefore, carefully examined every spring, the soil cleared away some inches in depth from the base of the stem, and the bark washed if necessary, so as to make sure whether the disease is present or absent.

It is objected to the orange that it does not come early to profit, but really, under proper treatment, it comes into bearing as early as many varieties of apple and pear, and, when once it begins to bear, it never leaves off, but continues to increase in fertility year after year for generations; for the orange far excels in longevity any other of our fruit trees. We believe there are numerous orange trees in Mr. Pye's garden at Parramatta upwards of 50 years of age still in full vigor, while on the continent of Europe there are living trees known to be several centuries old. In some of the best orchards at Parramatta, the crop of oranges has been valued at upwards of £400 per acre. Mr. Pye, some years ago, cut down a tree 40 years planted that for 20 years had yielded 300 dozens of oranges annually, and we have not the slightest doubt that equally good results may be obtained in the suitable portions of our own colony.

Those who cultivate oranges for market will, as a matter of course, grow such as will pay best, but they should certainly refrain from planting such inferior varieties as some of those offered in the Melbourne markets, which can be only grown for their productiveness, as they possess no other good quality and bring only half the price of the best varieties. Among the best market varieties are:—Parramatta Seedling, Poor Man's Orange, large and prolific, best adapted for marmalade; Siletto, Naval or Bahia, is also excellent for private use, being one of the best of oranges; St. Michael's is also suitable for both purposes; Mandarin, Emperor of China; the Blood Orange or Maltese is one of the best varieties; Teneriffe is similar in quality.—*Leader.*

MAHWA FLOWERS.—The export trade in Mahwa or or Mowha (Bassia latifolia) flowers to Europe for distillation, which attained such large proportions a few years ago, seems to have suddenly ceased. In 1884, 269,329 cwt., valued at £67,066, were shipped from India; in 1885, 30,372 cwt., valued at £6091, were shipped; now the export has stopped. These flowers constitute an important article of food among the natives.—*Gardeners' Chronicle.*

SUGAR REFINING BY LIGNITE.—The *Année Scientifique* states that M. Kleeman, of Schoeningen, has discovered a new method for purifying beetroot juice by lignite, which it appears possesses the property of purifying liquids. If pulverised lignite is mixed with a turbid fluid, or with one having a disagreeable taste or odour, a deposit is rapidly formed, and the liquid soon becomes clear and loses its bad smell. Cane, as well as beetroot sugar, may be refined by lignite, and the process is very economical. The sugars produced in this way have an agreeable taste, and the syrups completely lose their taste of beetroot.—*Journal of the Society of Arts.*

THE LARGE BAMBOO OF INDIA.—An a few days ago in the columns of the *Pioneer*, conveying a public-spirited offer from Mr. G. Jasper Nicholls, C.S., to send, at his own expense, to anyone applying a supply of seeds of the *Bambusa katang*. But probably few people not botanists appreciated the meaning of the offer. The *Bambusa katang* is not only the largest bamboo grown in India, outside of Burma and Assam, but from its habit of flowering only once in 55 or 60 years it is also excessively rare. Some specimens exist at Jubbulpore, where they are remarked by every visitor for their beauty and size; but until these should have arrived at the time for maturity and decay, in another 40 years or so, it was not known that there would be any seed procurable, in these parts of India at any rate. Mr. Nicholls, however, was fortunate enough to discover a clump in full flower recently on the banks of the Mahanadi, in Raipur, and knowing what it was, had all the seed scrupulously collected by the villagers, and in the hope of getting the tree widely distributed over Upper India, he is now offering it to the public. The *Bambusa katang* grows to a height of over 60 feet; its tall stem gives the best natural material for scaffolding and in beauty as well as size it may claim to excel all the varieties of bamboo known to the Ganges plain and Deccan highlands.—*Pioneer.*

SEED potatoes must be carefully selected if good results are to be realised. Scabby potatoes planted will yield a scabby crop, and disease put in the ground to grow does so while the increase from the seed potato is making. The "cheap and nasty" style of doing things in agriculture, as in many other industries, is not the most profitable.—*Planter and Farmer.* [Do the natives of Ceylon ever select seed in their agriculture? and has any one cultivator appreciated the pedigree principle? A good sweet potato is excellent: a bad one most ditasteful.—ED.]

HANDSOME TREES.—We have been informed of an atrocious piece of vandalism which merits condign punishment, if only the barbarous or malicious perpetrator or perpetrators of it could but be discovered. Two grand specimens of that beautiful ornamental shade tree—*Calophyllum inophyllum*—have been seen and admired for years past on the Cardwell beach by all who have gone on shore there, and the tree although indigenous to Northern Queensland and India is very rarely to be seen in this colony and does not take kindly to more southern latitudes. Old residents of the place take a great pride in these handsome trees, and they have deservedly been looked upon as being among the "lions" of Cardwell. To our astonishment we are informed that one of these trees has fallen by means of the woodman's axe, and that the remaining one is in danger of spoilation if not annihilation. The Divisional Board of the place say they have no control or responsibility in connection with the matter, and the entire population of the place is in arms against the spoiler; but the deed is done and cannot be undone, and unless power is granted—or exercised by those possessing it—to prevent the evil going further the remaining tree is as likely to disappear before this nineteenth century vandalism as has the other. The tree takes its name from its extremely beautiful foliage, the leaves being oblong with a rounded apex and fully six inches or more in length. It is known as a timber tree of considerable value, and often grows to the height of 100 feet in India, the wood being reddish, with a darker coloured heart-wood, and is moderately hard and close-grained. The seeds yield a dark green strong-scented oil, which is used in India for burning and also medicinally. Surely there are authorities in Cardwell who have sufficient powers vested in them to prevent and punish such outrages, and to allow such vandalism to pass unnoticed, unchecked and unpunished is, [illegible] disgrace to the colony and to nineteenth century [illegible] civilisation.—*Planter and Farmer.* [The tree alluded to, (mentioned recently in our columns, with reference to some fine specimens, recently in blossom, now in copious fruit in the Colombo General Cemetery,) is not, by any means valued as it ought to be as a shade and ornamental tree. It is one of the few trees which flourishes in the salt-laden sea-breeze.—ED.]

CEYLON LEATHER.

A London correspondent, writing by a recent mail, says that he finds it extremely difficult to satisfactorily account for the fact, that, while nearly every other description of Ceylon produce receives due appreciation in the London market, and fetches a price exceeding that of similar articles sent from other countries, the leather exported from this colony always realizes something below the rates obtainable for that sent from India and Rangoon. Strictly speaking, perhaps, we should have used the term "hides" in making this comparative statement. It may, however, be well understood, for of course, we do not export leather in its finished state as such. But why, he asks, can it be that buffalo hides sent from Ceylon as the rule only secure rates at the public sales something below those obtained for such as are sent from the countries abovenamed. He had heard it alleged that the quality of the hide may suffer from the fact that nearly all our island buffaloes, or a very large proportion of them, are pastured on the salt grounds on our coasts. Such pasturage as they obtain there, is no doubt to a very large extent subjected at certain seasons to the inroad of tidal waters; but then we may feel sure that even as regards India and Rangoon a very considerable number of the animals from which the hides exported thence are obtained, have similar feeding grounds.

This reason, therefore appears to us to be hardly a possible solution of the question. Indeed it would almost seem as if the effect of salt in the feed must go some way towards preparing the hides for subsequent treatment. We certainly do not see how it can exercise any prejudicial effect. Another reason suggesting itself is that the Ceylon shipments are greatly less in quantity to those made from competing localities, and buyers never bid so freely for small parcels as they do for considerable quantities of any description of article. But, apart from these two guesses, our correspondent feels there must remain some hidden cause which has not yet seen the light. As we have said, Indian and Rangoon or Moulmein hides top the market in competition with Ceylon; but again, Italian buffalo hides beat all others. The Italian buffalo leather, indeed, has a very marked pre-eminence in London sales. A friend of our correspondent once purchased a travelling trunk in Naples covered with this hide. That purchase was made 22 years back and he is assured that, notwithstanding the wear and tear of repeated overland journeys to and from India to which that trunk has been subjected, it is as sound and as serviceable as ever. Now there must be some reason quite apart from any natural peculiarities in the animal itself or from any circumstances arising out of the character of its feeding grounds, to account for the exceptional preference shown by buyers at home for Italian hides. It would make a considerable difference in the value of this article of our export list if any defect now present in our hides could be properly overcome. In respect of bullocks, we know that the scarifying and scoring of marks on their cattle by the Sinhalese not only disfigure, but greatly destroy the value of the hides, but this would not apply to buffaloes.

We are inclined to suspect that, after all, there may be difference in the character of the treatment by which the hide is prepared for shipment after having been stripped. All those who have prepared the skins of beasts that they have shot know how comparatively difficult it is to do this with efficiency if any time is suffered to elapse before the skin is pegged down after death. It would not be the first occasion by many in which our products have suffered in reputation for want of proper curing. There is an art undoubtedly in the preparation of hides as in any other form of preparing produce for sale, and, if our brethren in India, or the natives of Italy, possess and practise superior methods to ourselves, we can understand why London buyers give their skins the preference. The vast acreage of land which is available in Ceylon for the rearing of herds of buffaloes makes it desirable that an industry so suited to the instincts of a very large proportion of our native population should be fostered as much as possible. Can any of our readers give us information on the subject? Many of them have travelled in India or have visited the Straits Settlements, while not a few have spent some time in Italy. Were we able to make a comparsion of the various methods of curing adopted in those several countries with that in vouge in Ceylon, we should perhaps be able to arrive at a solution to our query.

All that bears upon means of improvement for our island industries ought to possess a great interest for every intelligent member of the community. As we have said, in many matters of the kind Ceylon has gone ahead of all competitors. When, therefore, we see that in one particular article of export she is lagging behind such competition, it behoves us to do our best to set the matter right. Is the question we have raised one arising out of natural disqualification, imperfections of breed, or some such agency? We strongly suspect not, and that, as artificial methods always admit of improvement, it only needs ventilation of the subject to induce those who may have some experience in the matter here and elsewhere, to come forward with their suggestions for effecting the needful improvement. The matter is one indeed so closely affecting the prosperity of the people, especially in the Uva and Eastern Provinces, that the Government might well be asked to cause enquiry to be made.

Uuca or Coca leaves in Peru have risen in price almost 15 per cent. The selling price being 1s 9d a pound, with an upward tendency. There is scarcely a months' supply of these leaves in the London market —such is the demand for cocaine.—*Nilgiri Express.*

Coffee in Southern India.—The unfavourable prespects of a month or two ago, have greatly improved since the rains began. Leaf-disease was prevalent throughout the district and was disheartening the coffee planters, but now it has disappeared and altogether indications are favourable. In the South and East crop will be as good as can be expected. Several small estates were recently sold in Ootacamund, by order of the Civil Court at ridiculously low prices. One coffee estate with a foreclosed mortgaged debt of 7,000 rupees realized 800 rupees only, and others proportionately small amounts. The continued depression in the coffee market at home prevents agents taking up the business and making advances, and for want of such assistance fine properties are lapsing into jungle. One of the Calicut firms is doing a little in the way of advances, but is feeling its way and picking and choosing. The Investment Company have taken over the business of Stane & Co. in liquidation, and the latter are setting up in the premises formerly occupied by the Cotton Cleaning Company. Their circular to their old constituents does not indicate any intention of travelling in former grooves,—*Ibid,*

CACAO: THE LONDON MARKET AND PRODUCTION.

In order to arrive at any correct appreciation of the movements in the cacao market it is necessary that the sources of demand for the product should be understood as well as the causes which lead to the fluctuations so frequently taking place in the value of the various kinds. Cacao differs from coffee in this essential, that it is used for purposes of manufacture, whilst coffee goes directly into consumption, though it may; perhaps, be urged that even if coffee is not manufactured it is considerably manipulated. Cacao is consumed by three classes of purchasers, each distinct from the other, and each having their special requirements. There is, first, the home consumption of the most ordinary description for the common flake cacao taken in very large quantities by the Government for use in the Navy, in Jails, Poor-Houses, &c., whilst the English makers of chocolates take only the lower-priced article. The chocolate-makers on the Continent are divided into two classes: those who flavor their goods with vanilla and other such substances for France and Northern Europe, and those who employ only cinnamon as a flavouring material. These latter make for Italy, Turkey, Spain, Portugual and other southern countries, and inasmuch as the lower kinds of cacao do not readily combine with the cinnamon flavoring, and more over *do* easily amalgamate with such substances as arrowroot, sugar, and vanilla, which enter into the composition of ordinary chocolates, these are in request in England and France, but not in the other countries named. You may notice that the highest-priced cacao is the Guyaquil, espceially the "Ariba" kinds, the reason being that this description is of the finest golden brown, and is of such a delicate nature as not to stand any adulterants or strong flavorings, and, as the Spaniards and Italians are extremely particular in regard to their chocolates, far more so than the French, Germans, or English, the makers for them will have none other, and do not care much about price in order to secure what they want. Ceylon cacao the most nearly of any approaches the Guyaquil description, especially in brightness of color; hence, when there is any short supply of the latter, there is found to be a stronger enquiry for Ceylon kinds of good quality. This was the case in the latter part of last year, when, owing to drought and consequent short crops in Guyaquil, shipments fell off from the ordinary average of 220,000 arrobas of 100 lb to less than one-half. The run upon Ceylon sorts, as you may remember, sent the market price over 100s. Since then, however, better times have occured, and this year it is expected the Guyaquil crop will amount to 340,000 arrobas.—London Cor. Local "Times."

CINNAMON: THE LONDON MARKET AND PRODUCTION.

After a protracted difference between the London brokers and the Cinnamon growers of your island, in respect of the holding of sales of spice, the practical men of the Lane have been enabled once more to adopt the old mode of quarterly, in perference to the ill-udged resort to monthly sales. On Monday next, the old system will be again adopted, that of selling on the last day of every third month, and so the 31st of May will henceforth be remembered as the restoration of the ancient order of things, whether it will help to restore the old scale of prices or any approach to them remains to be seen. A few days ago I had a long conversation with Mr. Kilby, of the old and well-known firm of spice brokers, whose acquaintance I had made forty years ago when First Sort Cinnamon was selling at eight shillings a pound. You may, perhaps, remember that Mr. Kilby, during the wordy contest *re* monthly Cinnamon sales, carried on for a long time, stoutly opposed the innovation on the ground that it would be detrimental to the interests of all engaged in the trade—growers, shippers and dealers. He reminded me that, in the controversy carried on upon the proposed change, he had predicted as a consequence a fall in the price of the article of thirty to forty per cent. And what has been the result? Second Sort spice was then a shilling: it is now seven pence!—a decline of quite forty per cent. In reply to my enquiry as to the effect of reverting to the old system he remarked that it was always a most difficult task to work up prices from a fall. The trade, once centred entirely in London, was now scattered over the world, and, although Ceylon still enjoyed the monopoly of the article, which no other country produces, there is a keen competition amongst sellers in various countries. Orders are now executed in Colombo for foreign houses at fixed rates, and those continental firms put their spice on the market in Competition with the London article, and so the price is lowered as well as the market. This system, added to the monthly sales, was exercising a disastrous effect on the cinnamon market. Whilst admitting his facts, I suggested that the diversion of the cinnamon trade had no connection with the change in the order of sales, but had taken place long previously, and was one consequence of the opening of the Suez canal, and it could no more be brought back to its old and accustomed channels than could that of coffee. I reminded him also of the existence of foreign mercantile firms in Colombo, who will, of course, conduct their business relations direct with their continental constituents rather than through the circuitous route of London. He, however, maintained that a proper conduct of the Cinnamon trade on the part of growers in Ceylon might be the means of raising the standard of prices to what they were five years ago. In reply to my further enquiry as to the competition of Cassia, he said he attached no importance to that; it was such a different article, and could only affect the fourth class of spice. As for the effect of over-classing cionamon, he said it was quite inoperative. The trade was not to be deceived by any such device, nor did the making up of low qualities of spice in small thin quills to resemble the finer sorts exercise the slightest influence on market prices, which depended on the intrinsic quality of the bark and not on its make up.—*Ibid.*

VEGETABLE PRODUCTS AT THE COLONIAL AND INDIAN EXHIBITION.

We propose in these notes to draw special attention to anything novel or striking in the collections of vegetable products from the several colonies and dependencies that may be likely to interest our readers.

Commencing with the West Indian Colonies, the finest collections of fruits are those of New Grenada and Jamaica. Those of the former colony are not only large and well preserved samples, but the fruits themselves are fine and extremely well grown. The Nutmegs (Myristica fragrans) are remarkable for their size as well as for the development and colour of the Mace. Here are also enormous clusters of fine fleshy Cloves (Eugenia caryophyllata), splendid Cola nuts (Cola acuminata); in the fruits, remarkably fine Liberian Coffee (Coffea liberica), Tamarind (Tamarindus indica), Bread Fruit (Artocarpus incisa), Sweet Potato (Ipomœa Batatas).

The Jamaica collection, though not such large specimens, are well preserved, and are a very interesting series. Besides many of those already mentioned are several others of considerable interest, such, for instance, as Anacacha tubers (Anacacia esculenta), an umbelliferous plant cultivated in the mountainous districts of Nothern South America for the sake of the tuberous roots, which form a staple article of food amongst the people. When boiled they are said to have a flavour between that of a Chestnut and a Parsnip. The arnatto seeds (Bixa orellana) shown in this collection are very fine and bright red in colour. As these seeds are valued for the colouring matter which surrounds them their commercial value is considerably increased by their plumpness and high colour. Arnatto seeds are imported into this country from the West Indies, East Indies, and Ceylon, besides which Arnatto paste is also brought from the last-named island, but as this commodity often reaches us in anything but a fresh state, and as it is used largely in cheese and butter-making it would be to our advantage were planters to send the seeds themselves, and of such quality as is shown in the Jamaica collection. It is,

however, only just to several of the other colonies to say, that their exhibits of Arnatto seeds are for the most part of good quality. Amongst other products less generally known are fruits of the Akee (Blighia sapida), a sapindaceous tree, native of tropical Africa, but introduced to the West Indies by Captain Bligh, of H. M. S. "Bounty" in 1793. These fruits are fleshy, somewhat Pear-shaped, but flattened on their sides. When ripe they are of a reddish colour with a yellow tinge. They dehisce by three longitudinal slits, each division containing a shining black seed partly enveloped in a white fleshy aris, which is the edible part and has an agreeable sub-acid taste, which seems to be developed only in tropical countries; those grown in hothouses here are said to have no such flavour, but to be very insipid. The collection from the island of Dominica is one of much interest, some of the exhibits being of excellent quality and unusual size; this is notably the case with the pods of the Purging Cassia (Cassia fistula), the soft, pulpy dissepiments of which is used in English medicine as a laxative, being imported from both the East and West Indies. The tree is well known in tropical and warm countries on account of its ornamental character, for which purpose, as well as for a shade-tree, it is much grown. In this court are shown some specimens of Cairo ginger in remarkably large brands, indicating, that if this quality of the ginger is equal to that of Jamaica it might be worth some attention. Antigua, St. Lucia, Tobago, and St. Vincent all make a good display, and each has many interesting exhibits which want of space alone prevents us referring to more in detail. There are also some striking exhibits from British Honduras, notably a magnificient slab of figured Mahogany, 10 or 12 feet, by about 4 feet wide. Honduras, it is well known, is a Mahogany producing country, from whence large quantities of this valuable wood are sent to England, but the dark transverse wavy lines as seen in this specimen, are exceptional in Mahogany, and if it were more frequent so as to be procurable in sufficient quantity a demand would soon be created for it for superior cabinet-work. A large and interesting collection of water-colour drawings illustrating the flora of the West Indies, by Mrs. Blake, wife of the Governor of the Bahamas, most of which are extremely well done, are displayed in the centre of the court. The whole of the West Indian division is well arranged and its general aspect pleasing, reflecting very great credit on Mr. A. J. Adderly, C.M.G., the Executive Commissioner for the West Indian Colonies.—JOHN R. JACKSON, Museum, Royal Gardens, Kew.—*Gardeners' Chronicle.*

SHADE-DRIED AND SUN-DRIED COFFEE.

NEARLY a year ago we commented on the alleged deterioration of colour in Indian plantation coffee, and endeavoured to find an explanation of the bad prices that had been realised by the previous season's crop. The numerous letters which we received about the same time from correspondents proved that planters were well aware of the importance of the subject. As might have been expected, unusual care was taken during the last season on estates and in curing establishments, and, as a result—although the season was on the whole unfavourable, owing to heavy rain in December—the account sales already to hand show, in most cases, a marked improvement, which we hope will be maintained to the end. At the beginning of crop, when everyone concerned was casting about for some means of improving his treatment of the coffee, information was received from London —so circuitous are the modes of communication between planting districts in this country—that the most surprisingly good results had been obtained by a few Coorg and Mysore planters from a new, or revived, system of drying their parchment under shade. The improvement was so marked, that some coffee done in this way realised £20 per ton better than another shipment from the same estate dried in the open. One planter, whose coffee sold for over £100 a ton, was said to have not dried it at all, but to have loaded it into carts from the pulping vats. We presume that in this case the estate was near the curing-works. The experiment strikes one as rather a dangerous one, though it has been tried, we believe, in Ceylon on estates near the railway, where coffee can be delivered at the Colombo works a few hours after its despatch. The plan, however, that is said to have answered best was to drain off the water in the sun for about twelve hours; then to dry down to about 40lb. per bushel under shade pandals; after which, the parchment could be reduced to any convenient despatching weight in the sun. The London brokers testified to the superiority of this coffee over the ordinary sun-dried, and the question arose, if it were worth while to adopt the system generally, or if the better price realised was merely accidental, and connected with the locality where the coffee was grown. The district which suffered most from the low prices in 1884-85 was Wynaad, and the Planters' Association there appointed a Committee to make experiments with a view to discovering where the fault in curing lay. The Committee's report has not yet been published, but it is understood that neither it, nor the Coast firms who cured the Wynaad crop, are able to detect any marked difference in the shade-dried over the sun-dried coffee. It may be admitted that nobody can speak with absolute certainty as yet, because the full results of the London sales have not yet reached India, and, in several cases, owing to the shortness of notice that was given, only the latter part of crops could be shade-dried; but it is worth noticing that the crop from Coorg, where the new plan was presumably more generally known and adopted, is spoken of in the brokers' circulars as very disappointing, and as inferior to last year's.

Without, however, attempting to guess what surprises Mincing Lane may have in store for planters, there are two facts which lead us to suppose that the good prices given for a few shade-dried crops last year was due to some other cause than the drying, and that it will be found unprofitable and impracticable to carry out the process on most estates. The first is, that from the time the parchment is taken from the vats till it reaches a fair despatching weight of about 35 lb. per bushel, the colour of the bean remains perfectly good, whether it is sun-dried or shade-dried, and nobody who has taken samples at different weights is able to perceive any difference between specimens undergoing the two processes. For peeling it is necessary to dry the coffee further down to about 28 lb. per bushel, and as it is impossible (except on an experimental scale) to accomplish this in the damp climate where the coffee is grown, it has to be done in the curers' yards. There is no doubt the colour does fade to some extent between these last weights, but, as far as experiments go, it fades in the case of shade-dried as much as in the other. Tedious as the process would be, this last reduction might be made under shade—it must be remembered that it was not done so in the cases we reffered to from Coorg—if the certainty existed of better prices being obtained, but, as far as we know, there is no evidence of this. The second objection to shade-drying is its great cost. In the ordinary process, and with fair weather, the parchment can be put into store after about three days' sun, and, on most estates, the barbecue space is only available for a quantity based on this calculation, so that even as it is, planters often find themselves a good deal hampered in rainy weather. Now, the Coorg advocates of shade-drying calculated that from thirteen to seventeen days are required for their system; hence at least four times as much room would have to be provided, and before people begin to cut out coffee to provide this, they will need some stronger assurance than they yet possess of the certainty of improved prices, and the absence of all risk, for, in a good many cases where the experiment was made last season, the shade-driers found themselves on the verge of disaster from their parchment heating.

It may, perhaps, be asked what steps may be recommended for avoidance of the repetition of the low prices realised in 1884-85. To a great extent,

doubtless, the difficulty is one that planters can grapple with without going much outside the ordinary groove. As we have said above, a great improvement is already visible in prices from the extra attention paid to curing this year. It is presumed that this will continue to be given in future seasons, and that whatever improvements may be possible will be made in buildings. Coffee should not be kept longer on estates than is absolutely necessary; it is often so kept in order to avoid sending small quantities down to the coast, as it is considered more convenient for the curing firms to receive a large consignment. But coffee kept amidst the alternating heat and wet of the planting districts would seem almost certain to deteriorate. The questions of manuring and shade, which have been persistently dragged into the controversy have, most probably, nothing to do with the question of colour; they are important in themselves, and cannot be too much attended to by planters; but a study of the prices realised in 1884-85 show that in some cases parchment from semi-abandoned estates commanded as high prices as that from highly-manured and well shaded ones. Shade and manure are two of the chief factors in making an estate pay now-a-days, but the colour of parchment has nothing to do with them.—*Madras Mail.*

AGRICULTURAL EXPERIMENTS.

At the present time much attention is being directed to the subject of agricultural experiments, and several county societies are organising various schemes with a view to verify or disprove the teachings of Rothamsted and Woburn, as regards their particular localities. Thus the Norfolk County Society are going to experiment on root crops; the Yorkshire Agricultural Society are following in a similar line; whilst the Bath and West of England have induced a large number of their members, in different parts of their extensive country, to go in for what we trust may prove most valuable work. At such a time, then, it may interest som of our readers to hear what have been the results of the work of the Sussex Association for the improvement of agriculture in 1885. It will be remembered that this association was formed a few years since, partly in order to test the correctness of results obtained by Professor Jamieson in Aberdeenshire as to the comparative effects of finely ground coprolites and superphosphate, and the question of division or dissolving in the case of steamed bone flour versus dissolved bones, inasmuch as the northern investigation appeared to indicate that the use of sulphuric acid was not only unnecessary, but actually injurious. This was indeed a result so surprising, and, if correct, having such an important bearing on future practice, that it was most important that similar experiments should be carried out under climatic conditions as widely dissimilar as possible; hence the Sussex experiments, which have been under the management of Professor Jamieson, whose opinions have naturally met with much opposition from many agricultural chemists.

The laying down of permanent pasture and the improvement of old pasture land were the subjects decided to be dealt with, as of great importance in a county where tenacious clay prevails to a large extent, and where nearly three-fifths of the entire agricultural area is occupied by pasture. Dry summers, though highly advantageous for most purposes, have not favoured the work either as regards seeding down, or applying manures to old pastures. Thus, at the Harvest Hill Station, where the experiments are on old grass, the drought prevented any beneficial influence from drainage; indeed, the undrained plots gave best results. Harrowing in renovating seeds was also a failure. Manuring, however, did good; the light and active annual dressings of manure gave better results than from the heavy and slow dressings, and from dung; and that the best results followed from annual dressings containing dissolved phosphate and nitrates of potash and soda. At this same station, a plot of the worst portion of the old grass has been ploughed out and resown, but, owing to climatic conditions, the results so far are anything but satisfactory; the plant is thin, though vigorous, and, in consequence of blank spaces, smothered with weeds. It will be desirable that this experiment should be carefully tested, because we believe that however poor old grass land is, it is capable of improvement by judicious treatment, which may include well harrowing the surface, and possibly in some cases subsoiling, rather than by breaking it out.

There are many interesting matters treated of in the report, the question of cost of different grass seeds for example. A table is given stating price per lb. and per million germinating seeds, which show that whilst catstail (Phleum pratense) costs only 3d. per million seeds, meadow foxtail (Alopecurus pratensis), which is at the other end of the table, cost 7s. 11d. per million seeds, and prices range from 2½d. to 1s. 6d. a lb., the lowest rate being that of Italian and perennial rye grass, which sufficiently explains why these grasses figure so largely in many seedsmen's mixtures. A table is given showing the cost per acre of different grasses for a full seeding of eight million seeds per acre, equal to one seed to three-quarter square inch: Phleum pratense, 2s. 3d.; Poa trivialis, 7s 2d.; Lolium perenne, 7s. 9d.; Dactylis glomerata, 13s. 4d.; Cynosurus cristatus, 19s.; Festuca pratensis, 33s.; Alopecurus pratense, 63s. 7d,

The experiments of the Sussex Society are not confined to grasses. On very poor sand at Hassocks a series of experiments are in progress, to prove the comparative durability of different manures on a rotation of crops comprising turnips, barley, hay, grass and oats. The results on the turnip crops in 1885 were as follows:—

		Weight in tons per acre.
(1)	10 cwt. ¼in. bones	12·61
(2)	15 „ dissolved bones	13·86
(3)	9 „ steamed bone flour	15·84
(4)	9 „ steamed bone and 1 cwt. nitrate of soda	16·96
(5)	1 „ nitrate of soda and 1½ cwt. nitrate of potash	5·13
(6)	10 „ ground coprolites	16·18
(7)	22 „ dissolved coprolities (superphosphate)	17·18
(8)	No manure	·53
(9)	5 cwt. bones, 3 cwt. dissolved bones; ½ „ Nitrate potash and 12 tons dung	16·18
(10)	6 cwt. steamed bone flour, ¾ nitrate of soda; ½ „ nitrate of potash, 12 tons dung	17·97

The interesting features of these results are:—First, the absolute necessity for phosphorus; secondly, the effect of ground coprolitis, and the very slight increase when they are dissolved, as seen by comparison of Nos. 6 and 7.

A subject of even greater interest is the comparative tendency to disease in the crop when treated with coprolites and dissolved coprolites, which was shown by similar experiments in Aberdeenshire, where in two plots, each 100th of an acre, that treated with coprolites contained only five diseased plants, a similar plot with superphosphate gave twenty-three diseased plants. We know that some sheep breeders have attributed increased tendency to diseases in their flocks to the use of artificial manure. It may possibly prove that, as regards one form, which contains free acid, there may be some truth in this idea. Experiments as to the comparative value of finely-ground coprolites, and similar quantities of coprolites dissolved, and steamed bones against dissolved bones, are so easily carried out, and the results are financially so important, that local societies will do well to advocate such tests. Yield of crop, proportion of disease, and chemical composition are the questions to be answered. Farmers are only beginning to understand the importance of such questions, or to have an idea of what a correct knowledge of manure, values means financially. We recently met with a

farmer who, by great industry, had studied the question and learnt the commercial and agricultural value of manures and farming on a large scale, who estimated the value of such knowledge as he possessed at a saving of fully £200 a year.

The Manchester and Liverpool Society are carrying out a series of experiments to determine the best mixture of seeds for (1) permanent grass, (2) for leys of two or three years, (3) the comparative value of different artificial mixtures on oats, and experiments on varieties of potatoes, and plots for the growth of the different grasses. Land has been provided on Mr John Roberts's farm near Chester, owned by Mr. W. E. Gladstone. The grass seed mixtures have been sown in a crop of oats, and each member of the society has been furnished with a plan of the plots and full particulars. The arrangements have been made by Mr. Robert Holland, the society's botanist; and in carrying out the details he has been ably assisted by Mr. John Roberts, the tenant of the farm, one who fully appreciates the immense importance of the work. The following extract from the report of the Experimental Committee will show the object in view:—

The committee suggest that, in addition to the practical test of grazing the permanent grass seeds next year, which the council and members may judge of for themselves in occasional visits, the society's botanist, Mr Holland, should make periodical visits of inspection, and report annually in the Journal on the quality of all the pastures, their growth in this and subsequent years, the degree in which the grasses are grazed to stock, their comparative value as pastures, their relative cost in seeding, and such other facts as would lead to a better knowledge of the best kinds and proportions of seeds to sow for permanent pasture.

We anticipate very important results from this movement on the part of local societies, and we feel sure that, if carefully and conscientiously worked out, these experiments will in time give data which will influence our practice, and lead to more economical and scientific agriculture.—*Field.*

DR. TRIMEN'S REPORT for 1885 on the various botanic gardens in Ceylon, of which he is Director, is a very satisfactory document, as such reports from our colonial gardens generally are. It contains a considerable number of meteorological observations, and describes the arrangements made to carry out the scheme of a garden at Badulla, in the new province of Ceylon, for which funds have been voted. The usual report on the distribution of plants and seeds is given, and then comes a long list of additions to the collections of plants at the various gardens, which is followed by some interesting notes on economic plants and products. Under this head he makes various recommendations and suggestions which will no doubt be of the utmost value to perplexed planters who are assailed on all sides by dangers which are only too apparent, but which it requires scientific training and investigation to combat. Thus he advises that tea and cinchona should not be grown together, as it is only in such cases that the planter's scourge, *helopeltis*, does any appreciable damage to tea. On the other hand, he thinks that the diminution in the cultivation of cacao, through dread of *helopeltis*, is unreasonable, for the insect only attacks cacao grown in the open, and not that grown under the shade of trees, for example. The Ceylon Herbarium has been arranged during the year in accordance with Dr. Trimen's "Systematic Catalogue of Ceylon Plants," and in the work of rearranging he was able to put together a series of notes describing about 250 additions to the flora of Ceylon, and 40 new species or varities. That much yet remains to be done is obvious from the fact that during 1885 fifteen additional have been discovered in the island, many of which are striking plants. The Government has approved the formation of an exhibition containing specimens of the plants, grains, &c., of the island. Like many other colonial officials, Dr. Trimen has been busy during the past year preparing for the Colonial and Indian Exhibition, where the series of woods in the Ceylon section was prepared by him.—*Nature.*

COFFEE IN CEYLON has come to a low pitch, but scarcely so low as the Editor of the "Journal of Horticulture" would make it out to be, when in writing on the "Colindies," he speaks of an average of 500,000 lb. of coffee berries being received in London from Ceylon. "Cwt" was probably meant, though of late years 200,000 cwt. would be nearer the average; but in "lb." this would be well on for 25 millions.

THE *T. A.*—A Fiji planter who has never been in Ceylon, writing by last mail, says:—"I feel I must express my acknowledgements and thanks that I have continued to receive your most valuable and practical paper most regularly. We have been for some time passing through a most trying time of depression in this colony, and it still seems very doubtful when and how any change for the better is likely to arise. Hoping however for better times yet."

ROYAL BOTANIC GARDENS, CEYLON.—Dr. Trimen's report indicates continued progress and usefulness in the gardens under his charge. A Thwaites Memorial, in the shape of an octagonal building in the ordinary Kandyan style, and modelled after a Sinhalese temple, has been erected in the garden. No rain fell in January at Peradenyia, but the total for the year was 92 inches, distributed over 146 days. At Hakgalla the rainfall was 83 inches, over 215 days. The maximum air temperature at this station was 79°, on August 31; the minimum 43°.5, on February 3. Coffee planting is steadily diminishing, but Tea has been exported very largely, and Cinchona bark also. In spite of an estimate of 70,000,000 of trees, and an acreage of 48,246 under Cinchona, Dr. Trimen counsels the further extension of planting. Caoutchouc and Gutta-percha trees of various kinds are mostly doing well; Sechium edule is mentioned as a promising vegetable, while the beautiful Carica cundinamarcensis is spoken of as "a very valuable introduction. Stewed, or cooked in tarts and puddings, it has very much the flavour of apples, and for mincemeat it is quite equal to them. It is also very good, when fully ripe, eaten raw with a little sugar." The Kumara, Ipomœa chrysorhiza has turned out very suitable for culture in Ceylon as a substitute for the Potato. A second edition of Dr. Trimen's useful Hand-guide has also been issued, with maps.—*Gardeners' Chronicle.*

THE PRODUCTS OF BORNEO.—In a report from Buinei, Borneo, it is stated that amongst the staple articles of produce, sago and gutta-pereha hold a prominent place; the planting of new lands with Sago Palm is making steady progress to meet the demand. During the year 1884 the supply of gutta-percha fell off, "but this was owing, to some extent, to the increasing scarcity of the gutta-yielding trees, which are destroyed for the sake of the immediate larger yield, and no system of planting being introduced to make up for the continual drain, the work of collection is gradually becoming more burdensome and less and less profitable. For a like reason the collection of gutta susiu, or India-rubber, shows a falling off, though in this case a rise in the market value would with less difficulty be met by an increased production. The cultivation of Gambier (Uncaria gambier) and Pepper, now amongst the settled industries of the country, do not make such progress as the resources of the jungle lands could well stand, nor do the liberal terms on which the Government are willing to make grants of land for agricultural purposes appear to attract the attention from outside which they deserve; still the production of Gambier last year was larger than in any previous year." "Rattans form another important item in the export from Sarawak, with the prospect of the trade increasing as the Baram district gets more thoroughly opened to collectors."—*Gardeners' Chronicle.*

COLOUR OF COFFEE.—There has been considerable discussion among the various Planters' Associations during the past year on this subject, but we none of us have apparently arrived any nearer the solving of this difficult problem. Shade drying was thought to be able to set the colour better: but from all accounts this is not the case, and coffee cured in this way has realized considerably lower prices than that dried in the open. It is probable that the seasons have more to do with colour than anything else.—*From Report Coorg Planters' Association.*

COFFEE.—At the late meeting of the Acclimatisation Society, the Governor, Sir Anthony Musgrave insisted very strongly on the value of coffee as an industry for Queensland. "The coffee grown here" he said "would not probably be so good in quality as Jamaica coffee, but it would make up in quantity for quality. It was a most important subject for the Government of this colony to consider." Interviewed subsequently he said that "the expenses attendant upon the construction and maintenance of proper mills was prohibitive upon small holders of land, costing as they did from £4,000 to £5,000 in initial outlay alone, but by the establishment of a large Central Mill, encouragement could be given to cultivators large and small, who could dispose of their produce much more profitably, than could be the case with sugar growers." Sir Anthony Musgrave is the owner of coffee plantations, and deserves to be listened to with attention on this subject.—*Mackay Mercury.*—[While Brazil swamps the world with coffee as it now does, the Queenslanders had better content themselves with going merely for local requirements, although we doubt if even that will pay.—ED.]

THE YIELD AND COST OF COCAINE.—Dr Squibb (*Ephemeris*, July, 1885) says the arrivals of coca leaves have been abundant, and the quality generally good. Assays of various samples gave proportions of alkaloid varying from ·38 to ·55 per cent., equal to 26·6 to 38·5 grains per lb. The latter should theoretically yield 43·36 grains of hydrochlorate, "but, although such coca has been worked, no such yield has been realised by the writer, and it is rather discreditable to have to say that not over 33 grains to the lb. has yet been reached, and this not as a general average." The price of coca leaves has been very uncertain for some time past, but it may be assumed "that good coca, giving an available yield of 33 grains to the lb., can now (June 29) be had at 50c. per lb." Dr. Squibb's calculation is, therefore, in English money:—

1 lb. coca leaves	...	...	...	2*s.* 1*d.*
Cost of extraction	...	...	...	5*s.* 0*d.*

for 33 grains, or say 2½*d.* per grain. Vial, label, and overweight in putting up brings this to 3*d.* per grain, to which he adds 2*d.* per grain for manufacturer's profit, as "such articles are not worth making unless the profit upon them be liberal, especially until the losses in acquiring a good process be fully compensated."—*Chemist and Druggist.*

LEMONS PRESERVED EIGHT MONTHS.—The following from the Sanford, Fla, *Journal* touches upon a matter of importance to fruit-growers and shippers, and should lead to experiments and tests in the direction named:—We have in our office a lemon, of common variety, that was clipped from the tree that bore it, with a number of others, in July last. It was grown by J. F. Prince on Dr. Gordon's place on Silver Lake, and, with a quantity of others—perhaps a half-bushel—was buried in the grove when clipped, as an experiment. Mr. Prince had forgotten the circumstance until a few days ago, when, while ploughing the grove, several of the lemons were upturned by the plough. Recalling the fact that he had placed them there, his surprise and gratification upon finding all of them in a state of perfect preservation can well be imagined. These lemons were buried in ordinary soil, and not under cover, and therefore have been subjected to the vicissitudes of weather, heat, cold and moisture. Query: If lemons will keep under such circumstances, why should not oranges? And if oranges can be kept thus, is not the question of the protraction of our marketing period settled? To us the lesson taught by Mr. Prince's experiment is a valuable one, if a lesson at all. It is at least a suggestion which producers should regard of sufficient significance to prompt further experiment.—*American Grocer.*—[The inference seems to be that oranges and lemons could be sent long distances packed in earth.—ED.]

HOW FOREST TREES SPREAD.—It is a wise provision, which insures the multiplication of our most valuable forest trees, that their seeds are winged, and so blown about or enclosed in nuts which are relished by squirrels and birds, and thus carried to new places. That a grove of beeches will almost always be succeeded by maples is an old saying.—*Southern Planter.*

TOBACCO IN DEVON.—It may be of interest to our readers, especially those residing in or near the county of Devon, to learn that Mr. Samuel Eliott (Lucombe, Pince & Co.) has been granted permission by the Board of Inland Revenue to make experiments in the growth and curing of Tobacco in that county.—*Gardeners' Chronicle.*

VALUE OF THE OLIVE TREE.—A gentleman, says the *San Francisco Herald*, has recently collected 12,000 cuttings of the olive tree for planting. The olive is most successfully grown from cuttings, and the 12,000 will make a fine grove. When set in an orchard in the usual form, they will cover 100 acres. An olive tree when ten years old is estimated to be worth ten dollars, and a grove of 100 acres, or 12,000 trees, will aggregate a value of 120,000 dollars. These are estimates made upon the value and profits made upon Mr. Cooper's olive trees, in Santa Barbara, and single trees elsewhere. The olive grows well throughout this region, and the demand for its fruit and oil is good and increasing.—*Burgoyne's, &c., Monthly Export Price Current.*

WARTS ON HORSES.—These excrescences are often very annoying to horses, and very unsightly, especially when occurring about the eyes. *Treatment*:—A wart having a broad base should be thus treated. Take a common suture needle and arm it with a double ligature, each ligature to be composed of three threads of saddler's twine, well waxed; pass the needle right through the centre of the wart close down to the base; tie each half separately with a surgeon's knot as tight as possible, cut the ends off pretty close to the knot, and in the course of a short time the whole will drop off. A wart having a small circumscribed pedicle may be removed by strangulation by tying a single ligature round its base. If the exposed surfaces should not heal readily moisten them occasionally with Friar's balsam, and if they show a disposition to ulcerate, sprinkle them with powdered charcoal and bloodroot, equal parts mixed.—*Ibid.*

CHINA-GRASS (BŒHMERIA NIVEA).—The frequent recurrence or re-introduction of China-grass or Rhea fibre to the notice of commercial men is a fact well known, and each time the plant is brought to notice some novel mode of preparing the fibre is announced, or some new machinery is invented. The latest of these is a patent of Messrs. Raabe, Zimmermann & Houchet, which cleans the fibre in a purely mechanical manner without any assistance whatever from chemicals. A handful of the stems of the Rhea is put into the machine at one time; they are carried rapidly through and delivered on the other side, when it is seen that the whole of the woody portion of the stems is broken and loosened, so that it is easily shaken out by again passing the partially cleaned fibre through a similar machine a second and third time; the fibre comes out quite cleaned of woody particles, and after it has been hackled it is as fine as flax, and, like flax, is of a greenish colour; the fibre, however, is in a perfectly natural state, being simply removed from its position in the stem, and after being woven it can of course be bleached like an ordinary flax fabric, or dyed if required. The inventors of this machine claim for its advantages over other machines for cleaning Rhea fibre because of its simplicity in preparing the fibre for spinning purposes by simply removing it from its position in the stem without weakening it by the action chemicals or bleaching compounds, besides which the fibre is removed from the stem in its entire lenght, which is, of course, great advantage in spinning.—*Gardeners' Chronicle.*

THE TROPICAL AGRICULTURIST, Vol. V.—Subscribers to our monthly periodical have now, we trust, received their June number, the twelfth and last of the fifth volume, with the title, preface and index. The compilation and printing of the latter necessarily delayed this month's issue, the delivery of which commenced last week. However, the first or July number of the sixth volume, will, we are glad to say, be published on its due date, and we think we may take credit—considering the drawbacks in a busy daily newspaper office—for the punctuality with which the ordinary issues of the "T. A." are supplied month by month. We can also testify to the continued appreciation of our labours both among European planters and native agriculturists: all speak of the usefulness of the "T. A." for its information and the ready reference it affords to any question arising in connection with their daily work, with the sales of produce (now stitched in separate sheets), &c. Nevertheless, our expectation that the "T. A." would come to be regarded as an indispensable part of the office furnishing on each plantation of any consequence, has scarcely yet been fully realized. The loss must be that of the estate or proprietor, more than of the printers, and in order to call the attention of agents and proprietors to the subject, we have prepared a 'circular' to be addressed to them which we reproduce here, as follows:—

We venture to call your attention to our monthly publication, the *Tropical Agriculturist*, now beginning its sixth year, and acknowledged on all sides to be the most useful and complete repertory of information for the tropical planter in the world.

It has been our aim from the beginning to put into its pages everything bearing on the practical work of the cultivators of Tea, Cinchona, Cacao, Coffee, Rubber, Palms, Fruits, Fibres, or any other of the many new and old products planted within the tropics, not only quoting discussions in our own and other Ceylon and Indian papers, but from our agricultural, scientific and general exchanges from all quarters; and by supplying a very carefully prepared index with each annual volume, to enable the planter to lay his finger on information bearing upon any plant or fruit tree, under his notice at the time.

We expected in commencing this undertaking that on every plantation of any importance, at least in Ceylon and Southern India, a copy would be filed for the use of the Manager, by order of the Proprietor or Agents. But although that has been done in a good many cases, there are a great many blanks, and now that through Tea, Bark, and other products some degree of prosperity is returning, we think it well to call the attention of proprietors to the great advantage of their Superintendents having the periodical filed and bound up in volumes on their estates. We may say that we pass over nothing we see bearing on tea planting or preparation, on improved means of dealing with Cinchona, Cacao, Rubber, &c., without placing it in the *Tropical Agriculturist*, and several experienced planters, both in India and Ceylon, have said no estate worthy of the name should be without this work of reference and information.

Mr. Thiselton Dyer (C.M.G.) of Kew, Dr. Trimen of our Ceylon Gardens, Dr. King of Calcutta, Dr. Bidie of Madras, Mr. D. Morris of Jamaica, and other similar authorities have spoken in the highest terms of its value to all cultivators: the first named stating:—

"Sir Joseph Hooker and myself always look out for the successive numbers of the *T. A.* with eagerness, and I keep a file in my office for reference. It is impossible to speak too highly of the utility of such a publication and of the way it is managed."

"It is an astonishing repertory of everything relating to the economic botany of the East."

Market reports of the sales of all produce are included in the local issues, so that tea-makers, cardamom and cacao planters and others can see what their own and their neighbours' produce has realized from month to month and year to year, as a guide and means of comparison.

We trust therefore that you will see your way to giving us an order for the *Tropical Agriculturist* to be sent and filed on each of the plantations in which you are interested, and it will be our endeavour to increase the usefulness of this Planter's *Vade Mecum* by every means in our power.

With our issue today, the Title, Preface and Index to Vol. V. of the *Tropical Agriculturist* is issued as a *Supplement*.

TEA IN AMOY, 22nd May.—Our tea manufactory has, with the commencement of the warm weather, started its operations afresh, and the former charge of 5 cents per lb. has been reduced to 3½ cents. Tea from Tamsui arrives freely, the steamers "Fokien" and "Formosa" bringing full cargoes.—*Daily Press.* [3½ cents of silver dollar equal to 7 cents of rupee?—ED. C. O.]

TRINIDAD.—The cultivation of tea, ground nuts and onions is spoken of by the Trindad *New Era* among the future minor industries of that island, That white elephant of the Trinidadians, the Government railway, is likely to be taken off the hands of the unfortunate taxpayers by a private company. This on the authority of the *New Era*, which also chronicles an accident on the line by which a guard lost his life.—*Dominica Dial.*

NATAL TEA.—I have had an opportunity of examining the samples of Natal tea that were sold this week, and give you the result of the broker's report on the parcel:—There is evidently the making of a fairly good marketable tea in the leaf, but, probably from inexperience of the maker, there was evidently a defect in the withering, and imperfect fermentation. In liquor, it came out fairly dark, but the leaf shewed up mixed brown and brown-green with but little of the fine bright coppery color of well-made tea. I hear that a Natal Tea Company is about to be floated, a small affair, but shewing how public attention and public capital is being directed towards this leaf. Next week's sales are not likely to be much above the average, though later in time there will be a fair quantity on the market.—Local "Times."

SILK.—Mr. T. Wardle, of Leck, has just returned to England from India after examining the cultivation of the silkworm and the methods in use of reeling the silk. He is satisfied that the fibre of the Indian silk was quite equal to that of Italian, and that improvement in the machinery and method of reeling was all that was required. The Indian worm, however, only spins 150 metres of silk, on one cocoon, while the more highly-tended and selected Italian worm produces 650 metres. He suggests that the Government should rear a limited quantity of cocoons, from which a careful selection of "seed" only shall be made.—*M. Mail.*

THE DEVASTATING AND PROLIFIC SPARROW.—That sentiment is not always to be trusted is seen in the ravages which rabbits have created among the crops in Australia. It was sentiment that induced their introduction, and it was sentiment that led an old Highlander to introduce the thistle, which it has cost more than one Colony thousands of pounds to extirpate, since it grew so rapidly and injured the wool with its burrs to such an extent that it had to be stamped out at any cost. Similarly, Australians complain of the humble and insignificant sparrow as a "nuisance." It was introduced in an evil hour to accentuate home influences, but has increased to such an extent that the Colonists have long been offering a reward for its head. Complaints are heard every now and then of he impossibility of keeping this pest down, and lately one man has told how in ten days they cleared his vineyard of a ton and a half of grapes, and stripped five fig-trees which had been loaded with fruit. Another has lost 30*l.* worth of fruit from a comparatively small garden. A third has had 15 acres of lucern grass destroyed, while a fourth says he had to sow his peas three times, and each time the sparrows devoured them. —*Colonies and India.* [Beyond all else the cherry crops suffer from the depredations of sparrows.—ED. C. O.]

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, June 3rd, 1886.)

A CEYLON TEA SYNDICATE: TO PROMOTE THE SALE IN NEW FIELDS.

We have much pleasure in calling attention to Mr. Rutherford's letter and draft proposal: there is nothing like "striking while the iron is hot" in order to get those interested to subscribe, and we certainly agree with the promoter that it is not a day too soon to prepare for "the 20 to 30 millions" lb. of exports which Ceylon is to show in a very few years hence. As for India, the estimate for the current season is 76 millions lb., of which at least 70 millions will be sent to Britain. When sufficient support is secured a careful revision of the draft proposal will no doubt take place and a committee and Office bearers be appointed:—

Heatherton, Ambegamuwa, Ceylon, 29th May, 1886.

The Secretary, Ceylon Planters' Association, Kandy.

Dear Sir,—To bring the suggestions which have been made in the local papers, as to the advisability of extending our markets for the sale of Ceylon teas to a practical issue, I have the pleasure to forward you the draft of a proposal I have drawn up for forming a Syndicate, under the auspices of the Association.

It has been urged by some that such a scheme is premature, as Great Britain can easily take and consume the few million pounds we send into the London market. This is undoubtedly true at the present moment, but, as this island in a few years will produce five or six times its present outturn, and there will be an increased export from India from the large areas put under tea in 1882-83, I consider that we cannot begin too soon to make the American and Canadian peoples acquainted with our teas.

If the scheme proves successful in creating a demand for our teas, and that demand be carefully fostered, a trade may spring up which will relieve us of a large proportion of our outturn, and consequently assist in maintaining a steadier price for our teas in the London market. This trade will take a few years to develop, but, should a developement take place, the demand for the tea will come to us when we shall most require it, viz., when our shipments are too heavy to be worked off in the Home market.

I place my views on the subject before you, so that you may put them in the hands of members of Committee in order that they may consider the subject before our next meeting.

To initiate the scheme a few estate names have been put down in a list herewith sent you, and these estates are prepared to give it support. I may add that the list has not been circulated in any district.—Yours truly. H. K. Rutherford.

Ceylon Tea Syndicate.

Proposal as drafted by Mr. Rutherford.

1. That a Ceylon Tea Planters' Syndicate be formed under the auspices of the Planters' Association for the purpose of pushing the sale of our teas in markets other than that of Great Britain.

2. That, as it is to the interest of growers (however small their out-turn may be) to extend the field for the sales of Ceylon teas, it is hoped that every grower of the product will join this Syndicate.

3. That members supply the Syndicate with such quantities of tea as they deem fit to foster the scheme of introduction into other countries.

4. That the Secretary of the Planters' Association be asked to become the Secretary of the Syndicate and for which work he be paid 1¼ cent per lb. of tea, which sum must cover shipping charges exclusive of Freight and Insurance. This method is suggested, so that the burden of the cost of the scheme may be evenly distributed among members.

5. That Agents be appointed in New York, Montreal, Quebec, Melbourne, Sydney and Dunedin, who have no interest in the sale of Japan or China teas. These Chief Agents to appoint Sub-Agents in the principal towns of America, Canada, Australia and New Zealand, whose business it will be to distribute the teas in small parcels and lots to grocers and private individuals.

Agents to be paid by commission on sales.

6. Teas supplied by the Syndicate to be consigned to the Chief Agents and when proceeds have been realized they are to be remitted to the Secretary who shall remit to members of Syndicate.

7. The names of likely persons or firms in America or the Colonies known to planters or Colombo merchants, who would be likely to take an interest in the sale of these teas, are requested.

8. Private parcels of tea to American or Colonial relations or friends to be sent through the Syndicate.

9. Great care should be taken by all members of the Syndicate to ship nothing but really good teas.

10. That before any shipments are made, full particulars be received from the appointed Agents of the Syndicate giving full instructions as to the class of tea required and size of packages most suitable, the quantity required to open up connections, the likelihood of success and all information which may be useful to the Syndicate.

11. Each member in forwarding tea to state to which country he wishes his teas consigned.

12. All teas before shipment to be examined, tasted, and reported on by an expert whose fees will be paid by the member shipping the tea.

List of Estates prepared to join in a Syndicate under the auspices of the Planters' Association for the introduction of Ceylon teas into America and the Colonies, should a scheme for such be sanctioned by the Planters' Association on the lines roughly sketched out by Mr. Rutherford in annexed Draft proposal;—

[Signatures to this list do not bind any one to become a member of the Syndicate should the scheme afterwards be altered and not then meet with their approval.]

Approved for the Ceylon Company's Estates, though I am not at present in a position to promise definite quantities.—(Signed) John H. Starey.

I approve of the scheme, but at present cannot say more than Mr. Starey.—(Signed) Jas. Hill, Messrs. Carson & Co.

THE COCONUT PALM AND LIGHTNING.

Sir Emerson Tennent, when noticing the various uses of the coconut palm, as enumerated by the natives, stated:—"One pre-eminent use of the coconut palm is omitted in all these popular enumerations: it acts as a *conductor in protecting their houses from lightning*. As many as 500 of these trees were struck in a single *pattoo* near Puttalam during a succession of thunderstorms

in April 1859.—*Colombo Observer.*"

Those connected with coconut estates are aware that besides the destruction of young trees by the grubs or beetles, they must lay their account to a varying but appreciable percentage of loss of trees at all stages of growth from the effects of lightning. For, these natural lightning conductors, with their tall stems covered with a generally smooth coating of siliceous matter (to the prevalence of which near human abodes, there can be little doubt, the inhabitants of Ceylon owe much of their immunity from lightning strokes), are themselves no more exempt from occasional destruction by "the electric fluid" than are artificial conductors formed of copper or other metal. Electricity seems sometimes to be generated and to be present in such abundance and such form, as not to allow of its being carried off insensibly, even by such a series of conductors as a grove of coconut palms; and then the palms, sometimes in large groups, are struck with fatal effect. On one occasion when a crash gave rise to the impression that "the sky had fallen," we felt certain that something had been struck and on going to the seashore we found seven coconut trees affected, some killed outright and others with only the edges of their branches singed. But ultimately every tree, however faintly affected, died. During the late monsoon storms, twelve fine palms, a little south of the Kollupitiya station, were struck. Five of these were practically decapitated and others were badly burnt. But some were only affected so that a slight brown colour showed on a few of the branches. Amongst these latter is a tree with a magnificent head of fruit, and this morning we expressed our fears, based on our experience, to a good native authority that this valuable tree was as much doomed as those whose vitality had been at once destroyed. He fully confirmed our opinion: the tree *must* die. Electricity is essentially mysterious in its origin, substance and action, but perhaps some reader who has studied the subject can help us to the philosophy of the curious fact we have noted. Human beings have been "struck" by lightning and suffered more or less severe injury, but have survived. Why should coconut palms, which have merely had their external parts, their foliage, almost imperceptibly singed, be as much doomed to death as those whose vital parts the fluid has permeated, the fatal result being only protracted in the one case, while it is instantaneous in the other?

PLANTING IN NETHERLANDS INDIA.

(*Translated for the "Straits Times."*)

In Banda, the freight charges to Holland weighing upon nutmeg planters shipping that spice thither have so made away with the profit, that the cultivation of that article no longer pays. Growers lose heart and from want of labour the fruit often rots on the trees.

At Surabaya, so says the local *Courant*, Chinese traders were by last advices failing continually, and business was slack. On the sugar estates crushing had begun, notwithstanding rainy weather, from further delay being costly and hazardous. The canes were looking well, and even unusually so in some localities. The price of sugar showed no encouraging sign of improvement in face of the increased quantity of beet raised in Europe.

Private advices from the Netherlands in the *Java Bode* state that the cinchona market was in a depressed condition. Business in quinine was slack as was the case also with so many other produce articles, that it is hard to say what product can be looked upon as yielding handsome profits with one exception. The lucky holders of shares in tobacco companies there get all the sunshines available to colonial planters. The same journal says that in these days of shaken confidence in business circles, there is one Java cinchona planter who in spite of the hard times, is able to report favourably on the outlook before him, though capitalists have been kept from embarking money in this line of enterprize by the recent rapid fall in the price of bark. Quinine, however, may fall lower still in value without impairing the paying character of estates with superior kinds of cinchona trees. A temporary fall in value, would indeed benefit Java growers by making the inferior Ceylon barks almost worthless. When thereby that island, now the greatest producer in the market, is driven from the field, a rise in price may reasonably be looked out for, or at least a steadiness of the market sufficient to ensure Java planters adequate profit keeping pace with continuous improvements in cultivation.

DELI NEWS.

Heavy rains have fallen throughout Deli swelling the rivers large and small, thereby bringing about more or less destructive floods, which also prevented the Races from being held at Medan on the 23rd and 24th May. The managing committee has determined upon putting them off still July, when there is greater likelihood of dry weather, Sunday the 11th July being the date provisionally fixed upon for holding them.

NEW MARKETS FOR TEA.

The question of opening up new markets for the extra outturn that in a few short years may be expected from the large area put out under tea is likely to become of sufficient importance to warrant deliberation and action on the Indian Tea Association. Hitherto the efforts made in this direction have resulted in very little that is practicable. A large quantity of tea was poured into Australia and forced on to the market by the extremely cheap rates at which it was sold. In consequence of this we are now getting three or four millions placed annually there,* but this represents but a fraction of the actual consumption of tea in the colonies, probably about one-seventh and yet we are content to court the market's favours, not by regular shipments, but by spasmodic consignments, when Calcutta prices are a little dull. Every garden now in existence should ship a small quantity regularly. It would not really matter if it showed a loss, as the quantity even if thrown away, would make no material difference in the dividend. A taste for Indian teas must be cultivated, for there is no doubt that Indian tea is not appriciated in the colonies to any great extent. Unless new markets are opened and that in a year or two, a heavy fall in prices is like to follow and it may become a panic, such as we had a few years ago. Should this take place, offers of tea to force new markets will not only be numerous, but generous in the extreme. This, however, will not be so effective as a little liberality now would be. In addition to what could be done by regular shipments to Australia, the question of opening up the markets of America is one of great importance. The effort previously made to put Indian teas on these markets was but a feeble one. Last year the annual subscription to the Association was reduced from one to half-an-anna, because there was no apparent use for a large cash balance. The amount was so equally distributed over all, that there was no hardship experienced: it might have been much better had the one anna contribution been continued, and the money employed to advertise Indian teas in America. A great deal of the success which

* Not quite two millions in 1885, so that if three millions are sent and sold in 1886, it will be well and the progress made since the fierce battle of 1880-81, may be reckoned good in the face of the powerful vested interest connected with the cheap and nasty but large profit yielding stuff from Foochow.—Ed.

Ceylon tea is achieving is due to the way their produce is brought to the notice of the public. The Ceylon people have, for instance, sent home a Commissioner to see that their teas receive their full share of attention at the coming Exhibiton.

In addition to the Colonial and American markets an endeavour should be made to push Indian teas in other directions, and none is more likely to carry off our low class teas than the native bazaars. This is a market that has never yet been practically tapped. Were the Indian Government, too, to do away with the amount of Red Tapeism with regard to Commissariat teas, they would not only receive many more tenders, but also a better article at half the money, or. at any rate, rather more than half.

It is practicallyimpossible on a tea garden to get boxes exactly the same size and sameweight,and this is required by Commissariat contracts. Why should the Government not accept the same amount of *actual tea* packed in any shaped case? instead of laying down a regulation as to the size, shape and form of the box.—*Indian Planters' Gazette.*

COFFEE, CINCHONA AND TEA IN JAMAICA.

We have been permitted to take the following very interesting extracts from the letter of an ex-Ceylon planter now in Jamaica, addressed to a friend in Ceylon. We hope to have the same privilege again or to hear direct, for it would be very interesting to learn how the "tea clearing" comes on and bears, as well as thews perience of coffee and bark. We quote as folloma:—

Jalica, 19th April.

I think at the time I wrote ast, I had not long been living on ——. Previous to that I had been living part of each week at an old coffee property. The walking and riding backwards and forwards and the moving of bedding, &c., was too much trouble and expense, and so I prepared to live a life in the bush entirely. Fortunately, I was never without an assistant and so could not be very lonely. At one time I had ——, an Oxford man, but he returned to England very soon. Then I had ——, a cousin of the two that used to be in Ceylon and at the same time ——. After the latter, ——, who is now planting tea in Ceylon. In fact, all my assistants have left Jamaica. Two hadn't enough capital to invest comfortably and the other two disbelieved in the stability of cinchona. As soon as —— left, I took sole charge of a cinchona clearing which gives me £60 a year. In July last —— came out and lived with me for three months. He was delighted with the climate of the hills and appeared sorry to have to return. As our Company were not advancing money for extension in cinchona or coffee, I applied for charge of another cinchona clearing. This place was to give me £5 per month, six months in the year. The other six months it was to be managed by one of the shareholders. As the Company had a large furnished house, in every way superior to our own, I decided to go and live there for a time, taking —— with me. So for some time my hands were full with plenty of work in supervising the three properties. This was in October and then —— said that sugar prospects being so bad and unsettled he thought if he could lease a coffee property with a good house, he ought to bring wife and children out. We had a try for Farm Hill but the proprietor would only sell and —— was not prepared to lay out any large sum. After a bit I thought of this place. I knew it had a fine house and a healthy climate and had just been put up to auction and withdrawn for want of a decent bid. We came and looked over the place and decided to make an offer to rent the house, works and coffee for £50 a year with (at first) the option of purchase at £1,000. This sounds ridiculously small (does it not ?) but then the coffee barely repays our outlay on it, of the most economical kind at present. The houseworks and barbacues must have cost £7,000 even in slavery times and they could not be erected for that now. The garden, house and barbacues cover three acres, the barbacues alone nearly an acre. The estate consists of 1,171 acres from 2,800 ft. to 5,600 ft. elevation. It has about 400 acres fine forest, 150 acres ruinate, 550 grass, scrub, &c., and 56 acres coffee, and even in this 50 odd acres are so scattered and thin that the average bearing is only 1¼ cwt. Our total crop in bushels of cherry will be under 400. I can't help smiling when I think of this *for a crop*, when I have picked more in *a day* in Ceylon. But this estate nevertheless has been a very fine one in days gone by; and I have been told on good authority that it has given its £7,000 clear profit in a year. This property was settled in the middle of last century. First as an indigo plantation and then as a coffee estate. There are trees still growing in the place nearly a hundred years old.

Want of regularly pruning and handling, constant heavy hoe weeding and general mismanagement have done their work and reduced these places to what they are now. As far as I can see from old trees growing on different plantations, the first planting resulted in as fine coffee fields as one could wish, quite as fine as the *best Haputale* coffee. But the most extraordinary thing is that this want of good cultivation does not appear to affect prices in the slightest. Last year, for instance, 138s per cwt. was touched in the Liverpool market by this property. So you see it is only quantity we want to make coffee planting in Jamaica an unqualified success and not quality. As I have shown, we have any quantity of land for coffee or indeed anything else but we want money. I confidently believe that if —— could afford to put a few hundreds into this place I could turn the money so invested to good account very soon. He is willing to do so and no doubt, will, if he can make anything out of his sugar crop. No doubt, you all work very economically now in Ceylon in these hard times, but I fancy even now, we in Jamaica, could give you a lesson or two in taking care of the pence, &c. Take this place for instance, the gross value of the crop will not exceed £335. Out of this we have to work the estate and pay every expense, you can think of, including broker's charges. Of course, salary I draw none, but work for my own interest. A Jamaica planter is contented with very small profits and how he lives, and lives comfortably too, is a wonder. I believe that tea would grow well here. We have good land with hundreds of acres of forest well situated for firewood, extensive buildings and a plentiful supply of water. The only difficult question is the labour. We have lots of people living all round us, but the men are accustomed to get 1s a day, the women 9d and the children from 4½d to 7d. Then again, we are only 20 miles from a shipping port and that as you know is not far from London. We are only five or six days from New York, three from Panama and five from Honduras. I intend planting five acres of tea for island consumption. We are protected by a very high duty 1s per lb., and no good tea can be bought here under 4s a lb. At the Government Cinchona plantation where there are some 1,000 trees or so a very good sample has been made by hand. It grieves me to learn that so many of my old Ceylon friends have been so completely ruined. The most of them I suppose ruined beyond all chance of making another start in life. The *Observer* containing that most interesting story the "Fifties and Sixties" I enjoyed

reading immensely; knowing as I did nearly all the movers in it—I often think of poor Mr. Wood and try to find out what estates he was in charge of. But even the oldest residents cannot remember. Our cinchona on —— is doing well. It is now two years and four months old. I barked one of the hybrids the other day and got 16 ounces of wet "stem" alone. But the soil in most places is very porous and soft. We had some 30 inches of rain in less than a month, 20 of it in two days and this caused slips of gigantic proportions. I measured over 50 inches of rain for the last three weeks in December 1885 at the station on the summit of the Blue Mountain Peak! Jamaica has suffered from a dry cycle for the past six years and we are now supposed to be entering the wet one. I wish the prophets may be correct, for then we shall do well with our coffee here. I have just had the pleasure of entertaining the manager of the Jamaica Railway for three days. He was very much struck with this place—think we have got it for little or nothing, and says we ought to stock it with cattle and sheep for breeding. He seems to think it would make a fine hotel for the Americans in the summer.

THE COMING PRODUCT.

King *Coffee* 's dead! We grieve for him
And mourn his short-lived reign,
For never shall we hope on earth
To see his like again.

Cinchona too once raised our hopes;
We thought we really had
A fortune, but to tell the tale
Is very, very sad,

Of how our hopes were dashed to earth,
For people will not drink
Quinine all day to make us rich,
Unreasonably we think.

And *Cardamoms* 'neath friendly shade
We tried, but oh! the price
Has fallen sadly, and we wish
We 'd never grown that spice.

And now, Queen *Tea*, our eyes are turned
With hopeful gaze to thee:
We look to thee to bring once more
Our lost prosperity.

Grow, sturdy plant! Thou carest not
For cold or cruel heat;
Soon Kaltura and Pedro's height
Will bow beneath thy feet.

Grow, sturdy plant! Our coffers fill,
Which long have empty been;
Grow on, and we will gladly own
Thee, gentle, Gracious Queen.

Grow, sturdy plant! If thou shouldst fail
To bring us timely aid,
Then must we leave fair Lanka's isle
Or droop and pine and fade.

Zulu.

"BETELNUT AS AN OBJECT OF TAXATION,"

Has been the subject of a discussion in the *Bombay Gazette* as the following letter will show:—

TO THE EDITOR OF THE "BOMBAY GAZETTE."

Sir,—It has for several years appeared to me to be extraordinary that during times when the financial prospects of the Empire are constantly in a state of crisis, it has not occurred to any of our budget-makers, financial advisers or others, to fill depleted treasuries with the produce of a just and legitimate tax on betel-nut.

It is possible that there are insuperable objections in the way of the effective working of such a tax; but I believe that these objections, if they exist, do not lie upon the surface; and I should be glad to hear them categorically stated with a view to examining their validity.

Superficially betel-nut is a legitimate object of taxation. It is a pure luxury, much more so at any rate than salt, and I consider more so than opium.

The income to be derived from a judiciously imposed tax on this article would certainly be large; and any difficulties that may be in the way of collection cannot properly be appreciated till we have heard what they are. *Prima facie* it is not easy to understand why collection should be proportionately more difficult in respect to this tax than it is found to be in other and far less remunerative departments of our scheme of Indian revenue.

As to the sentimental side of the question, the interested outcry of our native fellow-subjects would probably be as loud as it certainly would be unjust. The European official is already taxed precisely, or very nearly to the extent of the depreciation in the rupee. Since we are compelled to purchase four-fifths of the commodities and all the luxuries of our life from the English market out of a salary which bears no proportion in reality to its nominal value, nor to the value it was intended to have when salaries were fixed and covenants formed on the basis of promises having these salaries for their consideration. In addition to this we pay an income-tax which, while it produces, as far as Government servants are concerned an infinitesimal revenue, excites a wholly disproportionate feeling of hardship and discontent. As a matter of fact, I apprehend there can be no argument against the assertion that a rich native does not contribute any thing like a proportionate amount of his means in taxation to that contributed by his British fellow subject.

Touching objections theoretical or practical that may arise from the financial point of view, nothing can be said until we are in possession of more definite information. It may be that the scheme can be demonstrated on closer examination to be altogether chimerical; but it is one of such fair promise that I should at any rate be glad to see it fairly discussed.—Yours &c., C. S.

The tax would be difficult and costly to collect and would excite discontent and evasion. Betel is used by the poor to allay the cravings of appetite, and to say that it is more of a luxury than opium is sheer nonsense.

CHINA TEA AND THE CHINESE DUTIES THEREON—PRO ET CON.

It is of interest to watch the controversy in the *North China Daily News*, on this subject "K. C. Y." writes:—

It is not only the taxes levied by the Chinese in the interior, but the whole of the taxes (export duty, lekin, barrier squeezes, etc., etc.,) which I maintain will eventually cause the ruin of the China tea trade. The first principle in any trade before it can be said to be in a healthy condition is that the grower of the raw material shall get a fair remuneration for his labour. This was the motive power that caused the tea trade to assume the proportions it has already attained, and that has brought competitors into the field to share in the benefits which a generation ago were the monopoly of the Chinese. Through the short-sighted policy of China in maintaining a very high tariff, these competitors have now gained such a stronghold on many of the consuming markets that the question is at last forcing itself on the unwilling notice of the rulers of this Empire. The deterioration in average quality has not been nearly so great as the reduction in average price. The reduction in price comes out of the growers' pockets alone.

and there is consequently less and less inducement for them to give the same care and attention to the plants which they did in former years. The point has already been reached in many districts when it does not pay to plant more gardens, and if some relief does not come speedily we shall shortly hear of the tea gardens running wild, or of other crops being substituted for tea. The greater part of the money now paid as taxes would go to the grower for some time to come, and would improve his position materially. It is for this that I crave the earnest attention of all who are interested in the trade, and not with any idea that foreign buyers would reap any immediate benefit from the freedom of tea from all taxes. I want to see "a great deal more of the land and labour of China employed in growing a great deal more tea," and not that the trade should be strangled by the hands that should be the first to encourage it. In a very few years (four or five as the outside) India will be exporting its ninety or a hundred million pound, and Ceylon its fifty or sixty millions annually. With such competition we can only look for further decline in average prices, and China will not be able to adhere to the present prohibitive taxes if she wishes to hold her own in the trade. Without taxation she can produce tea quite cheap enough to meet any emergencies. One word as to possible improvement in manufacture. One of the best of the rolling machines used in Ceylon has been on exhibition for some months in Hankow, and as it meets with the approval of all who see it, we shall probably hear of others being ordered as soon as this one has been tried in one of the tea districts.

Mr. Henry Hertz of Shanghai replies :—

The theoretical view is that while the production is increasing rapidly in other countries, this is not the case in China owing to excessive duties; though I do not find it attempted to be shown even by the use of those complaisant instruments "statistics," that the trade is actually going behind. Against this I maintain, as the practical side of the matter, that we have more than a sufficiency of China tea to deal with, which I consider to be conclusively shown by the fact that it is impossible for anyone dealing largely in the article, without having resort to the ruthless process of selling by auction "without reserve," to be entirely quit of old stocks before the arrival of the new. When the day arrives that this is no longer the case, it will be time enough to think of opening the floodgates of supply by the removal of duties. In my opinion then, these act at present to some extent as a protection to the merchant, while their aforesaid removal would in a measure supply the place of a system of bounties to the producer. Not holding any brief on behalf of the latter, I prefer to advocate what I consider most beneficial to the interests of foreigners, and it was in this sense that I endeavoured to express myself at the recent meeting of the Chamber of Commerce. I was very pleased to find that my remarks on that occasion received substantial support from others well qualified to speak from experience.

"K. C. Y." in replication :—

It is not the inland taxation alone which I maintain is strangling the trade, but the whole of the taxes on tea, Export Duty, Inland Taxation, Barrier Dues, etc. It will be necessary to make tea absolutely duty free before it can be on a sound basis, and any reduction of taxation will be only a temporary relief. You state* "there is more or less loss on every pound of tea sold in London for less than nine pence." Nine pence is the equivalent of sixteen to seventeen taels duties paid, according as the estimate is made with commissions or without commissions, but everyone who has any practical knowledge of buying tea will tell you that supplies of sound common Congou continue to come forward when the price is Taels 9½ to 10, duties paid, and that they cease altogether when the price falls below Taels 9 duties paid. I therefore infer that the cost of this class of tea is between Taels 9 and 9½ duties paid. If Tea can be brought to the Shanghai market to sell at Taels 9 at 9½, fully half of which price goes in Duties and Inland Taxation, how very much better quality tea could be brought to market to sell at the same price, if free from all Taxation. Mr. Hertz and Mr. Young appear to be afraid that if taxation was removed China would swamp the consuming markets altogether, but my strong conviction is that instead of overloading the home markets with a low quality article we should be able to ship good quality tea at such a low price that it would at once command the attention of buyers and compete successfully with the produce of other countries. The export would right itself in a very short time. I should be glad if you can publish any information as to the relative cost of land in the interior of China and in India, and also give us the cost of labour in the two countries. As to comparing the consumption of 250,000,000 Chinamen with 150,000,000 Western men. I confess it is beyond my powers, but I would not mind hazarding a statement that the Western men use four or five times more Tea than the Chinamen do to make a cup and the Chinamen continue pouring hot water on the same leaves time after time whilst the Western men consider them exhausted after the first brew. Last season was a very exceptional one. The very low prices realized for first crop Teas the previous season and the unsettled state of affairs between England and Russia made Chinese middlemen very cautious. They anticipated that Russian buyers might possibly be out of the market for the season and that English houses would buy only on very low terms, but just as the season opened more peaceful news arrived and the middlemen reaped the benefit. The growers, however, suffered terribly and the first crop was some 70,000 ½-chests short of the previous season. This coming season there are unusually large preparations for making first crops, but it is yet too early to form any idea of total yield for the reason. Like Mr. Hertz I do not hold any brief on behalf of the producer, but I am desirous of seeing a fine trade put on a firm basis.

* We did not make any such statement.—Ed. *N. C. D. N.*

INDIAN TEA TRADE.

It is possible that you may have had sent to you the Report of the Collector of Customs at Calcutta on the River-borne traffic of Bengal &c. That report contains, however, remarks bearing so forcibly on the future of tea-cultivation in Ceylon, that it will scarcely be deemed to be superfluous if I give you an extract from it here. The officer named thus wrote :—

"The exports of tea have advanced, in comparison with 1883-4, by 7 per cent., with a decline in the average declared value to the lowest point yet reached, for with an increase in shipments of over four millions of pounds there is a decline in the total declared value of over four lakhs of rupees. There has been a steady extension in the production of tea, owing principally, as I mentioned in last year's report, to the opening out of new areas in Sylhet and the Dooars. These new gardens having been started as economically as possible, can produce at less cost than the older ones and make profits while the latter are losing. Prices fell heavily last year, and many of the older gardens were far from remunerative. It appears likely that proprietors will have to be satisfied in the future with lower prices than they obtained in past years, for with a large increase in production, unless the markets for it can be proportionately extended, the value of tea in the ordinary course must fall. I referred in last year's report to the growing importance of the tea industry in Ceylon, and to the competition that will ultimately be the result of the large extension of tea-growing in that island. The amount even now is insignificant compared with the exports of Indian tea, but it will increase year by year and the extension in cultivation already is said to have been from between 200 and 300 acres in 1873, to 48,000 acres in 1884. This is an enormous advance, and the production when the large available acreage, said to be from 150,000 to 160,000 acres, has been opened out and comes into full bearing will have a very sensible effect on the tea market. It has been estimated that about 70 million pounds yearly may eventually be the

outturn of Ceylon. Tea there has several advantages. First is the excellent quality of the tea produced, said to be equal to the very best Indian teas. Then an acre in Ceylon will produce half as much tea again as it will in India. The climate, too, is more to be depended on for tea growing; there is a good supply of labour, and the tea can be more cheaply shipped. Lastly, Ceylon is growing tea on our experiences and will presumably avoid our past mistakes. With all these advantages it is clear that the prospects of Ceylon tea are in the ascendent and that the expansion of tea-growing there will continue to be rapid."—*London Cor.*

ASSAM TEA COMPANY.

Capital paid up £187,160 in 9,358 shares of £20 each. Area under cultivation 7,608 acres. Directors Messrs. W. Prideaux, Chairman, Geo. Turnbull, A. B. Fisher, J. Graham, Q.C., Geo. Paton, M.D., A. Robinson, and Major-General Beadle.

The following is the directors' report to be presented to the shareholders at the annual general meeting to be held on the 7th prox., from which we gather that the cost of manufacture and bringing the tea to market in 1885 has been reduced to 9 4-5d. per lb. as compared with 10 1-5d. per lb. in 1884—a rate that still leaves room we think for further economy—while the gross sale price of the crop has increased, the average realised in 1885 having been 1s. 0⅝d. per lb. as compared with 11¾d. per lb. in 1884. The crop gathered in 1885 was 32,359 maunds or 4,030 maunds less than the Superintendents estimate, and 1,836 maunds below the outturn of 1884. The yield per acre was 340 lb —and the profit shown per acre just over £5—which as the capitalised value of the estates is but £25 per acre enables the board to declare the handsome dividend of 20 per cent. Last year's dividend was 14 per cent. It is interesting to note that 7 years ago (in 1878) the crop cost 16d per lb. and realised 21d. per lb., so that while cost has been reduced 6d. per lb. the value of crop has fallen 8d. per lb.:—To the Shareholders of the Assam Company. Gentlemen,—Your directors present to you their report of the operations of the company for the year which ended December 31st, 1885. The whole of the crop of 1885 having been sold, your directors have considered it expedient to let you know the result of the working of that year without delay, hence the earlier date at which this meeting is called. The average price obtained for the crop of 1885 is 1s. 0⅝d. per lb., being 1¾d. per lb. more than was obtained for the crop of 1884. The quantity of tea packed and dispatched from the gardens during the past season amounted to 2,588,775 lb. which is 322,425 lb. less than the Superintendent's estimate, and 146,907 less than was packed in the previous year. This short quantity was entirely caused by very unfavourable weather during the months of August and September which it is believed produced the same result in nearly all the tea plantations of Assam. The expenditure in India during the year was £99,697 12s., taking the rupee at par or £83,268 19s. 11d. after deducting the difference in the rate of exchange, being £11,803 17s. 7d. less than the expenditure of last year, and £2,119 8s. 0d. less than the Superintendent's estimate. The result for the year stands thus:—

Tea sales, gross proceeds				£138,650	16 5
Tea seed sold in India				3,480	13 10
Sundry receipts in India				1,949	3 7
Interest and Sundries				258	6 4
				£144,339	0 2
Expenditure in India in rupees at par ..	£99,697	12	0		
Less exchange.. ..	16,428	12	1		
	£83,268	19	11		
Expenditure in England	22,940	9	11		
Total Expenditure				106,209	9 10
Net profit				£ 38,129	10 4

The profit of the year therefore amounts to £38,129 10s. 4d., to which is to be added the balance carried from 1884 of £1,376 19s. 9d., making a total of £39,506 10s. 1d., out of which we propose to pay a dividend at the rate of 20 per cent, and to carry forward £2,074 10s. 1d. In January last we paid an interim dividend at the rate of 5 per cent. and the balance of 15 per cent. or £3 per share will be payable on July 1st. Mr. Phillips, our superintendent, returned to his duties in November last. He estimates the crop of manufactured tea for the current season at 2,890,200 lb., and the expenditure in India at R1,082,189. During the absence of Mr. Phillips, the superintendence of our affairs in Assam was entrusted to Mr. Newington, and Mr. Phillips has reported to us that on his return he found that Mr. Newington had performed his duties as acting superintendent to his entire satisfaction.—*H. & C. Mail.*

TROPICAL FRUITS FOR THE ENGLISH MARKET:

The West Indies at Covent-garden.

In that very useful volume entitled "Her Majesty's Colonies," issued under the authority of the Royal Commission for the Colonial and Indian Exhibition, we are told that the colony of British Guiana is suffering from the depreciation in the price of its staple product—sugar. That is only too true; but while the attention of manufacturers and other consumers in the United Kingdom is directed to its timbers, its fibres, its oils, and its gums, an enterprising shipping firm in the City has been planning and experimenting, and laying the foundation of a new export for the West Indian colonies, as well as a new trade for themselves, the development of which may, for all we know to the contrary, be the discovery of that Eldorado which the ill-fated Raleigh sought but failed to find there. In the book quoted from above, mention is made of many valuable products of the colony of British Guiana, industries which if called into existence and encouraged will largely contribute to her wealth; but no mention is made of the fruits, because when the book was written it was not considered possible to export the many fruits which flourish upon the rich alluvial deposit which forms the coast and river banks of Guiana, to the English markets, and export them, moreover, in a ripe and yet perfectly fresh condition. But steam and science have conquered the old limitations of time and space; and an old West Indian firm, Scrutton, Sons & Co., of 9, Gracechurch-street, in the City, have been the first to apply these to the development of what promises to be an important minor industry for our West Indian colonies. The competition in the sugar trade, caused by the foreign bounty system, is now running these colonies hard, and Messrs. Scrutton, Sons & Co., likewise men, have been casting about for a new trade to work with the sugar, and it is to the fruits of the colony that their attention has been directed. One of their ships was recently fitted with special chambers for the storage of the fruits, special machinery was designed and fitted up for producing the necessary temperature to preserve the cargo, and all was ready for the experiments. The "Nonpareil" "went sailing away to the West;" the "Nonpareil" has come home again, and the experiment has been successful beyond the expectations of the firm, while fruit experts who visited the steamer on its arrival expressed themselves highly pleased with the condition in which the fruit was landed. Mr. F. Scrutton came down to the *Pall Mall Gazette* office without delay, bringing with him some beautiful bananas, in fine mellow condition, and asked that a representative of the paper should be sent down to the docks to report upon the result of the ex-

periment. Next morning found a reporter going over the side of the "Nonpareil" as she lay alongside the wharf in the West India Docks at Blackwall. The steamer was discharging a cargo of sugar—the finest Demerara crystals; but it was not sugar that he had gone out into the wilderness of ships and merchandize for to see. In the captain's snug cabin, however, was Mr. Scrutton ready for an interview.

"Yes," he said, spreading out a large chart of the West Indies on the captain's locker, "I think this ought to turn out a very good thing for the colony, and a very good thing for ourselves. At any rate, our first experiment promises well, and I see no reason why we shouldn't educate English people up to a taste for bananas such as the Americans have. It is quite true, as you say, that they don't care much about them now, but that isn't their fault. They have n't had the chance of tasting real bananas yet."

"I suppose, Mr. Scrutton, the banana, like the tomato, is an acquired taste?" "Yes, that is exactly the case. Our people here have never had them long enough to get used to them. They are too poor in quality and too dear. Give them bananas both good and cheap and they will buy again, and will soon get to like them very much. Hitherto the bananas bought in England have been picked very green; they partly ripen on the voyage hitherto, but the ripening process is finished off in Covent-garden, where they are warmed up artificially in the merchants' own rooms. All this spoils the real flavour of the fruit; and what wonder, then, that the banana is not thought much of? Now the West Indian banana trade with America is assuming very large proportions. Some fifteen or twenty steamers are constantly running to the States with the fruit, and as the passage can be accomplished in six or seven days there is no need for artificial machinery. With us it is different because, with a passage of seventeen or eighteen days, the fruit, if picked when anywhere near perfection, would ripen too fast, and be useless when it arrived. The problem therefore was to devise some means of storing the fruit in a cool chamber, where all dampness in the atmosphere should be extracted, and where the ripening of the fruits should be retarded just so much as would leave it in perfect condition on arrival in the market. Our ships running to Demerara touch at Madeira on the way out, and our idea is to work a trade in vegetables—all the common greens which will not grow in the tropics—from that island to the West Indies, and then work the West Indian fruits homeward. We shall import the banana chiefly, and endeavour to popularize it, so to speak, but we hope to introduce many more of the fruits which flourish in the West Indies, but which are absolutely unknown to the untravelled Englishman. We have not brought home any large cargo of these other fruits this time; only 'sampled' them, as the Yankees say; but you shall see and taste them presently when we go below.

"There is no difficulty in getting large quantities of bananas. It is simply a question of demand, not of supply. Whereas, as in Madeira, the banana is but a season trade, in Demerara, or 'the land of mud,' as they call it, the fruit grows in profusion alongside of the sugar in the rich black mud on the coast and river banks. So if the English people want them they can have them all the year round, now that the problem of bringing them over is solved. The idea of working this trade originated, I ought to say, with our good Captain Boniface who has worked the experiment uncommonly well; but here comes the captain himself."

With this the captain walked in and joined in the conversation. A right good hearty fellow he was, a typical sea dog, with seventeen stone of geniality and salt yarns in equal proportion. Captain Boniface soon informed us that his good ship, the "Nonpareil" named, sailed out of this port about two months ago, and anchored at Madeira on the 8th of April. There the cool chambers were loaded with vegetables, cabbages, French beans, peas, artichokes, asparagus, carrots, turnips, celery, spinach, everything in the common green stuff way that you can mention, and all which fetch good prices in Demerara. Only those people who have lived for long in the tropics know what it is to hunger for a good fresh cabbage or any other green food. About ten days were spent in Demerara, and while the sugar was being taken on board our friend the captain was being towed up the creeks in a canoe by donkeys, his object being to explore the native plantations further inland. Here he selected a modest cargo of 400 banana bunches for his experiment, as nearly ripe as he thought prudent, and having selected the samples of other fruits, sailed away on April 30th, arriving in dock on Saturday last (May 29th).

"Now come below," said Mr. Scrutton, and, together with the jovial captain, we descended the hatchway into the fruit chamber. It was delightfully cool, the thermometer standing at 41 degrees. All round the chamber were racks, very much like an apple room in a country farmhouse, the greater part of the space being occupied by the bananas. A bunch of bananas in the green state in which they used to arrive was placed on the floor by the side of one of the bunches, all yellow and mellow, as they are to be imported for the future, and there could be no mistake about the improvement. In the adjoining chamber the special freezing machine fitted up by Mr. Haslam, of Derby, was at work, and here it should be stated how the temperature is managed. To put the fruit in a chamber of frozen air would quite spoil it, so the refrigerating machine is combined with a "blower," which simply drives a quantity of the outside atmosphere into a mixing chamber, tempering the frozen air to the requisite degree of coolness; then it is driven through air-holes into the fruit chamber. But inasmuch as the fruit must necessarily throw off a certain amount of moisture the air which is pumped in at one side is constantly being sucked out and re-dried at the other end, and so a continuity of coolness and dryness is preserved, and the ripening of the fruit is retarded. The captain watched the temperature very keenly every day, and regulated it according to the ripening of the fruit, and as this is the first experiment it is probable that the next supply will be if possible, in a still more perfect condition. Of the other fruits which Mr. Scrutton produced from the racks in this chamber there were several which may before long be well known in our markets, since they were all beautifully fresh and full-flavoured. There were the sapodilla, which looks like either a potato or a russet apple, and which tastes very much like a pear; the bel-apple, a nice-looking yellow pod very much like the seed of the passion flower, only larger, the pulpy seeds of which are the sweet part that is eaten; and a smaller fruit about the size of large plums, called the loquat. This fruit is very juicy and refreshing, and if imported in any quantity will certainly be in great demand. Then there were limes and pines, &c., while some strawberries were turned out fresh and cool from Madeira. Specimens of the vegetables which are taken from Madeira to the West Indies were there too, splendid cabbages of enormous weight, and tomatoes and other things. All were

in the best possible condition, and five minutes after we left the ship a Covent-garden merchant had purchased the whole of the contents of the chamber! Messrs, Scrutton & Co., now that they can bring the fruit over fresh, intend to draw the early fruits from Madeira as well, anticipating our hothouse strawberries by six weeks. Next trip they will bring 1,000 bunches of the banana, and when they have cultivated it scientifically there is reason to believe that some very fine fruit will be the result. At present, a native puts in a plant and it grows. That sums up the history of its present cultivation.

While the Messrs. Scrutton have been elaborating this idea, the Orient Company have been doing much the same thing in the way of importing fruits from Australia—there, however, they only cultivate English fruits—and so there is good reason to hope that we shall have the number of fruits in our markets largely increased and cheapened while our colonies will find a new and valuable addition to their export trade.

Indian Patents.—One of these is thus described:—Mr. George Greig, Engineer, of Harveston, in the County of Kincardine, North Britain—"A method of; desiccating air for drying purposes."—*Indian Engineer.*

Tea.—There are said to be 84 tea plantations in the Madras Presidency, covering an area of 7,553 acres, of which little more than half is under cultivation. Last year the outturn was 398,945 lb. The above are official statistics but are of doubtful accuracy.—*Nilgiri Express.*

The Old Pussellawa district is coming wonderfully to the front under tea: an experienced "V. A." in tea said not long ago that he had not seen in the island better tea of its age than a 100 acres field of about two years old on Peacock estate.

Trout in Nuwara Eliya.—We are glad to learn that the Assistant Agent of Nuwara Eliya proposes to try the experiment of introducing trout into the Nuwara Eliya lake and neighbouring streams, and subscriptions are invited to defray the expenses connected with it. The operations of reserving the young fry &c. will be conducted under the personal supervision of Mr. LeMesurier, and we are glad to learn that about R500 have already been subscribed for this purpose.

A Rack Railway, designed especially for tourist traffic, has been constructed up the sides of the granite cone of Corcovado, in the immediate vicinity of Rio de Janeiro. The mountain is 2,336 feet high; and, as it stands alone, a superb view of the grand harbour is to be had from its summit. The line starts in one of the suburbs of the city, 121 feet above sea level, and rises to the foot of the actual peak, an elevation of 2,198 feet. The total length is 4,144 yards, the width gauge 1 metre, the least gradient 1 in 25, maximum gradient 1 in 33, and maximum radius 6 chains. The steel rails are of the Vignoles pattern, 29 feet 6 inches long, and weighing 40·3 lb. per yard. The rack rail is similar to that of the Rigi Railway, and weighs 112·9 lb. per yard. The sleepers are 5·9 feet by 6·3 inches by 5·9 inches, and are of native wood. The chief works on the line are numerous retaining walls, a wooden viaduct, two plate girder bridges over deep clefts, and a wrought-iron viaduct of three spans, 426 feet long. The rolling-stock consists of two locomotives with inclined boilers, two carriages to hold 50 passengers, and two goods vans. The Tasmanian Government would do well to construct a railway of this kind to the top of Mount Wellington.—*Sydney Mail.* If the flow of tourists continues, we in Ceylon may see similar lines to the summits of Pidurutallagalla and Adam's Peak. —Ed. C. O.]

The Value of the "T. A." to Ceylon Estate Owners.—A planting correspondent wrote not long ago:—"I think proprietors should supply every tea estate with the *T. A.* The information in it with regard to everything in connection with tea &c. is invaluable: it would pay its value over and over again. Owners of estates should not leave it to hard-up superintendents to take it in."

A Hint to Planters.—Messrs. Carson & Co. are good enough to send us two samples of coffee beans packed in tin foil bags, rolled up and sealed with wax, which have been sent to them through the post from Gonamotava estate, Haputale, and they write as follows:—"The tin foil bags are very suitable for samples of coffee, &c., sent through the post; see two herewith; not the least torn. Though not so strong as parchment they are far less costly and apparently quite as safe."

Seed Oysters are being exported from Bridgeport, Conn., to England at the rate of from 150 to 200 barrels a day. The firm engaged in the business has two dredging steamers at work constantly on the beds off Southport. The seed are freed from all extraneous substances, tightly packed in barrels, and shipped via New York. By the Englishmen they are planted in the river Umber, in Brightlingsea, south of London, and at Carlingford in Ireland. The project is to cultivate the American oyster in British beds, and thus greatly increase the supply in the English markets.—*American Grocer.*

Brazil: Coffee and "Coca:" Compliment to Ceylon Tea.—We are permitted to quote as follows from a private letter of Mr. Scott-Blacklaw:—"I shall one of these days try to continue my letters on Mandioca cultivation. I have tried all I can to find some seeds of the Coca-Erythroxylon, but cannot find it in Brazil, and I know no one in Peru or Bolivia, who could send it. I shall make another effort first time I go to Rio. I have been written to from Ceylon and from India for seed. It is a pity you could not find some as it will take the place of tea and coffee, particularly of the former as a renovator of the physical energies. The leaf is shipped at Para but my friends there cannot procure me seed. It comes down the Amazon from Peru and Bolivia. I hope you are succeeding with tea. Coffee will never grow again in Ceylon. It has left it, the same as it has left the old Brazilian coffee districts. In these latter a little grows still in the shade and there are a few exceptional cases where the plantations have held out. But in the far interior where the railways have within the last few years been opened the produce is enormous and increasing in spite of shortness of labour. All our calculations as regards Brazil have come to nothing. Slaves get fewer everyday and coffee exports increase every year. Coffee has had to be abandoned in districts which combined would take in three times the area of Ceylon. It is very selfish of me to write you only when my tea is finished, the same as I accuse my boys of writing only when they want something. But really the tea was so nice. I take ill without it, now that it is done. I have kept one bottle of it in case of sickness! If the British India steamers call at Lisbon a box sent through them to be transferred to one of the Brazilian steamers would not cost so much as sending to England. I think they will book it through to Rio." What is stated about "coca" is of importance: Mr. Gordon Grinlinton at Portswood, Nuwara Eliya, has been interesting himself in this new product; we do not know if any other planters have done so?

Correspondence.

To the Editor of the "Ceylon Observer."

FIBRES AND THE FIBRE TRADE.

Paris, 14th May 1886.

Dear Sirs,—As you are so well connected with tropical agriculture, would you be in a position to get me the so-called Chinese Mulberry Bark (like post sample, I send you herewith) in large monthly quantity at fair merchantable value. If so, kindly place me into communication with some of your friends, or, if the trouble is not too great, shall be thankful to receive your personal communication on this subject. My sons, Messrs. Edgar and Gaston Heymans, established "General Merchants" at Hai-Phong (Tonkin) have not been able to procure me any from their locality. If you could find some other textile plants equally fibrous your samples and particulars shall have my very best attention and may lead to a large trade.—Yours obediently, EDWARD HEYMANS.

[Planters and others interested can see the sample sent to us at our office. The Mulberry Bark of China is of the White Mulberry (*Morus alba*), which was early introduced into Europe, and has now almost superseded *M. nigra* for the feeding of silkworms. Neither Ceylon nor India has any for export we suspect.—Ed.]

MR. JACKSON'S TEA MACHINERY.

London, 1st June 1886.

Dear Sir,—In Vol. V., page 815, a letter appears by Mr. James Irvine in which the following somewhat sweeping statement appears:—

"All our Tea Dryers in use rapidly wear and are not only costly to repair, but, as in the T Sirocco, the whole of the machine has to be taken to pieces to replace the burned plates." Will you kindly allow me to point out to your readers that there are no plates in our Victoria and Venetian Tea Dryers which come in contact with the flame, the heating surface being multitubular, and it is a well-known fact that cast-iron tubes have stood *night and day* work for five years in England, heating air to 1,000 deg. for blast furnace purposes.

Our Victoria Dryers have been at work for three years in Assam, and not a tube has burned through yet, and when last examined there was nothing to indicate the near approach of such a mishap.

Certainly none of our stoves in Ceylon or Assam have had to be replaced in any way. Our Tea Rollers in Assam are some of them *sixteen* years old and doing good work yet, and I trust I shall yet have the pleasure of saying the same of our dryers.

I should be pleased therefore if your correspondent will allow them a fair trial prior to passing judgment.—I am, dear sir, yours truly,

WILLIAM JACKSON.

THE CINCHONA BARK MARKET.

3, Crosby Square, London, E.C., 4th June 1886.

Dear Sir,—In calling your attention to the enclosed extract from the *Planters' Gazette* we would remark that if planters could be induced, for a time, to cease producing Branch Bark, which can leave little (if any) profit to them at present rates, and is to the advantage only of those who pack, carry and sell it for them, the result would be an immediate rise in the value of their better barks, a consummation which, we venture to think, would be very acceptable in these times of low prices.—We are, dear sir, yours truly,

ARMITAGE, FRY & Co.

The Market for Cinchona Bark and Quinine.

So far the hopes entertained that the present year would see an improvement in the value of quinine and cinchona bark have not been verified. Indeed the results of the last auction have revealed a level of prices previously unknown. The official quotation for bark amounts to no more than 3½d to 4½d per unit. We must go back to August and September of 1883, to find the parallel approaching such a quotation. Then however, the price of quinine was quoted at 8s to 8s 6d per oz. against 2s 6d for German tin and 3s for Howard's in oz. bottles at the present time. In both instances the primary cause can be traced to excessive supplies of bark from Ceylon, although the crisis of 1883 was intensified by the celebrated ring of quinine manufacturers, who had bound themselves under a heavy penalty not to sell the manufactured article under a certain price. The breaking up of that ring and the consequent improvement in the trade in the early part of 1884 are matters of history well known to those interested in this important branch of trade. In the present instance the low price of quinine is due to an entire absence of speculative demand in Europe and especially in America. The American demand so long looked for, showed signs of springing up in the early part of last month, but died away again immediately, some say owing to the unsettled state of the country consequent on the strikes, capitalists not caring to engage in outside speculations with an uncertain political future. In this country the iniquitous prices asked for quinine by the retail traders have quite prevented any general dissemination of the article, which people naturally supposed would be the result when a low range of prices was fully established.

Medical men can scarcely be aware of the extremely low rates ruling for quinine in the wholesale market, or they would not refrain from prescribing it on economical grounds, as too often happens. At present, as is the case with meat and bread, no one except the middle men are deriving any benefit from the unprecedented cheapness of the article. Until this matter is more fully gone into, and requisite retail competition secured, or else the preposterous charges now ruling fully exposed throughout this country, many of those in dire need of its beneficial effects are destined to be deprived of what is theirs by every right of man, through the self-seeking monopolists, who are not content with a profit of less than 150 per cent on the retail of this article alone.

The statistical position of the raw article is by no means unfavorable comparatively. January, 1886, opened with a stock of 62,217 packages of all barks, against 80,874 packages at the corresponding period of the previous year, and although the export from Ceylon shows an increase at the end of April of some three million lb. over that of the previous year at the same date, the stocks in London at that date were 63,951 packages against 78,925 in 1885, and 99,010 packages in 1884. The deliveries for the first four months of the present year amount to 21,100 packages against 18,634 packages in 1885, and 20,094 packages in 1884; the total landings for these months being 22,804 packages. It is unlikely that the present depression in quinine and bark will be of long duration. It has its origin from one or two causes, as specified above, the result of which will so re-act on both raw and manufactured articles as to curtail the supply, and so with the increased demand which time is sure to show, we may look for steady and progressive markets later on in the year. At the same time shippers should be warned of the necessity of checking their supplies as much as possible until the market has time to right itself.

INSECTS ON THE MANGO TREE.

Tattovancotty, Pallai, 14th June 1886.

Dear Sir,—I enclose in a match-box some leaves from a young mango-tree with what I believe to be the nest of some insects. I shall be obliged by your kindly ascertaining for me the cause; and, if injurious, what remedy should be used.

In a back number of the *T. A.*, a correspondent mentioned that the leaves of the kekuna, if put in a barrel and placed about a coconut plantation, would attract and kill beetles. What is the Tamil name for this plant.*—Yours faithfully,

FREDK. MORTIMER.

[Our entomological friend tells us :—" The excrescences are galls produced by the punctures made by some minute hymenopterous insect with its ovipositor in laying its eggs. The larva hatched from the eggs, reside in and feed on the galls, which increase in size with the growth of the larva—when the latter have arrived at the perfect state, they bite small circular holes through the substance of the gall, and make their escape. They do little or no harm."—Ed.]

THE "TROPICAL AGRICULTURIST" AND PLANTING IN SOUTHERN INDIA.

Naduvatum, Neilgherries, 15th June 1886.

To the Editor of the "Tropical Agriculturist."

Sir,—May I take the liberty to suggest that your valuable periodical would be still more useful to all Indian tea planters if you could see your way to add a couple of pages devoted to the account sales of *Indian* tea in London. I am sure the Indian subscribers, at least, would gladly pay an enhanced subscription for this extra. For the sake of obtaining this information I had intended subscribing to the *Indian Tea Gazette* but when I summed up the amount of information contained in a specimen copy, it seemed to me that I would be fain to comfort myself somewhat after the fashion Mr. Spurgeon recommends with regard to poor sermons when he remarked: "Though there is not much in the sermon you always have the *text*." (For "text" read "statistics"). However I thought better of *that* investment!

Perhaps you may be interested to hear of the outturn from a coffee estate in these parts which in spite of drought, leaf-disease &c., &c., gives its 20 cwt. per acre! The secret lies chiefly in *judicious* irrigation about blossom time. The cattle-manure, when applied, is not left to rot on the roots of the coffee bushes and thereby bring on a heavy dose of leaf-disease, but the "tap" is immediately turned on and very soon the manure is transmuted into a rich, but harmless, mould. The coffee bushes on this estate are never pruned, so that the bushes (or rather trees) have never been abnormally forced.

I trust to forward you copies of a rather voluminous correspondence with the Director of Agriculture at Madras, as soon as I can find the leisure.—Yours faithfully, NOVICE.

P. S.—A tremendous gale of wind here for the last forty-eight hours. Rainfall yesterday 5 inches.

June 16th.—The future lies with those planters who have had sufficient foresight to reserve a large area for grazing purposes. In many districts planters are obliged to resort to stall-feeding. On the western slopes of these hills the pasturage is unequalled in quality in the whole of India and the area is ample. A correspondent writes of miserable crops of coffee this season in Wynaad and is of opinion that cinchona will eventually be barked only once in two years in the Wynaad district.

Would it meet our correspondent's views if we gave the tea sales for Southern India, that is the Neilgherries estates, in the *T. A.*? Our South of India subscribers are numerous enough to claim this attention, but those in the North are, so far, a limited constituency.—Ed.]

* "Canarium Zeylanicum" is the botanical name but we on find no Tamil name. The Tamil name of *C. strictum* is *Kongilum marum*.—Ed.

ENEMIES OF THE COCONUT PALM:—No. I.

Pallai, 17th June 1886.

Dear Sir,—In the accompanying match-box I send you a beetle which has lately been committing a considerable amount of havoc amongst my young coconut plants, just two-and-a-half years old. Its mode of attack is to bore through the outer covering of mature leaves just below the surface of the soil, and to regale itself on the tender, undeveloped leaflets inside. The specimen sent you was extracted from a plant this morning, by means of a penknife, while it was busily engaged in its work of destruction.

Can you let me know whether it is the genuine "black-beetle" the *kuruminiya* (small specimen) of the Sinhalese or an entirely new enemy of the coconut plant? I have hitherto been under the impression that the *kuruminiya* was a much larger beetle than the one under review, and that, moreover, it was provided with a pair of formidable forceps to enable it to penetrate the tough outer coating which envelopes the heart of the coconut. The only weapon of destruction which the accompanying "varmint" appears to possess is the horn on the top of its head, which gains for him the familiar name (and the only one by which I have known him) of the "*rhinoceros* beetle."

If he really is the *kuruminiya*, could you or any of your readers kindly suggest a ready and effectual means of combating his attacks? I have been thinking of trying kerosene oil, but I see a writer in your compilation—"All about Coconuts," declares it to be quite useless in preventing the ravages of the "black-beetle." Yours faithfully,

COCONUT PLANTER.

No. II.

Pallai, 21st June 1886.

Dear Sir,—Will your entomological referee kindly oblige me with the names of the grub and beetle contained in the accompanying parcel, and also tell me whether they belong to the same, or to two distinct species? In other words; does the grub develop into the beetle? One would suppose so, as they are generally found together, nearly every decayed coconut stem containing from fifty to a hundred of the former, and one or two of the latter.

The beetle is of the same kind as the one sent you by me the other day, and which I mentioned as being so destructive to my young coconut plants. If they are allied to the grubs which are found in such large numbers, it is high time a war of extermination were carried out against the latter pest. Trusting the parcel will reach you safely, I am, yours faithfully,

COCONUT PLANTER.

[Our entomological authority states :—" The two beetles referred to in "Coconut Planter's" letters of the 17th and 21st instant are rhinoceros beetles, belonging to the family Dynastidæ, and the large white grub is the insect in its larva state. This beetle is the Kuruminiya of the Sinhalese. It does immense damage to coconut plants and trees. The natives extract them from the trees by pushing down a long wire rod barbed or hooked at the end, which transfixes the insect and admits of its being drawn out of its hole."—Ed.]

FIBRES AND THE FIBRE TRADE: THE SO-CALLED CHINESE MULBERRY BARK.

Colombo, 19th June 1886.

Dear Sir,—With reference to your note to Mr. Edward Heyman's letter yesterday, I believe that the bark referred to is not that of a real mulberry but that which is called the paper mulberry, the *Broussonetia papyrifera*, so commonly used for paper and cloth in China, Japan and the South Sea Islands. I cannot see any reference to the bark of the white mulberry having been used as a useful fibre with the exception of the one which I now send you.

Your readers will find useful articles on the paper mulberry tree in the *Tropical Agriculturist* for 1880-1 pp. 302 and 448, and I think it is to the bark of this plant only your correspondent refers. If it is now growing in Ceylon it must be as a rare plant.—Yours, W. F.

(*From Balfour's Cyclopædia.*)

"It is probable that most of the species of the genus Morus have bark of a sufficiently fibrous nature. But few, if any, seem to be turned to this useful account. Yet the bark of the White Mulberry seems from very early times to have been made into paper in China; for Marco Polo informs us that "the Grand Khan causes the bark to be stripped from those Mulberry trees, the leaves of which are used for feeding silk-worms, and takes from it that thin rind which lies between the coarse bark and the wood of the tree. This being steeped, and afterwards pounded in a mortar until reduced to a pulp, is made into paper, resembling that which is made from cotton."

NEW MARKET FOR CEYLON TEA:—THE MANUFACTURE OF GREEN TEA SUGGESTED.

Yatiyantota, 19th June 1886.

Dear Sir,—I am glad to see that the Ceylon planters have at last decided to take joint action in the endeavour to find fresh outlets for our teas, but I think the most important point is to try and stop the (now rather frequent) complaints of deterioration and falling-off in quality of our tea, as we should have little to fear from an overstocked market if we could always place teas of *uniform* good quality in the hands of our London brokers and thus secure a first place and the full confidence of the public; and the best way to effect this is to make all our new leaf (from recently-pruned bushes) *and all leaf that cannot be properly withered*) into *green tea*. The first flush from pruned bushes which is so useless for black tea makes the best green tea, usually valued at from one to two annas per lb. higher than that made from subsequent flushes, and as leaf intended for green tea is put into heated pans immediately it comes from the fields and withered in five minutes, the only two *legitimate* excuses a superintendent has to offer for making inferior teas are entirely done away with. But so long as we are compelled to manufacture *all* our leaf into black tea, we cannot hope to gain the confidence of our customers as to entirely stop the complaint. Fully one-third of our shipments are spoiled by new leaf, and who has not at times found it impossible to wither leaf well, either from the weather being too wet and cold or too hot and dry, want of sufficient space during a rush or other unavoidable causes?

It would be taking up too much of your valuable time and space were I to attempt here to prove all the arguments in favour of converting a portion of our crop into green tea, so I will content myself by merely mentioning a few of the principal points in its favour which I am prepared to discuss (either through your columns or at the meetings of the P. A.) if asked to do so, and I believe I could prove these to the entire satisfaction of all interested parties;—

1st.—That the first cost to individual proprietors in purchasing and setting up the necessary apparatus for manufacturing green teas would not exceed R50 each.

2nd.—Even should it be found necessary to abandon the enterprise through inability to find a market for green tea, the said R50 spent on the apparatus would not be entirely thrown away.

3rd.—An intelligent *black* tea maker could learn the work by two or three lessons in as many days.

4th.—The chances of finding a remunerative market for all the green tea we might have to make (in order to improve and maintain a uniform quality in our black tea, say, ⅛ our total outturn) are by no means small, and at least as good as we have of finding fresh outlets for *black* teas. All information on the above points will be supplied if asked for.—Yours truly,

OLD PLANTER.

P.S.—As another means of improving our tea (and perhaps lengthening the life of our bushes), I would strongly recommend a heavy pruning only once in 18 months instead of yearly; but more of this anon.—Yours, etc., O. P.

[America still consumes some green tea, but the great market on which the Indian planters counted in Central Asia seems now to be very limited. Pity it is that the practice of adulteration should have excited a prejudice against all green teas.—Ed.]

Java and Fiji as Sugar Producers.—Mr. Mason of Fiji in arguing for confederation and protection to colonial produce, instituted an astounding contrast, thus:—"I may tell you that at the present time labour in Fiji costs 1s 6d a day for every man, and in Java 6d. That is one of the reasons why you in London can buy sugar at the grocers cheaper than you can buy the article at the mill in Fiji."

Mr. Jackson's Tea Machinery.—The letter in another column from Mr. William Jackson the well known and very successful tea machinist, is worthy of and will doubtless receive the best attention of our planter readers. It is called forth by some remarks from Mr. James Irvine in which that gentleman failed to do justice to the solid and lasting character of Mr. Jackson's machinery, while he did not discriminate, as Mr. Jackson points out he ought to have done, between Sroccos, the plates of which are heated by the direct action of flame, and the plates of the Victoria and Venetian Driers which receive their heat from a multitubular arrangement of stout iron. Of course no material exposed to heat or friction can last forever, but Mr. Jackson is justified in dwelling on the facts that none of his stoves have as yet shown any signs of the destructive action of fire while some of his rollers are still working in Assam after a lapse of sixteen years. We are but expressing the opinion of all who have seen the Venetian Drier, when we say that it comes as near perfection, for the purposes for which it is intended, as any handiwork of man can reach. From the moment the withered, rolled and fermented leaf is put in at the top, it is not, necessarily, again touched by the human hand until it emerges below as fully roasted tea, after having fallen from one series of plates to another as the action of a handle is applied. The Victoria is a still more advanced machine and calculated to do more work in a given time, but is considerably more expensive, and a shrewd planter speaking to us on the matter of tea roasters recently, said he would rather have two Venetians than one Victoria machine; because if the one Victoria went out of order the work would come to a standstill, while even if one of the Venetians were disabled the other would be available.—We have not yet seen Mr John Brown's Tea-Dryer, which is also self-acting and highly spoken of.

"My Poultry and How I Manage Them by an Indian Henwife," * is a first-rate book of practical hints on the rearing of poultry, and being written for Indians is of more value to us in Ceylon, than English manuals on the subject. This little pamphlet of 40 pages contains eight chapters, of which subjects are: I. Houses, Sheds, &c.; II. Breeds to Keep; III. Crosses; IV. Management, Food, Cost; V. Sitting Hens, Nests; VI Hatching and Rearing of Chickens VII. Slight Ailments and some Diseases of Fowls; VIII. General Remarks and Hints.—Reading the book over carefully and weighing the directions, we note so many points of importance not generally known or understood that we feel inclined to quote largely, or better still to advise the reader to invest in a copy. In the chapter on management, the writer insists on the importance of regularity and cleanliness. We will now give a sample of the hints:—

According to season and weather the birds ought to be let out of their houses as early as possible, either into their yards or their shed; they enjoy the cool fresh morning air and almost invariably run off to drink water; therefore their trough, or tin-plate, or earthenware vessel which holds the water, having been emptied and cleaned the night before, must be filled at once with clean fresh water; do not let the fowls wait too long for their morning feed, which ought, if possible, to consist of soft food. The house or box ought then to be cleaned and scraped, perches occasionally wiped over with a rag damped with kerosine oil, grass in nests shaken up or renewed, stray feathers picked up either in yard or house, as the birds might be tempted to swallow them. If the fowls have a grass-run, so much the better; if not, grass or vegetables cut up must be freely given once a day; and, perhaps, a scanty feed of corn of some sort in the middle of the day; at that time also the water ought to be renewed, except in short cold winter days, when it might not be necessary. Shortly before the birds go to roost in the evening a good feed of sound grain ought to be given, for a long night is before these always hungry creatures. All dry grain is best given to fowls by being thrown far and wide over the ground.

Great care should be taken not to make the food too moist, only enough milk or water must be added to make it crumble: season with a little salt, and when cold or very damp with a little cayenne pepper. Potatoes or the peel only boiled soft, cabbage, turnips or any other vegetable cut up and boiled and mixed with bran, barley-meal or ground Indian-corn is excellent food; onions, chives, garlic, raw and cut up fine, then added to the above mess is most wholesome.

Where only a few fowls are kept, sufficient scraps of meat will be had from the table to supply their want for animal food; when at liberty, they forage for themselves, but in confinement it must be given, or they will fall off in condition and laying, and by-and-bye they begin the vice of feather-eating.

In summer a piece of sulphur should be put into the drinking-water; during the rains or cold weather a few drops of a solution of sulphate of iron every other day in the drinking-water is bracing and useful.

Speaking of the quantity of food required by each fowl, they say:

Four ounces, or two chittacks, of grain per diem for each grown-up bird is about a fair average of what will keep a fowl in good condition and laying order, provided animal food and green food is added on to it.

In answer to the all-important question: "can you make it pay to keep fowls"? The author gives the following calculation:—

Supposing a hen of your own rearing stands you at six months old R1-4; she begins to lay at that time, and being a fair average layer, lays in a year's time 160 eggs, value R5; you kill her and value her at the lowest at As. 8 as a table-fowl; meanwhile she has cost you a year's feeding at 1 anna per week=R3-4+R1-4 as by above=R4-8 against R5-8; you have enjoyed your eggs and the fowl on your table and you made the profit of R1 in 18 months on an outlay of R4-8, not taking house and attendance into consideration; nor, on the other hand the pleasure you derived from the bird.

But we must leave the poultry-keeper to study the book itself it he would fully understand the business of managing his birds.

The Ceylon Tea Houses at the Exhibition are thus noticed in the London letter of the *Indian Planters' Gazette*:—

I was very pleased to see at the Exhibition that the exhibits of Indian teas stand solely upon their own individual merits, and that the name of the agents appointed by the Indian Tea Districts Association to represent the Association and take charge of the Indian tea exhibits nowhere appears in connection with the display of the samples. This is in itself noteworthy, and fair-play requires that it should be known that no advantage whatever has been taken for advertizing purposes of the opportunity afforded. Whether this is due to the right feeling of the firm or to stipulations made by the Association in the contract, I know not, the fact remains, and that, so far as the industry is concerned, is the chief point. I did not enter the tea-room where Indian tea is sold in the cup, and I must therefore withhold any remarks upon that section. I did, however, avail myself of two of the Ceylon tea-houses, and this from the accident of their positions being favourable for sight-seeing, an accident which I am thereby induced to think will count for much in the patronage bestowed by the public, which will, from this happy circumstance, flow more readily towards Ceylon than towards India. This accident of situation, coupled with the excellent quality of the tea sold in the Ceylon tea-houses, is a decided advantage not to be estimated too lightly in the race for favour at the Exhibition. Ceylon has certainly luck as well as enterprise on her side. Thus, the chief attraction, so far as exhibits are concerned is decidedly the "Durbar Hall and its native artisans in the court-yard thereof." "Old London" is perhaps the next most popular detail. These two are *vis-à-vis* and at their very doors Ceylon has an attractive tea-bungalow, with tile-pictures of tea gardens set in the tile wall. Here the tea is excellent and served by Sinhalese "boys" in their native costume. An old ruddy Falstaffian John Bull hailing from northern latitudes, sitting at a neighbouring table, felt sorely taken in, when, having been supplied with his tea-pot and regulation three biscuits, light as snow-flakes, he found that "bread and butter," "buns," &c., were not to be had on any terms, biscuits being the only edible provided at these tea-houses. At these biscuits he looked askance: his massive fists had no grip sufficiently delicate to raise such trifles without pulverizing them ere raising them from the plate, and he knew it, and refrained from the attempt, looking at them from time to time between the sips and cooling puffs blown from his porcine cheeks, as though he should like to take "them things what they give him for his 'tea' and naught else" home to his family hearth and frame them as mementoes of "the ceremony at which he saw the Queen and all the Royal family, and them things too is all them there Londoners' appetites is fit for at tea-time!" Doubtless, like the rest of us, he sometimes judges by solitary experiences. He had been there a quarter of an hour when I left but he had not in that time made up his mind as to how he could get them into his hat without crushing them into dust, but he did want to take them away badly, even the elephants on Scindiah's gate-way saw that. Again, outside in the grounds, on the most frequented walk and offering the best view of the illuminated fountains, Ceylon has a row of tea-houses as last year. The Indian tea-house, though *vis-à-vis* on the opposite side of the grounds and offering perhaps almost as good a view, is not stumbled upon in the ordinary course of a visitor's walk and has to be almost searched for to be found. More Indian tea-houses are required, and perhaps may be in preparation, though not yet opened.

Coffee Crops in Coorg.—Mercara, 21st June—The prospects in Coorg for next coffee crop are poor and I doubt if it will be much over half the last. Rain in South Coorg fell early but the result have not been satisfactory. In North Coorg it fell late but after the blossom came out showers damaged it. So altogether planters have made up their minds to make the best of it by practising economy as far as consistent with fair cultivation.

The Market Value of Tea Property in India.—In the Report of the Dooars Tea Company the astonishing fact is mentioned that an estate consisting of 2,200 acres of excellent tea land, 400 acres of which were under tea of the best quality, had been offered to the Company for £6,000, or little more than £2 10s per acre! As mere forest land, the place would be cheap at this rate. The place must surely be unhealthy and the labour supply difficult to keep up.

Quinine Production.—We learn from a home contemporary that "there are now seventeen quinine factories in the world—six in Germany, four in America, three in France, two in Italy, and two in England. The annual production amounts to about 2,250,000 ounces." We believe this must be under the mark. As regards "Dutch Quinine," the *Chemist and Druggist* states:—

"The shareholders of the Amsterdam Quinine Works met on April 30th last to consider the position of the company, and to hear the annual statement referrring to the course of the business in 1885. The accounts show an absolute loss of over 40 per cent of the paid-up capital; and under these circumstances the shareholders were asked to decide as to the continuation or winding-up of the concern. No decision was arrived at, and the meeting adjourned pending the result of certain negotiations now being carried on by the board of directors."

From the *British Trade Journal* we quote:—

"Several Amsterdam firms have petitioned the Dutch Minister for the Colonies in favour of increasing the number of Government auctions of cinchona bark from two to eight per annum, in order that Amsterdam may be better able to compete with foreign markets where regular sales are held."

A Ceylonese Student at Cirencester.—It is interesting to learn of the progress of Mr. Drieberg, junior, of Colombo, at the Royal College, Cirencester. He entered there in September last, after taking his B. A. degree at Calcutta, where he was a student both at the General Assembly, and Presidencye College. Mr. Drieberg intends taking the full coursd at Cirencester of 2½ years, and also the diploma of the Royal Agricultural College, London. From the "Class and Prize list and Diplomas for the Spring Session 1886" (at Cirencester) we learn:—

The following deserve Honourable Mention:—(Qualifying marks 2,250), Dricberg, 2,279; Agriculture.—600 Marks, Class 1 B., 7 Drieberg, 498; Farm Journal, Class 1 B., Drieberg, Highly Commended; Class 1 B.—Mineral, 6 Drieberg 459; Chemical Manipulation, Drieberg, Very Highly Commended; Book-keeping 300 marks, Class 1 B., 4 Drieberg, 282; Class 1 B.—Pneumatics, 1 Drieberg, (Hon. Cert.), 291; Class 1 B., 8 Drieberg, * 237; Class 1 B.—Mensuration, 9 Drieberg, 222. Veterinary Medicine and Surgery.—300 Marks, Class 1 B., 8 Drieberg, 217; Practical work at the Veterinary Hospital and Hospital Journal. Class 1 B., Drieberg, Commended. The following have passed the Preliminary Examinations for the Diploma of Membership in their respective Classes in order of Merit:—Class 1, Drieberg.

Mr. Drieberg ought certainly to come out well-bualified for practical work in Ceylon or any other colony.

* Has still to pass in identification of Fossils.

Good for Coconut Oil.—Some comparative experiments, conducted under the superintendence of the Hydrographic department of the United States Navy, as to the efficacy of oil in calming heavy seas, are reported to have demonstrated that the use of mineral oil for the purpose is not to be recommended, but that the importance of carrying a supply of vegetable or animal oil, to be used in emergencies, cannot be over-estimated.—*Pharmaceutical Journal.*

Esparto from Almeria.—In consequence of the increased use of wood-pulp in the manufacture of paper, the export of Esparto from Almeria to Great Britain has decreased, the amount shipped last year being 12,000 tons and the average price £5 5*s.* per ton free on board. From Oran and other African ports large shipments of Esparto were, however, made. —*Gardeners' Chronicle.*

Indian Labourers in Mauritius.—*Commercial Gazette* discussing a question of the wages, writes:—By all means let men be paid the full current value for their labour—but no more; and, in the purchase of that labour, the Director of the Botanical Gardens, who is the best judge of its value, should be left to decide what it is worth. We are pleased to see that His Excellency the Governor pledged the government to adopt the course here pointed out. We cannot, however, agree with His Excellency that a coolie drawing R240, or even R192 a year, can be correctly called a *poor* labourer. Compared with an English, Scotch, or Irish labourer we should call him a rich man. By preference he elects to live upon a handful of rice; whilst his clothing consists of a pocket handkerchief and a gunny bag. Shoes and stockings he wears none, and his laundry expenses do not amount to much. He has, or might have a respectable deposit in the Savings Bank, or, if he has not, he has most likely a respectable sum buried under the mud floor of his hut. Our envy was excited only the other day by the sight of thirty good sovereigns worn as a neeklace by an Indian lady whose clothes would have borne—washing! By all means let these people be paid the full value of their labour whether that value be high or low. But let us not talk of them as "poor" people when their earnings are, relatively speaking about three times the amount which Europeans receive both for manual and brain work

Kapok.—A short notice regarding the cotton, known as "Kapok" in Java, appeared in the proceedings of the Horticultural Society of India for Nov. last, since when Dr. Baumgarten of that place was addressed on the subject as there seemed some obscurity as to the name of the tree yielding it; he writes as follows—"Enclosed, I send you seeds of the Kapok tree, and some of the Kapok itself, though the plant grows everywhere in India, especially in Bengal. The quality of the cotton is much superior here, though, and I attribute this to the greater heat of our dry season. The Latin synonyms are Gossampinus alba, *Humboldt*; Bombax petandrum, *Linnæus*; Eriodendrum anfractusum, *Decandolle*. The Kapok in only used to fill up mattresses, chicks, etc. So far as I am aware there is in the whole of Java no Kapok plantation. In each village there are some trees, the fruit of which is sold by the natives for one rupee per thousand. When cleaned the price is R30 to 50 per picul (*i.e.*, 130 English pounds) the price is now very high, but I don't doubt it will rise more when the use is more known. Several people here tried to make from the Kapok tree a culture, but all attempts failed, the cause of which must be sought in the enormous salaries." [We learn that the Ceylon trade which had grown to be of some importance to natives and others in the Colombo and adjacent districts is in danger of being superseded by the cheaper supplies which can be got from Madras, Bombay and Calcutta.—Ed.]

THE COLONIAL EXHIBITION.

British Guiana,—The collection from this colony is closely contiguous to that from the West Indies. The entrance to the court is flanked on either side by magnificient squared trunks of green-heart (Nectandra Rodiæi) and Mora (Dimorphandra Mora, better known as Mora excelsa). The first of these is one of the tallest of the forest trees of the Guiana forests, growing in clay soil near the rivers and creeks. Logs, it is said, can be obtained from 18—24 inches square and 70 feet long. Greenheart is one of the most durable woods known, and it is one of the eight first-class woods at Lloyds. It is used for ship's keels, and other timbers for house framing, mill timbers, wharves, and, indeed, for almost every purpose where great strength and durability are necessary. The bark is well known in medicine under the name of Beeberu bark, and is the source of the alkaloid Beeberine, which is used as a tonic and ferbrifuge in place of quinine. The seeds are also used medicinally by the natives in cases of diarrhœa, and when ground mixed with other meal are used as food in times of scarcity. The Mora is an extremely strong and durable wood, and is not only used extensively for outdoor work and ship-building, but also makes good durable furniture, though somewhat too heavy for ordinary kinds. Several varieties of the trees are known in different localities, each having a distinct name. The tree grows to a height of 200 feet, and logs can be squared 24 inches. The bark is used medicinally in dysentery and also for tanning, and the large seeds are ground to a meal, ond mixed with Cassava as an article of food.

Besides the two woods here mentioned, which are the principal timbers of the British Guiana forests, there are many others of very great value, the botanical source of a large number of which is unfortunately still unknown. An excellent collection of some seventy-eight samples of the woods of the colony are exhibited by Messrs. Park & Cunningham, of Georgetown, whose aim is to bring them to the notice of English cabinet-makers with a view of introducing them to the English commerce. By far the most beautiful wood for cabinet-work, however, is the Letterwood (Brosimum Aubletii), which has a reddish-brown ground and black wavy markings representing letters, or rather the marking of a leopard skin. This wood is valuable for inlaying and for making choice walking-sticks; it is hard, and takes a splendid polish. The tree is not abundant, and in the largest trees the heartwood, which is the figured part, is but small —a tree of 20 inches diameter, having only 7 inches of heart. Two telegraph poles of Wallaba (Eperua falcata), as prepared for use in Georgetown, are exhibited. These posts, it is stated, do not require treatment with tar or other preservative, and last from fifteen to twenty years, even when placed in marshy situations where they are surrounded with water for weeks together. The trees are very plentiful, and grow to an average height of 80 feet.

Besides woods themselves, wood products are also largely shown, notably the Woodskin canoes which the Indians make from a single piece of bark stripped from the trunks of Hymenæa courbaril, or the Locust Tree, and from the Purple Heart (Copaifera pubiflora), and C. bracteata. These canoes are sometimes made large enough to accommodate fifteen or sixteen persons.

Amongst food products of the colony, those of the bitter Cassava plant (Manihot utilissima) deserve a notice. Cassava meal, Cassava bread, and Cassareep are all fully illustrated. They are described as "very important articles in the cookery of the Indians, the former being the 'staff of life,' and the latter its sauce. Cassareep is the principal ingredient in the famous 'pepper pots,' and may be used as a sauce in European cookery." Cassareep does indeed come to this country, usually in ordinary black wine bottles, and forms an excellent adjunct to stews and hashes.

Some remarkably fine samples of Balata are exhibited. This substance, it will be remembered, has been recently treated of in an elaborate and exhaustive report by Mr. Jenman, the Government Botanist of British Guiana. It is intermediate in character between gutta-percha and india-rubber. It has very great strength, and as it does not stretch under tension it is unequalled for machine-bands and similar purposes. On the whole, the British Guiana collection is one of much interest.

Hong Kong.

This collection does not contain anything very striking from a botanical point of view. There is a good collection of eighty-six specimens of Chinese woods, which were collected and named by Mr. Charles Ford, of the Botanical Garden, Hong Kong. There is also a fine collection of the now well-known China matting, which Dr. Haast has shown is made of the culms of Cyperus tegetiformis, the varieties of designs and patterns of which are, for the most part, extremely good. The numerous applications of rattans and bamboos for a variety of articles of domestic use are also of considerable interest; besides which there is an extensive collection of Chinese drugs, a large number of which are of vegetable origin; they are, however, not in a very satisfactory condition, either with regard to the specimens themselves or their labels.—*Gardeners' Chronicle.*

ESPARTO AND DATE PALM IN TUNIS.

Consul-General Playfair has recently furnished to the Foreign Office a very interesting report of a consular tour along the coast of Tunis in October and November last, from which we abstract the following notes. Writing of Susa, Mr. Playfair says the principal articles of export are olive oil and Alfa or Esparto-grass. The trade in this latter, it is said, ought to be the most important on the coast, but it is being rapidly annihilated, owing to the unwise restrictions placed upon it by the Tunisian government. This valuable fibre is found in Algeria, Tunis, and Tripoli. It was first brought into use by Mr. Lloyd, owner of the *Daily Chronicle*, who had an establishment at Oran, and up to the present time the trade has remained almost entirely in the hands of the English. In Algeria it is encouraged in every way. Two lines of railway have been constructed to convey it to the coast. Nearly 100,000 tons a year are exported, and there is no duty whatever on it. In Tripoli also, which exports 60,000 tons per annum, it is free. In Tunis, on the other hand, the duty is most onerous, and, strange to say, not uniform at all the ports The most highly taxed is that shipped at Susa, as the fibre there is erroneously assumed to be of better quality than that of Sfax.

Referring to the Lotus of the ancients, Consul Playfair says:—"Much controversy has arisen regarding the plants which so enchanted strangers as to tempt them to desert their companions and their fatherland. The passage in the *Odyssey* (ix. 90) is as follows:—'On the tenth day we set foot on the land of the Lotus eaters. . . . Now when we had tasted meat and drink, I sent forth certain of my company to go and make search what manner of men they were who live here upon the earth by bread, and I chose out two of my fellows and sent a third with them as a herald. Then straightway they went and mingled with the men of the Lotus eaters, and so it was that the Lotus eaters devised not death for our fellows, but gave them of the Lotus to taste. Now whosoever of them did eat the honey-sweet fruit of the Lotus had no more wish to bring tidings nor to come back, but there he chose to abide with the Lotus-eating men, ever feeding on the Lotus and forgetful of his homeward way.'

"Most writers have been content to follow Shaw, generally the most accurate of observers, who identifies the Lotus with the *seedra* of the Arabs, the *jujube* or fruit of the Zizyphus. The wild variety is the common scrub of the country near Algiers, where Shaw resided; it becomes less common as we approach the south, and I neither saw nor could I hear of

the existence of a single plant in Djerba, which island Shaw never visited. No human being who had ever tasted its fruit once would care to do so again; it is not, in fact, possible for either man or animals to exist upon it. There is a cultivated variety somewhat more palatable, but still it is by no means a luscious fruit, or worthy of immortality. It seems to me unnecessary to go out of the way to search for the Homeric food; the island is covered with it at the present time; no greater blessing than it was ever bestowed by Providence on man, and no other fruit is so all-sufficient for human sustenance as the 'honey-sweet Lotus' of the ancients—the Date of the modern Arab.

"The Date of Djerba is excellent, though inferior to that of the Djerid, which is certainly the finest in the world. This latter, however, is always found abundantly in the Djerba market. As this is the first place where the Date forms the daily food of the inhabitants, at which coasting vessels from the east would touch, the fruit would naturally produce a deep impression on travellers. The wine made from the sap of the tree is as familiar as the fruit itself, and may have contributed to render the sailors oblivious of 'their homeward way.'"—*Gardeners' Chronicle.*

THE HIMALAYAN LARCH.

The Himalayan Larch (Larix Griffithii), was discovered in the Bhotan Himalaya by the celebrated botanist and traveller, Dr. W. Griffith, whose enormous collections of plants lay, for many years after his death, buried in the cellars of the old East India House in Leadenhall Street; nor was the tree known to botanists till it was re-discovered by myself in the East Nepaul and Sikkim Himalaya in 1848. It is the only Indian species of the genus, and it is a remarkable fact that Larix is the only genus of Conifers which is common to Europe and India, and which is not found in the Western Himalaya. The genera are Pinus, Abies, Picea, Tsuga, Cedrus, Cupressus*, Juniperus, Taxus, of which all but Tsuga, Cedrus, and Cupressus occur throughout the length of that vast range, the exceptions being that the first of these is confined to the Central and Eastern Himalaya, and the two others to the Western half, as Larix is to the eastern. Turning now to the distribution of the other Old World Larches, L. Europæa occupies a very narrow area, along the great mountain ranges of Central Europe, from Dauphiny to Styria, and is found nowhere to the north or south of these limits. The Siberian Larch, L. Ledebourii, has its western limit in North Russia and the Ural, reappearing eastward at intervals throughout Northern and Central Siberia, and southwards in the Altai Mountains. L. dahurica begins in the country from which it takes its name, and advances thence eastwards, and no doubt these or other species occur in the mountains of Western China. Thus there appears to be a great gap in the distribution of Larix, extending from Styria to the Eastern Himalaya, for no Larch has been found in Greece, Turkey, the Caucasus, Asia Minor, Syria, Persia or Afghanistan, but curiously enough, this interval is to a great extent occupied by Cedrus, which, commencing in the Western Himalaya, is continued on thence to Afghanistan, and reappears in Syria, Asia Minor and North Africa. When we become acquainted with the geological ages at which these genera first appeared on the globe this fact in their distribution will, no doubt, prove to be of great significance.

The Himalayan Larch (Larix Griffithii, Hooker fil. and Thompson) is a small tree, not exceeding 40 feet in height, with precisely the habit of L. Europæa, var. pendula, which it so closely resembles as to have deceived myself and others. It differs from that plant in the very large cones with very long points to the exserted bracts. It is called Sah or Saar by the Lepchas of Sikkim, and Boarga sella by the Nepalese, who informed me that it was found as far west as the heads of the Cosi river in Eastern Nepaul. It occurs only towards the heads of the valleys near the snows, many miles from the plains of India, at elevations of 10,000 to 12,000 feet, and where I first saw it it clothed old moriones; and though subsequently met with on grassy or bushy slopes, it was only when there was much rock and free drainage. The wood is regarded as the most durable of all the Sikkim Conifers, and is easily split into planks, but all of those that I met with were small, soft, white; I never saw any hard, close-grained red wood, like that of the Larch in Switzerland, which may be accounted for by the extreme witness of the Sikkim climate.

The cultivation of the Himalayan Larch in Europe has hitherto proved a total failure, at least as far as I have ascertained. I sent quantities of the seed to Kew in 1848, which germinated freely, and hundreds of plants were raised and widely distributed but in every case these succumbed, in a few years, to virulent attacks of Coccus Laricis. Repeated importations of the seed into Kew and elsewhere have met no better fate. I have often been shown L. Europæa for L. Griffithii, sometimes with the most positive assurance that the tree was received as such from Kew, but in no instance have these borne the unmistakeable cone of the Himalayan Larch.—F. D. HOOKER.—*Gardeners' Chronicle.*

* Cupressus funebris, though found only in the Eastern Himalaya, is undoubtedly planted there, nor did I see it anywhere but close to temples or monasteries.

FORESTRY.

CONSIDERATIONS PRELIMINARY TO PLANTING.—Draining should be well attended to, and every foot of wet surface rendered sufficiently dry for the growth of trees. This does not, as is erroneously believed, necessitate the drains being deep—18—20 inches in depth, and 2—2½ feet in width at the top, being usually sufficient for clay, and 24 inches to 3 feet often required for moss. Deep drains are very objectionable in plantations, and where choice can be made, rather keep closer together, and make more of them for the same outlay.

The ground should be very closely examined, surveyed, and laid off, so as to enable the planting to be done in groups—such as soft moss for Norway Spruce, clay for Oak or Beech, gravel for Scotch Fir, loam for Larch, Poplars and hard woods.

All rank herbage should be thoroughly subdued according to its kind. Whins, Broom, Brambles, and such-like may be kept down by close cutting, while Heather and rank grasses are most properly subdued by burning; and where Heath is the principal growth it is to the advantage of the young trees that the Heath be burnt at least three years previous to planting. Next to destruction by rabbits I believe more injury is done to young trees by planting them amongst rank Heather and other herbage than any, if not all others put together. I have repeatedly witnessed plantations linger for years between life and death amongst rank Heather, and could only satisfy myself as to the cause of such unaccountably retarded growth by taking up some of the trees and examining their roots, when I found them so badly rooted that a tree 3—4 feet high would almost have gone into a 4-inch flower-pot without confining the roots, for the simple reason that there were scarcely any to confine. It is sometimes the wisest and best thing to do with a young plantation in that condition to set fire to it and burn off every vestige and to plant it anew with small plants suited to the soil and exposure, &c.

Some years ago a landed proprietor in Aberdeenshire sought advice about a young Larch plantation which he observed was not thriving. The trees were all growing amongst luxuriant herbage, and not a few amongst ferns, or rather Brackens. We suspected at once what was the matter, and dug up a tree here and there to show what was the cause of the slow growth and stunted condition of the trees. It is from the lower branches that a young tree derives its principle nourishment, and if these are deprived of their vitality from any cause it follows as a natural and certain result that the whole economy of the tree's

growth is interrupted, and in many cases the plant is thrown into a state of ill-health or chronic disease. If trees were only grown in accordance with the laws of Nature there would be little or no room for complaints about insects destroying them. Trees like everything else, have their natural enemies, but a great many insects found on trees, especially of the beetle tribe, are there, not as enemies at all, but from beneficent motives, or at least to do benevolent rather than malevolent work, by putting out of existence trees already diseased, dying or dead. Paring of the turf is also a plan often adopted and highly commendable, and when burning the surface is impracticable this is the best alternative system to adopt.

Boring the ground by means of the forester's footpick may or may not be considered a preparatory work, but rather an actual part of the planting itself. Be this as it may, it is generally done before the plants are put into the ground, although it can be done afterwards, as it sometimes is, and with very satisfactory results.

Another, and by no means unimportant consideration, preliminary to planting has reference to ornamental effect in the flat, tame landscape. Mountainous and hilly ground so very naturally indicates how and what to plant, that less consideration is there required than when the surface is uniform and level. The plain, however, usually consists of more fertile and valuable land than the mountain, and therefore the area that can be afforded for planting is correspondingly less. There is, however, in the plain a compensation for this of no small magnitude, namely, every single tree so situated imparts to the landscape, an effect equal, and often much superior to, a large area on the hill. From this it is not to be inferred that the plantation on high ground is not a prominent and commanding object, and usually seen from a greater distance than a tree on the plain; but what is here meant is, that a row of trees stretching across a plain district of country, or even a small group or a single tree, adds much more to the clothed appearance of the landscape viewed from nearly the same level, than an infinitely greater extent of plantation would do in an undulating district; it should therefore be kept in mind in preparing for planting what the real and true effect will be on level ground when the trees are grown up, in comparison with what is produced in a mountainous district, and that an acre, or even a single tree on the plain, is equal to many on the mountain side.—C. Y. Michie, Cullen House.—*Gardeners' Chronicle.*

Note on Quinine Sulphate, by Dr. O. Hesse.—This is part of a highly technical controversy and we content ourselves with quoting the conclusion of the paper in the *Pharmaceutical Journal*, thus:—"Commercial quinine sulphate contains a sensible percentage amount of of hydroquinine, and that for every unit of hydroquinine sulphate a result would be obtained the same as if 0·42 per cent of cinchonidine sulphate were present. It is for this reason that the amount of cinchonidine sulphate is generally indicated too high by several units per cent by the optical method. Instances have indeed been met with in which the optical method has given data indicating the presence of some two per cent of cinchonidine sulphate in material that did not contain a trace of it. This elucidation of the subject may at least suffice to show what value is to be attached to the statements of Dr. de Vrij as to the amount of cinchonidine sulphate in quinine sulphate, so far as they are based upon the application of the optical method of examination."

Care of the Hands.—The *Scientific American* says, "There are not nearly as many secrets in hand treatment as people imagine. A little ammonia or borax in the water you wash your hands with, and that water just lukewarm, will keep the skin clean and soft. A little oatmeal mixed with the water will whiten the hands. Many people use glycerine on their hands when they go to bed, wearing gloves to keep the bedding clean; but glycerine does not agree with every one. It makes some skins harsh and red. These people should rub their hands with dry oatmeal and wear gloves in bed. The best preparation for the hands at night is white of egg with a grain of alum dissolved in it. Quacks have a fancy name for it; but all can make it and spread it over their hands, and the job is done. They also make the Roman toilet paste. It is merely white of egg, barley flour and honey. They say it was used by the Romans in olden time. Any way, it is a first-rate thing; but it is a sticky sort of stuff to use, and does not do the work any better than oatmeal. The roughest and hardest hands can be made soft and white in a month's time by doctoring them a little at bed time, and all the tools you need are a nail brush, a bottle of ammonia, a box of powdered borax, and a little fine white sand to rub the stains off, or a cut of lemon, which will do even better."

Olive Oil in Tuscany.—In a report on the trade and commerce of Leghorn it is stated that the Olive crop during the season 1885-86 throughout Tuscany was very short. The yield of Olive oil is consequently estimated at barely one-tenth of a full crop. The fruit while still on the trees was considerably damaged by severe frosts, hence much of the oil made was of very inferior quality. Nevertheless, in a few sheltered localities the Olives escaped injury, and yielded oil of perfect quality, but the production of such oil has been on a very limited scale. Under these circumstances the prices of the finest qualities of Tuscan oil, which are generally considered much superior to the best growth of other soil-producing districts of Italy and of France, might have been expected to rule very high, particularly as in Tuscany stocks of Olive oil of the previous season's crop were quite exhausted. But, owing partly to good Olive oil crops in the districts of Nice, the Italian Riviera and Bari, and partly to the general trade depression and fall in values of almost every commodity, new Tuscan Olive oils have fetched comparatively low prices. The Olive trees are generally in fine condition, and promise well for next season.—*Gardeners' Chronicle.*

Cultivation of Cinchona in Europe.—In a recent issue the *Athenæum* quotes from M. Vogel (*Biedermann's Central Blatt*) that is a "very remarkable fact in relation to the chemical action of the solar rays, that cinchona trees growing in hothouses in Europe develop no quinine in their bark." This is contrary to the experience of the late Mr. J. E. Howard, who took a warm interest in the propagation of cinchona, in his own hothouses. On one of these he rote as follows in a paper contributed to the BritishwPharmaceutical Conference, 1880:—"I found that canker had invaded the plant to a serious extent; and, after trying in vain some heroic remedies, I determined to root up the calisaya, and if possible gain some useful information as to the cause of its death. The age of this tree was eight years, the height between 7 and 8 feet, but would have been much more had I not been compelled to cut off the top some years before in accordance with the requirements of my conservatory. Before doing this I succeeded in taking a strip along this upper portion and renewing the bark under moss, as practised in India. The girth of the stem at the base was 9¾ inches, and about 6¼ inches at the summit (where cut off). The result of the analysis of the bark of my tree was as follows:—*Calisaya Angelica quill*: 1·25 sulphate of quinine, 0·70 cinchonine, 0·15 quinidine. *Calisaya Angelica stem bark*: 3·20 sulphate of quinine, 1·50 cinchonine, 0 32 quinidine. *Calisaya Angelica root bark*: 3·95 sulphate of quinine, 1·00 cinchonidine, 4·00 cinchonine, 0·27 quinidine. This must be considered satisfactory for a tree grown under glass in England." This is a direct contradiction to Mr. Vogel's statement. We take it that what is meant is that the solar rays have the effect of decreasing the percentage of alkaloids, and not only so, but have the power of causing degeneration of the quinine. This is not a new fact. It was first observed by Mr. MacIvor, and no further back than last year Mr. David Hooper, Government quinologist of Madras, referred to the point in his paper communicated to the Aberdeen conference.—*Chemist and Druggist.*

ORANGES.

Practical information for busy, practical men is the demand of the times. We have been constantly in receipt of letters asking for information relative to tropical fruits, especially regarding the different varities of oranges familiar to this market. Mr. J. H. Wright, the well-known fruit dealer, who has already contributed through our columns the best articles extent relative to bananas and coconuts, has kindly given us a third article of exceptional value relating to oranges. The original paper was read on April 16 before, the Bayonne (N. J.) Scientific Club, and illustrated by an exhibition of twenty-five different varieties of oranges; the orange tree in full bloom, leaves and blossoms from the Government gardens, contributed by Mr. Wm. Saunders, Superintendent; microscopical exhibit of the orange blossoms and the living mites which live beneath the scales, so frequently seen on the outside of the orange, and various products made from oranges. Mr. Wright has since revised his paper and added thereto, and now places every reader under obligations to him for specific trade information, the result of the life study of one possessed of exceptional power of observation and the faculty of gathering information and making it tell for the benefit of others.

The orange, one of the most popular members of the citrus family (or as it was called by the ancients, the "Golden apple,") is probably the oldest known fruit in existence. Zealous euthusiasts trace it back even to the garden of Eden, and insist that the grape or forbidden fruit was the original golden apple which Eve plucked from the forbidden tree and gave to Adam; hence the name "forbidden" or "grape" fruit by which this species of the orange is known to commerce. Some ignorant and superstitious people still claim that the dark spots usually found on the stem end of "grape" fruit are the imprints of Eve's fingers which have appeared upon this species of the orange ever since the fall of Adam. And from this species of the citrus family it is claimed by some, sprang what is now known to us, as the orange. This fruit is now imported under the name of "grape" or "forbidden" fruit, deriving that name from its growing in clusters similar to grapes, and the dark spots, alluded to as the imprint of sin, being occasioned by one fruit pressing tightly against the other. The orange now flourishing so extensively from the tropics to the 42nd parallel of north latitude would lead many to suppose that it was indigenous to those parts where now found growing; but ancient historians and pomologists tell us that the true and original home of the bitter orange was India, and China of the sweet orange.

Galessio, who was the first to trace the history of the orange, asserts that the Arabs penetrating farther into the interior of India than any other foreign nation had done before, discovered the orange flourishing there and held in high esteem by the natives. So, from the jungles of India the Arabs conveyed the sweet orange into Persia and Syria, and the bitter orange (now called the Seville) found its way into Arabia and Spain. And although the orange made its appearance in Europe in the fourth century, it was not until the fourteenth century that it became widely diffused, and spread through Portugal, Sicily, St. Michel, and the islands of the Mediterranean and West Indies, and not until the Spanish and Portuguese landed and penetrated into this country did the orange find a home in the semitropical portion of America. And while the orange was so highly esteemed by the ancients for its medicinal qualities, it is surprising how little attention the present generation gives to the many virtues enclosed in this little golden ball of fruit. A prominent physician once remarked that were his patients to eat an orange or two every morning they would require but little medical attention; for throughout the entire range of fruits that have attracted the attention of the medical profession as a means of alleviating many of the ills of mankind, there has been found none that has so many diversified uses as the luscious orange, particularly in cases of low fevers and malarial complaints, and it should more largely take the place of the unpleasant drugs so extensively used, to the great disgust of the patient. No fruit compares in cheapness with the beautiful and luscious orange, and particularly so now that our own country is raising the finest oranges in the world, the fruit selling at a price within the reach of the most moderate purse. At this season of the year (April) most of the oranges received in New York come from the islands in the Mediterranean, while a liberal supply is received from Jamaica, and a few from Cuba and Porto-Rico and some from Florida and California.

MEDITERRANEAN SUPPLY AND TRADE CUSTOMS.

A few words in relation to the manner in which the orange traffic is conducted in each of the above-named places may not be amiss at this time. Prior to 1830, the importation of oranges was quite limited; sailing vessels were exclusively employed in transporting the fruit to this country until 1860, when the experiment was made of substituting steamers in place of the sailing vessels. Three cargoes of about 7,000 boxes each were received direct from Sicily, but the experiment proved a failure, the importers losing heavily by the operation, the steamers not being adapted to the carrying of fruit, and the cost of transporation being too great. Sailing vessels continued to do the orange traffic until 1870, when a regular line of steamers with improved ventilation, was successfully established between New York and Palermo. With the steady increase in demand for the orange, new lines have been formed; until now there is scarcely a week during the spring months that New York does not receive from one to three cargoes of oranges and lemons from the island of Sicily and other parts of the Mediterranean, the total shipments to the United States last season (1884-85) being 97,000 cases and 1,368,000 boxes. The little island of Sicily with an area of about 11,000 square miles, has a population of over three millions, or an average of 250 souls to the square mile, a large portion of whom are engaged in orange culture. Lands from the lowest valleys to the highest mountain, even to within a few miles of the crater of Mount Etna, are covered with orange trees, bearing annually their thousands of golden balls. The average yield of an orange tree varies as to its age and location, coming into bearing when raised from seed at about the eighth year, or from graft or bud in 3 years. The first year's yield is small, varying from 25 to 200 oranges, which are apt to be coarse and large, having a heavy, rough skin, with a dry and tasteless pulp. As the tree matures, the fruit increases in quantity and improves in quality, until it becomes of a desirable medium size, with silky skin and full of juice. A tree well advanced, yields from 500 to 2,000 oranges, but there are trees, even in our own country, that have yielded 10,000 oranges annually.

While in our imagination we are visiting this wonderfully productive island of Sicily, let us follow the orange from the grove, through the packing house on board the steamer, thence to America. The gathering of the orange is done by men and boys, who are provided with light ladders, the fruit being placed in baskets lined with cloth, and held by a strap attached to and passed about their shoulders. The fruit being picked from the trees, is left with the stem on the orange, which is afterwards cut quite short with a sharp knife or shears, hence the name, "stem cut." The object in leaving a small portion of the stem on the orange is to prevent the air from reaching the nine to ten compartments that all centre at a point immediately under the stem, which forms nature's seal, excluding the air, which would cause rapid decay. From the groves the oranges are carried to

THE PACKING HOUSE OR MAGAZINE,

where they are placed in trays to cure or sweat out (as it is called) for a few days. This is found necessary to insure transportation, as an orange when removed from the tree will soon become moist, small drops of water appearing on the skin, and if wrapped in paper at once would soon decay, but if allowed

to dry off thoroughly will keep for months. The assorting and wrapping is done mostly by young girls and women, who get on an average a salary of from nine to sixteen cents per day, and on that pittance live and enjoy life better than some of our millionaires do in this country. At the packing-houses or magazines, the fruit is assorted with the greatest care by experienced Italian girls who will take two or three oranges in their left hand from a box or tray, make a rapid movement with their fingers, that will revolve the oranges in their hands with almost lightning rapidity, examining them on all sides. One or two may be thrown into the basket of a neighbour to the right, and one into the basket of one opposite. Were you to take an orange from each of those baskets, you would probably observe no difference in them, and wonder why the separation was made, but if you were to ask the bright-eyed Italian girl, she would show you a small spot on one, or the absence of a stem on another, sufficient to warrant the fruit being rejected or packed as a second grade, the imperfection in both cases causing rapid decay. The oranges are then sized, wrapped and packed in boxes to suit size of fruit. The smallest size being designated "00," meaning the smallest, usually numbering 300 or 360 to the box. The next grade being a little larger are called "0," and pack about 200 to the same size box, while the largest size is termed "imperials," and packed 160 to the box. The usual way to determine the number of oranges in a box without counting them all, is, if they are packed straight, count one layer of one end of the box; if it is packed in rows of 5 and 5 it would make 25 to a layer, and as there are 4 layers to a side, you multiply the 8 layers by 25, and you have 200 the number in the box, or if it be a box of large Imperials you will find it to count 4 and 5 making 20 to the layer, and 8 layers gives you 160 oranges to a box. This rule is a safe one to apply to all fruit packed in Palermo or Sicily; but in Catania, where little regard is paid to the sizing of the fruit, it may have the appearance of being Imperial size on top but "00," below. After years of experience, the buyer becomes familiar with the brand on the boxes of reliable packers and can feel confident of what he has in the boxes without examination. Let us return to the magazine, where the boxes are strapped, stenciled and put on board the steamer, perhaps 20,000 boxes or more ready to start for America. As soon as the vessel is loaded, a manifest is made out of the lots, their marks, and to whom consigned in New York. This manifest is at once sent by the fastest mail to New York where a catalogue is prepared by Messrs. Brown & Seccomb, fruit auctioneers, who sell at auction all the Mediterranean green fruit upon arrival. The steamer when loaded, starts for New York, and as it passes out of the Mediterranean through the strait of Gibraltar the signal station agent at the Rock notifies by cable the Maritime Exchange in New York that a fruiter has just passed, giving her name and destination. Eighteen to twenty days is the usual run for a fruit steamer from Gibralter to New York. Upon her arrival at New York Messrs. Brown & Seccomb advertise when the steamer's fruit will be sold and at what pier it may be examined. Repairing to the dock, the fruit merchant is presented with a catalogue of the cargo, showing the number of boxes in each line or lot, and a woodcut of the mark on the boxes of that line, one or two boxes each line being opened and placed on the pile that such sample is to represent. The merchant after examining the fruit as to size, quality, and soundness, puts some hieroglyphics opposite each lot on his catalogue to indicate its condition and value to him, the better to guide him in buying when the fruit is offered for sale at the auction-room. Oranges coming from Havana, Porto Rico, and Jamaica or usually disposed of by the importer or commission merchant to whom consigned. Until recently it was a rare thing to see any barrel oranges offered for sale at the fruit auction room. Each country has its peculiar style of package for shipping its fruit. From the island of Sicily we receive the oranges in boxes, made in two sizes. For the largest size oranges, called Imperials the box is of the following dimensions; $11 \times 14 \times 26$ inches, and for the regular or ordinary size, $10 \times 14 \times 27$ inches. From Joppa (in the Holy Land), we receive oranges in what are called flats or half-boxes, measuring $5 \times 14 \times 27$ inches. From Naples and Sorrento the same box is used as in Sicily. It may be of interest to know that since 1850 nearly all of the orange boxes used for the Mediterranean trade, have been made in the State of Maine, five or six cargoes of boxes in shucks being annually shipped from Bangor, and put together by the natives. Previous to 1850 the boxes came from Trieste in Austria, but their yearly advance in price drove the orange exporter to look to other fields for supplies. The Yankee box makers of Maine took advantage of the situation, and have held the bulk of the trade ever since Valencia in Spain, uses cases instead of boxes to send oranges to America; unlike the boxes the cases have three compartments. There are four sizes of cases used, medium large, extra large, and mammoth or coffin cases; the dimensions of the largest are $15 \times 18 \times 46$, and medium, $12 \times 16 \times 40$. As these packages are so much heavier than the Sicily boxes, it is necessary for them to be roped or corded, and for that purpose is used a rope made from the Espatto grass which resembles the cat tails grown in our salt meadows. This cord is largely made by the convicts in the prison; is very strong, and costs far less than machine-made manilla rope. The Valencia orange differs but little from those grown in Sicily as to sweetness and flavor, neither being a perfectly sweet orange, but what is termed by the trade a pleasant tart; those grown in Naples and Sorrento are of a pale color, and considered the sourest orange imported, which is accounted for by its coming from the most northern portion of the country where oranges grow. It is a noticable fact that the nearer the Equator the oranges are grown the sweeter the fruit, and the further north the sourer. Even the seed from the sour orange of the Mediterranean when planted further south produces a sweet orange.

WEST INDIA SUPPLY.

Leaving the Mediterranean and drifting south, the first orange district we encounter of any magnitude is Cuba, where but little attention is given to the cultivation, assorting or packing of oranges. Not the slightest care is given to the sizing of the fruit, or the selection of the package used for transportation, barrels being used exclusively, without regard to what they may have previously contained, whether potatoes, flour or cement. This orange (the Havana) is without doubt the sweetest orange grown in the world; in fact, when fully ripe, is so sweet as to be almost insipid. While it is a general favorite in its season, it is always highly prized in the sick room.

Next in order comes Porto Rico, situated two degrees south of Cuba, in latitude 18 degrees, which island produces an orange lighter in color than the Havana and about as short-lived. Their favorite and only mode of shipment is to send them to New York in bulk, as it is called; that is, to rig the hold and deck of a schooner into bins about three feet deep and fill each of these with loose oranges, thrown in without being wrapped or sized. As there are but few cargoes come from Porto Rico and they arrive during the months of February and March, when we have plenty of oranges from other ports, they are not looked upon as one of the standard oranges of commerce.

Next in order comes the wonderfully productive island of Jamaica. Like Porto Rico, it is situated in latitude 18 degrees, its shores washed by the warm waters of the Caribbean Sea. From this island, 100 miles south of Cuba and 1,450 miles from New York, comes a most excellent orange, and one that is daily increasing in public favour. The best varieties are grown on the Mandeville mountains in the Manchester, Clarendon, St. Catherine and St. Anns parishes, and are fit for a king. In fact, I have paid $12 per barrel for a certain mark of this fruit known as the K brand—the highest price ever paid in New York for a line of barreled oranges—in its original package,

as it was landed from the vessel, and I found ready sale for the same at $15 per barrel.

The shipper of this celebrated brand (Mr. S. Kennedy of Jamaica), not content with the extravagant price his oranges brought, allowed himself to be inveigled into a contract with a certain New York firm that proved disastrous to shipper and contractor alike, for instead of keeping up the standard quality, as of previous shipments, he allowed the mark to deteriorate, thus losing its prestige, and from that day to this I have never bought a single barrel of the once celebrated $\frac{K}{S}$ braud, now no better than any other brand.

I simply cite the above to show how even a brand of oranges can reach the pinnacle of popularity, and like frail humanity, by some misdeed, sink into utter oblivion. Other shippers have taken lessons from this and maintain their standard of excellence in quality and packing, so that such marks as the $\frac{N\ G}{S}\ \frac{M\ E}{M}$ and others have gained a most enviable reputation, not only for the shipper in Jamaica but for the receivers in New York, Messrs. Goodwin & Sturridge, whose reputation as reliable trustworthy dealers is certainly worthy of emulation.

The fruit just spoken of, coming, as I said, from the Mandeville district, on the south side of the island, rivals all other oranges grown in Jamaica, although some very good fruit comes from the north side. It has not the keeping or eating qualities of the oranges grown on the soth side, for this part seems to be expecially adapted to orange culture, both in soil and climate, the fruit actually growing wild in many places, without the slightest cultivation, and where the mere keeping down of the brush would convert the trees into beautiful orange groves.

Like Havana, Jamaica ships most of the oranges in barrels, but, unlike Havana, Jamaica, is more careful in the selection of the package, usiug as far as possible a new sixteen inch head barrel, with the staves broad and full of holes for ventilation. While Havana sends the fruit to New York unwrapped and unsized, Jamaica pays great attention to the grading of the oranges, carefully wrapping them in brown straw paper. Great care is bestowed in packing choice brands in regular layers from the top to bottom of the barrel, the average count being about 350 to the barrel.

Jamaica has made such rapid strides in orange culture during the last quarter of a century that had not Florida come to our relief the Jamaica orange would now be enjoying almost a monopoly in New York markets as the only genuine sweet orange to be relied upon for late winter and spring trade. The orange tree is so pliable under conditions imposed by art, that in Jamaica it can be made to produce a crop at any desired time of the year. Its blossoming may be hastened by cultivation and irrigation, and it may also be retarded by suppressing the blossoms. This retarding process, I am informed, is extensively resorted to by the Spanish colonists in Nicaragua and Honduras.

HOME PRODUCTION.

Having thus carried you through the orange fields of nearly every foreign land that sends its fruit to the United States, let us now take a look at the orange belt of our own favored country lying principally in Florida, Louisiana and Southern California. To the Spanish Catholic missionaries it is generally supposed that Florida is indebted for the introduction of the orange, they having brought the seed of the sour or Seville orange from Spain, and as the fruit multiplied the seeds were scattered by the Indians throughout the State, which probably accounts for the numerous wild orange groves found near the banks of the rivers and lakes, formerly the favorite camping grounds of the Seminole Indians. Later the sweet orange was introduced from Europe and planted in St. Augustine (the oldest city in the United States).

At the close of the civil war small plantations of sweet oranges were found throughout the State, consisting usually of a few trees growing around dwellings. At the close of the war many of the old trees were bearing liberal crops of such luscious fruit as travellers from all parts of the world had never before eaten. The excellence of the American orange set enterprising Northerners to thinking there was money in orange culture, and the general climate of the State made the enterprise doubly attractive. Capitalists seeking health in that warm climate soon invested in lands and started groves from seeds; as shipments of fruit were made North and large prices realized. Others purchased wild groves of the sour orange and grafted or budded the sour stock with the sweet, the last process securing a more vigorous tree and one that will last for centuries. The orange fever spread among the natives, who began to realize that within their very door-yards lay a fortune they had never dreamed of. So they went to work with commendable energy, until Florida is becoming a vast forest of orange groves, having at present hundreds of thousands of trees, producing last season about eighty millions of oranges, and giving rise to the question. Will not the business be overdone? To which we readily answer, No. With the small area within the United States capable of producing oranges this will be impossible.

With its present liberal supply Florida furnishes but about one-tenth of the oranges consumed in the United States. New York City alone is said to consume more fruit than any other city in the world, not excepting London or Paris. The area of the States with climate suitable for orange growing includes portions of California, a very small part of Louisiana and the whole of Florida. A trifling area as compared to the vast sections of the United States which will be well filled with inhabitants long before the orange-growing section can be brought into bearing. The present yield of fruit grown in the United States furnishes hardly an orange a year to each inhabitant. Taking our population at 60,000,000, judging from the past, it will probably in the next thirty years double; to furnish such a population with one orange a day will require no less than 43,800,000,000, so there is but little danger of the production ever meeting the demand of our country.

Of the average age of the orange tree nothing definite can be said, but it is generally supposed that with all conditions favorable, such as soil, climate and proper attention, the orange trees are good for a century or over. In fact, at Cordova, that far-famed seat of Moorish splendour, there are still remaining a number of monster orange trees known to be seven hundred years old. Their trunks are partly hollow, their bark cracked and rough, yet each year, those dingy old giants yield their seven and ten thousand of luscious oranges as if yet in the hey-day of their youth. Even in England, at Hampton Court where the tree is raised only as a curiosity and is carefully sheltered by glass, there are several trees that are known to be over three hundred years old. There is also an orange tree in the Convent of St Sabine, at Rome, which is known to be over 680 years old. So it is no rash assertion to make that no orange grower in this country will live to see his trees cease to yield him an income.

OTHER FOREIGN SORTS.

While we recognize but two varieties of oranges, the sweet and the sour, there are as many distinct varieties as there are of apples. I will speak of a few varieties that are never, and others that are hardly ever seen in this country. The Chinese have by careful study and long cultivation succeeded in dwarfing the orange-trees until they have them growing in flower-pots, bearing fruit regularly, but in size no larger than a cherry or plum. Another variety grown in China and never seen in this country is the "coolie orange." It resembles in size and appearance our tomato; this variety has a thick rind, is quite juicy, and the tree a great bearer. There is also the "sucking orange," so called because the skin is so thin and adheres so closely to the flesh that it

cannot be peeled; in flavor it resembles the mandarin orange. At Singapore is grown an orange that is of a deep green color, about the size of an apple, with thin skin, and peeling off readily. It is juicy but very sour (said to be very bad for the teeth; the rind when broken emits a strong odor, partly orange and partly citronella. I am informed there is an orange grown in Siam that is called the King orange, so named from receiving such royal recognition, that any subject finding this tree growing without the walls of the royal garden, must give immediate notice to an officer of the Government, or be decapitated. The tree is then destroyed, as none but members of the royal family are allowed to eat of that fruit. It is described as having a transparent green skin when ripe, and a pink pulp, that can be seen through the skin, and is of a most delicate flavor. In Europe, when oranges were first introduced they were looked upon as only food for kings, and were offered as rare gifts to the crowned heads.

Of the many species of oranges that find their way to this country, I have been able to gather in a few days over twenty different varieties, including the Florida, California, Havana, Porto Rico, Jamaica, Valencia, Messina, Palermo, Catania, Joppa (or Holy Land orange) Naples, Sorrento, Seville (or bitter), the tangerine, mandarin, blood, oval, navel, grape, or "forbidden fruit," Pumallos, and Shaddock and Chinese. Of these we will speak in turn as they make their

APPEARANCE IN THE NEW YORK MARKET.

First, in the fall, comes the Havana, which is now about done for this season. Next comes Jamaica and Porto Rico; then Florida and California; then from the Mediterranean we receive the Valencia, Messina, Palermo, Catania, Joppa and Naples; these Mediterranean varieties lasting through the spring and summer months, while the trees in Florida and the West Indies are recuperating and getting ready for next fall's supply.

DISTINGUISHING FEATURES.

A question is often asked, "Why should not all the oranges grown on so small an island as Sicily be called Sicily oranges instead of Palermo, Messina and Catania, and in what way do they differ?"

If you will refer to a map of the Mediterranean Sea, and look at the island of Sicily, you will see on the eastern shore the location of Catania. About forty miles further north is Messina, and about one hundred miles west of Messina is Palermo.

From these three ports come the best of the Mediterranean oranges and lemons, the choicest varieties coming from Catania and Messina. It would be hardly fair to award the "palm" for the finest fruit to either, as both of these districts raise some of the finest oranges grown in the world. Catania is situated near the foot of Mount Etna, in the eastern portion of Sicily. Hundreds of orange groves extend far up the sides of that famous and once turbulent mountain, receiving a most bountiful supply of sunlight. Its southern exposure makes it a favorable situation for producing excellent fruit. In that section are a large number of trees that bear the much-sought for and attractive looking oval or egg-shaped orange, and this has given to Catania oranges a prominent place among the choicest varieties coming from Sicily. Prior to 1852 the American market knew nothing of the Catania orange, at least by that name, as all the fruit grown there was taken in small sailing crafts to Messina, and there sold to be graded and packed in Messina boxes, and shipped to this country as Messina fruit. In 1851 an enterprising English firm built at Catania a packing house (or fruit magazine as they are called there), for the purpose of packing and shipping Catania oranges and lemons to all points. The first cargo of 5,000 boxes coming to America from Catania arrived here in the year 1852, consigned to and contracted for by our late highly esteemed and veteran merchant, G. H. Renaud, then a member of the importing firm of D. Gillmartin & Co., of New York.

While the better grades of Catania oranges usually command a high price, more value would be attached to them if greater care was given to sizing the fruit properly, as is done by reliable packers in Messina and Palermo. While the Catania orange and lemon are pleasing to the eye, they will not keep as well as the Messina and Palermo fruit, and for that reason are seldom stored or put away for summer use, as is the case with the Messina oranges and lemons, which seem to have better keeping qualities, as do all fruits grown further north. (The same is true of American fruit, apples in particular.) There is so little difference between the Palermo and Messina fruit that we will not attempt, at this time, discuss their merits or demerits, other than to say that both the last named ports are entitled to much credit for some very choice fruit. The "Sorrento" fruit comes from the port bearing that name, which is about 150 miles north of Messina, near Naples, on the main land. This fruit is apt to have a thick skin and is of a pale color. The orange is not so sweet as those grown on the island of Sicily.

Very few of the Mediterranean oranges keep as well of late as in former years, when less attention was paid to irrigation than at present. The very wet condition in which the orange groves are constantly kept has a tendency to force and soften the fruit. As regards quality, I should place the varieties in the following order: Messina, Catania, Palermo, and Naples or Sorrento.

The Orange coming to us from the greatest distance is the Joppa, or Holy Land orange, but as it has no especial attraction beyond that of coming from the Holy Land, few shipments are made to this country, owing to the great cost of transportation, the fruit having to be sent to Liverpool, then re-shipped to New York. The fruit is mostly oval, or egg-shaped, and ranks with the Sicily orange as to flavor. It finds a ready market throughout Turkey. Russia having established a regular line of steamers between that Empire and Syria, the Joppa orange is being largely introduced into Russia. The orange groves throughout Syria are very near the sea-coast, very few groves being found successfully growing more than four miles from the sea. As there is but little or no rain in Syria from the 1st of May until October, irrigation is the only means of keeping the trees alive, each one being surrounded by a little bank of earth to keep the water about it. The trees are left without irrigation until the last of June, when the leaves begin to curl a little; then they are watered by streams coming down from the mountains of Lebanon. From Naples and Sorrento, near Mt. Vesuvius, we receive an orange similar to that grown further south in Sicily, but it is pale in color and very sour. These conditions are accounted for by the fact that Naples occupies a position so far north—in the 42nd degree of latitude, the same as the New York.

Surprise is sometimes expressed that oranges can be successfully raised at Naples and Rodi. Many theories are advanced, some claiming that the icebergs and cold currents from the Arctic Ocean hug our shores closely and lower the temperature many degrees below that of Italy, which is constantly fanned by the warm winds coming across the Mediterranean from the great deserts of Africa. Among the smallest varieties of oranges that we receive are the tangerine and the mandarin, sometimes called the "kid glove" orange, from the readiness with which the skin is removed without soiling the hands or even the gloves. The tangerine and mandarin are often associated as one and the same fruit, but such is not the case. While of the same family and closely allied, they are not identical and should not be confounded. The tangerine is in color a deep dark red when fully ripe; in shape it resembles a small flat tomato. The tangerine is a thorny tree, and is supposed to be of Chinese origin, but has been largely distributed from Tangier, a spot in Western Africa, where it has flourished for fully 200 years. From Tangier the Portuguese carried it to Brazil, and from there it made its way into Florida. The mandarin resembles the tangerine in general appearance, except in color, the mandarin being a golden yellow. The tree, unlike the tangerine, is thornless, and is supposed to have come from China, deriving its name from the mandarin, a high official in China.

The mandarin and tangerine are becoming popular oranges in Florida and when sent to the northern mar-

kets about the holidays command a very high price. As the Florida mandarin and tangerine begin to disappear about the middle of March, their place is taken by the same variety from Sicily, lasting until the summer months. Jamaica also raises the tangerine to some extent, the fruit being larger than that grown in Florida or Sicily. In the early season they lack the rich, spicy flavor of those grown in Florida. Within the last few years a new variety of orange has made its appearance in our market; it is called the navel orange, deriving that name from the curious formation on the blossom end of the fruit. For many years this orange has been a great favorite in the Bahia district of Brazil, where, it is claimed, by long and careful cultivation it has become entirely seedless, thus preventing its propagation only by grafts and buds. When grown in Florida, where it was introduced from Brazil a few years ago, a few seeds sometimes appear. The orange is unusually heavy, sweet and juicy. On the Pacific slope in Southern California, the navel orange is extensively cultivated, but as the stock buds or grafts were introduced from Australia, the orange differs somewhat from the Brazil navel, as the blossom end is not so broken and the orange is more of the oval or egg shape. The other variety grown in Colifornia is the plain seedling. The best varieties are known as the Riverside. California is fast coming into prominence as a competitor for the orange trade, it supplying all the markets west of the Rocky Mountains. It bids fair to demand a good share of the trade east of the Rockies even as far as Buffalo, thus interfering quite materially with the Mediterraneau orange trade, as the supply from both points appear in our market at about the same time.

THE BLOOD ORANGE.

Another very curious and popular orange is the blood. The general appearance of the tree, leaf and flower differs only from other orange trees in its absence from thorns. Its fruit is distinguished by a color of blood which develops itself gradually as the fruit begins to ripen, little by little the blood-colored spots appearing in its pulp as it advances to maturity these enlarge, becoming a deeper blood color, finally embracing all the pulp and spreading to the skin, which becomes a brighter blood color, the longer it is allowed to hang on the tree. This variety of orange has provoked much discussion, and many theories have been advanced as to its origin, some claiming it was produced by grafting the orange into the pomegranate tree; others that it was simply a freak of nature. From conversation with Mr. Rose, manager of the New York Fruit Exchange, who spent twelve years in orange culture on the island of Sicily, and from Mr. G. Amoroso, one of the most experienced grocers in Sicily, and other orange importers and growers, I am positively assured that the blood orange is as distinct a variety as is the Baldwin apple from the Greening, and as a graft from a Baldwin apple tree upon a Greening tree, will produce a red Baldwin apple, so the product of a bud or graft from the blood-orange tree, when grafted or budded into any other variety will surely be a blood orange, thus proving beyond a doubt that the blood orange is not a freak of nature, but a distinct and separate variety, produced hybridizing the orange with the pomegranate. In the start the blood-orange is grafted from the orange to the pomegranate tree, and in two years time is again grafted from the pomegranate to the orange, so as to secure a regular supply of bloods, which otherwise would soon die out, the pomegranate being short-lived. I have given this species special attention owing to the various opinions—purely guesswork or theory—expressed both upon the street, among the fruit trade, and in the newspaper columns; for that reason I have interviewed the above-named gentleman, whose opinions I accept and present by permission as indisputable authority. Another variety of curious formation is the oval or egg-shaped orange, coming mostly from Sicily. In flavor it is no better than the round orange, but from its odd formation is eagerly sought for by the fancy fruit dealers of our large cities and commands a high price.

While we are considering the smaller varieties most familiar to us we should not omit a passing glance at the largest species of orange grown in the world. There are two varieties, the "Shaddock" and "Pumalos," which differ only in outward formation, the Shaddock being round and the Pumalos pear-shaped. Both have a skin of a golden colour, while the pulp of both is pink. They are used only for attraction or made into marmalades. The pulp is eaten by some and is said to be palatable, but care must be used in separating the flesh from the skin that separates the compartments of the Shaddock, the Pumalos and the grape, or forbidden fruit, as it is very bitter. This fruit is of Chinese origin, but was brought from Asia by a Captain Shaddock, whence its name.

SUMMER ORANGES.

The question has been frequently asked: "Why are Rodi oranges called summer oranges?" If the reader will refer to a map of Italy he will find that Rodi is situated on the Eastern shore, in the province of Foggia, about 160 miles southeast of Rome. It lies at the mouth of Gargano Bay, between the 42nd and 43rd degree of north latitude. That is a point so far north as to prevent the orange from ripening before March and April. It reaches our market in June, or the early summer months, hence the name "summer oranges."

In variety they are the same as those grown at Messina and Palermo. Owing to the heavy foliage of the trees the fruit is lighter in color than that grown in Sicily. Rodi is frequently visited with cold wind and hail storm. At the season when the orange is reaching maturity the result being the injury of the fruit to such an extent as to cause large black scars to appear on the skin of the orange when ripe, thus greatly depreciating its commercial value. Coming into this market, however, when most other varieties have disappeared, they usually command a high price.

Much might be profitably said about the different diseases that affect the oranges and tree as well as facts relating to articles manufactured from the orange, such as the oil that is made from the skin for flavoring purposes, which sells for about two dollars a pound, and the oil that is distilled from the orange blossom, which sells for fifty dollars a pound and is used for making perfumery. In foreign countries the skin of the orange is used quite extensively, being dried for fuel, as the oil it contains causes it to burn fiercely, making a very hot fire.

You have already followed me, in imagination, over 25,000 miles, through the principal orange districts of the world, and I land you safely in our own happy land, where a kind Providence has favored a portion of our country with a climate suitable for growing this golden fruit. To the orange grower in that favored portion we say: "Go on with your good work. Multiply your groves and scatter your health-giving fruit over our land until the orange shall be a familiar fruit in every home from the lakes to the gulf, and from the Atlantic to the Pacific."—*American Grocer.*

Coconut Pudding.—One large cup bread-crumbs; one coconut, pared and grated; one tablespoonful corn-starch, wet with cold water; half cup of butters one cup of sugar; two cups of milk; five eggs; nutmeg and rose-water to taste. Soak the crumb in the milk, cream, butter and sugar, and beat in the yolks, then add to the soaked crumbs. Stir in corn-starch, beaten whites and flavoring—at last, coconut. Beat hard and bake forty-five minutes in a buttered pudding-dish. Eat cold.—*American Grocer.*

The Australian Fresh Fruit is now regularly on the market here, and, I am pleased to add, is very appreciated. Tasmanian apples at 4d a pound are naturally acceptable at a time when the market is all but denuded of home prooduce. The Ceylon tea, too, meets with much approval, and sells at the Exhibition at 3d a cup. This should be a hint to some of our Queensland planters, for I have always myself been of the opinion that tea may be profitably and extensively cultivated in that Colony.—*Anglo-Australian in European Mail.*

TEA, CINCHONA BARK AND COFFEE IN THE UNITED STATES OF AMERICA.

London, 4th June 1886.

Enclosed are extracts from the annual reports of the Chamber of Commerce of the State of New York for the year 1885-86 which can hardly fail to be of interest to the growers of tea, bark and coffee in Ceylon. While these papers were being transcribed, your *Weekly* paper of 11th ult. came to hand with the report of the special general meeting of the Colombo Chamber of Commerce summoned to consider a letter from Mr. Thomas Dickson on Coffee Adulteration.

In view of the present position of the coffee enterprize in Ceylon, it is not surprising that the Chamber should be lukewarm in this matter. The chairman apparently felt that some apology was due for this, saying that the ground taken up, viz., that the question does not now materially affect Ceylon, is not a very high one. To one reading the enclosed extracts and comparing the relative positions of tea and coffee in the United States and the United Kingdom, it would seem that if the Chamber is to consider the material interests alone of Ceylon (and what other interests fall rightly within its province ?), it would be suicidal to raise a finger to help the great rival of tea to supplant the latter in the United Kingdom also.

The story of the consumption of tea "this once overshadowing industry," as it comes from the United States, has indeed "a melancholy tinge." If cheap and pure coffee has carried all before it on the other side of the Atlantic, why not on this side also ?

In the interests of temperance, by all means let all of us take the side of tea and coffee against alcoholic drinks. But the fact must be recognized that there is, beside the great temperance struggle, domestic strife in the temperance household. Tea and coffee are open rivals for the affections of drinking humanity. In this rivalry, the interests of Ceylon and those of the Colombo Chamber have passed since 1880 from coffee to tea, and there need be no coyness in avowing the fact. W. M. L.

(*Extracts referred to*)

The Coffee Trade.—With very low prices for sugar, a large consumption of coffee may always be looked for. With low prices for both, its cheapness as a good staple increases the favour in which it is regarded by the labouring man. It has already taken the place of tea, the "poor man's diet." The improved methods of roasting have greatly contributed to this result. The per capita consumption of the United States is now estimated at 9·31 pounds, against 7·61 in 1879, an increase of 22 per cent. The average price of Brazil cargoes for 1879 was 14·85 cents; that for last year 9·01, a decrease of nearly 40 per cent; the price of last year was the lowest since 1852, and the consumption greater than ever before recorded. The variations in the market have been slight. The highest point, 10¼ cents, was in January; the lowest, 8¼ in December; the average 9·01 for fair Rio, the standard for comparative quotation. Experience has shown that the Exchange which opened two or three years since with great flourish of speculation, has proved, as open markets always have and always will prove, an equalizer of prices. The electric system of communication and the cheapness of transportation are now such that the margins for profit between cost of production and price to the consumer are extremely small. The tendency is, therefore, to the concentration of the trade into few and strong hands. The total receipts of coffee at all the ports of the United States was two hundred and forty-seven thousand tons in 1885, against two hundred and thirty thousand tons in 1884; an increase of seventeen thousand tons. The total deliveries for consumption were two hundred and thirty-five thousand tons in 1885, against two hundred and twenty-four thousand tons in 1884; an increase of eleven thousand tons, or 5·3 per cent. The increase over the consumption of 1879 has been more than fifty thousand tons, or about 25 per cent.

The Tea Trade.—The reports of this once overshadowing industry have still a melancholy tinge. The causes of the continued depression are plainly stated to be that our supplies have far outrun our consumptive requirements. Unfortunately this staple does not grow in value with age, like its great rival coffee. Stocks must be marketed. To this, rather than the general stagnation in commerce, is the distrust of the future to be attributed. The Importers' and Grocers' Exchange has not as yet proved to be more than a convenient place for the acquisition and distribution of statistics, but sooner or later will play an important part in the trade. The exclusiveness which governed the China trade is already of the past.

Annual Review of the Coffee Trade of the United States.—The more prominent features of the coffee trade of the United States during 1885 have been, first, a further increase in consumption as compared with previous years; second, an extremely low range of values throughout the year; and third, the change that has become established in the methods of conducting business, more particularly with respect to the product of Brazil, which constitutes the bulk of our supply. Increased consumption has been due partly to the growth of population, but unquestionably the most important element has been the increasing popularity of coffeee as a beverage among all classes, while its relative cheapness to consumers as a food staple has not been without its influence. The extent to which roasted coffee is now prepared and distributed has had much to do with its increased popularity. So long as this preliminary preparation had to be accomplished in the kitchen, the loss and labour that was entailed deterred many from its use. A lack of care or experience in this important process was apt to cause waste, in addition to the uniform and imperfect results obtained, but this has been entirely obviated by the erection of large roasting establishments throughout the country, where, with the aid of improved machinery and by the utilization of many ingenious inventions, this labour is all performed perfectly and satisfactorily, and consumers are enabled to obtain from retailers an article that is thoroughly prepared for cooking. This fact together with the relatively low prices that have been established during the past two years, has made coffee peculiarly the poor man's diet, and greatly popularized and extended its use with all classes. The extent to which low prices have influenced consumption may be readily appreciated from the fact that the average price of fair Rio during the year under review is the lowest since 1852. The changed methods of doing business relate to the manner of importation and sale. Jobbers and roasters now supply their wants chiefly by purchases made direct in Rio; that is instead of coffee being imported here for sale, its sale has been accomplished in most instances before it is shipped, and the seacoast ports have become clearing-houses and distributing centres rather than marts where actual merchandise is bought and sold. The net results of low prices and new methods of business have been narrow profits to importers and dealers, and a year of trade that, while in no sense disastrous, has not proved one of singular prosperity to those engaged therein. These features have not been confined, however, to the coffee trade alone, but have characterized, to a greater or less extent, the operations of the year in almost every department of commercial activity, and may be readily traced to the natural development of the tendencies of the times, after experiencing a long period of trade depression and the practice of close

economy. The existing condition of affairs has resulted from keen competition, a radical improvement in the methods of transportation by water, as well as on land, increased facilities for rapid communication with all parts of the world, the abundance and cheapness of money, the closer relations existing between buyer and seller, and a consequent disposition to trade upon a narrower margin of profit. The fact that the yearly average price for fair to prime Rio is the lowest since 1852 is the best proof of its relative cheapness during the year, but the very narrow fluctuations of the market have been of still greater importance in restricting the opportunities for obtaining more than a living profit. During ten months of the year values drifted slowly backward and forward within the limited range of 1 per cent, or between 8¾ and 9¼ cents for fair Rio, the highest prices having been made during January and February. A moderate crop has been followed by a still larger one, and the prospects for the future now point to a crop of enormous proportions, and the largest ever known. Furthermore, there has been no distinct speculative movement, and buying and selling has been of the hand-to-mouth character, that has deprived trade of its most elastic qualities. During the first three months of the year the impression prevailed that the yield of the crop would fall short of the estimates, and, accordingly, that before the close of the crop year, higher prices would prevail, which, in connection with the facilities afforded small traders throughout the country for purchasing direct from Rio, stimulated buying and led to a liberal stocking up. The warehouse deliveries from the seacoast ports for January, February and March, showing a heavy increase, being 266,815 bags in excess of the corresponding period in 1884, which is about equal to the increased consumption shown for the whole year; but, instead of advancing, values continued to decline, and purchases made on the basis of January and February prices must have been disposed of at a considerable loss. The load so easily taken on certainly acted as a dead weight upon the market during the first six months of the year, and its influence was not wholly eradicated during the remaining half. At no time since then did a sharp demand prevail, and almost constantly the country was being urged to buy rather against general inclination, which necessarily dulled the edge of spirited trade and resulted in a sluggish uninteresting market. According to the tabulated statement printed on a previous page it will be observed that consumption east of the Rocky Mountains has increased in comparison with 1884, 11,855 tons, or 5·3 per cent, which, although not as great an increase as shown the year previous, nevertheless means about one-half pound more for every man, woman and child of our population, which is a very considerable expansion, considering the relative proportion of this population that are not coffee-drinkers. This brings the per capita consumption of the country up to about 9·31 pounds, against 7·61 pounds in 1879. While the United States as a whole is one of the largest consumers of coffee in the world, its population is not so universally addicted to its use as in Holland, where the per capita consumption is about 21 pounds, or in Denmark and Belgium, where it amounts to about 13½ pounds, but with these exceptions we are the largest individual consumers of the beverage. In this connection it is worthy of remark that Great Britain shows a steady decrease within the past few years, the quantity imported last year, which amounted to 41,000 tons, being less than one-half what it was four years previously.

Cinchona Bark Trade.—The one great feature of the past year has been low prices. The extreme fluctuations ranged from 4d to 7½d, or say 8c to 15c. per lb. per unit. The supply, however, of one description or another, has been, in the London market, ample. Our American market has lost nearly all its importance, and we have to rely almost entirely on London. South American Bark is imported in very small proportion, while, on the other hand, we notice an increase of Calisaya Bark, and we expect still larger arrivals of this kind in future of the cultivated qualitise, but we expect from Colombia only shipments of the quantities which are stored there, waiting better market prices. The cultivated Calisaya Bark which has appeared in market is very rich. It should be remarked that the shipments of Ceylon Bark were, for the first half of the season of last year, very heavy, and prices for Bark were very much depressed, and shippers lost money; consequently the Bark shipped for the second half of the season was less in quantity than anticipated, and the total for the year that reached market only corresponded with that of the previous season. The stock remaining in Colombo at the close of the season, on the first of October, was about 4,000,000 lb., and this quantity being shipped during the last three months of the past year, from October 1885, to January 1886, overflowed the market and caused another depression in prices which decreased shipments. All reports from Ceylon say, that the harvest of Cinchona Bark will be smaller this year than heretofore, but low prices are anticipated. The arrivals of Bark may be limited, but should much higher prices set in, shipments will increase. The imports of Java Bark in Europe have not increased in proportion as expected. Attempts have been made to import Ceylon Cinchona Bark directly to New York. We have always thought that this business should afford an advantage to both the exporter and the importer and for our home manufacturers. This is a matter of the first importance, so as to be no longer obliged to rely on London; and certainly every encouragement should be given to such an enterprise, by paying as high prices as possible, so that the net result would be improved by direct imports to New York. The fluctuations in Quinine for the past year were 30 cents per ounce, and during the last year rates were very low, falling to a point never before reached. It was noticed as a remarkable fact in reference to 1881 that foreign Quinine was sold in Europe as low as 3s 6d per ounce, with Bark ruling at 4½d per unit. In 1885 foreign Quinine was actually sold at 2s 6d per ounce, with bark at very nearly the same value per unit as in 1884.

The following table, from 30th June 1881, to 30th June 1885, has been compiled from statistics kindly furnished by the Hon. William F. Switzler, Chief of the Bureau of Statistics, and will repay a careful perusal:—

Imports of cinchona bark during the past five years.

Years.	lb.	Value in dollars.	Average value per lb.
1881	4,219,403	1,846,280	43·8
1882	5,010,547	1,846,375	36·8
1883	3,639,315	1,205,606	33·1
1884	2,588,307	718,035	27·2
1885	3,559,691	913,189	25·7

THE "TROPICAL AGRICULTURIST."

A gentleman resident in the Central Province who has as good opportunities of knowing what is of benefit to planters as any one we know, sends us the following explicit testimony to the value of the "*T. A.*":—

"Since its commencement, I have regularly seen, and perused the *Tropical Agriculturist*. There can be but one opinion that its scope and object are highly important, and that it supplies a distinct desideratum, which it is to the interest of every estate proprietor to have available in the bungalow for the use of his locum tenens, or superintendent. As a magazine it provides interesting and instructive fresh literature at intervals, deprived, as most in Ceylon are, from easy access to libraries, and as years go by it will growingly become "The Ceylon Encyclopedia" with reference to agricultural operations. Viewing estate property, as practically a permanent investment to some one the trifling charge of R12 per annum—a rupee a month—is, certainly of no account, provided the separate numbers are kept, and bound together yearly as a book of reference,

for the benefit of the manager, and his suceessors. In that light, as the property of an estate to be handed over just as much as its office furniture few proprietors would probably refuse to authorise its being taken and filed regularly (if the periodical was brought under their notice) more especially as on looking over the most recent volume one cannot fail to see how much valuable information on 'Tea'* has been collated. In the belief that 'Tea' will restore prosperity to Ceylon, and that plantation property is a good investment for capitalists, such should not omit the office and connected equipment so advisable on all 'pucka' estates, a part of which would be 'the *Tropical Agriculturist*.' I find I have gone on writing, but as I am getting the numbers, for the past year ready to be bound, the volume is before me."

LETTERS FROM JAMAICA:—NO. XI.

WEATHER AND CROPS—JAMAICA FRUIT TRADE—A SHOCK OF EARTHQUAKE—JAMAICA COURT AT THE EXHIBITION.

Blue Mountain District, Jamaica, May 1886.

This year seems so far to be making up for those that have passed since 1879 when there was a heavy flood followed on 18th August 1880 by a severe hurricane. The May "seasons" appear to have set in, in the style one hears of from old inhabitants: indeed since the beginning of the year there has been a prevalence of showery, yet not unpleasant weather, but very few days suitable for curing coffee for market as it is here styled. Crop in the Blue Mountains is now well advanced, most properties have already secured more than half their estimates, and in some cases it is hoped they will be exceeded. The quality this year is excellent, the beans specially fine and heavy, so that our planters are hoping for our customary high prices, for very little of such fine *colory* goes nowadays into the home markets. The weather has been most favorable for the black "creole" settlers, whose *grounds* have so long been suffering from drought, this will supply them plentifully with provisions and make them all the more disinclined to work. However, I will do them the justice to say that the women will turn out to pick coffee: one estate near this picked 9 tierces in one week, say 63 cwt., which is remarkably good for a Jamaica estate, as none of them exceed 200 acres of coffee, but are considerably less in extent, though spread over a large area in detached fields; this separation by bush, and growing forest, makes Jamaica less likely to suffer such a disaster as Ceylon has undergone from over cultivation of one product, massed together in its thousands of acres, utterly obliterating the indigenous jungle.

The Jamaica Fruit Trade seems to be flourishing, the winter is doubtless the best season, before the oranges and bananas, from the more northern producing countries can reach the American markets. We had a man up here a few weeks ago, coming from Morant Bay some 23 miles offering 1s 6d a bunch for bananas which price would pay handsomely. A great many coconuts are also sent to America, but in the husk; there are no mills evidently on the north side, for turning the kernel into coconut oil and poonac. The production of fibre is being urged by the local *Gleaner* on all lowcountry planters and settlers, but there seems to be a sad lack of enterprise in Jamaica, or disinclination to turn off long-trodden paths; or there is a lack of capital, which the doing away of the consignee's loan as a *primary* claim on a property, should now do away with, as in future all claims on an estate will have priority in accordance with the dates of the loans made upon them, and registered in the Registrar-General's Books.

W. S.

* "Tea" is the subject of 143 references to papers and articles in the volume for 1885-6; "Coffee" of 52 references.—Ed.

How to make Good Coffee.—The Atlanta *Constitution* has published a Georgia woman's recipe for making coffee. It's nonsense. Her coffee is "allowed to boil a while." Thus she gets rid of the fine aroma and extracts the tannin, which is not healthful. Now, let any woman who has not a reputation for fine coffee try this recipe. Buy the best coffee and grind it to the consistency of ordinary cornmeal. Into a French teapot put an ounce of coffee for every person. One pound of coffee will make sixteen cups, and no more. Have everything clean, and as soon as the water in the teakettle begins to boil moisten the coffee gently, and leave it to soak and swell for three minutes; then add a little more water; dont be in a hurry; continue to add water until you have obtained not more than a large coffee cupful of the extract. If carefully done the entire virtue of the coffee will be in the cupful of liquor at the end of five minutes. For four persons use a quart of pure milk and have it piping hot; heat the large cups by pouring into them hot water; now divide the coffee into the four cups, each of which will be one quarter full; fill with the boiling milk. This is pure breakfast coffee, the coffee of the gods, of which no man after drinking would be so base as to call for a second cup. Such coffee connot be had at any restaurant in New York. He that drinketh in this morning will be unhappy if he fails to get it tomorrow morning but these instructions must be followed to the letter

Coca Cultivation in Java.—The following short notice appears in the *Medical Journal*, No. 5 (het Tijdschrift voor geneeskunde) contributed. In the pamphlet of Dr. Nivinny, entitled "Das Cocablatt," among other assertions it is stated that Erythroxylon coca was successfully introduced into Java by Dr. J. K. Hasskarl in 1854, but that he was prohibited from extending the cultivation by express orders from the chief of the Medical Service in Netherlands India, who looked on any extension of such cultivation as dangerous to the colony. Can nothing be brought forward by any official scientific society—for instance by the Society for the Advancement of Medical knowledge in—favor of the coca cultivation in Java? or can it be that the chance of adding perhaps 3 per cent of mentally and physically demoralized "co-queros" (coca abusers) to the adult male population of Insul-India, which already numbers 5 per cent of intemperate opium smokers, outweighs the great benefits to be derived from the bringing of cocaine within the reach of the million; which benefits will be vastly increased whenever the experiments now being made of the internal use of an infusion or decoction of coca shall be found to produce favorable results—for instance in the case of parturientes—leaving out of present consideration the great financial advantages which coca cultivation promises.—Translated for the *Observer* from the *Indische Opnemer* of the 20th May. [From the spelling it is evident that Dr. Nivenny's pamphlet is a German publication. It seems strange that the *Opnemer* neither contradicts nor admits the statement regarding the intervention of the authorities in stopping the cultivation in question. From other notices of coca in the Netherlands India papers it does not appear probable that such action has been taken. —*Note by translator.*]

THE CHEMISTRY OF TEA.

Although we agree with Mr. Barber that Dr. Watt was mistaken in supposing that damage to tea-lead was due to badly prepared tea, the real cause being almost invariably badly seasoned wood acting chemically on the lead, we yet feel that the researches of the professional chemist may largely aid the operations of the professional tea-maker. For instance, in regard to the process which is generally known as "fermentation," a term for which "oxygenation" has been latterly substituted, an authority we have consulted refuses to recognize as true fermentation any process promoted by the oxygen of the air. The question, therefore, arises, is the change which rolled tea-leaves undergo, in the process of which they are as much as possible *guarded from direct contact with the outer air*, true fermentation, or merely oxygenation, whatever the latter may involve? Tea-leaves contain a normal proportion of sugar and starch, which are not in themselves ferments, but they are, of course, liable to the action of ferments and fermenting agents, whether associated with them in the crushed leaves or extraneous. But, if the generally-received doctrine be true, that fermentation depends on the presence of the spore of an organism which feeds on and so ferments the sugar, then the professional chemist, who must be a good microscopist, ought to be able to tell us, what specific organism the spore represents,—whether the yeast plant, *Torula cerevisæ*, or some other. That question decided, the chemist might be able to observe and instruct the tea-maker to observe and decide, by a careful use of the microscope, the thermometer and other appliances and tests, the signs in the life-history of the spore, temperature raised by fermentation and other indications, the period when fermentations may best be arrested by the leaf being subjected to the action of fire. Oxygenation seems a more pleasant term to use than fermentation, but, as even those planters who prefer the former term admit that oxygenation, if allowed to proceed too far, will end in putrefaction, we feel inclined to believe that the saccharine matter in tea-leaves is acted on by some vegetable germ derived from the atmosphere in the same way that the yeast spore acts on the sugar in malt used for transformation into beer. It is highly probable that the spore is that of a different organism, however, the action of which as a fermenting agent may be slower and less violent as a heat-producer? Such are some of the points on which tea-makers might benefit by the examination and advice of professional chemists. But, as we have said, every tea maker is really a chemist in degree, and what seems wanted is that chemical knowledge in the case of the tea maker should in certain directions be amplified and extended. A peripatetic chemist, therefore going the rounds of the various tea factories, pursuing researches into the chemistry of tea with the aid of practical men, and giving those practical men the benefit of theory founded on science, shewing them the reasons for processes which by rule of thumb they have perhaps long practised, and recommending improved methods as the result of research, might confer great benefit on the tea enterprise as well as on himself, for in this, as in other cases, the labourer would be deemed worthy of his hire. We may probably be revealing unjustifiable ignorance, when we ask, has the development of any spores of minute organisms ever been observed in tea leaves undergoing the process of fermentation? Messrs. Gow, Stanton & Co. do not seem to recognize fermentation due to the presence of vegetable spores. Their language indicates a belief in chemical changes effected by the air, irrespective of the germs which inhabited it. We quote from one of their circulars, as follows:—

"Without further considering the intermediate processes of rolling, &c., we come to the firing. About this operation there appears to be mistaken views. Tea must not be calcined. This is the whole secret. The leaf, when in its withered state (properly withered that is), contains most delicate chemical products, to be dealt with very differently from what on many estates it now is. The process too prevalent is, to "fire off" quickly, and such a process at the high temperatures now used really burns out its active principle. Analytical experts declare that when the leaf is properly dried, the tannin or astringent principle remains undisturbed. The aroma of the leaf is dependent on the careful application of heat at a certain maintained degree of temperature. Then, too, with a very high temperature the process of firing destroys the gum and the theine, leaving the almost charred woody product behind, which, when infused, gives such unsatisfactory results, and leads to so many complaints of quality. From our own personal knowledge of tea-planting we venture to ask planters, when dealing with 'green' leaf, to keep the following facts before them, viz:—Starch is universally diffused throughout the vegetable economy, especially in leaves, that the absorption of oxygen from the air converts starch into sugar, and that the green resinous principle of the leaf diminishes in quantity while oxygen is absorbed. The excellence of black tea depends upon the management of the leaves in such a way that the above noted chemical changes may take place."

But the question we should wish to see authoritatively decided by a well qualified chemist, is,—Can the mere oxygen of the air absorbed by starch, converting that starch into sugar and diminishing the proportion of green resinous principle, in the tea leaf, account for the changes which take place in rolled leaf during the process in which the colour passes from vivid green to bright copper? Do or do not some of the teeming life germs with which the atmosphere seems to be loaded, have as much or even more to do with the chemical change, than even the absorption of oxygen? Can oxygen indeed be absorbed by the moist, bruised mass, perfectly pure and unaccompanied by spores which when they come in contact with sugar produce "fermentation?" Will some expert kindly reply?

MR. SHAND'S LECTURE ON TEA.

Dr. Watt of India and Mr. Barber of Ceylon on the Chemistry of Tea. Mr. Barber has sent us a very interesting letter from which we quote as follows:—

On Wednesday Mr. Shand read a paper on British-grown teas and treated the subject in its many aspects, domestic, sentimental and political. After this Dr. Watt, one of the Commissioners for India, spoke of his experiences in India and on tea matters generally. At the end he wound up by referring to bad packing and faulty manufacture, rapid drying and wrong fermentation and such other "rot" that he knew nothing of, but deemed fit to speak about, in order to say that he thought chemistry and science could help the tea planter to avoid certain consequences and in order that he might in short teach his grandmother to suck eggs. Excuse this vulgarism. I can find no better words to express my disgust at treating a London audience to faults manifold and pernicious in their results, just after a paper treating on the excellence of British-grown teas as against foreign teas.* He said 1st, that we fired off too fast, that in preparing botanical specimens they dried slowly with blotting

* Dr. Watt has done good service in classifying and describing the vegetable products of India, but his contention that badly fermented tea corrodes the lead of tea chests, exposed him to deserved ridicule. —Ed.

paper, &c., forgetting that they remain in the infancy of the art just where they were before, while we advanced from sun-drying to "chboolas," and thence to siroccos and Victoria driers. Besides, there is no analogy between drying a single leaf and treating 8 or 9 thousand lb daily rolled and smashed to a pulp. The one needing a drying to *preserve the specimen*; the other to produce a distinct aroma, the result of brisk firing. The man had no authority to speak as he did on a subject foreign to him. He next thought that some tea that had been found damaged suffered in consequence of faulty fermentation and warned tea planters and again thought that science (chemistry) would soon help us out. He was wrong again, for green teas that are not fermented at all from Japan and China are found to keep well, as the most fermented teas of the early season from Ceylon. Fermentation cannot affect the question in the least; moreover, chemistry is not of the least practical use. If merchants and brokers in London thought so, they would not go to the expense of keeping tea-tasters at high salaries.* A few bottles of chemicals would be sufficient to solve all difficulties. Now I may mention to you that I read several books down to Pasteur on fermentation and had a miscroscope in use for days at Blackstone in the hope of applying chemical aid to ascertain the right fermentation, but to no purpose. It is not of practical utility. As the tea-taster's palate fixes the value, the tea-maker's eye and sense of smell should fix fermentation—and we should rise superior to the delicate tests of chemistry and the troubles of a laboratory, as we really have. Well, now, having given you an idea of the ground on which I stood you will understand that I could not allow these statements to go unchallenged. I therefore made a statement to disabuse the minds of the audience. I saw Young and the pilgrim T. Gray among the number who approved heartily of all I said and cheered lustily. I cannot produce now all that was said but I daresay Mr. D. W. Ferguson will tell you all—or the substance. However I give you the circumstances that will show how false an impression the audience would have carried away home had there not been some contradiction. Hughes, the chemist and another were present. The former came to me and had a talk with me and said he disagreed with me. I said he was not expected to agree. I had already said, however, that I was prepared to correspond with any chemist on the subject, or to discuss the matter, and I was not prepared to grant that fermentation was answerable for damaged condition on arrival. I daresay, you will have the substance of the speech. Several present obtained my address and you may be sure I shall spare no pains to let them know what Ceylon tea is. Shand is very busy. His room or office by the Ceylon Court is always full, and he is doing great service. The Ceylon Court is the best frequented, and Ceylon tea is the most in demand. There are appus serving. It was a good idea altogether. I have not the time to write more this mail. The first batch of rollers are being shipped and shipping will go on once a week now. They came from a splendid factory, where I saw about 1,400 British workmen at work.

Tea Prospects.—The weather reports from the tea districts are generally favourable. At Chittagong, however, the late very heavy rain has done some damage, and in Kangra and Kumaon several gardens have suffered severely from hailstorms.—*Pioneer.*

* But tea-tasters and tea-makers are really chemists.—Ed.

CEYLON UPCOUNTRY PLANTING REPORT.

THE PANIC FOR COOLIES—PUBLIC TEA SALES—THE ECONOMICAL MAN ONCE MORE—FOWLS CLEARING TEA LAND OF GRASSHOPPERS—QUALITY OF TEAS.

5th July, 1886.

The panic there was some time ago regarding coolies has pretty much subsided, not, however, without having left some evil results in the affected localities, in the shape of heavy advances and an unstable working force drenched in debt. The men who were wrought on by the idea that there would be a scramble for labour, did their very best to bring this undesirable state about, by recklessly bidding higher than their neighbours, and giving a cooly such a value in his own eyes, that it must have tickled Ramasami when in a thoughtful mood he cast up his honest deservings, and totalled his "modest work." Looking as he always does to his master for leading, it is but natural that he should appreciate himself at the extravagant though factitious value which his timid employers are too apt to set on him while in a state of panic; and when the planter goes in for a large labour force at any cost, recruited from he knows not where, Ramasami is not the one to neglect such an opportunity of dipping deep into the planter's purse, and getting himself into that state of indebtedness, which to the Tamil mind means honourable respectability, but to ours has a decided flavour of the very reverse. The amounts which have lately been given for some gangs of coolies, if my information be correct, are startling enough. But coolies from the Coast are not hard to get, neither are they unwilling to come. Besides this if the thing is gone about in the right way—on such sensible lines as Mr. William Smith indicated—ten rupees expended on the raw article, recruited on "the village green," will give a much more satisfactory result than twice or three times that money when it goes to buy up those wandering reprobates, who, ever dissatisfied are always on the move, and whose acquaintance with Chetties, Afghans, and other money-lending harpies, are about as co-extensive as their knowledge of the present race of durais, and the geography of the planting districts. Even good coolies get unsettled when there are kanganies going about offering R10 and more a head, with a background of indefinite promises. but it is the wanderers who first respond. That we will want a large increase of our Tamil labourers goes without saying, but if that were the only difficulty we had ahead of us in regard to our new enterprise, we might account ourselves happy and dismiss it from our minds.

The collapse the other day of the public Tea Sales, does not give one a very exalted opinion of the enterprise of our present race of buyers. I suppose that there were reasons for the extreme caution displayed; yet being in telegraphic communication with the London market one would have thought that a less timorous policy might have been the result. The public sales don't always do the best r the seller, as witness a lot I heard of the other day which was thrown back on the broker's hands, the buyer maintaining that he had bid one cent less than that entered in the broker's contract. This same lot was shortly afterwards sold privately at an advance of 4 cents a pound on the auction price!

I have been told that there is one, evidently the economical man once more, who is trying to cover his bungalow supply of rice out of the samples he gets from Colombo. He complains sadly, however, that the samples are very small, not enough even for one dish;

nevertheless he has hit upon a plan which he hopes will do well for him in every way. With a zeal for fair dealing, he has requested that a sample from each bag should be sent so as to put a check on anything like mixing, and if can carry that point, he will have all his anxiety altogether removed regarding his bungalow rice supply!

The ravages of the grass-hopper on tea planted at stake is often so worrying, as to make the planter almost regret at times, having gone in for tea. How to prevent the insect from carrying on its destructive work is however the difficulty, and yet when you see the tender shoot laid over, you feel savage enough and would gladly try something to save others from similar misfortune. I understand that this hard problem how to checkmate the hopper, has been solved by the simple plan of getting together a lot of village fowls and herding them over the field, in which the tea seed has been planted. The fowls take kindly to the grass-hopper, and very soon reduce their numbers.

In America it is a common enough thing for a man to go in for "a hen ranch." I knew a a Ceylon planter who tried it, and did not make a fortune by it; but then he depended on his fowls alone. A hen ranch on a tea garden would be altogether different, for besides their use in clearing the land of grass-hoppers, the birds might be supposed to fatten for the table, and thus more than cover the outlay connected with their upkeep.

In these days when the tea planter is being preached to on all hands regarding the necessity of keeping up the quality of his teas, I fancy that we will have to recognize the fact that soil, elevation, and plants are factors which the skilled manipulator has to take into account. One of the most successful tea-makers in the island, when visiting a friend lately, offered to take charge of the three days' making, and promised to turn out a sample of tea which would equal his own. He did his best to bring about this result, but failed. Although he somewhat improved the quality, still it was a long way from that which has raised his name and that of his estate into the first rank. How was this? Had the soil, elevation, or kind of plant anything to do with it? Whatever was the reason, there was the hard fact that a man who can regularly turn out teas of the first grade while on his own estate, yet failed to do it with leaf grown at a different elevation and on different soil. PEPPERCORN.

OVERPRODUCTION OF TEA.

The June number of the *Revue Coloniale Internationale* contains articles of interest in French, German and English. Amongst the latter we find an article entitled "Overproduction and Tea Culture" by R. A. K., translated from *De Indische Mercuur*. It commences as follows:—

Ask whom you will; ask the whole world round, where, at present, is there any prospect of earning something? Where does business flourish? What persons, what trading-houses can candidly declare that they are progressing in prosperity?—There are but very few and those solitary cases, that can be pointed at who can say so. If there are—as regards Netherlands and the Netherlanders—a few banks and money establishments, at Deli and Billiton, a couple of railway companies and newspaper undertakings, almost all is said.

The history of former ages shows periods of general depression and of dearth and famine; but if you investigate the causes, these will be found to be war, persecution for the faith, plague, floods or similar calamities interfering with the regular production, and thus putting a stop to all trade for want of available commercial wares, or else for lack of sufficient security to persons and goods. Whereas *now* that depression prevails everywhere, and though there is no question of a general famine as used to rage in times of yore, yet when a number of individuals and families are really starving, *now* the case is just the reverse: not the stoppage of productiveness, but over-production; not a lack of available commercial wares, but accumulation of stock and excess of supply; not the absence of security for persons and goods, but (save very local and transient exceptions) order and peace everywhere, accelerated expedition of merchandise, and rapid and convenient locomotion for the traveller.

Where then lies the fault? Have fields, gardens, pastures and woods become less productive? Does the miner dig less treasure from the ground? Do the fishermen's nets and hooks capture less prey? Have the means of communication by land or water become more imperfect or expensive? Is there any lack of intelligence to render the work efficient and economical, in short, to make it productive? Is there a paucity of labouring hands? By no means. Science has extended her benign power over all human transactions. Botany, Zoology, Chemistry and Mechanics have exerted their beneficial influence on agriculture and cattle-breeding; gardening and forestry are attended to with greater care and consideration than formerly; mineralogy and metallurgy instruct the miner; chemistry, electro-magnetism and all kinds of scientifically improved instruments and appliances everywhere facilitate the labours of the manufacturer, the mariner, the fisherman, the architect; and now, where force falls short—where the human hand, the ox and the horse, the windmill and the water-wheel, which formerly were all in all, prove insufficient, steam steps forth in a thousand ways, and furnishes force to any amount.

Then to what or to whom is the fault to be attributed? Man alone is in fault himself. His extravagant desires and his want of sense are the fault of all this. We are—and with cause—proud of the scientific attainments of the 19th century, but, alas! we overlook the fact, that commonsense is often lamentably in the rear. Merchants, ship-owners, railway-kings and statesmen, who have mayhap often chuckled at the story of the six gates of Abdera as a skit on the silly application of the rule of three, apply that very rule to enterprises, to which the six gates of Abdera might be rightly termed mere child's play. The greatest, and in its consequences the most ruinous, affair of this kind, of which recent times have offered us the painful and striking spectacle, were the railway speculations in America.

Details of railway speculation in the United Sates are then given. The conclusion is:—

The cupidity of the would-be millionaires has levelled a severe blow to the prosperity both of America and Europe; and nobody is able for the present to compute how much time it will take ere commerce, agriculture and trade will emerge from this pool of overproduction, in which they are all in danger of being submerged. This one example of *Abderitism* will suffice for my present purpose, though innumerable instances might be produced in other departments.

And then the writer goes on to deal with our Ceylon tea enterprise, thus:—

Let us hope that good sense has been purchased in proportion to the enormous penalty? It is not only a sad, but also a grievous spectacle, surrounded as we are by so many examples of misery resulting from over-production, still to see persons, who not only refrain from warning against it, but who do all their best to increase the evil with all their power; who summon up "all hands" to give even a greater expansion to this existing over-production. What precedes reflects near about the course of my ideas while reading a pamphlet published the other day, entitled: *The Ceylon Tea Industry, an opening for men of moderate Capital. By John Hamilton (late of Ceylon).* To those who take an interest in Colonial agriculture, the vicissitudes of culture in Ceylon are generally known, and so I need not here enlarge upon the incidents in that Island with respect to coffee and cinchona. With truly admirable energy did the capitalists and planters of Ceylon, when coffee

and cinchona threatened to collapse, seize upon a new culture — that of tea; and however alarming this new rivalry may be for existing concerns of a similar nature yet no tea-planter, whether he may have established gardens in Assam, Darjeeling, the Nilghiris, in Cachar, Bagelen, the Preanger-Regencies, in China or Japan, can take it amiss if his "fellow-planter," endeavours with courage, energy, and perseverance to keep himself standing by tea-culture, when coffee and cinchona leave him in the lurch. If, however, the new culture in Ceylon really proves such a boon to the embarrassed planter, we must question whether the clatter with which the novel industry is trumpeted forth be not a great folly.

Not only in special papers, but in almost all other newspapers and periodicals, we find articles and computations to prove that the Ceylon tea possesses qualities superior to all other existing teas: that the rapidity with which the produce extends is amazing; and that in a few years, it will amount to forty millions pounds English. The Englishman, otherwise so practical, seems for the moment to be blind to the impending danger of over-production:— "The more tea Ceylon produces, the sooner we shall have sufficient to displace the China-crop," I read lately in the Indian Planter's Gazette. I hope they may; but I am not so very sanguine about it, after the ample experience of the consequences of over-production, which the tea-planters, too, have so amply experienced these ten years. The present crop of tea out of China is really more than sufficient to render the competition with that mighty tea-growing country very keen; and it is at any rate extremely dangerous to expedite the natural course of production of any article whatever by artificial stimulants.

If Mr. Hamilton is seriously concerned for the welfare of the tea-planters in Ceylon, and the prosperity of their industry, he could pursue no more unadvised course than thus enticingly summoning all "men of moderate capital" to repair to Ceylon and thus increase the already great number of tea-planters.

Indeed, the price of tea has declined so considerably from the rates at which it stood some 10 or 12 years ago, that, for planters who have not happened to work under exceptionally favourable circumstances, it has already become a question of "to be or not to be"; and that they have only succeeded in holding their own by great exertion, judgment and parsimony, or, as the saying is to get on a little by hook or by crook. If affairs flourish in Ceylon, . . . we cannot but congratulate the good planters on their success; but in their own special interest as well as that of other tea-planters, we would hope they will have the good sense of working on quietly, without any clamour, and that they may thus be left at leisure to lay by something against a rainy day, before the tea-business becomes, like so many other businesses, a wild contention of offers at lower and still lower prices; and ere not only the present planters, but moreover the "men of moderate capital," called upon by Mr. Hamilton, pull each other to pieces, as we say, while the tea-market itself is overwhelmed with tea.

This boasting about Ceylon's tea-production has sometimes led me to suspect whether there is not a little mystification in the case. I must candidly confess that the perusal of the above-mentioned pamphlet, "endeavouring to give a short account of the rising tea-industry in Ceylon, possibly destined, erelong, to make this island the Tea-garden of the World" as the esteemed author concludes his treatise, has not cured me of my doubt. What must a tea-planter think of a communication, for instance, as that about the Mariawattie-estate, occurring in the work, which plantation is said to have produced in the last two years successively, upwards of 1,100 lb. of tea *per acre*; on which he very justly observes, that it is "a feat unequalled by any estate in the world?"

This produce would be equal to:

1,763 half kilos per Bahoe
or 2,469 „ „ per Hectare.

Another article, viz, one in the Indian Planters' Gazette of the 19th of January 1886, I found also highly remarkable. It is entitled "Notes of a Visit to the Planting Districts of Ceylon; by an Assam Planter" (signed) J. O. Logan. From this paper it appears first of all, that the writer is an Englishman, then that he is a tea planter and must therefore be considered as a competent judge; the article gives also the impression of being written without any partiality. The writer relates, that he and another tea-planter visited several tea-districts in Ceylon; and that each having done this by himself, they finally compared notes. The opinion of the two experts agreed in regarding the climate and rainfall as very favourable to the tea-culture; not so unconditionally favourable was their opinion of the soil; at least the conclusion is, that tea may succeed very well in Ceylon, if the plant be judiciously cultivated and carefully treated *at all events when manure can be applied*; "but, alas!" adds the writer, "at present neither of these conditions are being fulfilled; tea is planted *anywhere and everywhere*; almost any land is thought good enough to grow tea on, etc."

The system of plucking and pruning as practised in Ceylon is decidedly condemned by the planter from Assam. The average wages of coolies throughout Ceylon stated as being 5 1-3rd annas = 33 Rupee cents per day, or 9 Rupees per month. Women 25 Rupee cents or 4 annas per day. It is difficult to deduce hence any comparison with our wages in the Dutch Indies, on account of the uncertainty of the comparative value of the Rupee to the Dutch currency, and the wages not being invariably the same in our colonies. The 33 R. cents would make about 39 cents Dutch Currency. "A remarkable tone of sanguine boastfulness runs through all the literature," observes our Englishman, "and much of the conversation about tea in Ceylon." "There is another aspect of the enterprise" he continues, "that struck me forcibly. Everyone seems to be planting tea, with the intention of selling to some one else, and clearing out of the island as quickly as possible. This is speculation, not investment; and is wanting in the elements of stability." How far this may be true, the writer of the present lines dare not decide; but he believes that it would be acting more in the veritable interests of the Ceylon tea-planters and of all their "fellow-planters" to warn them of the dark, ominous cloud, gathering over their heads, than to write such pamphlets as the one we have just discussed, by which one may become an accomplice in the ruin of others.

The principle on which the writer would aver us act is truly Dutch: if you have a good thing keep it dark so as to secure a monopoly of its benefits. About Ceylon and its tea, as about other countries and their products what is wanted is the truth and what Mr. Hamilton quoted about Mariawatte and its yield, is true. On the other hand we have the statements of the Indian planters. We in Ceylon do not overlook the danger of over-production, but we have good reason to believe that the quality of our produce will assert itself in the sharpest competition.

TEA PROSPECTS.

The fact that tea is now, as it has always been, the most important article of a grocer's trade, is sufficient reason why those whose interests are so materially affected by it should make it their constant study, and seek to understand every aspect the subject may present. Of such vital consequence is the working up of a good tea trade to grocers that, if they desire to succeed in their calling, too much attention cannot be bestowed by them on this department. With regard to the prospects of the new tea season 1885-86, although things are still slow, there are signs of rather more trade throughout the country, and it will not be denied that the season has opened under more hopeful auspices than did the last. Stocks are down one-half, while consumption is on the increase, and probably the only cause that militates against an immediate rise in prices is the uncertainty as to future supplies. Another reason for tea remaining at present

low rates is the eagerness of the public for anything and everything that is called cheap. This rage for cheapness has been fostered by dealers and worked upon by present giving shops and the like, until at last the retail prices of tea have been forced down to a point at which it is impossible to provide a really good article. In all probablity a reaction will sooner or later set in, and the demand will be for quality; then will be the grocer's opportunity to prove to consumers that long study and experience of the trade enables him to supply the want, as no mere novice or dabbler in the trade can. Of good tea there will be no lack if only the demand is alike good and the public are able to appreciate it and willing to pay a fair price. It is unnecessary to remind our readers that the quantity of tea exported from China to all countries is only a tithe of what is actually produced in that vast country; nor that the Chinese have for centuries made the growth and preparation of tea one of their staple industries, and have succeeded in bringing it to the highest state of perfection. But, besides China, the capacities of other tea-growing countries are practically unlimited, and in this way the annexation of Upper Burma may be reasonably expected to yield great results to Anglo-Indian enterprise. Advices from Calcutta state the probable export of Indian tea to this country for the coming season as about 64,000,000 lb. which, if correct, is only a little ahead of last year, but it is acknowledged that the supply might be immensely augmented in the future, and in all probability it will be. In considering tea prospects the rapidly growing importance of Ceylon as a tea-growing country must not be overlooked. Already it occupies no mean position, since the crop of the current season is expected to reach 6,000,000 lb., or fully 10 per cent of the whole production of Indian tea; this quantity, however, the planters predict they will be easily able to double next year, and three years hence they hope to have their export up to 20,000,000 lb. Nor is it only from Ceylon that large imports of tea may be expected, but Java, Brazil, Florida, and even Natal, are all coming competitors to be taken into account; still in spite of all this promised abundance, we are prepared to maintain our conviction that tea, bearing its present duty, is destined to rise. In India we are told, with the best known appliances and the most careful management, Tea can be grown at a minimum of 10d per lb. In such a season as 1884-85 that would yield very little profit on medium crops, while on inferior sorts it might mean actual loss; and it is in the order of things for skilled labour to increase in value. There is also a homely saying about a bird in the bush, and the fact that stocks of tea in this country are now so low, is certainly some temptation to bold operators to hold lay of the market and try to twist it up. Such an incident may develop any day, while the unsettled state of political affairs and the consequent uneasiness felt in commercial quarters lead to the fear least advantage should thereby be taken to enrich the few at the expense of the many. The great desideratum for the country at this juncture is confidence at home, with the opening up of new markets for British trade. While little can be expected from our Continental neighbours, and perhaps even less from America, there is much to be done in India, and it is in that country and China with Burma, that the great field of future commerce must be looked for; and hence we judge that a great extension of the Tea trade is one of the things that may be confidently reckoned upon and should be prepared for.—*Grocers' Journal.*

PLANTING IN NETHERLANDS INDIA.

(*Translated for the Straits Times.*)

COFFEE AND SUGAR.—PLANTING DEPRESSION.

The Java *Bode* of the 18th June asserts that hard times indeed are in store for the planting and mercantile community in that island. The low rates for sugar ruling in East Java where no more than 8 guilders per picul has been offered will only allow growers just to pay expenses under favourable circumstances. The only too probable result will be the closing of most of the sugar mills and the bringing down of many mercantile houses in Java. When closing is once proceeded with there is every reason for fearing that more than nine-tenths of the mills which now further so much wellbeing among the people around, will shut up, and the natives in the neighbourhood will find themselves without money to pay up the heavy taxes now bearing them down and also without sufficient food. The outcome will most likely be a storm which, unless curbed in time, will become only too widespread. Another portion of the population, namely pretty nearly one-third of the European element, will be involved in the almost unavoidable ruin of the sugar growing industry. It is a moot point whether they will quietly bear with their becoming paupers. The times even now are distressing enough. Misery is rife among the lower classes of European society in Java who, in default of honester means of earning a livelihood, have been driven to begging, robbery, smuggling, and even worse callings. Should this disorganization bring on disturbances when even these means fail, putting them down will be hampered by the insufficient number of troops available for service. The widely prevalent depression of trade and industry in Java has made itself apparent in the yield of taxation, a marked falling off being only too evident. The outturn of every tax has fallen below the estimate, sometimes as much as one-half. The coffee yield has diminished alarming, and the land-tax does not come up at all to the mark of the assessment. Yet the expenditure shows steady growth for all that. What with failing revenue, crippled planting enterprise, a weak army and navy, and beri-beri stalking over Acheen, the outlook for Netherlands India is far from being cheerful and encouraging. There is no hope for the better from changes in the machinery of the Home Government. The Parliamentary elections in Holland has resulted in a majority for the Liberals who, when they do come to power will assuredly go on with the present colonial policy of laying on more and more taxes regardless of the consideration whether they prove burdensome to the people or not.

Ravages by Locusts in the Philippines.—On Sunday, the 23rd May, there passed over the bay at Iloilo a cloud of locusts so thick, says the *Porvenir de Bisayas*, that at times it was impossible to see the neighbouring hills of Guimaras. A part of the cloud settled on one of the vessels in the bay, completely covering it, and the crew killed an immense number of the insects in driving them off. The insects were moving in the direction of Negros Island, which we learn from a subsequent issue of the *Porvenir*, was suffering severely from their ravages, all the fields being invaded by them. The authorities had issued notifications regarding the means to be taken for their extermination, and the Governor was going out in person to see that the measures laid down were properly carried out.—*Daily Press.*

Shea Butter Tree.—M. Heckel whose researches on the alkaloids of the kola nut are so well known has recently called the attention of the Academy of Sciences of Paris to the importance of the Shea butter tree (*Butyrospermum Parkii*) as a source of gutta-percha. The milky juice of the trunk when solidified has, he states, all the appearance and properties of gutta-percha. The tree can be tapped when four years old, grows readily in argillaceo-siliceous and ferruginous soils, and is found over a large area. M. Heckel also suggests that the *Bassia* trees of India should be examined with respect to the character of the milky juice they contain.—*Madras Mail.*

Correspondence.

To the Editor of the "Ceylon Observer."

THE CEYLON FISH-CURING ENTERPRISE.

New Peacock, Gampola, 28th June 1886.

Dear Sir,—An important industry has lately been inaugurated, in the island, viz., Fish-curing. Having had several cwt. of said Hambantota fish, from Messrs. J. Auwardt & Co., Colombo, in behalf of my coolies, I am very favourably impressed with their quality. I found them a wholesome, good food, when compared with the *carawaddy*, our poor coolies usually have to put up with (simply sun-dried without salt and in a high state of *fetor* before reaching Ceylon from India). With your permission I would make a few remarks on this industry. I would first like to offer a few hints to the *promoters* of this industry which, if attended to, would improve the quality of the fish :

Firstly.—Thoroughly wash the fish and free them from all blood (sea water is sufficient for this purpose.)

Secondly.—Take the head off, and two thirds of the backbone.

Thirdly.—The *salting* of the fish, should be carried out as follows :—When the head and backbone have been removed, and the fish thoroughly washed, then carefully begin in laying the fish singly, *head* and *tail*, into neat two or three feet squares, giving each layer an *abundant* supply of salt, carefully sprinkled over every part ; over each three feet square heap, place a layer of boards, and on the top of the boards, put over each heap, five to six cwt. of stone; the pressure produced, has the effect of causing the salt to permeate throughout the fish and at same time the fish gives off the fatty or oily matter more or less in all fish, which is found to be impreservable, *even by salt.* All the fish I had contained the rancid oil in them, because no pressure was applied, or, if applied, the head and backbone being left on them prevented an even pressure on the substance of the fish, and consequently the non-expression of the oil or fatty matter. The pressure should last for five or six hours. Then turn the squares (and re-salt) for other three or four hours. Nothing more is wanted, but three or four days of Hambantota *sun*, to make a perfectly wholesome food, cheap wooden presses on the *lever* or *screw* principle would be better than heaps of stone, if to be had.

I presume the retention of the head and backbone (although unfit for food, and most detrimental to speedy and safe curing of fish in a tropical country) is on the score of economy, not to loose weight. Does it not strike the promoters of Fish-curing, were they to well salt heads, backbones and offal and allow the sun to dry the last particle of moisture from them, that they would prove a valuable fertilizer if sent to Colombo and placed under our now silent coffee peelers for trituration. I believe they would soon be in demand, at R50 to R70 per ton, when the value of such a promoter of tea leaf became known.

I most candidly believe the Fish-curing industry, if fostered and promoted all around our seaboard, would be of far greater value to the natives of the country than tanks and roads in districts where there are no population, and where sickness in the form of fever render's life a misery, while the whole seaborde of Ceylon is healthy for natives, as seen by their robust health, while 20 miles inland you come to the poor wretched fever-stricken villager, *pot-bellied by enlarged spleen*, emaciated and spindle-*shanked* from the want of nourishment.

Would it not show wisdom and humanity in our rulers, if some of the large sums of money annually squandered on irrigation works (which never have *nor ever will pay*), were used to promote Fish-curing. We never can rob the "vasty deep of its wealth, while every R10 taken out from it is real wealth without the slightest drain on the national store. I have known a small seaport town on the east coast of Scotland draw a quarter of a million of money from the sea in six weeks' time, which when divided among the 7,000 inhabitants showed itself in their wellbeing and social condition. That there are splendid fisheries all around the seaborde of Ceylon with an abundant supply of naturally formed salt for the preservation of fish, it has long been a wonder some of our wise rulers never thought of devoting the *planter-earned* sums to such a purpose.

Let the Powers-that-be think of the poor planter and cooly, who will soon again be exporting their 60,000,000 to 100,000,000 lb. of tea, and giving the C. C. S. another chance of raising their pay all round, off their hard earnings, the coolies' and planters' pay being an uncertain quantity, varying with the times, but the C. C. S. once increased (let the times be ever so hard) never alters.

Dear Editor, I could give you many more hints, how the poor native could be benefited, were the wild irrigation mania, once *cured*. Just think of Kandoila and Rugam, &c., and now Ellahara to be.

—Yours truly, W. SMITH.

TEA MACHINERY.

Lunugala, 29th June 1886.

Dear Sir,—In your Saturday's issue I note Mr. Jackson's letter dated London, 1st June 1886, also "Notes and Comments" on same. Mr. Jackson quotes from an article of mine written for the "Ceylon Advertiser," on fuel for tea estates, in which I wished particularly in the first place to show how real was the difficulty which planters would have to contend with in obtaining fuel on many estates, and in the second place recommending the uses of petroleum as the cheapest fuel, easiest of transport, and the least liable to burn out fire-bars and plates or any other iron, especially cast-iron, brought into immediate contact with a dead white heat such as is produced by coke or anthracite coal. I have in no way criticised Mr. Jackson's machinery, but if Mr. Jackson has succeeded in getting cast-iron tubes which will for any lengthened time stand the direct action of a fire at white-heat in contact with the iron, he has achieved a great success. I have had heavy iron tubes or pipes in a Clerihew house burned through very quickly, and I have had the heavy fire-bars of an engine burned in one day by bad stoking. Of course there is a great deal in stoking as everyone knows.

I have not in any way criticised Mr. Jackson's machinery, but it is by no means perfect yet: in fact the last roller which I have not had an opportunity of seeing, I am told, is a departure altogether from the double action of two planes working at right angles, and the box or chamber for the tea in the new machine is rotary whilst the table is stationary. As I told Mr. Jackson the last time I had the pleasure of seeing him and talking with him on these matters, my objections to his machines were first the excessive cost which placed them beyond reach of the great body of tea planters, and second the power required to drive them. JAMES IRVINE.

THE PROPOSED CEYLON TEA SYNDICATE.

Louisa, 30th June 1886.

Sir,—I presume it is generally understood by the Committee who have the above scheme under consideration that, to introduce Ceylon teas into foreign countries, each agent must have recourse to his own method of action.

In this connection I am very much interested to know how the American general agent, stationed, say, in New York City, is to push a tea of which he has, say, one hundred samples, and but a meagre supply of any one of them. "Why, he must advertize!" says one.

Now, I wish to know how he intends advertizing? Through the medium of newspapers and printed circulars I presume. Such a plan of advertisemet would, no doubt, suit a nice homely little town like Adelaide; it *might* do for a city like Melbourne; but in New York city this method of advertizing is not likely to attract much custom. The most successful system of advertizing in America that I know of is that of free distribution of samples among the better classes of citizens, each sample being left at the house, and with it a blank order already addressed to the appointed agents who must, of course, be in a position to supply according to sample sent.

I may mention that the matter of delivery of goods is much simplified in America by the establishment of the National Express Co. Suppose A. B. receives a sample of tea, and with it a short account of the scheme in question, as also some interesting matter regarding the "far-off island of Ceylon" so well-known as the place where "every prospect pleases," &c. He either tries the tea (probably will) or he gives it to his servants to try, which, after all, is perhaps the best way to find out the intrinsic value of the article. He also finds an envelope addressed to the agent of the "Ceylon Tea Syndicate" enclosing a blank C. O. D. order, which he fills out and mails. The agent, on receipt of order, sends the parcel required with invoice to the nearest Express Co.'s Office, who pay the amount due at once to the said agent, and deliver the goods "straight away" to the consignee, who is charged a small commission over and above the cost of tea as per invoice, to pay the Express Co. for their trouble.

This system known as C. O. D. (collect on delivery) is perfect in so far as it makes bad debts impossible and insures speedy delivery. The one thing necessary in carrying out this line of business is *power to supply* any demand made upon any article so introduced, and to be able to supply it *according to sample*.

To give an agent this power, he must be allowed to bulk all teas *of a kind* together, or what is better have them bulked for him, before dispatch, in Ceylon. To avoid any question as to the unfairness of bulking "my good tea with thine which is (of course) inferior" an expert would have to be appointed, having full powers to judge and if necessary condemn any tea which he considered not up to a *certain standard*, which of course would have to be fixed and clearly stated by members of the Syndicate.

This standard (which must be high) might be fixed by defining clearly what sieves are to be used by all members sending in their teas through the Syndicate to the several countries, each respective agent having it in his power to suggest any change which he deemed advisable in advancing our interests in his own special market. I am told Ceylon teas "won't *mix*." This may be so although I have never seen it tried to any great extent, that is, Ceylon tea with Ceylon tea.

That Ceylon teas cannot compete with Indian teas, so far as mixing with China teas is concerned, we all know, but would the bulking of say 50 Ceylon teas from different estates turn out a bad sample, provided that these teas are well cured, equally sized, and individually tasted and passed by an expert?

Then as to an equal distribution of all necessary costs, which would of course be heavier at first than afterwards. I would suggest that individual consignments be sent to the bulking centre (wherever it may be) in lots of 1,000 lb., each lot to constitute one share, each shareholder to be responsible for his own interests according to the number of shares he holds.

I consider my suggestion wise for the following reasons:—First it will insure quantity and equality in what is put before the American public as "Ceylon tea." Secondly, every member will have his fair share of the proceeds, inasmuch as all teas will have to be passed by an expert before bulking.

On the other hand, all will share alike in the first expenses of advertizing and all other necessary expenses in connection with the furtherance of the scheme.

In conclusion let me add that I put this letter before the public as a suggestion and nothing more. If it can do no good, I sincerely trust it will do no harm to a scheme which must in one way or another be carried out if our Tea Enterprise is to end in success. That foreign markets *must* be opened for our tea is the unanimous opinion of those interested, and our thanks are due to Mr. Rutherford for taking the initiative in the matter.—Yours faithfully, J. McCOMBIE MURRAY.

LOSS IN WEIGHT ON TEAS.

1st July 1886.

Dear Sir,—Can you or any of your readers inform me *why* it is that an allowance is made to purchasers of Indian and Ceylon teas of 1 lb. in every package weighing over 28 lb. gross? Thus the unfortunate planter who lives so far from the cart-road as to render packing in chests out of the question is mulcted in close on 2 per cent in London, while his more fortunate neighbour who being close to a cart-road ships in chests loses only 1 per cent or under. Should a planter ship in boxes and the gross weight be over 28 lb. his loss in weight would be 4 per cent—of course this all in addition to any actual loss of tea there may be in bulking &c. in London. I am not yet quite sure whether the *Purchaser* or the *Broker* or *Merchant* benefit by the 1 lb. allowance. I only know that someone gets the allowance—and presumably the Purchaser, or failing him the Broker—for samples?

I never could understand how the loss in weight of from 1·90 to 3½ per cent arose until I hinted at theft in the docks as the cause, remarking that I had put half lb. extra into last shipment of half-chests and half lb. extra into previous shipment of full chests, each shipment containing close on the same amount of tea. To my astonishment the loss in weight on the half-chest shipment was nearly double that on the full-chest one and my enquiries elicited from my Broker the custom of allowances as mentioned above—presumably to the purchaser. This no doubt may suit Indian Tea Companies who possibly may get a sort of return commission out of it, but in the interest of individuals an effort should be made to stop the custom while our industry is in its infancy.—Yours truly, dear sir,

ECONOMY.

P. S.—Is this return of from 1 to 4 per cent given to purchasers of China teas as well as to those of Indians and Ceylons?

[We are assured that the custom of allowing 1 lb. on every package at home applies to all teas and that it is for shrinkage (in the timber of the chests) for leakage, &c. But the several questions raised by our correspondent well deserve to be enquired into by the Planters' Association. —Ed.]

MANURES FOR COCONUTS.

1st July 1886.

Sir,—Can any of your readers tell me how to apply burnt coral (unslaked) to coconut plants 2 to 5 years old: how much might safely be put to a plant, how applied, and how far from the trunk of a tree might it safely be spread, rather how near it? I am not asking for suggestions from any theorist, but a practical coconut planter who has either used lime, or has seen it used for coconut plants, and can therefore at least speak from practical observation. The information now asked for will be thankfully received by several coconut estate proprietors and especially by, yours faithfully, AGRICULTURIST.

P. S.—Salt too is, I believe, used by many as a stimulant: the same information regarding it will be welcome.

[We have no doubt that our Hapitigam Korale correspondent will be able to answer these queries. —Ed.]

Tea.—The report of the directors of the Kangra Valley Tea Company shows that the outturn was 88,102 lb. which is considerably in excess of the three previous years. The average price obtained was annas 10-0¼. The expenditure averaged annas 9-0¾ per lb. The Retail Depôt at Prince's Hall, Piccadilly, has paid expenses, and the quantity of tea sold there considerably increased. The estimate for 1886 provides for an outturn of 85,000 lb. fine tea at an expenditure of R33,067. The gross receipts for the year were R55,485, and the expenditure R49,842, leaving a profit of R5,643 which has been carried forward.—*Pioneer.*

Tea Factories.—Mr. J. Capper in a few remarks made after the reading of Mr. Shand's paper estimated that during the next six years, for Tea Factories in India and Ceylon, as much as one million sterling of home manufactures (iron, glass, machinery, &c.,) would be required. This is certainly a moderate estimate; for in Ceylon alone before six years are over, there will probably be 1,000 Tea Factories, big and little, and considering that some of the Factories already completed have run away with two or three thousand pounds and mainly for imported material, the million sterling, if prosperity favours the tea enterprise, will be a good deal exceeded, if India is counted as well.

Centigrade and Fahrenheit.—The Centigrade thermometrical scale is now becoming so frequently used in English books that a short method of turning incomprehensible Centigrade into intelligible Fahrenheit will be a desideratum. The rule is simple, and the operation, after a little practice, may be performed mentally. All one has to do is to double the Centigrade number, take a tenth away from it, and add 32 to the number obtained. Let us take 60 deg. Centigrade. Twice 60 is 120, take one-tenth away, *i. e.* 12, and 108 remains, which, added to 32, makes 140, which is the answer. Taking a more difficult number, 32 Centigrade, we double and obtain 64, from which we take 6·4, leaving 57·6, to which we add 32, the total being 89·6.—*Indian Gardener.*

Island Industries.—I stated in my first article that for the present I should defer alluding to the pearl shell and beche-de-mer industries beyond the remark that they are a well-established, profitable business. If, however, they are to continue so permanently, some legislative enactments will be necessary; some precautions will have to be taken to prevent these valuable marine productions of Queensland from being utterly swept off the coast. At present everyone appears to take everything he can get for fear of leaving it for somebody else, and however prolific these marine creatures may be, such inroads must bring them to an end at last. The pearl shell oyster must at any rate be amenable to scientific cultivation, and undoubtedly some measures should be taken to assist them in the propagation of their species, and to protect them from the ravages of both their natural and unnatural enemies.—*Townsville (Queensland) Herald.*

Tea Drying.—Mr. Gibbs sums up the philosophy of tea drying in these three sentences:—

1. That the tea should be kept in gentle but effectual movement, so as to separate every leaf from every other leaf, and allow the dry air to get at both sides.
2. The application of as much air as can be introduced without blowing the charge out of the machine.
3. The skilful adjustment of the temperature of that air so as to obtain the highest drying power without injure to the product.—*Nilgiri Express.*

The Yield and Condition of Mariawatte.—The following facts concerning this well-known estate, which have been forwarded us, are well worth reproduction:—The original 100 acres of the estate has given 420 lb. for the half-year just ended, 30 acres having been pruned last October, and 70 acres in April-May of this year. It is estimated that the estate will repeat its previous record, if not exceed it, which certainly shows that it has in no way suffered by reason of the heavy and abundant yields of former years. The 70 acres pruned this year were plucked continuously for 18 months, and the April-May pruning has so far proved successful, as the bushes are full of vigor, and look fit for big flushes. Mariawatte, much lauded as it has undoubtedly been, is probably acre for acre the most valuable and prolific estate of any in the world. —Local "Times."

Coral Leaf.—Among the curiosities now shown at the Colonial Exhibition is one specially interesting to ladies in search of novelties. This is the coral leaf which has been recommended to attention by the English Consul at the Bahamas as a valuable discovery for millinery purposes. It is lighter than jet in weight —a great desideratum in head-gear—it can be dyed any shade or bleached the purest white, and, being of a very pliable nature, is said to twist into the most perfect and artistic specimens of hats and bonnets. Ingenuity has been sorely taxed to provide a headdress that shall not outrage artistic feelings, and at last there seems a hope that in the coral leaf has been found a hygienic and tasteful solution of this difficult problem.—*Home News.*

Trade in Dried Fruits and Vegetables in Austria.—The immense importance of the trade done in the above useful articles of food by the Americans especially, and in a less degree by the Germans, French and Swedes, has at last appealed to the minds of the more apathetic Austrians. An experimental station fer research into the best methods of producing first-class marketable commodities has been established by Graf H. Attem's at St. Peter's near Gratz, and the results obtained are so encouraging that it may soon be looked upon as a certainty that the home-manufactured articles will take the place of the imported ones, and that considerable impetus will be given in that country to the cultivation of the various vegetables and fruits that can be dried with the best results. The *K. K. Oesterreichischen Pomologen Verein* has sent out a pamphlet recently, in which the various important uses to which the dried goods can be put are succinctly pointed out, especial emphasis being laid, owing to their extreme portability, on their use by the army and navy, hotel keepers, and dwellers in towns, who, by being far removed from sources of supply, or by reason of their comparative dearness, are debarred from the enjoyment of these health-giving articles of consumption.—*Gardeners' Chronicle.*

NATAL TEA.

TO THE EDITOR OF THE "COLONIES AND INDIA."

Sir,—You have from time to time kindly published my communications relative to tea culture in Natal, in order that people in this country interested in one of the burning questions of the day (*i.e.*, what to do with our boys) might be informed of the opening for capital and labour existing in the Colony to which I belong.

In the issue of your journal last week you furnished particulars of the public sale of a small consignment of tea from Natal, averaging 1*s.* 7*d.* per lb. in bond, and this price was realized in the teeth of the broker's report that the tea was over-fired or burnt, and irregularly fermented, being details of faulty manufacture which experience will remedy.

The tea itself contains the elements of good quality, only needing the guidance of an expert or experience in the manipulation to do it full justice.

From Messrs. Gow, Wilson & Stanton's Indian and Java tea report of the 11th inst, I quote the following as an idea of the current price of Indian teas in London:—Fanning, red to brown, strong rough liquor, 7¾*d.*; Broken Tea, fair brownish to blackish, strong liquor, 8½*d.*; Pekoe Souchong, fair blackish greyish, useful liquor, 10¾*d.*; Pekoe, fair greyish to blackish, some tip, useful liquor, 11¼*d.*

It is evident from the foregoing that Natal planters have a cheering prospect to stimulate them to use every exertion to produce quality rather than quantity, for the deduction is that good tea will return a good price, as the great bulk of the tea which reaches this market is of very inferior quality or strength.

There was opened yesterday at the Colonial and Indian Exhibition a new tea pavilion for the sale of Natal tea by the cup, which was largely patronised, and the quality of tea supplied afforded great satisfaction, freely expressed by the public.

In the Natal Court tea from various estates is shown (a parcel of a ton from one); photographs of plantations are on view, and every information can be afforded.—I am, &c., Morton Green, Brixton Hill, June 15, 1886.

HYDROQUININE.

Some years since (*Pharm. Journ.*, [3], xii., 905) in a paper describing several alkaloids found in the mother-liquors obtained in the manufacture of quinine, Dr. Hesse gave some account of one containing two atoms of hydrogen more than quinine, to which he gave the name "hydroquinine." In many respects it resembles quinine, dissolving readily in alcohol and ether and forming a crystalline hydrate when precipitated from the solution of its salts by ammonia. Its rotatory power is less than that of quinine. The solution in excess of sulphuric acid has a blue fluorescence, and with chlorine and ammonia the alkaloid gives the same reaction as quinine. The therapeutic action of this alkaloid has recently been studied by Seifert, who finds that it is an antipyretic superior to salicylic acid and kairine, reducing the pulse and the temperature with abundant transpiration. The dose is about the same as that of quinine and its continued use is not attended with disagreeable effects. There is reason to believe that the presence of this alkaloid in commercial quinine sulphate may have been the cause of the exaggerated estimates of the amount of cinchonidine in that article, as will appear from a paper on this subject by Dr. O. Hesse that will be published in this Journal next week. Meanwhile it may be mentioned that M. Armet de Lisle has addressed to the Académie de Medicine a formal protest against the statement made by Dr. de Vrij that the quinine sulphate of his manufacture contains 12·448 per cent. of cinchonidine sulphate. Another circumstance which appears to throw considerable doubt on Dr. de Vrij's results is the amount of water of crystallization which he gives for quinine sulphate of English manufactures viz., 10·85 and 5·72 per cent. In any case it seems very remarkable that he should regard such a small amount of water of crystallization as being the reason why a particular make of quinine sulphate commands a higher price than others. The *Pharmaceutische Zeitung* also calls attention to the fact that according to Dr. de Vrij's statements the quinine sulphate made in Germany would not hold the first rank as to quality, and it is suggested that German manufacturer of this article should take steps to furnish such an explanation as is desirable in regard to this subject. —*Pharmaceutical Journal.*

THE CINCHONA MARKET AND PRODUCTION IN CEYLON.

Our readers will without doubt have taken due note of the last local sale, on Thursday, of 72,829 lbs. of cinchona bark with the analysis and the prices realized. We cannot but regard the continued fall in bark, both locally and in the London market, as eminently unsatisfactory, not only so at the moment as it affects producers who are forced to realize their crops, but more particularly as being entirely without the slightest gleam of hope for a better condition of the market in the immediate future. Some of the bark at the sale to which we refer, analyzing 2 per cent of quinine, appears to have realized about 21 cents per unit, a figure to which we think we are justified in applying the word miserable. Shortly after the great rush for cinchona planting had fairly begun, there were many who were unable to see where a market could be found for the enormous production of quinine which seemed to be quite possible in the future, and who confidently foretold the consequences which would follow in its train. But the opinions of many eminent specialists were put forward in contradistinction to this, and planters were told that quinine could be used for brewing beer, for fixing dyes, for tanning; and for a variety of purposes from which at that time its excessive cost debarred its general use. It was boldly asserted that a reduction in price by 50 per cent would leave an ample margin for immense profits to growers, and that such a reduction would induce the use of quinine as a medicine to an extent far beyond the imagination of the men of that day. The Chinese, for instance, were to cease the use of opium, and exist on quinine as a preventive to the ague-fevers so common along the principal rivers of China, and which had mainly induced the habit of opium-smoking. We were told on one occasion by an eminent medical authority that, as there was only a certian portion of the world's surface that would grow cinchona, were every acre of that portion planted up with trees, it would not supply all the quinine for which a market could be found when the drug fell in price, something to about half the extent it has done since. How far such dreams have been realized it is not necessary for us to point out. The hope and fears of many years' experience of the cultivation, the loss of millions of trees by canker and wet, the devastation of plantations consequent on the necessities of impecunious producers, and the thousand and one causes which have resulted in the paralysis of the cinchona industry—overweighted as it has been by super-abundant supplies—the old fields of supply in South America being all but abandoned, in consequence of the reduction in value of bark causing collection to be unremunerative—in spite of all these things, the prospects of cinchona growers in Ceylon and the East Indies exhibit no sign of being bettered. It is at any moment sufficient to overwhelm the existing markets of Europe and America. Over and over again have we been told that the supply from Ceylon must shortly be reduced; it was impossible that any year in the future could show such an output of bark as we had seen in the past. It has been asserted that a variety of causes had reduced the acreage of trees in Ceylon so seriously that a very important reduction must of necessity be shown in the export of the present season, and as a consequence we might look with certainty for a rise in the value, which would altogether alter the appearance of the market. With such prospects as these the hopes of producers have

been buoyed up for months, nay for years, past. Even local experts, as well as such authorities as Mr. Moens, seemed really to imagine a radical change was imminent, and that it was quite impossible Ceylon could this year export anything approaching to the total during the year ending 31st October 1885. And, what so far as we have gone, is the actually reality? The export to date, is no less than lb. 11,608,621 against a total for the same period of last year of lb. 8,020,117. Turning to the railway returns, we find that for the week ending 23rd May, cinchona bark was carried at the rate of 158 tons, against 98 tons in the corresponding week of last year, and again on the 31st May, 128 tons against 113 last year. It must not be forgotten that though the cinchona harvest may be well considered as closed for the season in the districts which are affected by the South-west monsoon, the bark from Uva and Udapussellawa will only now begin to be taken in. The coffee crops of the spring season having been secured, attention will be paid to cinchona harvesting, which will be none the less on account of a falling off in the produce of coffee as regards the estimated outturns. The railway return does not of course include all the bark that comes down from Haputale and other districts which are served by the Ratnapura road. As far as we can learn at present our estimate for the current season made at the end of last year will have to be raised in accordance with facts, to no less than 15,000,000 lb. This enormous mass of cinchona bark cannot fail to disorganize to a large extent the markets of Europe and America, and it is impossible to foretell to what extent prices may eventually fall in the immediate future. It is equally impossible to say when any improvement may be looked for in this respect, as the necessities of producers may compel them to harvest their crops as heretofore. It may be well to allow our imagination to pourtray what might have been the present state of the market had the efforts of cinchona planters been crowned with the success that they had anticipated. Let us suppose for a moment that the millions and millions of plants which were put out had arrived at maturity, and that the older coffee districts were a forest of huge cinchona trees, stretching for miles along the slopes of the hills in every direction. It may bring but little consolation to think of it, but, had this been reality, the bark of the cinchona tree would not command sufficient value to pay for its harvesting, and the planter, with apparently countless wealth at his very door, would have been as completely a ruined man as if his coffee had been abandoned and nothing planted as a substitute. The product which is now renovating his fortunes would have found no place under the shade of the branching cinchona trees, and Ceylon would have been the scene of disasters even more complete than those that have already befallen her.—Local "Times."

JAVA: TRADE AND COMMERCE FOR 1885.

Report of Consul McNeill on the trade, commerce, and general matters relating to the Island of Java for the year 1885:—The year 1885 has been an unfavourable one for the trade in Java, and though no actual financial crisis occurred as in the year previous, a general feeling of depression has been felt throughout the year.

Sugar.—The crop has again been a good one, though not so abundant as in 1884, the outturn being about 15 per cent. less, say a little over 5,000,000 piculs, or about 300,000 tons. Prices varied considerably in sympathy with European advices, the market opening at fl.9 c.50 to fl.9 c.75, and rising steadily from fl.12 to fl.12 c.50 per picul, but declining at the close of the season from fl.11 to fl. 10 c.50 per picul. Had rates remained at the level at which first sales were made, the result would have been, as a rule, very unsatisfactory to planters; and it is a matter of congratulation that the markets in the consuming quarters advanced in the manner they did. A large proportion of the crop was again shipped to Europe on planters' account. An area under cultivation is reported to be well up to last year's and a good crop—unforeseen circumstances excepted—may be looked for in 1886. The disease in the canes, alluded to in my last two reports, has increased in some districts, but diminished in others. The damage done by it has not, on the whole, been great; and it is generally considered that by careful planting and manuring it can be easily grappled with.

Coffee.—The crop has been an exceedingly poor one, the production of the Government gardens having declined to 499,909 piculs, against 1,011,787 piculs in 1884 and 1,072,492 piculs in 1883. They yield from private plantations has also proved much under the average outturn, though the decrease is not so marked as in the case of the Government coffee. The quality of the crop has been poorer, also, owing to long-continued drought, and the presence of the leaf-disease in many gardens. Prospects for the coming crop are, however, fortunately brighter, leaf-disease not having yet shown itself to any great extent.

Rice.—The crop has been an enormous one, and consequently prices have fallen to an unprecedentedly low level. The quantity exported was more than double that of the previous year, viz., 27,939 tons, against 10,360 tons.

Tea.—The number of plantations under cultivation have remained almost stationary, but owing to unfavourable weather the yield of 1885 shows a slight decrease, the exports having been 2,568,675 kilos., against 2,904,567 kilos. in 1884. Exports to London amounted to 1,705,850 kilos., and to Holland 750,446 kilos. The preparation has been paid more attention to with favourable results. A considerable quantity of seeds from Assam has been imported.

Imports.—Our markets have been in a more depressed and unsatisfactory condition than has been experienced for many years past, owing principally to the decreased buying power of the native population, and the more than adequate supplies which have continued to come forward during the year. The market was already overstocked with goods of all descriptions at the end of 1884, and the heavy arrivals thrown during the twelvemonth on a falling market served to depress prices still, further. During the last three months of the year business almost came to a standstill, as dealers at last lost confidence, owing to the progressive decrease in prices, and were frightened to operate with the possibility of having their purchases left on their hands in consequence of a further decline. The poverty of the natives is attributed to the very considerable depreciation which has occured in the value of rice, combined with the increased pressure used by Government in the collection of the land tax.

Cattle Disease.—In the beginning of the year cattle plague broke out in the eastern part of the island, in the Passaroean Residency, and as there had been no transit of cattle from or to this district, which had remained free from the disease up to this period, the origin of the outbreak appears to have been spontaneous. In May the plague appeared in the western part of the island, in the Bekassi district, near Batavia, where it prevailed with considerable severity, but owing to the strenuous exertions taken by the Government, it disappeared almost entirely after the lapse of two or three months. In August there were some few cases of cattle plague and foot-and-mouth disease in the neighbourhood of Batavia, but in the following month the disease was officially reported to have disappeared. In December there were a few cases of cattle plague among the buffaloes in the Krawang Residency. The staff of veterinary surgeons, appointed by the Government for the inspection of cattle and suppression of diseases numbered at the end of 1884 seven Europeans, assisted by 13 certificated natives, while several Javanese were also in receipt of medical instruction to qualify them for future service.

Customs Receipts.—The following have been the customs receipts in Java and Madura during the years 1884 and 1885:—1884, fl8,968,825 c67; 1885, fl8,251,193 c33. The returns therefore of last year show a decrease on that of the preceding year of fl717,632 c34.

Government Railways.—No new lines have been completed during the past year. Progress has, however, been made with the lines between Djokjakarta and Tjilatjap, and with the small line connecting Sourabaya

with the mouth of the Kaliemaas River, whilst the survey and the provisional plan of the line between Tjilatjap and Tjitjalengka, and the surveys of the lines from Djokjakarta to Willem I. *via* Magelang, and from Magelang to Poerworedjo, have all been finished.

Private Railways.—The line between Batavia and Bekassie, mentioned in my last report as having been commenced, has been steadily progressing during the past year, although considerable difficulty has been experienced in purchasing the land through which the line passes. A line connecting Tagal and Balapoelang *viâ* Bandjaran, with a branch line from the latter place to Pangka, has also been commenced.

A concession has been granted by Government for a line from Cheribon to Samarang *via* Tagal and Pekalongan, whilst another has been asked for a line starting from one of the stations on the Djokjakarta-Tjilatjap Railway to Bandjarnegara *via* Poerwokerto, Soekaradja, and Poerworedjo.

A steam tramway has been opened during the year, connecting Poerwodadi and Goendih (Central Java).

Several concessions have been asked and granted for tramways throughout the island, but none of them have up to the present been commenced.

Other foreign Orientals	A	2,603	2,632	2,755
„ „	B	20,760	20,676	21,659
Total		26,764,152	27,099,205	27,316,867

The above is exclusive of the army and navy, the former of which consisted of 14,982 Europeans and 15,254 natives, and the latter of 2,762 Europeans and 1,021 natives on December 31, 1884.†

The number of British subjects resident in Batavia, Samarang, and Sourabaya, the three principal ports of Java, at the end of 1885 were respectively 68, 21 and 56.

Steam Communication.—The British India Steam Navigation Company, Limited, commenced in October last a monthly service between Calcutta and Adelaide and back *via* Singapore, this port, Brisbane, Sydney, and Melbourne, and the steamers of the Eastern and Australian Steamship Company, which run between China and Australian ports, have again commenced, touching here at irregular intervals. As regards communication with Europe and Netherlands-India no alteration has taken place. The competition between the various lines of steamers, both Dutch and English, running between this island and European ports, is becoming very keen, and the supply of steam tonnage, except at the height of the shipping season, has been in excess of requirements. The contract with the Netherlands-India Company for the conveyance of Government goods and passengers will expire at the close of 1890, and next year tenders will be invited by Government for a new contract.

Batavia Harbour Works.—The buildings in connection with the harbour are being steadily carried on. The Custom-house, railway station, telegraph office, harbour-master's office, &c., mentioned in my last report as being in course of erection, have now been completed. The service of trains between Tandjong-Priok, where the harbour is situated, and Batavia, a distance of about six miles, has lately been greatly improved, there being now sixteen trains each way daily, with the exception of Sundays, on which day there are only five trains each way. There is and assistant harbour-master in attendance at Tandjong-Priok every day, so that ships can now be cleared in and out there a change of considerable importance to shipmasters.

* A. Java and Madura; B. other possessions in Netherlands India.

† The total European population of Netherlands India in 1884, therefore was 64,509.—Ed.

Native Labour.—Native labour is in request here for the tobacco estates of Sumatra, and a large number of natives have been engaged to work there under two year contracts, whilst a trial lot of about 100 have been drafted during the past year to work on sugar estates in Queensland.

Eruption of the Volcano Smeroe.—On the night of April 18 an eruption of the volcano Smeroe, situated in the eastern part of the Island, occurred, and immense volumes of lava poured forth from it, which almost entirely devastated the neighbouring coffee estate of Kalibening. The manager, some overseers, and natives belonging to the estate lost their lives during the eruption.

Import and Export Duties.—A strong movement has of late been made by the commercial and planting communities to have the export duties on sugar, coffee, and tea abolished, and it is expected that they will be, or at least reduced, during the coming season, increased duties being levied on some articles of import to compensate for the loss of revenue.

Hypothecation of Standing Crops.—In order to assist planters who have lately had to contend against low prices for almost all kind of produce, the Governor-General, at the close of 1884, made certain provisional regulations, sanctioning the hypothecation of standing crops. These regulations were only valid for twelve months, but in January of this year (1886) they have been rendered permanent by the granting of the Royal sanction.—*London and China Express.*

YERBA:—ILEX PARAGUAYENSIS.

BY HENRY DAUBER, JUNIOR.

In Paraguay the *Ilex Paraguayensis* grows uncultured in very extensive forests called "Yerbales." It is also common to some provinces in Brazil, to the territory of Misiones, and to Corrientes, one of the northern provinces of the Argentine Republic. This plant, which belongs to the order *Aquifoliaceæ*, is often called also Brazilian holly, on account of its resemblance to the holly shrub and its being an evergreen; it seldom attains a height exceeding ten feet. The leaves, which when dried almost exclusively constitute the yerba, or tea—sometimes known in commerce as "Yerba-Mate"—vary from two to five inches in length, and from three-quarters of an inch to one inch and three-quarters in breadth. They are simple, shiny, very short stalked and of a dark green colour, which assumes a lighter hue beneath. The fruit is red and somewhat smaller than a wild-berry, containing four seeds, all of which are seldom in full development. Yerba has been known to the Guarani Indians (once a large and powerful tribe, but now almost exterminated) from time immemorial; to trace back the period when the leaves of the *Ilex* were first used for infusion is impracticable.

The *Ilex Paraguayensis* has been exported, and planted in two or three countries in the South of Europe, where it appears to have acclimatized itself, naturally not developing as perfectly as in its own natural regions. If cultivated (as it was to some extent some years ago, before the expulsion of the Jesuits from Paraguay), its leaves yield a far more agreeable beverage than if uncultivated.

On receipt of a substantial sum of money the Paraguayan Government grants concessions to companies to gather the leaves during the season, February to July. These companies fit out expeditions, consisting of natives with their families. A suitable spot is selected in the midst of the yerbales, and here the expedition camps. The first operation is to construct a number of ranches, roofed with palm leaves or thatched with straw; these being the abode of the men and their families as long as the leaf-gathering period lasts. Next a space of ground is cleared from all incumbrance and rendered as smooth as its physical condition will permit, being then beaten hard with wooden mallets. The leaves of the ilex are gathered but very often branches, or perhaps almost whole trees are chopped down, placed on the space of ground previously alluded to and left there a few days, the

sun partially drying them. An arch called an "emramada," by some "barbagua," is then made, upon which the sun-dried branches with the leaves attached to them are placed. A fire is lit under this arch and is constantly kept brisk till the leaves are completely dried. Great precaution is always taken to prevent the leaves from roasting or igniting. This operation terminated, the branches with the leaves still adhering are placed on the mallet-beaten space of ground and beaten with sticks, the leaves of course falling off partly in powder. Portions of the stalks get detached also, this being the reason that they generally constitute a portion of the yerba. Care must be taken not to deprive the young trees entirely of their leaves, as otherwise they will not grow, but remain mere bushes. Other more advanced methods for the preparation of yerba have lately been in use in some parts of South America; in one locality large ovens are used to dry the leaves, which are afterwards reduced to power by stone mills. Large iron dishes are also employed occasionally for the purpose of drying the leaves. These advanced processes yield a yerba that unquestionably is contaminated with less mineral matter than the yerba prepared by the primitive process.

The final operation is the packing. The mode almost exclusively in use is: bullock hides are steeped in water and sewn at the sides and bottom, the upper part remaining open for the introduction of the yerba. This package, which resembles a bag, is called a "tercio" or "seron," the latter being the name used by the Spanish. Yerba is rammed into one of these packages; when full the aperture is sewn up. The "tercio" is then pounded with mallets till it acquires an oval shape, and left to dry in the sun, becoming in a few hours as hard as stone. In this quaint enclosure, in which it is very well preserved, yerba is exported to the different South American markets. From Brazil, and occasionally from Paraguay, it is packed in barrels. A "tercio" full of yerba generally weighs 200 to 300 pounds.

The expeditions are fatal to many. The heat in the "yerbales" is extremely excessive, causing death from sun-stroke very frequently.

Three sorts of yerba are prepared, namely, caa-cuy, caa-mirim and caa-guaza; the prefix "caa" denoting leaf in the Guarani language. Caa-cuy.—The new leaves from the small branches, dried in the sun. It is consumed on a very small scale, is of a yellowish-green colour, and is rarely exported, as it invariably loses its aroma very rapidly, consequently being of little value on reaching its destination. This variety contains no stalks. Caa-mirim.—The leaf carefully separated from the stalks and dried. It preserves its aromatic properties longer than caa-cuy, but the demand for it is as limited in one case as in the other. Caa-guaza, or "Yerba de Palos" (yerba of stalks, Spanish), is the third and last sort, and is composed of leaves and stalks, which have passed through the drying processes. Is the variety known all over South America on account of preserving its aroma for a considerable length of time.

In Brazil a tea resembling yerba, called congonha, is prepared from the *Ilex congonha* in a similar manner to yerba; but its use has not become very general yet. Other teas from different species of *Ilex* are prepared in South America, but their use is limited to the inhabitants of the localities in which they are prepared.

Paraguay tea is often called "mate." This, however, is not correct. Yerba, the Spanish word for herb, is the only name the tea has, whilst mate is the name of the vessel in which the infusion is made; this probably accounting for the tea being erroneously called mate. This receptacle is like a pumpkin, though smaller, and is the fruit of a creeper common to Brazil, Uruguay, Argentine Republic and several other countries in South America. A hole is bored on top of the mate, which has been dried in the sun, and the seeds extracted. It is used as a cup for the tea. The infusion is called mate, deriving its name from the cup. Porcelain mates, wooden mates inlaid with silver, and polished coconut shells are also used as receptacles for the tea, in several cities.

Mode of Infusion.—Three or four tea-spoonfuls of yerba are put into the mate, and boiling water poured up to the brim of the cup. A tube, made of silver or electroplate, having one end widened out and perforated with small holes, is placed in the mate. Through this tube, called "bombilla," the infusion is taken, or rather imbibed as hot as possible. Most South Americans use no sugar, perferring the characteristic bitter taste; some, on the contrary, like it sweetened, while a third lot make the infusion with boiling milk, sugar being used in this instance.

Yerba has a very sustaining effect on persons who constantly drink its infusion. Conflicting opinions however, respecting its effects on the constitution are held by eminent men. M. Sellieu recommends Paraguay tea as being pleasanter to the taste and less injurious to health than China tea, whilst Professor Bentley affirms it to be more exciting, and when taken to excess to produce a kind of intoxication. It may nevertheless be said, that the sober portion of the inhabitants of South American Republics cherishes yerba as the great natural beverage, deriving nutriment and the greatest comfort from its use. It has been attempted to introduce yerba into this country, but, probably owing to the want of knowledged as to its preparation, the attempt has, so far, not been successful. I think it can be safely predicted, that were it brought systematically before the British public, it would soon become a favourite beverage, and prove a valuable rival to other imported teas.

I will now endeavour to give an approximate idea of the quantity of yerba which is annually consumed in some South American countries, with which I am more or less intimately acquainted. The figures I give are gathered from official sources, and therefore, should be considered reliable. The total imports of yerba to the Argentine Republic in 1880 (notwithstanding its own production) were about 14,000,000 kilos. Towards this Brazil contributed 9,000,000 and Paraguay 5,000,000. One thousand kilos, within a small fraction being equal to an English ton, the preceding figures represent as near as possible 14,000 tons. If now we consider that only 280,000 kilos of China and Indian tea were imported during the same period, it will be evident that for every pound of tea fifty pounds of yerba are consumed in the Argentine Republic. The consumption of yerba is larger in the country than in the towns. European habits of different sorts, owing to the mixed population of the large towns, have gradually made even the natives acquainted with not very wholesome beverages, at any rate far less so than yerba.

The Argentine Republic produces yerba only in its most northern latitude, comprising the province of Corrientes and the territory of Misiones; the former province even importing 500 tons annually from Paraguay. Entre Rios, not self-producing, imports nearly 1,000 tons per annum from Paraguay. Santa Fé, the great agricultural centre of the Republic, consumes over 4,000 tons yearly. The provinces towards the west, separated from the Republic of Chili by the Andes chain of mountains, are the smallest consumers of yerba, owing especially to their distance from the producing districts. The Republic of Uruguay, with a population of about six hundred thousand, imports annually an average of 6,000 tons, against only 80 to 100 tons of China and Indian tea; *ergo*, for every pound of tea over sixty pounds of yerba are consumed. This shows that the average annual consumption is 23 pounds per head, most of which is of Brazilian growth; 5 to 1 as compared with Paraguay yerba.

Although the consumption of yerba in the Argentine Republic (population three million) is apparently less than in the Republic of Uruguay, it should be borne in mind I have not taken into consideration its own production, which though inferior in quality to the Paraguayan or Brazilian, is largely used by the inhabitants of the northern provinces.

Like tea in England, yerba is almost exclusively the hot beverage at a family table in the countries mentioned: only it is taken in larger quantities. A visitor

to Montevideo or Buenos Ayres would not get the infusion at the cafés (as I have said, European habits prevail in the large towns), but he would hardly get anything else in the country. The camp people often remain without anything but yerba for considerable intervals. Wherever visitors put in an appearance they are certain to obtain yerba, and though it may seem strange to European notions they are not required to pay for it. In short, throughout the country both friends and strangers find yerba to be an important element in social intercourse.

Below I produce an analysis which I have conducted upon a bulk sample of the caa-guaza species from Paraguay.

Mechanical Analysis

Leaves	64
Stalks	36
	100

Preliminary Analysis.

	Per cent.
Moisture (at 100° C.)	9·407
Matters extracted by ether	8·920
Soluble vegetable matter	51·667
Woody fibre (cellulose)	18·406
Ash (mineral matter)	11·600
	100·000

Organic Analysis.

Moisture	9·407
Yerbeine*	3·355
Tannic acid	5·220
Oil (volatile	0·064
Fat	1·711
Chlorophyll	2·064
Wax	0·420
Resin	3·800
Sugar	4·031
Dextrin	1·160
Albumen	4·510
Carbohydrates (soluble)	34·252
Woody fibre (cellulose)	18·406
Ash† (mineral matter)	11·600
	100·000

Calculated upon 100 parts of ash:—

Carbonic oxide	11·724
Sand (insoluble in HCl)	1·224
Silica	10·413
Phosphoric oxide, P_2O_5	10·421
Sulphuric oxide, SO_3	1·413
Ferrous oxide	0·250
Alumina	1·310
Lime	28·163
Magnesia	12·304
Potassa	8·672
Soda	12·122
Chlorine	1·984
	100·000

* This is the active principal or alkaloid of yerba hitherto called by others caffeine (the active principle of coffee). Dr. Peckolt found in air-dried leaves from Parana 1·6 per cent. and Professor Hoffman 0·3 per cent.

† *Inorganic (mineral) Analysis.*—In 100 parts of yerba:—

Carbonic oxide, CO_2	1·360
Sand (insoluble in HCl)	1·142
Silica	1·208
Phosphoric oxide, P_2O_5	1·209
Sulphuric oxide, SO_3	0·164
Ferrous oxide	0·029
Alumina	0·152
Lime	3·267
Magnesia	1·427
Potassa	1·006
Soda	1·406
Chlorine	0·230
	11·600

After infusion yerba has the following composition, the moisture being taken at 9·40 per cent.—

	Per cent.
Moisture	9·400
Vegetable matter	87·060
Ash	3·540
	100·000

Yerba yields 28 per cent. soluble matter in boiling water, of which about 8 per cent. is of the ash constituents.

The lare quantity of albumen contained proves yerba to be a nutritious diet.

The volatile oil, belonging to the phenol group, I obtained by distillation from the matters extracted by ether.

The estimation of tannic acid I conducted throughout according to Mr. Procter's method, which gives very satisfactory results.

I have lately seen an analysis of yerba, showing no ash whatever; this to me is totally inexplicable. Compared with Chinese teas, the ash in yerba is greater. It has been observed by different chemists that the more costly teas contain less ash than cheaper qualities. In all the samples of Chinese teas, analysed by a Russian chemist, the quantity of ash was found to be in inverse relation to the quality, as indicated by the price; the ash being especially high in teas adulterated by admixture with other leaves. In case of Japanese teas analyses do not all agree with this.

Dr. Peckolt is reported to have found in yerba gathered in Neufreiburg:—

	Per cent.
Oxide of manganese	8·958
Sodium	10·062
Potassium	14·615

As will be noticed the percentage of soda and potassa, which I find in the ash, bears no sort of comparison to the amount Dr. Peckolt found contained in the leaves. But even supposing that his results, in potassium were obtained from 100 parts of ash, this would amount practically to double the percentage found by myself, and would represent an extraordinary richness of that element. Further, I fail to discover the minutest trace of oxide of manganese in the sample I possess.—*Pharmaceutical Journal.*

Chena Cultivation.—In a brief editorial on the Province of Uva, the "Dinakaraprakasa" suggests that for the encouragement and assistance of the poor cultivators that they may be allowed by Government to cultivate chenas (burn forests), and grow such vegetables, as cucumbers, potatoes, &c. They should be supplied with a good kind of cotton seeds. A small amount of the proceeds sale of these vegetables, &c. should go towards the rent of the lands thus cultivated.

Darjeeling Tea Prospects.—The Darjeeling correspondent of the *Englishman* says:—"The weather in this district during the last fortnight has been all that could be desired for tea manufacture. A hot sun with an occasional heavy shower brought the leaf out in abundance, and many factories have been obliged to work night and day to keep pace with it. A change in the weather has just now taken place, amounting almost to a disastrous storm. In some parts of the district the wind blew a terrific gale, and the cold rain has sent the temperature down considerably. This will somewhat stop the growth, and give the planter time for packing and despatching. Most gardens are well ahead of last year, and although very poor prices were realized at the first Calcutta sales, the teas manufactured to date are quite equal to those of previous seasons for quality, if anything better, and it is expected that when this fact is established on the London market the prices will become better, both here and at home, for Darjeeling teas. It has been an excellent season for leaf so far. Red spider has increased rapidly with the late favourable tea weather, but this heavy rain will prevent any further spread, besides washing off a great deal of that already in existence."—*Pioneer.*

THE OUTLOOK FOR CINCHONA GROWERS.

The present critical state of the cinchona bark market is a serious matter for cultivators who contemplate harvesting this year. Last September we said that prospects were hopeful for planters, as a syndicate had been formed in the United States, to shut out English and German made quinine, its members having determined to manufacture enormously, and even to sell at a loss for a time if they could effect their purpose thereby. As a matter of fact, prices did rise much higher in October than they had done for a long time, but this was followed by a sudden fall, from which there has as yet been no recovery. In an interesting review of this branch of trade Mr. Moens, the ex-director of Government Plantations in Java, explains how this depression came about. When the increased demand for bark last autumn began to be felt on the Continent and in London, stocks being at the time rather low, brokers, thinking that consumption had overtaken production and that the "unit" would soon be at 10d. advised those who wished to be before the rush of South American bark which such a rise would let in, to hurry home their produce. The rush arrived as was expected, but it was from a different quarter. Ceylon had not been exporting as largely as usual, and it was supposed that so much cinchona had been harvested to pay for tea extensions that very little remained. But encouraged by the brilliant prospect held out to them, the Ceylon planters managed to bring their total exports for 1885 to the enormous total of 12 million lb.; and the news of these shipments, which, it was feared, would swamp the market, had by the end of December driven the "unit" down to 4d. Mr. Moens thought when he wrote that this last effort, must have exhausted supplies. "I am of opinion" he says, and am confirmed in it by statements of very reliable authorities in Ceylon, that the exports from Colombo will not in 1886 attain the high figure of the preceding year, but will gradually fall off." He has probably changed his mind by this time for, notwithstanding the falling market, over 10 million lb. have by last accounts been already sent from Colombo this year, as against 6 millions for the corresponding period in 1885. A great deal of this is rubbish that will probably be sold in London for a farthing a pound, and will hardly pay for carriage to the coast, much less for freight and charges, but the uncomfortable fact remains that the total consumption of good and bad bark last year was about 20 million lb., and that if Ceylon goes on at this rate for the remaining six months of 1886, it will supply the whole quantity required itself.

But this after all, is very improbable. In the first place the months of March and April in Ceylon are considered the best to coppice in, and a great proportion of the bark must be from trees which have been thus cut down. In the second place, the south-west monsoon, which is now on, will for some time render any further harvesting almost impossible. Nor need the fact of this large export necessarily be discouraging to Indian planters. As far as can be learned, little or no cinchona has been planted in Ceylon during the last two or three years, since the planters there became convinced of the success of the tea enterprise, and to a considerable extent the above large output is got by working trees at an absurdly early age. It may become an unpleasant necessity to shave *succirubras* 3 feet high, but it can hardly be expected to conduce to the longevity of a plantation. It would seem almost certain then that future years will show very considerably smaller bark exports from Colombo. This is admitted by every one in the island who is acquainted with the planting districts, and, indeed, the continued large yield seems to have surprised the planters themselves. But while we anticipate a large decrease we are not amongst those who imagine that the fall will be to zero. A large acreage of cinchona is still carefully cultivated in Ceylon, and even should tea continue to be a success there, it is unlikely that for as many years as we need calculate about, it will entirely supersede the earlier enterprise. Those who speak of the probable rapid extinction of the Colombo bark export perhaps hardly realise what such an event would mean. Of the total of the 20 million lb. used in manufacture last year, Asia contributed the following proportions:—Ceylon 12,000,000 lb., Java 1,300,000 lb. and India 600,000 lb. of which last no less than 100,000 lb. was from Government plantations. It is in fact hardly recognised that, largely as it is extending cinchona cultivation in India is very much a thing of the future as far as making its influence felt in the European markets is concerned. The large export from Java, was, as we pointed out some time ago, the result of the extensive coppicing and uprooting which took place last year, on its being determined to replace the inferrior varieties with *ledger*; this is an encouraging fact for Indian planters, for it will check production for some time to come. Nor can too great stress be laid on the huge increase in consumption of quinine which has followed its drop in price. Mr. Moens states, for instance, that the total imports of bark in the five years 1865-69 were a million lb. or less than Ceylon alone sent to Europe in 1885; yet at the end of last year stocks were 19,000 packages less than in the year before, and, moreover, a great deal of what did remain unsold consisted of the comparatively worthless *cuprea* bark, which is always avoided as long as possible by buyers, thus showing that manufacturers were able to absorb nearly all that came into the market. The value of the cinchona alkaloids is becoming more generally known all over the world, and in India especially, where the lower grades are largely sold in the bazaars; the opening out of Africa is also causing a constantly increasing demand; as is the employment of the bark in manufacturers not connected with medicine, especially in brewing.

To summarise the prospects of Indian growers, we think that an improvement in price may be expected at the end of the year, or early in 1887, when most of them will be offering their bark in London. For the next few months a rise cannot be expected, for even should the Ceylon export fall off, buyers will not be inclined to pay highly for a product that they cannot be sure the market will not be glutted with at the first return of prosperity. As for those whose plantations are not coming into yield for a year or two, the outlook is very hopeful, for there is very little planting going on except in India and in Java, and should Ceylon send away even a quarter less than she does at present—and this is a smaller decrease than most people acquainted with the subject anticipate—a glance at the figures given above will show what room would be left for Indian bark. The only competition planters in this country would have to fear for the present would then be South America, and as the bark from that country cannot be made to pay at present prices, a large rise in value must take place. Mr. Moens alludes, in passing, to the competition of the Madras and Bengal Governments with private enterprise. As a former head of a cultivating department in

Netherlands India, he cannot be expected to be violently opposed to the system, but he condemns the practice of local sales, and the wasteful manufacture of the Government febrifuge, "by which 40 per cent of the alkaloid is destroyed." He does not notice the liquid febrifuge with which experiments are still, we believe, being carried on. The question is one which must, sooner or later, be decided by the Government handing over their plantations to be worked as commercial undertakings by private owners; and the subject has been taken up with this view by at least two Associations in this Presidency.—*Madras Mail.*

CEYLON AT "THE COLINDIES."

The following is taken from the "*Exhibition Supplement to the Colonies and India*":—

The effect of the Ceylon Court as we look on the arches of the roof coloured in yellow, the sacred colour of the Buddhists, and red, and the many pictures—Sinhalese paintings running all round the Court in a frieze, telling the Birth Stories of Buddah—with the porch at the entrance from the Private Exhibition Gallery, resembling a giant "lych gate," is exceedingly quaint, bright, and pretty. The first impression is favourable, and this is more than confirmed on closer acquaintance. The gateway through which we enter has a solid, rich, massy air, constructed as it is of ebony, with tamarind pillars, the beautiful longitudinal grain of the coconut palm, and the high relief of the frieze and panels carved in Calamander wood. This gateway is a fac-smile of one carved in stone at the ancient Royal City of Yapahu. Above in very high relief, seemingly of stone, is the figure of Gautama Buddha, wrapped in contemplation, some ten feet high. Flanking on either side of the figures are two elephants carved in ebony, with ivory tusks.; Starting with Buddha Gautama, Prince Siddartha, son of Suddhudana, King of Kapilavastu, on the borders of Nepal, born 600 years B. C., we shall not lose sight of the Great Teacher who early taught "what light shines beyond our broken lamps," or of the elephants until we quit the Court of Ceylon.

On each side of the entrance arch two tall palmyra palms—one polished, one *au naturel*—stand as sentries, there are high dadoes of the many-grained, beautiful woods, and in each corner is raised a pyramid of woods, the effort being very happy. In the smaller trophies some 250 kinds are shown, and in the larger planks are Calamander (or Coromandel), flowered satinwood, ebony, tamarind, coconut and other exquisite specimens, the strange names of which would express no meaning to the casual visitor. Here it may be as well to call atention to the decorations on the walls—large palm flappers, arms, spears, shields and implements, both of the aboriginal inhabitants, the Veddas, and of the Sinhalese; painted masks used by the Devil Dancers and in Sinhalese comedy; skins of leopard, sambur, axis (or spotted deer), buffalo, wild boar, bear, and tiger; peacocks' tails; antlers, tusks, and tushes, and representations of mythological animals taken from sculptures on ruined monuments in Ceylon—the goose, horse, bull, lion, and, naturally, the elephant.

Facing us are cases of a series of "C's"—cinchona cinammon, cloves, coconut, cacao, cardamoms, and coffee, all well worthy of examination. The cinnamon in large bales—two and a half millions of pounds' weight are exported annually; the cinchona in an artistic trophy and in cases—Jesuits' bark *in excelsis*. and yet our troops in the Soudan were without quinine; the coconut in all its products—coir and copra, oil and fibre, ropes and nets, walking sticks and artistically-carved nuts, and arrack made from the sap, in samples of fifty-year-old spirit—a fine liqueur—and some distilled but the other day—not only "a torchlight procession going down one's throat," but an entire display of fireworks, including Catherine wheels and fiery serpents. A model of a still is shown and also of a "pot" still, to avoid what they term in Ireland and Scotland "the gauger." Mr. David Smith, M.P. for Brighton, from his estates at Kadirane, Negombo, Dimbula, and Badulla—winner of many medals, from our 1862, to Paris, 1878—and Messrs. Leechman, of Colombo, contribute two exhaustive collections. In cases here are spices and flavourings, nutmegs, both unpeeled and peeled, and mace, vanilla, and pepper. On the right hand side, against the wall, all the varieties of rice are shown, including the grain unhusked, or paddy, and the rice of commerce, as we know it. Tea, shown on the left of the Court, in singularly handsome cases, is an assortment from twenty-one districts, varying in elevation from the sea level to an altitude of 6,500 feet. In photographs, the entire story of tea-growing is given. Planting a new clearing, pruning, plucking, and weighing, withering on trays, rolling, fermenting, firing, sorting, packing, and shipping, together with views of tea fields and stores. Sugar, arrow-root, and cassava flour, are exhibited; and tobacco, both in leaf from Jaffna and Batticaloa, and in the Dumbera cigars of Mr. J. K. Ingleton. On an exquisite table of Calamander wood in the centre of the Court, is a large ivory tusk, carved into the semblance of a coconut flower resembling a number of ears of "Champion" wheat. This is a veritable Curio. And in an interesting display on the left, Messrs. A. M.—C.M.G.—& J. Ferguson, of the *Ceylon Observer*, Colombo, present a series of their publications, and their well-known "Handbook." Now, in the centre is a "Hackery"—a light cart, resembling a buggy, for trotting bulls. This should prove a new sensation for the Paris Hiopodrome or our William Holland. In case to left, on the lower shelf, a collection of Ceylon shells; above, boxes and book-shelves and other articles in porcupine-quill work, carved ebony boxes, plaited boxes from Matara, moonstone jewellery, musical instruments, coconut-shell carving and a wonderful gathering of tortoise-shell work, turned to every purpose, from chairs to cigar-cases, combs to paper-knives—a pretty show of a characteristic art of Ceylon. This tortoise work is an important industry on the southern coast at Point de Galle and Colombo. On the right, Mr. C. W. Rosset, in two cases, presents his ethnological collection from Maldive Islands, an exhaustive gathering needing a catalogue to itself. Photographs of the natives of the Maldives the Vedda Country, the ruins of Anuradhapura and Ceylon scenery, are to be seen on adjacent screens. In the centre, a finely-inlaid table of various woods in curves, on which lies a large block of water sapphire. Now, on the left, we can pass under a giant samboo arch to h Ceylon Tea House, the four Ceylon carriages built in Colombo, and Old London, and on the right to to the Imperial Gallery. Now a case of ivories, large tusks, tushes and teeth, with carvings, palm trees, a coconut flower, elephants, the stands of cut teeth, teeth cut into boxes, showing a charming wavy grain, lacquer and painted ware in boxes large and small, betel boxes, vases, cups, and "ringer" jugs. And in the corner the curious painted wood furniture, the decoration in rings of diverse colours, from Tangalle. On the left, Kandyan silver work from Ratnapura, Kegalle, and the Kandy Art Association; and in loan exhibits, Low Country silver work, brass work from Colombo, Jaffna, Negombo, and Batticaloa, and some charming specimens of bowls of copper, brass and silver—the effect of the raised decoration being delicious. Sacred books of Buddha written in Pali characters on palm leaves, robes of Buddhist priests, fans, and alms bowls—these mostly lent by the High Priest of Adam's Peak, to which the "grand old gardener" is supposed to have climbed, leaving Mrs. Eve-Adam to await his return—are here. These books lie flat and have a cover top and bottom, on the latter being two pegs, on which through holes the leaves pass. These, with arms, figures of Buddha sleeping will repay patient inspection. Behind, a series of water-colour views of the beautiful scenery, by Miss Gordon Cumming; of the island is a marvellous map by D. C. Gabriel Perera, S. Benedict's Institute, Colombo. The Benedictines of old had their *Scriptorum*, in which they produced the illuminated MSS. and "Books of Hours" so highly prized, and this would not be considered unworthy of the old skill. With a pen Mr. Perera not only gives a map of Ceylon,

fine as if engraved, showing the provinces, towns, roads, railways, heights of mountains, mean temperature, area, population, average rainfall per annum, but also, in a border most artistically designed and drawn, has placed sixty medallions of the animals and birds of Ceylon. The best of our Sixth Standard Board Schoolers, after this, may take the rearmost of back seats. In centre, model of Double Canoe, with palm-lea :covered deck house. Other models shown on cases and elsewhere are the canoes with outriggers, safe and swift, carts, bullock carts, a padda boat for cargo, and a pearl-fishing ballam (or yawl), with crews, divers, and all equipments. The two principal exhibits come next. On the one side, ebony furniture—admirably carved sofas, chairs, cabinets, and tables, with large tusks mounted on stands as sentinels, and a screen of ebony wood with exquisite embroideries of flowers on black cloth. On the other to the left, about the prettiest and most effective furniture in the Colinderies—a book case, five cabinets—three large and two small—chairs in Calamander-wood, the grain a picture in itself. These flanked by sentinel tusks. These have been lent by Mr. C. H. de Soysa, J. P., to whom the Court is much indebted for contributions, from arrack to gems, and hunting trophies to jewellery. Indeed, tusks are in evidence on every side. The method of capturing wild elephants is shown in two models of kraals, with the hunters, the tame or decoy elephants, the wild ones, the palm trees, all carved in ebony. In one is also given a Kandyan chief entertaining a party; whilst a Sinhalese Strauss and his band, discourse music, mostly on tom-toms.

An extensive display of lacc from Galle, Cotta, and Negombo, including the loan collection of Miss A. E. Ferguson, is set in large cases on each side of the Court. There are cases of arms—jewelled, gold, silver, and bronze—Sinhalese swords and daggers, daggers mounted in silver and gold, with uncut rubies and other precious stones, gold filagree work from Jaffna, gold plate set lent by Mr. C. H. de Soysa, elephant-teeth boxes set in gold, and in ebony coconut writing desk with a tree in silver, and other numerous objects of *brick-a-braccrie*. Then four Dagobas, two silver, one gilt, and a large one of brass, models of those standing, and now the only remains, save the ruins, of a Buddhist Temple (where was the collar bone of Buddha in a dish), and the Sacred Bó tree of the chosen capital of King Pandukabhaya, the capital for twelve centuries, Anuradhapura, founded 437 B.C., and said to have been 250 square miles within the walls. The group of two leopards, representing the death of Ranger, a hound —the assassin having been killed by mere pluck, with a knife, by Mr. Beauchamp Downall—surrounded and set out by Elephant Trophies, big bones, skulls, tusks, tushes, pads, tails and saw-fish swords, lent by many, including Mr. A. N. Birch, C.M.G., Messrs. C. H. de Soysa, Fanshawe and Swyney, will attract attention, artistically grouped by Mr. Rowland Ward. The case of shells of the Tamblegam Lake oyster *Placuna Placenta*, from Trincomalee, showing the almost transparent semilucid shell with prismatic colours like a bubble, and the pearl oyster in its various stages, from the baby of three, six, and nine months of age to the adult of five and a half years, and the chank shells, not unlike our whelks, used for cutting into rings, with the fine gauges for size, are both interesting. The fishing canoe has a quaint stone anchor with hole bored through it, shaped like an old-fashioned weight used by divers to lower themselves quickly. Facing this is a case of jewellery, which should prove, and is, one of the magnets of the show. Here is a moonstone belt, a girdle of light, the *facsimile* of the silver casket which holds the sacred tooth of Buddha at Kandy. The view of the Temple is on the walls of the Entrance Hall, and the porch of teak, with its carved pillars and plafond in nine panels, the stone balustrade or low wall, both within and by the Ceylon Tea House, are all faithful representations of divers portions of the Dalada Maligawa, the Temple of the Sacred Tooth. In this case, beside the moonstone belt are the gold collar, with its lion (not elephant) emblems, and gold belt with jewelled medal of office of Diwa Nilame, who may be seen outside the Court in the warriest of war paint and the most gorgeous of hats, in company with a gentleman that looks, with his blue gold-laced tunic and gold shoulder-belt and rather incongruous silk *jupon*, like an admiral in petticoats. An "ola" box of *carved* silver for the sacred writings in "Pali" on palm leaves a silver box to hold a book, rude coral necklaces with gold beads, contrasting strangely with necklaces of pearls, fitted for an Empress, a Tsarina, or our loved Princess, the Rose of Denmark. The three cases of gold and silver ware and jewellery will well repay an hour's detail. The elephant's foot pads, used as flower vases, with Latania Borbonicas, look well: but the cases of precious stones, though they will welcome the coming, will not speed the parting guest. Here will be found the marriage stone—ruby and sapphire, blue and yellow sapphire, combined in one stone; white sapphires, tourmalines, chrysoberyl, chalcedony, jargoons, spinels (these latter very effective and cheap), amethysts, cat's eyes, moonstones, star stones, topaz, hyacynths, aquamarines, rubies, zircons, dalam, a sand blended of chrysoberyls, sapphires, and rubies, alexandrite (green by day and red by night), ruby crystals and sapphire matrixes, and crystals of corundum or sapphire, are an Aladdin's Cave of jewels. But with a glance at Miss North's paintings, the model of the Breakwater at Colombo, the plumbago carvings and the use made of plumbago by Morgan Brothers in their famous crucibles, the skin of the scaly anteater, we leave, and so, as Buddha himself greeted us at the entrance, a yellow-garbed Buddhist priest bows us out of the Ceylon Court—by the Sal tree beneath which Buddha, prince, priest, and prophet, breathed his last—which owes so much to the taste and liberality of its Commissioner, Mr. A. N. Birch, C.M.G.

TEA AT 4½D PER LB.—What wiseacre was that who spoke of throwing away tea which sold at this rate in public sale? Why throw away "4½d" or bury it in the earth? Times are too hard for that; as the tea had to be made, the 4½d per lb. is so much to the good. Fine plucking—in some places very fine—and sifting, can give us 1s 3d, 1s 6d, 1s 9d and even 2s for select parcels; but it is quite possible that the estate getting 4½d for its worst may pay its proprietor better taking quantity and prices all round.—*Com.*

TEA CULTURE IN CEYLON.—The London *Field* of June 5th has the following notice of Mr. Hamilton's pamphlet—a notice which cannot fail to do good by attracting increased attention to our new and great industry:—"The Ceylon Tea Industry, an Opening for Men of Moderate Capital, by John Hamilton (late of Ceylon), London, Skipper and East. This little pamphlet, contains in a condensed form, a great deal of useful information with respect to an industry that is at the present time being successfully carried on in Ceylon, and which bids fair to restore the island to the prosperity that existed previous to the failure of coffee through disease, and the consequent depression, which culminated in the crash of the Oriental Bank. The author, in turn, deals with the most material facts connected with tea cultivation in Ceylon—such as the tenure of property, means of communication, labour supply and the suitability of the soil. He argues that the disease which has proved so destructive to the coffee-plant is never likely to injure the tea leaf, which, from the difference in its structure would be able to resist its attacks. After giving the prices per acre at which lands can be purchased at the present time, he recommends Ceylon as affording a good opening for younger sons possessed with a small capital, and concludes with some very sensible remarks on the future market for Ceylon tea."

BRITISH-GROWN TEAS.

We take the following account of the meeting where Mr. J. L. Shand read his paper, from the *Home and Colonial Mail*:—

In the Conference Room of the Colonial and Indian Exhibition, Mr. J. L. Shand, of the Ceylon Court, on Wednesday, June 9th, read a paper upon "British-grown Teas." The meeting was presided over by Mr. A N. Birch, C.M.G., Executive Commissioner for Ceylon.

The Chairman, in a brief speech, introduced Mr. Shand, whom he said would give thoroughly good and reliable information.

Mr. Shand opened his paper with a reference to the question whether the tea-plant was indigenous in China or was introduced from India, and said it had finally been decided that it was introduced at a very remote period from India. It was not known when tea first became an article of diet, but its properties quickly received recognition in China, and a thousand years ago it had become the national beverage there. Early in the seventeenth century, tea was introduced into Europe by a Dutch company. It gradually gained ground, and in the domestic history of England there was nothing more remarkable than the hold which tea had taken of the people. A hundred years ago 18,000,000 lbs. of tea came to Europe, of which two-thirds was taken by Great Britain. Every reduction of duty in this country was accompanied by a proportionate increase in the consumption, so that in 1845, when a further reduction of duty was contemplated, Parliament was informed on high official authority that, the imports of tea having reached 40,000,000 lb., it was probable that the limit of consumption had been touched, and that a fresh reduction could only be followed by a loss of revenue. That was in 1845, and, though there was now a tax of 6d per lb. on tea, equal to an *ad valorem* duty of more than 50 per cent., the consumption in 1885 was 180,000,000 lb., or within a fraction of 5 lb. per head of population. What but a few years ago was used as a luxury by a few, had become an article of daily consumption in almost every household in the kingdom. (Hear hear.) To show the importance of the subject, he might mention that the tea duty last year brought into the Exchequer £4,795,000—nearly four times as large a sum as the duty on wine produced—and that the tea industry was the agency by which countless thousands in the Mother Country and in the Colonies earned their livelihood. Enterprise had developed in India and elsewhere, food supplies hitherto undreamt of, and, as visitors to the Exhibition had an opportunity of learning, England had attained a position never touched by any nation before, for in her dominions she had the power to produce every requirement and every luxury of life, and, if it were necessary, could be independent of the markets of the world. (Applause.) The discovery that the tea plant was indigenous in the Indian forests was made sixty-five years back, and a committee was soon afterwards appointed to consider the best methods of cultivating the plant in India. Great difficulties were encountered, many of them being placed in the way by the Chinese; but gardens were formed, the enterprise grew, and British-grown teas, which in 1865 formed but 3 per cent. of the total quantity consumed in the United Kingdom, amounted to 16 per cent. in 1875, and to 33 per cent. in 1885. India had 250,000 acres under tea cultivation, and produced 70,000,000 lb. of tea; the capital invested in the industry was £16,000,000; and a quarter of a million of her Majesty's subjects who indirectly contributed to the income-tax of Great Britain, were engaged in it. (Hear, hear.) The tea plant was introduced to Ceylon from China about the year 1842, but it was not till coffee was stricken by disease that attention was generally directed to the cultivation of tea in Ceylon. In 1873 a small parcel of 23lb. of tea was exported from Ceylon. This year 9,000,000 lb. would be exported, and, estimating from the acreage now planted with tea, the export in 1890 would be 40,000,000 lb. There were 120,000 acres planted with tea, which gave employment to a considerable number of Britons and 150,000 British subjects, and the area was being rapidly increased, In the Exhibition there was also tea from the Fiji Islands, Natal, and the Straits Settlements. The cultivation of tea had been successful in Natal, and a large quantity of land was being taken up for that purpose. The teas of Natal, as well as those of Fiji, would eventually find a market in Australia, but it was to India and Ceylon that the people of England must look for a pure tea produced by their own fellow-subjects. Mr. Shand then gave some particulars about the growth and preparation of tea in India and Ceylon, and went on to say that the people of Australian colonies were the greatest consumers of tea in proportion to the population. The consumption per head of the population was as under:—Australian colonies, 7·66 lb.; New Zealand, 7·23 lb.; Great Britain, 4·90 lb.; Newfoundland, Canada, and Tasmania, followed closely; various British possessions, 1·66 lb.; the United States, 1·30 lb.; Holland, the largest European consumer next to Great Britain. 1·05 lb. In Spain which was the lowest on the list, the consumption was only ·01 lb.; in other words, the Englishman drank 490 cups of tea for every cup taken by the Spaniard. Tea was said to be a source of nervous disease and no doubt it contained properties which, if misused, might become injurious; but the table he had quoted from showed that the English people at home and abroad were by far the largest consumers of tea in the world, and probably they were the least nervous race: It was unfair that there should be such a high duty on tea. The duty on sugar had been removed, but that on tea remained, because the tea interest had not such a preponderating Parliamentary influence as the sugar interest. Tea and sugar might be said to be equally necessaries of life and yet, while the former yielded 2s 6d per head of the population, the latter was untaxed. Tea was year ily year being more largely produced by ourselves, while sugar was being more and more poured into our markets from other countries. In such light esteem was sugar held by the trade, that frequently the purchaser of a pound of tea was presented with a pound of sugar. Suppose the duty on tea were reduced to 3d per lb., and a duty of ½d per lb. were placed on sugar, there would be a considerable margin left in favour of the Exchequer. The British sugar-grower and refiner would benefit, because the cheap Continental sugars would feel the tax most; the average consumer would suffer only in an imperceptible degree, and a great stimulus would be given to the consumption of tea. Proceeding to consider why British people should drink British-grown teas, Mr. Shand said that those teas came into the London market pure. There was no recorded evidence of adulteration having ever been discovered. The adulteration of China tea, on the other hand, had been the subject of several volumes, and of special legislation. The purity of Indian and Ceylon teas made them more sensitive than the ordinary China mixtures. It was not necessary to put such large quantities into the teapot, but it was all the more necessary that the water should be boiling, and that the tea should not be allowed to stand too long. Disappointment should not be felt because the liquor was not black; that was in consequence of the tea being quite pure and unmixed with black-lead or indigo. If Indian and Ceylon tea were fairly tried and carefully treated, they would be found more economical than China teas; they placed within the reach of all a beverage economical, pleasing, and nourishing. Though the grower sent his teas to London pure, they generally had to pass through the hands of the retail dealer before they reached the public, and the temptation to use up cheap China teas by mixing them with the pure Indian and Ceylon products was so great that it had become the custom of the trade to make the mixture, and much tea was being sold labelled Indian and Ceylon which contained but a very small proportion of those teas. Another reason why British-grown teas should be consumed by

British peop'e was that they were produced by our fellow-subjects, and that the industry furnished an outlet for the congested population of these isands. In conclus'on, Mr. Shand expressed his readiuss to give further information about Ceylon tea to anybody who might ask for it. (Applause.)

Dr. Watt, in charge of the Indian exhibits, said it was not generally known that tea was really a forest tree, and not a bush. In their natural state in the Indian forests, some of the tea trees were fity feet high. He had been unable to find in the fild plant any trace of the disease from which the wultivated plant suffered. With regard to the concroversy as to whether tea was damaged by the lead in the boxes, his own opinion was that the fault was ito be found in an imperfect knowledge of the fermentation of tea befor packing. He had seen tea which was tainted though the lead was not perforated; and he had analysed tea in one instance in which the lead was perforated, and had not found any trace of lead in the tea. He was not aware of any chemist having discovered tea actually poisoned by lead, and he thought that the tea-planting industry ought to bring science to its aid in the matter of fermentation. He thought, too, that the tea industry suffered from too much selection, and he could not see why the planters should not mix their own teas, instead of leaving the retailers to do it, and get brands which should be known as theirs. If a garden sent one quality of tea, and one only, he was sure the industry would benefit. (Hear, hear.)

Dr. Robert Pringle, of H. M. Bengal Army, said he looked upon the tea trade of India as one of the greatest undeveloped industries that that country possessed. Tea was a very good saddle-horse to put indigestion on, when one liked to shift the responsibility from irregularities in diet; but he would like to treat those people who talked about tea being indigestible, not with his medicine chest, but with a muzzle. (Laughter.) After speaking of the importance of doing all we could for the natives of India, Dr. Pringle condemned the tax of 6d. per lb. remaining on tea, and with regard to fermentation, said that the Government ought to consider it their duty to settle that point. It was far more important morally to do that than it was to have a first-class analyst to see that the opium went out in good condition. (Hear, hear.) In reference to the disease, it was his opinion that it was brought about by over-cultivation, just as the disease of coffee was. Where there was not over-cultivation there was no disease.

Mr. T. J. White, who lived for many years in Ceylon, confirmed Mr. Shand's figures relating to that colony, and said he knew of no part of the world in which the climate was more healthy or more favourable to long life than the hilly country there. Some years ago a police magistrate in Calcutta told him that tea from the North-Western Provinces of India injured his nervous system and that he had since drunk Assam tea without feeling any ill effects.

Mr. F. R. Saunders, who had long been a resident in Ceylon, said the consumption of British-grown tea ought to be encouraged because the industry provided employment for people of those countries of which we had taken possession, and of whose interests, therefore we ought to take peculiar care.

Mr. Moreton Green spoke of the growth of tea in Natal, and said there was in the Exhibition more than a ton of Natal tea, which would be on sale in the course of a week.

Mr. Capper remarked that British tea-growing promised to be very useful to our home industries, for every tea estate in Ceylon was being provided with British-made machinery, and he had no doubt it was the same in India. Not less than half-a-million of money would be spent by Ceylon in the next few years on machinery.

Mr. Barber, as a tea planter of Ceylon, denied that tea-drying was a process which was hurried ove (Hear, hear)—since the tea was kept for a month ween the processes of drying and packing. (H hear.) Tea manufacture had been raised to the dignity of a fine art, and he did not believe it could be helped by chemistry. Any deterioration in the tea was due not to bad fermentation, but to bad wood or bad packing.

A gentleman in the room mentioned that several Indian planters had told him that they hoped for assistance from chemistry. (Hear, hear.)

Dr. Pringle, replying to a statement made by Mr. White, said that our soldiers in the Afghan war used tea from the North-West Provinces, and he believed they did not prove themselves to be particularly nervous. (Applause and laughter.)

The proceedings closed with votes of thanks to the Chairman and Mr. Shand

THE OUTLOOK FOR TEA.

Apart from the consensus of opinion in Mincing Lane, that, from circumstances of weather, pruning and plucking, and also perhaps, as is charged, some want of care in preparation, the Ceylon teas recently sent to market have not been up to the previously high standard of quality, there can be little doubt that the low prices and semi-panic in the London market which reacted so adversely on local sales and planters' interests, were due mainly to the overloading of the market not only with good tea but with absolute rubbish from China. In the interesting report by Mr. Consul Sinclair of Foochow, which we this day quote in our planting columns, it will be seen that he actually mentions tea being made of leaves which had been five years on the trees! It seems doubtful if leaves can cling to even an ever-green shrub (we mean, of course, the *same* leaves) for five years, and perhaps what is meant is that old and neglected and inferior bushes, which had not been touched for five years, had latterly been plucked for tea-making purposes, under the influence of speculative demand, following the cessation of war and the opening of markets wholly or partially closed during the war. The remedy suggested by the worthy Consul of uprooting the old trees and planting afresh is certainly heroic, but it is questionable if he realized what the costliness of such a process would be, even where labour is so exceptionally cheap as it is in the tea districts of China. Besides which there would be an interval of non-productive ness in the comparatively cold climate of the tea regions of China, of from four to five years. We suppose those familiar with tea culture would rather advise that the old bushes should be so pruned as to compel them to yield good flushes, while young plants to replace those of them which showed signs of decay were growing. What seems evident is that China, if money is offered, can produce large quantities of tea, the bulk of it inferior. Mr. Giles is very sanguine about Formosa as a producer of fine quality teas, but, until "the savages" are exterminated or civilized and that beautiful island is fully peopled with Chinese, it is not likely to prove a very formidable factor in the question of tea production. We are taken by surprise by what is said about brick-tea made from good tea-dust for the Russian market, because all previous accounts led to the impression that brick-tea was composed of old, coarse leaf and stems. If a good market offered for bricks made of tea-dust, we see no reason why India and Ceylon should not successfully compete with China in that direction. But we suspect the Indian and Ceylon dust and broken teas are superior to the China brick-tea, notwithstanding the Consular opinion as to supplying the army. It is quite evident that a crisis produced not only by over-supplies from China, but, as Mr. J. L. Shand points out, from disturbances in the

home political world, will pass away and better prices return. What Ceylon planters have to continue to do is to produce as cheaply as they can, but always to keep in view QUALITY which will enable them to hold their own in competition with teas which are now being grown "from China to Peru."

In this connection it is interesting to learn that Mr. Gow has consented to read a paper before the Dimbula Planters' Association for the benefit of Ceylon tea planters. Added to his prolonged experience as a planter in Assam, and his acquaintance with the London tea market as the head of a well-known broking firm, Mr. Gow has now acquired a very fair idea of the Ceylon planting districts; their capabilities and advantages as well as drawbacks. We are glad to learn from Mr. Gow that on the whole he is well satisfied with Ceylon. He has had occasion already to report favourably on the prospects of tea here from a business point of view to London firms, and Mr. Gow's report on the Degalessa lands for the Kelani Tea Company, shows that he thinks highly of Ceylon as a tea-growing country. But, as might be expected from an old Indian planter, tea-maker and tea-seller, Mr. Gow sees many things capable of improvement as he goes about the districts, more particularly in connection with "plucking" and manufacture. He has already given evidence of his ability to improve the local system of tea preparation by the admission of several planters who have had the benefit of his advice and instruction; and while we can scarcely expect Mr. Gow before the Dimbula Association to tell us all he knows about our tea and the proper system of preparation, still the presentation of his opinions and ideas, even after a general fashion, cannot fail to be interesting and instructive. Mr. Gow is particularly strong as to the proper modes of "plucking," "withering" and "fermentation" of the leaf so as to do justice to its chemical properties, and the appearance and trial in Colombo, shortly, of his own "witherer" (for which at length the local patent has been granted) will add to the interest felt in what our correspondent describes as "Mr. Gow's new system of tea manufacture."

PLANTING NOTES FROM UVA.

RAINFALL AND GOOD CROPS—COFFEE IN NATIVE GARDENS —THE RAILWAY WANTED—CATTLE MURRAIN—CRIMES— PADDY CROPS—BAD ROADS.

HAPUTALE, 10th July.

There has been more wind and rain up here during the last two months than usual at this time of the year. During May and June we had very strong gusts of wind at times, and the rain was accompanied by thunder and lightning and hail stones on one occasion. You will see by the following what the rainfall for six months has been on the Haputale Pass compared with the rainfall for the same period in 1885:—

	1886. Rainfall.	No. of days.	1885. Rainfall.	No. of days.
January ..	9·53	21	1·41	14
February..	0·84	6	0·72	5
March ..	1·29	8	4·72	10
April ..	11·84	15	5·09	16
May ..	9·43	20	12·21	20
June ..	2·40	10	4·64	17
	38·33	80	28·79	82

Nearly 10 inches more rain in almost the same number of rainy days both years. The month of July commenced very wet and monsoonish, and from 1st to 7th there were six wet days and a rainfall of 2·35 inches recorded, and for a time planters of the higher estates who depend chiefly on spring crop, and *August blossoms*, were getting very anxious about the weather changing to fine and dry, which, I am happy to say, it looks like during the last day or two. On all the higher estates, there is abundance of wood in fit condition for a grand blossom and bumper crops, if the weather will only keep fine for the next month or six weeks. The autumn crop now on the trees, especially on some estates below the Pass, are exceptionally fine, and the Laird of Kelburne particularly will reach the island in time to see one of the biggest crops picked not only from his own property but from many other estates in Haputale. The *native gardens* also show abundance of crop wherever the coffee is in condition and not neglected. All over Uva leaf-disease is gradually disappearing, and coffee regaining vigour every month. A year ago I thought, and many other experienced planters as well, that many places on the Haputale Pass would never recover and were doomed to extinction, as far as coffee was concerned; but after a visit to Haldummulla a few weeks ago I was most agreeably surprised to find the coffee everywhere—on estates and native gardens alike—looking most luxuriant, very free from leaf-disease and bearing very fine crops. Now would be the time for any sceptic and disbeliever in the future of coffee (at least on this side of the country) to come and see our estates. For my part I would just as soon plant coffee as tea on new land and virgin soil in Uva. If the crop of 1884-85 was a short one, that of 1885-86 promises so far to be one of the largest dispatched from Uva for many years back.

Cattle Murrain or hoof-and-mouth-disease has been prevailing for some weeks past amongst cart bullocks on the Ratnapura road and village cattle. Why the Government do not adopt or even attempt some remedy to try and stamp out this dreadful animal epidemic, to is a mystery, and one which "no fellah can understand." Year after year tens of thousands of cattle of all kins are carried off or die of this disease, and the wonder is that any are left in the island of the old stock of indigenous cattle. Why not legislate on the subject and have a *Medical Ordinance* for the villagers and their sick cattle? The Medical School or College in Colombo annually turns out a number of cheap doctors to practise on the public and delight the coffee planters, and the country is getting overstocked with them. Out of their superabundance a few licensed cattle or bullock doctors might be manufactured to try their skill on the quadrupeds. Besides sick cattle, in this sporting age, there are any number of mangy-hounds in towns and country that owners would gladly pay handsomely to see cured. Why not have a *veterinarian* class attached to this so-called college and make the subject of endemic cattle diseases, murrain, hoof-and-mouth-disease, a special study. Was it not by legislative act and severe penalties attached that rinderpest, was stamped out in Europe and other countries? A great deal more might be written on this subject but I am afraid it would be labour in vain. Our paternal Government might reply it was interfering with the poor natives and distressing to impose upon them the burden of looking after their sick cattle. It is only the planters who require looking after, and Ordinances for Cattle Trespass, Cattle Stealing, Medical Aid Wants, Cooly Ordinances, Register Keeping, Immigration Returns, Birth and Death Reports &c. The poor native must be left to live just as he pleases, rob, murder, ravish, commit arson, and live at his European neighbour's expense. J. A.

GEMMING.

An enterprise (writes a correspondent) in which the general public seems entirely left out in the cold is that of gemming. The most casual glance at the Ceylon Court of the Indian and Colonial Exhibition cannot fail to strike any one with the immense value of stones yet unfound even in this one productive island. A good deal of business also is carried on in this court, sapphires and rubies being bought and ordered by many ladies

attracted by lower prices than are usually asked by jewellers. Why a company has never been formed for the purchase and working of gemming land in Ceylon and India strikes me as strange. If a few ounces of gold were to be found in any new region the noise of it would be blown abroad, and the wildest hopes entertained—especially by some well-known company promoters—of fortunes to be speedily unearthed. And yet the value of the gems other than diamonds sold yearly in this country alone must be considerable. From whom do the jewellers procure these gems? We presume they have agents in the different countries who barter direct with the native dealers, or else are supplied by "middle-men" in the form of gem merchants. The native dealers again—we can answer for those in Colombo and Galle—never own any pit or plot themselves, but again deal through agents, whose time is spent purchasing stones from villagers up in the gem-producing districts. Every intermediate profit made is immense. In the districts of Saffragam and Ratnapura the wretched Sinhalese, who own small pieces of land beside the streams, where they work like slaves, often up to their waists in water, derive but a precarious income from their really valuable labours. The travelling moormen who command a little ready money frequently purchase sapphires, rubies, and cat's-eyes upon which a profit of a thousand per cent. is deemed to be erring on the side of moderation. Ready money could purchase tracts of gemming land in the most favourable localities, and a systematic plan of jewel-digging be entered on under European supervision. Many of the best rubies never reach this country, but are bartered to native chiefs in a clumsily cut state, often to be buried, lost, or hoarded away by some dying miser. Many a fine stone, worth some hundreds in London as a brilliant, has been cut into thin plates resembling glass, changing its value to almost nil.

No European mineralogist has devoted himself to finding out from where these stones spring which are washed down the streams and deposited in layers of gravel under the river bed. We cannot help indulging in fascinating dreams of some huge matrix of jewels high up among the mountains whose splendour one charge of dynamite might expose. All the gem pits are in low ground. The gems become more and more triturated during their descent down stream, until they are termed "tusi," or dust. This ruby dust can only be used for cutting and polishing. The fact that the supply of these gems is not yearly decreasing points most plainly to the conclusion that somewhere a matrix exists. Leaving, however, these Utopian ideas alone, the ordinary process of gemming in the low ground is one which should commend itself from its prospect of really handsome profits. If all these dealers, agents, and merchants, both native and European, can manage to make a living from the enterprise in addition to the heavy profits made by London jewellers on coloured stones, then it would seem rational to suppose that shareholders of a well-managed company might find they had not embarked in an unremunerative venture.

I expect at no distant date to find the chief gem enterprises worked by English companies in the East Indies, just as has been effected with the gold mines, but with perhaps more profitable results. A geologist who can discover the real matrix of the ruby and the sapphire will no longer need to write pamphlets or read lectures in order to gain an income, but will soon be heard of in financial circles as the "Jewel King".—*Pall Mall Budget.*

CEYLON TEA AT SOUTH KENSINGTON.

To the Editor of the "Home and Colonial Mail."

Sir,—Your contributor "Assam" intends to convey the impression that Mr. Shand's able paper on British grown tea was meant as an advertisement of Ceylon teas generally. This is nonsense, if he will pardon my saying so. The paper deals exhaustively with the subject, and reference was made to Fiji, the Straits Settlement, Natal and other tea growing countries. "Assam" seems to forget that as Mr. Shand pointed out, tea was introduced into Ceylon from China about 1842, so that "Assam's" sneers about the speaker's reference to "that island as *it* were the home of the industry" falls rather flat. If Ceylon planters have managed to advocate their tea successfully at home so much the better for them. Indian planters have had the same chance. There need be no jealousy or unpleasant rivalry between Ceylon and Indian tea planters. Let the best and cheapest tea, I mean that which is laid down upon the best terms, command the best market. There is plenty of room for all of us. We planters have yet much to learn and competition will keep us awake. Our planters are awake I can assure you, and the shipments of tea from Ceylon are merely a tithe of what may be expected when confidence is quite restored, and capital more easily obtainable.—Yours, &c.,

A Ceylon Planter.

INDIAN AND CEYLON TEA.

To the Editor of the "Home and Colonial Mail."

Sir,—Your correspondent 'Assam' touches lightly on a subject which some of us shareholders in Indian tea companies would like to see harped upon with a heavier hand. Since the coffee and cinchona planters of Ceylon turned their attention to tea they have had a wonderful run of luck, not only with their crops and prices, but in the manner in which their tea has been advertised at home, For many years China was the only tea producing country recognised by the British matron and her daughters. India was only known to her as the land of rupees and indigo, from whence shrivelled relatives, who had disappeared as cadets, returned as wealthy but delicate old men to finish their days at Cheltenham or Bath. The Indian tea industry, which has been steadily developing for years was scarcely known until recently outside the immediate circle of the few interested in large concerns like the Assam Company. It is only in recent times that Indian tea has been heard of by the tea consumer, for until lately it lost its identity in a judicious blend, and its value was too important as the component part of a mixture to be worth selling alone. Perhaps those who produced it were too content with the high prices then received to trouble themselves about this, and supineness was the result. Anyhow, the dealer and grocer ruled the roast and nothing was said by anyone. With the fall in prices came a change, then the planter became anxious to be brought into closer contact with the consumer. A Tea Districts' Association was formed in London, and there was something like a stir. But after all it did not amount to much. There was much cry and little wool. That which the Indian tea producer has taken years to attempt is accomplished by the Ceylon planter in a very short time. Ceylon tea, I venture to affirm, is better known to the public at home than Indian, and this is mainly because the interests of Ceylon have been well pushed, no opportunity having, on her behalf, been neglected, and her representatives and friends have been far more lively than their neighbours in India. Possibly I am utterly wrong but I have less faith in the ultimate success of tea cultivation in Ceylon than many. The estates in the island are heavily mortgaged as a rule, the land is consequently forced, and crops are gathered to the full extent of the yield. This will cause a day of reckoning, but apart from the question of how long it will last, I cannot help admiring the pluck of the planters in the island, and I am positively envious of their good fortune in having some clever heads amongst them who have pulled the

wire to some tune and raised the drooping fortunes of the planters there. If Ceylon continues increasing her outturn of tea at the present rate we shall see a tremendous glut in the market before long, and then let those engaged in the China tea trade look out. According to my view China will not be able to hold her own, and the result will be disaster. If planters in India and Ceylon can place their teas in the London market at low prices the game will be theirs, but it is quite certain some gardens will go to the bad. I advise all shareholders in tea to make careful selection before the evil day comes, and I also urge upon investors in this class of security to see that the companies they invest in are strong in the "Reserve" department, and also take a great interest in details, even to the nature of the machinery used. Trusting you and your readers will pardon this rambling letter from an old man.—Yours, &c.,

An Old Indian Fogey.

COFFEE, &c., PLANTING IN NETHERLANDS INDIA.

(*Translated for the Straits Times.*)

By last advices from Sourabaya the commercial outlook was gloomy indeed from the rapidly increasing number of Chinese insolvencies without any prospect of improvement in the near future. Some idea of the reach of the evil may be formed from statistics bearing upon the subject drawn up by the Agent of the Java Bank there, to show the extent of the losses suffered by the mercantile community in that quarter from failures and liquidations among Chinese so far as known. Many other merchants during that period had been obliged to make arrangements with creditors to which naturally as little publicity as possible was given. The statistics given, incomplete as they are, extend from the 1st April, 1885 to the corresponding date this year, and show figures of such significance that one wonders how it is possible, under these circumstances, for any mercantile firm to have courage to continue carrying on business there. The number of officially sanctioned bankruptcies in Java during 1885 amounted to 69, the lion's share, 38, falling to Sourabaya. In the statistics of the Java Bank, there are enumerated 50 failures and 22 liquidations at that city from April 1885 to April 1886 with liabilities coming to 2,459,581 guilders and assets estimated at 838,520 guilders. Bad as the present situation of affairs is, there is every likelihood of its becoming even worse.

The *Java Bode* has been informed on reliable authority that tea planters in Java will probably do good business there partly in consequence of the high prices which European dealers now give for that article, from its having so vastly improved in quality owing to better preparation for the market than formerly. Another reason for this anticipation is the greater yield available which in its turn resulted from the drought prevalent in 1885 and from the fewness of that destructive insect, the *Helopeltis Antonii*, after the rainy season had once fairly set in. This small winged insect has wrought havoc on the estates of tea and cinchona planters estimated at thousands of pounds of crop from its influencing indirectly the quantity of the outturn by destroying the young leaves on plants and trees. With regard to tea the evil consequences become immediately manifest but, as to cinchona, they are betokened by retarded growth and the consequent slight increase of the bark inweight. Hitherto no better means of checking this pest has been known than that of setting women and children early in the morning and at nightfall to catch them, owing to these insects not flying out in the day time. On cinchona estates the leaves attacked by these insects and in which they have laid their eggs are gathered together and burned.

TEA IN INDIA:—THE OPENING SEASON.

Owing to the late opening of the rains in many of the principal districts in Assam, the season will not be an early one, and, perhaps, considering that stocks are so high, it is well that it should be so. Al round the question is being asked, what sort of prices are to rule this season? When such good judges as some of our best brokers were so much out last year in their forecast, it is problematical to say how prices will go. Another question which is agitating the minds of planters just now is, what class of tea to make? It makes little difference into how many classes a tea is divided, provided the manufacture has been sound from the beginning and a sufficiently large number of chests put into each break. About 14 or 15 years ago in Calcutta, a *poojah* sale of 3,000 to 4,000 chests was looked upon as huge, and now-a-days, several brokers sell more weekly, so that some idea may be formed of the work they have to get through, to meet the requirements of the trade. Besides a very large quantity of the tea so dealt with is not bulked, and so the labour is more than doubled.

It is a difficult matter to keep even the best tea-house entirely free from damp; but a small tea bulking-house could be made not only impervious to damp, but almost air-tight. As soon as the tea was made without any assortment whatever, it might be passed into this house, and there assorted into kinds and packed into boxes. The temperature of the bulking-house could easily be regulated by pouring the heated air from the sirocco, or other dryer used, into the house, if need should arise, or else conducting it outside the building in a tube made with a closing valve. In the case of using the sirocco, we mean the new T shape, the top trays would require to be enclosed, this it seems to us, should prove no detriment. In the first instance, when assorting the teas into classes, there is no necessity to keep them long exposed and lose aroma, for they can easily be put back into original boxes leaded and merely tacked down here and there with a little solder. As soon as sufficient is assorted for an invoice, these solder tips may be opened, and the whole tea thoroughly mixed, finally fired, and packed ready for shipment. It may be objected that there is a great waste of tea lead, and also that large bins capable of containing 15 to 20 chests are far more economical, but it is contended, that they do not give the same results in retention of flavour and now every day this is becoming more essential, as tasting can scarcely keep pace with the requirements of the trade. We have it on fairly good authority, that many teas are bought entirely by the smell, and in America this is a very common way. Retention of aroma is thus a most important consideration and deserving of careful attention. In order to maintain the character of Indian tea every care must be taken with manufacture, else prices are sure to go down, and many concerns are quite unable to stand a drop in prices.—*Indian Planters' Gazette.*

HUMUS AS A CROP NUTRITIVE.

The vindication of the character of humus as an important source of crop nutrition—disparaged by Liebig, with his mineral theory—may be said to have resulted from the researches of M.M. Schlesing and Muntz, continued by Mr. Warrington, of Rothamsted. These chemists have fully demonstrated the important action known as nitrification, carried on by bacteria to which the name *micrococcus nitrificans* has been given, the result being the production of nitrates in soils rich in

organic matter, or humus. In order to test the importance of this process of soil fertilisation, or, rather, of conversion of elements of fertility from an inert state to one suitable for the nourishment of plants, Professor Laurent, of the School of Horticulture, Vilvorde, Belgium, last year carried out some careful experiments, a record of which has been sent to us. Buckwheat was grown in pots under four different conditions, namely;—1. In natural soil; 2. In earth first sterilised, but afterwards inoculated with bacteria of the soil; 3. In sterilised soil; 4. In sterilised soil with the addition of chemical manures. The conditions of the experiment were such as to exclude the inoculation of the sterilised soils in the third and fourth series. On the occasion of the first observation recorded the plants of the first series were the most robust; those of the second were healthy, but not as forward as the first; while the plants in the soil free from bacteria were comparatively puny; though those of the fourth set, having the aid of artificial manures, were superior to those of the third. The results were summarised in the following table, averages being given:—

Series	No. of Leaves, Aug. 28	No. of Leaves, Sept. 11	No. of Flowers, Sept. 13	No. of Seeds, Sept. 29
1	9	15	126·33	94·67
2	6	13·17	128	96
3	3·62	6·62	58	23·5
4	4·6	10	88·4	66·75

Thus, it will be seen, says a writer to the *Standard*, the action of bacteria in nitrifying the organic constituents of the soil had a greater fertilising effect than chemical manures consisting of nitrate of potash, undissolved phosphate, sulphate of lime, sulphate of magnesia, and sulphate of iron.—*European Mail.*

Peaches and Plums.—"New Galway" has long been famous among Ceylon planting districts for its fruit-trees, and "Warwick" estate in that district stands out very prominently. We have lately had the opportunity of appreciating delicious plums and peaches from Mr. W. I. Cotton's orchard on this property. When the railway gets to Ambewela, Mr. Cotton ought to lay himself out to find a market in Colombo for his fruit.

Tea at Hankow,—A correspondent writes from Hankow to a Shanghai paper dating his letter the 31st May, as follows:—"Some ten days ago I wrote you concerning the sad state of the tea market and on the possibility of the bankruptcy of many of the native tea merchants, consequent on the high prices paid in the interior. Little did I think then that the losses would be of so disastrous a nature as to affect the minds of those most deeply interested, but I have now to record the deaths by suicide of two men by opium poisoning at Hankow, and of one by drowning at Hankow. Rather than lose face by their liabilities, these three men have destroyed themselves, and as this is only the commencement of the season, what we may expect later on is sad to contemplate."—*Daily Press.*

Tea in Japan is thus reported on in the *Japan Weekly Mail* of June 5th.—The Tea trade has been large, nearly 20,000 piculs of leaf having changed hands, but prices have been somewhat irregular, fluctuating a dollar on most descriptions. There appear to be ample supplies to meet a large demand. Again the *Japan Weekly Mail* of June 12th reports:—The Tea trade which closed last week with a downward tendency in prices, has again been extensive, though heavy stocks of leaf and free arrivals have induced a fall of a dollar per picul on all grades. The second crop has commenced to come in, and the supply appears to be equal to the demand, and likely to continue so.

Advices from Assam (20th June) say that the coming tea crop will be very short and below the estimates. Cholera is raging on some gardens, and the coolies bolting into the jungle to die. The tea-seed crop is good, but being plucked off and thrown away, in order to increase the yield of leaf—last year's shipments of seed to Ceylon having been unsatisfactory, both to seller and buyer (consignments *said* to have left Calcutta in good order, proving to be *rotten* on arrival in Colombo), have not been encouraging.—*Cor.*

Drought and Heat in South Australia.—Dr. Schomburgk in his report for 1885 on the Adelaide Botanic Gardens, from which we shall extract copiously in the *Tropical Agriculturist*, states that the rainfall of last year was only 15·887 inches, or 5·272 below the average for 40 years. In five months, September-January, only 3 inches of rain fell. The heat was terrible: maxima being attained, of 182 in the sun and 115 in the shade! No wonder, if crops failed and general depression existed. After the heat came a temperature of 29° and 30° in May and June, with frost. Not an equable climate certainly.

Petroleum as Fuel for Tea Furnaces.—In the Western and Eastern Hemispheres petroleum, in more or less degrees of purity, is found superabundantly in North America and on the shores of the Caspian and in more moderate quantities in Burma and in portions of north-western India. It seems probable therefore that, as far as price is concerned, the substance, probably in its impure state and perhaps mixed with coal dust or other substances, can be supplied at a price which would render its use economical in tea preparation, where supplies of timber fuel have been exhausted and cannot be supplied cheaply. But the question remains can the strong and penetrating odour of naptha be so expelled that there may be no danger of its injuriously affecting the flavour of so delicate and sensitive an article as tea? We suppose modern science will prove equal to the solution of this problem.—We have since learned of a patent "hydro-carbon fuel" (petroleum and water, mingled in a fine jet), so free of smell that a chop can be cooked over the flame. We are going to make enquiries about it.

Tea in Japan.—The *Japan Gazette* thus refers to the opening of the tea season:—Our tea season 1886-87, is bidding well to be quite as sensational as that of 1882-83, and results will probably be the same in heavy and disastrous losses. Early this week circulars announcing important reductions in overland freight both by regular mail steamer as well as per sailer and rail were sent round and concurrently exchange rates declined, which seemed to embolden buyers, and in consequence an excited and somewhat indiscriminate demand was established. Grades mostly in favour were teas for price, and rates paid preposterously high considering quality obtained. Settlements for the first six days of closing week amount to the large total of 17,090 pcls, against arrivals as reported 19,080 piculs, so stocks in hand are only but very moderate and native dealers appreciating the circumstances, are more than firm in their demands. To criticise prices would be a work of pure supererogation, the same old madness seems still to afflict the buyer in Eastern Chaazse: a sort of *bete noir* seems to bestride him as pertinently and tenaciously as ever the Old Man of the Sea harrassed Sindbad, and until buyers can convince themselves that it is more or less a barren honour, that of being largely represented on the home markets with first and early shipments, so long will strained and extravagant prices prevail in the East.—*Daily Press.*

Tea at Foochoow.—The following was issued in the form of an express at Fochow on the 31st May:—"In consequence of the unnecessary quantity of dust having been packed in the 600 half chests of Congou purchased a few days ago by a certain foreign firm the purchaser has the right to refuse to take delivery of such, and on being informed of the fact, the Chinese seller indignantly resorted to the tea guild where a meeting took place yesterday at 7 o'clock p.m., and it is reported that a resolution has passed to stop transactions with this very firm, and in consequence of which every foreign merchant, who is a member, has a right to ask the Chamber of Commerce to put a stop to such unjust proceedings of the native sellers, and that the foreign merchants must be unanimous in body and mind to boycot one or two Chineese tea hongs for every act of unworthy transaction so that their haughtiness may be repressed." The signature "Disinterested" was appended.—*Daily Press.*

The Hankow Tea Trade.—From a letter in the *Hongkong Free Press* we quote as follows:—

> The hurly burly's done,
> The battle's lost and won,

and the damage has been done so far as the tea season of 1886 is concerned; for the present passivity, standing as it does in the strongest contrast with the excitement and action of the last week in May, is the sure and certain sign that "the war is o'er." Buying has proceeded since the opening of the season as if the crop were neither large nor early. Now, as regards the size of the crop. There is already a visible excess of between five and six million pounds in the first crop, made up by an increase of 80,000 half-chests Hankow, and 30,000 half-chests Kiukiang teas. Is this over-production or not? Is this the disease which a sagacious merchant at a recent meeting of the Chamber of Commerce complained that the trade was suffering from? If tea should pay after all, the retrogressive cry of over-production should be stifled for ever. In respect of the quality of the crop, it is universally admitted here that it is superior in "cup" to that of the last few seasons. In "make" it may be relegated to the "Can pass" class. The Chinese have made the successful attempt this season to place practically *the whole of the first crop* in front of buyers before the end of the month, but this has been done at the expense of the 2nd and 3rd "*packs*," whose "uncouth" appearance, despite a redeeming set-off in cup, affords sure evidence of a too hasty toilet. A judge of great experience says:—"The leaf (of 2nd and 3rd packs, of course) has come to market much in the same state as when *it fell*, or was picked off the trees. The result of all this is that there is a large supply of good and fine tea *at a much lower cost than usual*, whilst the medium and lower grades are mostly so unsightly that any cup quality they may possess, must be very heavily handicapped." The *tendency of prices* all along has been downward; partly from the intense anxiety of teamen to clear out; partly from the grue some nature of the telegrams from London. It may be desirable here to attempt to remove the impression which has obtained amongst the uninitiated that the early purchases of fine and finest teas were made at excessive rates, some 10 to 15 per cent higher than usual. This impression is altogether a wrong one; for the unexceptional practice has been so to *shorten* prices that the laying down cost has really been moderate in the extreme. The "original contract" and the "final ship off" prices have borne no relation whatever to one another. And when it is remembered that *cuts* have been inflicted varying from Tls. 3 to Tls. 15 a picul, it is not difficult to understand that the high cost was more imaginary than real. Never, perhaps, has there been a season when such *cruel cutting* has been in vogue, and the sooner this unsatisfactory state of things comes to an end, the better for everyone all round. A continuation will lead to unutterable grief somewhere. [From the above it will be seen that the making of tea from *fallen leaves* is deemed possible! Such tea must be vile rubbish.—Ed.]

Wire Fence should not be stretched too tightly. The contraction of the iron in cold weather breaks many wires.—*Nilgiri Express.*

Tea Prospects.—A planter writes:—"Who is the man who sounds the note of alarm from Udapusselawa by asking the question, 'Will 200 lb. an acre pay?' Surely a much better return than this can be confidently looked-for from so fine a district. Surely too the cultivation is not yet in a sufficiently advanced stage for any one to limit its yield to such mean figures. Methinks he serves his district but scurvily, and I hope someone will come forward with a brighter prospect for the district which has done such wonders in coffee production.—*Cor.* [The Udapusselawa man is mild compared with other critics: one of the latter, an experienced planter, the other day ventured to say that "half the area planted with tea in Ceylon would give 200 lb. per acre, and half would not"! —Ed.]

Bulking Teas on Estates.—A Ceylon proprietor writes:—"Mr. —— (a well-known London broker) advises me most strongly not to bulk my teas. He says, as a director of large Indian Tea Company he has found it a mistake. I myself bulked all my invoices for seven months; the eighth month I sent a break unbulked, and to my surprise the dock charges were the same as before in *account sales*. I wrote for full particulars of dock charges for that and previous seven breaks and found in every case my bulked tea had been rebulked in London though I had never had a complaint and was under the impression that I was saving money by bulking teas. I venture to say that many planters who are under the impression that they are saving by *bulking on estate* would find their mistake, as I did, if they insisted on getting the *items* of the heading 'dock charges' appearing in their account sale."

Petroleum as Fuel in Russia.—Crude petroleum and residuum as is wellknown are largely used for fuel on the steamboats running on the Caspian and the Black seas, and on the Volga river, and also in many Russian oil refineries. Recently Mr. Koribut-Dashkevitch patented in Russia an apparatus for heating stationery engine and locomotive boilers with petroleum. This consists of an iron cylinder, divided into two horizontal chambers, the upper for petroleum and the other for steam. At the ends of both chambers fine tubes are arranged in semi-circles, the tubes for steam extending at an angle of 45° to those of petroleum. The boiler is first heated by means of wood or coal in order to obtain steam enough to atomize the petroleum, which drips from the tubes. Then the petroleum is ignited, thus heating the boiler with liquid fuel. The chambers are connected respectively with an oil reservoir and the steam tubes of the boiler. Through the holes made in the sides of an oven comes a free current of air in quantity sufficient to make combustion complete. It is claimed in Russia that Dashkevitch's apparatus makes petroleum an easy, efficient and economic fuel.—*Bradstreet's.* [The above is interesting with reference to the possibility of crude petroleum or some preparation of the substance being used as fuel for tea curing. In such an event it seems obvious that special furnace arrangements will have to be made, or the hydro-carbon patent process introduced.—Ed.]

TROPICAL GARDENING.

Human nature, as a rule, exhibits a craving for things hard to be obtained. Setting the fashion of the period on one side, nothing shows this more plainly than the popular taste or longing for plants which are natives of a different clime to the one in which we reside. In a temperate clime tropical plants are considered essential, while if we are residing in a tropical one, then how beautiful to our ideas is the vegetation of the temperate region. Residents in Jamaica are no exception to the general rule. The native trees, the almost endless list of herbs and flowers, beautiful in their formation, their variation, their numerous hues and colours, are by the majority of residents totally disregarded, and satisfaction is sought in the introduction of the flora of other countries often no better, seldom as good, as those of native growth were their beauties fully appreciated. The attempt to cultivate these introductions often results—as might be expected—in complete failure, seeing that most of them are natives of temperate climes. The question is often asked here, "Why is it I cannot get such a plant to grow?—why do my Dahlias and Gladiolus so rapidly degenerate?" which, though apparently a very simple question in itself, involves a description of the principles of vegetable physiology, which is generally for the most part quite unintelligible jargon to the querist, and therefore if given falls flat, with the result of leaving the hearer still unconvinced, and with the determination in his mind to "have another try." Flower gardening in Jamaica, especially among the European residents, consists in the main of a series of attempts at the cultivation of that class of plants usually to be found in the well-kept gardens of residents in a temperate clime. In the mountains at high altitudes, where the climate is favourable, these trials are attended with a fair proportion of success, but on the plains the same exertions result, as a rule, in disappointment. Some may say, "But tropical plants flourish in a temperate climate." So they do, but then the means taken to enable them to do so are adequate to their requirements. There, every protection is afforded them; houses are built, a costly system of providing them with the proper temperature is followed; soil is brought (sometimes for hundreds of miles) suitable to their requirements, and the knowledge and experience brought to bear upon the cultivation of plants render is a much easier task to the cultivator there than to the cultivator in Jamaica, where the means of instruction in these matters are not so easily obtained. Who would think of building a house, to be permanently kept at a much lower temperature than the open air, in the Liguanea plains or other similarly situated place? Yet this is no more absurd than to apply heat for raising the temperature, for it would be done with the same object—viz., that of maintaining a suitable temperature. It is a well-known fact that many plants belonging to the warmer European and Asiatic countries grow well in Jamaica with a little care, and give a fair return for the labour expended upon them; but in nearly all of these the close observer will detect a degeneracy, a falling off from the original type, so gradual, yet so complete, that in course of time they become changed in such a manner as to be scarcely recognisable. An incident in the life of the great botanist, Linnæus, plainly indicates that temperature is one of the first points to be studied in connection with the cultivation of plants. A person had a favourite plant; he supplied it with heat and moisture, and, indeed, with every-thing he considered it to require; the result being that it grew "small by degrees, and beautifully less." Linnæus, then a young man, but a student, requested that he might be intrusted with its treatment. After attentively studying the plant, he withdrew it from its previous situation and pampered treatment, and placed it in a corner where the cold, the wind, the rain, and the frosts of winter, could exert their influence with impunity. He had placed it in its element, in its proper temperature, and under natural conditions, and was rewarded by seeing it grow and flourish. Such are the lessons to be learned by those who are fond of cultivation; nothing but a watchful eye on every requirement can conduce to success. If we see a plant flourishing, find out its family, and then subject its congeners to the same treatment, and in many cases success will ensue. In Jamaica there exists an enormous amount of material for experiment and improvement; pretty way-side flowers, which if developed with half the amount of skill expended upon similar things in Europe, would repay the labourer a hundredfold. It should be remembered, however, that it is no use to attempt to control Nature; that is beyond the art of man; but by a careful study of the various forms she assumes to attain her ends, he may assist her in all her efforts, and thus add much to the beauties of the vegetable kingdom. It is not to be thought for a moment that the writer deprecates the enjoyment by those who wish to do so of their taste for the growth of plants not indigenous to the country, but he wishes to indicate to them that they cannot reasonably expect "great things" from such cultivation. The writer's ideal of a tropical garden is that it should consist of a collection of the many handsome native trees, shrubs, ferns, and palms, and such other things as are indigenous to the climate, or can be obtained from countries enjoying a similar one. By grouping the most striking species in prominent localities, noting their time of flowering, and also the time when their foliage is in its fullest glory, for the sake of giving them proper arrangement; by filling secluded nooks protected from the sun's rays, and where the wind cannot ruffle their delicate textures, with the finer species of Ferns, of which no country, for its size, in the world possesses a greater variety than Jamaica, we should have something upon which the eye could rest with enjoyment at every season, and the garden would never be without some feature of interest to the true lover of nature. Have you a dry spot where nothing appears willing to grow? Then assemble together the different species of the Cactus tribe. The succulent Euphorbias, and other allied genera, and what was formerly nothing but "Macca"* will, by its various and curious habit of growth, become of interest to its possessor, and will enlighten the visitor as to the many strange forms of vegetable life to be found in the island. Old trees which cannot be conveniently removed can, by putting in a plant of Bougainvillea or other climber at their base, be formed in a year or two into an magnificent spectacle. Growing fences should be planted around the boundaries; bushy trees for wind-breaks, and small flowering plants and shrubs for foregrounds, suitable plants for which can easily be obtained at the local gardens supported by the Government. An avenue of Palms, a woody retreat surrounded by groves of the Orange, the Citron, or the Jasmine, a corner in which bulbous and other plants of low stature find congenial home, borders well protected for plants noted for their beautiful leaves, and others for their flowers, are things which should be sought for, found, and admired in every tropical garden.—*J. H. Hart, Jamaica in "Gardeners' Chronicle."*

Silver-leaf Disease.—There is a condition of things in stone-fruit trees, such as Plums, Peaches, Almonds, Apricots, and also in Portugal Laurels, which, for want of a better name, we have called silver-leaf. We have repeatedly examined such leaves, but never found any further injury than a separation of the upper skin from the substances of the leaf—whence the peculiar colour. It appears that in France the affection is called "plomb" (lead), and it has recently been studied by M. Prillieux, who, however, does not seem to have been more successful than his predecessors in ascertaining the causes of this malady. The disease is a serious matter in Plum orchards, as it generally causes the death of the tree.—*Gardeners' Chronicle.*

* West Indian terms for any thorny plant.

KILLING SCALE BUGS IN FLORIDA.

The method adopted by one Florida orange grower to rid his trees of scale bugs will undoubtedly interest some of our own people, and we suggest that the plan looks reasonable and might be profitably tried in sections where black scale exist. A writer in the Florida *Agriculturist* describes the process as follows:—

"A successful farmer and orchardist from Wisconsin, has a thousand young orange trees in Florida, not yet in bearing, which for years had been the scaliest trees I have ever seen. He was much perplexed, but not the man to give up the fight discouraged. He remembered that in early life he had fought insects successfully by throwing dry ashes over his fruit trees early in the morning when the dew was on. It occurred to him that soap might do good. He bought a box of common bar-soap, and cut it into oblong pieces the size of one's thumb, but not quite so thick, and stuck four or five on thorns, well up in each tree.

"When he returned in the fall, he found every tree clean and thrifty, except a very few from which the soap had been taken or got off. These latter was as scaly and scrawny as before. On most of the trees there were small remains of the soap still on the thorns, and on all the white coating that had been dissolved and washed down over the bark. Each spring since, before going north, he has applied the soap, always with the same happy results.

"I will add that his trees came out of the January freeze better than the average. Nothing lowers the vitality of an orange tree like scale in any and all of its half dozen forms. Nothing is easier killed in its earlier life, but most difficult when fixed on the bark, encased in its coat of mail of gum, which nothing seems able to dissolve or penetrate. Perhaps alcohol or naphtha might do it.

"The young scale (long scale for example) just hatched walks over the bark about four days, a tiny insect, so small and delicate as to be visible only to the keenest naked eyes. In this period of activity she mates, and is then ready to settle down for the balance of her brief life. She then inserts the beak of her head into the bark, and nestles down snugly. Her legs being of no further use soon fall off; gum exudes and encloses her completely, except a pair of breathing holes in her sides. Thus secure, she lives on the juices of the tree, and completes her life work of producing some 30 eggs for the continuance and multiplication of her species.

"A probable explanation of this soap remedy is that it is operating during the whole scale season. The dews and rains slowly dissolve and carry down the soap over the branches and trunk, and the insect thus finds its bane and perishes before it can settle down to its destructive work."—*Rural Californian.*

THE PUSHING OF INDIAN TEA.

The pushing of Indian tea is one of such paramount importance, that this must form the excuse for so soon again referring to it. Intrinsic merit sooner or later brings anything to the front, whether it is merchandise or brains. Indian tea up to date has achieved all its success through its intrinsic merit; it has been very little helped by advertising or puffing. Had Indian tea not been intrinsically good, it would have disappeared from public view. Annually there is a marked increase in the quantity consumed by the public, principally in Great Britain and Ireland. Had Indian tea been pushed in the same way as Ceylons have been, instead of an annual consumption of 60 millions, we should have had no stocks left at all now, and Indian tea would have been in a better statistical position than it now is. As it is with exchange so uncertain Banks are unwilling to do business except at ruinous rates, so that some means should be taken to avert calamity. It is significant that in the vicinity of great centres of population in Britain, for instance all round London, almost no pure Indian tea is to be met with, whilst Ceylon and occasionally Darjeeling teas (pure), can readily be bought. Wherever one goes Ceylon teas stare one in the face, done up in neat little packets of ½lb. and 1lb. At first the natural conclusion that one comes to is that the Ceylon planter has sprung a mine upon his Indian brother, is sending home the tea done up thus; but upon enquiry it turns out that the manipulation is effected in London, by the agents prior to delivery to the country dealer, showing how extremely careful the Ceylon agency houses are to place their wares before the public in a taking way. Nice little lead packages neatly done up with a taking label are infinitely more likely to attract attention than a great huge unwieldly chest roughly made. China teas are also got up in neat little packages, quite ornamental, and the tea dealer is proud to put them in his window, but when one does come across, or, rather ask to see the original case of any Indian tea, he finds it consigned to the background altogether, simply on account of its appearance. Of course put up in an attractive form tea thus must cost a little more, but looking at the enhanced values that Ceylons obtain, we doubt if it does not do far more than pay. With many gardens it is not a question of paying but of existence, and we consider that it is worth the while of some estates to do up their teas in this fashion so as to make them more attractive. Doing the teas up even in, say, five-pound packages with the "Linberry" patent cloth on paper would be a step in the right direction. We understand that the cost is very much less than tea-lead, and the weight for carriage is also much less. In addition the facilities for putting on a nice label are very much greater, and the paper would show off a label much better. The "heathen Chinee" takes care to cover his box with all sorts of heiroglyphics, which although perfectly unintelligible to the outside public, form an attraction, and no doubt even now assist to carry off the wares. The British public in this age of rapid progression are not easily satisfied, and competition is so great that Indian planters and agents must put Indian Tea before the public in a more presentable form. A few years ago it was supposed that the merit of the liquor of Indian tea had to a great extent done away with the necessity for paying so much attention to the appearance of the leaf. It is questionable if this so now. A large quantity of Indians is now bought from appearance, owing no doubt to the extraordinarily large amount of sampling, which falls to be done from the very large increase in imports. The generality of Indians are too leafy and large, and the dealers complain that the teas are too large in leaf to sell by themselves and that it necessitates a blend with China in order to make them a good marketable commodity. Another thing that strikes one with regard to Indian tea is the general complaint that it is not to be bought. What is called Indian is only a blend. In the case of Ceylon tea each little ½lb. package is labelled and guaranteed.—*Indian Planters' Gazette.*

THE INDIAN AND COLONIAL EXHIBITION AT SOUTH KENSINGTON.

Next in order to the Mauritius Court in the Eastern Arcade may be noticed the exhibits of the *Straits Settlements.*

An article which deserves a brief notice is coffee-tea. It appears that the Malays do not use the coffee berry, but prefer the leaves, giving as a reason that they contain a larger quantity of the bitter principle and are more nutritious. The mode in which they prepare the leaves for use is as follows:—A number of young leafy twigs are gathered and broken into lengths of about 12 or 18 inches. These are obtained largely from the suckers, which are allowed to grow for that purpose. The twigs are arranged between two strips of bamboo tied at the ends, so as to form a dense disc of green leaves about 18 or 20 inches in diameter, the free ends of the bamboo being used as a handle by which to move the leaves

to and fro over the fire, so as to prevent them from burning. The leaves are arranged all on one side and the stems on the other, in order, that the whole of the leaves may be equally exposed to the heat without nterfering with the drying of the stem. The process is completed when the leaves have turned to a rich brownish-green colour and have become crisp and brittle. The flavor and quality of the leaves depend on the care bestowed on this operation; if carefully performed the raw vegetable taste is entirely dissipated, which is not the case if sufficiently done. When singed, or overdone, the aroma is lost. It is also very necessary to have a clear smokeless fire, the creasote and other empyreumatic bodies contained in smoke spoiling the flavour of the leaves. This object is attained by using dried bamboo sticks as fuel. Previous to being used for making tea the dried leaves, which are very brittle, are rubbed to powder between the hands. The powder is then infused in boiling water exactly as in making tea, except that it is used in much larger quantities. It produces a dark brown liquid, looking like coffee, smelling like green tea and tasting like mixture of the two.* Mr. N. M. Ward, who had been for many years accustomed to the use of this coffee tea in Sumatra says of it:—

"While I find the use of the berry for a few days invariably to produce on me, as on many others, the effects of nervousness and bilious obstruction, I drink a strong infusion of the leaf daily with evident benefit to my health and strength. As a restorative on exhaustion from the severeties of labour or of the weather, from heat or cold, or long exposure to rain, I know nothing superior to it. . . . Of its nutritive power no proof can be stronger than that it suspends hunger and enables the labouring man to pursue his work for hours after he would otherwise be unable. . . . With a little boiled rice and infusion of the coffee leaf a man will support the labours of the field in rice planting for days and weeks sucessively, up to the knees in mud, under a burning sun or drenching rains, which we could not by the use of simple water or by the aid of spirituous or fermented liquors. I have had the opportunity of observing for twenty years the comparative use of the coffee leaf in one class of natives and of spirituous liquors in another, the natives of Sumatra using the former, and the natives of British India, settled here, the latter, and I find that while the former expose themselves with immunity for any period to every degree of heat, cold or wet, the latter can neither endure wet, nor cold for even a short period without danger to their health."†

Specimens of the coffee leaf tea were exhibited in London at the International Exhibition in 1851, together with caffeine prepared from them. Dr. John Gardiner, the exhibitor, subsequently took out a patent for preparing the leaves. According to a further statement made by Mr. N. M. Ward to the late Mr. D. Hanbury‡ the leaves could be prepared and packed Sumatra at a cost of 2*d.* per lb., and would even then afford sufficient profit to the planted especially if grown on low lands where berries are not freely produced. The leaves were analysed by Dr. Stenhouse, who found them to contain more caffeine, than coffee berries and as much as mate or Paraguay tea.§ Being thus rich in caffeine, if a little scientific skill were devoted to producing and retaining the aroma, there seems to be no ostensible reason why roasted coffee leaves in powder should not replace much of the chicory and other substances now used to cheapen coffee.

The seeds of *Bassia Latifolia* and the oil expressed from them, which in the Mauritius Court were labelled "illipe seeds and oil," are exhibited in the Perak collection under the name of "suring seeds and oil," while the name of "illipe nuts" is applied to the seeds of a Dipterocarpous tree, probably *Hopea macrophylla*, or an allied species,* which yield the fat known in Borneo as "minjak tangkawang," specimens of which are in North Borneo Court.

Several resins also derived from the same natural order, and marked "*Dipterocarpus Sp.*," are exhibited under the various names of "damar sesa," "damar" and "mata kuching," or cat's eye damar, and "damar renkong;" most of these come from Larut, Perak. They do not present a very bright appearance, but may be more valuable than their appearance indicates. The damar mata kuching is indentified by Professor Van Eeden as the product of *Hopea Mengarawan*, Miq.

The lesser cardamom (*Amomum Cardamomum*), shown at the same stand, was formerly official in this country, and is easily recognizable from its globular shape and smooth surface. The seeds closely resemble those of the official cardamom in flavour. They are used in medicine by the natives as a carminative. Another cardamom, unnamed, from Gapis, Perak, is labelled "wild cardamom."—*Pharmceutical Journal.*

REPORT OF THE ADELAIDE BOTANIC GARDENS.

BY DR. R. SCHOMBURGK.

Botanic Gardens, March, 1886.

I have the honor to submit to you my report upon the progress and condition of the Botanic Garden and Park, and of the Museum of Economic Botany, for the year 1885. That year, I regret to say, was one of the driest and most ungenial that I have ever had to contend with, the rainfall having been no more than 15·887 inches. This is 2·851 inches less than the fall of 1884, and 5·272 inches below the average rainfall during the previous forty years. The minimum rainfall during that time was 14 inches. The spring and summer were very dry; during September, October, November, December and January no more than 3 inches of rain fell. The heat during these months was abnormally great, the maximum in the sun being 173° and 113° in the shade. The highest temperature in the sun was 182° in January, 1882, and 115° in the shade.

Such a temperature after a drought of nearly three months' duration could not fail to be most injurious to all vegetation, but especially to those trees and shrubs which are natives of cooler climates. It will be gratifying to all those who take an interest in this establishment to learn that the damage done to the plants, and the losses sustained, have not been so great or so extensive as might have been expected. It is a matter of sincere congratulation to know that the supply of water at high pressure is sufficient for the community, and that the Government has allowed me an unlimited quantity for watering purposes; but for this the unfavourable season would have proved most destructive to the vegetation in the gardens, and many very serious losses would have occurred. Most of the men employed in the garden have been engaged during the last three months in watering only, and I must continue to employ them in this manner throughout the season if the drought does not break up. Such a season could not fail to be disastrous to the farming interest—and we have had one of the worst crops of wheat hitherto recorded. In some parts of the colony the crop has been a total failure. The average yield is about three bushels to the acre, which is the smallest yet known. The fruit crops are about up to the average; but some fruits, especially those of the apples, have not attained their usual flavor and perfection. During May and June we had to suffer from severe frosts. The temperature on several nights was as low as 29° and 30°. As might have been expected, such weather had a very injurious effect upon the garden, and the tropical and sub-tropical plants and shrubs suffered greatly. In the spring, the cold and dry weather considerably retarded the growth and development of the florists' flowers. This was especially noticeable amongst the annuals, especially phloxes, stocks, &c. The commencement of the rose season was very promising. The first flowers reached

* See *Pharm. Journ.*, [3], xiv., p. 182.

a size and perfection not often noticed, but several hot days were experienced, and the whole of the blossoms, as well as the small buds, were destroyed.

With reference to my attempt to acclimatise the four new plants introduced last year, viz.:—the Cheese-maker, the *Kumara*, Eland's Boontjes, and the Tree Tomato, I have to state that, with the exception of the Tree Tomato, the plants, considering the very unpropitious season with which we were visited, afford hopes that they can be acclimatised in South Australia. It is perhaps premature to say positively that this can be done without at least another year's trial. The Cheese-maker (*Withania Coagulans*, Dunn.) has found a congenial climate in south Australia. The shrub has grown vigorously, and has stood the drought and hot weather uncommonly well, for its growth was not even checked. I am convinced that this plant will thrive with us. The "Eland's Boontjes" (*Elephantorrhiza Burchellii*, Benth.), which, as I mentioned in my last year's report, I had received from Mr. Wood, Director of the Botanic Garden, Natal, were planted in pots, and kept in the houses during the rainy season. During this period the plants died down. In the spring (September) they were planted in the experimental ground. They had already formed tubers of the size of small radishes. They soon began to sprout. Although their growth had been slow—perhaps owing to the dry season—the plants are healthy and strong. I kept several plants in pots; those kept in the shade-house show a more luxurious growth than the others. I entertain hopes that this plant will become acclimatised in this colony although it would be premature to hazard a positive opinion as yet. The experience of another season is necessary to determine that point, last season being very unfavorable for all outdoor plants. Of the *Kumara* (*Ipomoea chrysorrhiza*, Forst.) I am able to report favorably.

The *Kumara* has recently been introduced into the East Indies. It has produced first-class crops, and is highly spoken of. Dr. Duthie, the Director of the Botanic Gardens at Saharanpur, in his last report, says, "I consider the *Kumara* to be a very valuable addition to our varieties of vegetables."

The Tree Tomato *Cyphomandra betacea*, Hook).—I regret to say that this plant has proved itself to be quite unable to resist this climate in the open air. Our summer is altogether too dry, and our winter too cold. In the stove-house the plant grows vigorously.

I have sustained another failure in growing the Nielgherry nettle (*Girardinia Leschenaultii*, Gaud.), belonging to the natural order of *Urticeae*. It possesses in a strong degree the stinging properties of the common nettle, and it grows on the higher ranges of the Nielgherry hills. The plant yields a valuable fibre, which the natives obtain by first boiling the plants, in order to destroy its stinging energy. The fibre is of considerable value. It is of great fineness, and is worth, in England, £200 per ton. [R200, much more likely.—Ed.]

I received the seeds from India. The young plants grew well in the spring, but they failed under the trying hoot weather in the summer.

Insect Powder Plant.—I am glad to say that at last I have succeeded in introducing those valuable plants *Pyrethrum carneum* (Bbrst.) and *Pyrethrum roseum* (Bbrst). They are natives of the Caucasus, and perennial herbs of the order *Compositae*. A powder made from the dried flowers has been long in use in Persia and in Russia for the destruction of fleas and other insects. According to "Smith's Dictionary of Plants of Domestic and General Economy," the plant from which the powder was prepared was for a long time kept secret. It was eventually discovered by an Armenian merchant, who communicated his discovery to his son, who, in 1828, manufactured the powder for sale. It is estimated that the quantity of this powder consumed in Russia alone is nearly one million pounds a year, and is now in popular use everywhere. I understand that the Agricultural Department of Victoria has lately imported and distributed the seed of the *Pyrethrum*, in order to promote its cultivation and the production of the well-known powder in Victoria. I raised about a dozen plants from imported seeds. They were planted in various localities in the garden, and I am very glad to say that, in despite of the very unfavorable season, they have grown uncommonly well, and have flowered freely. I have not the slightest doubt but that these plants can be easily acclimatised in South Australia.

Rhopala (Spec.).—Mr Thiselton Dyer, the Director of the Botanic Garden at Kew, has favored me with a parcel of the seeds of a remarkable tree, a species of *Rhopala*, belonging to the natural order of *Proteaceae*. It is a native of Columbia, and possesses the property of being indestructible by fire. Mr. Dyer remarks upon this tree as follows:—"The *Rhopala* is a small contorted tree, growing to about twenty feet in height. It is remarkable for being absolutely indestructible by fire, in large districts where the dry pastures and bush are burnt twice a year. Its resistance to fire enables it to exist to the exclusion of all other trees and bushes, as a perfect natural plantation. The periodical burning destroys everything except this tree. The resemblance to a plantation is moreover enhanced by the circumstance that the trees never form thickets, and they are thickly and almost systematically dispersed over the land. The tree delights in the most sterile soils, but always of a stony or shingly character. Sometimes it grows in places so barren that even grass cannot exist. This suggests the idea that it may be turned to account in sterile districts within the tropics." [This tree ought to be tried on the Ceylon patanas.—Ed.]

Ferns.—The collection of ferns has been enriched by the addition of thirty-six interesting species, which now numbers 407 species. We have added five species to the Lycopodiaceæ, bringing the number up to thirty-four. All the Ferns in the Fernhouses and those distributed through the stove and other houses show a most luxuriant growth, the result of careful attention.

One of the most interesting events which occurred in the garden last year was the flowering of a large specimen of the Yucca filamentosa. The plant is about twenty-five years old. It has reached the height of 18ft., the circumference of the stem one foot above ground is 7ft. 4in. The bare stem is 14ft. high, It produced its first upright flower-stalk in 1873. After this had peen cut off, a number of young shoots sprung up around the crown, which formed a globular head. Last year it flowered again; and this time, instead of producing upright flower-stalks, it threw out eight pendulous flower-stalks, each about three feet long, and containing about 300 flowers. The sight was magnificent, so much so, that I append a drawing of the plant in flower to this report.

The number of new plants of economic value and of those available for ornamental purposes, not including Florist's flowers, amounted to 353 species. The collection of plants has thus been augmented from 12,160 to 12,513 species.

I find that it will be necessary to remove a number of the old gum trees which have died or are dying out, and I regret to think that in the course of a few years very few of these will be left in the park. The great difficulty will be to remove these giants without injuring the young trees which have been planted in their neighbourhood. They will have to be taken down piecemeal.

Retrospect.—In closing this report I have thought that it would be of some interest if I were to give a short retrospect of the progress of the Botanic Garden since the year 1879. It must not be supposed that the value of the garden is confined to the pleasure and amusements it affords to the inhabitants of Adelaide and its suburbs, or to visitors from the country, as well as those from other colonies and foreign parts. It has the high function imposed upon it of spreading a scientific as well as an economic knowledge of the flora of this colony to other parts of the world. By this means an acquaintance with one portion of the resources of the Province is placed within the reach of the scientific world through the agency of institutions similar to that over which I have the honor to be Director. The continual interchange of specimens of plants enables the recipient to acclimatise large numbers of trees and shrubs. After experience of their habits, and their adaptability

to different climates has been established in this way, their distribution amongst those who are engaged in the practical business of agriculture and horticulture follows. In like manner the benefits of the interchange of plants and seeds with other countries cannot fail to become of the highest value to the cultivators of our own soil by extending their resources in new directions, and consequently increasing the value of their possessions. To this end the distribution of rare and useful plants amongst farmers and others has been continuous—indeed almost contemporaneous with the establishment of the garden. By the introduction of plants, trees, &c, a wide field of experimental as well as economical cultivation can be opened out. Its tendency is to enable the agricultural industry to broach out into new and useful enterprises, and to render it less dependent upon the cultivation of cereals alone, which experience, especially the last few years, has shown to be most precarious. As yet no very great results have sprung from this, but signs are not wanting that the use of new plants is gaining ground. A few years will, I trust, prove that the time and trouble which have been expended in this way, and the energy that has been applied to the dissemination of the knowledge necessary to the successful cultivation of foreign plants, grasses, seeds, and roots have not been exerted in vain. [Then follow details of improvements and additions made.—Ed.]

THE COLONIAL EXHIBITION.

Straits Settlements.—This collection is a very large and varied one, and occupies a cosiderable space in the east arcade, near the Hong Kong court. The exhibits are largely drawn from the vegetable kingdom, articles in native woods and bamboo largely prevailing. The following are a few of the most remarkable exhibits from the point of view in which we are specially interested. Several varieties of Gum Damar are shown, which, though called gums, are really resins exuded mostly by Dipterocarpeous trees. These resins are sometimes used for varnish making, but they appear to be used by the natives also for giving light, for here are exhibited implements called Damar-holders, which are described as being used as candlesticks, indicating that the Damar is burnt as an illuminant; the smoke given off must, however, be abundant and stifling.

The fibrous husk of the betel-nut (Areca catechu) is shown as a paper material, and as a waste product is said to be produced in almost unlimited quantities. Considering the very general practice of betel chewing by the natives of the East, and the abundance of fruits produced, as well as the thickness of the fibrous husk, the adaptation of this hitherto useless material would seem to be a very probable benefit for the countries where the betel-nut palm is common.

The fruits of Coix lachryma, better known, perhaps, as Job's Tears, are, as is well known, frequently used for necklaces, bracelets, and similar articles of personal adornment, but specimens are shown here of a dark-coloured elongated form, which are stated to be grown in small quantities by the Malays, and eaten in the same way as rice, or made into a sort of bread. Another food-product of very much more importance is sago, from the trunk of Metroxylon sagu, which is cultivated extensively about Singapore for commercial purposes. Pearl sago is known in trade in different sizes, classified as small, medium and large, but samples are here shown the "pearls" of which are as large as marbles.

The young leaves of Nipa fruticans are, it seems, used in the Straits for making cigarette papers, not that paper is made from the leaves, but that strips, of the leaves themselves are used for holding the tobacco. Regarding tobacco itself there are many samples of very creditable appearance, and some cigars of very curious shape, being short and pointed at the ends, and thick and flattened in the middle. They are exhibited by the Deli Langkat Cigar and Cigarette Company, and are called by the euphonious name of "Little Devils," the trade mark of which is a black devil rampant.

British North Borneo.—In this collection tobacco also forms an important exhibit; there are some fine brands, but the tobacco is mostly of a dark colour; the cut tobaccos are in long thin threads so common to Siamese and other Eastern sorts. A report on this tobacco from experts in Amsterdam, dated so recently as April last, says, "The quality is beautiful, soft, and strong, and has that elasticity which is so liked for cigar purposes. The burning is sufficient, although the ash is not quite white, but our brokers say that this will improve by further fermentation. In general the opinion is in every respect favourable, and valuation above the average of Sumatra tobacco. . . . We further have to observe that we did not mention to our brokers where it came from, and they therefore thought it was Sumatra tobacco."

Special attention is also drawn in this Court to the woods of the country, many of which are described as being both useful and ornamental. Unfortunately, however, the forest trees of Borneo are but little known botanically, and two or three only have other than native names. The whole of them, however, are good specimens of large size, well seasoned, and carefully smoothed or polished. In some notes on these timbers and their uses it is stated that some of them are valuabe for world-wide uses, and exist in such quantities as render the use of them available in those countries where wood is scarce. In consequence of the figure and colour of some of these woods resembling certain well-known commercial kinds they have been named in trade Borneo Mahogany, Walnut, Cedar, Ironwood, and so on. Under the Malay name of Mirabou, the wood of Afzelia palembanica is shown. It is described as being plentiful in some parts of Borneo, and valuable for furniture, as it does not warp; is very durable, has a fine figure, and takes a good polish. It is proof against the attacks of ants, and can be obtained in logs 30 feet long and 2½ feet in diameter. Three different woods, known respectively as Rassak Banaar, Rassak Diaim, and Rassak Bungah, and said to be the species of Vatica, are highly valued for their hardness and durability for house building, planks, piles, &c., all of them being proof againt the attacks of insects.

A wood called in Malay Salangau, Seriah, or Majon, and in English Borneo Cedar, appears to be one of the very valuable woods of the country. It is described as a tall handsome tree, probably belonging to the order Dipterocarpeæ, and found formerly in abundance in the Malay Archipelago, and still obtainable in large quantities in British North Borneo. Several varieties of this wood are known, all of a more or less reddish colour, and all suitable for furniture. Although easily worked it is strong and tough, and takes a good polish. It can be supplied in any quantity in logs 40 feet long by 5 feet diameter. Perhaps one of the most striking woods shown in the collection is that of the Kayn Kapor (Dryobalanops aromatica); it is the source of the well-known Sumatra camphor, which is found crystallised in interstices in the wood, sometimes in large masses. It is not so volatile as ordinary camphor, and is harder and more brittle; it is bought in quantities by the Chinese, who value it for its many supposed properties. The tree also yields by incision a fragrant aromatic oil. The wood, it seems, is very durable, easily worked, and is much used for house building, planks, &c. A very fine plank of this wood is shown. Some interesting samples of "Tankawang" fat or vegetable tallow are shown in this collection; the fat is poured into the hollows of big bamboo stems some 2 feet or more long, and labelled as of two qualities, one being made from large berries, and one from small. The fat is used for frying fish, making cakes, and lubricating machinery. The source of the vegetable tallow is not accurately known, but it has been attributed on the one hand to a Dipterocarpeous tree, and probably a species of Hopea, and on the other to a Sapotaceous tree, and perhaps to a Bassia. See *Pharmaceutical Journal*, Nov. 24, 1883, p. 401; December 15, 1883, p. 462; and December 22, 1883, p. 481.—John R. Jackson, Museum, Kew.—*Gardeners' Chronicle.*

FACILITIES FOR BOTANICAL RESEARCH.

Under this heading Professor Bower, who recently visited Ceylon, writes the following interesting article in *Nature*. Colombo, it will be seen, is recognized as the Clapham Junction of the East:—

In an article under the above heading, published in nature, vol. xxxi. p. 460, I endeavoured to draw the attention of our younger botanists to the importance of extending their studies over a wider field than is at present usual, and mentioned some easily accessible stations at which students might observe tropical vegetation. Since that article was written, I have had the opportunity of acting on my own suggestion, and of visiting Ceylon; I am therefore now in a position to enlarge upon my previous suggestions, and to fill in from personal experince many details which, though often trivial in themselves, may yet bring the possibility of Eastern travel home to the mind of some in such a way as may lead to future action. But while giving some account of the facilities for botanical work in the East, care must be taken not to overcolour the picture; it happens too often that writers of an enthusiastic bent raise expectations in the minds of their readers, which actual experience can only disappoint: in the following paragraphs I shall endeavour to make a purely matter-of-fact statement, and leave the colouring to be filled in at the will or opportunity of the reader. Taking first Peradeniya, we may consider what are its attractions as a station for botanical work, and then pass on to discuss the relative merits of other stations.

In the first place, hardly any port in the east is more accessible than Colombo: it has been aptly called the "Clapham Junction" of the East: the steamers of all nations meet there, and the competition between them produces a moderate scale of fares. Once, there, a direct train service lands the traveller in about three hours almost at the gate of the Royal Gardens; the mechanical discomforts of many a journey to remote districts in the United Kingdom are greater than this. The cost of the journey will vary according to the line of steamers selected; by the Peninsular and Oriental line a return ticket can be had from London to Colombo for 90*l*., 100*l*., or 110*l*. according as the return journey is completed in three, six, or twelve months. The charges on the Messageries Maritimes are about the same. The Star, Clan, and British India lines make more moderate charges, but the pace is correspondingly slower. It is little use making a journey of more than 5000 miles for a brief visit; and it may be presumed that, except where the circumstances are extraordinary, students would find it convenient to stay in Ceylon for three or four months, or more. Little is to be gained by scamping an expedition such as this, in which it may often happen that a man may gain his first and last experience of tropical nature; further, the surroundings are so new that it is some little time before one with even a good knowledge of our temperate flora can accommodate himself sufficiently to them to carry on successful work. We may then regard the cost of the journey as 100*l*., and the time required to make it a success about six months. The choice of season is an important point; in a country of alternating wet and dry periods it is well to experience both, and for the botanical collector it is important that collections should be finally made up in dry whether; it would be found that leaving England in November, and landing at the beginning of December, the weather would still be wet and vegetation luxuriant, but preservation of dry species would be difficult; a gradual change would be experienced, till in February and March the dry and hot season would have come in, vegetation would be more or less checked, and the preservation of dry specimens would be easy. Returning towards the end of March the English winter would be past, and, if he be a teacher, the traveller would be in time for the summer session in our Universities or medical schools.

Once on the spot the first question is one of accommodation. At Peradeniya there are neither hotels nor lodgings; a house must be taken and temporarily furnished, and it is surprising how cheaply this can be done. I took a small bungalow, the rent, of which was R40 per month; friends lent me some articles of furniture, and an expenditure of R150 supplied all else that was required for temporary housekeeping. The cost of keeping house, including the wages of two native servants, rent, &c., with a margin for incidental expenses, may be set down at about R250 per month; allowing further some R200 for travelling expenses, it will be found that R1,500 will represent the total necessary expenses of residence in the island for four months. But in its present depreciated state, the rupee is worth only about 1*s*. 6*d*.: it will therefore be sufficient to lodge about 115*l*. at a bank in Ceylon to cover all necessary expenses for four months' residence. I would not advise, however, that that exact sum only should be transferred; it would be more prudent to allow a margin for possible contingencies. The total expenses of a six months' trip to Peradeniya may thus be set down as 250*l*. But there are various ways in which strict economy might reduce the cost, while if two friends were to club together, their individual expenses for housekeeping would be considerably below the sum above stated for one. Thus it will be seen that neither in difficulty of transit nor in point of expense are there sufficient obstacles to prevent a visit to Peradeniya, or some similar station, finding a place in the programme of the career of an average botanist. One of the chief obstacles will be felt by many to be the loss of possible opportunities while absent, or the break in continuity of teaching, or other work in which a man may be already engaged. I venture to think that these are much overrated objections; and against them may be set the very great advantages which a tropical visit carries with it. A further question is, at what period in a man's career will a visit of this sort best repay him? Some will say immediately after taking his degree, but I am inclined to think that even a first-class man is at that time hardly prepared to make the best of the opportunity should it offer. The experience gained by a few years of teaching and of original work at home will indicate what is to be expected and what is to be looked for, and will fit a man in many ways for striking out new lines for himself, even if it have not already defined for him a clear line of research. On the other hand, it is important that travelling should be undertaken before a man settles in life, so that his mind may be as free as possible from distractions and anxieties.

We may now pass on to consider what are the specific advantages presented by Peradeniya as a station for botanical work. It is, as I have said, easily accessible; being more than 1,500 feet above the sea, the excessive heat of the low country is avoided, and it may be regarded as a decidedly healthy place. Secondly, it is situated in a central position, both as regards the whole island, and as regards the chief lines of communication by rail and road. Thus it is easy to gain excess to the low country by train to Colombo, whence roads, traversed often by horse coaches, will lead alone the coast, or inland in various directions; or, taking the upcountry line, Nuwara Eliya may be visited, which lies about 6,000 feet above the sea, and would serve as a good centre for working the higher levels; or again, a journey northwards by train and coach to Anuradhapura would give an insight into the low-level vegetation of the drier northern districts. From the above notes it will be readily seen how varied is the character of the country within easy reach from Peradeniya, presenting within a comparatively small area districts varying from the sea-level to 8,000 feet, and including both damp and relatively dry areas at low levels. This in itself would lead one to expect a rich and varied flora; and in fact the list of native plants now numbers some 3,000 species, a very considerable proportion of which are peculiar to the island. These and other natural advantages are,

however, eclipsed by the importance of the Royal Gardens themselves as providing a field for those hitherto unfamiliar with tropical nature. Here, there are collected in a small area a great variety of species, both native and imported; truly no botanist who has resided at Peradeniya can any longer complain of want of scope; if he does not find ample material for future work, he can only lay the blame on his own want of imagination. In the excellent herbarium and library, as well as in the fine series of coloured figures of native plants which are lodged in the Garden, he would find the greatest assistance in recognising and naming plants collected; while lastly, in the presence of the Director, who is the best living authority on the flora of Ceylon, are found those social and scientific elements which go far to enhance the pleasure of a visit to Ceylon.

In my former article mention was made of Java, where the Gardens of Buitenzorg, presided over by Dr. Treub, present great attractions for botanists. In my case, shortness of the time at my disposal prevented a visit to this famous Garden, and probably the same difficulty will present itself to others. There is, however, one conspicuous advantage which it possesses over Peradeniya as a station for botanical research, viz, a well appointed laboratory.* If, as seems not improbable, a Journey to the tropics and a period of steady work among tropical plants become a usual prelude to a career of active teaching in botany, ought not the English to provide themselves with some suitable station for such work? Is every man, whether well-to-do or impecunious, to depend upon his own resources alone for laboratory accommodation, re-agents, glass, and all other accessories necessary for his work? or are we to be content to send our botanists to suck what advantage they can from the hospitable Dutch, just as we send our forestry students to study with the French? Surely it would be a most legitimate way of extending the usefulness of the Garden at Peradeniya, and, in a small way it is true, of guarding the credit of England as a tropical Power, to establish a laboratory for the use of travellers. It need not be a large or conspicuous building. Dr. Trimen tells me that suitable accommodation for the present could be found in the buildings already standing in the Gardens, and probably 100*l.* would cover the initial cost of supplying the bare necessaries of life in the laboratory. The knowledge that such accommodation would be found at the other end would certainly encourage those who are doubtful to undertake a Journey to Ceylon.

It may be noted that no mention has been made of the Western tropics as a field for research; there can be no doubt as to the richness of the field, but I am not aware that there are any stations in the West which can compare with Peradeniya or Buitenzorg in convenience, accessibility, and general adaptation to the requirements of those who contemplate only a comparatively short visit.

Lastly, the cost of the journey will be found to be the most frequent deterrent from undertaking it; 250*l.* is a large sum to spend upon six months' work which can bring no direct financial return, however great may be the ultimate advantage gained from it; travelling Fellowships are few; but still there are other sources from which grants may well be made to assist really promising students in attaining so desirable an end; and it is to be hoped that it may be regarded as a legitmate and not unfrequent outlet for public or private grants, to enable young men, who will ultimately engage in teaching, towards the attainment of experience which must always be of value to them in the exercise of their profession.—F. O. Bower.

* The laboratory, herbarium and a splendid library are located in a splendid hall, which the gardens at Buitenzorg and the cause of science owe to Governor-General Charles Pahud, whose name is unfortunately associated with an inferior species of cinchona. The Buitenzorg gardens are of great extent and species are carefully arranged in groups. The numerous varieties of palms and pandanus are specially remakable. There is one particular palm with a scarlet stem which is a veritable thing of beauty.—Ed.

THE COLONIAL EXHIBITION.

The Coconut Palm in the Indian Court.—As supplementary to the description of the manufacture of coir matting, given by Mr. Jackson in a recent number, it may be interesting to furnish a few details as to the importance of the trade in coir and coconut-oil, and to draw prominent attention to one of the most complete and varied collections of the products of this palm ever perhaps shown, and which is now on view in the economic and commercial Indian Court of the Exhibition at South Kensington, prepared by Mr. M. C. Pereira of Bombay. The value of the coconut-oil, nuts, and fibre which we receive annually, exceeds half a million sterling. The oil and coir are chiefly received from Madras and Ceylon, the nuts from Brazil and the West Indies.

The collection of Mr. Pereira will be found near the bamboo trophy, and his descriptive enumeration of the exhibits (eighty-three in number) deserves a more extensive publicity. First is shown coir, the fibre obtained from the husk of the coconut, which in this state is used for stuffing cushions, beds, pillows, making rope mats, cordage, &c. Spoon made of the shell, used in the cook-rooms of Europeans, and by the natives for drinking gruel (rice conjee); it has the advantage over the metallic one of not corrodiug. A drainer used for draining food that has been fried in *ghee* (clarified butter) or oil; a large ladle, used for water; a smaller one, used by the natives for taking out oil for daily use from an earthen vessel containing the yearly or quarterly stock; it is not corroded by the oil. Hubble-bubble; or hookah of the poorer classes. beads, made of the shell. Vinegar, made of the juice or sap of the palm. Pickle made of the pith of the top of the fresh tree, with vinegar of the juice (toddy) of the same palm. The spathe of the blossom, the rib of the leaf. A broom made of the leaf-ribs: these are much used for sweeping purposes. A strainer made from the bracts of the tree, by which the leaves are held firm to the tree. It is used for straining (toddy) coconut-juice and coconut-milk, and for general straining in the cook-room. Wooly floss, much used as a styptic for cuts by the toddy drawers and cultivators. The blossom in the state when it is tapped for drawing juice (toddy). Chain used round the waist to retain the loin-cloth: the size is for a child—set in metal it may be used as a watch-guard. Drum made of a piece of the trunk of the tree. Wood, pieces of rafter made of the lower part of the tree, 10, 20, and 25 feet in length. Oil, as expressed in the native mills for commerce. Oil extracted from fresh coconuts by rasping fine, drying and pressing between coir, and twisting with the hands, or by extracting the milk and seperating the oil by heat. It is used internally in lieu of cod liver oil, and externally tor ulcers with good results. Coconut hair-oil, arrack, a spirituous liquor, 60° u. p., distilled from coconut juice (toddy) and drukhot. Punch made from the juice of the coconut palm, with spices and sugar, from the recipe of the Portuguese. One or two cupfuls are drunk hot for a cold. Liquor made of toddy by re-distillation, 20° u. p., formerly much used for making medicinal tinctures and country brandy; a coconut (the fruit takes a year to ripen). A sweetmeat prepared from the kernel of the nut; another kind is flavoured with saffron. Splints made of spathe of the blossom used for this purpose by the toddy drawers and natives of Goa, &c. Door mats made of the fibre, of many shapes and sizes by natives, and in the gaols. Buggy mats and carriage mats are also shown. Floor mats are also made in Malabar, and in the Bombay gaols of different sorts and colours. A bird-cage made of the rib of the leaf. Horns, large and small, made of the leaf of the palm give a loud sound when fresh. Toy-parrots in cage, made by children, of the leaf

of the palm. Cadjan or woven leaf of the tree, used for thatching houses; has the advantage over tiles of keeping the house cool. The astringent root is used medicinally, and as a gargle for sore mouth. Coir ropes of various sizes are extensively used for different purposes. An oil bottle hung beneath the labour cart with castor-oil and brush in it for lubricating axles. Immature nut, used medicinally as an astringent; children are fond of it.

Trough made of coconut tree used for catching water drawn from a well with a Persian wheel for irrigation purposes, of which a model is shown. A conduit as put under the trough for conveying the water. Piece of the adapter used for connecting the native still to the condenser. Tuntuna, a native musical instrument used by the poorer classes. Piece of beam of the shape used for houses. It is also used for fishing-stakes in the sea; generally two coconut trees make a stake 60 to 70 feet long. A rosary-box made of immature coconuts.

Charcoal powder, the burnt shell, used for preparing black and lead coloured washes for houses. Broom made of the ribs of the leaf, used by the Bombay and other municipalities for sweeping roads, streets, yards, &c. Brooms made of the stems of the blossoms and nuts are used by the cultivators for collecting dry leaves for burning on the fields. Crab traps are made of the stems of the leaf, and fish traps of the ribs.

String of Pots.—This is made of the fibre of 60 or 70 feet in length, and about fifty or sixty earthen pots fixed to it and put on the Persian wheel, which in rotating brings up the pots filled with water and takes down the empty one.

Vio.in used by the lower classes of natives, particularly the Gosavies, a class of professional beggars. A sling, used for keeping sundry articles of food out of the reach of cats, rats, and ants, by hanging it on a hook to the ceiling. Tied to the ends of a bamboo it serves for carrying water-pots, baskets, &c. A small one is used by milkmen for carrying milk for sale.

Flesh-glove, used for washing and rubbing cattle and horses. Tar with acetic acid, made by burning the shells in a pot with a small hole in the bottom, placed on another, heated by fire on all sides. It is used by the natives for ringworm and skin diseases. A brush made of the husk of the nut for cleaning sieves, washing baskets, and rice-strainers. Sugar and molasses made of the toddy or juice in Goa.

A band peeled from the outer part of the stem of the leaf, which is used as a cord by the toddy drawers. A gilded coconut, offered by the higher classes of Hindoos to appease the sea on the coconut fair day. At weddings the bridegroom and bride carry it in their hands. Coconut husk, used as fuel, especially for baking purposes and for making fibre; scoops made of the shell—the round and deep ones are used as drinking cups. Neck-belts, used for yoking bullocks and buffaloes to carts, ploughs, oil-mills, &c. Sack, used for sending out articles in; a somewhat similar one is attached to the cart for carrying straw or grass. The pedicles of the blossom are used for tooth brushes, and the peduncles are used as brushes for whitewashing houses, &c. A blind, used for blinding bullocks and buffalo while yoked to the Persian wheel, oil-mills, &c. Nest, made by birds out of the fibre of the leaf. Soap, made with coconut oil, which holds a larger percentage of water than any other soap. Rings, whips, neckties, rattles, crosses, puzzles, and toys are made of it, also cricket-pads of the wood. Poonac or oil-cake from the native mill, used for manure and feeding poultry. A patensur or ship and fishing boat, made by boys of the fisherman class.

Copra or kobral, the dried albuminous kernel of the nut—the stem used as a broom. Model of a charpai or cot used by the natives. Crude potash from the stem of the leaves; they produce 20 per cent, of ash. Abortive coconuts used as floats for beginners in swimming. The spadix, prepared for drawing juice or toddy. A thin slice is cut from the palm stem three times a day. The juice flows from this and drips down into an earthen pot suspended on purpose. A small piece of the leaf is fixed above to prevent the bottom of the pot from touching the point, the sheath of the leaf covering the mouth of the pot to keep out flies.

Cultivation.—This useful palm requires considerable care and cost to bring it to the state of bearing fruit. The ripe good-sized nuts from an old tree are kept in a well of water for three months, until they germinate; they are then put into the ground in beds of fifty or a hundred, and watered every day. In three months more they begin to grow up, and after three years or more they may be transplanted in regular spaces of from 15 to 20 feet, watered regularly every other day, and manured occasionally. In about twelve or fifteen years they come to bearing, but the yield is in proportion to the care taken to water and manure; at this stage the value of the tree is from £2 10s. to £3 each.

Ceylon.

From Ceylon it is officially stated that the cultivation of the coconut palm, with its multifarious uses, is the most important in the life of the low-country Sinhalese. The spirit he drinks is distilled from the sap, the kernel of the nut is a necessary element in his daily curry, the "milk" of the nut is the beverage offered to every visitor; his only lamp is fed from the oil; the nets for fishing are manufactured from the fibre, as is also the rope which keeps his goat or cow from straying; while the rafters of his house, the thatch of the roof, and the window-blinds, are made from its leaf and wood. The extent and value of the cultivation of this palm may be gathered from the fact, that while, as already stated, its many products are a universal necessity in the daily life of the island population of 3,000,000, the export of oil, copra, and fibre, exceeds in amount £700,000 annually, and the revenue derived from the excise duty levied on the spirit (arrack) distilled from the sap exceeds £170,000.

The shipments of coconut oil from Ceylon in 1884 were 383,955 cwt., valued at £447,948; and of arrack, 140,742 gallons, value £24,290; exclusive of the coir-fibre, £77,454, and nuts, £6,900. Under the name of poonac, 150,000 to 200,000 cwt. of coconut oil-cake is also imported annually for manure from the Malabar coast, to the value of £60,000 to £70,000.

Besides India, coconut products are shown in the Ceylon, Fiji, the West Indian Courts, and Honduras. The value of the exports from Fiji in 1884 were:—

Coconuts	£2,219
Copra	59,241
Coir-fibre	1,301
	£62,761

Trinidad has 3,000 acres planted with coconut palms. About 5,500,000 coconuts were shipped from Jamaica in 1884, which realised nearly £21,000.—P. L. Simmonds.—*Gardeners' Chronicle.*

The Bark of the Sapu Tree as a febrifuge is thus noticed in an account of the Mauritius Court in the *Pharmaceutical Journal*:—"The bark of *Michelia Champaca* is stated by Bouton to act very effectually as an antiperiodic, and to clean the tongue in fever and subdue nervous symptoms."

Petroleum Fuel.—At the conclusion of a paper on petroleum by A. H. Samuels, F. C. S., he stated:—I must not omit to mention the use of the special product of petrol distillation for fuel. The Russians call it astatki, and Messrs. Nobel's fleet of petroleum vessels on the Caspian Sea are all worked entirely with this astatki. It is burnt by being passed along a narrow tube, and as it drips from the tube a current of steam is blown through it and scatters it in a fine spray, which keeps in a continual blaze. Various patents have been taken out for burning petroleum for fuel, and is likely to supersede coal at sea owing to its great cheapness and economy as regards bulk.—*Pharmaceutical Journal.*

Root-worms in the Sugarcane.—M. Treub, the excellent Director of the Buitenzorg Botanic Garden, has published an account of a third species, Heterodera javanica, which affects the roots of Sugarcane in the same manner as the two other species, H. Schachtii (found on numerous plants, especially in Beetroot), and H. radicola, also found in numerous plants.—*Gardeners' Chronicle.*

Maracaibo Coffee.—Consul Plumacher, in his annual report just submitted to the State Department on the commerce of the consular district of Maracaibo, says that coffee continues the principal product of that region, and New York its most advantageous Market. The export of coffee to the United States, which was thirty million pounds during 1884, was less than twenty-eight million pounds during 1885. The production of coffee was not less than heretofore, but low prices led inland producers to store and hold their coffee to await better prices. Recent revolutions and low water in the rivers have also interfered with the shipment of coffee from the interior to ports of export. The exports have been mainly in American bottoms. The new crop promises to be plentiful and good. The export of cacao is steadily increasing, and will probably be doubled by the completion of railroads now in course of construction. The demand and prices for hides and skins were uniformly good. Commerce at Maracaibo suffers from a monetary crisis, revolution, monopolies, political uneasiness, postal irregularities, and prevailing low prices of principal articles of export. The total expots of the year to the United States were estimated at $2,827,682.—*N. Y. Commercial Bulletin.*

The Trade in Jute.—Some curious facts in connection with the trade in manufactured goods between Germany and England are brought to light in a report by H. M. Chargéd' Affairs at Dresden "on the effects of the German Customs Tariff Reform of 1879, and on the revision of 1885." The points with which we are more immediately interested are those treated of in chap. 4 under the head of "Jute Manufactures," in which Mr. Strachey says:—"Germany began to spin and weave Junte fibre about a quarter of a century ago. In 1874 the spindles were estimated at about 17,000; they are now nearly 60,000. These may seem miserable figures by the side of the 18,000 Indian spindles, to say nothing of the Scotch, but they show the vigour with which the youngest of the textile manufactures has been pursued by the Germans. All the coarse Jute tissues such as granary sacks, baggings, hessians, and tarpaulins, are now made in Saxony, Prussia, Bremen, Gua Elsass, and elsewhere in the empire. When spun in high numbers the fibre has a fine golden glance, and in its natural shade, or dyed, may be woven into cloths and plushes of great durability and beauty. Jute may also be printed or interwoven with cotton, woollen, and silk, making the cheap and effective furniture stuffs now so largely used in hotels, railway stations, theatres, &c., and in Germany in private houses. It is hardly a secret that the fibre of the Corchorus capsularis is the real component of most of the real Algerian curtains positively imported from Algiers, of the genuine cloths of Smyrna, of the undoubted tapestries of Teheran and Herat. Germany contributes her share to the productions of all these fabrics, whether sold under their proper names, or under the more attractive foreign euphemisms. Chemnitz and Zittau in Saxony, Elberfeld, and some other Prussian wool centres, now compete with the analogous goods of Paris, Amiens, of Tourcoing and Roubaix, and with our own made in Bradford and Huddersfield."—*Gardeners' Chronicle.*

The Colonial Exhibition.—One of the most interesting of the minor features consists in the illustrations of the uses made of flowers, grasses, &c., for ornamental purposes. In the Cape Court, for instance, a botanist of our acquaintance who has made the Restiaceæ a subject of special study for nearly a quarter of a century, and has been twitted for his devotion to so unattractive and so generally useless a race of plants, was delighted to find his favourites thought ornamental enough by the Cape ladies to be used as decorations for their hats, together with leaves of the Silver tree (Leucadendron), everlasting flowers, &c. In the West Australian Court are some ornaments constructed of what we take to be scales from the involucre of a Protead. They are effective, but we have not yet been able to examine them closely. Popular names are, as usual, an intolerable nuisance; some magnificient things are made in various Australian Courts from "Cedar," but the Cedar of one court is not the Cedar of another; and whatever be the true name neither of them is entitled to be called Cedar; the collections of timber, economic plants and their products by Baron Von Mueller, Dr. Schomburgk, Mr. Brown (South Australia), Mr. Bailey, the colonial botanist of Queensland, the officers at the Cape and Natal, British Guiana, Canada and India are full of interest to the botanist and cultivator. Baron Von Mueller sends his wood samples in the form of little books, which admit of the various sections, transverse, vertical, or radial, being seen, while it allows the specimens to be packed book-fashion in small compass. Each "book" has for title the name of the plant from which it is produced. Mr. Brown mounts small sections of wood bark, &c., with the dried flowers on grey board—the whole very neat, compact, and effective. The Queensland woods are in the form of small slabs let into card-board mounts like photographs. The photographs of the Melbourne and Sydney Botanic Gardens, as well as those of Ceylon and Calcutta are excellent. Our readers will be familiar with some of these from the illustrations that we have from time to time published. The Botanic Gardens, Ballarat, is, however, new to us. The models of fruit from Australia are interesting, but their interest is lessened by the considerable importations, in excellent condition, of fresh samples.—*Ibid.*

Coco-De-Mer, or Double Coconut.—Frederick Stearns has on exhibition, at his office in the laboratory, two specimens of the Coco-de-mer, or Double Coconut, a remarkable fruit of one of the largest and most wonderful palm-trees. They were sent him by the Hon. E. V. Mussey, United States Consul at the Seychelles, a small group of islands in the Indian Ocean, north of Madagascar. This palm-tree, it is stated attains a height of 100 feet, its stem being nearly two feet in diameter, bearing on its summit a crown of fan-shaped leaves. It is remarkable for growing in a socket of a hard, woody texture, perforated with holes made by the roots. This curious appendage derives its origin from the Coteyledon, which in the palm attains the extraordinary length of 2 feet, growing downwards like a root, having the germ seated in its thickned end. When perfect, the thick end opens on one side, like a sheath. In time, the nutriment of the nut becomes exhausted, and the part of the cotyledon between it and the young plant withers. The latter, however, maintains its placental vital connections with the sheath end of the cotyledon, which is henceforth nourished by the plant, and increases in size with its growth, which thus continues seated in the cradle of its birth through life. This formation appears, however, to be common to the palms, but very much more largely developed in this variety. The fruit is a large oblong nut, covered with a thin rind. After the removal of the outer rind it has the appearance of two oblong nuts firmly united together, often weighing 30 to 40 pounds. They are borne in bunches, each consisting of nine or ten nuts, so that a whole bunch will often weigh 400 pounds. It takes 10 years to ripen its fruit, the albumen of which is similar to that of the common coconut, but it is too hard and horny to serve as food. The shell is converted into many useful articles by the natives. The leaves are made into hats, baskets, and the like. The demand of late years has become so great that in order to obtain the leaves the trees are cut down, and, as no care is taken to form new plantations, it was at one time feared this palm would eventually become extinct. In 1861 the leading botanists in England petitioned the Government for its protection. By more recent information, however, it appears that in one island alone there are many thousands of these palm-trees.—*Detroit Free Press.*

ADULTERATION OF COFFEE.

Planters' Association of Ceylon, Kandy, 13th July 1886.

The Editors, *the Ceylon Observer*, Colombo.

Sirs,—With reference to your editorial note in regard to the leaflet on the subject of the adulteration of coffee mentioned in Mr. Shand's letter published in your issue of yesterday, I now beg to enclose a copy of it.

The Planters' Association and Chamber of Commerce were recently invited by Mr. Thomas Dickson, Managing Director of the Scottish Trust and Loan Company of Ceylon, Limited, to again move in the matter, when it was decided that the subject be brought before the Associated Chambers of Commerce of the British Empire by Mr. F. W. Bois, the delegate of the Ceylon Chamber of Commerce, but I think Mr. Shand's statement that the Planters' Association of Ceylon was not asked to join in the particular movement under remark is correct.—I am, sirs, yours faithfully, A PHILIP, *Secretary*.

(*Printed under the Authority of the Indian Coffee Planters' Committee.*)

COLONIAL AND INDIAN EXHIBITION (LONDON, 1886).

INDIAN COFFEE, ITS USE AND ADULTERATION.

Samples of Indian Coffee, 230 in number, have been arranged at the Exhibition, by the Indian Coffee Planters' Committee, under the sanction of the Royal Commissioners. These samples represent (1) the "cherry" (that is, the coffee fruit as plucked from the tree); (2) the "parchment" bean (that is, the berry when pulped but enveloped in an outer skin or husk, resembling parchment); and (3) the berries stripped of this covering, and sized and sorted as they come into the English market, before roasting. The coffee thus exhibited is from the crop of 1885-6, produced by British planters in the following districts:—Mysore, Coorg, the Wynaad, the Neilgherries and Travancore. Upon coffee estates in these districts the investment of British capital is annually increasing, and the finest coffee which comes into the English market, fetching higher prices in many cases than even Mocha coffee itself, is grown in the districts above mentioned.

Visitors are invited to test the quality of the coffee by purchasing, in the coffee stalls of the Royal Commission, cups of Indian coffee, or they may buy at the same stalls packets of roasted coffee, ground or unground which may, if they wish, be forwarded to any address through the Parcels Post. If desired, unroasted coffee will be supplied.

Coffee, when carefully made, with a sufficient quantity (say from an ounce and a half to two ounces to a pint of water), is, perhaps, the most delicious and refreshing of all non-alcoholic beverages. It produces a buoyancy and exhilaration which are not followed by reaction or subsequent depression; it acts as a stimulus to the mental powers, lightens fatigue, sustains the strength, whether under mental or physical exertion, and contains medicinal and restorative properties long recognized as of the highest value. No other beverage so amply repays, by its aroma and fragrance, a little care and attention in preparing it. In every other civilized country, excepting the United Kingdom and Russia, it is among non-alcoholic beverages that which is most largely consumed.

In the United Kingdom its consumption, unfortunately, has been hindered to a great extent by many and shameful adulterations carried to such lengths that large classes of the population hardly know the flavour of genuine coffee. Chicory is the chief ingredient in the cheap mixtures, because it soon makes hot water black, thick and bitter, and so little gives apparent strength to what may contain little of the coffee berry. Among numerous other substances used to adulterate coffee are burnt sugar, roasted and ground roots of dandelion, carrot and parsnip, together with beans, lupins and other seeds. Notwithstanding the provisions of the Adulteration Act, and, indeed, under cover of these provisions, the adulterants above-mentioned are made up with coffee in different proportions, and are everyday sold, especially among the poor, labelled as coffee mixtures. They are also sold under various high-sounding names to consumers among the middle and upper classes.

An analysis of forty-three samples of coffee and coffee mixtures purchased in London during March and April 1886, shows an average proportion of coffee in these samples of just fifty per cent, added to fifty per cent of burnt sugar and various vegetable substances. Twenty-two of the samples bear a label very commonly used; and nine of those contain from sixty-two to ninety-three per cent of chicory, &c., averaging seventy per cent of other substances than coffee. These mixtures are sold at prices ranging from 10d up to 1s 4d per pound. The price of the pure Indian coffee sold in packets at the Royal Commission's stalls is 1s 4d per pound. Upon a moderate calculation the vendors of many of the wretched compounds just mentioned must be realizing profits of something like a hundred per cent, and the worse the mixture the greater the profit.

On this subject the Committee may cite the following extract from the Annual Report of the local Government Board for 1884-5 (pp. cvi, cvii:—"Coffee continues to be one of the chief subjects of adulteration, and about one-fifth of the samples examined were reported against. The peculiarity in one case was that the berries were actually shown to the Inspector, and were ground in his presence, so that there seemed to be no likelihood of adulteration. Chicory, however, was found on analysis to be present, and the vendor was fined. It is possible that this fraud was due to the revival of an old practice of compressing chicory by machinery into the size and shape of coffee-berries. These sham berries are mixed with real ones, and the purchaser, who sees what he believes to be coffee being ground before his eyes, is hopelessly deceived. As chicory only costs threepence or fourpence per pound, the fraud is very profitable. It is no rare thing for so-called 'coffee' to be sold which proves on analysis to be composed of one-fourth part of coffee added to three-fourths of chicory."

From an abstract of reports made by the public analysts contained in the same official document (p. 298) it appears that, out of 357 samples examined in the Metropolis during the year 1884, fifty-three, or about fifteen per cent, were adulterated. In various counties of England and Wales adulteration was still more general, for out of 981 samples examined 219 were adulterated, or about twenty-two per cent. And these were not the coffee "mixtures," which may be sold as such if so labelled (see section 8 of Sale of Food and Drugs Act, 1875), but samples sold as pure coffee.

Thus it appears that from the sale of coffee mixture enormous profits are realized by vendors while the public palate is depraved and genuine coffee discredited. In the interest of consumers, as well as of British producers and importers, the Indian Coffee Planters' Committee wish to point out that pure and wholesome coffee may be bought at reasonable prices, varying, of course, according to quality, but often little if at all exceeding the prices charged for spurious fabrications. This Exhibition, with its samples of genuine products from the Colonies and India, appears to offer a legitimate opportunity for pointing out the wholesale manufacture and retailing of spurious compounds in the United Kingdom, practices most prejudicially affecting consumers, and also seriously discouraging British enterprise in the growth and importation of coffee. Visitors are respectfully invited to note these facts, and not allow themselves to be deluded into the belief that coffee mixtures are aught but a miserable substitute for genuine coffee.

A Few Practical Hints to coffee-drinkers:—*

1. Raw coffee (the unroasted berry) if kept in a dry place improves with age.

2. Those who wish to enjoy coffee in perfection should have it fresh roasted.

3. If the usual rotating cylinders are not available, it is easy to roast coffee over a clear fire in an earthenware pipkin, or a small frying-pan: it must be kept constantly stirred to prevent burning; the time required is from 15 to 20 minutes.

4. Roasted coffee should be kept in an air-tight vessel; the Viennese prefer a glass bottle to a canister. Coffee is very absorbent, and according to good authorities, should at no time come into contact with metal.

5. A mill, though convenient, is not essential. The Turks do not grind their coffee, but pound it in a mortar with wooden pestles. Brillat Savarin, the great French epicure, who tried both pounded and ground coffee, preferred the former.

6. One ounce of coffee to a pint of water makes poor coffee; an ounce and a half to a pint makes fairly good coffee; two ounces to a pint make excellent coffee.

7. Such coffee mixed, with half, or even three parts, its bulk of boiling milk, forms an ideal breakfast-food for body workers and brain workers. A very small quantity without milk, taken after a full meal, stimulates the stomach to the necessary effort of digestion, and wards off the drowsiness which often follows satiety.

8. This neat infusion is generally known as "black" coffee. But genuine coffee, when infused is not very black. An excessive black colour is given by means of burnt sugar, and is no sure indication of strength.

9. It is a mistake to suppose that costly and cumbersome machines are necessary for making coffee. The Brazilians insist that coffee-pots should be made of porcelain or earthenware, not metal. Excellent coffee may be made in a common jug provided with a strainer.

10. Warm the jug, put in the coffee, pour boiling-water on it, and the thing is done.

11. Coffee must not be boiled; let it gently simmer; violent ebullition dissipates the aroma.

12. If a quantity be wanted, good coffee can be made some hours beforehand, even overnight if necessary. For this purpose use any large earthenware vessel; heat it to receive the coffee; fill up with boiling-water; protect the contents from the air by a wet cloth over the lid or other covering. When required, pour gently off the clear infusion and heat it to the simmering point.

13. Complicated filters are unnecessary if your coffee be pure; if mixed with chicory, dandelion root, roasted acorns, roasted cabbage stumps, or other forms of vegetable offal, which on boiling disintegrate and yield a thick, starchy, albuminous, sugary soup, you will then want an ingenious filter.

14. According to recent German analyses, the dietetic value of a cup of coffee is more than twice that of a cup of tea; as a stimulant a cup of coffee has more than three times the value of a cup of tea.

MR. RUTHERFORD ON THE DETERIORATION OF CEYLON TEA.

10th July.

Sir,—The following have been given me by various tea planters as the causes which they consider have brought about such a great fall in the price of Ceylon teas this season:—

No. 1 considers that the poor quality is because there have been those conditions of heat and moisture to produce leaf flush, without the plant drawing upon the minerals of the soil, and that on this account there is a poverty of cellular tissue.

No. 2 does not believe in the deterioration of quality, and attributes the low prices entirely to larger supplies and a depressed trade.

No. 3 considers that, as a rule Ceylon eatates are plucking coarser leaf than they did in the days when Mr. Cameron was among us.

No. 4 considers that much better tea would have been made had there not been such a lack of electricity in the air this season—a fact which, he says, he has particularly noted.

No. 5 considers we have been working our bushes too hard, and that they are on many estates becoming exhausted; and if good quality is to be maintained we *must* manure.

No. 6 considers that low prices might to a certain extent be averted if London brokers would not so invariably sell *without* reserve.

None admit that tea-makers have become careless in the manufacture of their teas, and none attribute a deterioration from using any particular roller or dryer.

The above expressions of opinion are from those who have given some attention to the subject; and, although none of them may have hit upon the true reason for the great fall in price and alleged deterioration, their opinions may assist others in solving the mystery.

H. K RUTHERFORD.

Local "Times."

CEYLON REVOLUTIONIZING THE MARKETS OF THE WORLD.

IN RESPECT OF CINCHONA BARK AND CARDAMOMS. IN FIVE YEARS, MAY NOT THIS ALSO BE THE CASE WITH TEA?

The time was—not so long ago—when "New Products" were the subject of contempt on the part of a great many people in Ceylon. The old coffee planter wedded to his staple and justly proud of a plant that had so long been the mainstay of the colony, for years poohpoohed the cry over "new products." Absent proprietors, as in the case of Mr. Wm. Smith's partners in Craigie Lea, some dozen years ago, would have nothing to say to cinchona on their plantations. Who would devote time and money to a "medicine plant?" "Intelligent natives" for a long time, thought it a poor look-out when they saw their European neighbours and superiors given over to experimental nurseries and gardens with a variety of new-fangled notions about bark, rubber-juice, cacao-pods and even the despised native cardamoms. Officials, with one notable exception, generally looked upon the "New Products" era as the beginning of the end, and many of them rather chuckled over the thought that Ceylon was in a fair way to relapse into the paradise described by Mr. Wm. Charles Gibson when there was no coffee planter in the island to worry and disturb Her Majesty's Civil Service. We have spoken of one notable exception. We refer to Governor Sir Wm. Gregory who was so far ahead of the Service and of the generality of planters, as to devote special headings and paragraphs in his Opening Speeches year by year to Cinchona, Cacao, Tea, Rubber, &c., long before those industries had been practically appreciated on our plantations.

But the day of small and despised things is at end, and lo! the little one has become a thousand. Who would have believed in 1861 (the year that Clements Markham brought the first cinchona plants to the East), or in 1871 when our total export of bark was 80 pacakages valued at R313, or even in 1881 when it had reached 1,100,000 lb., that in 1884-5-6 it would be found that Ceylon had completely revolutionized the ancient South American trade in cinchona bark and acquired the complete control of the European market?

* Most of these "hints" are condensed from "Coffee and Tea," a lecture given by Dr. G. V. Poore, at the Parkes Museum, 74 (a) Margaret Street W., where persons desiring to pursue the subject further may obtain copies of this lecture (price 1d) or by writing to the Secretary.

Sending from 11 to 15 million lb. of bark of all grades into the European market in a single year, the produce of Ceylon may now be said to equal, if not exceed, that of all the rest of the world put together! And yet less than seventeen years ago, the Director of our Botanic Gardens (the late Dr. Thwaites), had to beg, and beg in vain, to have a trial given by our planters to his cinchona plants, offering them as a free gift! The cinchona planting industry has indeed become a veritable giant in Ceylon; the shipment of a couple millions lb. of bark in a single month from Colombo is not now deemed extraordinary and as a correspondent well says elsewhere, it depends entirely on Ceylon producers whether the price of this product should rise again, or fall to a mere fraction of what it was a few years ago. There is certainly reason therefore for a Cinchona Planters' Syndicate in this island.

But it is not simply in respect of cinchona bark that the markets of Europe have been revolutionised. There is another "new product" despised and comparatively little known, and yet it has put many useful rupees into the pockets of numerous Ceylon planters during the last five years, until now the cry comes from the brokers and merchants of London that in respect of CARDAMOMS too, Ceylon has revolutionised the trade of the world as centred in the great distributing metropolis. How strange this result! Ceylon began by shipping only 5,000 lb. of this product so recently as 1876, and now we are up to 205,000 lb. for 9½ months with the probability of touching 250,000 lb. for the twelve months ending 30th September next.

It is surely then no small compliment to the energy of our planters and the world-wide importance of their industry in this island, to learn that in respect of two of our new products—Cinchona and Cardamoms—the whole trade of the world has been revolutionised through the influence of Ceylon. Who daresay that it may not be possible in five or seven years hence, to say the same thing in respect of "TEA"? We ought to have taken special notice before now of the fact that in April last Ceylon had made another great stride forward, in shipping over one million lb. of tea in the one month. The day is not far distant, we believe, when the same quantity will be shipped in a week from Colombo. There can be no question that we are, as a colony, in for "a big thing" as the Americans would say, in respect of "tea." The sooner our neighbours in India, Java and China realize the fact, that this little island is bound to go on exporting 12, 20, 30 and 40 millions of lb. in successive seasons until, perhaps, the 50 or 60 millions are reached, the better for their own peace of mind and business arrangements. It is impossible to arrest the great enterprise in which practically the entire planting community of Ceylon are now engaged. CARDAMOMS has done great things; CINCHONA can shew marvellous results (and CACAO or COCOA should not be forgotten); but among all the NEW PRODUCTS OF CEYLON, none are so full of promise, potency and revolution as regards the markets of the West, and the prosperity of this little island, as TEA.

EXHIBITION CONFERENCE ON FIBRES, DRUGS, &c.

(*From a London Correspondent.*)

20th June 1886.

A notice was issued from the Colonial Exhibition dated 15th June, signed E. C. Buck, inviting gentlemen to meet at a Conference at the Economic Court in the Indian Department on fibres, silk, drugs, gums and resins, minerals, oils, oil seeds, timbers, tanning materials and food stuff. The first meeting was on the 16th instant, when Dr. Forbes Watson, Messrs. Christy, Routledge, Collier, Cross and Johnston attended. Dr. Watt had the different fibres laid out in bundles, but owing to the want of commercial information no practical results were arrived at. One gentleman asked the names of the fibres referred to in *The Times* 31st May. Dr. WATT replied that the names of the fibres could not be given as some visitors at the Exhibition who had their attention called to these fibres had undertaken to patent the employment of two for certain purposes. This created considerable surprise to the gentlemen who were asked to attend this conference. Mr. Cross working with Mr. Bevan and Mr. Johnston asked if the Indian Government would pay for a chemical report upon the fibres from India if he examined them chemically and microscopically. Mr. BUCK said that he was confident that the Indian Government would not pay any expenses as they were most anxious that this expense should devolve upon merchants in England, and this was one of the reasons why they hoped to form a Colonial and Indian Museum. Mr. Cross then asked, supposing he did the whole of this work, would Mr. Buck undertake to have the whole published at the expense of the Government. He replied that if the future recipients of the Indian collection would not support the expense, he undertook to say that the Government would do so. It is rather a singular coincidence that on the same day as this first conference was held that a letter should appear from Mr. T. Christy, F.L.S., in the *City Press* upon the subject of Colonial Museums.

THE PRICE OF QUININE.

Quinine, the alkaloid of cinchona that is most largely used in medicine, is now lower in price than it has ever before been in the history of its manufacture. When Congress removed the import duty on the various salts of quinine in July 1879, the price of sulphate of quinine of American manufacture, was $3.35 per ounce in bulk, but since that date the price, with the exception of a few slight fluctuations, has steadily tended downward, until at the present time the American drug is quoted at 68 cents per ounce in bulk, while the foreign article is quoted at about four cents per ounce less.

The question naturally arises as to what extent did the removal of the duty affected the price of the drug. Immediately after the removal of the duty there was a decided fall in the price, occasioned by large quantities of foreign sulphate of quinine being sent to this country, but it was not long before prices advanced, not to the same point, however, as prevailed at the time of the removal of the duty. The cheapness of the salts of quinine is almost entirely due to the low price at which the cinchona bark, from which they are obtained, is now being sold, and the bark is cheap because it is in plentiful supply. For many years quinine manufacturers in this country and abroad relied principally upon South America for the supply of cinchona bark, and, as the amount furnished was insufficient, the price was high; but during recent years the efforts made by the English and Dutch Governments more than twenty years ago to grow the cinchona tree in other places have begun to bring forth good results, so that the bark, instead of coming almost exclusively from South America, is now supplied from the East Indies, Ceylon, Java, etc. The first shipments from Ceylon, which is now one of the largest growers of the cinchona tree, were made

n 1869, and did not exceed a few pounds, but now the exports of bark from this island annually amount to over 15,000,000 pounds.

With the cheapness of sulphate of quinine there followed an increase in the consumption, for the world's production is now greater than ever before. Not only is this increased output shown by foreign manufacturers, but American producers have largely increased their production of sulphate of quinine during the past few years. The American industry is carried on by a few large manufacturers in New York and Philadelphia. We are unable to show the increase in production in this country, as it is impossible to obtain statistics from the manufacturers of their output: but, as all the bark used in this country is imported, an examination of the Customs returns will give the imports of bark, which will fairly show the increase that has taken place in the production of sulphate of quinine. The imports of cinchona bark in the fiscal years ended June 30th, 1884, 1885 and 1886 were as follows: For 1886 the statistics for nine months of the year only were at hand, so that a careful estimate for the balance of the year has been made and added to the imports for the nine months.

	Pounds.	*Values.*
1884	2,580,052	$717,614
1885	3,513.391	914,508
1886	4,100,000	830,000

It will be seen that the increase in the imports since 1884 has been nearly 60 per cent. While the imports increased the average import value per pound decreased, being 28 cents in 1884, a little over 26 cents in 1885, and only 21 cents in 1886.

Although American manufacturers are producing large quantities of quinine, a considerable amount of the foreign drug is being imported, but the quantity is now much less than it has been. In the nine months ended March 31st last, the imports into this country of the salts of quinine amounted to 1,469,901 ounces, valued at $759,669 against 1,716,897 ounces, valued at $1,405,957, imported in the corresponding period of last year. The American sulphate of quinine, although somewhat higher in price than the foreign article, is preferred by most consumers because of its known purity. Foreign quinine is brought here in bulk and in some cases is adulterated, but if the consumer takes proper precautions in purchasing, the quinine he obtains is considered in every respect equal to the American product.—*Bradstreet.*

THE AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

Besides a mass of other interesting matter, the latest issued volume of the transactions contains a history of the institution, rise and progress of the Society, by Mr. A. H. Blechynden, the Secretary. From this valuable paper we learn that this Society which has done so much to promote the material progress of India, was founded in 1820 at the suggestion of that wonderful cobbler, William Carey, the Baptist missionary, "who combined with his attainments as an oriental scholar and author, a knowledge of botany, agriculture and horticulture." A marble bust of this great and useful man occupies a conspicuous place in the Society's meeting-room in the Metcalfe Hall. As Secretary and then President, Dr. Carey, saw great improvement as the result of the Society's efforts but we can imagine his surprise if he could see the India of today with its enormous production and export, not only of rice and cotton but of wheat, linseed, jute, tea, &c. There are two significant notes to the following effect:—

Scarcely 40 years have elapsed since the first shipments of jute on a large scale were made from Calcutta, and now, independently of local consumption, which is annually increasing, the exports exceed 360,000 tons. Fifty years ago, not an ounce of linseed was exported from India. During the current year (1885), about 448,000,000 pounds have been imported into Great Britain to the exclusion of Russian produce!

If only a cheap method of cleaning Rhea fibre could be established, the probability is that India would outstrip China in the production of this fine fibre. The exports of Sugar and Silk from India have declined, but in the case of sugar the satisfactory reason is that the local consumption has so largely increased as to leave little surplus. From first to last the Society has laboured to encourage the production of all valuable vegetable products, whether indigenous or introduced. To this end they established gardens, in which gardeners were trained and whence plants and seeds were distributed. They sought and disseminated information, and offered prizes for special papers and essays. How they helped forward the enterprise in tea, a plant which was not generally known or believed to be indigenous for fully ten years after the founding of the Society, is thus recorded:—

Tea Cultivation in India.—This important subject has naturally received much attention at the hands of the Society from the time when public enquiry was first called thereto to the present. The valuable reports of Drs. Griffith and McClelland on the tea plant of Upper Assam, and on its physical condition with reference to geological structure, soils and climate, will be found in the transactions of the Society. The result is a matter of history. The Government of India acted as pioneers, and then, when the culture was fairly established, transferred their experimental plantation to the now well known "Assam Company." Several other gardens were subsequently formed in Assam and also in Cachar, where the plant was likewise discovered in 1855 to be indigenous by Captain Verner, the Superintendent of that district, who communicated the fact to the Society in an interesting paper printed in Vol. 9 of the Journal. It was found, in a comparatively short space of time, that this most valuable plant could be successfully grown in several other parts of India, in Darjeeling, and certain other Himalayan localities, in the Punjab, Hazareebagh and Chittagong.* So numerous were the specimens submitted to the Society during several years on the earlier stage of this industry, that a Special Committee was appointed to examine them, and many reports will be found in the pages of the Transactions and subsequently of the Journal. Before leaving this section, it may not be out of place to put on record the fact that the Museum contains a specimen of the first production of Tea from the Assam Gardens, which was forwarded by the Indian Government for sale in the London market in 1839 or 1840. In less than half a century the produce of British India has increased from a few hundred pounds (90 chests), of which this first consignment consisted, to upwards of sixty-five millions! Is it unreasonable to suppose that before this century closes it will reach a figure of not less than one hundred millions, or two-thirds of what is now supplied to the English markets by China and Japan? Upwards of 300,000 acres of land are now under tea cultivation in India.

* Its culture has recently been most successfully attempted on the abandoned coffee gardens of Ceylon. The quality of the produce is second to none other in the East. About five million pounds have already been exported in 1885. The tea plant has also been recently introduced into Natal in South Africa.

It is a curious fact, however, that the true nature of the indigenous tea of Assam, was not for some years recognized, in consequence of Dr. Wallich, an eminent botanist, and at one time Secretary of the Society, insisting that it was a camellia! Tea is allied to the camellias, but the difference in foliage and flower is great. Our experience is that in reverse proportion as a tea-plant simulates the foliage of camellias, is its flush-yielding quality.

As our readers are aware the production of tea in India in 1886 is estimated at considerably over seventy millions of pounds, the contingent from Ceylon going far to round off the figure of 80,000,000 lb.

Amongst the other important articles to which attention was devoted were: sugar, cotton, silk, tobacco, coffee, fibre-yielding plants, maize, paddy and cereals. In 1843, attempts were made to get Indian wheat admitted into England at the same rate of duty as wheat from Canada. It seems to us now monstrous that grain should be the subject of discriminating or of any duties in Britain. The influence on India of the abolition of the corn laws has been great. Greater still has been the effect of the opening of the Suez Canal and the construction in India of railways, so that Indian wheat has taken a foremost place in the food markets of the world. Forage plants and tanning and dyeing substances received much attention, as also plants yielding oils, fats, &c. The Society helped to bring Gutta-percha into notice, and they did not lose sight of Vanilla or the great and successful experiment of introducing the Cinchonas into India. Wool and cattle received a good deal of attention. We quote another paragraph :—

Library and Museum.—A portion of the abovementioned space is appropriated for the library, which now comprises several thousand standard works and Transactions and Journals of Societies, treating principally on Agricultural, Horticultural and Botanical subjects. It also contains a small museum and models of implements. A room is set apart for the reception of seeds which are annually imported from foreign countries for distribution to members.

Again :—

The publications of the Society have been steadily continued. The "Transactions" (8 volumes) were superseded by the "Journal," of which 21 volumes have been issued, namely, 14 of the *old* and 7 of the *new series*. Some of the earlier volumes of the Transactions have been translated into Bengali, and a volume in the same language entitled *Krishi Patha* (Agricultural Gleanings) has been issued. A mass of useful information connected with the introduction into India of plants of commercial value has likewise been published in a separate form, irrespective of the Journal. In addition to these the "Proceedings" of each monthly meeting have been regularly printed for the last 50 years, as soon after the occurrence of each discussion as possible, for the purpose of furnishing distant members with an account of the doings of the Society, and also to put into the hands of congenial institutions the nature of the information brought forward for discussion. To enumerate even a little of the mass of valuable practical information and useful reading, embodied in the abovementioned publications, would far exceed the limits of the paper; suffice it to say, that they refer, among other subjects, to cotton, sugar, indigo, tea, coffee, tobacco, rice, silk, wool, vegetable fibres, cochineal, caoutchouc, lac-dye, Indian fruits, manures, timber trees, topographical account of various districts, many of which are treated very extensively and satisfactorily.

Much of the work of the Society has been accomplished or has been taken up by other agencies, as Mr. Cogswell showed in his presidential address in 1882 :—

"In former days the Society stood alone as the depository for all matters connected with agri-horticulture, and the Government of the day recognized it as a very useful medium of communication with the public. Now, however, times are greatly changed. The Government of India have inaugurated a department of their own, whilst the Government of Bengal have established an Economic Museum, to which are naturally referred specimens of produce which were formerly submitted to this Society. Again, certain industries have their own publications, such as the *Indian Tea Gazette*, the *Indian Forester*, and for general subjects the *Indian Agriculturist*, consequently the Society's Journal has become an annual instead of a quarterly publication. If, however, we refer to the monthly proceedings during the past few years, we shall find that they contain many subjects of great interest."

Amongst the articles in this volume is an elaborate paper on Rhea, which we mean to transfer to the *Tropical Agriculturist*. Amongst the selections is a translation from the French of a detailed paper on the Vegetable Products of Japan, containing much interesting matter, as the following extract will show :—

It may be stated, briefly, that the uses of the bamboo in Japan, comprise nearly all the requirements of the Japanese. The large kinds, such as the *Matake* and the *Maso*, are used for making the timber work of houses, of coach-houses, clothes-horses, silk-filatures, roofing, spouts, toll-bars, bridges, foot bridges, pallisades, ladders and all purposes for which thick and strong stems are required. When the Japanese wish to utilize the bamboo, they commence by rendering it more supple and less hard by soaking it in boiling water, or by exposing it to the action of steam. These same kinds are also used for water pipes. The Japanese remove the divisions which are in the stems, when these are opened, they rub them over with oil both inside and outside, and then blacken them with fire; they thereby become more resistent, impermeable, unassailable throughout, and can remain a long time under ground without rotting. The same process is employed in China. The *Matake* and the *Moso* are also utilized for kitchen utensils, such as buckets for drawing water, and measures of capacity. They are also employed for rafts, and for mats for boats. The reefs of sails are made with the *metake* bamboo and the sails themselves are frequently made of mats twisted in plaits of the same. Cordage, ropes, the straps which are used to fasten bales of merchandize, are of bamboo, nearly all kinds are utilized for this purpose. These bands are not perhaps so durable, as those made of hemp; but they are prepared at a much more moderate price, Baskets for fruits and fish, for cleaning and holding rice, for silkworms eggs, and sieves, are made of plaited bamboo. The bamboos *Metake* and *Chino-take*, the *Bambusa aurea*, *Quilioi violascens* and *nigra* are employed for the handles of musical instruments, also for lances and arrows, canes and rods for fishing, and for games. With the stems of thinner bamboos: *Metake*, *Hatchiku*, and *Chino-take*, *B. aurea*, *Quilioi nigra*, they make beds, chairs, footstools, couches, furniture of all kinds, and the stairs which the Japanese often cover with the lacquer varnish. Musical instruments, especially most kinds of flutes, are made with thinner kinds. The *B. nigra* and the *Sudzu-take* are used for the outer-casing of pipes. The trade of such in bamboo is considerable and necessitates the employment of a great number of boats which are specially used for that purpose. And so with opium pipes which are often made with the *Metake*. They are the object of a special trade. Among the most important of industries with the bamboo, that of hats may be alluded to, which are principally made in the department of Kanagawa (province of Musai). Screens and fans are also made of bamboo, trimmed with paper with well executed designs. According to Mons. Verdier-Latour, the trade with fans to Europe and America is very important. The town of Osaka has furnished, by itself, annually four millions of fans of the value of 480,000 francs. Their price varies from 4 francs 50 cents to 20 francs.

the hundred. This will give one an idea, with the number of fans used in the interior of Japan, of the real importance of the industry with fans and screens. The handles and frames of umbrellas are made of bamboo, the latter covered with paper oiled with the *Urushe*. There is a large trade in these, as also of lanterns, mats and window-blinds made with plaited bamboo. Another well executed industry is that of cups and saucers in porcelain, covered outside with finely woven bamboo; these porcelains are principally met with in the Province of Suruga. Ornamental furniture is also covered with fine woven bamboo. It is in that province (Suraga) we find the best executed works in bamboo.

Many other uses are mentioned. We can only repeat our conviction that India, and we may add Ceylon, owe much to the Society whose career and operations we have glanced at.

CEYLON TEA IN ENGLAND.

It is impossible to read without some feeling of alarm, the remarks made by our London Correspondent in his last letter relative to the quality of the island tea now being vended in London. It has been repeatedly pointed out how essential it is that our planters should endeavour to secure quality and not quantity alone in the outturn of their estates. We believe that that caution has been taken well to heart, and whatever may be said of the complaints from Mincing Lane, the faults referred to in our London Letter are referrable, not to any shortcomings on this side, but to the conditions which prevail on the other side of the water. But it is of comparatively slight importance with whom the blame rests that so-called "Ceylon" teas of such markedly inferior quality are supplied to the English consumers. The fact remains, and it is one which, if not grappled with, must largely and seriously affect the prosperity of our growing industry.

We were well prepared to hear that ordinary retailers in London and other English cities and towns resorted to discreditable means for lowering the standard of Ceylon teas sold by them in accordance with their practice with so many other articles of consumption; but we were, until recently, quite unprepared to hear of charges of a similar character brought against firms of known reputation who have made the supply of such teas their speciality, and have boasted of the good they were doing to our planters and our young but promising staple planting industry. It is dangerous, indeed, to find our enemies among those of "our own household." If we cannot rely upon such men to deal honourably, how little can we feel reliance or expect higher dealing, among the class of retailers to whom we have just referred? We shall have to consider in such a case how we may best be assured against a course, the result of which can only be to arrest and destroy that appreciation of our island teas which has so grown within the last few years in England. We thought the question "Where can we be sure of obtaining pure Ceylon tea?" had been fully and satisfactorily answered, and it is most regrettable to find that our English friends constantly discover that their reliance has been misplaced. It will be of no avail to go on largely increasing the area of the cultivation of tea in this island if its reputation is ultimately to sink in the consuming countries to the level of that of those inferior growths so largely of late years imported from China. We have all seen the results of such exports from the last-named country. We have seen the China tea exports fall off in quantity year by year until there seem to be strong signs that the great tea trade of the celestial Empire is permanently on the wane. There is no room to doubt but that this has been due to the competition of the superior qualities hitherto furnished from the tea producing districts of India In that competition Ceylon is now sharing, and so successfully that even India herself is feeling the pinch of it. Are we to go back from that position? Manifestly we must do so, if complaints such as are now made to us from consumers at home are allowed to continue. It is vital to the best interests of this colony to prevent there being any good reason for these complaints; and means should at once be considered and adopted for checking the dishonesty or carelessness of those by whom our teas are distributed in England. How this may best be done is therefore the question to which we desire to call the urgent attention of those interested. Its solution is of public importance, and we greatly doubt if it can be arrived at with out public action.

It is suggested to us from home that there should be established in London a confederation of our leading tea growers and exporters which shall, by advertisements, make itself widely known throughout the United Kingdom and other consuming countries, and which shall adopt such a system of guarantee for all teas imported under its auspices that their quality may at all times be relied upon. The gentleman who makes this suggestion, adds: —"I fear you may be unwilling, indeed be most averse, to any course which may seem to tend to set public action against individual enterprize. But the matter is too grave in its ultimate bearing upon the revival of prosperity in your island to permit of our setting such considerations too prominently forward. If you feel you cannot rely upon such individual enterprize, your planters must plan some method to save themselves, and so some course akin to the suggestion I make, must necessarily be adopted."

Our friend was, of course, not aware when he wrote, of the proposal on this side for a "Ceylon Tea Syndicate," nor of how fully the very subject he dwells on, had been discussed and action matured with reference both to the United Kingdom and other tea-consuming countries. We are still of opinion that America (the United States and Canada) present the most promising field for an extension of the consumption of our own and Indian teas; but certainly a most important part of the work of the Syndicate, must now be the establishment of an agency or agencies in the Mother Country where consumers of Ceylon teas can be quite certain of always obtaining the genuine article.

That the result must prove inimical to the success of those who have hitherto been endeavouring to establish a special business in England in Ceylon teas must of course follow. But how can the Ceylon planters help this when so many persons have continued to act so as to justify charges such as those to which our London Correspondent has given publicity? It would never do for the producers to sit quietly looking on, while all their best efforts are negatived by the want of proper care—to use the mildest phrase—of those in whom they have hitherto trusted. The demand for Ceylon tea at the India and Colonial Exhibition is a proof of how it is appreciated by the English public when and where its purity can be guaranteed. Are we to see the prospect of such appreciation receiving fuller development, sacrificed to the interests of a few individuals, or to that dishonesty of the relating class, which has, unhappily, become proverbial? The answer to this question will no doubt be afforded after a very practicable fashion by the Ceylon Tea Syndicate.

THE MADRAS CHAMBER OF COMMERCE AND THE MADRAS GOVERNMENT ON THE GOVERNMENT CINCHONA PLANTATIONS.

The Government of Madras has sent us the following important correspondence :—

Read—the following letter from P. Macfadyen, Esq., Chairman, Chamber of Commerce, Madras, to the Chief Secretary to Government, dated 4th February 1886 :—

I have the honour to inform you that the attention of the Chamber of Commerce has recently been directed to the extension of the number of trees in the Government Cinchona Plantations near Ootacamund. According to the Administration Report it appears that that number advanced from 1,122,766 to 1,620,744, or by about 45 per cent in the year ended 31st March 1885, and the Chamber has reason to suppose that in the current year the work of planting fresh trees over and above the replacement of those that die or are felled has not been intermitted. I am therefore desired to submit, on the Chamber's behalf, that such extension seems opposed to the spirit in which the plantations were set on foot as well as to spirit of the Government of India's policy of encouraging private enterprise.

2. The Chamber has no reason to suppose that the plantations were established as a commercial enterprise in view to the creation, for the exclusive benefit of the treasury, of a lucrative industry hitherto unknown in India. The scourge of fever had, from time to time, brought very forcibly to the notice of the Government the suffering and loss that were due to the want in this country of a febrifuge that could be brought within reach of all classes. The experiment of obtaining the cinchona plant in its native habitat, of transferring it to, and of acclimatising it in, India was one that entailed heavy expenditure which it was vain to expect private individuals to incur on philanthropic grounds. It came, however, legitimately within the province of the State to expend public money in giving a fair trial, under competent scientific directions, to the experimental cultivation of a plant that offered a defence against the most fertile of all the causes that contribute to the mortuary returns. The Government, therefore, took a broad view of its duty in this matter, and it succeeded beyond its most sanguine expectations in its benevolent scheme. It was possible for the State to patiently wait for a return on the large investment that it made in the cultivation of the exotic. That return eventually came, and not only was the surplus of revenue over expenditure from 1860-61 to 1884-85 R5,51,743, but the Government now possessed in the plantations an estate that would realise a large sum of money were it offered for sale tomorrow. Thus the enterprise has not only been successful as proving incontestably the suitability of the climate of the Nilgiris—as well as of other hill ranges in India—for the growth of cinchona, but it has yielded the State a handsome pecuniary profit. But it is no more consistent or desirable for the Government to make money by cultivating cinchona than by cultivating coffee, rice, indigo or cotton. The Government has established the fact that the cinchona tree flourishes in India, and there has been no reluctance on the part of private individuals to avail themselves of the offer of seed at low prices which was made by the Government. No longer, therefore, is the Government the only grower of the tree, but private plantations are assisting to cheapen the drug, or to achieve the object that the Government had originally in view. But private enterprise cannot compete on equal terms with the Government, which has the command of the public purse, and is free to sell at a loss when it cares to do so. The *raison d'être* of the Government Plantations exists no longer, yet the plantations are being extended with an assiduity worthy of a very opulent Joint Stock Company ambitious of paying handsome dividends to shareholders. In 1877-78 the number of plants was 569,031, and the net profit for the year was R2,88,980. Now, as has been shown above, the plants are three times as numerous. The Chamber fails to comprehend the aim of such extension, and I am therefore to submit that in the Chamber's judgment it is time for the Government to reassure planters by announcing that the State, so far from increasing the severity of the competition that it offers to private enterprise, will gradually retire from the field, permit the usual operations of the laws of supply and demand, and confine its own attention to the introduction and acclimatisation of new varieties of cinchona for the guidance and encouragement of those who engage in the production of the plant.

Order of Government—dated 15th June 1886 :—

In the letter read above the Chairman of the Chamber of Commerce states that the attention of the Chamber has recently been directed to the extension of the number of trees in the Government Cinchona Plantations which advanced from 1,122,766 to 1,620,744 in the year ending 31st March 1885. The Chairman then proceeds to notice that the object with which these plantations were set on foot was to provide a febrifuge which could be brought within the reach of all classes, but he urges that private growers of cinchona are now assisting to achieve this object, and that the *raison d'être* of the Government plantations, therefore, no longer exists. The Chairman states that he is accordingly directed to submit that as private enterprise cannot compete on equal terms with the Government which has the command of the public purse and is free to sell at a loss when it cares to do so, it is time for the Government to reassure planters by announcing that the State will gradually retire from the field and permit the usual operations of the law of supply and demand.

2. As regards the extension of the number of trees, it will be sufficient to observe that the increase which is caused almost entirely by renewals is apparent only; for, with the exception of one or two pieces of land of inconsiderable area which were added to the plantations for the purpose of rounding off the estates where danger from fire was to be feared, no new land has been planted in recent years. The reason of the ostensible increase is that when plants are first put down they are placed at comparatively short distances apart for the purpose of affording mutual shelter, but as soon as they have become firmly established, they are thinned to a very considerable extent. For example, on the Government plantations the plants are first planted out usually at intervals of 3 feet, but are afterwards thinned out until the space between each tree is 9 feet, *i. e.*, out of every nine trees planted only one is left to attain maturity.

3. Turning now to the question of the suggested retirement of the Government from the cinchona enterprise, His Excellency the Governor in Council cannot admit the *raison d'être* of these plantations no longer exists. It is true that the price of sulphate of quinine has, of late years, fallen considerably, but it is still so high as to be prohibitive to a very large majority of the natives of this presidency. The desired febrifuge must be sought, therefore, in some cheaper preparation of cinchona bark than sulphate of quinine, and although the extract recently prepared by Mr. Hooper has met with some measure of success, this problem must be regarded as one that has not yet been fully solved.

4. Nor can it be admitted that the plantations have yet completely served the second of the purposes for which they were established, viz., the conduct of experiments and investigations in connection with the culture of cinchona. Many most valuable results have already been obtained, but in a report made to this Government in 1883, Dr. Trimen, one of the greatest living authorities on the subject, pointed out that there are many questions of the greatest importance to cultivators of cinchona still pressing for solution. As examples of these, he mentioned the causes of the difference in proportion and quantities of the alkaloids in barks from trees of identical botanical type, the testing of the results which Mr. Broughton obtained from experimental manuring, the cause of the increase of alkaloids in renewed bark, and, lastly, the influence of age on the alkaloids. These investigations, Dr. Trimen considers, can only be carried on in a Government establishmnet, as the work must

be performed by a resident analyst and must, of necessity, be spread over many years.

5. Lastly, His Excellency the Governor in Council cannot admit the correctness of the argument, implied rather than expressed, that the connection of the Government with cinchona planting has interfered with the usual operation of the law of supply and demand. It might be sufficient to reply to this that the outturn of the Government plantations is so trifling when compared with the total quantity of cinchona bark placed on the market, that prices would not be perceptibly influenced even if the Government bark was sold at a loss. As a matter of fact, however, it was always been sold by public auction, and the prices realised have been those ruling in the market at the time of sale.

INDIAN AND CEYLON TEA.

Intrinsic merit sooner or later brings anything to the front, whether it is merchandise or brains. Indian tea up to date has achieved all its success through its intrinsic merit; it has been very little helped by advertising or puffing. Had Indian tea not been intrinsically good, it would have disappeared from public view. Annually there is a marked increase in the quantity consumed by the public, principally in Great Britain and Ireland. Had Indian tea been pushed in the same way as Ceylon has been, instead of an annual consumption of 60 millions pounds, we should have had no stocks left at all now, and Indian tea would have been in a better statistical position than it now is. As it is with exchange so uncertain Banks are unwilling to do business except at ruinous rates, so that some means should be taken to avert calamity. It is significant that in the vicinity of great centres of population in Britain, for instance all round London, almost no pure Indian tea is to be met with, whilst Ceylon and occasionally Darjeeling teas (pure), can readily be bought. Wherever one goes Ceylon teas stare one in the face done up in neat little packets of ¼ lb. and 1 lb. At first the natural conclusion that one comes to is that the Ceylon planter has sprung a mine upon his Indian brother, is sending home the tea done up thus; but upon enquiry it turns out that the manipulation is effected in London, by the agents prior to delivery to the country dealer, showing how extremely careful the Ceylon agency houses are to place their wares before the public in a taking way. Nice little lead packages neatly done up with a taking label are infinitely more likely to attract attention than a great huge unwieldy chest roughly made. China teas are also got up in neat little packages, quite ornamental, and the tea dealer is proud to put them in his window, but when one does come across, or rather ask to see the original case of any Indian tea, he finds it consigned to the back ground altogether, simply on account of its appearance. Of course put up in an attractive form tea thus must cost a little more, but looking at the enhanced values that Ceylons obtain, we doubt if it does not do far more than pay. With many gardens it is not a question of paying but of existence, and we consider that it is worth the while of some estates to do up their teas in this fashion so as to make them more attractive. Doing the teas up even in, say, five-pound packages with the "Linberry" patent cloth on paper would be a step in the right direction. We understand that the cost is very much less than tea lead and the weight for carriage is also much less. In addition the facilities for putting on a nice label are very much greater, and the paper would show off a label to advantage. The "heathen Chinee" takes care to cover his box with all sorts of hieroglyphics, which although perfectly unintelligible to the outside public, form an attraction, and no doubt even now assist to carry off the wares. The British public in this age of rapid progresson are not easily satisfied, and competion is so great that Indian planters and agents must put Indian tea before the public in a more presentable form. A few years ago it was supposed that the merit of the liquor of Indian tea had to a great extent done away with the necessity for paying so much attention to the appearance of the leaf. It is questionable if this is so now. A large quantity of Indians is now bought from appearance, owing no doubt to the extraordinarily large amount of sampling, which falls to be done from the very large increase in imports. The generality of Indians are too leafy and large, and the dealers complain that the teas are too large in leaf to sell by themselves and that it necessitates a blend with China in order to make them a good marketable commodity. Another thing that strikes one with regard to Indian tea is the general complaint that it is not to be bought. What is called Indian is only a blend. In the case of Ceylon tea each little ½ lb. package is labelled and guaranteed.—*Nilgiri Express.*

Tea Rollers.—Three new patent Tea Rollers are likely erelong to be dividing attention with those now in use: they are Gilruth's (to be manufactured in Calcutta); Michie's, and Hutsen's. The last is described as being very compact, handy and likely to be successful machine.

The Crocidolite.—If our readers have before heard of this semi-precious stone they have the advantage of us. It is thus noticed in the Exhibition Supplement to the *Colonies and India*:—The crocidolite, of which there is a great abundance found in Griqualand West, is a stone containing a large amount of asbestos in different stages of formation or disintegration. It takes a beautiful polish, and many fancy articles are now made from it. The crocidolite working and polishing is another industry lately added to the several specialities peculiar to the Cape. We have been told by a dealer in precious stones that about five years ago they purchased crocidolite in England by the carat, giving 25s per carat for it.

"Crocidolite."—In the "Manual of Mineralogy" by Professor Dana (Trübner, London), I find page 246, chap. xiv "Iron ores—Crocidolite has a fibrous structure much resembling asbestos and has been called *blue asbestos*; color lavender-blue or leekgreen. Hardness=4. Gravity=3·2 to 3·3. From South Africa.—*Cor.*

The Indian Coffee Planters' Committee (says *Colonies and India*) have issued a little pamphlet which, besides affording some interesting particulars of the samples of Indian coffee now exhibiting at South Kensington, also gives some useful hints about the properties of coffee and the best way of preparing the "fragrant berry" for the table. Good coffee is not always to be had, and when it is forthcoming it is too often spoiled in the "making." A study of the samples of Indian coffee displayed at the Exhibition, combined with practice of the rules set forth in the leaflet referred to, should enable everybody to avoid the adulterated article, and to drink the real product in perfection. The samples, 230 in number, which have been arranged by the Indian Coffee Planters' Committee, under the sanction of the Royal Commissioners, represent (1) the "cherry" (that is, the coffee fruit as plucked from the tree); (2) the "parchment" bean (that is, the berry when pulped but enveloped in an outer skin or husk, resembling parchment); and (3) the berries stripped of this covering, and sized and sorted as they come into the English market, before roasting. The coffee thus exhibited is from the crop of 1885-86, produced by British planters in the following districts:—Mysore, Coorg, the Wynaad, the Neilgherries, and Travancore. The finest coffee which comes into the English market, fetching higher prices in many cases than even Mocha itself, is grown in these districts, and upon coffee estates there the investment of British capital is annually increasing.

Correspondence.

To the Editor of the "Ceylon Observer."

TEA MAKING AND THE FUTURE FUEL SUPPLY IN DIMBULA, &c.

Dimbula Planters' Association, 7th July 1886.

Dear Sir,—I am requested to forward to you for publication the enclosed interesting letter.—I am, yours faithfully, GEO. BECK, *Hony. Secy.*

Lippakelle, Dimbula, Ceylon, 29th June 1886.

George Beck, Esq., Hony. Secretary, Dimbula Planters' Association.

Dear Sir,—Seeing that many of the estates in the Dimbula district (and this applies equally to some other planting districts) are without reserves of timber and erelong will be forced to import fuel of some kind, not only for tea-making purposes, but some day even for their coolies, it becomes a serious question, and one which it behoves planters to take in hand at once, how the cheapest fuel is to be had. I need hardly point out at this moment, how necessary it is becoming to keep down at the lowest point, everything that goes to make up the cost of the production of tea, and it appears to me that this matter of the fuel supply of the near future is so vital, that it calls for the immediate consideration of the Planters' Association of the island.

The choice at present seems to be between coals, patent fuel and petroleum, and it is more especially to the last that I now wish to direct attention, not only as now becoming procurable in any quantity, but as being less bulky, and, as I understand, in every respect, a cheaper and, for our purposes, likely to be the most serviceable description of fuel. Placed as Ceylon is between the Black Sea and Suez on the one hand and Burma on the other, we ought to be most favourably situated as regards cost of carriage from all three. From the first the supply would appear to be practically unlimited; the Red Sea promises great things; and Burma, I know, from some experience of that country, can now export a large quantity at low cost. It is to the last named, which lies nearest our doors, that I would particularly call attention. The oil wells are situated in Upper Burma, now part of the British Empire and within a mile or so of the river Irrawaddy and the produce is brought down by boat (in bulk principally) to Rangoon, the voyage from which to Colombo is a very short one. Hitherto this petroleum has been a royal monopoly, but as the British Government cannot recognize monopolies, the result will be, this industry will shortly be thrown open to British traders, and the production of the wells, which have so far been worked in the most primitive native fashion, will increase tenfold. I may add here the oil is very fine

I regret that I am unable to furnish any statistics of supply or cost from any of the above sources. My object in writing is rather to urge the importance of getting all necessary information without delay, as to how far it is practicable to have our wants supplied, which, I would submit, falls within the province of a Planters' Association. I think it would be well to apply to the Chief Commissioner of Burma, Rangoon, who can, no doubt, give much valuable information as to the supply, and also to communicate with the Rangoon Chamber of Commerce whom it would be well to inform of the probability of a large demand springing up in Ceylon for petroleum. This will serve to call the attention of the mercantile community to a new opening for trade, of which it is natural they should avail themselves.

I would also suggest that the British Consul, say at Odessa, be written to for information regarding the supply and cost of the Russian article which is now largely consumed in Russian steamers and manufactories, the result of whose actual experience it would be valuable to know. What may be the real importance of the Suez find of petroleum (fortunately at *this* end of the Suez Canal) the representative of the British Government in Egypt ought to be able to testify to.

It occurs to me that perhaps the most practical commencement in this matter of fuel would be, for the different Planters' Associations to call for returns from all tea estates of their probable fuel requirements. There would then be something more or less definite in the extent of demand to hold out to induce supplies.

The only other suggestion I have to make is, that it would be well to consult makers of tea-driers like Messrs. Jackson and Davidson how far it would be practicable to burn petroleum without injuring the tea, and how far, and at what cost, their furnaces could be adopted to this purpose.—Yours faithfully

K. C. MACIVER.

COST OF TEA PREPARATION, &c.

Balmoral, 9th July 1886.

Dear Sir,—In your *Tropical Agriculturist* of this month I have carefully read the answers of the Sub-Committee of the Maskeliya Planters' Association on tea manufacture, and in the 34th answer I find it stated that the "cost of manufacture per lb. made tea including superintendence 5 cents, plucking 12 cents, manufacture 3 cents, packing 3 cents, transport 1 cent." Will you kindly explain why manufacture is *twice* entered, first at 5 cents and secondly at 3 cents per lb.? Will you also inform me if in the charges abovementioned, the following items are included, viz., chest, lead, hoop-iron, nails and solder? An early reply will much oblige, yurs faithfully, R. B. L.

[We have referred to a good authority who states:—Perhaps if the word 'including' were omitted the sentence would be more intelligible. I believe it means:—Cost of manufacture per lb. made tea—superintendence 5 cents; plucking 12 cents; manufacture 3 cents; packing (including chests, lead, &c.) 3 cents; transport 1 cent: total 24 cents." Thus, if superintendence, or more plainly superintendents' salaries, be deducted, the actual cost of plucking the tea. leaf making it into tea, packing and sending it down to Colombo is cents nineteen per lb. of made tea: these rates are considered low.—Ed.]

TEA-MAKING AND BURMA PETROLEUM AS FUEL.

Colombo, 10th July 1886.

Dear Sir,—Referring to Mr. K. C. Maciver's letter, addressed to the Honorary Secretary of the Dimbula Planters' Association, which appears in your last night's issue, it may be of service to those who take an interest in the matter discussed by Mr. Maciver to know that our senior is proprietor of the Rangoon Oil Company, at whose works in Rangoon the crude oil from Upper Burma is manipulated and made into the different kinds of mercantile oils, such as Burning Oil, Lubricating Oil, Ordnance Oil, &c., &c. If those who wish information respecting supply, prices, &c., will be good enough to formulate their enquiries and send them to us, we will be happy to forward them on to the agents of the Company in Rangoon, who will be able to answer them satisfactorily. The Company's Oils are not unknown in the island.—Yours faithfully,

CARGILL & Co.

CEYLON TEAS FOR THE UNITED STATES.

Louisa, Talawakele, 13th July 1886.

Dear Sir,—I have to thank you for the kind notice you inserted in the *Observer* of the 12th. We have almost decided to leave by the "Clan MacArthur" on the 3rd September and I hope

to come to some agreement with the members of the Syndicate, or their representatives before that date. I am in correspondence with American connections, late of Ceylon, with regard to co-operation in driving the Ceylon tea trade in the States. I consider co-operation *necessary* to success when the immense field represented by the United States of America, is taken into account, and, should my correspondent fall in with my views, I think good business may be anticipated so long as the proprietors of Ceylon unite in the one common cause and endeavour to enlarge the market for their produce.

It is better for the owner of an engine-boiler to provide the boiler with a safety value *previous* to explosion. The unanimity of the Ceylon planters with regard to the Syndicate scheme seems to me to be a *proof* that they are *unanimous* in the opinion that their present field is too limited, and that to save themselves, they must bestir themselves; in short find a safety value in the markets of other countries. I note in Mr. Shelton Agar's letter dated 8th inst., that he considers "the mixing of two, three or four different 'brands' is admitted to be the best plan for getting at a *really good* beverage." From this I understand that Ceylon Teas *do mix*, that is, *one* with *another*. I have never ventured an opinion of my own as yet; but from what I hear from authorities on the subject I gather that a mixture of low-grown with high-grown teas turns out a *perfect* liquor, inasmuch as the low-grown teas give pungency, and the *high-grown* flavour.

Should the foregoing statement be correct, there can be little doubt as to the advisability of bulking Ceylon teas sent by the Syndicate to the *world*. That *difficulties* with regard to bulking the several teas sent by different estates through the Syndicate, will *have* to be met and *dealt* with, is a matter of certainty; and to be overcome, a corresponding ability on the part to the expert employed must be looked for in order to *meet* these difficulties. Given then that the idea of general bulking is good, where should the expert be located? Surely, where he has the easiest means of communication with those with whom he has to deal, that is in the *very* neighbourhood of the planters (certainly *not in* America or Australia or any other country where it is not at all improbable agents would take the matter into their own hands and bulk for themselves). One advantage of general bulking would be the interest of noting the difference in prices obtained in the several countries *for the same tea*.

Naturally the more extensive the field the greater the expenses incurred *at first*, but nothing could point out the path of profit to the proprietor better than the Syndicate bulked tea, exposed to public trial in the several countries suggested in draft proposal now being circulated.—I am, your very sincerely, J. McCOMBIE MURRAY.

THE PRESENT POSITION OF THE CINCHONA MARKET: A CEYLON CINCHONA PLANTERS' SYNDICATE WANTED.

14th July 1886.

Sir,—The present position of the cinchona market is worth the attention of all interested in its cultivation. The large quantity of bark which has been sent into Europe during the last three years has brought the price down to a level which has virtually destroyed the Columbian trade. Many of those connected with it have been ruined, and thousands of men employed in it left the country. It is generally admitted that a rise in the value of bark to 9d a unit would be required to admit of a revival of the enterprise.

Ceylon is now supplying nearly ¾ of the bark manufactured in the world. The increase in the consumption and manufacture of quinine has been so considerable that the latter has fully kept pace with the production, and the stocks of bark in Europe are by no means large: indeed, at the end of 1885 Mr. Moens gives them as 19,000 packages less than they were two years ago.

It is only the immense supplies which Ceylon continues to send into the market which keeps the value at its present low point. Any important decrease in the shipments from this, would immediately produce a rise in the price. It is thus no exaggeration to say that the market is at the present moment entirely under the command of Ceylon cinchona growers.

If all who possess cinchona will cease harvesting *branch* bark, and agree to send away in all cases just *half the weight* of good bark which they have dispatched during this season, they are likely to obtain as much money for the reduced quantity as they have this year for the larger amount. The operation is surely simple enough; the result can hardly be doubtful. If Colombo merchants will only combine with growers to restrict the supply for the next year or two, the value of our export would probably be increased by several hundred thousand pounds whilst the present wholesale and in many instances premature destruction of a produce which is of immense value to the world would be prevented.—I am, sir, your obedient servant, A PLANTER.

LIBERIAN COFFEE FROM JAVA.

Sir,—I received from Sourabaya this week a sample of Liberian coffee with a request that I would get it valued and tried. It had been grown on land in the middle of Java. The fermentation and treatment it had received had entirely cleared off all the skin and it left a beautifully bright berry. The valuation ranges from 55s to 68s and perhaps more as it was the finest sample that had ever been seen here. Some was roasted and tasted by experienced coffee buyers without knowing anything about it and they pronounced it very good and equal to fine old East India or Java coffee: it had, they say, the clean yellow look about it. There is a great difference over the price of ordinary Liberian coffee coming from Ceylon which I maintain requires more careful fermentation and cleaning.—Yours truly, THOS. CHRISTY.

London, June 24th.

CEYLON TEA AND COCOA AT THE EXHIBITION: A RELIABLE OPINION.

Kandy, 15th July 1886.

The Editors, the *Ceylon Observer*, Colombo.

Sirs,—Reference having been made to the quality of the Ceylon Tea sold in the cup at the Colonial and Indian Exhibition, it may not be out of place if I quote the following extract from the letter of a correspondent received yesterday. He has, I need hardly say, no interest whatever one way or other, and the remarks are quite spontaneously made in a private letter. He writes:—"It (the Colonial and Indian Exhibition) seems to me simply admirable at *every* point, and is being enormously successful. We had pure and most delicious Ceylon Tea in the verandah, and bought some at 2s 6d per lb.; also some chocolate (purity guaranteed by your Association). It was of fine flavour, but a little sticky and not quite equal in *manufacture* to French, I thought. I assure you, we scrutinised everything most closely and were thoroughly delighted. The photos illustrating your Tea industry were uncommonly good."—I am, sirs, yours faithfully,

A. PHILIP.

LABOUR SUPPLY FOR TEA CULTURE.

Rattota, 18th July 1886.

Dear Sir,—I am afraid considerably exaggerated notions as to the extent of our future labour requirements have been prevailing lately, and have given rise to a good deal of unnecessary alarm. People have been speaking and writing about one cooly and a half per acre being required for tea, whereas as I hope presently to show you an average of half that will probably be more than tea can afford.

In the days when coffee gave crops and working short time was not the rule, it used to be calculated that every cooly working on an estate cost R100 per annum, and I presume the same figures would still hold good. Let us try an estimate on this basis and see how it will work out. For the purpose of argument we will suppose the island to be yielding an average of 400 lb. per acre, that it is put f.o.b. at 35 cents per lb.,—both pretty liberal figures you must admit. So you have on one side

400 lb. tea at 35 cents..		R140·00
and on the other		
Superintendence on 400 lb. at 5 cts. per lb...	..R20·00	
Packing and transport at 4 cts. per lb.	16·00	
Colombo charges ,, 1 ,, ,,	4·00	40·00
Leaving you the cost of *one* cooly for a year..		R100·00

out of which you have to pay for manure, tools, repairs to machinery and buidings, medical charges, money charges, and all the other etceteras, which go to make up a monthly report. A smaller yield or a lessened cost of production would obviously reduce the amount available for labour proportionately.

From the above it seems pretty clear that a much smaller labour force than is commonly supposed will meet our wants unless we have grievously overestimated the profits to be derived from tea cultivation.—Yours truly,

GEO. WAUGH BURNET.

[We can scarcely follow Mr. Burnett in all his conclusions. That tea culture, continued practically over the whole year, will require more labour than coffee did is certain, but of course the expenditure on labour as on every other detail must be reduced, in sympathy with reduced yield and low prices. But if economy in labour is carried below a certain point, it is clear, estates cannot be kept in proper order.—Ed.]

"CROCIDOLITE."

Customs, 19th July 1886.

Sir,—The enclosed is a specimen of "Crocidolite" but the head of the stick which I send by bearer is a much better specimen. If you care to cut up and examine the smaller piece you are welcome to keep it, but please return the stick when you have done with it. There is a curious popular error in the pronunciation of the word, most people call it "Crock-o-dile-ite" as if connected with the Saurian which frequents our waters. The proper pronunciation is "Cro-sid-o lite" with accent on the second syllable.—Yours faithfully,

C. E. DUNLOP.

[We are much obliged to Mr. Dunlop for a sight of his handsome stick surmounted by a round head of crocidolite with moving rays as striking as if it were a gigantic cats's-eye. The smaller piece we have kept to experiment with, as he has kindly suggested.—Ed.]

TEA LAND IN THE LOWCOUNTRY, &c.

Dear Sir,—In days gone by when a 'cute man selected and planted up a coffee estate in some unknown locality, if the venture turned out a success, there was then a rush for *all* the land near or adjoining the place without regard to the condition of the soil and its suitability for the product to be planted. It seems as if this practice obtains now for a great many places have been planted when much superior though isolated blocks could be got farther off. The so-called Kelani Valley district is certainly a good one for tea, chiefly as regards rainfall, but there are many blocks lying out and near it certainly superior in many other respects. This Kelani Valley district is made up of patches of other districts and extends from the foot of the Dolosbage and Kadugannawa hills, right down to Labugama. The planting commenced midway, but the tendency is to buy and open southward and westward to Labugama, and again near the hills of the Central Province where the soil is richer and the rainfall the same as on the hills. Much of the land in Kegalla as in Yatiyantota will soon be under tea. In the early days of coffee planting there were several estates in this district opened on fine heavy forest lands, selected owing to the soil being equal to those found in the Central Province; unfortunateiy the climate was too warm and only the shaded native coffee lasted till leaf-disease swept that little off. There is of course an immense tract of land lying south of the Kelani Valley district down to Morawaka suited for tea, but the planting of this will be a matter of time. No one is so mad as to select a block in such localities where fever will drive away superintendents and labourers and where it is not easily accessible owing to the want of roads. There are many blocks of abandoned estates in Kegalla and Yatiyantota owned by parties in Europe and chetties on the Coast, places "sold up" and purchased at Fiscal's sales for debts. These are of course now much sought after, as they are in healthy localities, with good roads to them opened years ago. It is preferablo to pay R20 to R25 an acre for such, than to wait *over* 12 months and pay about R13 for Crown land in almost unapproachable localities however tempting the soil &c. may seem. It is not easy to secure in the Kegalla and Yatiyantota districts Government land averaging 250 acres. The blocks surveyed are small and not adjoining, fields and native chenas intervening. The original purchasers of Government land so far back as 1846 obtained *tracts* of 400 to 2,500! acres, and these were subsequently cut up by the owners and sold to many who sank their money in coffee. All that these estates then shewed was *leaf* in such profusion, as to tempt others to buy and try to make the places pay. The old Kandy road promises once more to make itself useful, for much of the land in and about Kegalla and Ambepussa will be planted with tea and those who do not mind an extra day's or two days' delay will be able to place their tea in Colombo by the road much cheaper than by sending it to a branch station and thence by rail! The lowcountry estates seem to have an advantage over those in the Kandyan districts in the matter of labor, for the women and children leave their homes even if 4 miles away and pick very satisfactorily, beating the Tamils, and I am certain that with this new industry a good many rupees won't find their way to the Coast. One gentleman gave a small field to a Sinhalese woman to weed on contract and she gave satisfaction and she profited too, for she asked for a contract for three years to weed the whole estate! Of course the removal of Sinhalese laborers *from their homes* to places over *a day's journey* never did and never will succeed, but otherwise the employment of them as laborers for most kinds of work, is not a loss or disadvantage. When the Tamils leave their homes they are prepared to do so as temporary exiles. In the coffee districts in Southern India, they are as unreliable as the Sinhalese, so long as the estates are not a few miles from their homes. That the Sinhalese will not emigrate is a nonsensical idea. All won't, but a good portion of genuine rustics are quite prepared for temporary exile especially after hearing of the benefits the small party of them in Queensland are deriving, so much so that some mean to stay away altogether!

Cannot some measures be adopted to induce the petty land-owners to grow cacao in the Yatiyantota, Kegalla and Ambepussa districts? In small plots between 30,000 to 40,000 acres can thus be made to yield this more stable product. If they planted *tea* our labour supply in the lowcountry will be lessened, while the benefit to the Sinhalese will not be much with such a product.

B. T. J.

TEA CULTIVATION IN SOUTHERN INDIA AND CEYLON.

(*The Editor of the T. A.*)

Sir,—In a late number of the T. A. a correspondent writes about the Tea Estate Superintendent who orders his men to cut 300 holes a day and other nonsense of the same kind not worth repeating. To beginners like myself, it would by more to the purpose if he told us the number of holes a cooly might fairly be asked to cut as a day's work. I myself get 60 holes (1 × 1½ ft.) a day out of my men. I find a man can fill from 300 to 400 holes a day and one man can plant carefully 800 plants per day. As regards plants I prefer 18 months' old plants as I can then stump both the tops and the roots of them and plant out in ordinary damp weather. Plants of that age and so treated begin to grow almost at once.

As regards the alleged deterioration of Ceylon teas, can close planting have anything to do with it? I myself plant indigenous 5 × 4 and good hybrid 4½ × 4 but do not know that I am right. M.

Southern India, July 12th.

[Our correspondent will very soon have authentic information as to the practice in Ceylon in the "Tea Planter's Manual."—Ed.]

Tea in Assam.—We call special attention to the Report on Tea Cultivation in Assam printed elsewhere. In round numbers the increase in the six years 1880-85 has been in clutivated land:—

Mature plants	...	40,000 acres
Immature ,,	...	4,500 ,,
Total...		44,500 acres,

While the increase in total area is enormous, no less than 455,500 acres; the area held has, in truth, nearly doubled.

China Teas.—Of the new season's China tea the *Grocer* says:—"China has already been warned that, if she does not make teas better suited to the British palate than those forwarded of late years, she will lose her hold of the London market, and we think that the threatened loss of us as a nation of customers has not been made in vain, for the teas now arriving from that quarter are, if a correct opinion can be formed from the first shipments, superior to those sent here in 1885. Samples from the Glenogle were to be seen in Mincing Lane by 6 o'clock on Monday evening last, and were pronounced as being decidedly above the average of recent years. Further inspections have confirmed this impression, and most of the dealers are quite pleased with the new teas, as they possess rare good keeping qualities. There are some judges, however, who complain of the teas being thin and light in the cup; but this may not be the fault of the teas, but only because the 'fire' on them has not had time to go off before they were landed; and the best China authorities say that, give the new teas time to develop, and they will in the course of another week or so turn out to be thicker, better, and stronger than they are now."

Chestnut Water, also called Water Caltrops (*Trapa, natans*), an acquatic plant belonging to the family Onagrariaceæ. It is a native of Southern Europe and has creeping, floating stems, producing hair-like roots, from which rises a cluster of triangular, toothed floating leaves with swollen foot-stalks which buoy them up. The flowers are small. The lobes of the calyx two or four, increasing in size, and with its tube involving the ovary, which becomes a hard, horned fruit about the size of a chestnut. They contain much farinaceous matter, and form a considerable article of food. In Italy they are known by the name of Jesuit Chestnuts, and in France as Water Chestnuts. In Cashmere the seeds of *T. bispinosa* form an important article of food to a large population. *T. bicornis* is also extensively used for food in China under the name of Ling. The stiff, horn-like projections of these fruits convey to the mind the idea of Caltrops.

The New Green Bug has, we regret to hear, worked its way up from the Northern districts through Pussellawa and Pundaluoya to the coffee in the adjacent corner of Dimbula, and it is merely a question of time until it crosses the river to the poposite division of the district. Mr. Bosanquet of Yoxford considers the pest much worse than the old black bug, and he is not sure of its identification in Nietner. The leaves with the insect require to be examined. But it is a matter for congratulation that tea should have been so generally planted in Dimbula before this pest appeared. From a careful observant planter, since writing the above we have received the following:—"I send you herewith some specimens of what I call the new bug as well as a few of the brown and white. The new bug is easily distinguishable by its being on the upper sides of the leaves and on the berries, which was never seen with the old bug. I could not get any good specimens of the old brown bug as the rains have washed it away from most of the estates; a few weeks ago I had any quantity of it. The new one seems indifferent to weather. My idea is that the new bug is a descendant of the old one on the theory of evolution. I do not think it agrees with the one described by Nietner as it is green to the end of its existence. The old bug never killed out coffee as this one does, nor did it march steadily on from district to district as this one does, and it gave way to several remedies, whereas I have found nothing which will keep this one in check. I shall be interested to hear what your entomological referee says of it, though he has probably had it under observation before this. Its disappearance as far as my experience of it goes is only coincident with the death of the coffee over the greater proportion of the estate, a patch here and there may unaccountably recover from an attack. I believe there are some who think this nothing more than the old bug; but they can have had no experience of the districts north of Kandy. I send a spray of tea also on which bug is present which looks like a cross between the brown and the green. I hope the specimens will arrive fresh; should they not do so, I will find other means of keeping the branches alive."—We sent the specimens on to our entomological authority, who, after examination and consideration, wrote:—"I return Mr. ——'s letter. The scale bug that has attacked his coffee is undoubtedly the pale green bug that is destroying the coffee in some other districts. It is not described by Nietner, and cannot have come under his observation, but still it may have been in existence somewhere in his time. Mr. —— remarks that 'the old bug never killed out coffee.' It is possible, however, that a bad attack of the 'old bug' might prove fatal in the present weak condition of the tree. Nietner's Lecanium coffeæ (brown or scaly bug) may be found in small numbers, on the brinjal plant in Colombo. It is of a pale brown colour."

The Cultivation of Rice will soon become one of the leading occupations of the Northern settlers in Australia. Rice grows there so easily, says the *Queenslander*, and yields such heavy crops of good quality, that it wants no prophet to say that the farmers will soon turn to it as a substitute for maize.—*M. Mail*..

Furniture Polish.—

Yellow wax	1½	oz.
Common soap	6	„
Carbonate of potash	½	„
Water	10	„

Heat and stir all together until a milky mixture is formed, then transfer to a stone bottle and add

Turpentine .. .. .. 15 oz.

by small portions, shaking well all the time. Continue to shake occasionally until cold, then add 1 oz. of solution of ammonia.—*Chemist and Druggist.*

"Pink Ivory."—Amongst the specimens of woods in the Natal Court, one is thus described:—The specimens of native woods are very interesting, many of them taking a fine polish and showing a beautiful grain. One used by the natives in making ornamental assegais and sticks, and called by them *umumoi*, is exceedingly pretty, and the most unique as regards colour. It is as pink as the old-fashioned cabbage rose, is very close grained, and, when polished, looks like what the Natal colonists call it, "pink ivory." A piece of it can be seen in the lid of a box made of several native woods. This box contains sixty different native medicines, and is in itself a great curiosity. —*Exhibition Supplement to the Colonies and India.*

The Export of Copra from Fiji is thus given by the *Fiji Times*:—

The proper figures of actual local export as given by the Receiver-General are as follows:—

1875 ..	2,397	tons
76 ..	1,603	„
77 ..	4,404	„
78 ..	5,372	„
79 ..	2,772	„
80 ..	5,242	„
81 ..	4,779	„
82 ..	5,480	„
83 ..	4,892	„
84 ..	4,978	„
85 ..	4,888	„

The Receiver-General gives all the above figures, as those of the export of copra raised in Fiji, except the last. This can be checked by taking the nut export, reckoning 90 nuts in a bag, according to the new practice adopted since '83, and calculating 5,500 nuts as equivalent to one ton of copra. It will be found that the result adds on 175 tons, which is purely European produce, as natives do not export nuts.

Pearl Shells and Pearls in the Western Australia Court are thus described in the Exhibition Supplement to the *Colonies and India*:—We see the crown and glory of the West Australian section, the trophy of giant mother-o'-pearl shells, a S. Simeon Stylites of nacre, glistening and glinting in silvery sheen, no less than one thousand shells being used in its construction. Would you see them separately, here they are ranged against the wall, the contribution of Messrs. McRae & Harper, twenty-three shells weighing 2 cwt. These are the bodyguard of the treasure of the show, the "Southern Cross Pearl," a perfect cross formed of nine pearls together into one solid mass—no freak, rather a faierie fancy, of nature. This was found at Roebourne, W. A., in 1884, by Shiner Kelly, of the schooner "Ethel," and opened by a lad named Clarke, in the presence of his father. This *lusus naturæ*, which has been inspected by Her Majesty, the Prince and Princess, and all the Royalties who have visited the Colinderies, is valued at 10,000*l*.—a present to give a wife or a sweetheart—"a lass and a lac," the toast of Clive's chaplain. Half, and only half, of the story of the pearl fishing industry is told in the cabinet representing the depths of the sea, with pearlshells and curious formations of coral. The black fellows need no diving dress, but go under water, as do the sponge fishers in the Mediterranean when they dive from their speronares. The pearl industry owes much to the enterprise of Mr. E. W. Streeter whose son was the plucky diamonder of Kimberley Cape Mines—the eminent jeweller, who has an establishment at Cossack, and a fine display of pearls has been set on view.

A Veterinary Class in connection with the Medical College in Colombo is suggested by an Uva correspondent with reference to the prevalence of cattle murrain, and the suggestion is one deserving of the special attention of the Government. There is nothing, next to seasonable weather and water supply, of so much importance to the native agricultural class in Ceylon—and this virtually means the mass of the people, both Sinhalese and Tamil—as the preservation of the health of their cattle. And we cannot conceive of anything more practically important than the spread of a sound knowledge of the proper treatment of cattle among the headmen and intelligent leaders of the people. If the sons of village headmen, after the completion of their ordinary education, were induced to pass a year or two in attendance on a Veterinary Class under proper guidance, a great deal would soon be done for the inculcation of proper treatment of cattle throughout the villages and rural districts. The Government by some little mark of distinction to such as secure a certificate of attendance and attainment of a certain amount of knowledge, would very speedily secure ample attendance, and still more if it were understood that in the selection of minor headmen, such certificate-bearers, other things being equal, would have preference. But the first point is to get the special Veterinary Class established, and this Sir Arthur Gordon in conjunction with his Principal Medical Officer can easily manage if he sets about it in earnest. It might be possible, too, for the Director of Public Instruction to allow some of his rural teachers to attend the class, so as to enable them to help the poor people with advice during a season of murrain or other trouble with their cattle.

Large and Moderate breaks of tea are thus noticed by *The Produce Markets' Review*:—As the Tea trade increased, and with it the necessity for disposing of a large portion of the imports by public sale, it was found a few years back that the system of offering parcels in lots of six or nine packages made the auctions insufferably long. It was therefore suggested that the lots should be materially increased in size—say to the extent of 36 or 50 packages in each. Some of the leading importers and buyers were desirous of trying an even more sweeping change, and began to offer entire parcels in single lots. This no doubt, materially shortened the sales, but it was found in other respects very injurious, because it led to greatly diminished competition. The smaller buyers were often prevented from buying, first, by the size of the lots, and next, by the fact that, in order to purchase, they had to bid an advance of ¼d. per lb., which often rendered the Tea too dear. The leading China importers, therefore decided to try the plan of offering their Teas in lots of 36 half-chests, and the result was quite satisfactory. Competition was much increased, of course, in itself, tended to maintain prices while buyers could often afford to give an extra farthing for 36 half-chests when they could not do so for 200 half-chests. There has been some discussion on this subject, though arising out of another matter, at the China sales this week, at which the system of offering tea in lots of 36 half-chests was generally approved, and it is understood that the example of the leading importers is likely to be followed in this matter in the China sales.

Tea.—The intelligence from home by telegraph is rather more encouraging for our staple: doubtless the tea dealers in the North of Ireland, where much of our fine teas go, have more confidence in their business, now that "Home Rule" is shelved if not for ever laid in its extreme form. It is pointed out to us that many of the London broking houses are largely interested in Indian tea estates and teas, and therefore their judgment on the young and vigorous Ceylon rivalteas must be accepted *cum grano*.

Indian *vs.* Ceylon Teas.—Of last week's sales of Indian and Ceylon teas the *Produce Markets' Review* says:—"The demand for Indian tea has been less active, and owing to the poor quality of most of the supplies, lower prices, with few exceptions, have been established. The better descriptions of Indian teas are now in a much smaller compass, and remain comparatively firm. More especially has this been the case with good Broken Pekoes, for which there is brisk competion. The market has been largely supplied with Ceylon teas, and although they have met with a good enquiry, prices generally have been favourable to buyers. With a continuance of large supplies from Ceylon, the values of fine Indian teas, notwithstanding their comparative scarcity at the moment, are not likely to advance further, as the briskness, strength and growing similarity in flavour of some of the Ceylon sorts, make them generally excellent substitutes for Indian teas.

Sugar in British Guiana.—The weather since sailing of last mail has been too dry for planting operations, but yesterday and today rain has fallen in abundance all over the countries gladdening the hearts of our planter friends. The growing crop in this country are described as very fine and above an average. The same may be said of Essequebo, but Berbice has suffered severely from drought, and the rain have come too late to admit of making up lee way. Nothing much doing in way of sugar making beyond a few pieces to give plants and the juice is poor in sacharine. Strange to say with complaints rife of want of work on the part of transcient labourers, we hear great complaints from planters of their planting work being kept back for want of hands at fair rates of wages. Some put this down to the very liberal wages which are paid by those prosecuting the minor industries. Where six dollars per acre is readily paid for cutting down an acre of sage ready for fire stick and the fork and $16 per acre is paid for forking an acre of ground all over; (and this work can be done in a fortnight by an able-bodied man, which means $8 per week), the cane planters have indeed formidable opponents to compete with.—*Royal Gazette*.

Coffee:—Brazil Crops and Increased Consumption.—Say James Cook & Co. in their *Weekly Despatch*, July 2nd:—The total export for crop year (1st July to 30th June) is telegraphed as follows:—

For Europe	1,051,000 bags	Rio	3,614,000 Bags
,, United States	2,440,000	,, ,,	
,, Elsewhere	114,000	,, ,,	
,, Europe	1,175,000	,, Santos	1,658,000 Bags
,, United States	475,000	,, ,,	
,, Cape, &c.	8,000	,, ,,	

The Brazilian crops for the three seasons ending 1883-4 average 5,530,269 bags, and if estimates are correct, the average for the three seasons ending 1886-7 will be somewhat above 6,000,000 bags. This appears, perhaps, beyond current views, but friends adhere to there estimate of *Santos* of about 2,800,000 bags, and reckon the quantity left in the interior of 1885-6 at 200,000 bags. The *Rio* receipts are now mostly new coffee of small bean. *Santos* markets very active, *Rio* strong and advancing. It will be interesting to note at the close of 1886 what the deliveries have been, The returns of the duty payments for 1882 led us to calculate upon requirements of 360,000 tons for Europe. If we are right in considering the present delivery from January to May as actual consumption, we should be inclined now to reckon upon 435 to 440,000 tons as necessary this year for European wants, and America we should assess at 220,000 tons, though, so far, the figures point to no reduction. This would place the consumption of coffee for the twelve months, say at 660,000 tons, an increase since 1882 at the rate of 3¾ per cent per annum.

Tea Crops and Prospects.—Writing in June, Messrs. Hulbert & Co. made the following remarks: what is said about exhibition samples and labour of tasting so many samples, deserves attention:—Reports of the New Crop state that most gardens in Assam and Cachar are backward, but in Darjeeling the weather has been more favourable, and the quantity manufactured to date compares well with last year. Estimates for next season place the available supply of Indian for the United Kingdom at about 72 millions, against Imports of 67 millions for 1885-86, or an increase of 7½ per cent. If we assess the arrivals of Ceylon for the same 12 months at 15 millions, we have a total of 87 millions for the season, 1886-87, and allowing 3 millions for anticipated export to Continent, &c., we shall require an average monthly delivery of 7 millions to dispose of this supply, or an increase of 1½ millions per month, as compared with the past season. This we maintain can well be effected by a slight decline in the price of common Teas, by which means a large proportion of low China Congou will be reduced to a point at which it will not pay to import, and the market will be gradually relieved of the over supply. The results of last season were very bad to importers at the beginning and the end, although from October to December fair of profits were made; no doubt our market was inflated at that period, which led Calcutta buyers subsequently to pay high prices, but the quantity of early and late shipments was much overrated, and this we think is responsible for much of the wide margins between Calcutta and London prices. On the whole, Assam showed the best quality, but this as usual was not maintained when the quantity of leaf to be manufactured became much larger. Cachars have been, with few exceptions, poor throughout; also Darjeelings, which were lacking both in strength and flavour. Teas from Kangara were generally without point, although a few good parcels were sold in the early part of the season. Dehra Doons occasionally showed improvement, and we think will be in better demand if managers could make them a little more brisk with a fresh smell to the dry leaf. Owing to the firmness of the common grades during the past season we are likely to get a large quantity of low class Teas this year, and we would advise managers not to neglect quality, but to devote their attention to manufacture and endeavour to obtain the best result possible from an average amount of Leaf. We think it most necessary that increased facilities should be given to buyers on this market to get through the enormous amount of tasting by reducing the number of samples for public sale. Importers would not suffer by bulking the lower grades of different gardens when character is equal, as in Tea for price, the garden mark is not of much importance, and the Trade have no objection to dividing a line of such Teas into lots of 24 or 30 chests, to suit the smaller houses. With the increased supplies from India and Ceylon, unless something is done in this direction it is not unlikely that we all arrived at a deadlock before long. We have noticed the Indian and Ceylon Tea samples at the Colonial and Indian Exhibition, and while much struck with the beauty of their appearance, and the care bestowed on manufacture, we hardly consider that this is sufficient to bring the article prominently before the notice of the public. Such choice specimens as we have seen do not accurately represent the merchantable article, and must only confuse the mind of the beholder; we should have thought that if a few standard qualities selected from each district were prepared for tasting at fixed periods, and the public invited to pronounce their opinion, it would have assisted to a larger degree in extending a knowledge of the article.

HOW LEMON, ORANGE AND BERGAMOT ESSENCE IS MADE.

Wallace S. Jones, U. S. Consul at Messina, gives the following interesting account of the manufacture of essential oil (essence) from the peel of the lemon, sweet orange, sour orange and bergamot, and also of the extraction of the lemon and bergamot juice, in the island of Sicily:—

Essence of Lemon, Orange and Bergamot.—The operative with *three* strokes of a sharp knife peels the lemon lengthwise, then cuts it in two and throws it into a basket; the peel falls into an earthen platter below the chopping block. Before the essence is extracted the peels are soaked fifteen minutes in water, which causes them to swell and offer a greater resistance when pressed against the sponge. In his left hand the operative holds a sponge, through which, that he may grasp it more firmly, runs a piece of reed cane. The peel, piece by piece, is pressed against the sponge two or three times in succession, simple pressure being supplemented by rotary pressure. The rushing of the oil cells liberates the essence therein contained. The sponge when full of essence is squeezed in an earthen vessel that the operative holds in his lap. It is the outside of the peel that is pressed against the spoon, as the oil glands are in the epicarp. This can be ascertained by holding the pressed peel to the flame of a candle; if it neither crackles nor affects the flame the cells are empty. This process yields along with the essence a small quantity of the juice and feccia (dregs). The feccia is composed of the membraneous residue of the oil cells and the resinous substances transfused throughout the epicarp of the lemon and orange. It is of a mucilaginous consistency, and of a pale colour. It has not been analyzed chemically up to date, and is put to no use. The seperation of the essence, juice and feccia takes place of its own accord; if the earthen vessels are not disturbed the oil floats on the juice and the dregs fall to the bottom. These three products of different density derived from the peel have no affinity with one another. As the essence rises to the surface it is transferred to bottles and left a few days to settle; it is then drawn off with a glass siphon into copper cans, which are hermetically sealed. After the essence has been expresed the peels are pressed (to extract what little juice they may contain), and are then thrown on the manure pile and *well* rotted—or they would make too heating a fertilizer.

In a bergamot essence establishment at Reggio, on the mainland, I recently saw in operation a hand machine for extracting essential oil. A thermopneumatic essence extractor worked by steam power, has also been invented, but the primitive method of hand-work still generally prevails in Sicily.

The yield of essence is very variable. Immature lemons contain the most oil. From November to April in the Province of Messina, 1,000 lemons yield about fourteen ounces of essence and ten gallons of juice. This industry is carried on during five months of the year. An operative can express three baskets of lemon peel (weighing 190 pounds) a day. He is paid seventeen cents a basket. The essence is so valuable that the operators are closely watched, as they are most ingenious in secreting it.

During the year 1885 the essence exported from Messina were valued at $982,894, of which sum $137,375 were shipped direct to the United States.

Lemon essence is quoted here to-day at $2.47 per pound.

Bergamot essence $2.45 per pound.
Sweet orange essence $2.30 per pound.
Sour orange essence $1.90 per pound.

The copper cans weigh (on an average) four pounds, and contain twenty pounds of essence each.

Lemon peels, valued at $980, were exported to the United States in 1884.

Six men work up 8,000 lemons a day, two cutting off the peels while four extact the essence of juice, and obtain:

Eighty-four gallons of juice.
Seven pounds of essence.

Which, after deducting the cost of labour, fruit, and incidental expenses, leaves a net profit of $6. Speculators frequently adulterate the essence, but these frauds are easily detected.

Lemons grow on clay soil yield more essence than those grown on calcarious or rocky soil.

Extraction of Lemon Juice.—Closely connected with the extraction of essence from the lemon and bergamot is the extraction of lemon and bergamot juice. When the juice has been concentrated by boiling it is called *agrocotto*. Lemons unfit for exportation are used for this purpose.

The method in use is as follows:—On the marble bed of the press are superposed nine mats (made of bulrushes) three feet in diameter; in their centre is a hole six inches in diameter; their outer edge turns back a half-foot. These mats are filled with peeled lemons, and piled one on the other. A following block is placed on top of these mats. These presses have two wooden screws, firmly set in masonry, about six feet apart. There is a tap for each screw; the taps are worked down by hand-lever. The juice flows from the bed of the press into tubs. If the juice is to be exported raw, sound lemons only are pressed; if the juice is to be boiled, which is generally the case, 25 per cent. of spoilt lemons may be used. Lemon juice does not keep well unless boiled. Sound fruit when pressed yields a slightly perfumed yellowish juice. The lemons remain in the press twelve hours. Independently of the intrinsic quality of the lemons, the amount of juice and its degree of acidity varies from month to month. The yield is greatest in the spring, but of less acidity, owing to the winter rains.

There is a machine for cutting up the lemons, but the Sicilians are wedded to their old methods of hand labour.

In 1885 the concentrated lemon juice exported from Messina was valued $298,707, of which $49,203 worth was shipped to the United States.

Taxes in Italy are very onerous. Manufacturers fearing an increase of taxation, should the extent of their business become known, are so reticent that it is impossible to ascertain accurately their profits from the lemon juice industry. It may be safely said, however, that their profits are very handsome.

Concentrated lemon juice is quoted at $160 a pipe (105 gallons).

Concentrated bergamot juice is quoted at $130.50 a pipe (105 gallons).—*Florida Dispatch.*

Useful Grass for a Warm District.—A sample of a rare and valuable grass named Euchlæna (Reeana) luxurians, the teasinte of Central America, was exhibited (writes the *Leader*) at the show of the Belfast Horticultural Society. This splendid grass comparable in size with the pampas grass, is one of the best and most productive forage plants known, the leaves attaining a length of 3 feet. A large number of stems, says Baron von Mueller, springs from the same root, and attain a height of 11 feet or more. The young shoots, when boiled, constitute a fair culinary esculent. As to its prolificacy, it is said that Dr. Schweinfurth harvested at Cairo from three seeds a return of 12,000 in one year. The plant particularly in its young state, is remarkably saccharine. Vilmorin estimated that one plant is sufficient for two ead of catttle during twenty-four hours. It is already grown in Queensland, where Mons. Thoset, at Rockhampton obtained plants 12 feet in height and the same in width, in damp, alluvial soil, each with 32 main stalks bearing nearly 100 flower bunches. It is rather slower in growth than maize, but lasts longer for green fodder, and not so hardy as sorghum. As a forage plant it is without a rival in climes free from frost. It likes humid soil best, but is able to resist extreme dryness. It is therefore, certainly worthy of extensive trial wherever frosts are light, for though a tender plant it would not likely be killed by a light frost after being thoroughly established.—*New Zealand Paper.*

"THE TROPICAL AGRICULTURIST."

(From a Planting Correspondent.)

The new volume of the *Tropical Agriculturist* reached me a few days ago, and I have revelled in its contents for 3 or 4 hours after dinner every night since. What a wonderful compendium of information it is. I was not surprised with the work, as after the Directory it would take a great deal to excite such a feeling, but I made a discovery in connection with it which caused me a good deal of annoyance. It was this, that *all* the useful information which at great expense of time and trouble, I had clipped from the columns of the daily paper and pasted in a book kept for the purpose, reappears here ready to my hand at a moment's notice by reason of the index, saving me all the trouble of searching through a volume of indexless pages, and is besides augmented by a vast amount of valuable information which I had no other means of reaching. I found the book of immediate practical service to me too, on a question of horse-power which I had to settle at once, and upon which I would probably have had to take and pay for an engineer's opinion. I doubt whether he would have accepted the price of the *T. A.* as his fee. You may naturally ask why I have not been a regular subscriber all these years. I was under the delusion that I couldn't afford it. New books, magazines, papers &c. cost me on an average fully R200 a year. When the *T. A.* was first published, I said "No, I cannot afford it. I've reached my limit of expenditure on literature." But I must in justice to myself explain that I was under an entirely erroneous impression regarding its price. I cannot tell you how, but some way or other I had got the notion into my head that it cost R20 a year, and the impression was only removed by the appearance of your recent circular. You know how hard it is to remove such impressions. Having once made up your mind that a thing is unattainable you cease to think of it, so it was in my case, and it was only when I sat down to address my proprietors on the subject of its being subscribed for by the estate that I discovered my error. That letter was never sent. I want the *T. A.* all to myself from this date. Why it 's little more than the cost of a dozen of beer, and there are few men in Ceylon who regulate their house expenses so carefully that a single bottle of beer more or less per month would be reckoned of importance.

COCONUT CULTIVATION IN CEYLON: THE APPLICATON OF LIME.

(By an old Coconut Planter.)

The *Tropical Agriculturist* has not succeeded in lighting up some of the dark places in the land of its birth, witness the enquiries of "Agriculturist" in *Ceylon Observer* of 8th July. As, however, I have never been appealed to in vain for any information that my reading or experience can supply, the following are my views regarding the use of lime in coconut cultivation :—

The amount of lime directly required by the coconut plant, is so small that two bushels per acre would be an ample supply for ten years, supposing the soil originally deficient in that element.

Lime is not used in agriculture as a direct manure, but for its chemical and mechanical action on the soil. Quicklime warms a cold soil, opens and loosens a stiff soil, and quickens into active fertility an inert soil. The application of lime is always beneficial on heavy compact loams, and in combination with draining on flats where the rain-water is neither readily absorbed nor flows freely off, such soils contain much organic matter in an inert state, which the contact of quicklime, reduces to the state of available plant food. On what are called hungry soils, that is, poor loose sands and gravels, the application of lime can do nothing but injury, except in minute quantities. On such soils as lime will do good to, not less than 20 bushels to the acre should be given (50 bushels is better), and in this climate it should be dug or ploughed in to save it from being washed off in heavy rains. It should be spread as equally as practicable over the whole surface.

THE ASSAM TEA REPORT.

The Secretary to the Chief Commissioner of Assam has just issued the usual Report on Tea Culture. During the course of the year 21 new gardens were opened and 10 closed. The tendency is still apparent, and probably will be for a considerable period, of amalgamating smaller gardens with larger. The total number of gardens in existence at the end of 1885 was 911.

The following figures exhibit very clearly the steady growth of the industry :—

Years.	Under mature plants. Acres.	Under immature plants. Acres.	Total area of land held by tea-planters. Acres.
1880 ..	120,512	33,145	566,277
1881 ..	133,293	25,134	706,648
1882 ..	156,707	22,144	783,362
1883 ..	161,707	27,716	923,664
1884 ..	158,158	31,694	913,476
1885 ..	159,876	37,634	921,891

From this table it appears that there has been a decided increase since last year, both in the area under cultivation and in the total area held by tea-planters ; and it is satisfactory to note that the tea industry continues to expand in Assam. The Deputy Commissioner of Nowgong says :—

"To make tea cheaply the area, wherever practicable, must be increased. The same establishment and the same buildings do for, say, 150 acres as for 100, while the cost per pound is materially reduced."

The Deputy Commissioner of Sibsaugor writes :—

"The theory of extension is that more work can be got out of existing establishments, * * * and experience seems to show that much larger areas can be worked under the same supervision than was formerly thought possible."

The Deputy Commissioner of Cachar also takes the same view, and quotes the opinions of some of the leading planters in his district to support it.

The total area returned as under cultivation is 197,510 acres, as against 189,852 shown at the close of 1884. The details according to the various districts are given below :—

District.	Total area under mature and immature plants. 1884.	1885.
Cachar	52,333	53,205.
Sylhet	30,822	86,288
Khasi and Jaintia Hills	30	30
Goalpara	495	495
Kamroop	6,343	6,321
Durrung	16,679	18,125
Nowgong	10,854	11,606
Sibsaugor	43,884	43,622
Lukhimpore	28,405	27,818
Total	189,852	197,510

The figures given by district officers for the years under report give a total yield of 53,617,620 lb., or an increase of 2,490,82 lb., when compared with 1884.

The estimate of the Tea Association was 51,226,605 lb. that is, something less by 2,392,015 lb. than the figures of the district officers. This difference is explained by the fact that many native and private European con-

cerns have no Calcutta agents, and they, of course, give no returns to the Tea Association.

The following table shows the yield per acre for the Brahmapootra Valley, the Surma Valley, and the whole Province respectively, according to the returns:—

	Yield per acre.	
	1884.	1885.
	lb.	lb.
Brahmapootra Valley.....	354	359
Surma „	279	305
For the whole Province	323	335

Here, again, the figures of the Indian Tea Association are less than those of the district officers for the reason noted above. Lukhimpore stands first in order of productiveness. The Deputy Commissioner writes:—

"I take the three largest concerns in the district. I can vouch for the absolute correctness of the returns from these gardens; they are Hilika and Hookunguri, representing an area of 1,560 acres of mature plant in one unbroken expanse, Talap with 1,020 acres, and the gardens of the Doom Dooma Company with 1,555 acres. The yield is as follows:—Hilika and Hookunguri, 1,399,040 lb. Talap, 782,200 lb. Doom Dooma, 1,089,287 lb. The average yield per acre is 790 lb."

The Commissioner of the Assam Valley district remarks that the printed reports made by Directors to shareholders corroborate these figures. The Deputy Commissioner gives the yield of three more gardens in Lukhimpore as follows:—

	lb.	Average per acre.
Khobong	282,720	589
Panitollah...	436,320	595
Sookerating	224,800	702

The average outturn of the whole district is 479 lb. This outturn is, indeed, remarkable, if compared with that of some other districts. In Kamroop, for instance, the gardens managed by Europeans exhibit an average yield of 189 lb., and the native gardens still less.

The estimates as to cost of production are not altogether trustworthy and vary considerably.

The following are some of the district figures:—

	Cost of cultivation per acre. Rs. As. P.	Cost of manufacture per lb. As. P.
Cachar	67 0 0	5 0
Sylhet	49 7 3	8 5
Durrung	25 0 0	3 0
Nowgong	70 0 0	6 0
Sibsaugor	95 0 0	5 9

The Deputy Commissioner of Kemroop says the cost of cultivation varies from R22 to R140, and of manufacture from 5 to 9 annas. The Deputy Commissioner of Lukhimpore says the returns vary so much that it is impossible to say what the costs are. There can be no doubt that the chief reason why the figures under these heads are always so unsatisfactory is because of the number of different interpretations put on the words "cultivation' and "manufacture." Another reason is that no returns are sent in or separate accounts kept by managers showing the different expenditure incurred in each phase of the production. In future, planters and agents will be asked to give the average cost of tea laid down in the sale room in Calcutta or London. This is in accordance with the opinion of the London Tea Association, who consider that it is the only possible way of arriving at a fair estimate of the cost.

The prices obtained by gardens throughout the Brahmapootra Valley were generally better than in 1884, and seem to have compensated for a bad outturn. Those obtained by gardens in Cachar, on the contrary, continue to range low. The Deputy Commissioner of Sibsaugor writes as follows:—

"Prices were better than last year to the extent of about an anna-and-a-half per lb. Especially good prices were obtained at the beginning of the season. This was attributed by the London brokers to the good quality of the tea. Later in the season the untoward weather* produced its effect on the quality as well as the quantity of the outturn, and prices waned accordingly. The prevalent fears of over-production were not, apparently, justified by the event. In spite of the large supply thrown on the London market by Ceylon, the stock on the merchants' hands in December was less than at the end of 1884. Altogether firmer prices did much to compensate for one of the worst season's production known for many years past."

The Deputy Commissioners of Durrung, Nowgong, and Lukhimpore all write in the same strain, bearing witness that prices ranged higher than in 1884. Mr. Aitchison, of Dalu, Cachar, writes:—

"Though the yield of Cachar gardens was generally good and heavier than previous years, great complaints have been made, both by the Calcutta and London tea brokers of the quality of the teas, until towards the end of the season, when some slight improvement showed itself. Prices have, therefore, ruled lower than in 1884, especially in London market. The difference in the prices between 1884 and 1885 in the Calcutta market is hardly apparent from the figures given, but the actual fall for the average of Cachar teas, I should think, would represent about half-an-anna per lb. The Calcutta market began strong for all teas, and high prices were realised even for Cachar teas for the first two or three sales, it then fell to almost the lowest ebb it has ever been at for Cachar teas. About the end of September it suddenly took a spring, owing partly to some improvement in the quality and lower exchange, as well as to a slight hardening of the London market."—*Indian Planters' Gazette.*

CEYLON UPCOUNTRY PLANTING REPORT.

LOW PRICES OF TEA AND MODEST TEA FACTORIES—"GREEK MEETING GREEK"—FUEL SUPPLIES AND TIMBER RESOURCES—CENTRAL FACTORIES—CACAO—ADVANCES AND KANGANIES.

20th July 1886.

The rapid and serious fall in the Price of Tea which we all deplore, and which, although anticipated by some wiseacres, has found us more or less unprepared for, is having one good effect in putting a stop to the absurd competition that was springing up in regard to Tea Factories.

The Ceylon planter is all the better of a curb; for his nature is such that he puts into his work all the heart and soul he has, and cannot rest until he has gained for himself a place in the first rank. When he takes up a new industry he generally manages to knock his rivals into "a cocked-hat" with the, alas! sorrowful sequel of too often coming out of the struggle pretty much in the same condition himself. When this sort of thing happens with the outside world, it is not hard to conjecture the nature of the friendly competition which is engaged in when Ceylon planter strives with Ceylon planter. Then it is "Greek meeting Greek," and the heights and lengths to which they will go in the "tug of war," are measured very often by the fullness of the purse or the extent of the credit. One man builds a finely lighted and spacious factory, stocks it with the best machinery procurable, oversteps his estimate in a princely way, and to the planting world for a little while, the building marks as it were the highwater limit as to factories.

Bye-and-bye, however, you hear of a bigger and better than this, and the factory which a little while before was regarded as a model, and to which streams of visitors kept flowing, is looked upon as a matter-of-course, and the tide rolls elsewhere. Now, however, that the fancy prices have disappeared, and the necessity arises of girding for the struggle which seems inevitable, this race for

*N.B.—The effect of weather on the quality of tea, —Ed.

fine factories will have to be given up. From humbler buildings it will be quite possible to send out as fine teas as ever.

Already I hear of amended plans, and overhauling of estimates in regard to factories; and small gardens are less anxious to see their names figuring in the broker's circulars, giving up, when practicable, the fondly hoped-for tea-house, contented to sell their leaf, and sink the estate's individuality in some well-known mark.

That there is wisdom in this course, is undoubted; and although we all believe that there is in each of us, potentialities as to tea-making which, if awarded a suitable sphere, would astonish our Indian brethren and drive "the heathen Chinee" to despair still the necessity may be laid upon us to postpone the manifestation of these high qualities, and direct our energies into a humbler channel.

As to our future FUEL SUPPLIES on estates without TIMBER RESERVES, there does not seem to be any kind of definite idea where they are to come from. The old coffee stumps are meanwhile standing us in good stead, but this, the last service of an old friend, is within hailable distance of the end, and then what? "We will be sure to get something," is the comforting assurance of those who have not yet had to grapple with the difficulty; but what that something is, is like the unexpressed emotions of the man who "never told his lord." Oil, coal, coke and other things have been suggested and if the margin of profit in tea manufacture was to remain even as it is today, there might be found in some such substances a suitable substitute for wood.

But besides these, there is the idea of a CENTRAL FACTORY to which neighbouring places might send their leaf, provided that it could be so arranged that every contributing estate had a share in it, so that what might be earned there might not pass into alien hands, but flow back again to the planter in the form of dividends. The providing fuel for such a district tea-house could be managed so as to reduce its price to the lowest, while the cost of manufacturing might be less than could possibly be done in the smaller but private tea factory, and in all probability better too.

The fine showery weather which we are having at present, and which is so good for the young tea-plants, has also been clothing the CACAO with new verdure, and covering stem and branch with clustering blossoms. As a promise for next half-year, it is indeed a glad sight, while it shows us how much depends on seasons in the cultivation of this tea. The welcome shade is everywhere springing up, and when it has grown high enough it is to be hoped that the bad effects of dry seasons will be considerably mitigated if indeed not altogether disappear.

In these days of increasing ADVANCES and COOLY crimping, the wily KANGANI manages "to score," having been kept so close up for some years back; now that the sun of his prosperity is beginning to shine, he shows an alacrity to enjoy its cheering beams to the full, that speaks volumes for the unchangeableness of his nature. What is a kangani without an advance? In his own eyes and that of his gang a mere nobody, and, alas! he knows it. A planter the other day paying off a lot of coolies was asked for the usual letter, which absolves a neighbour from unneighbourliness if he chooses to employ the gang, and opens the labour market wherever it is produced. But it was not the common "tundu" that was going to please. The kangani wanted his advances to be stated with R100 added! This little addition which his "durai" was coolly requested to certify, was an ingenious dodge for raising the wind. He said he had other debts besides the estate advance, and hit upon this charming plan of liquidating them. When the planter refused to state aught else than the truth, the man went off to his head kangani, got from him a Tamil "tundu," with the advances increased by R100, sought for work, and obtained it, on the terms as stated in the Tamil letter. Somebody was let in, for the money was all paid, and the kangani for the time being was satisfied. Moral: Beware of head kanganies' "tundus." PEPPERCORN.

CINCHONA CULTIVATION IN SOUTHERN INDIA: GREAT RESULTS.

Addressing a Special meeting of the Wentworth Gold Mining and Indian Estates Company Limited, Mr. Ryan said: * * * I pass on to the question, which will naturally occur to each shareholder, "What have I got for my money in Wentworth?" I will not answer it from facts of my own; but so lately as the 7th of May last a valuation was put upon the Government plantations which run on all-fours with ours, and which I am bound to say cannot compare with ours. If I take those figures as my basis our estates are worth at this moment £188,000. I go further. The other day a leading Coast firm was asked to value the property of one of our neighbours, and, if I take their figures, our estates are worth £194,000. This is external evidence. (Cheers.) Now let us see what the trees have done. The returns from your bark have maintained this vast area, and have more than paid for every expenditure. They have brought the younger fields to maturity. Not a call has been made for that. The last two calls were entirely for extensions. The estate has been self-supporting. You had a right to expect up to this date 145,000 lb. of bark of the value of £10,000, and you have actually received 141,000 lb., of the value of £8,200. You were led to expect £10,000, and at the values upon which that estimate was framed (3s for renewed bark and 1s 6d for natural bark), I should have been able to give you £4,000 more than you had any reason to expect, but at that time quinine was 12s, and now it is 2s 4d. I know some are disquieted about what they suppose to be the enlarged area brought under cultivation, and the great drop in the price of quinine, but I do not share their fears. (Hear, hear.) I have been at considerable pains to gather the statistics of the world. I find that there are, or will be in the very near future, something like only 31,000 acres under cultivation—that is, where cinchona is cultivated and that the requirements of the world will be something like 35,000,000 lb. of bark, whilst the production will fall short of that considerably. I think that that ought to point to us the advisibility of being ready to supply any deficiency. And then I think we lose sight of the larger consumption of quinine. In the Madras Presidency Official statistics, compiled by Dr. Bidie, the head of the Sanitary Department, show that there are over 200,000 preventible deaths a year in the Madras Presidency if quinine could be brought cheaply to the doors of the population. Multiply that 200,000 by 100 to represent those who recover, and you will find what a blessing quinine will be to this enormous mass of people, and what a favourable opportunity it offers to us as growers of the bark. Only lately I was reading a most interesting article upon a new use for quinine. They have extracted a most beautiful blue dye, and they only want a mordant to give it commercial value. There is no end to the use to which quinine may be put, I am sure the day is far distant when I shall not be able to send home bark that will pay a profit.—*Nilgiri Express.*

USEFUL DOMESTIC HINTS.

"Y."—Grease spots may generally be removed from the most delicate materials by the employment of benzine or oil of turpentine, care being taken that sufficient be employed to remove all line of demarcation. Oxgall is particularly useful in extracting grease stains from woollen goods. If the stain be very thickly crusted nd old, it may be sometimes advantageous to soften

the grease previous to the application of benzine by means of a warm iron laid on a piece of thick blotting paper which has been placed over the spot. To remove grease or oil from white linen or cotton goods use soap or weak lye. From coloured goods warm soapsuds. From woollens soapsuds or ammonia. From silks benzine, ether, ammonia, magnesia, chalk, yolk of egg, with water. From a carpet, upon the grease stain lay a little damp Fullers earth, and after standing for some time, rub it gently into the carpet, and then wash off by using a little carbonate of ammonia, and the colour will be restored. For all kinds of fabrics chloroform is best, but must be carefully used. Stains of paint or varnish, after being softened with olive oil, may generally be removed by the same means as ordinary grease. Saturate the spots with a solution of equal parts of turpentine and spirits of ammonia ; wash out with strong soapsuds.

"Marian."—To Clean Kid Boots.—In the first place the boots should be thoroughly cleansed from dust and dirt, and this is best done with a sponge and milk, than rubbing with a clean cloth. As long as the boots are tolerably new, this is all that is required. Afterwards mix a little oil and ink, and keep this well rubbed in when necessary. They should be done long before they are wanted to be worn, and they should be carefully kept from the dust. It is far better to do them yourself ; they will last twice as long.

HOUSEHOLD HINTS.

Oil of lavender will drive away flies.

Grained wood should be washed with cold tea.

Copperas mixed with the whitewash put upon the cellar walls will keep vermin away.

Ceilings that have been smoked by a kerosene lamp should be washed off with soda water.

Drain pipes and all places that are sour or impure may be cleansed with lime water or carbolic acid.

Strong brine may be used to advantage in washing bedsteads. Hot alum water is also good for this purpose.

The warmth of floors is greatly increased by having carpet lining or layers of paper under the carpet.

Cayenne pepper blown into the cracks where ants congregate will drive them away. The same remedy is also good for mice.

If gilt frames, when new, are covered with a coat of white varnish, all specks can then be washed off with water without harm.

If a little salad oil is mixed with mustard for the table, it is greatly improved.

Moth-infested articles should be saturated in naphtha or benzine. It injures nothing and kills the destroyer.

It soothes a feverish patient to bathe him with warm water, in which a little saleratus has been dissolved.—*Australasian*.

DR. TRIMEN'S LECTURE ON THE VEGETATION OF CEYLON.

LONDON, 2nd July 1886.

After all, I was present at the delivery, last Saturday, of Dr. Trimen's lecture on the vegetation of Ceylon in the conference hall at the Colindian Exhibition. The attendance was not large, and unfortunately, owing to the defective acoustic properties of the room and the voice of the lecturer being pitched too low, a great part of the interesting paper was lost to the audience. However, Dr. Trimen has kindly sent me the paper to look over, so I am able to summarize its contents. Before proceeding to do so, however, I may mention that the chair was occupied by our former Governor Sir Wm. Gregory, who was supported on the platform by Mr. Geo. Vane, C. M. G. (whom I was glad to see looking as young and active as ever) and Mr. J. T. White. Among those present were Mr. George Wall (whose eyesight has happily not totally been lost to him), Mr. and Mrs. D. Morris, and Mr. J. H. Barber. Your lady correspondent "Penelope" was also there, and will no doubt refer to the lecture in her letter by next mail. The chairman in introducing the lecturer dwelt for some little time on the natural beauties of Ceylon, apologizing for the length of his remarks by stating that his heart was full of Ceylon, and "out of the abundance of the heart the mouth speaketh." Dr. Trimen's paper opened with an apology for introducing into the series of lectures one of a scientific character but went on to show that after all no apology was required, "for Ceylon owes everything to its plants and its agriculture and the climate which fosters them. Its ancient renown, and its prosperity under European rule, have alike depended upon its vegetable productions so freely and abundantly given, and if a disregard of nature's unvarying rules have brought about in several cases the inevitable penalty one cannot but recognize with gratitude and admiration the wonderfully recuperative powers of the land, which indeed seem able to prevail over almost every natural drawback and artificial obstacle." The lecturer then went on to call attention to certain characteristics of the physiography of Ceylon which are generally overlooked, there being in fact two distinct regions in our island the wet and the dry. A large map hung on the wall, showing the rainfall in the different parts of the island, was freely used by the lecturer in illustrating his remarks. Dr. Trimen then went on to show that there were great differences in the vegetable productions of these strongly marked climatic districts, and the more prominent of these were referred to; and the remarkable fact was mentioned, that by far the greater part of the trees and shrubs which produce the splendour which strikes the eye of the visitor are not natives of Ceylon at all but foreigners. It is chiefly in the low moist district of the island, that these are so frequent, the original forests having been destroyed by chenaing and part of the land being now under cultivation with paddy, jak and breadfruit trees, &c., while the rest was almost worthless, being covered with lantana and the small bamboo. The Sinharaja forest between Galle and Ratnapura is the most extensive remnant of the original forest, and the characteristics of this were described, the most valuable of the timber trees being the calamander and the nedun. On the summits of isolated rocks also, such as the Hayeock and the Millowe hills, which the chena cultivation has not been able to reach, a number of remarkable species mostly peculiar to Ceylon, are found crowded together. Dr. Trimen then referred to the remarkable fact that about 800 species (30 per cent) of the whole number of plants found in Ceylon are peculiar to the island, and that they are related far more closely to the floras of the Malay Islands and Peninsula than to those of Southern India. The lecturer then referred to the belt on the hills about Adam's Peak up to 3,000 feet which has since the British occupation been brought under coffee, cinchona and tea cultivation and where foreign weeds have taken the place of native ones. The true hill region (above 5,000 feet) was then examined, that height been chosen because it was the limit fixed by Government, above which no forest land was sold. The trees of this region were described, and it was stated that the flora here resembled more that of Southern India than that of the Malayan peninsula. The patanas were then described, and it was said that the cause of the marked separation between these and the forest was due to an equilibrium having been arrived at by the vegetation, so that one was unable to encroach on

the other. The dry regions of the island were then touched upon, and the lecturer expressed the opinion that there must be a certain amount of truth in the native traditions, that these parts, where the stupendous ruins are now found, were once "the granary of India." On this subject Dr. Trimen remarked:—

Modern experience shows us that, given only water continuously, the soil is capable of great things; it is I think in many parts more productive than in the parts of the island more favored by rainfall. If then the great tanks, sluices and anicuts, whose magnitude and skilful construction still fill us with wonder, were ever in good working order an immense amount of land may have been under cultivation and very fertile. But beyond the ruins of these vast works we cannot now trace any evidence of a large population; unbroken forest covers everything. The question is of great interest, for if the country were really occupied by a large and industrious people engaged in paddy cultivation, we have to believe that the comparatively short space of 1,000 or 1,200 years has been sufficient to completely restore an aboriginal forest vegetation over a large tract of country. But the explanation may perhaps be found in the consideration that probably no great extent was cleared and cultivated at any one time or for any long period. It is well known from the native records of the island that the population was constantly being driven from one district to another by the frequent invasions from India, and thus their fields would be abandoned after comparatively short periods of culture. At that time too, it must be remembered, as helping to account for a more rapid return of natural forest vegetation, that there had been no importation of the exotic tropical weeds which now so rapidly occupy open ground and give no chance to the natives to resume their position.

The vegetation of the region was described as very monotonous, and the chief species of trees were enumerated. The plants of this dry region were shown to be essentially those of the Carnatic and Coromandel coast, and so far as the flora is concerned one would judge the separation of Ceylon from India to be recent. The lecturer concluded as follows:—

I might continue this sketch of Ceylon botany further to give some account of the flora of of the river—banks and the great ruined tanks of the seashore, the coconut groves, and the mangrove swamps, but I have already been led into too much technical detail. Besides, there is little of special significance in these aspects of vegetation concerning Ceylon. The floras of tropical seashores are remarkably similar everywhere; doubtless many seeds are imported directly by the waves and currents, and possibly this may have been the case in Ceylon with the coconut itself, the original home of which noble palm still remains one of the unsolved problems of geographical botany. I will therefore not enter into this or other of the special points of interest which suggest themselves. I have endeavoured in this address rather to awake your interest by briefly calling attention to some of the larger questions which arise when one attempts to understand the present distribution of plants, in even one small island; and if I have succeeded in doing so, I shall feel that this rather technical lecture is justified.

On the conclusion of the lecture the chairman called upon Dr. Cleghorn to speak, which that gentleman did briefly being followed by Mr. D. Morris, who at some length dwelt upon the more remarkable features of the vegetation of Ceylon, and stated that the two sights which made most impression on himself were the talipot trees in blossom along the Kandy railway line and the gigantic rhododendrons in blossom on the Nuwara Eliya patanas. He passed a eulogium on the work which Dr. Thwaites and Messrs. Geo. Wall and Wm. Ferguson had done in connection with the botany of Ceylon, and spoke in the highest terms of praise of the energy which the Ceylon planters had displayed in introducing new products when old ones failed. Dr. Carruthers, President of the Linnean Society, then spoke, and expressed the hope that in the dry regions of Ceylon, irrigation might effect such a change as had taken place at Salt Lake City, which from being a barren region had become a most productive one. Mr. J. H. Barber then spoke briefly as representing the planters of Ceylon, and a vote of thanks to the lecturer proposed by the Chairman and another to Sir William for presiding, proposed by Mr. Geo. Wall and seconded by Mr. Barber, brought the meeting to a close.

THE EXTENT OF CINCHONA CULTURE IN JAVA.

The Dimbula Planters' Association took a sensible course in asking the Colonial Government to obtain from the British Consul in Batavia, reliable statistics of the cultivation of cinchonas in Java, but perhaps the reason why no acknowledgement of the letter addressed by Mr. Beck to the Colonial Secretary has been received, is due to the fact that the letter was not sent, as it ought to have been, through the Central (Kandy) Association. Due courtesy to that Association was not shown in the course pursued, and how the interests of the general body of planters was consulted by Mr. Beck first and the Association afterwards, in keeping to themselves information so important, *if true*, as that communicated by Mr. Mundt, perhaps they will explain.

We have no hesitation in saying, that, if what Mr. Mundt stated to Mr. Beck has been correctly repeated by the latter, to the effect that there are 175,000 acres of five years old cinchonas in Java the whole or the greater part *Ledgerianas*, then the Dutch Colonist most grossly exaggerated,—from want of careful collection and weighing of facts, we presume, for, be it observed, he said he never saw the vast area of cinchonas the existence of which he so confidently asserted! The senior editor of this paper was in Java in the closing period of 1881, that is less than five years ago, with the advantage of the guidance through the cinchona region of the Preanger Regency of Mr. J. B. Moens, the Director of the Government plantations, who most readily supplied all available information regarding the character and extent of the cultivation. The distinct impression left on our mind was that in Western Java, where the cultivation was originated and to which it was mainly confined, the number of estates, apart from the Government plantations, could then be counted on a man's fingers, some being merely in the course of formation. The Government Gardens themselves, though carefully cultivated, were really of limited extent, while the valuable *Ledgers* like many other rare and valuable plants, were chary in yielding seed: some seasons scarcely any was gathered; and even when good seasons occurred, the seed harvested was sold at high upset prices. Subsequently to the period of which we have spoken, Mr. Moens visited the eastern part of Java and stated that he had found *Cinchona officinalis* flourishing on some estates there, after a different fashion to the spindly plants of that species which he showed us in the mountains around Bandong. But although the plants were represented as good, there was no indication that the extent under them was other than limited. Mr. Moens since then has, from his residence,

while on leave, in Holland, issued several papers on the cinchona enterprise, its position and prospects. We may rely on it that he kept himself well informed of the progress of private culture of the fever trees in Java, and he has never represented the extent of this private culture as a specially important factor in estimates of the total production of the world. It was not until 1882 and 1883, in reality, that Ledger seed was available and disposed of in any quantity by the Batavian Government. Then, no doubt, considerable areas of nursery ground were prepared and sown, but we have no hesitation in saying that the requisite labour for planting 175,000 acres, or half, or quarter that area, was not and is not now forthcoming. If there are at this moment 20,000 acres of cinchonas in all stages of growth, in Java, that we confidently believe is the very maximum. A reference by our Government to the British Consul in Batavia, will no doubt result in approximate figures being produced; but, if Mr. Macneil, the present Consul indicates that Mr. Mundt's figures are other than the wildest exaggerations, we shall be much astonished. For neither in Mr. Macneil's latest report nor in those by his predecessor Mr. Cameron, any more than in Mr. Moens' well-considered papers, have we ever seen the slightest hint given that the private culture of cinchonas had progressed in Java at the utterly incredible rate stated by Mr. Mundt.

The silence of both authorities is only negative evidence, to be sure, but under the circumstances such evidence is very significant. Those who have not visited Java, and carefully investigated its systems of tenures, culture and compulsory service, can have little idea of the "labour difficulty" in that magnificent island of twenty millions of a population. There are plenty of people, but very few willing to work, or at liberty to work away from the rice fields and other lands which they hold on condition of rendering service to Government, or to estate-owners, who are also the feudal lords of villages connected with their estates. The reason why sugar cultivation made such enormous progress in Java, was, that a parentally despotic and benevolent Government supplied European or other planters, whom they favoured with land, the labour attached to the land and actually, through the co-operation of the Java Trading Company, with capital! The system has been materially altered of late years, the proportion of labour exacted by Government itself having been lessened, and no such interference (now being gradually withdrawn,) as took place in favour of sugar planters, has been repeated or will be repeated in favour of private cultivators of coffee, tea or cinchona. Some years ago Mr. Pretorious, a member of the Java Civil Service and Private Secretary to the then Governor-General, was deputed to Ceylon specially to inquire into our system of road construction and upkeep by means of the Thoroughfares Ordinance. He fully discussed the question with us and when we stated, as we correctly did at that period, that practically all the inhabitants of this island liable under the Ordinance, paid a money commutation for the six days per annum of labour required from them, the real work on the roads being performed by a class of immigrant labourers, who worked for wages, the Dutch Civilian's countenance fell, and he said "such a system would be impossible in Java, where service is already exacted from the people and where there is no immigrant class to fall back upon." There is, as a matter of fact, no class of absolutely free labourers in Java, except it be the Chinese, and beyond the precincts of the great towns we never saw "John Chinaman" at work, unless as an artizan or labourer on railway construction, or as a contractor to supply manure to estates. The Javanese agriculturists are not strictly slaves, but they hold their lands not "in free and common soccage" as the highly favoured Sinhalese and Tamil yeomen do here; but on condition of yielding certain service to the lord of the soil, whether Government or proprietors to whom Government has sold or leased its rights. No doubt of many the cultivators of the rich rice-lands of Java have time at their disposal, over and above that exacted by the tenures on which they hold their lands and the exigencies of their own cultivation and harvesting, but the Malays have as little liking for steady work as the Sinhalese have, and it was quite an exception for Mr. Moens to issue a Report in which complaint was not made of the paucity of labour on the Government cinchona plantations. If, then, Government experienced this difficulty when dealing with forest lands outside the boundaries of settled population, we leave our readers to judge how much greater the difficulties of the private planter must be under similar circumstances. It was equally a rarity for Mr. Moens to issue a Report in which the ravages of *Helopeltis* were not recorded; and if canker is not quite so great an evil in Java as it has proved to be in Ceylon, we suspect there is ample compensation of disadvantages in the damage done to the bark as well as the leaves by the insidious sucking insect. For all the reasons stated, we entirely distrust, as wild and unreliable, the statement made by Mr. Mundt to Mr. Beck of 175,000 acres of 5-year old cinchonas in Java, which will be fit for shaving two years hence, the bark so gathered in quantity and quality casting Ceylon into the shade. There can be no question that Java with its rich volcanic soil and its suitability for the culture of the rich *Ledgeriana*,* is destined ultimately, to be a formidable competitor with Ceylon in the cinchona markets of the world, and a debade hence it may really supply the world from something like 100,000 acres of mature trees. But up to the end of 1890, at least, we suspect the most formidable competitors with Ceylon cinchona planters will be their fellow-planters.

Since writing the above we have referred to what Mr. Mundt said to our reporter in March. He did not specify any acreage in cinchona: merely asserted vaguely and generally that a very large extent of ground was planted with really good cinchona yielding 10 to 11 per cent sulphate of quinine. Mr. Mundt also regretted the absence of roads and railways in Java "which prevented *millions* of acres of good tea and cinchona land being planted up." Now, in the first place large as Java is, it is densely peopled and the best lands are either under culture, or, after exhaustion abandoned to the everywhere prevaelnt *alang alang* (illook) and *lantana*. In the Preanger Regency we saw valleys of ten square miles in extent occpuied by *alang alang* and *lantana*. A large portion of the untouched forest, again, is on the tops and sides of volcanic mountains, elevated and steep, and therefore not available. There are not *millions* of acres in Java suitable for cinchona and tea, and if there were and railways were running through them, the labour difficulty on which we have dwelt, would render the clearing and planting of such land a slow process, not to speak of the deterring influence of markets which would be utterly swamped by the produce of half or even a

* Mr. Mundt's 10 to 12 per cent quinine in the bark, is as wild as his other statements regarding 175,000 acres in the south of Java, which he had never seen. Bark with 5 to 8 per cent will be very good for an average. A return of 12 per cent is extreme and such as Mr. Moens got only from a few specially choice old trees.

quarter of a million acres of each.—We may mention that before Mr. Beck's letter appeared, we had taken steps to procure information from reliable correspondents in Java on the subject of Cinchona Cultivation. In our last Handbook, after carefully considering the Reports from Messrs. Moens and de Romunde and different Consuls, we put down 11,000 acres and 15,000,000 trees for Java. This may be below the mark, but we shall want good evidence before we credit anything over 20,000 acres to our South-eastern rival.

TEAS AND THE TEA MARKET.

That China teas can be turned out of the fines quality both for flavour and make, we had practical demonstration some two years ago in the coast ports of the Far East. A Canton merchant in showing us over his store, brought out from his bins, samples of some of the finest teas exported from China—teas which realized fancy prices and the supply of which he intimated could easily be increased, if only there were sufficient encouragement in demand at a remunerative price. There can be little doubt that under the stimulus of Sir Robert Hart's remonstrances with the mandarins, "John Chinaman" in his tea districts generally this past season, set himself to pluck fine and manufacture more carefully than usual. Here is what Messrs. Rucker and Bencraft in their circular of the 1st instant say on the subject of the new season's China Teas:—

"The opinion we formed of the quality of the Crop has been confirmed, and it cannot be found fault with except for a certain lightness in liquor. The leaf is of remarkably fine quality, and we do not think has been equalled since 1865. We learn that results have been disappointing to the Chinamen who have been urged to manufacture Tea of higher quality, and who were encouraged by last year's prices to expect better results this season. Seldom has a fine First Crop come to a more apathetic market on this side, and we doubt whether the Elections can stand as much of the blame as last time."

The question of profit therefore will not encourage the Chinese to continue a large supply of fine teas.

As regards Ceylon teas, before the 'new Season's China' came into competition, there seemed to be an inclination to bear hardly on our shipments and as some believed, to endeavour to get 'Ceylon' graded permanently as inferior to 'India' and very little above 'Java' kinds. We have received information from several responsible Ceylon planters which points to determinedly prejudiced, rather than equitable criticism, and we are promised a selection from the reports of London brokers and buyers extending over some time past, to show the inconsistency and unreliablity of much of the testimony against our teas which finds its way from "the city" eastwards. Here is an extract placed at our service from the private letter of a gentle man who knows what good tea is and who has followed the development of our Ceylon industry. He writes from London under date 1st July to a friend in Ceylon as follows:—

"It is not the truth that the Ceylon teas have gone off in quality. Every planter could not have begun manufacturing bad teas. The fact is, our buyers see and know that a large lot of tea will be produced in Ceylon, and they are determined to lower the price. These buyers are banded together in a way and are, I fear, seconded by others—men who buy in teas for grocers. The question is: why do some of our selling brokers value the Ceylon teas so low, and some selling brokers write in their reports that the Ceylon teas have deteriorated? It seems to me as if some of them were playing into the hands of the buyers. I heard that at one sale the brokers who had described the Ceylon teas as 'deteriorated' were cheered in a way. Other markets will be found for Ceylon teas, and everyone who can must be his own selling merchant. The merchant who sells the tea to the grocer does not let the latter have the tea any cheaper, although he pays so much less for it now."

Leaving the question of alleged deterioration of Ceylon teas on one side, there can be no doubt that the "budget scare" of April 1885, is a good deal to answer for the disorganisation of the tea market during the present year. The "Produce Markets Review" discusses this subject fully and shows that the fact of the stocks in the public warehouses of the United Kingdom at the end of June being 21,000,000 lb. greater than in 1885 is due to the disturbance in the regular course of deliveries last year by the fear of an increase of duty. The same authority anticipates a steady improvement now, because not only are prices unprecedentedly low, but the stocks in the hands of the grocers "are undoubtedly smaller than they have ever been in proportion to the weight consumed." This is cheering news to our planters, apart from the evidence afforded that there has been a tendency to persistently unfair criticism in reference to our Ceylon teas and their alleged deterioration.

One matter however must be specially guarded against or Ceylon teas and planters must continue to fall in the estimation of buyers. We have before us documentary evidence to prove that in a purchase of a parcel of teas through Messrs. Wilson & Co., brokers, of Colombo in April last, the whole aggregating some 450 lb., there has been close on 20 per cent loss through *short weight*, after making all the usual allowances. These teas bore a recognised estate mark, and the buyers say that in Calcutta, their claim for the value of 76 lb. short weight would be at once recognised; but in Colombo, the Brokers find such claim is ignored. This is a matter which ought to be looked into at once by all the Brokers and the Chamber of Commerce; for the evidence that "short weight" is an experience attaching to teas bought in Colombo far more than to teas bought in Calcutta, is overwhelming. Planters must see to the fault being rectified, or exposure of the careless, will have to follow in the interests of the community.

LIFE ON A TEA PLANTATION.

The following interesting letter we have received from Mr. D. Slimmon who is engaged on a large tea plantation at Cinnamara, Jorehaut. Our correspondent was for some time before his present appointment in the sale rooms of Messrs. Gow, Wilson and Co., of Rood-lane, E C., tea merchants and planters. The writer says:—The Assamese about our district and northern Assam are of a white sun-burnt complexion, with a decided resemblance to the Mongols in their features; some may be seen almost as white as Europeans. In habits, they are a very lazy, easy going people, displaying very little intellectual power, and however anxious the Government may be to employ them in public offices, the majority of the best posts are filled by Bengalese. In the working of our estates, very little local labour can be obtained, and even the little we have is very uncertain: five to six hours is a good day's work for an Assamee, and then you don't get him every day. The only work they care for is pruning, basket making, or other light work; hoeing and such other manual labour is out of the question. As a rule they live in villages, scattered all over the country, each jât, or caste, having separate townships; for seldom do people of different jâts live in the same village. A zigzag path (East Indians could not make a straight one), a clump of bamboos, and a grove of Pân Tamel trees is a sure sign of a village or what was once the site of a "Gâôn." These

deserted Gáons are very numerous in Assam, partly caused by the ravages of the Burmese, when they conquered the country, killing or carrying away the inhabitants as slaves, and partly from the superstitious ideas of the people. For instance, if fever, smallpox, cholera or some other deadly disease attacks the village, the inhabitants immediately say that the place is haunted, and in many cases they leave it *en masse*, and settle elsewhere. The Assamee at home rents a parcel of land from Government, at a small yearly sum. In April he plants his dhan (rice), and quite contentedly waits until it grows, reaping it about October. Low-lying land adjoining a jan (shallow wide river) as a rule grows the best dhan, the reason being that the dhan requires a great deal of moisture. The only agricultural implements used are a rude wooden plough, consisting of one upright pole, and a wooden socket projecting from the bottom; this is drawn by a couple of bullocks or a buffalo; for harrows, a bunch of prickly bushes tied together is used; for reaping, the usual implement is a billhooked knife, about nine inches long; for threshing, the old plan is adopted of treading out the corn by bullocks; for winnowing the dhan they use is a sort of plated tray, and they shake it up and down something like what was done in England long ago. When all is gathered in, the native sells part of his grain to the Bengalee coolie for about three rupees per maund (80 lb.), the remainder he keeps for himself and family, and as their food almost wholly consists of curried bhat, pigeons, fish, goat's flesh, &c., they live quite happily and contented. Such food as beef, mutton, fowls, and the much hated Gáhori (pig) are forbidden by all their religions save in a few cases where the jât is of the lowest description. The native houses are built of bamboos, plastered over with a mixture of clay, &c., and the long jungle grass serves as an excellent roof. There are no windows, chimney, or wooden floor; the earth rubbed over with water soon hardens and assumes a glossy appearance, and as there are no nails in any of the inmates' boots it never gets loose. In religion the natives are very mixed, but the greater portion are Hindoos and Brahmins. They have two great feasts yearly, one in April called Bor Behu, and another in December named Soot Behu. The principal parts consist of killing a few goats as sacrifices, feasting, music (such as it is), and dancing for several days, Intoxicating liquors are prohibited by their religions, but the natives are fond of smoking hookahs and chewing cân tamel, a kind of hard berry about the size of a marble, and growing on a kind of palm tree.* Chewing cân tamel seems worse than the obnoxious habit of chewing tobacco, it makes both the lips and teeth quite red. The Assamese, like other Orientals, marry very young, First of all a bargain is made between the father of the young man and the father of the girl. The matter being talked over the young man's father agrees to pay the girl's father a certain sum. This is called the betrothal, and to confirm the contract a feast is given to the friends of the girl by the father of the young man. When the boy reaches the age of 14 or 15 the marriage takes place; friends of both parties are invited, and a great feast is given, lasting several days, at the close of which the bride and bridegroom are carried to their house shoulder high. In clothing, the Assamese differ very little from Bengalese as far as style is concerned, but their tastes just lie in opposite directions, the Bengalese liking showy dress, such as red, yellow and green, while the Assamese wear spotless white, very often native silk. In Lower Assam the natives are called Kacharese, being a much finer class of men then those met with in Upper Assam. They travel about a good deal, and play much the same part as Irishmen do at harvest time in England and Scotland, coming up here to work on the estates while their dhan is growing, getting together a few rupees and then returning to their homes. They are fair workers with the hoe, but are often very troublesome customers to deal with; a manager who will employ more than 100 of them at once is thought a bold man. Besides Kacharese, we have similar visitors from the hills called Kiâ às. These people can handle an axe or a knife with much adeptness, and they are generally employed cutting jungle. While at work they keep time to every stroke with their war cry, which sounds something like hae hoe, and when walking along the road in single file you will often hear the same hae hoe to every step. They are a very dirty lot of people. Nothing makes a better feast for them, than a roast dog stuffed with rice, or an old Gharry bullock. They seldom even wash their faces. They are very warlike people, some tribes are quite independent, and many are the feuds between the different tribes; sometimes 100 will be killed at once. The real labouring classes of Assam, so to speak, are the imported Bêngalese. These coolies are imported by owners of estates, all their expenses are paid in consideration of their giving an agreement for a period of years, at a certain wage per month, at the expiration of which agreement they are free to go where they please. In most cases they remain there all their life or at least 10 or 15 years; when they reach a certain age, they are called dependents and receive a pension, so that they are better off than some people think. Those who leave after serving a number of years generally take up a piece of land, build a house and setttle down, having saved enough money to keep them the remainder of their lives. In this way Assam is being rapidly colonized by Bengalese and the Assamese in their turn are dying out. Their houses are built much in the same style as those of the Assamese, but all are together; the village, so to speak, is generally known as the lines. In religion there are all sorts. Two general festivals are held annually, one in March called the Fugwa, and the other in September called the Doorga Pooja. The Fugwa consists of a great feast at which everybody puts on his showiest clothes. Music and dancing and painting each other's faces with a kind of red powder called "Fakwoogooie" are among the things indulged in, and at the end of it all drink is used to excess. The Doorga Pooja is the greatest festival of the year. The ceremonies differ according to the particular part of the country. The chief office consists in sacrificing goats, pigeons, &c., to the god Kali. If the first stroke of the axe kills the goat that signifies that it is accepted, but if it should require two strokes, it is counted as a bad omen. After the animal is killed the blood is daubed on a long bamboo with the tips of the four right hand fingers. A piece of cloth to serve as a flag is afterwards fastened on the end of the bamboo and placed upright in the ground to commemorate the event. Another part of the business consists of an image of Kali being thrown into the river, and if it sinks that is taken as signifying a good season, but should it float, it is regarded as the omen of a bad season. There are many other ceremonies some performed by elephants, &c., the conclusion being much like the Fugwa, and Ting Ting heads are rather fashionable when work is resumed. The favourite Bengalee liquor is lau pani, a kind of intoxicant made from fermented rice—I mean favourite because they cannot afford to pay for European liquors, though whisky or beer seems to be liked uncommonly well when the Sahib gives them any. In clothing nothing is "too loud for the natives. They are also very fond of jewellery. Bracelets are worn on the arms and ankles; rings in their ears, noses, toes and fingers. A little casket is hung round their necks from infancy to keep away the evil spirits. In regard to tea planting a few particulars may be of interest. The seed for the tea resembles black marbles. We plant about January in a piece of good land, about four inches apart. These plants soon appear above ground, and in about nine months' time they are about two feet high. In December they are removed into the new clearance prepared for them, and planted at intervals of 6 feet by 5 feet. It takes two years more before they yield any leaf, and then for the two succeeding years they yield but very sparing quantities. Plucking generally commences about the end of March, and is carried on all through the year until December. The leaves after being plucked are spread on trays to wither them; this operation in fair

* The arekanut is, of course, referred to.—ED.

weather takes about twelve hours. Afterwards the leaves are rolled and fired by machinery: then they are picked, sifted and finally fired before being packed. From December to March the bushes are pruned, clearances made, building and sundry other operations are carried on. Hoeing and cultivation, of course, is done all the year round. This is absolutely necessary, owing to the rapid growth of jungle. The principal beasts of burden are the elephant, buffalo, and bullock. Horses are foreign to the Assamese, and are only used by Sahibs for riding and driving purposes. The climate for about four months of the year resembles July in England, only there is little or no rain. The remaining eight months are not quite so nice, heavy rains and a hot sun causing a moist heat. English people here as in other foreign countries, are very sociable with each other, and many are the pleasant days and evenings spent at tennis, polo, and cricket. English flowers and vegetables grow splendidly out here; nearly every resident has a garden worth looking at. Orchids and geraniums are to be found as common as any other kind of jungle; any tree with good shade is almost sure to have an orchis somewhere about it. There is plenty of shooting to be had from the tiger down to the snipe. Jackal hunting is greatly resorted to now, and many fine runs are made over the "Pitars."—*Grocers' Chronicle.*

TEA PREPARATION IN JAPAN.

(From the *Indian Tea Gazette.*)

Like everything else with this painstaking people the greatest attention is paid to detail. Commencing with the growth of the plant, and its incessant manuring, the utmost care is bestowed in protecting the bushes alike from frost in winter or from undue sun in summer. This is done, where necessary, by the use of mat covers raised on poles about 8 feet high; and when riding across the Tea lands in June the time when the young leaves are fully developed the whole cultivation is seen under matting. The tea plant, as with us, is raised from seed, although the Chinese propagate extensively by cuttings. The first plucking commences in the fourth year, at the commencement of the summer. Only the youngest leaves are then taken. A month later a second gathering takes place, and sometimes, at a like interval, a third light plucking follows. It will thus be seen that succulent leaf is always ensured. Prior to 1,570, we learn, it was the custom to immerse the leaf in boiling water immediately after plucking, and, after drying in the sun, to make the leaf into powder; but in the year 1700 the system of "panning" was introduced. Strange to say, powdered tea, both then as now, is the most esteemed by the Japanese for their own drinking, but, owing to its more laborious preparation, it is an expensive luxury, and its use is confined to the wealthier classes, none being exported. The infusion is drunk without milk or sugar, and is best esteemed when of the colour of pale sherry. During manufacture an incessant "tasting" goes on, and any errors in preparation are thus quickly detected and remedied, with the result that Japan teas are noted for their uniformity in cup. In fact the preparation of good tea is considered by the Japanese almost an art, and none but tried and skilled workmen are employed. The leaves, immediately after being gathered, are taken to the factory. Here the stipules are separated by means of a Bamboo sieve, and all impurities removed. Then follows a process of artificial withering, which is effected by "steaming" the leaf, over water heated to 200° F. in a covered pan. After this, the leaf is uncovered and turned and aired by means of fans made of a frame of split bamboo covered with paper. When perfectly cooled, the leaf is taken to the dessicating box, underneath which is placed the fuel. When the fire is quite bright a sufficient quantity of straw is burnt to obtain a layer of ashes in order to prevent the too direct action of the radiating heat. During the process of firing, the leaves are continually rolled between the hands until they commence shrivelling and are nearly dry, when they are transferred to another firing box for complete dessication: when this has been effected, the leaf, assorted into three qualities or sizes, is placed in sieves of copper wire, and gently rubbed between the palms of the hands to further equalize the make. Sifting then takes place through bamboo sieves of six different degrees of fineness, and this sifting, for the higher qualities of tea, is repeated several times,—the powdered tea even as often as ten times, which expenditure of time and labour renders this kind of tea extremely dear. The temperature of the room in which the firing-box is placed is very high, and doors and windows are kept closed. After final sifting into varieties, all faulty leaf is carefully picked out by pincers. Before packing, the Tea is again heated, and trodden down into the chest by coolies with bare feet.

Adulteration is almost unknown in Japan, and Government inspectors have to pass all Tea before shipment. From the first stage of growth with the careful manuring of the plant, to the final manufacture and packing, the most minute attention to detail is given. The chests themselves are models of strength and neatness, and the marking is very carefully attended to. Owing, also, to the uniformity of the wood used, the weight of the contents of each package is also uniform, and is accepted as per invoice, invariably, in America. We might do worse than follow more closely the painstaking system of the Japanese.

It is not likely that Ceylon will take to withering their leaf by hot steam any more than in this warm climate to protecting the bushes by mats. But there seems to be some philosophy in the expedient of modifying strong heat by means of ashes, and the idea is worthy the attention of those who use "chulas".—ED.]

JAPANESE TEA BOXES (AND ADULTERATION OF TEA IN JAPAN.)

Kintyre Estate, Ceylon, 8th June 1886.

Sir,—I was somewhat astonished when reading your article on "Tea preparation in Japan" (which appeared in your issue of 1st May), to read that "Tea adulteration is almost unknown in Japan;" together with general advice to Indian Tea Planters to follow the painstaking system of the Japanese. Last year I had the pleasure of visiting Japan, and during a stay of some 7 to 8 weeks I saw a great deal of the Japanese Tea Industry, and the conclusion I arrived at was that at least three-fourths of the tea that leaves Japan is beyond doubt adulterated; and in four large godowns—two of which were at Kobe and two at Yokohama—I had the opportunity of seeing the adulterating process carried out openly with no effort at concealment. The Tea, as prepared by the Japanese, is certainly pure, and your description, in your article which I am now referring to, is a fair one, though perhaps it would lead readers to conclude that it was carried out in large factories similar to the "Indian" ones. As a general rule, however, the tea belongs to peasants, who prepare their few pounds a day over a single pan in their dwelling-houses and then sell the prepared leaf to dealers who then mix their various purchases together, sort them and send them to the Treaty Ports for sale. It is there bought by Europeans, and then commences the clever and systematic adulteration and final preparation for shipment. The Tea, when it enters the European godowns, is of good quality, looks more like quills than Tea the appearance, however, of course varies according to quality; in colour it resembles dead twigs, being a green-brown colour, more brown than green. In this state it is put into iron pans measuring 21 inches by 13 inches deep, of which in most factories there are some hundreds built into brickwork chulas with charcoal fires underneath. As the pans get hot the Tea, which before this operation was only three parts fired, begins to get soft; at a given signal by the head manager, generally a Chinaman, a spoonful of a mixture of gypsum, soap stone, and Prussian blue is poured into the pan (which bye-the-bye contains 5 lb. Tea), and this mixture is rolled and rubbed by hand into the Tea. As the heat increases the moisture all evaporates and the Tea takes its twist again and comes

out of the pan hard and crisp, of the pale blueygreen colour common to all green Teas. So thorough is the mixing of the colour that, unless an expert, one would be unable to tell by the infusion, or by looking at the infused leaves, which was the "faced" and which the unfaced Tea. The reason given me for this adulteration was, that, owing to the Tea being made in small quantities here and there, and at uncertain times, and only three parts fired by the natives, it was found that as a rule, if merely refiring was resorted to, the Tea turned a dirty brown colour and lost its appearance, and it was therefore necessary to resort to artificial means. I noticed myself that some of the worst class Teas after being coloured looked much on a par in colour with the first class Teas, and this no doubt has also something to do with the system. I maintain therefore that until this practice of adulteration is put an end to, which will not be before the country is thrown open to foreigners, we have little to fear from competition with the Japanese.

As regards their neat packing and packages to which you refer, we have no doubt something to learn, and in Ceylon the business in importing momè and cedar wood boxes from Japan is assuming large proportions, as Ceylon planters find they get a good box of even weight, light, free from injurious smell and cheap. At present these have been kept from the Indian planter owing probably to *vested* interests and proposed commissions of the Calcutta merchants not being considered good enough. As my sole aim has been to keep down prices and give a really good box (and as you know, Mr. Editor, I have *no* pecuniary interest in the concern) Messrs. J. Murray Robertson & Co. of Colombo at present can give full information and price lists, and they are about to arrange, if possible, for a large agency at Calcutta. They fully recognise the fact that small profits and quick returns are what is wanted to ensure success, and they now undersell, slightly, all local made boxes—while to suit Ceylon and Indian planters they have pursuaded their Japanese friends to add new dove-tailing machinery to their plant, and all boxes now made for these markets have one inch dove-tails. The momé wood boxes have no sort of smell, and are about perfection. In this respect, therefore, I would point out to brother planters independent of agents, that they have a chance of learning something from the Japanese; and these packages once used will probably never be discontinued.—Yours truly, dear Sir,

H. DRUMMOND DEANE.

—*Indian Tea Gazette.*

CRYPTOMERIA JAPONICA BARK SHINGLES.—In notes on the International Forestry Exhibition, we find it stated:—

There were specimens of the bark of *Cryptomeria japonica* used for roof shingles; these shingles are usually employed under some other roofing substance, when they are said to last 40 to 50 years; if used alone, they last half that period only.

This is the tree from which the tea boxes we receive from Japan are chiefly manufactured. The tree is likely to do well at and near Nuwara Eliya.

CEYLON TEAS AND THE FUTURE OF MARKETS.—There is much in the letter of Mr. H. L. Forbes deserving the careful consideration of all interested in our tea industry—and who is not locally? Following on our remarks of yesterday on the alleged deterioration of Ceylon teas, we may say that if such a scheme as Mr. Forbes proposes is seriously taken up, Mr. J. L. Shand would be just the man to further it on the British side. *If* our teas have at all deteriorated, the only cause, we suspect is atmospheric, a cause operating in India also, for Indian teas are proportionately down. Political troubles have, no doubt, depressed the market, and the enormously increased exports in the early part of the season from China, must have influenced prices seriously. As happened with Ceylon coffee, so will it be with Ceylon tea. It was after a commercial crisis and low prices, admitting of very general and increased consumption that Ceylon coffee took first place in the markets. So, we believe, it will be with Ceylon tea:—

"Though we fell, we aye got up again,
And sae will we yet."

CHICAGO AS A TEA MARKET.—The following from *Bradstreet's* is commended to the attention of the future Ceylon Tea Syndidate:—A new departure was made in the tea business last week in Chicago which it is confidently claimed will cause considerable changes in the marketing of teas in this country. The idea carried into execution was that of auctioning off teas at lower prices than can now be made at the eastern seaboard. The teas,* owing to the completion of the Northern Pacific Railroad, can now be brought direct to Chicago from the Pacific coast, and it is claimed at fully ¾c. less per pound for freight alone than it would cost to bring it via the Suez canal and New York. The first sale was well attended, and buyers were present from as far east as Rochester, N. Y. The prices obtained were lower than were anticipated, but the company managing the scheme is reported to be amply satisfied with the first experiment.

THE TALLEST ACCURATELY MEASURED SEQUOIA (WELLINGTONIA) standing in the Calaveras Grove, California, measures 325 feet, and there is no positive evidence that any trees of this genus ever exceeded that height. Of late years, explorations in Gippsland, Victoria, have brought to light some marvellous specimens of Eucalyptus, and the State Surveyor of Forests measured a fallen tree on the banks of the Watts River, and found it to be 435 ft. from the roots to the top of the trunk. The crest of this tree was broken off, but the trunk at the fracture was 9 ft. in circumference, and the height of the tree when growing was estimated to have been more than 500 ft. The tree, however, was dead, though there is no doubt that it was far loftier than the tallest Sequoia. Near Fernshaw, in the Dandenong district, Victoria, there has recently been discovered a specimen of the Almond Leaf Gum (Eucalyptus amygdalina) measuring 380 ft. from the ground to the first branch, and 450 feet to the topmost twig. This tree would over-top the tallest living Sequoia by 125 ft. Its girth is 80 ft., which is less than that of many Sequoias, but, as far as height is concerned, it must be considered the tallest living tree in the world.—*Scientific American.*

THE COFFEE AND CARDAMOM CROPS OF COORG FOR 1884-85 are thus noticed in the Administration Report:—

The coffee crop of the past year is returned at about 4,007 tons, and though it fell short of previous expectations, the outturn can hardly be deemed an unfavourable one, being less by a little over 1,000 tons than that of the preceding year, but exceeding the crop of 1881-82 by nearly the same quantity. Of the whole quantity about 75 per cent was sent to the Western coast for shipment. These figures as to outturn and export are, it may be stated, approximate only. They were obtained from the returns of the Toll-gates which are placed on all the roads leading out of Coorg. Allusion was made in last year's report to the rapid fall in the price of coffee after the year's crop had been exported, owing to the over stocked condition of the Home Market. The local price, (which is affected by the Home Market rates) had fallen to R31 per cwt. in 1883-84, and dropped further to R26¼ per cwt. during the past year. The effect has been to a very general extent, a disastrous one upon coffee industry, and the evidence of it is seen in the large outstandings of coffee assessment remaining uncollected this year. The Commercial and Agricultural depression has also seriously affected the market for cardamoms. The price of cardamoms fell from R300 per cwt. in 1883-84 to R141—8—0, and so, although the crop has been a large one, the growers have not profited by it to the extent anticipated.

*That is Japan and China teas.

Correspondence.

To the Editor of the "Ceylon Observer."

MR. AGAR ON THE ALLEGED DETERIORATION OF CEYLON TEA: REMEDIES SUGGESTED.

SIR,—There is a great deal in what "Experientia Docet" says in his letter to the local "Times" as to "deterioration" of our teas, and no doubt one of the principal causes for want of strength in liquor is want of strength in our tea bushes. Some may remember the cry out there was made years ago about cinchona bark when the drop took place. The Colombo merchants took the planters to task for sending down stuff taken from 18 months old trees!

What are we doing now? Just the very same, only harvesting tea leaves instead of cinchona bark! *Maturity is everything*, coupled with a *judicious selection* of the *seasons*, for *pruning* and *plucking*.

While on the subject of deterioration, and the very poor prices realised lately in the local market for our teas, I would suggest some alterations:

1st.—Allow "breaks" to be put up at auction *as a whole*, or in grades, to suit *the seller* as well as the buyer.

2nd.—Fix a day *once in the month* for *tea sales*. My argument for the former is, that the owner of a "break" objects to its being pulled to pieces and peradventure, the "tit-bits" taken out. This lands him with a "ragged lot," which is not by any means desirable. For the latter I maintain that weekly sales contribute but *small* parcels, which have no attraction for Calcutta, or outside buyers, who might otherwise be represented.

If we could catalogue something like 300,000 to 500,000 lb. *monthly*, a "fillip," may be given to the *trade* which it sadly needs at present.—I am, sir, yours faithfully, SHELTON AGAR.

MR. BECK AND THE FUTURE OF THE CINCHONA MARKET.

SIR,—With reference to a leading article in your issue of the 18th instant, and which treats of the improbability of Java sending forward such quantities of bark as to materially affect prices, I quote from a letter which was written by me on May 30th, and read at the last Committee meeting of the Dimbula Planters' Association on the 3rd instant:—

"Mr. G. Mundt, President of the Java Planters' Association, stated to me that, within two years from now, Java will practically supply the demand of the world with high-class cinchona bark; that the area under cultivation is equal to 175,000 of our acres, and is planted with ledgers averaging from 10 per cent to 12 per cent; that 1,500 trees are planted to the acre, and that the age of the youngest planting of this vast acreage is five years, the oldest six years; that the weight of what Java can supply has never yet been felt because these enormous plantations have not been operated upon, as no tree in Java is shaved until its seventh year, and canker is almost unknown; that in his (Mr. Mundt's) opinion, when Java sent in its vast contribution, say in two years from now, our three per cent barks would not fetch much more than branch now fetches." Mr. Mundt said that he had no interest in the Companies, who are almost the sole proprietors of the acreages he named, his interest in cinchona comprizing only 70 acres of high class *ledger*, and that he had never personally visited these great cinchona fields, as they lie remote from him on the Southern side of Java. Since Mr. Mundt left Ceylon we have heard of canker shewing in Java, but this, if true, cannot benefit us, as it would serve only to precipitate the harvesting of bark, which under ordinary conditions, would not have been exported for another two years.

I proposed to the Association that a subscription should be immediately started to enable those interested in the future of cinchona to send one of our number to visit Java with the same object in view which doubtless brought Mr. Mundt here, but the Association did not think this desirable, and proposed that the Colonial Secretary should be communicated with and requested to obtain through the British Consul at Batavia the required information. I append a copy of the letter I wrote to the Colonial Secretary on the subject, and to which, up to date, I have had no reply.

GEO. BECK.

(*True Copy.*)

To HIS HONOR, THE COLONIAL SECRETARY.

Sir,—I have the honor to inform you that, at a Committee meeting of the Dimbula Planters' Association, held at Dimbula Hall on Saturday, the 3rd instant, a letter was read by me in which I pointed out the great desirability of finding out what acreage of land in Java is planted with cinchona, its variety, and the probable quantity of bark which will be exported from Java during the next two years; as this quantity, if ascertained, would greatly influence operations on cinchona in Ceylon. I had received certain communications from Mr. G. Mundt, President of the Java Planters' Association, which led me to believe that within the time mentioned, viz., two years, Java would export so enormously that the enterprize in Ceylon would be rendered almost unprofitable, as Java possesses trees yielding bark of such superior value to any grown in Ceylon. Mr. G. Mundt said that he had made no personal inspection of the part of Java where the great fields of cinchona exist, but he had every reason to believe that the acreage under that cultivation is enormous.

A resolution was passed requesting me to communicate with you, and ask you to communicate with the British Consul at Batavia, and through him to obtain, if possible, thoroughly reliable information on the subject, which is one of vital importance to the generality of the planting community of Ceylon.—I have, &c. GEO. BECK, Hony. Secy.

Henfold, Lindula, July 7th, 1886.—Local "Times."

INDIAN COFFEE: ITS USE AND ADULTERATION.

North Mysore Planters' Association,
Koppa, 16th July 1886.

DEAR SIR,—The enclosed pamphlet drawn up by the Indian Coffee Planters' Committee comprising representatives from Mysore, Wynaad, Coorg, Neilgherries and Travancore, is now being largely distributed at the Indian and Colonial Exhibition. I should feel much obliged if you could find space for it in one of your valuable papers.—I am, dear sir, yours faithfully, ROBERT BUCHANAN,
Hon. Secretary.

[We have already given the contents of the very useful and timely 4-page pamphlet.—ED.]

CARDAMOMS IN CEYLON AND SOUTHERN INDIA.

Mysore, 16th July 1886.

DEAR SIR,—As many Ceylon men greatly wished to compare their prices with the two premier brands of Southern India, I would draw their attention to page 4 of "Ceylon Produce Sales List" at the end of the July number of the *T. A.*, where by an oversight certain sales of the celebrated M. M. M. (Munjanpulla) and C. C. C. (Cadamoney) have found a place among Ceylon sales.* I have often wished to give you a fair comparison and the opportunity has just occurred. Two and sixpence is equal to seven shillings a few years ago, and this shows the drop, the irrecoverable fall that has occurred in the cardamom market.

* We mean to include India in future.—ED.

It may be good news to your readers to hear that the fancy bleaching has, as I foretold, been found out to be but a superficial excellence. It caught the broker's fancy for many years in the case of the brands above-mentioned as being unique and apparently superior; but it is one of the tricks of trade—just as boiling pepper on the same properties—which have but a limited existence. Now, you ought to invent a dodge to add to the aroma of your already highly-flavoured tea. I hope to hear that salaries have reached more respectable figures, and that commissions on profits have become general. "Muzzle not the ox that treadeth out the corn."—Yours truly, ABERDONENSIS.

[Our correspondent promised to tell us something more particular, about cardamom preparation in India.—ED. C. O.]

ENEMIES OF CROTON-OIL PLANTS.

Wattegama, 24th July 1886.

DEAR SIR,—By this post I send you some beetles and caterpillars taken off Croton oil trees. I find they eat flowers, leaves, tender branches, skin of the fruit, and even tender fruit.

I may here mention that up to January last (some 9 years since I first planted croton) I never saw any insect attack and injure the croton plant or tree.

I had a small patch ½-acre attacked in January which was soon checked by picking the beetle, throwing ashes over, and then shaking the trees when the caterpillars fell off. I purchased some village fowls who soon picked them up and fattened on them.

I quite agree with Mr. Westland that taken in time the damage will not be much, as the trees soon recover. I have another attack of this pest now.—Yours faithfully, J. HOLLOWAY.

[COLOMBO, 28th July 1886.—The caterpillars I do not know. They are probably the larvæ of some small moth. The other insects are not beetles but bugs belonging to the family Scutelleridæ. Length half-an-inch, breadth three-tenths of an inch ground color metallic green, which in some positions has a coppery tinge; three oblong blue-black spots in a line across thorax close to head; three large ones beneath them, with two smaller ones on each side of the row; six large spots on Scutellum in two longitudinal rows with a black pear-shaped line between the four upper spots. The immature insect is of a more rounded form and the black markings are rather differently arranged. They vary in size according to their age. These insects appear to have a wide distribution and are sometimes common in Colombo.—*Entomologist, Asst. Feree*—ED.]

DETERIORATION IN THE QUALITY OF CEYLON TEAS.

26th July 1886.

DEAR SIR,—Many opinions of late have been given as the causes to which can be ascribed the deterioration in the qualities of our Ceylon teas. Many of them are mere conjectures, and, if our teas have actually fallen in rank, from the first teas in the world to a mere average, too many opinions cannot be obtained, if in the end, *one* can be given and proved to be correct.

My own idea is, that far too much is made of this supposed deterioration.

That it may exist to a small extent is perfectly possible, and I think if it does, it is solely and alone due to the vast quantity of leaf now manufactured from immature bushes. But, that it does exist to the extent home dealers would wish us tounderstand, I do not for one moment believe. Dealers in tea are no more exempt from the "customs of the trade," than dealers in other products; and my firm belief is, tea-tasters often, and many of them invariably, suit their palates to the "requirements of the trade."

I never did much believe in tea-tasting; my own little personal experience of London tea-tasters being that on *three* opinions on *one* sample, I had values ranging from 10d to 1s 4d; one reporting "poor thin liquor," and another "rich, etc.," and "considerably above the usual run of Ceylon teas," and all these from supposed competent men.

Tea-tasters' mouths, like other folk's, vary according to state of liver!

To find the reasons for the deterioration of our Ceylon teas, I think we have to look to home. Till within the last twelve months our exports were not much felt in the London market. Our teas were reckoned as "fancy teas" of a high quality and fetched, not fancy, but *real* values. Why are not these *real* values obtained now? I think the reasons are obvious. I repudiate the idea that there is any appreciable change in quality. High-class manufacturers in the island are turning out their teas as before, many of them have no leaf from young bushes to affect them, they manure as they did before, pluck in the same way, and bar that their bushes may be a year older, and their factories fitted up with more approved machinery, no reason, atmospheric or otherwise, can be ascribed to London reports on quality, without going into the "secrets of the trade." It is an extraordinary and significant fact, that the observer of the various marks and prices of our various estate teas cannot help having of late remarked, that while sundry marks have fallen from 2d to 3d per lb., others have hardly altered at all; if not, why not? I fear we are being duped. As a rule, London dealers in Ceylon teas, have been and are dealers in Indian and China teas for years, have vast interests directly and indirectly in the advancement, or at any rate keeping together, of these latter countries and their teas. They find Ceylon imports have increased and are increasing to an alarming extent, and what is natural, they begin to think which business will pay or does pay them best. The advancement of the one must mean the keeping back of the other, and in the equalising of the value they keep the whole business together, *and they keep back Ceylon Teas.* They cannot serve all masters, and so endeavour to make all equal. I think Ceylon teas and India teas may now be said to be very nearly about equal value in Mincing Lane; any way they are fast approaching that end. Are they in reality? Certainly not. Prices for the same article for some time proved this.

Retail dealers have likewise damaged our character; they cannot afford to sell our teas pure and simple; profit on such would not be sufficient, and the means lost of disposing of the cheaper and more paying descriptions. So long therefore as the above goes on I see no prospect of improvement. As Ceylon exports increase we may see a rise in prices, as then it may pay the dealers to give up the one and take to the other, but as business is being done at present our teas, I do not think, will ever again rise to their *real* value. Political disturbances in Great Britain may account for a general depression in all trades but not to the equalising of articles unequal in value.

My firm impression is gathered from facts, and from some commercial experience in E. C. in years gone by. There exists a ring to keep Ceylon teas back, that the said deterioration in quality is a mere humbug and excuse, and that by the few in Ceylon who are in a position to do so, a firm and

determined stand must and will be made to break this monopoly, not only for their own benefit, but for the general good of the planting and commercial interests of Ceylon.

Toward the Tea Syndicate, when I am in a position to do so, I shall certainly give my strongest support. I heartily believe in its proposed schemes, but of its success I am sceptical, simply that so few, not *will not*, but *cannot* support it. I have read several of the papers going the round for signature, and these at once show up in vivid clearness the sad position seven-eighths of the Ceylon tea estates are in. It is what was to be expected. The tea industry has commenced where the coffee ended, viz., in the one word—*involved*. How many good and worthy men must have seen these papers and inwardly thought "I wish I could sign it," —not only planters, but our Colombo merchants. Therein I fear will be the failure of the Tea Syndicate. "Willing to support to the utmost but cannot," must be the reply of quite seven-eighths of our tea estates. No one knows this better than he who advances the necessary and in return demands his necessity. Commissions must be got, the middleman has always lived, and must live, and the public must not be supplied with a pure and unadulterated article to the detriment of an adulterated one. The London merchant will not support a Syndicate to take business out of his own hands; he cannot allow his Colombo agent to support such, and therefore the Colombo agent through no fault of his, cannot allow his constituents to sign away his produce.

What therefore can the one-eighth left do towards supporting a Syndicate which must, if success be looked for, be on a large scale? A *sample* Syndicate will not do, it must be a *stock* Syndicate: can these few, therefore, "Freemen" as I may call them, support solely and alone this new enter prize? Will their entire produce be alone sufficient to stock the proposed experimental new markets? And will they be willing for the good of themselves, and the Ceylon community at large, to risk their all in a new venture? I doubt it. I sincerely trust I may be very much in error as regards the signing of the Tea Syndicate paper by many Colombo friends, and that many in the Fort may be in a position to support so worthy an undertaking. Many of us wait anxiously for the result.

Of the various products shipped from Ceylon, tea is the only one which can pass direct from the producer's chest, packed on the estate to the consumer's bag, across the counter. Could the few Freemen in Ceylon arrange to carry out so worthy and honest a business, I fancy we should hear no more of deterioration in quality of tea. To carry out business of this kind, the few must be prepared for a desperate struggle against desperate odds, but the end must be victory. Various institutions of the kind have been formed, and I suppose their results have been as small and various as their capital and the mixtures they sell.

The sales of pure Ceylon tea at the Exhibition must now come to an end and the more's the pity. If no effort is made to keep up such a laudable trade, results must be disastrous in the extreme. Vile mixtures again throughout Great Britain be sold to the public, and if such were not marked "Ceylon Tea" it would be allright. But they will be labelled as such, and purchasers of Exhibition Tea will come to the conclusion that after all there is something in deterioration of Ceylon Tea. What can be done? I only see one way, the result of a conversation I had with one of our largest and I doubt not free-est Tea producers in the island:—

'Endeavour to form a Company. Capital £20,000 to £30,000. Establish shops throughout the United Kingdom (thank God it is still likely to be united!) From these shops, dispose of only one grade of Tea. Supply such Tea marts direct from the Ceylon Agent or Manager, and supply the consumer direct from the chestbulked in Ceylon.'

All Ceylon planters who can, will support with their entire crops paying a concern. Their Teas must be sent to Colombo, to be valued, accepted or rejected, and bulked there. They can draw on the Company's capital against their invoices, and receive payment in proportion to value put upon their Teas by the disinterested manager and taster, in Colombo. The profits on sales need only be half the profits made by the home grocer, and with no sucking middleman. I fancy to 1s 6d would be a fair price to reckon for their *whole* season's crop, and if they were also shareholders, 15 per cent to 20 per cent would be a safe estimate for their invested capital. Could such a Company be floated under able management in London to begin with, and then in the chief towns of Great Britain and Ireland, and in Colombo, I doubt not every share would be taken up by *outsiders* within a couple of days of the Prospectus appearing before the public. The result would be, I doubt not, similar to the various Co-operative Associations of which so much was written *against*, when they were first established. Purchases could also be made on highly remunerative terms in the local market if supporters' teas were insufficient to meet the demand.

If you consider these ideas worthy of publication I should be glad of their appearing also in your Overland issue*, as through our worthy Planters' Commissioner something might come of them.—

Yours truly,

H. L. FORBES.

CALCUTTA BOTANIC GARDENS, are among the finest of the kind in the world, considerable success has attended the growth of mahogany plants, of which there are 20,000 seedlings. In the Madras Gardens also these seedlings are pushing forward with immence strides. The paper mulberry tree finds a congenial soil in Bengal. It supplies the material from which the *Tappa* cloth of Polynesia and the bulk of the paper in China and Japan are manufactured; and its bark is considered to be among the best of paper fibres. The expenditure on the Calcutta Gardens last year amounted to R69,870.—*Madras Mail.*

COFFEE.—The statistics of coffee cultivation on the Nilgiris usually furnished are stultified by the inclusion in the figures of Waste land, not cultivated, but forming part of every holding. On the Nilgiris, the Government Assessment is charged on the entire area of the estate, including forest and land retained exclusively for purposes of grazing and this introduces the factor of error in all the returns. We have been at some little pains to eliminate the waste from the figures and to give only the actual area covered with full grown coffee. Immature coffee is not deserving of consideration as for some years, owing to adverse influences and low prices, no extensions have taken place. The following will be found as nearly correct as possible:—

			Acres.
Todanaad	...	...	1,720
Parunganad	...	...	5,115
Mekanaad	...	...	2,965
Kundahs	...	...	500
		Total...	10,300

This makes ample allowance for recent abandonments which may be reckoned at 2,000 acres if not more.—*Nilgiri Express.*

* Also in *Tropical Agriculturist*.—ED.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, June 12th.—

Scour in calves has been rather general of late in France and Belgium. An agriculturist writes, that he rears 30 calves yearly, and never yet lost one from diarrhœa; nor has any one who adopted his remedy, viz., when the first symptoms of the disease set in, he makes the calf drink one or two quarts of cold water after it has suckled; if very young, one quart will suffice. Continue this during eight days till the diarrhœa has stopped.

What is the value of the residue-roots and stubble, left behind in the soil after the crop has been reaped? The materials taken from the air and the soil during the development of the plant, are not all exported with the harvest. There remain in the soil some quantities, very variable in chemical richness and amount, following the nature of the crop, and calculated to enrich the layer of arable earth. Phosphoric acid, nitrogen, lime, magnesia and potash are the chief plant-food ingredients left behind. Those crops whose residue contains most mineral or nitrogenous substances, will proportionably be the most valuable. Taking some luzerne, red clover, sain-foin, rye, colza, oats, wheat and barley, and carefully removing all foreign substances from the roots and remnant stems, an acre of luzerne, and red clover will leave of such residue 4½ tons; rye and sainfoin, 2½ tons; wheat 26 cwt., oats, 28 cwt., and barley, 18 cwt. In mineral richness, clover, rye, oats and luzerne respectively, are the best, and barley the worst; while in point of nitrogen, the order is: clover, luzerne, sainfoin, rye, colza, oats, wheat and barley. In both cases, clover is at the top and barley at the bottom of the comparisons. Further; clover and barley leave behind in the soil, the following proportions in pounds per acre, of—lime, 257 and 38; magnesia 48 and 3; potash, 81 and 10; phosphoric acid, 74 and 12.

Hence, the quantities of nitrogenous and mineral matters thus left behind in the form of stubble and roots, is not unimportant, and to be remembered when manuring for succeeding crops. But it must not be forgotten at the same time, these food ingredients cannot be utilized, till the residue has been destroyed and transformed, under the influence of the microbes of the soil and chemical action.

The late M. Bouley, head veterinary inspector, laid down, that the shoeing of horses, was intimately connected with the prosperity of a realm. He classed the "farriers," among the useful arts. It is difficult in any case to conceive, how the "noble animal" could be utilized in civilised countries, on paved or macadamized roads, without an iron-protected hoof. Over natural roads, hard or rugged though they may be, the ordinary growth of the horny shield of the hoof, is ample protection. Should the wear and tear be excessive, why, the animal must be allowed, as with the Boers, to lie by till the horn grows. A footsore horse soon becomes lame, unless in the absence of a farrier, rice straw boots be resorted to, which was the custom in old Japan. Even the Arabs, though their horses have but sandy tracts to patter over, esteem a shod horse, of greater value than one left to nature. In modern horse-shoeing, France has much leeway to make up, and so it is not surprising that a society is to be formed for promoting improvements in farriery. This ought not to be, as the Gauls shod their horses before they were conquered by the Romans, just as do their descendants in modern France today. And it was William the Conqueror who introduced farriery into England. The shoe is the fulcrum, the motive power of the horse. The horny part of the foot grows all the same, whether shod or free; but if the former, it has to be periodically pared to keep it in shape, in harmony with its plate armour. Hence, for working horses especially, the necessity of periodically changing the shoes. The hoof would become disproportionately long, and the grip, the motive power, or sustained balance of the horse, would be deranged. If it be essential not to wear away the hoof quicker than it grows, it is also important to not permit it so to develop, as to waste the animal's power of draught. The hoof is only the covering, the shell or case, over a very sensitive organ. Too often the principle was to rasp the hoof so as to make it fit the shoe. Nature was compelled to be subservient to man's errors. All the art of shoeing consists in making it not a fetter, but a buffer or shield, against extra wear, over artificial surfaces. There are farriers who forget that the fore foot, which is round, is of the same importance as the hinder ones which are oval. French farriers ought to pare less and trust more to the rasp-save for the front of the foot, than the knife. to secure equality of level on both sides. Shoes ought not to be either too heavy or too light; neither too small nor too large. There is also something to be effected in nails and nailing on, and a greater readiness to try new models, no matter whether they be shoes from America or England.

THE COL-IND EXHIBITION.

CYPRUS.—The exhibits from this recent addition to the British possessions are not numerous, but they are nevertheless of very great interest, particularly from an antiquarian point of view. There are, however, comparatively few vegetable products, and these include sections of the principle timber trees, and collections of fruits and seeds, none of which call for any remark except, perhaps, some fine pods of the Carob bean, St. John's Bread or Locust (Ceratonia siliqua), and a sample of a coarse kind of molasses or honey, extracted from them. These dark brown or blackish beans are well known in most towns, and are usually to be seen in small shops in poor neighbourhoods, being sold to children who eat them for the sake of the sugar they contain. About 30,000 tons of these beans are annually shipped from Cyprus, the average price being about £3 per ton. They are principally used for making the patent cattle foods now so much advertised. At one time Locust pods had a reputation for clearing the voice, and were used for that purpose by singers.

An object of especial attention from Cyprus is the native cart, such as has been in use for over 2,000 years, and is still used in the island. Its construction is of the roughest character, the wood being simply hewn with an axe, and the whole put together without the use of a nail.

QUEENSLAND.—This court is contiguous to Canada, and the first things that strike us on entering it are two magnificent trunks of Australian Cedar (Cedrela toona); one of these measures 20 feet 5 inches in girth, and the other 18 feet 8 inches; each trunk is about 14 or 15 feet high, they are said to weigh 5 tons each and are the largest logs in the whole exhibition; they are certainly most noble specimens. A piece of each is cut out in front, and polished to show the grain, which is even, of a beautiful deep red colour, easily worked, and takes a good polish; the wood is very generally used by cabinet-makers in Queensland and New South Wales, as well as in India and Burma, where the tree also grows. The trunks in question were grown on the Blackall Range in the Moreton district. Woods are particularly well shown in the Queensland court; the collection is very complete; they are all carefully selected and are well cut, polished, and labelled, and amongst them are some or more than usual interest, especially amongst the Liliaceæ, Palms, and Filices, such, for instance, as Dracæna angustifolia, Ptychospermia Normanbyi Licuala Muelleri, Dicksonia Youngii, &c. These, of course, are more of scientific than commercial interest, but there are a very large number that should attract the attention of the cabinet-maker. An excellent descriptive catalogue of these woods has been prepared by Mr. F. N. Bailey, F. L. S. (Colonial Botanist), which consists of eighty-six pages, and treats of 427 woods arranged under their natural orders and genera.

NEW SOUTH WALES.—Though the collection from this colony is very extensive, and there are

some fine sections of timber, the vegetable products on the whole are not striking, nevertheless there are some interesting exhibits, for instance, a large quantity of a wooly substance like fur is labelled "Pulse from base of stalks of Macrozamia spiralis," a new product, it would seem, from a Cycadeous plant, used we suppose, for stuffing cushions. A curious and interesing ethnological collection is shown from New Guinea, amongst them several singular wooden drums ornamented with festoons of the hard seed shells of Pangium edule, which are probably used for the rattling sound they would give when shaken, as well as for their ornamentation. One case is filled with the celebrated Cabbage tree hats made from the split and plaited leaves of Livistona australis. They are labelled as being made of "grass grown and plaited by natives;" the price of a single hat varies from 15*s.* to 20 guineas.

WESTERN AUSTRALIA.—The most remarkable exhibits in this court are the marvellously fine specimens and blocks of Jarrah wood (Eucalyptus marginata). A portion of one enormous trunk lies on its side, the cross section of the base of which is highly polished, showing to great advantage the beautiful deep red colour of the wood. A magnificent specimen of curly Jarrah, which has dark, wavy, transverse markings is also shown. It is called a counter top—much too beautiful, however, for such a use—and measures probably 14 or 15 feet long, by some 2 feet or 2 feet 9 inches wide. The woods shown in this court, like those from Queensland, are exceptionally well prepared and polished. Jarrah wood is well known to be the most desirable of all woods for moist or damp situations, indeed it may be said for any situation, as it bears not only changes of temperature without injury, but it also resists the attacks of Teredo, white ant, or any similar destructive agency. As proof of its durability a specimen is shown that has been lying on the beach at Bunbury for a period of thirty-six years, where it has experienced the action of the waves, sun, wind and sand without any apparent injury. Several other interesting wood are to be seen in this court and one notable object is a Black Boy trunk (Xanthorrhœa) 20 feet high—a remarkable specimen, beside which is a fine specimen of Kingia australis in flower.

VICTORIA.—Here, as in the other Australian courts, the products of the genus Eucalyptus are very prominent. Mr. Joseph Bosisto, the President of the Victorian Commission, who has been so long and so well known for his work in the development of the oils and resins of the Eucalypti, is a prominent exhibitor of these products, amongst which are essential oils of Eucalyptus amygdalina, E. globulus, E. oleosa, E. dumosa, E. citriodora, E. obliqua, &c. These oils have antiseptic and disinfectant properties, and that of E. globulus is tonic and stimulant. Here also are cigarettes of the leaves of Eucalyptus globulus, recommended for bronchial and asthmatic affections; Eucalyptus disinfectant pastiles, the fumes of which are said to be of great service in diseases of the respiratory organs, and to have the effect of driving mosquitos out of the room. The resin of the Black Boy or Grass-tree of Australia (Xanthorrhœa australis) is also shown. It is soluble in spirit, producing a deep amber colour, employed in staining wood to imitate Cedar and Oak. It is stated that in Mr. Bosisto's factory in Western Gippsland 12,000 lb. of Eucalyptus oil are annually produced, and as many as six tons of Eucalyptus leaves are manipulated daily. There is a remarkably good collection of Victorian woods, each specimen having a representation of the plant yielding it painted upon it: a slab of Eucalyptus rostrata measures some 10 feet by 3 feet. An excellent catalogue of Victorian exhibits is published by authority in which are many useful notes on the woods and other vegetable products.—*Gardeners' Chronicle.*

CEMENT FOR AQUARIA.—The *Polytechnisches Notizblatt* gives two recipes for a cement for joining glass, wood and metal. The first consists of a mixture of equal parts of shellac and powdered pumice-stone, to be used while warm; the second is obtained by melting ordinary brimstone in a ladle, and adding an equal proportion of powdered pumice-stone. The pumice-stone in both cases must be thoroughly dried before mixing, as it is apt to absorb moisture from the air.—C. W. QUIN.—*Indian Gardener.*

DEWS.—Mr. George Dines, who has made extensive experiments and observations on the formation of dew, finds that the depth of deposit in England in an evening rarely exceeds a hundredth part of an inch, and that the average annual depth of the dew deposited upon the surface of the earth does not exceed an inch-and-a-half.—*Ibid.*

THE WILD POTATO.—The last word has not been said yet, and to all appearance it will take long in the saying. We have before us a communication from Mr. Alphonse de Candolle, in which he contends for the specific identity of Solanum tuberosum and S. Maglia. M. de Candolle finally admits—1. Solanum Bridgesii, to which he refers Baker's S. tuberosum (partly); and 2, S. tuberosum of Linnæus, under which he includes as varieties, *a*, *chiloense*, from the island of Chiloe, and which he considers the nearest to the cultivated potato; *b*, *cultum*, the cultivated variety (as a whole including numerous variations); *c*, *Sabini*, the tuberosum of Sabine in *Trans. Hort. Soc.*, the S. Maglia of Hook. fil., *Bot. Mag.*, t. 6756; *d*, *Maglia* of Baker and others, a Chilian maritime plant. 3. S. Mandoni, a species from the mountains of Bolivia. We shall revert to this interesting communication on another occasion.—*Gardeners' Chronicle.*

RED RUST ON ROSE LEAVES.—Could you tell me the cause of the rust attacking the Rose so early in the season? I have known the rust very often to appear in the month of August, but it is quite new to me so early. Some people say it is cow manure that will breed it, and top-dressing will breed it—we have it just the same, top dressing or not. I attribute the cause of red rust to extreme climatic changes. *F. N. O.* [It is impossible for cow manure or top-dressing to "breed" this or any other fungus. All funguses grow from spores just as flowering plants grow from seeds. Over-manuring may in some instances predispose certain plants to fall before the attacks of fungi, and top-dressing, if it contains dead Rose leaves with the resting-spores (Phragmidium) of red rust, may start the disease in spring. The botanical name of red rust is Coleosporium pingue; it should be looked for in its early state, and hand-picked and burnt. The fungus is unusually common and early this season. Fungi vary in their time of growth, according to the season, just as flowering plants vary. *W. G. S.*]—*Ibid.*

FLORAL DECORATIONS.—The *Indian Gardener*, in an article on this subject writes:—"Amongst our flowering shrubs also we may find much variety; take for instance the many forms of Hibiscus, Ixora, Gardenia, Barleria, Eranthemums, &c. Climbing plants also furnish much useful material, amongst which may be mentioned the Passifloras, Allamandas, Begonias, Petrea, and Beaumontia grandiflora, one of the most beautiful of all climbing plants, and last, but not least, the Antigonons. Ascending yet a step higher we possess a wealth of material in many of our gorgeous flowering trees; take for instance the Indian Laburnum (*Cassia fistula*), Bauhinias, Lagerstörmias and the gorgeous Poincianas. Poinciana regia has been so extensively employed in street planting and in the decoration of public and private gardens in Calcutta and many other parts of India as to have caused many people to become thoroughly prejudiced against it, and it must be admitted that the dense sheet of vivid crimson which a well flowered specimen presents during the months of April and May, has anything but a soothing effect, under the influence of a punkah and the many other luxuries of indoor life this prejudice may be laid aside, and we would strongly recommend those who have never tried the experiment, to employ the flowers from any well coloured specimen, judiciously blended with Gardenia or any other choice white subject using the leaves of the Poinciana for garniture; if judiciously arranged this has a most pleasing effect."

CEYLON exhibits some fine specimens of cinchona bark at the Colonial and Indian Exhibition. Although the best days of this cultivation in Ceylon are now past, it will long be remembered that great energy was given to it not long since, when their supplies flooded the market and brought down prices. At the present time cinchona cultivation by itself does not pay, though it is an important auxiliary. The Ceylon planter also gives much attention to cardamoms. *Burgoyne, &c., Prices Current.*

The MEDICINAL USES OF LEMONS AND ORANGES have often been pointed out and dwelt upon. Some time ago, writing to a leading horticultural London journal, Dr. Bonavia referred to the remarkable uses of some species of citrus in cases of intermittent or malarial fever. For this disease the Italians use freshly-gathered lemons; and the good effects have been confirmed by English doctors in Rome and elsewhere. Dr. Bonavia had tried the lemon in North-west India, both on a considerable scale and with beneficial results. He had stated that for simple intermittent fever, without any other complication, a decoction of lemon was equal to quinine in its effects. Speaking of the depressed state of the lemon trade in Sicily, he had suggested that in the place of allowing the fruit to rot, chemists should endeavour to extract the active principle, and turn it to account. All things considered, its uses being so varied and beneficial, the cultivation of the lemon should be carried on wherever the fruit would grow.—*New Zealand Paper.*

SUCCESSFUL PEACH GROWING.—I am pretty safe in saying that fruit growing is carried on more extensively in Earl Fortescue's gardens at Castle Hill than at any other Devonshire garden, the Pine-apples, Grapes, Peaches and Nectarines, and Figs commanding most attention there. One of the orchard-houses is 325 feet in length. But it is of the earliest Peach-house I wish to speak. This house is a lean-to building, about 30 feet in length by 15 feet in width, and contains four trees, the back wall being clothed with a Dr. Hogg and an Early Alfred Peach, and the roof is almost covered with the growths of two dwarf standards of that good old variety, Royal George, which represent the perfection of training I did not count the fruits on the back wall; suffice it to say there were abundance; but I had the curiosity to record those under the roof, and they numbered just 300, and fast ripening; I enclose one herein, together with some of the finest and healthiest Peach leaves I have ever seen.—W. NAPPER, Alphington Cross. [A very fine fruit. ED.]—*Gardeners' Chronicle.*

A VERY SIMPLE MEANS of rendering all kinds of fabrics which are starched uninflammable, is to add a little sal ammoniac and plaster of Paris to the starch, or to dissolve borax 12 parts, and Epsom salts 9 parts in 80 parts of warm water. The tissues to be prepared are dipped in the solution until thoroughly saturated, then starched in the ordinary way. They are then wrong out, pressed, wrapped in a cloth and passed through the mangle, after which the articles are ironed while still damp, or the necessary quantity of starch can be stirred into the saline solution. Vogt recommends sublimed sal ammoniac, 2 parts; sulphate of zinc, 1 part; water, 15 or 20 parts; and the starch to be mixed with this solution. Siebrath says, good results may be obtained by steeping the dresses in a solution of 5 per cent. alum, and 5 per cent. phosphate of ammonia. Nicol advises a bath composed of alum, 6 parts; borax, 2 parts; tungstate of soda, 1 part; dextrine, dissolved in soap lye, 1 part. The following have appeared in a German journal:—Sulphate of ammon., 8 parts; carbonate of ammon., 2½ parts; boric acid, 2 parts; borax, 1¾ parts; starch 2 parts; water, 100 parts. The fabric to be passed through this mixture boiling hot. Another recipe is:—Boric acid, 5 parts; sal ammoniac, 15 parts; potash felspar, 5 parts; gelatine, 1½ parts; starch paste, 50 parts; water, 1,000 parts. This solution to be applied with a brush.—*Burgoyne, &c., Prices Current.*

WHETHER COWS ARE IN CALF.—"Enquirer" on this subject may try the following, given on the authority of the *American Dairyman*:—"Let a drop of fresh milk fall into a glass of pure water. If the milk promptly disseminates itself through the water, the cow that yielded that milk is not with calf; but if it sinks to the bottom of the glass as it falls upon the water, and does not produce but little of a milky cloud, the cow is pregnant. The specific gravity and viscidity of the albuminous milk being heavier than water, thus retains the drop of milk and causes it to sink." To find if a cow is in calf, the usual method is to thrust the points of the fingers or thumb against the right flank of the cow, when, if the calf is about six months old, a hard lump will be felt bounding against the abdomen; but Youatt strongly objects to the punches that are frequently given by way of trying if a cow has a calf in her—punches which, he had no doubt, were sometimes the cause of difficult or fatal parturition.—*New Zealand Paper.*

TUBEROSES.—The Colonies just now are in the ascendant, and we Britons are about as proud and self-conscious as any old hen and her chicks—and we have reason to be. In these days demonstration is everything. It does not do to read of the battle of Waterloo, that may have been true or not, but we did not see it. Captain Cook may have discovered that part of Australia known as Botany Bay, but we were not there to see him do it. Nevertheless the exhibits at South Kensington furnish proof sufficient even for an examiner, and so we trust the illustration we now give of Tuberose growing in Natal such may afford satisfactory evidence, even to those who have not been there, that there is a colony as Natal, and that the Tuberose is grown there pretty extensively, furnishing employment to Europeans and to natives, and thus contributing not only to the luxuries of the "classes" at home, but supplying also a potent factor in the spread of civilization among the masses, black as well as white. Messrs. Edwards & Bell, of Pietermaritzburg—to whom we are indebted for the photograph whence our illustration was taken—tell us that they have under cultivation more than 12 acres of the "double South African Tuberose," and which is grown chiefly for the London and the Paris markets. Polianthes tuberosa was first mentioned by L'Escluse (Clusius) in 1594, and was probably originally introduced from Mexico. The name of Polianthes is derived from *polios*, white, and *anthos*, flower, and must not be confounded with Polyanthus—from *polus*, many, and *anthos*, flower—a term applied to umbellate Primroses.—*Gardeners' Chronicle.*

ILLIPE OIL FROM MAURITIUS, as shown at the Exhibition is thus noticed by the *Pharmaceutical Journal*.—"Specimens of a white solid fat prepared from the seeds of *Bassia latifolia* (*Sapotaceæ*) are exhibited by M. C. Lienard under the name of illipe oil. This is used in the island as a substitute for lard for cooking purposes. It would probably form a valuable oil for soap manufacture. several of the Sapotaceous trees yielding, like the Shea butter tree, a fat containing a small quantity of a substance resembling gutta-percha, the presence of which prevents the rapid wasting away of soap made with it that is characteristic of the soaps made with coconut oil. In India it has long been used in preparing common country soap. It contains stearic and oleic acids, and another acid said to have the formula $C_{16}H_{20}O_2$. According to Cooke's "Report on the Oils and Oil Seeds of India," it was stated in 1843, by the Director of Price's Patent Candle Company, that illipe oil was worth £8 less per ton than St. Petersburg tallow for the manufacture of candles, but that large quantities could be used in this country if it could be supplied at £35 per ton. The value of the oil in Bombay is about 8s. for the Surat maund of 37½ lbs. The seeds yield about 33 per cent of oil, which after saponification yields 40 per cent. of inodorous translucent stearic acid. The oleine obtained by training, *i. e.*, melting and cooling to a temperature which allows the stearine to crystallize out, is very pure and resembles olive oil in appearance and properties." There follows this statement:—"The curious statement is made under cinnamon wood that the roots yield an excellent yellow dye." Camphor candles as made from a substance obtained from cinnamon roots we have heard, but the yellow dye is new to us.

AGRICULTURAL CHEMISTRY.

The following is the simple result of a comparison of a large number of analyses of soils—good and bad—and plants grown on different soils, to determine what was necessary for ordinary field crops.

All the fertile soils contain the following :—

First—Silica or sand.

Second—Alumina or clay.

Third—One oxide, either of iron or of magnesia.

Fourth—One alkaline earth, either lime or magnesia.

Fifth—One alkali, either potash or soda.

Sixth—One mineral acid, either muriatic or sulphuric, or phosphoric.

Seventh—Vegetable acid, or decomposed vegetable matter.

And in all fertile soils, the fourth and fifth were in such quantities as to neutralize the sixth and seventh. The poor soils either wanted some of the necessary ingredients, or had an excess of acid or alkali. And in all such cases there was an excess of acid, except in one soil there was an excess of soda.—*Nilgiri Express.*

AGRICULTURAL NOTES IN THE CEYLON LOWCOUNTRY.

You correctly interpreted my feelings when announcing that the worthy Director of Public Instruction had anticipated my suggestion that Agricultural instruction be imparted to the villagers. I was very glad at the announcement, and hereby presume, on behalf of the poor *goiyas*, to tender to Mr. Green my best thanks for the interest he takes in a body of men in whom his brother officials in the Revenue line interest themselves only to exact taxes in good and bad years alike. If all officials take as great an interest in the natives of this country as Mr. Green, it will be a happy day for Ceylon.

I would humbly suggest to him that his scheme can be made more comprehensive without any extra expenditure. An Agricultural Instructor will have his time haug very heavy on his hands in directing the cultivation of four acres of land in any one spot. Besides, the *efficient* cultivation of four acres of land by the senior boys of any school will be a task that it will not be wise to attempt, for failure will have a very pernicious effect on a people so conservative as the *goiyas* admittedly are, and who cling so tenaciously to time-honoured customs. My suggestion is that three schools be selected round each centre, and within, say, a day's reach of it, and that to each school be attached about one acre of land. An acre of land will be within the resources of any one village school to cultivate with its senior boys, while the junior boys can be detailed to do the weediug—a very necessary operation in the successful cultivation of paddy. The Instructor can move about from school to school with his Agricultural implements, and impart the necessary practical instruction. If it be not possible to cultivate all four plots in one season, two can be cultivated for the Yalla and two for the Maha crop. By this system Mr. Green will be able to impart the blessings of the proper cultivation of the soil more speedily through the island than by selecting only six schools at a time. I hope Mr. Green will see fit to consider this suggestion.

Any information we may want as to the mechanical improvement of our soils, or the use of suitable manure to add to their fertility can be more cheaply and readily purchased of an Agricultural Chemist. Agriculture in Europe and Agriculture in this Island are widely different. The main branch of Agriculture there is the cultivation of cereals; here perennials. In Europe all the available plant food in the soil is taken up in turns by a rotation of crops; no such thing is possible here. The rearing of stock for breeding and for the butcher, and for dairy purposes is one of the principal sources of income for the British farmer. There is no market for it here. The acquirement of all knowledge is ennobling and useful, but in this utilitarian age, when a money value is placed on it, one may fairly ask whether any branch of knowledge that does not yield adequate results is not dearly bought.—Local "Examiner."

DRUGS AND DRUG SALES.

Whatever may be the results of the Colonial and Indian Exhibition in developing the natural resources of the British possessions, the fact of such resources being brought under the very eyes of the English public must result in some good. In scanning over the trade reports of the London drug sales this is brought forcibly to our mind, when we perchance read that a certain drug is scarce in the market, and all the time we know that the plant furnishing it is very abundant in many of our colonies, and we cannot for the life of us see why such and such a drug should be scarce. Take, for instance, the article *Cassia Fistula* which was reported in the middle of May to be of "somewhat lean quality," and "very scarce," when only a few days previously we had seen quantities of the finest, fattest pods imaginable in almost every West Indian Colony at the "Colinderies," and moreover, there are few trees having a wider range of distribution over the tropics, either naturally or by cultivation than the *Cassia Fistula*, for on account of its handsome appearance, and its freedom in flowering, it is much grown as an ornamental plant. Bentley and Trimen, in their "Medicinal Plants," say of this tree that "it is truly indigenous as well as much planted in many parts of Peninsular India, Ceylon, Java, and the Philippines, growing especially on the lower hills, and ascending to 4,000 feet. In tropical and sub-tropicle Africa it is now found apparently wild in many places, and is possibly indigenous, though usually a planted tree; it is frequent under such circumstances in Egypt. In the New World it has no doubt been introduced, and the beauty and fragrance of its flowers has caused it to be a favourite tree for planting in the West Indian Islands, especially Jamaica, in Central America, and Brazil. The showy flowers appear in May and June, and the large pods are ripe in the following February or March." Considering all this, and considering the ease with which the pods can be shipped, there should be no scarcity of such an article. Again, under Anatto we read that there was at the same drug sales as that quoted above, a fair supply of Ceylon seeds and paste, but that the latter had an "odour anything but fresh, which would not render its use in cheese and butter-making advisable." There was, however, at the sale a quantity of good bright West Indian seed of new import. Here again the exhibits at South Kensington, especially in the West Indian Court, are for the most part remarkably fine and bright, and if it be possible to send such samples for exhibition, it should not only be possible, but planters should consider it a necessity for their own reputation, as well as for that of commerce generally, not forgetting consumers in this country, to cultivate the very best products, and to prepare and pack them with the utmost care.—*Burgoyne, &c., Prices Current.*

[Ceylon could supply any quantity of *Cassia fistula* pods and *anatto* seeds, were there only a remunerative market. *Cassia fistula* the Indian laburnum, now becoming pretty common in Colombo flourishes on the east side of our island and is particularly abundant on the lower ranges of Haputale running down to the Hambantota terai and on the road from Haldamulla to Bilhool Oya. It is difficult to preserve this tree and *Alstonia scholaris*, as the natives strip the bark off both for medicine.—ED.]

LIVERPOOL imported 4,800 tons of Para rubber in 1885, against 4,610 tons in 1884. The total exports of Para in 1885 to all parts of the world amounted to 12,500 tons. The produce of Manihot Glaziovii impored into Liverpool was only 85 tons of most satisfacttory quality.—*Nilgiri Express.*

PALMS AND THEIR USES.

From an article so headed, in the *Indian Gardener*, we quote as follows:—

COCONUT (*Cocos nucifera*).—A palm, native of the coasts of tropical Africa, India, Malay and Islands of the Indian and Pacific Oceans. It is generally cultivated throughout all tropical countries, but thrives best near the sea, and requires no special care. The tree varies in height from 50 to 100 feet, and has long-winged leaves, the so-called nuts being produced in bunches of 10 to 20 or more together. They are of a triangular form, about a foot long, consisting of a thick coat of fibre, enclosing a hard shell, which, with its contents, is known as the coconut. It is commonly said that the uses of the coconut are as numerous as the days in a year, affording food, drink, domestic utensils and materials for building and thatching. In some parts of India and other countries, the white albumen of the nut forms nearly the entire food of the natives, and the white fluid or milk serves them for drink. It also yields wine and sugar. Coconut-oil is obtained by pressing the albumen. When fresh it is transparent, and is then used in cookery. Large quantities of it are imported into this country under the name of copra; the thicker portion, called Stearine, being used for making candles, while the clear oil is used for burning in lamps. The well-known substance Glycerine is obtained in the process of purifying coconut-oil. Formerly the fibre was used for making coir ropes only, but within the last 30 years it has been manufactured into floor-matting, brushes and brooms, and is used for stuffing cushions, as well as for many other purposes. The hard shell is made into cups and other domestic utensils. The wood is known as porcupine wood.

COCONUT DOUBLE (*Lodoicea seychellarum.*).—This may be considered the largest and most remarkable of palms. It is a native of a small group of islands in the Indian Ocean called the Seychelles. It is said to attain a height of 100 feet, its stem being 1½ to 2 feet in diameter, bearing at the summit a crown of fan-shaped leaves. It is remarkable for growing in a socket of hard woody texture, perforated with holes made by the roots. This curious appendage derives its origin from the cotyledon, which in this palm attains the extraordinary length of 2 feet, growing downwards like a root, having the germ (plumule) seated in its thickened end. When perfect, the thick end opens on one side like a sheath, out of which rise the first succeeding leaves of the plant, roots also being produced, which make their exit by piercing the end of the sheath. In time the nutriment of the nut becomes exhausted, and the part of the cotyledon between it and the young plant withers. The latter, however, retains its placental vital connection with the sheath end of the cotyledon, which is henceforth nourished by the plant, and increases in size with its growth, which thus continues seated in the cradle of its birth through life. This formation appears, however, to be commmon to the palms, but very much more largely developed in the Lodoicea. The fruit is a large oblong nut, covered with a thin rind. After the removal of the outer envelope or rind, the fruit has the appearance of two oblong nuts, firmly united together, and often weighs 30 to 40 lb. They are borne in bunches, each consisting of nine or ten nuts, so that a whole bunch will often weigh 400 lb. It takes ten years to ripen its fruits, the albumen of which is similar to that of the common coconut, but is too hard and horny to serve as food. The shell is converted into many useful articles by the natives, but the most important part is the leaves, which are made into hats, baskets, and the like. The demand has of late years become so great that in order to obtain the leaves the trees are cut down, and as no care is taken to form new plantations, it was at one time feared this palm would eventually become extinct. In 1864 the leading botanists in this country petitioned the Government for its protection. By more recent information, however, it appears that in one island alone there are many thousands of trees.

A FEW HINTS ON MANAGEMENT OF TEA PLANTATIONS IN INDIA.

The following hints were written several years ago and as they contain matter which may be generally useful, it is deemed advisable to reproduce them here:—

Treatment of Coolies.—There is a great deal in this. I do not mean for a moment to say you can always keep your temper with them, but in many instances harsh tones are used when absolutely unnecessary and do no good, but a lot of harm, as you will find when you come to having to renew their agreements. There is an art in the management of coolies which few know, or knowing can put into daily use. The following are a few general hints which I do not say are infallible, but which, in my experience, I have found very successful:—Don't bear a grudge against any cooly. If they mis-behave punish and be done with it and never allude to the offence again. In some instances a glass of grog after punishment is a very good thing, and ask the offender when giving the grog why he, or she, was so foolish as to make you angry, &c. Impudence and impertinence check in the bud, command respect by your actions, treat the sick kindly, obtain the confidence of your people, never fail to fulfil your promise, if possible, or explain the cause of failure, deal fairly with your people, demand obedience, and at once check the slightest disobedience of orders. Insist on your system being carried out to the letter and after a time things will work almost mechanically. Kindness in the most of instances will be found successful.

Muster of the coolies.—Insist on every cooly being present who is able to attend and let the sick attend the dispensary for medicine, &c., thereafter; see that you are at muster yourselves. In a few instances I have noticed the *sahib's* absence.

Compounders.—In almost, in fact I may say, in every instance, too much is left to these people, they are inexperienced and as the most of their books are kept in English, I have to request that the European in charge sign the sick list book daily, the same as the *kamjari* and take more interest in the sick, *i.e.*, seeing them oftener, and seeing that they have every comfort in a moderate degree at any rate.

Lines.—The cleaning of these is somewhat neglected. I would like this done without fail every Sunday the coolies have leave; if they were, there would be little to do and the coolies would be healthier themselves.

Weighing of Leaf.—I particularly wish that in every instance the coolies receive pice for extra leaf immediately the leaf is weighed. The system of after payment I do not approve of, neither do the coolies, for all extra work let *ticca* pice be paid the evening the work is done. *Cacharries* only may be paid as heretofore, and you will find your coolies more ready to do extra work when required. This, as far as practicable, of course, your personal attendance at the weighing and disposing of the leaf I expect, when inconvenient let a trustworthy man give the pice.

Papers.—There is yet vast room for improvement in the filing and keeping of these. Some of you are very careless, and will, I am sure, have to pay for your negligence some day. It is very easily done, if done when it should be, *i.e.* immediately on receipt thereof.

Marriage among Coolies.—Before marriage, or as soon thereafter as ever possible, the usual agreement and marriage contract be signed, and in no instance is any one to allow one man to keep two women without my special permission. Of course this does not apply to the past, but to the future. The two-wife system is bad and in every instance leads to squabbling and annoyance.

Withering and Plucking of Leaf.—I am now more convinced than ever that the two great secrets in making fine strong teas are plucking every seven days and withering the leaf well, followed up by proper fermentation, depend the quality of the teas

manufactured more than on anything else, the forenoon's leaf according to the weather and leaf space should be spread very thinly, and *if possible not touched* again until removed to be rolled, the turned about and trampling the leaf while green bruises the leaf, and causes redness, spread what evening's leaf you can thin and the balance thick, short of beating, but I think that medium system bad, the thickly spread leaf would, of course, require to be spread thinly next morning after the rolling commences, or as soon as there is space for it. It is impossible to over-wither leaf short of redness, and you will kindly all remember that next cold weather a quantity of those "hakes" for salonies will be required, as many as you have space for, in fact you can hardly have too many, and see they are ready *before* they are required for next season, things *must* be ready for manufacturing in good time, let anything else be behind rather than firing and withering arrangements. Seven days I do not think a bit too soon for plucking, as the season draws to a close it may be.

Live Stock.—A little more care might, with advantage, be bestowed on the bullocks by feeding them at some place where you can see they are getting what they are supposed to get, and by applying regularly medicines to any sores they may have from time to time.

Manure.—A great deal might be done to collect a quantity of this by throwing in old thatch, jungle, &c., &c., to the cowhouse, this should be done immediately where practicable, as too much time has already been lost this season and there will always be use for it in the cold weather for applying to sickly plants, &c. More attention must be paid to this in the future, as we all know what good manure does to the tea-plant.

Nurseries.—Land for this purpose should be selected without delay, as I want the jungle on the land cut in September next, and the seed put in all nurseries before the end of the year if at all practicable. A good nursery should be put in yearly whether necessary or not; it will always prove useful.

Rice Bags.—Hitherto these have not been looked after as they should have been; no bag of rice should be given from the godown before first obtaining a bag, those who have not a bag must buy one; the bags when empty should be dispatched to the rice supplier to be so filled, with the least possible delay, carefully sewn up in bags or boundles of 30 to 50 each, *i.e.*, in such number as will make a convenient parcel.

Packing and Weighing of Tea.—See the tea weighed yourself personally and immediately enter in a scroll book for the purpose the weights; see the boxes are properly soldered before the tea is put in and the tops of the boxes before the lids are nailed on; there is room for improvement in this too much confidence in the *mohories* often.

Sorting of Tea.—At no stage allow the tea to be rubbed through the salonies; if the tea be damp put it over the *dhools* if necessary, or put it in the sun till dry; when the tea will not go through the salonies freely collect in the hands and give a sharp squeeze and let go at once, repeating this as often as necessary until all is passed through; when any class of tea is uneven you will find putting it twice through the last sieve equalise it considerably *waste* in the picking and sorting which might be avoided by having sufficient cloth and more care in the spreading, those who have not enough of cloth had better get enough at once, it is no loss a few rupees spent for this purpose, it can be the means of saving if properly used.

Recruiters.—I have not yet made up my mind about them quite, but will not send them away before the end of September or beginning of October, and think that other arrangements than those hitherto in force must be made in the way of their remuneration, which may result in our not getting the men to go we would like, but doubtless we will have plenty to pick from, the more time-expired men who go the better, I think, is we are certain of the new and by no means certain of the old. I think a plan somewhat like the following would suit: their expenses, of course, and R3 per head commission for every working cooly they bring and return within 6 months, if not back within six months no pay at all; it is ridiculous their staying away nine months and a year, &c.

Fermentation.—Where there are rolling machines the rolled leaf should be put over the *dhools* immediately the rolled leaf comes out of the machine, and I think by the time the tea is made the fermentation will be found sufficient. When rolling is done by the hand the balls should be the colour of a new copper coin before being broken up and put on the *dhools*.

Rice Account.—See that this account is properly kept you are responsible for this as much as for the cash you get, any loss should be pointed out to me on my visits to the garden, when I will give the necessary orders about it.

Implements.—Great carelessness with regard to these is displayed. I doubt if at any one garden there is a proper account of these kept. I must now ask you to send me an implement account monthly with your accounts deducting any lost or useless monthly. I feel sure that lots of these are stolen and lost and no notice taken of them; coolies or others losing implements must pay for them.

Casualties among Coolies.—These should be notified at once as they occur, this will save no end of bother in making up the cooly returns, &c.

Suggestions.—You would all greatly oblige by carrying out mine when given and I would suggest a note book for that and other purposes; once I tell you a thing I dismiss the subject from my mind, but am often disappointed in finding things left undone which ought to have been done. I do not think for a moment that anything of the kind is done intentionally, but simply from forgetfulness and you would all relieve my somewhat heavy burden *if you would just do what you are told to do;* you can hardly expect me to remind you of every little thing all of you, although I daresay you think that I am pretty ready with my whips !!!! Never mind, shoulder to shoulder is the way to get on with our work and you will all admit that the "whips" are often required long before the question is put.

In conclusion.—Be careful of your health; the most of you when wet might change a little sooner and when not feeling very well take medicine to prevent illness—prevention is better than cure. Wishing you all well, nothing would please me better than to see you all prosperous and with all the "whips" believe that you have a friend in the undersigned,—THE OLD BOSS.—*Indian Planters' Gazette.*

THE TEA ENTERPRIZE IN NATAL

is thus noticed in the London letter of the *Indian Planters' Gazette*:—

This week I am in a position to add to my remarks of last week upon Natal tea, the following information obtained at the Natal Court of the Colonial and Indian Exhibition, through the courtesy of the gentlemen in charge of the exhibits of that Court, Mr. Morton Green, who took great pains in supplying me with the necessary details. It appears that tea-planting has made greater progress in Natal than might be supposed from my last letter, though it is still in a very tentative condition with the exception of Mr. Hulett's venture. Roughly speaking, tea-seed was first obtained some ten years or so ago, by a Mr. J. Brickhill, an old resident, much interested in trying various experiments. This seed he planted in his garden and for years confined himself to the cultivation on merely a garden scale, making sufficient produce to supply his own domestic requirements. Having the reputation of being a theorist, his little experiment attracted but little attention at the time. Gradually, however, as his guests became assured that the tea he drank and offered them was really of his own growing, the idea dawned upon one or two

other residents in search of the great desideratum of Natal—a good export article—that this might after all be found in tea. Mr. J. L. Hulett, M. L. C., of the Kearsney Estate, Natal, was one of the first, is not the first, to take the matter up seriously. Mr. Green informed me that Mr. Hulett is most enthusiastic as to the future of the industry, also that though Mr. Hulett is anxious not to allow it to be inferred that he has any idea of parting with his property, or even with an interest in his plantation, he his ready and most willing to give every information and reasonable assistance to any one who may feel disposed to try tea-planting in the colony. It appears that there are no practical tea-planters employed in Natal and therefore the reason for remarks last week, *re* want of technical skill in sorting, as evidenced by the samples on show, is not far to seek.

The estates are all apparently too small as yet to pay for a skilled planter's supervision of the manufacture, seeing that local science is fully equal to the mere requirements of planting and cultivation. So far as these are concerned, the numerous photographs on view at the Exhibition speak very favourably, both as to the method adopted and the state of cultivation. In the manufacture, however, there is much to learn. Need I say more on this point than that a considerable number of samples were sent over in brown paper packets—not by Mr. Hulett—and as if this were not enough to make a planter's blood run cold, without a particle of inner lead or foil lining!! Tea has been tumbled into, and the lessons of experience are all being acquired at first hand. The marvel is that the estates should present the remarkably neat and technically excellent appearance they do. The Natal planters are decidedly men of independent judgment and it is a trifle amusing to note one or two evidences of this, as showing how little beholden they are to Indian experience and how completely they ignore trade prejudices. One tea garden's proprietors, Messrs. Clayton and Ashwell, of the Island Farm, Stanger, Natal, have a printed circular for distribution at the Exhibition. I enclose a copy for your own verification of the following quotations. This circular is signed by the "London Agent" of Messrs. Clayton and Ashwell, his name being, "E. J. Clayton, Cobb's Court, Carter Lane, London, E.C." This gentleman's name not being familiar to me in the tea market here, nor his address that of a Lane neighbourhood, I was puzzling over the matter when my attention was attracted to the imprint on the back of the circular, which reads, "E. J. Clayton, *Printer*, Cobb's Court, Carter Lane, London, E.C." Experience and trade prejudices (may I assume from this) are deemed as of little importance at the London as at the Natal end of the string. My assumption will be justified in planters' minds by the following quotation from this interesting circular:—

"In order to secure an independent *status* for their teas with the home consumers, Clayton & Ashwell have resolved to dispense with the process of sifting, and to pack but one quality, which will thus combine the delicate flavour and aroma of the finest Pekoes manufactured, with the stronger (sic!!) and colouring qualities of the Souchongs"(!!) Can't one picture an Assam *Chabungalow-sahib* singing, Oh! Happy land! from all percentage free! The idea is not original, and for small quantities may pay, but for large quantities the trade requirements as well as prejudices will render the plan impracticable. The scheme is conceived in error and will tell in the long run against Natal, if carried out for some time by outsiders, as it will prevent the tea becoming known in the trade and will deprive it of the trade interest. This result is fatal, in the present state of competition, unless Natal proprietors are prepared to spend huge fortunes in advertising. The next illustration of the independence of judgment to which I have alluded, may be taken from the selection of machinery made by Mr. Hulett for tea-rolling and drying. Instead of acting upon the results of Indian experience he has preferred to start with machinery practically unknown to tea-planters except in the case of one Sirocco. I do not blame him for this, as his reasons may have been good ones, and he appears pleased with his selection, according to my authority *The Natal Mercantile Advertiser* of the 14th April. From an interview published in that paper I cull the following items. The Kearsney Estate, belonging to Mr. J. L. Hulett, is 5 miles beyond Stanger. The massive block of gum trees on the estate, situated on a prominent hill, is a landmark for several miles, and is said to be visible from Amatikula, Zululand. In the upper floor of the tea-house which floor has a superficial area of about 5,000 square feet, the withering is done, assisted by a Greig's withering and drying machine. The tea is rolled in a Greig's roller. The other machinery consists of a Sirocco and sieving machine turning out four qualities. The engine is a horizontal one of 12 H. P., the boiler being multitubular and placed outside the building. The bushes appear to reach an Assam growth. One tree measures 10 feet across its flat top, others are close upon that size. Mr. Hulett has about 130 acres planted out under tea. About one-half of this area "has been plucked," but most of it has been "tipped." Off the estate Mr. Hulett had made at the time of the interview 34,000 lb. and expected to get 41,000 lb., estimating the area of trees over 2 years old at 65 acres, which is the age at which they appear to commence regular plucking! This gives an allround average of 600 lb. per acre for young and old, and leaves 2,000 lb. for the tippings from the under 2-year-old bushes, on 65 acres. Not bad, and if true will take the conceit out of some of the best Assam gardens, age for age. The interviewer, however, somewhat qualifies these figures by adding the note, that they may be corrected by Mr. Hulett, so as yet they must not be accepted as authorised. Round the Kearsney Estate is a complete ring of tea plantations, the proprietors of which own among them some 800 acres of land, not yet, however, all under tea. Mr. Hulett by no means confines his enterprise to tea cultivation and the following quotation from the interview alluded to above, will go towards proving the suitability of the climate for tea. Mr. Hulett grows in orchards, orange trees, lemon, loquot, Brazilian cherry, apple, guavas of all varieties, nectarine, peach, vine, jack-fruit, mangoes (several kinds), roseapple, pineapple, &c., while in the lower orchard are limes, quinces, &c. Oranges and mangoes are produced by hundreds of thousands, pine apples and loquots by tons, and so forth. The preserved fruit industry of Natal is making great progress and some of the guava jelly I have lately tasted is better than any I have tried in India. Chutneys (mango and other) are also well prepared.

The following proprietors are also exhibiting samples of Natal tea. Mr. J. Brickhill, Umbilo Estate; Mr. S. E. Large, Mid-Illovo Estate; Messrs. Lyle and Reynolds, Kirkley Vale; &c., &c.,

I have been promised that three samples of tea from Mr. Hullett's estate shall be packed and soldered down, and handed me on my next visit to send out to you; as I thought it might prove of interest to your readers, were you to get three brokers to taste and report upon these samples, in committee, or independently, as you think best, with the object or publishing their reports. For these samples, as for much of my infomation, I repeat, I have to thank Mr. Green to whose energy and method the chief credit of the excellent arrangement of the Natal exhibits is also due. Natal Exhibitors have certainly every reason to be satisfied with the hearty and intelligent way in which he does all that man can do with the utmost patience, to advance their interest. He gave a glowing account of the climate of Natal, which he described as not excessively hot even in the districts suitable for tea, "and then there are the highlands approachable by railway, as far as Pietermaritzburg, which is already at a considerable elevation, and after that, the post-cart will convey the traveller in search of a spell of temperate climate to the hills themselves where wheat is cultivated, and where frosts are not unknown." He further added that Mr. Hulett is of opinion tha

a small capital will suffice to begin with in tea-planting, as if the young man is worth anything he will soon live off the produce of his land, farm and orchard, whilst waiting two years for his tea bushes to come into remunerative bearing. Two years is, Mr. Green assured me, the age at which tea in Natal commences to be remunerative!

Since writing the above I have, with two brokers, tasted a small envelope sample of the Broken Orange Pekoe I brought with me from the bulk from which I have asked that a sample should be prepared for you. Alas! though crisp and to all appearance sound, it is musty, so, as this involves a further visit to the Exhibition and another trial, I am afraid there will be some delay in sending you out your samples.

Labour averages from 20 to 25 shillings *per mensem* and the labourers are fed off the "meahes" (Indian-corn) &c., produced on the estates. Some acquaintance with the language and habits of the people has to be acquired to start with, in order to arrange for the constant changes which take place, and also to ingratiate oneself into their good opinion, which latter once gained, is productive of faithful service. The natives soon after the newcomer's arrival, bestow a characteristic native name upon him, and this name counts for much; if it has any bearing upon medicine, so much the better for his *prestige* and influence. The native women do not work at present.—PERIPATETIC PLANTER.

MUSHROOM CULTURE.

Is thus noticed in the proceedings of the Horticultural Society of India:—

Some fine mushrooms, exhibited by Mr. H.W. Newton, for which a special prize was given at the Society's annual show, attracted so much attention and enquiry, that Mr. Newton was asked to favour the Society with a few notes as to the culture he adopted, which he very kindly responded to as follows:—

"Directions taken from a short pamphlet on the growth of mushrooms, published by an eminent English Firm (whose mushroom spawn has been celebrated for many years) modified to meet the requirements of growth in lower Bengal.

My method of raising mushrooms is a simple one. I grow them in the open, but a dark cellar is preferable. I make a bed 16 or 18 inches deep, which I fill up with short horse-dung after exposing it to the sun for two or three days to allow the moisture to evaporate. The bed should be well beaten down to retain the heat, and when the temperature is down to 85 or 86, it is fit to spawn. The spawn bricks should be broken to pieces about an inch or an inch-and-a-half in size, and placed in the dung at intervals of say 3 or 4 inches. The bed should then be covered over with 2 inches of fine sifted garden mould and well beaten or trodden down. Generally the mushrooms appear in about 6 weeks to 2 months from time of spawning the bed. If the bed should become very dry, it may be watered, but water should always be sparingly applied. It should never be given in great abundance at one time; still mushrooms like a moist fixed temperature, which may be produced by occassionally damping the walls, floors, &c."

At the meeting, Babu Pratapa Chandra Ghosha made some interesting remarks on the subject, which he was requested to embody in a paper on the subject, to be published with the Proceedings:—

NOTES ON MUSHROOMS.—The delicate appearance of some of the edible fungi has from time immemorial tempted man to use them as articles of food. As it is always difficult to distinguish the poisonous from the edible varieties, the Sastras have enjoined a wholesale prohibition of the use of these ephemeral esculents. Nevertheless the use of Mushrooms as an article of food is as old as Manu, the Lawgiver. It is still used extensively in the dry regions of Bengal, and also in the valley of Kashmir. The varieties known in Bengal are the following:—

1. Phudki-Chhatu (the small and the large); 2. Puwal-Chhatu; 3. Kádán-Chhatú; * 4. Durga-Chhatu 5. Urji-Chhatu; 6. Kud-Kudi-Chhatu; * 7. Kat-Chhatu; * 8. Govar-Chhatu; 9. Indu-Chhatu; 10. Pachan-Chhatu; * 11. Kondka-Chhatu; 12. Gundura-Chhatu.

Of these, those which are marked with an asterisk, *i. e.* No. 4, 7, 8 and 11, are considered unfit for food. None of the above named 12 varieties of truffles and mushrooms are cultivated in Bengal. Indeed, the cultivation of these ephemeral vegetable growths is unknown. Some, however, attempt to raise a few poor specimens of the 2nd variety, Puwal-Chhatu, by allowing waste paddy straw to rot in a heap, and depending on chance for the germination of these fungi. It is not known to the cultivators of Lower Bengal that these esculents may be reproduced by their spawns.

Of all these varieties Urji-Chhatu, is considered as the most delicate in flavour. They are found generally under ant-hills or dhipis as they are called. In the Bankura and Birbhum districts, these are collected by the low-caste-dwellers of the forest known as *Buno*, and sold to the villagers in exchange for rice, tobacco or salt. A kind of *Pelao* is made with these fungi, and I must acknowlege that they are not at all inferior to Pelao made with meat. In the Kashmir Valley the Guchha is much used. This fungus has the closest resemblance to the truffles of Europe. It is sold in the Kashmir shops in a dry state, and the older the article the greater is its value. The Kashmirians seem to be aware of the fact that the objectionable properties of fungi are minimised by keeping. Fungi growing on cow-dung, and those with dark stems are considered as poisonous. The idea of raising truffles and mushrooms on beds of horse-dung or any dung whatever is most repugnant to the feelings of the people of this country. But it is otherwise elsewhere.

The "Dublin Gardner" for 1883 gives a latter of Mr. Barter in which the advantages of mushroom culture are fully set forth. A mushroom bed of less than an acre in area is reported to have supported 4 families, *viz.* the lessee of the ground and 3 familes of workmen, each of whom received wages of £1 a week. The rent for an acre of land being £12 per year, the grower expecting upwards of 5 tons of the esculent vegetable, which sells at the rate of 1 shilling per pound. Reports are also given of the result of sowing a bed 20 yards long by 2½ feet wide with mushroom spawn. In one gathering the yield weighed 160 lb. Another bed 25 yards long and 2½ feet broad yielded at the first gathering, good marketable mushrooms, 76 lb. in weight. In the second gathering the yield attained its maximum of 200 lb. and in the 3rd gathering which was at an interval of a week, the yield was 80 lb. It will thus bee seen that in 3 weeks this small bed yielded 360 pounds of mushroom, or vegetables of the value of £18 sterling. The beds were in all these cases formed of stable refuse evenly spread in a covered place, the temperature of which was preserved at an uniform standard. It is needless for me to note that the cultivation of the edible fungi has proved to be a very profitable and easy business.

The prospects of gain as well as the utilising of subterranean caves which are lost to the world except for the entertainment of the curious, have induced Mr. H. C. Haney to draw the attention of the American authorities to introduce the cultivation of mushrooms in some of the galleries of the Mammoth cave. He recommended for this purpose the avenue known as "Auduleon's Avenue," which is nearly half-a-mile long, and in which the temperature remains even, almost throughout the year; this avenue, together with that portion of the cave which was formerly resorted to by consumptive patients but now abandoned, and which is known as the great Bat-room, is pre-eminently suited for the cultivation of mushrooms. The accumulated guano of bats was considered to form a desirable bed for the nourishment of the spawn.

Thsi proposal was brought to the notice of the public in 1882, and ever since, portion of the cave mentioned above, has been yielding mushrooms by tons. Cultivation of mushrooms in subterraneous caverns is not confined

to America. The caves at Montrouge have 6 or 7 miles run of mushroom beds, and they give a daily yield of 400 pounds of fungi. The cave near Frebilion on favourable days has been seen to yield so much as 3,000 lb. of mushrooms to the Paris markets, and the beds from which this enormous supply is raised, measure nearly 16 miles in length. The cave at Mery belonging to M. Renaudot, in 1869 was reported to have had 21 miles of beds under cultivation. The produce gave occupation to several houses in the neighbourhood, one of which was said to export 14,000 boxes of dried mushrooms to England.

The procedure usually followed in underground cultivation of mushrooms about Paris is as follows:—Long narrow beds of stable refuse (dung) are carefully spread, and all bits of horse-shoes, and broken nails, are carefully picked out. In dry weather a small quantity of water is sprinkled on the beds, and then the spawns are squeezed on them. In a few hours the beds are covered with this excellent vegetable. It has also been observed that the presence of a small bit of iron or old nail seriously interferes with the germination of the fungi. For further particulars on this point the reader is referred to the article on Potato and its Culture, which appeared in the Journal of this Society for 1871, vol. 2, part II, pp. 304 and 305, and also to Mr. Broome's paper on Truffles in the Journal of the Royal Horticultural Society for 1886.

Mushroom cultivation is a simple and profitable business, and the mushrooms, if properly cooked, are considered as one of the daintiest nitrogenous food. But there is always some risk in the promiscuous use of the article. In New Zealand large quantities of mushrooms are grown under the shade of felled trees for exportation. The books give the following as the edible varieties of Mushrooms and Truffles:—

1. Agaricus campestris. This is the ordinary mushroom which is grown in the subterranean beds of Paris. 2. Tuber Æstivum (Truffle); 3. Agaricus proceus; 4 Agaricus ostreatus; 5. Agaricus melleus; 6. Agaricus orcella; 7. Agaricus primulus; 8. Marchella esculenta; 9. Hydnum repondum; 10. Fistula hepatica; 11. Coprinus coneatus; 12. Maramunius oreades; 13. Boletus edulis; 14. Lycoperda giganteum (Young).

But there are others which, to an ordinary observer, appear so very like the above, that they are often mistaken for them, and their use has been seen to be followed by most deplorable results. The last number of the "Scientific American" supplement, January 9th, p. 8357, gives some of the characteristics of this "King of Mushrooms," (Agaricus procerus) and the best mode of preparing the same for the table; for a great deal depends on the kind of treatment which a mushroom receives before it reaches the table. For further details and original information on the point, the reader had better refer to the illustrated article mentioned above.

Some thing ought to be said about the poisonous nature of the great many varieties of mushrooms. M. T. A. Palmer, in the "Moniteur Scientifique" for 1879 says, that there are three ways in which the poisoning takes effect—

1. *a.* It acts as an indigestible matter, which occurs in the case of coriaceous species.
   b. Some of the edible species when decomposing emit sulphuretted hydrogen in such a sufficient quantity in the stomach as to cause vomiting.
2. *a.* Gelatinous.
   b. Acrid.
3. Those which contain a subtle alkaloid, known as or similar to Amanitin. This poison has no antidote. In its action it is at first slow, but in 8 to 15 hours it causes stupefaction, nausea, diarrhœa, delirium and death.

It has been ascertained that mushrooms containing Amanitin impart the poison to better varieties if they are placed in the same vessel.

To cure suspected varieties, Professor Ponfick, of Breslau, recommends repeated washing with cold water, which he says removes, to some extent, the poisonous alkaloid, but boiling, he believes, removes all. The water in which mushrooms have been washed or boiled is poisonous, and should always be thrown away. While on the mushrooms, it would not be out of place to invite attention of members to the phosphorescence of some fungi. Tulsane, who has written a great deal on luminous fungi, describes the following as the most common:—

1. The "Foxfire" Agaricus olarious of South Europe.
2. Agaricus igneus of Amboyna.
3. Agaricus Gardeneri of the province of Gayaz, in Brazil, which appears on dead leaves, and which is known as Flor de coco amongst the people there.
4. Agaricus lampas of Australia.

Dr. Hooker describes this luminosity as common in the Sikkim varieties, and the light emitted by some is so strong, that Mr. J. Drummond, writing from the Swan River, states that he was able to read a few lines of a newspaper by placing on it a specimen of the same. Rev. M. J. Berkley, in *Gardeners' Chronicle* describes an Andaman variety, the Agaricus emerici as giving light at night. The Thelephora phosphora and the Polyporus sufurus are the most luminous amongst the American varieties.

Most Mushrooms while decaying have been seen to emit light, but this is generally accompanied by some chemical change which turns the mushroom blue when its head or stem is broken and exposed to the air On this subject Schoenleen says that the resinous principle of the mushroom does not seem to possess the power of coloring itself, except so long as it is in contact with the parenchyma of the plant. M. Müntz in the "Chemical News" for 1874, states that fungi placed in oxygen evolve or emit carbonic acid gas, but if oxygen is excluded from them, they produce a considerable quantity of hydrogen.

It would not be out of place to mention that the force evolved by a growing mushroom is enormous. The soft and esquilent bulbous vegetable has been observed in its growth to evince such an amount of vigor and energy, as to prenetrate and burst open a flooring of asphalte, and gravel about a foot thick in a few hours. The case is recorded in the *Scientific American* for August 26th 1882, in which the floor of a grain elevator in Buffaloe, N. Y., was burst open by a stem of a mushroom two inches in length.

CITRON CULTURE IN CORSICA.—The Citron seems to be the most important article of trade in Corsica. It is stated to have much improved of late, after some years of stagnation. The 1885 crop was very large. About one-fourth of the annual produce is usually exported to England in brine, to be there manufactured into candied citron. The remainder formerly went to Leghorn, to be manufactured for Holland and America, but two large preserving factories are now at work at Bastia, and the whole of this important manufacture will probably be carried on in the island in future.—*Gardeners' Chronicle.*

CINCHONA CULTURE IN JAVA.—We call attention to Mr. Christie's letter and reassuring information on page 167. Mr. Beck has been telling us that he thinks Mr. Mundt made a blunder in converting his "buows" (1¾ acres each) into acres; but he says truly enough that even 20,000 acres fully stocked with 6 and 7 years old trees yielding bark with 5 to 8 per cent quinine, would tell heavily on the cinchona market as the crops began to come in. There is a report of Java bark yielding up to 10 per cent, having been sold lately by private sale in England.

UTILISATION OF SAWDUST.—It is at times difficult to find any use for sawdust, but the following is a way of deriving advantage from it:—Water is added, up to a degree of plasticity; the mixture of one to three parts of resinous sawdust and one part of washed kaolin is ground and pressed by means of a press. The lumps thus obtained are dried in the air, then placed in a stove, and, lastly, vitrified in the ovens under white-red temperature. These blocks can be sawn, planed, and polished in the shape of incombustible bricks, which are used in America for building houses.

Correspondence.

To the Editor of the "Ceylon Observer."

CINCHONA IN JAVA:

THE EXAGGERATED STATEMENTS REGARDING THE EXTENT OF CINCHONA CULTURE IN JAVA ATTRIBUTED TO MR. MUNDT.

St. Andrew's, Maskeliya, 30th July 1886.

DEAR SIR,—That there has been some great mistake in connection with Mr. Mundt's statement quoted by Mr. Beck, regarding the acreage of cinchona in Java, the annexed extracts show. They are taken from Van Gorkhorn's "Cinchona Culture" published in 1883.—Yours faithfully,

THOS. NORTH CHRISTIE.

(Extracts referred to.)

"The produce of the plantations of the Dutch East Indian Government exceed as yet that from all the private growers together in Java. In the meantime these last are continually extending and within a few years the relation may be reversed, and we believe the exports from Java will exert a certain influence upon the cinchona trade even of the globe. The private speculations are still quite young; a few only, Kramang, Buitenzorg and the Preanger, on the private estates of Pamanochan, Tjasem and Tjiomas, and the baschold estate Maspada, possess important exportable plantations. * * * The culture in Java as regards extent is not to be compared with that of British India or Ceylon. Whilst in the former we reckon plants by the hundred-thousands, in the latter they already reckon them by millions. * * * On the other hand the results of the Government undertaking are attracting more and more the attention of the landowners, and from various quarters there constantly come requests for plants and seeds. In 1874 for the first time, a plot of waste land was requisitioned, specially for cinchona culture. From day to day this occurs in the Preanger, already there are perhaps twenty plots worked with that end in view, besides others still whereon coffee or tea is cultivated as well as cinchona. For five years past, direct encouragement has not been required, rather it may be said that a temporary exaggeration has prevailed, resulting in a feverish hunt for lands. * * * According to the Colonial return of 1879-80, 26 leaseholders are busied with cinchona culture in Java, 9 as the chief concern, 17 as subsidiary. We cannot consider these returns as complete."

ENEMIES OF CROTON-OIL PLANTS.

Watagama, 31st July 1886.

DEAR SIR,—Since sending you the caterpillars and beetles which attack the croton-oil plant, eating the leaves, bark of tender branches, the outside of the fruit pods and even the young fruit, I have reason to alter my opinon in treating them as a small enemy: the attack by this new pest was this time over an entire field of eight acres in different parts. I did all I could at first to destroy them, but their numbers were millions, and I had to let them have their own way; at least I thought it cheapest at this time as crop was about all gathered and I intended to cut down a lot of the trees (as my shade was too thick). After this crop was over in a week's time the whole eight-acre field was under bare poles, not a leaf left on the trees and even the bark eaten off from all small branches. Yesterday I sent you the moth of the croton caterpillar of which there are thousands now flying about, most difficult to catch This is a sure sign the next attack will be worse than the last; so there is nothing for it, but to cut down the trees and keeping them down until next attack is over. The question is will the caterpillar attack any other plants or die for want of food? They did not attack any other plants or trees except keppettiya shrub and trees, which they treated same as the croton-oil plant. From what I can ascertain from the Sinhalese, it appears this caterpillar is an old enemy of the keppettiya tree (the leaves of which is much used to manure betel-vines, and wood for the charcoal used by the gold-smith), and makes its appearance in great force about once in ten years and then after twelve months or so disappears again. It is to be hoped such is really the case: there are other croton fields in this district which have not been attacked as yet. I now send you a moth found with its eggs on a tea leaf (?).—Yours truly, J. HOLLOWAY.

DETERIORATION OF CEYLON TEA.

Watagama, 1st Aug. 1886.

DEAR SIR,—The subject of the deterioration of Ceylon teas has of late given rise to voluminous correspondence, and it has been accounted for by many ingenious theorists. I am amongst the number of those who are profoundly sceptical on the subject, and, therefore, I take the liberty of addressing you. Of the fall in prices for all teas, Indian and Ceylon, we are too well aware; the question is whether, owing to climatic influences, deterioration of soil, or ignorance or carelessness on the part of tea makers, the teas now being sent from Ceylon are of inferior quality to those sent away in previous years. I question this very much indeed, and without some satisfactory proof, the onus of which lies with those who make the assertion, there is reason on the side of those who decline to join the present chorus. A very large amount of tea is now being made from leaf picked off young bushes, and on many old estates the leaf from young land is now being mixed with that gathered from the old fields. Such leaf, as we all know, a large proportion of it frequently bangy, will not make good tea. I have it on the authority of one of our best known tea-makers, who sees a great deal of the country, that by a strange coincidence last year several of the best known estates pruned late and pruned heavily, and as we all know well, whilst the best teas are made before a heavy pruning, the worst teas immediately follow it. Now the chief complaint appears to be of the irregular *fermentation*, the London correspondent of the "Times" stating that "various samples after liquoring showed the leaf of a deep dirty brown instead of the bright copper hue which well-made tea should invariably possess." Now this statement I cannot agree to, leaf from young bushes recently topped, and the early pluckings from heavily pruned tea will not ferment satisfactorily, and no amount of skill or care can get a "copper-coloured infusion" from it. That amongst the numerous new marks appearing in the sale lists everyday, there is much undesirable tea of faulty manufacture I would not deny for one moment, but I question if many experienced tea planters can say that they find that *with the same leaf* they cannot and are not making as good liquoring teas this year as last. It is quite probable that in many places, where firing machines have just been erected, some of the earlier breaks, before manager or coolies have mastered the working of the machines, may show traces of overfiring. It is probable also that this evil is aggravated by an attempt on their part to get the machine to work up to its advertised capacity. Coarse plucking also has in many cases been adopted by those who went into the market with fine teas to make a name for the estate. A few cases of inexperience and change of system apart, I challenge the assertion that under similar conditions equally good teas are not made this year as last. We have had no *proof* whatever to the contrary merely the

ex cathedra statements of certain brokers who may or may not be exaggerating the effects arising from the causes previously indicated. At this juncture, Mr. Gow, a gentleman of many years' experience in Mincing Lane, and previously in Assam I believe, comes amongst us and condemns the whole system of working tea in Ceylon from the plucking to the packing it is said. Those who put faith in such sweeping condemnation of the island industry can hardly remember that up to quite recently, with a few exceptions, the manufacture of Ceylon tea was pronounced perfect or nearly so, whilst the present system of pruning and plucking as generally practised are the outcome of several years' experience of our soil, climate and bushes. That we have all much to learn no one will deny; readiness to avail himself of the knowledge and advice of others is characteristic of the Ceylon planter, but on the other hand we have learnt much and gained great experience since tea was in its infancy, and a stranger should be very diffident in his criticism till he has learnt something of the peculiarities of the object of it. I must apologise for the length of this letter, and will close it with an expression of belief that in a very short time, the tea from mature gardens will be of as high a standard as ever, without any radical change in our methods of working, whilst young gardens will improve as bushes get more fully formed and experience is gained.—Yours faithfully, T. C. OWEN.

II.

Rookwood, Hewaheta, 2nd August 1886.

Dear Sir,—I have been asked to make public my opinions as to the cause of the falling-off in our teas this season, which opinions I have often expressed to friends. I gladly do so and trust they may lead to discussion for the good of all concerned.

I have always admitted there has been a slight falling-off, but I will not admit there has been a serious one, or that we have any cause to fear for the future of our staple :—

1. The article sold has always its share of blame in a falling market, therefore a low market this season is partly to blame for the crying down of our liquor.

2. Some few marks in Ceylon have plucked above their standard, thinking at the time not so much of their nett profit per acre as of obtaining a higher price in the market than their neighbour, and why not? when they were only "playing at Tea." Now with larger acreages and an estate entirely dependent on Tea, the style of plucking which gives the best results per acre in returns is studied, and not the highest market average, if this is beyond their legitimate standard. I years ago stated in the various districts I visit, that as all soils and all climates were not equal, even on estates with a common boundary, so all Teas could not show equal value, if the best was to be made of the estate, and that it was our first duty to endeavor to discover our best paying standard yield with a certain average price, and *to stick to it* allowing our neighbour to get his 1d or 2d more per lb. without regret.

3. *Manufacture* has a little to answer for with some new marks. A little knowledge is a dangerous thing; our novice tries to "get color" when his leaf is not in a fit condition to give it; result, over fermentation, giving a thick dull liquor flavourless and sometimes verging on rottenness.

Over-fired teas, more especially *with choolah firing over charcoal*, or burnt teas.

Our novice generally tries to pack away his teas into bins roasted to a degree, and this is how it happens, working his sirocco at too high a temperture with too little roll on his trays, and not turning his roll often enough. Or with charcoal firing—and this mode of firing is the chief cause of burning with the novice—over-firing his fine teas from not sifting often enough, and lighting the fires in the choolahs themselves, instead of putting in live charcoal, from an *outside* furnace; result of dead charcoal in the choolahs, a smoky flavor, want of briskness in the liquor, and with the greatest heat in the choolah at the most critical time just as the firing is being finished, burnt teas. The choolahs should be charged with red-hot charcoal, and kept at the same temperature throughout the firing. The hand should never enter the tray while it is over the fire or fine tea falls through and smokes that in the tray;—another hint for the novice.

4. *Plucking*—Cruel treatment of the bush early in the season from over anxiety to get in large pluckings when tea bush has not matured sufficiently after pruning, to give the yield asked;—first pluckings after pruning result in poor thin liquor as a matter of course—and by thus pushing the bush prematurely we have unhealthy wood to work on during the rest of the season, and defeat the objects in view, getting neither quantity nor quality. It is a *sine qua non* to get either one or the other, we should have a healthy foundation for our flush—a healthy new shoot—(because allowed to develope) from our topping or pruning, clothed up to a certain point with *new* leaf. The following flushes also allowed to have a healthy leaf or leaves, according to the style of plucking one so often sees which I call "grazing" on the bush. It is sometimes difficult to make the anxious proprietor or superintendent believe that by a few careful rounds—working his bushes on certain fixed rules—he will later in the season benefit by his forbearance at the beginning of it, although for the first three months his neighbour, acting differently, is ahead of him. This is too deep a subject to enter into more fully here, suffice it to say now, extremes either way are bad, too gentle a treatment causing a loss in yield without any advantage to counterbalance it; too harsh treatment causing a loss of yield, and giving poor liquor for the current season, and half the next.

5. *Pruning*.—A heavy pruning, necessary under certain conditions, of the bush results in poor liquor, at from three to six months from the first round of plucking, according to elevation.

The temporary falling-off of the Rookwood liquor so far this season is due to this cause. And I think I am right in placing the temporary falling-off of Loolcondura also, to the same cause.

I have from the first pruned according to a fixed rule, (after trying many experiments on an old plot of tea), and following this rule, I cut too hard wood this season, well knowing what the result would be, but also knowing this treatment was necessary, and I do not think there will be any complaint of poverty of the Rookwood liquor from July for the next 4 years, with the exception of two breaks in each season following the topping. A particular style of pruning then necessary at stated intervals, means *pro-tem* thin liquor.

Including para: 1, add one or other of the above reasons and I think we can account for the deterioration, temporary only, of most of our teas. Good liquor (provided we have good soil and good jât at our back) is to be made from good wood, brought to a stage of development, without respect to the age of our bush, at from 18 months old upwards.—Yours truly,

C. SPEARMAN ARMSTRONG.

MULBERRY BARK AND COCA SEED.

London, 15th July 1886.

Dear Sir,—*Paper Mulberry Bark.*—I have this here now having bought at auction and can get hardly anything for it. I only paid a few shillings for the whole lot. I knew it was valuable but fibre is so plentiful no one cares to work at new things, so they go as "waste."

Coca Seed.—It is very difficult to grow; if a seed is opened carefully, the green leaf may be seen inside and yet it won't grow. I have three parcels here now brought home by collectors of seeds and I was asked one shilling per seed; as I desired proof of the seed being alive, a sample was given me but none germinated.—Yours faithfully, T. CHRISTY.

[We have been favored with practical instructions for coca planters received from South America which will appear shortly.—Ed.]

MR. IRVINE AGAIN WRITES ON UVA TEA.

Madulsima, 28th July 1886.

Dear Sir,—I have from time to time written a good deal on Uva and its prospects as a tea-growing district, and my statements have frequently been called in question by my friends, sometimes as a mere difference of opinion, and frequently on the ground that the district was untried, and that I had been many months absent from it, whilst tea was being planted, also that from my long connection with the district I was prejudiced in favor of it, and that I wished by writing up tea, to advocate the extension of the railway to Badulla town. I will admit that there may have been a small modicum of truth in these statements, but I must utterly deny ever having made a wilful misstatement or stated anything which I did not implicitly believe myself. My knowledge of tea in Uva dates months farther back than most people suppose, for on Kottagodde estate I cultivated for several years a small piece of tea planted by Mr. Bertlin from the same China seed introduced by Mr. Worms on Rothschild estate. No tea was ever made, but the tea was cultivated and regularly pruned and flushed freely. On Pedro estate, which has both the Uva climate and soil, Hybrid Assam tea introduced by Capt. Bayley has been growing and flushing freely for the last 12 years at an elevation of, say, 6,500 feet; besides these there were many isolated patches of tea in Uva, all of which grew freely; but my statement that Uva would produce not only the largest yield per acre but probably the finest tea grown in the island, was a bold assertion to make but I hope soon to see it fulfilled. This statement was based on my knowledge of the soil and climate of the various districts comprising the province of Uva and on the condition and appearance of the tea I had seen growing, as compared with tea in other districts. There are few extremes of heat and cold and the range of the thermometer at any given elevation is less than in most hill districts: the climate is one of continual or alternate sunshine and showers, seldom any long-continued drought and rarely any long continuance of heavy monsoon rains or blustering winds. The tea plant has here found a home more congenial than its native habitat in Northern India and it may be fairly assumed that tea grown under such favourable conditions will produce the finest product of the shrub. As for my advocating railway extension by writing up Uva tea, the question is a very simple one: either my statements have been altogether wrong and exaggerated, or it will take no great array of figures to show that more transport accommodation will be required up and down to carry our tea than ever it did to carry our coffee. I have been some weeks in this district and have seen a large acreage of tea, though I have not been in Haputale yet; and having devoted the greater portion of my time to the tea cultivation of the district, and having also sampled the teas just beginning to be made, I consider myself in a position to have formed not a fancied but a just and real opinion as to the capabilities of Uva as a tea-producing district. The oldest cultivated tea in Madulsima is on Galoola. The field is a small one, two and a half years old, planted at slope. I have seen no finer tea in the island. Younger tea of various ages is equally good. On Uva estate tea 18 months old and cut down to the quick has grown and is flushing splendidly even during what is our dry season. The capability or rather the capacity of Uva tea for flushing has been a much debated question, but anyone who has seen the flush now coming on will have no further doubt on this point. Tea will flush perfectly, and I would place the yield of Galoola under proper treatment at 600 lbs made tea per acre. The Uva estate tea promises quite as well as to the strength and quality of the samples or experimental small lots of tea manufactured, they have mostly proved satisfactory. In the course of a few weeks the Galoola factory will be at work as well as several smaller or temporary factories, and before 1886 has come to a close Uva tea, I fear not, will have proved for itself the superiority I have always claimed for it. I have now written enough on what my friends are pleased to call my latest hobby; let someone else take up the pen.

JAMES IRVINE.

[We hope that Mr. Irvine's rather sanguine expectations may prove correct and that the Uva superintendents and planters will each and all do their duty and prove themselves well forward in the race among champion tea makers, for there is as much in the manufacture as in soil or climtae.—Ed.]

DURIAN FRUITS GROWN IN CEYLON.

31st July 1886.

Dear Sir,—About twenty years ago I read an account in the *Ceylon Observer*, from the pen of "Josias Scadder," of some Durian trees which produced fruit on an estate in Nilambe, and shortly afterwards some one sent me a section of the prickly rind of a fruit grown at Galle, where there are a few trees which I believe bear fruits regularly, and about August 1884 I pointed out to Dr. Trimen the first fruits produced on the old tree in the Royal Gardens, Peradeniya, in the fork of the main drive and the road leading to the old residence occupied by the late Dr. Thwaites. He replied: "Yes, but come and see a tree near the entrance to the Gardens," and sure there it was so loaded with prickly globular fruits about the size of the small jak fruit, called Kuda Heraliya that all the branches had to be supported with props to prevent them from breaking. It is a great pity that Mr. Scowen did not take a photograph of this tree at that time.

A week ago I received a prickly fruit from the Government Agent, Galle, which I put on a table in the dining-room, and at once an odour somewhat different from "the spicy breezes which blow soft o'er Ceylon's Isle" began to pervade the house, and the Durian fruit which left no doubt of its identity was ordered out to the bath-room! Next day I broke up the fruit, and though it appeared to have been pulled before it was ripe, the pulp surrounding the seeds agreed with the graphic description given of it by Wallace, but the odour from it was so strong that it was again ordered out to the bath-room and the door shut on it. I took a section of it into the *Observer* Office for

the editor's inspection, and that of visitors, but when the inmates of that office "*felt the smell*" of the Durian, it was ordered out, and the attenuated odour of it was endured at a distance!

The name of the tree which produces this fruit is Durio zibethinus, Lin. The generic name Durio is derived from Duryon, the name of the fruit in the Malay language, which comes from Dury, a thorn, in the same language, in allusion to the prickly fruit. The fruit is used as a bait to entrap the civet-cat, which is very fond of it: hence the specific name.

The odour from the fruit is so strong and disagreeable that the Dutch ladies in Java decline to see visitors when eating this fruit and the message that they are eating Durians is sufficient explanation for their non-appearance.

It belongs to the section Sterculaceæ, or Bombaceæ of the natural order Malvaceæ, and in the first volume of the Flora of British India, p. 351, published in 1875, other two species are given besides this one, viz., Durio zibethinus, D. C., D. Malaccensis, Planch (perhaps the wild form of the Durian), and D. oxleyanus, Griff. A tall tree of Ceylon and Malacca is so like the Durian in many respects, that the late Dr. Gardner called it Durio Zeylanicus; but the late Dr. Wight had already figured and described it as Cullenia excelsa in honor of the late General Cullen, resident at the Court of Mysore? This is the Katu-hodu of the Sinhalese, and the Wild Durian of Ceylon.

Nearly every author from Rumphius and Dampier, have given full and particular accounts of this fruit, but the extracts appended will suffice.

W. F.

(*From the "Treasury of Botany."*)

The fruit varies in shape, being either globular or oval, and measures as much as ten inches in length; it has a thick hard rind, entirely covered with very strong sharp prickles, and is divided into five cells, each of which contains from one to four seeds, larger than pigeons' eggs, and completely enveloped in a firm luscious-looking cream-coloured pulp, which is the eatable portion of the fruit. This tree is very commonly cultivated throughout the Malayan Peninsula and Islands, where its fruit, during the period it is in season, forms the greatest part of the food of the natives. Considerable diversity of opinion exists among epicures as to the relative merits of several well-known tropical fruits, including the Durian, the mangosteen, the cherimoyer, and the pineapple, any one of which is made to occupy the foremost place, according to individual taste. The flavour of the Durian, however, is said to be perfectly unique, and it is also quite certain that no other fruit, either of tropical or temperate climes, combines in itself such a delicious flavour with such an abominably offensive odour—an odour commonly compared either with putrid animal matter, or with rotten onions. It might be supposed that a fruit possessing such an odour could never become a favourite; but is is said that when once the repugnance has been overcome, the Durian is sure to find favour, and that Europeans invariably become extremely fond of it. Mr. A. Wallace observes that 'a rich custard highly flavoured with almonds gives the best general idea of it, but there are occasional wafts of flavour that call to mind cream-cheese, onion-sauce, sherry wine, and other incongruous dishes. Then there is a rich glutinous smoothness in the pulp which nothing else possesses, but which adds to its delicacy. It is neither acid, nor sweet, nor juicy; yet it wants none of these qualities for it is in itself perfect. It produces no nausea or other bad effect, and the more you eat of it the less you feel inclined to stop. In fact, to eat Durians is a new sensation worth a voyage to the East to experience.' The unripe Durians are cooked as a vegetable, and the pulp of the ripe fruit is salted and preserved in jars; while the seeds are roasted and eaten like chestnuts. [A. S.]

(*From "Cameron's Malayan Peninsula."*)

Entitled, however, to some prominence as being fruits which are indigenous, and in a great measure peculiar to the island, are the mangosteen and durian. The first is the seductive apple of the East, far more delicious and delicate in flavour than its English prototype; by many it is declared, par excellence, the finest fruit in the east, if not in the world. The durian differs essentially in nature as in appearance from the mangosteen; it grows on a very tall, wide-spreading tree, and does not ripen on the extremity of the branches, but like the jack and some other fruits, drops by a short stalk from the trunk, and the thickest of the branches. It is somewhat less than a man's head in size; outside is a thick, prickly husk, in the inside chambers of which lie the sections of the fruit, consisting of a number of seeds of about the size of a walnut, surrounded by a soft, pulpy substance, like custard in appearance, which is the edible part. The taste of the fruit it is impossible to describe, but the smell of it, from which the flavour may be judged, is such that no gentleman in England would care about having one in his house; even in the Straits it is never set upon the table. The Malays and natives generally are passionately fond of it, and will go through any amount of hardship to procure it. A former King of Ava is said to have spent enormous sums to obtain constant supplies; and the present king keeps a steamer in Rangoon awaiting the arrival of supplies there. The fruit as soon as received is sent up the river as speedily as possible, to the capital 500 miles distant. With Europeans the liking for it is, I think, in all cases acquired; the first venture is generally made in bravado, and so singular is the fascination it possesses, that if the new arrival can overcome his repugnance sufficiently to swallow the coating of one or two seeds, he will in probability become strongly attached to it.

I do not think, however, that the most passionate lovers of durian are disposed to acknowledge their taste There is something decidedly unclean about the fruit; a tacit acknowledgment of this is, I think, to be gathered from the fact that it never appears on any gentleman's table, but is devoured in silence and solitude in an out-of-the-way part of the house, and a good bath indulged in afterwards. I cannot forget the exclamation of an old Scotch lady in Batavia, well-known there, when she saw a newly-arrived countryman of her own being sorely tempted to try the strength of his stomach on a full-grown durian.

"Maister Thampson! Maister Thompson! ye ma'na eat that; it'll no' agree wi' ye; and, besides, it's a maist unchaste fruit." The old lady was right and hit the proper expression.

(*Appendix.*)

Doorian—Durio zibethinus.—This fruit is well-known from the descriptions of travellers. Those who have overcome the prejudice excited by the disagreeable fœtid odour of the external shell, reckon it delicious. From experience, I can pronounce it the most luscious and the most fascinating fruit in the universe. The pulp covering the seeds, the only part eaten, excels the finest custards which could be prepared either by Ude or Kitchener. Bontius says it proves laxative, diuretic, and carminative; but when eaten in too great quantities, that it predisposes to inflammatory complaints. The natives consider it to possess aphrodisiac qualities. It is certainly in some measure exciting.

INJURY TO TEA FROM IRON?

2nd August 1886.

DEAR SIRS,—Much writing and controversy has for some time been going on in the local press about an inferior quality of tea now and for some months past being placed on the Colombo and London markets, and various reasons given as to its cause. An idea has struck me as to whether the much increased quantity of iron used in making machines sold recently by manufacturers and importers of rollers, driers, &c., in which iron comes in direct contact with the green and

moist leaf—whether this may not to a very great extent account for this falling-off in quality?

Colonel Money in his Essay on Tea says there is nothing more injurious to tea than iron coming into contact with it in its manufacture.

ENGINEER.

HOW A COOLY IS TO GET IN AN AVERAGE CROP OF TEA?

Ambagamuwa, 2nd Aug. 1886.

SIR,—In answer to your footnote to Mr. Burnett's letter in Saturday's issue, let us take the recognised task of a cooly and see how he is to get in an average crop. Say the cooly works 20 days a month for 9 months in the year at plucking=180 days. By "M. P. A." answer to this questions, made-tea costs 12 cents per lb.; green leaf is 3 cents; and the coolies' task is 12 lb. green leaf average which gives him 36 cents' pay per diem. So we have a cooly getting 3 lb. made-tea for 180 days=540 lb. per acre, an average crop? But then average cost per lb. of made-tea per acre does not exceed 12 cents per lb. when the yield is only 200 lb. per acre. So surely with 540 lb. he would pluck double the quantity of green leaf, say an average of 24 lb.=6 lb. made-tea (at 1½ cents and 6 cents per lb.) and a yield of 1,080 lb. per acre an average crop, Mr. Editor? and if with 540 lb per acre he can pluck 24 lb. how much more, and so on.

INFINITUM AD ABSURDUM.

ALLEGED DETERIORATION OF TEA.

Rookwood, Hewaheta, 3rd Aug. 1886.

DEAR SIR,—To supplement mine of yesterday, a friend lately out from home tells me he was assured, by a City tea expert, that the cause of the deterioration of Ceylon tea was due to the exhaustion of our soil, and to prove it, produced a sample of Rookwood, as one of the old marks—manufacture perfect, yet showing a poorish thin liquor. Now we know it has been stated by some few of the Indian planters that our teas would be but a flash in the pan. We had no soil to work on. "Worn-out and washed-out coffee estates turned into tea gardens, with no future before them," as remarked by the garden manager, then in London, to his directors a few years ago in answer to questions by them, the Lebong Tea Co., I think, but I am open to correction. And again tea existing on a thin covering of surface soil, formed of decomposed vegetable matter, subject to rapid exhaustion, and entire loss from wash on our steep land. Now with regard to the "actual proof" from its liquor, of the exhaustion of the Rookwood soil. How sudden this must have been! Up to the very last invoice before pruning we find its liquor commended, and the usual average price obtained as for that season. Invoice 1 of the new season—*i. e.* after pruning, shows liquor proving exhaustion of soil—how rapid! Poor Ceylon, truly we have no future before us; but how will our City man account for the sudden resuscitation of soil (not manured during the interval), six months after his sage remark, for if with good manufacture, but with persistently thin liquor, in invoice after invoice we have proof of exhaustion of soil, what will sudden improvement in liquor with the same style of plucking and manufacture go to prove?

Exhaustion of soil will take place without manure, but with tea this is so gradual as to be almost imperceptible to our generation. I cannot discover it with tea twenty-one years old, it is not apparent in its luxuriance of growth, and its liquor is as good now as it was ten years ago. Some of our Indian friends (practical Indian planters who have travelled through our various districts know better) think we are dependent on surface soil and worn-out coffee estates. Any real planter knows tea thinks but little of the surface soil, when it has once got hold of the ground; and while admitting that a very few of our worn-out coffee estates have been planted with tea, I do not think the proprietor himself, or the most sanguine of us expect them to last at a paying rate with increased age, and a lower market, whatever they may do at present; but their loss in the future will not affect our exports a decimal point. As for the rest, our coffee estates,—carefully selected land, always well worked, and with but little exhaustion from crops, and that little from the surface that we do not actually require for our tea,—will yet prove some of our best gardens. The very peculiarity of tea is our best safeguard, its taking its nourishment from where coffee never reached: it is, in fact, even in an old coffee estate growing, so far as it is concerned, in virgin soil. Wash we had to guard against with coffee, and if successful then, how much more so can we be with tea, where we can cut our drains closer, as we have not to be so careful of our surface moisture as with coffee. With ordinary care in selection of site, and with ordinary cultivation to follow, I can see an everlasting future before us, now as ever. Some of us, I believe myself among the number, have been accused of bombast, but I do not think we deserve this; all we wish for, I am sure, is, that the truth should be known concerning us, and if, before condemning our soil and prophesying our speedy downfall, those doing so had honestly inspected our various districts, and seen our tea growing, they could not have made the sweeping assertions they did, and publicly too. This letter may seem to apply more directly to my own garden. I do not mean it to do so in any way. It so happened, my own garden was brought forward by an expert in tea to prove exhaustion of our soil was the cause of the falling-off in our teas. I have endeavored to show the folly of this statement, which affects the whole island. I yesterday accounted for the temporary "falling off" in my liquor; add the market to this, the near future will prove I am right; and I would conclude by saying

1. Exhaustion of soil cannot be so sudden or so general as it must have been in Ceylon this year to be the cause of poorer liquor from young and old gardens alike.

2. It would show itself in the general growth of the bush and in yield as well as in liquor.

3. Without cultivation, *i.e.* manuring—and there has been none worth noting—exhaustion would continue, showing worse results as the season works on, and not better.—Yours faithfully,

C. SPEARMAN ARMSTRONG.

COFFEE: SPRING CROP PROSPECTS IN HAPUTALE.

4th August 1886.

SIR,—Your issue of last evening giving late returns of rainfall in Haputale, signifies another disastrously short crop there, *unless* the weather takes up *at once*. 30th July report is as follows:—

"We had a spell of 'fine' dry weather till the 28th when it rained at intervals nearly all day. It has been dry since then, and I hope it will continue so; otherwise I fear we must expect another bad crop." Since then, the reports by telegram (*vide* Post Office list) mention *nothing but rain*, heavy rain!!

The "Ultima Thule" correspondent (*nil desperandum*) who writes so confidently of coffee being yet "King" again, as regards *profits*, must try and explain the change of seasons when he writes

again. How many favourable "dry" seasons have been experienced in the last nine years in Uva. Coffee must have sun in due season or crops will always be disappointing, leaf-disease or no leaf-disease. The seasons have changed and there is no blinking our eyes to the fact: whenever good crops are got in Uva nowadays, it is by a sort of "fluke." As there can be now no dependence placed on our getting favourable blossoming seasons there, so no dependence can now be placed on our getting paying coffee crops. No matter how healthy and vigorous coffee may be, *it must have the sun in due season.* As regards prices, coffee looks grand now: this time next year we may see 'good Ceylon middling' again at

FIVE POUNDS PER CWT.

The Future of the Nilgiris.—The *South of India Observer* remarks:—"This district, we feel sure, has a great future before it. Before long the railway will be brought to Coonoor, if not to Ootacamund, and thus the trade of the place will be immensely increased. The coffee industry may revive; and it may play an important part in the district, and fortunes may be made. Gold may yet produce great results. The capabilities of the district are only just beginning to be discovered," and, finally, our contemporary thinks "the population is sure to be greatly increased when the railway has been established."

Coal in India.—The result of Dr. Warth's explorations in the Salt Range is, that he estimates at least 1,000,000 tons of coal may be obtained from the Dundote plateau, and at a recent conference it was decided to arrange for the practical working of the scheme. The coal is not of the best quality; but it is calculated that it can be delivered on the Punjab Northern section of the North-Western Railway at a cost of R6 per ton, and that its economic value as fuel will be R14 per ton, which will represent a saving on that section of the line amounting to R1,15,000 per annum. The North-Western Railway administration will work the colliery.—*M. Mail.*

Cinchona Plantations, after all, do not seem to be very highly valued in Java to judge by the following extract from the *Straits Times* (translated from a Java paper) received by this mail:—"The times at present are so hard in Java that, daily, estates, formerly valuable indeed, pass under the Auctioneer's hammer at ridiculously low prices. An allotment worth several thousands of guilders could only be disposed of for one hundred. A plantation stocked with superior varieties of Cinchona brought only twelve thousand guilders. So it goes on day after day. These properties mostly pass into the hands of Chinese. The outlook is indeed so gloomy that a general bankruptcy among the planting community is not at all improbable, unless prevented by unforeseen circumstances."

Aluminum Works and Corundum.—The Work of developing power on the creek and putting up the mammoth building for the aluminum manufactory (or aluminium if you want it decidedly English) is now far advanced. Hitherto the process of obtaining aluminum has been very expensive, through a combination of chemical agencies and heat. At the works the corundum will first be subjected to intense heat, then broken and ground to powder, after which it will be fused in hermetically sealed crucibles by the powerful electrical current generated by the employment of the largest dynamos that have ever been constructed. The product is the pure aluminum, of which the yield from the corundum is about 50 per cent. No doubt is entertained of the success of the electrical process, which, although so recent a discovery as not to be described scientifically in works, has been thoroughly tested. Large quantities of the alloy will also be manufactured at the works, requiring it is estimated, from 10 to 20 tons of copper a day when the works get to running to their full capacity. As a very serviceable alloy may be made with only five per cent of aluminum, it is evident that a very large amount of copper will be required.—*Lockport Union.* [As Ceylon is rich in corundum, we may probably see the substance utilized some day for the production of the light white metal.—Ed.]

The Neilgherry Company.—The London correspondent of the *Times of India* gives the following:—"The Neilgherry Company, Limited, has been incorporated with a capital of £100,000 in £1 shares, of which 30,000 are reserved in part payment to the vendor, and the balance has been offered for subscription here this week at par. The Company has been formed for the purpose of acquiring, carrying on, and extending the business of the Neilgherry and Southern India Lands Investment Company, Limited, (which was established in 1878, for the purpose of advancing money on the security of coffee and other estates) and to acquire in addition, under a separate agreement with the Agra Bank, Limited, coffee cleaning works at Coimbatore and Beypore. Also to carry on a general agency business in Southern India, making advances on coffee, tea, cinchona, rhea grass, and other produce, preparing, curing, shipping and forwarding, selling same on commission. The prospectus states that the coffee cleaning works are fully supplied with modern machinery in complete working order. The Coimbatore establishment is represented to be very advantageously situated on the plains at the foot of the Neilgherry hills, adjoining a station on the Madras Railway, and commanding not only the coffee from the Neilgherries, but also from the Kotagherries, Anamalais, Koondahs and Shevaroys. The works at Beypore are situated at the mouth of the Beypore river, whence the produce at Coimbatore and the Wynaad is shipped on board the steamers for the London market. By thus combining the business of the Investment Company with that of coffee cleaning, shipping, and selling on commission, the Directors are satisfied that a safe and profitable business will result. The income of the Company will be derived from the following sources, among others: 1.—Interest on investments on mortgage (9 to 10 per cent is the current rate). 2. Interest on advances against hypothecations of crops. 3. Commission for financing crops. 4. Cleaning, curing, and transporting crops. 5. Commission on sale of crops. The Directors say that a careful consideration of the figures laid before them justifies the expectation of earning a dividend of at least 10 per cent, besides providing for a substantial reserve fund. This was the rate of dividend (free of income-tax), paid by the old Company—whose business was limited by its memorandum and articles of association to advancing money on mortgages of estates only for the years 1881, 1882 and 1883. The head-quarters of the Company in India will be at Coimbatore, and its affairs there will be under the management of Mr. William Cottrell who has had many years' experience in the business contemplated, and who is now on the spot. The directors are:—Mr. D. F. Carmichael, late Senior Member of Council, Madras; Captain P. H. Hiwett; Mr. William Maylor, late of Messrs. Pierce, Leslie & Co., Malabar Coast and London; and (after allotment) Mr. G. R. Briggs of Messrs. Livingston, Briggs & Co., Directors of Neilgherry and Southern India Lands Investment Company Limited. I should mention that among other assets to be acquired are forty-nine mortgages upon properties in Southern India representing a total of £19,035, which the Company is to get for £10,175; and the total price to be paid is £50,000—exclusive, I read, of the price of the coffee curing business of Stanes & Co. to be taken over from the Agra Bank."—*South of India Observer.*

PRACTICAL HINTS ABOUT TEA.

(By an Old Hand.)

HOW TO GERMINATE SEED.—Choose the sunniest slope you can, near water; form beds 2½ or three feet in width; put a margin of boards round the bed, level carefully the surface, making it firm; on this lay a layer of clean river sand two inches deep, on this lay the seed *two seeds deep;* over this another layer of clean sand 1 to 1½ inches; afterwards cover with mana grass to the depth of an inch, water well twice a day; as soon as the seed shows the direction of the root germ, then plant into nursery beds, taking care the seed in no case be put deeper in the soil than one inch; then shade with fern and keep well watered till fairly above ground.

WHEN AND WHAT TEA PLANTS SHOULD BE PLANTED.—A plant of 12 or 14 months old, stumped in the nursery before being removed for planting with every root carefully preserved and put into a hole sufficiently large to receive it without doubling any of the roots, is in my opinion the perfection of a plant. Then, again, a plant well-grown at 6 or 7 months old, when it can be removed with all its roots entire stands a better chance than an older plant, the roots of which will be injured more or less, even with the greatest care, in removal from the nursery. These are the plants which one sees to stand still for six months after planting, many of them losing their leaves owing to evaporation from the plant being greater than its own powder of absorption from the soil: in a word keep your plants till they are ready for stumping, or plant them out of a well-prepared bed entire when six to even months old.

AGRICOLA.

SUGAR IN JAVA.

(Translated for the *Straits Times.*)

There is every prospect of the sugar yield in Java proving a source of heavy loss to growers there this year; prices now for No. 14 have fallen to even 8½ guilders per picul. At this price sugar growing will soon cease to pay, especially now that the burden of taxation on the planting community has been rendered still more grievous by heavier auction dues and enhanced import duties reaching 10 per cent. The power of the people to bear the additional taxation, so says the *Sourabaya Courant* has become so enfeebled that the taxes collected in the first five months of this year show an alarming falling-off. The import duties alone compared with the corresponding period of last year show a decrease estimated at 234,000 guilders. Statistics of piece goods imported show conclusively that articles formerly in demand only find buyers now when of inferior quality.

REVIEW OF THE AUSTRALIAN TEA SEASON OF 1885-1886.

In view of the early opening of the new tea season on this side (probably about the 10th July), we take our usual retrospective glance of the operations in the tea market during the last twelve months ending 30th June 1886.

The total import into all the colonies and from all quarters amounted during the following seasons to, say:—

	lb.
1885-86	23,498,882
1884-85	20,780,816
1883-84	16,350,289
1882-83	22,564,831

The imports for season 1882-83 proved excessive, and were only adjusted by the light imports during 1883-84; and taking the result of the three years' imports from 1882 to 1885, it appears evident that when imports exceed 20,000,000 lb. weight the quantity is in excess of the present colonial requirements, and loss must result to importers, and this proved no exception during the season just closed.

INDIAN TEAS.—Mr. J. Osland Moody reports:—The exports from Calcutta to Australia and New Zealand for the last four years, from 1st May to 30th April stand thus:—

	lb.
1886	1,729,517
1885	1,525,982
1884	340,613
1883	2,723,268

showing a steady increase over the last two years, though not equal in quantity to season 1883.

For the same period the following are the shipments to Great Britain:—

	lb.
1886	65,858,071
1885	61,570,719
1884	58,067,180

showing a large and steady increase, whilst the export from Ceylon alone now reaches 4,500,000 lb., and is advancing by rapid strides to the front as a large producing country and of the highest class of teas.

CEYLON TEAS continue to find their best market in Great Britain, and lead the van in prices. So little comes here they are not worth noticing.

JAPAN TEAS continue to be imported to trifling extent, but show no movement in price quality.—*Melbourne Age*, July 1st.

THE ALLIGATOR-APPLE, ANONA POLUSTRIS, L. PRODUCING RIPE FRUIT IN COLOMBO.

Of the custard apple order (Anonaceæ) we have in Ceylon the large prickly sour sop, Anona muricata, L. The custard apple, or bullock's heart, A. reticulata, L, which tastes like a custard mixed with some gritty matter in it. The sweet sop, called in Ceylon, the custard apple, A. squamosa L., and I understand the cherimoyer, A. Cherimolia, Dun., grows at Peradeniya and Henaratgoda, but I have not heard of their bearing fruit in Ceylon. I now send you a ripe fruit of the alligator apple, Anona polustris, L., grown in the Circular near the Museum. This fruit as you will see is a good deal like the bullock's heart in shape, but much smaller in size, and having a good deal of the fragrance of a ripe apple. It is of a light yellow color, and perfectly smooth like a mango. The small tree or large shrub from which this has been taken has about two dozen more on it. From the "Official Guide to the Museums of Economic Botany, of the Royal Gardens Kew" I take the following short notice of this plant and its fruit:—"A small tree abundant on marshy shores in Jamaica; the fruit said to be narcotic and even poisonous, is eaten by alligators as it drops; the wood known as corkwood, is used for stopping bottles and lining boxess." Mr. Nock no doubt can tell you if it is eaten in Jamaica. The cherimoyer is spontaneous from Peru to Mexico, and has been naturalised in Jamaica, all the others mentioned here are natives of Jamaica and some of the other islands of the West Indies, but none are natives of Ceylon or India.

W. F.

WHITE CASTOR CAKE AS A MANURE FOR TEA AND COFFEE PLANTERS.

Mr. John Hughes, the wellknown Agricultural Chemist, never omits an opportunity of supplying useful information through the *Tropical Agriculturist* to the planters of Ceylon and India. From the following contribution it is evident that equally for tea as for coffee, white castor cake, rich in mitrogen, potash and phosphoric acid, is one of the best manures which can be used:—

79, Mark Lane, London, E. C., 10th July 1886.

During my residence in Colombo in 1878 several analyses of the abovenamed cake were made by

myself on behalf of the Planters' Association, and the results are to be found on page 15 of my official report. These analyses, however, deal only with the organic constituents, and give the proportions of oil, albuminous compounds, mucilage, fibre, &c., and do not afford information respecting the chemical composition of the mineral portion or ash of the cake. I have therefore obtained a fair average sample direct from India and hope the particulars of the analyses may be of interest to the readers of the *T. A.*:—

In 100 parts of white castor cake:—	
Water	7·94
InOrganic matter (containing Nitrogen 7·55)	85·17
Mineral matter*	6·89
	100·00

It will be noticed from these results that while castor cake is very rich in nitrogen, containing indeed twice as much of this valuable constituent as ordinary bone dust, and five times as much as would be found in 100 lb. of parchment coffee; so that the application of 100 lb. of this cake should supply as much nitrogen as could be removed by 500 lb. of parchment coffee. Further, the mineral portion (6·89) is twice as much as I found in well-prepared parchment coffee from the neighbourhood of Badulla (see page 110 of my report) which contained 3·30 per cent of ash or mineral matter; so that as regards these constituents castor should be well adapted to supply a very large portion of the mineral constituents of coffee even supposing the soil did not do so as is usually the case.

Thus, in every 100 parts of cake I find 2·68 of phosphoric acid as against ·26 in 100 parts of the coffee and 1·35 of potash, against 1·34 in coffee (which is practically the same), soda ·67 against ·06, and, lastly, ·50 of lime against ·19 in coffee.

Castor cake yields an ash specially rich in phosphates of potash, lime and soda, and these exist moreover in a form readily available as plant food as fast as the cake becomes decomposed in the soil. For comparison with the leaves of the coffee tree, I may mention that in every 100 parts of partially dried healthy leaves I found by analysis:—

Water	9·75
Organic matter (containing Nitrogen 2·67)	82·65
Mineral matter†	7·60
	100·00

* Consisting of:—

Phosphoric Acid	2·68
Potash	1·35
Soda	·67
Lime	·50
Magnesia	·28
Sulphuric Acid	·12
Chlorine	·07
Oxides of Iron and Alumina	·29
Quartz sand	·93
	6·89

† Consisting of:—

Potash	2·08
Lime	1·69

From these results it will be seen that coffee leaves, are really far more exhausting to the land than the parchment coffee, and if the tree can produce plenty of leaf naturally, no manure should be necessary in order to produce the coffee bean or seed which in this case is certainly not an exhausting crop. Planters know from sad experience the baneful effect of wind and wash which strips off the leaves and hurries them off down to the nearest stream.

It is well however to remember that these leaves if gathered green and made into composts with a little lime, will furnish an excellent natural manure as will readily be seen if the results of the above analysis are compared with those of castor cake. These leaves contained 2·67 of nitrogen or nearly ⅓ of that in castor, while the lime 1·69 and potash 2·08 are both in considerable excess of that found in the cake. In phosphoric acid however the leaves are much poorer, there being only ·35 against 2·08 in white castor which is certainly a most useful cake for supplying phosphates as well as very rich in nitrogen.

In looking out for valuable manuring materials planters should therefore look well to the chemical composition of the several *substitutes* for the grand and universal manure namely *farmyard-dung* which has been the only one employed to any extent in ages past and which, as regards its general character, may be taken as a safe guide to the planter abroad as well as to the farmer at home.

We must examine the composition of the ash or mineral portion as well as the amount of nitrogen yielded by cakes and manures, for, as we have seen in the case of white castor cake, every 100 lb. of the cake supplies 2·68 of phosphoric acid which is equal to 5·85 lb. of phosphate of lime or as much as would be found in 1,000 lb. of parchment coffee. JOHN HUGHES, F.C.S.

THE *T. A.*—I have always looked upon the *Tropical Agriculturist* as a "standard work," and as such it is a book of reference to be placed on the planter's book-shelf.—*Planter.*

NITRIFICATION IN SOILS.—Dr. Taylor, Editor of *Science Gossip*, in writing to the Melbourne *Argus* makes the following remarks on this important subject:—

Among agriculturists possessed of genuine scientific tastes, there are few subjects regarded with more interest than the relation of free nitrogen to soils. The discovery that nitrifictation in soils was due to organisms whose activity can be arrested by chloroform, so that no nitrification takes place when their vitality is thus suspended, has made the inquiry more interesting than ever. The French chemists have always distinguished themselves in researches relating to this subject, as everybody knows who has studied Professor Ville's work on artificial manures. Recently the attention of the French Academy has been directed to it. Messrs. Bertholet and Andre have been at work upon it for many years past. Lately they have been concerned in finding out some means of indicating the proportion of nitrificatory organisms in different soils, and they conclude that some idea of their abundance may be formed by a quantitative analysis of the carbon entering into the constitution of their tissues. It is inferred generally that the analysis of the ammonia present in the soils should be made without any dessication, and that arable land (when watered) tends continually to liberate the ammonia of the ammoniacal salts contained in it.

THE DETERIORATION OF TEA.

SIR.—The question of the causes of deterioration of Ceylon tea must always be a very important one to planters, and one which cannot be investigated too thoroughly. Evidence now appears to be forthcoming to show that it is no mere cry of the London dealer in the usual depreciatory manner of the buyer. I have now been more or less a tea-maker for the past four years, having had varied experience during that time, and think I can account for the falling-off in strength, this being the chief cause of complaint.

To those who have not fully investigated the growth of plants it is usual to believe that the leaves simply act the part of the lungs, and that their various other economies are performed chiefly by other organs, such as the branches, trunk, and roots. Now, the life of a tree is first its leaves, and then its roots. The terminations of the latter, called spongioles, have almost an equal importance, being rather more to a plant than the mouth of an animal, as they have some potent affinity for the nourishment they assimilate. The roots of some plants can penetrate tolerably hard rocks—the olive; for instance—and anyone who has had much experience of manuring with coarse bone-pieces will frequently have observed the facility with which even a coffee-root can pierce through a hard, flat piece of bone.

The leaves are, however, of really more importance; not only do they inhale and exhale, but they elaborate the sap. Thus, besides being lungs, they are the chief digestive organs of the plant. It may be said that whatever good comes out of the tea plant, whether in shoots or seed, is the result of the elaboration of the sap in the leaf cells, and this elaboration progresses more or less perfectly according to the health and vigour of the tree. In a throughly healthy individual, the foliage will be more or less profuse, and, where it is scant or unhealthy, there will also be a corresponding failure of the sap, which naturally will fall off in either quantity, or quality, or both. In this it will be very like a much vexed matter of domestic economy—our milch cow. We all know how difficult it is to get our quantum of good milk, and the sooner we apprehend the position that abundance of milk usually means an abundance of good food, so much sooner do we benefit by carrying out the principle.

The first external indication we have of a tree being unhealthy is its foliage, and immediately afterwards there will always be a corresponding unhealthiness in the roots. Indeed, the injury is felt throughout the whole organism. As with animals, some kind of plants have a greater recuperative power than others. We say of a cat that it has nine lives. Our experience also shews us how difficult weeds are to kill; yet I fancy if we grew a weed as a cultivated plant, and continually deprived it of its leaves and young shoots which have very much the same function as the leaves, it will soon indicate all the delicacy of a cultivated plant, and if we continued our harsh treatment over a period of years it would probably develop a disease injurious to all individuals of its race, and in this manner might become a very delicate plant to grow.

Tea is one of the most robust plants in the vegetable kingdom. It will not die out in scrub and weeds. If cut down, it shoots up with great vigour; its recuperative powers are prodigious. If growing amongst grass, the latter may be fired, and the tea will all shoot out afresh.

It is, however, apparent to all that, after tea bushes have been cut down, the first shoots, when manufactured, produce a very thin infusion, and I would ask whether this may not be owing to scantly foliage. As I have said, the tea plant has a strong, vitality, it bursts out into renewed life with all apparent vigour, but does not this shew that it is abnormal and that something is wanting? Most certainly there must be a great shock to the plant throughout its entire system; sometimes we notice here and there a bush which does not recover.

There is much importance to be attached to what Mr. Rutherford asserted in his letter; that where tea bore well, manuring would be necessary. Of course, where soil is rich with manure applied, the means of rapid recovery are easier for the plant; yet all considered, even allowing the most valuable constituents of the soil to be present in almost any quantity, the foliage of the plant must to an extent be maintained. Leaf-disease shows how absolutely necessary leaves are to coffee; so it is with tea.

I consider, whatever task you put upon a perennial tree or plant, whether it be in yielding seed or leaf-that there must be an adequate foliage to perform the economies necessary for the effectual production of this leaf or seed; that, if the foliage be insufficient, the produce will naturally be wanting, and I believe this has more to do with the falling off of the strength of Ceylon tea than any other cause I know. The Israelites found it hard to make bricks without straw; an animal would not survive being deprived of the whole of its lungs and the greater portion of its organs of digestion; yet we expect a tea plant to live, thrive, and yield us leaf shorn of both of these. The only wonder to me is, why does not strike, work altogether, collapse and die, or cease to be productive, like our coffee. Unless we are more lenient to it this may eventually result.

There is without doubt much in the manure theory, but I believe far more in our treatment of the organism itself, the first consideration. As far as my experience goes, I have never obtained good tea except from good foliaged bushes, and I believe before long we shall see much lighter pruning adopted throughout the island, or, possibly two light instead of one heavy pruning in the twelve months.—W. F. L.—Local "Times."

No. II.

SIR,—With regard to the alleged deterioration of Ceylon teas, allow me, in the spirit that in the multitude of counsellors there is wisdom, to make the following remarks. To say the least of it, it is peculiar that every new field's teas, on introduction, have attracted considerable attention, and produced the highest prices in their early start. Few, however, have been able to retain this favourable position for more than a season. Indian planters remember this was the case with the Dooars gardens, for, when their teas came in limited quantity, buyers seemed to desire nothing else than the strongest liquors for which they are so noted. Planters in Darjeeling, the Terai, Cachar, Sylhet, and, lastly Assam, were furnished with Dooars samples as guides. Every one setting to work to produce the requisite article—some vain enough to imagine they had succeeded—were surprized to find that the success attained in the Dooars only lasted a season, for the following year Darjeelings were required for flavor only. Most then attempted to give their teas Darjeeling character. Few arrived at this happy climax, when, in the next season, Assams were in demand, and their selling price above all others.

The majority of Indian planters now recognize that the market is always capricious. Some usually get good prices, and all, especially at the commencement of the season, strive by the most careful plucking and manufacture to force their mark into position.

Truly, there is every excuse for many Ceylon men believing that this season's teas are so inferior simply because fetching pence below last year's average, and doubtless will attribute it to every cause but the right—prices have gone down. What has been apparent to all outside of the island for so long is a fact, namely, *quite fancy prices were being paid for Ceylon parcels.*

When things settle down at home, probably these teas will regain favor; but that they will speedily reach the enormous figures paid when the supply was uncertain, the large acreage coming into bearing in the near future should forbid the most sanguine to expect.

In the meanwhile, the hints dropped by Mr. Gow regarding the bushes having a browsed and broom-like appearance, and being consequently incapable of putting forth shoots (flushing) suitable for making

superior tea, may or may not be affecting the quality and should commend itself to serious notice.

When the late Mr. Cameron came to this island to find its resources at the lowest ebb, coffee and cinchona almost dying out, with some land under tea doing little or nothing because not properly understood, he started to show what tea would immediately yield—*to show that he could do something with it, and that quickly.* It was indeed a bold stroke and deserved success which dicated such close (the closest possible) picking, *actually taking the half of every leaf the tree put forth in flushing* (*where he had not already taken the whole one*). The outturns procured were in many instances as fabulous as the prices obtained.

Assuredly the end justified the means; the prices would have compensated handsomely, and, what is more, the gardens stood it wonderfully well. Mr. Cameron knew rightly that places in India, with the combined effects of droughts, hailstorms, excessive heat alternating with bitter cold, not to mention blights, could scarcely have lived under such treatment. Certainly, their outturns would never have been what they are. He had here a better climate to work on, but even this advantage may be abused by this kind of treatment.

It becomes now a moot question—how long it may be carried on with impunity (comparatively) here?

When thus put before those interested, many unhesitatingly tell you that they do not cultivate the bushes for appearance, nor yet for posterity; some even go so far as to inquire what posterity has done for them? Met with such reprovals, how difficult Mr. Gow will find it to advocate more gentle treatment of the bushes, more especially when he will be told that the soil here is wanting in depth and quality, as found in other fields. Is not this, though, the strongest possible plea in favor of the more rational treatment of the plant?

The system of picking, which by long teaching finds most followers in India generally, is probably the best, because, costing little, the bushes can, whilst yielding both quality and quantity, do so with the least possible injury to themselves.

Thus, after pruning, the bushes are allowed to run, say, from five to seven leaves and a bud. Some shoots mostly in the centre of the bush, at once outstrip the rest. It becomes necessary to check them, and those that have reached the desired number of leaves may be ripped, taking one leaf and a bud as nearly as possible at the union of stem and leaf; in a week or ten days (providing they are not side shoots) more are ready, and should be taken.

Coolies will not bring in large quantities at this rate. They should not be expected to do so, for the object is to form the bush: thus the most careful picking is required at this stage; that is, when the bush is making what will eventually be pruning wood, upon which depends the season's, as well as the following season's, crop. Any care expended upon it is afterwards amply repaid. After these shoots are more or less uniform in height—that is, each stem having as nearly as possible the same number of leaves, it will be found that, from the two upper leaves of the ripped stems, the primary useful (so to speak flush) comes. These are allowed to run, say, to four or five leaves and a bud. At this time the side shoots will, stand in danger of being broken; so they are taken, and with these two leaves and a bud from the four or five leaves of the primary shoots, when at least two leaves whole (some count the eye as one) should be left. These two leaves will in turn put forth other shoots or flush. In short, for the first ten or twelve rounds the pickers require special attention to prevent them nibbling or picking young undeveloped shoots, which is never overlooked. Later in the season, however, it ceases to be of such importance. Every cooly is paid according to the quantity (with due regard to quality) of the leaf plucked, and then it does not signify so long as one leaf is left.

And now, mark: the picking of half leaves is never encouraged (it is doubtful whether it ever withers or ferments well), there being always in the season a sufficiency of mature leaves ready for the weekly plucking; if not, the number of pluckers is diminished. Should it occasionally happen (through drought or blight) that there is little, or no leaf, there is nothing left but to wait for it. What is put off, or has to be waited for, is not lost. In the same way little notice is taken of bangy bushes or shoots. By leaving them they right themselves in time. If taken off, the second leaf is nearly always hard; any way it is impossible to make good tippy tea with bangy leaf.

The application with some modification (say less whole leaves, but leaving entire leaves and not persistently tearing every leaf in half) of the Indian system, which is the outcome in many cases of dearly-bought experience, is about the only way of preventing the browsed apperance complained of, which must in time materially decrease the outturn in Ceylon, or, it may be, worse—bring some dreadful blight in its train, and make the balance unworkable by killing out half the plants.

The worst that can result from a fair trial of the modified system is that tea thus treated may require more frequent (it may be yearly) light pruning, and possibly let us hope give partial exemption from heavy pruning with a good, if not superior, all round tea at some cents per lb. cheaper.

With a climate perhaps second to none in suitability for tea, proximity and cheap carriage to port of shipment, which give at once cents. per lb. advantage in every lb. manufactured, the only danger in the race for wealth appears to be that of killing or crippling the goose from which all expect the golden eggs.—J. E. L. H.—Local "Times."

July 22, 1886.

[The impression created by this letter is that in India now, half leaves are not plucked. Is that generally the fact, and has the practice of taking only whole leaves extended to Ceylon? Is it beyond doubt that half leaves do not ferment well?—ED.]

1,200 ACRES OF TEA in one proprietor's hands is a good deal, but this is the fortunate case of Mr. Jas. Blackett of Dolosbage who, moreover, has the satisfaction of knowing that his fine-looking fields are all grown from a good jât of tea and all promise luxuriant crops of good leaf.

TEA ROLLING.—A planting correspondent writes:—I have just heard that J. McInnes, Walker & Greig's Manager in Badulla, has finished a hand-roller suitable for small tea estates. He expects it to roll from 80 to 90 lb. of leaf an hour and the probable cost of the machine will be about *R150*, so small is the roller that 2 coolies can carry it.

THE VINE ON OUR MOUTAIN PLATEAUX.—We understand that Mr. Gordon Grinlinton has been successful in growing grapes of a fair quality at Portswood near Nuwara Eliya. This is the first time we have heard of the vine fruiting at so high an elevation in Ceylon. Jaffna and Dumbara are usually the situations associated with grapes, although the climate and soil of Uva in many parts ought to be admirably adapted for vine culture.

CASSIA LIGNEA AND THE CHINAMEN.—According to the report of the Superintendent of the Afforestation Department of Hong Kong for 1885, there is a great difficulty in growing this tree, as the following extract from the report will show:—"The plantations of Cassia Lignea that were made on the hills north of Aberdeen would probably have been in a thriving condition by this time but for the persistence of the Chinese in breaking off the leaves and branches of the plants. They appear to attach some importance to the plant as a medicine, and despite the vigilance of the forest guards, they succeed in keeping the plants in an almost leafless condition. Even in the Botanic Gardens, where the plants are protected by iron tree-guards and wire netting, they have killed several plants by presistently defoliating them and wrenching off the branches."—*Gardeners' Chronicle.*

MORE ABOUT INSECT POWDER.

STOCKTON, Cal., JUNE 4.

TO THE EDITOR OIL, PAINT AND DRUG REPORTER.

In your issue of May 26, you published an article from the *Druggist's Circular* under the caption of "The Truth About Insect Powder," which we have read with interest as it is a fair statement of the qualities of different kinds of insect powder now upon the market.

The writer of the aforesaid article has however failed to explain how that powder manufactured from flowers similar in appearance and condition, may materially vary in strength and power as an insecticide.

Having been engaged for several years in cultivating the plants and manufacturing the powder therefrom, we have ascertained that much depends upon the conditions of the atmosphere during the time the plant is maturing and while the flowers are being dried after they are picked. The value of the powder depends upon the quantity of essential oil contained in the flowers of the plant. This oil is partially soluble in water and when rains or heavy dews fall upon the plant, while the flowers are maturing or while they are being dried, the effect is particularly injurious to the powder. Consequently the dryer the atmosphere during the time the plant is in blossom and afterward while the flowers are being dried for grinding, the stronger and more effective will be the powder produced therefrom. Powder made from flowers that have been grown and cured under favorable conditions, may be kept in cans hermetically sealed for years without losing its insect destroying properties, and consumers of the powder will always find it cheaper and more satisfactory to purchase in cans rather than in bulk, and if but a limited quantity is used they had better purchase in small cans, and there is no reason why the smaller packages should not be kept by all dealers,

BUBACH PRODUCING AND MANF'G CO.

COLLECTING THE ORANGE FLOWER CROP IN FRANCE.*

BY I. CREUSE.

The usual time beginning the collection of the crop on the Mediterranean shore is from April 25 to May 1, and the gathering lasts about one month or five weeks. The quantity gathered, rather small at first, gradually increases, and after May 10 reaches its full proportion.

The orange tree, indigenous in India, is thought to have reached Arabia towards the end of the ninth century, but made its appearance in southern France only during the sixteenth; at least, such is the period at which it began to be mentioned. At any rate, the orange groves of the vicininy of Hyères were in 1556 reported to have the appearance of large forests, and the trees were equally cultivated at St. Chamas, Fréjus, Cannes, Vallauris, Aix, and in Marseilles itself.

At present Vallauris, whose name apparently comes from *Vallum aurantii*, or its Provençal equivalent, is the headquarters of the orange flower industry, and has lately acquired considerable importance. The climate of the place, being a very temperate one, is quite favourable to the cultivation of the orange trees. As no less than fifteen distilleries for making orange flower water and neroli are located in Vallauris, the town may justly claim to be the centre of this sort of manufacture.

The picking of the flowers employs no less than two thousand persons. As the crop usually averages one million kilograms, that is, one thousand tons, its importance, notwithstanding the variations of prices, is easily understood as a source of revenue for the localities where the orange tree is grown for its flowers alone. The variety cultivated is the *bigaradier*, or bitter orange, producing very fragrant blossoms but bitter fruits. From 1880 to 1882 orange flowers sold from thirty to sixty francs a hundred kilos. In 1883, frost having destroyed most of the crop, the prices rose to three hundred and sixty francs; but last year it remained between seventy-five and one hundred francs. The coming crop promises to be fair. Some groves have suffered from frosts, but the evil is not general, and there are good prospects of a fine quality of flowers.

The yield of neroli greatly varies according to the season when the flowers are collected. Those gathered at the beginning barely produce half a gram to the kilo of blooms (one-half of one per thousand), while near the end of May they afford one gram or more. Hence the average yearly yield of essential oil is seventy-five thousand kilos, or about one hundred and sixty-five thousand pounds. To this may be added from twelve to fifteen hundred tons of orange flower water which is produced at the same time as the essential oil.—*Pharmaceutical Journal.*

* From the *Drugists' Circular*, July.

CINCHONA BARK PROSPECTS.

As a general thing, operators in quinine are not disposed to place much faith in bark statistics, but they nevertheless have an influence in directing the market for the alkaloid. The excessive stock of barks in London is said to be a great bearish element, and that the declining tendency of quinine is to be attributed more to that fact than anything else, but the trouble is that figures are accepted as representing the supply and demand without proper investigation. A correspondent takes the Ceylon *Observer* to task for not placing London bark statistics in their true light, and explains that a large proportion of the stock is composed of old importations of Cuprean bark for which there is no demand, presumably on account of poor quality. The large number of packages usually reported as the London stock gives out an erroneous impression when not accompanied by an explanation. The correspondent in question reduces the actual stock at least twelve million pounds by giving the weights of the packages, many of which are serons weighing about one hundred and fifty pounds each, and cases of druggists' quills which do not average as a rule more than one hundred pounds each, and bales of Java bark weighing from one hundred to one hundred and fifty pounds each. The weight of the packages being over-estimated heretofore the stock was made to appear much larger than it really was.

By advices received last Saturday, we learn that operations in the Java field are exciting great interest in Ceylon, and planters in the latter place are seeking information from every channel possible to ascertain the future possibilities of competition. An anxious correspondent writes to the *Straits Times* for information on this point, and adds:—

As the future of the Java field is being watched with interest by quinine manufacturers, as well as planters in Ceylon and elsewhere, we give below an extract from a Java paper called the Sourabaya *Currant*, which gives a gloomy report from that section. Speaking of a disease attacking the roots of cinchona trees, in West Java, it says:

A letter from a Ceylon planter is published in the *Tropical Agriculturist* just to hand, in which he says:—

"Having had occasion to travel in several districts in search of a piece of land for cinchona, I was very much struck at the small area in cinchona chiefly in the olden districts—of course, I mean, compared to what it used to be two years ago. Most certainly Ceylon is not likely to export the quantity of bark that has lately overflowed the market, and so on.

Cinchona planters in Java are not taking kindly to the Amsterdam market, as they find it more to their interest to ship bark to London, owing to quick settlements, a more businesslike method, and higher prices realized for Java bark in the English metropolis. Amsterdam will not likely create a stir as a competitive bark market, for the present at least.

We have attempted in the above remarks to throw some light on a very dark subject, but the half has not been told. A veil of secresy covers the whole cinchona and quinine industries, and it cannot be lifted except by some one in the inner circle. Foreign papers don't seem to realize the importance of thoroughly

investigating the extent and prospects of cinchona planting, and are content to publish the usual board of trade statistics without question. The work will devolve upon an enterprising American paper.—*Oil, Paint and Drug Reporter.*

THE QUININE MARKET.

By the time the Reporter is published, the present anxiety over the probable outcome of the bark sale on Tuesday will either be relieved or deepened. The interest manifested in the developments on that day is unusual, and in some quarters there is a faint hope of a strengthened market, although every indication points directly against it in the shape of alleged immense shipments of bark, loss of confidence and demoralized traders. The bark market especially is characterized by an absence of confidence, which did not emanate so much from the increased supplies as from the manner of conducting business at the sales. Many operators in this market place little or no importance in the wired intelligence from abroad as to prices realized per unit for bark. They had their confidence shaken by evidence of crookedness to blind the unsuspecting public, and do not accept as reliable the tests as announced at the sales. This growing suspicion is confirmed by a correspondent in the current issue of the *Tropical Agriculturist* who calls attention to the wide difference in analysis and value between a test made by a chemist employed by the planter and the analysis and valuation made in London. The difference was twenty-two cents per pound! The first analysis showed a smaller amount and to every appearance was honest, but the second one was artificially increased with the evident intention of swindling the buyer. This experience however is rare; the alleged crookedness is generally the other way, and instead of the planter receiving the benefit, the buyer and commission agent are intrigued against him; for instance, we are informed from London that a seller of barks on commission received a handsome bribe to have his barks analyzed a much lower percentage than actually existed, and by this means they were sold for about one-half or one-third of their real value to a bark speculator.

Under these circumstances the quinine market would be indirectly influenced, and when all confidence is lost in the bark sale reports, their importance will cease as a barometer for quinine values. Not only has faith departed from the bark sales, but it is firmly believed that statistics are also doctored for effect; this belief has become so well grounded in some minds that very little reliance is placed in the periodical announcements of the position of barks. The quinine market, it is thought, will have to stand on its own merits independent of the crude material, but this is hardly possible.

The present situation is not very encouraging for business. Buyers of quinine could have loaded up last week at fifty cents for either spot or July and August shipment, but only a few availed themselves of the opportunity. Outside parties were rather anxious to release spot stocks at that price and cover with deliveries during next two months at same figure, but a halt was called on Saturday and holders were found to be firmer. This was caused by the action of one large holder who prevented a serious break in the market by withdrawing all supplies on Saturday and declining bids of fifty cents, which would have been gladly accepted on the day previous. This had the effect of changing the whole tone of of the market as the lowest figure quoted since then by outside holders was fifty-two cents. A portion of the supplies changing hands at fifty cents last week was on account of American manufacturers. At present writing, American brands are unchanged in price, but a lower range is expected to prevail if the declining tendency in barks is unchecked. In the meantime, three foreign brands are favoring buyers at lower figures than quoted this time last week.

The *Planters' Gazette* of Ceylon* in a recent issue warns barks shippers of the necessity of checking their supplies as much as possible until the market has time to right itself and adds:—"It is unlikely that the present depression in quinine and bark will be of long duration. It has its origin from one or two causes, the result of which will so react on both raw and manufactured articles as to curtail the supply, and so with the increased demand which time is sure to show, we may look for steady and progressive markets later in the year."—*Oil, Paint and Drug Reporter.*

THE COLONIAL EXHIBITION No. VI.

FIJI.—The products of these islands occupy a comparatively small space, and though there is but little of absolute novelty among them there are, nevertheless, some of considerable interest. The coconut and its products, as might be supposed, is fully represented, as well as Candle-nuts (Aleurites moluccanus), the oil of which is used for illuminating purposes; and Dilo-nuts, the kernels of Calophyllum inophyllum, from which an abundance of oil is obtained having a high reputation for the cure of rheumatism. Tapa cloths are also abundant, the entrances to the court being hung with curtains of this material, which, as our readers will know, is the beaten-out bark of the Paper Mulberry (Broussonetia papyrifera). Amongst the many valuable woods that are found in the Fiji islands the "Visa" and the Sandal-wood will attract most notice, for here is shown a canoe cut out of a solid "Vesi" trunk. The tree which furnishes is a leguminous one (Afzelia bijuga), and the wood is heavy, close and even grained, and of an intensely dark brown colour. The natives use it not only for canoes but also for pillars for houses, bowls in which to serve kava, war clubs, &c. The Sandal-wood (Santalum yazi) was, it is said, "at one time plentiful in various parts of Fiji; but in the early stage of settlement its destruction must have been most indiscriminate."

Under the name of Bandina Boxwood some blocks are shown of a remarkably hard wood, which appeared upon examination to be suitable for engraving purposes. It is, however, of a dark brown colour, which, it seems, unfits it for the better kind of work, Upon submitting a sample of this wood to an expert, he reported that the wood has no special claim in consequence of its dark colour. This, he says, considerably reduces the value, as it could only compete with inferior Box, which is at present supplied in sufficient quantity. He explains this objection by saying that "cutting upon wood is like drawing upon paper; if it is tinted, there must be a limit to the density of the tint, or your drawing will be absorbed by the tint upon which it is drawn. An engraver would have difficulty in observing his progress while doing his work." The plant producing this Bandina Boxwood is at present unknown, but it is stated that should it prove useful it could be had in any quantity up to two feet in diameter from Fiji, and the other outlying groups of islands in the Pacific.

Some fine masses of Kava root (Piper methysticum) are shown, also powdered Kava root. This, it will be remembered, is the source from whence the Fijian beverage called kava is made by masticating the root and ejecting and fermenting the saliva. It is known to have diuretic properties, and has latterly attracted some notice for its medicinal value in this country. Quite recently, indeed within the last few weeks, a spirit prepared from Kava root has appeared on sale at the refreshment bars in the Exhibition. It is a colourless liquid and is sold in square white glass, capsuled bottles, with labels fully describing its virtues. It is called Yagona, the finest Kava Schnapps, or aromatic gin, and its value is set forth as follows:—"The active principle of this agreeable and splendid beverage is prepared from the root of the Piper methysticum, a species of Pepper. The root is called Yagona by the natives of Fiji, and from

* *Tropical Agriculturist*, no doubt meant.—ED.]

it they make their national drink, which is diuretic rather than intoxicating. Yagona has been the Royal drink of the Fijian and Samoan chiefs from time immemorial, and it is to its constant use that chiefs and people alike owe their robust health, in spite of the depressing influence of their tropical climate. This premitive and unsophisticated liquor regulates the action of the internal organs; it possesses remarkable soothing properties; it is a health stimulant, an excellent brain-feeder, a wonderful restorer of faded energies and of exhausted nerve-power. It is a preventive to gout and rheumatism. To those engaged in heavy intellectual labour it gives renewed energy. It is a veritable Elixir of Life. As a diuretic it is unrivalled, and it imparts a purity to the blood."

If the general use of the "Yagona" should be the only result of the Exhibition, it will finally have fulfilled a great mission!

A little *Handbook to Fiji and Catalogue of the Exhibits* has been issued under the authority of the Executive Commissioner, the Hon. James E. Mason, M.I.C., and this contains some interesting facts on the culture of the Cocoanut, Cinchona, Coffee, Cotton, Sugar, Tea, Tobacco, &c. Of the latter we are told that though it flourishes in all the islands of Fiji, it is most largely cultivated, and reaches its greatest perfection in the "Colo," or highland provinces of Viti Leon. the largest island of the group. All sorts of Tobacco seed have been grown, including Virginia and Latakia. The natives smoke their tobacco rolled up into "saluka" or cigarettes, the wrapper used being the dry leaf of the Plantain. Connoisseurs are very particular in the choice of their wrappers, and will only use the leaves of certain sorts of Plantains. Tobacco is an important iota of native life. Without it and kava no import-discussion can be conducted.—*Gardeners' Chronicle.*

SOME STATISTICS ON THE QUININE INDUSTRY.

MEMPHIS, Tenn., May 26, 1886.

TO THE EDITOR OIL PAINT AND DRUG REPORTER.

We will esteem it quite a favor if you will answer for us as promptly as possible, the following questions bearing on the quinine trade:

1. What was the price of quinine in the United States when the duty was removed, July 1st, 1879?
2. What was quinine worth in London, Paris, Germany and Italy, July 1st, 1879, or when the duty was removed in the United States?
3. What was the product of cinchona bark in Ceylon, South America and Java, in 1869, 1879 and 1885?
4. What was the price of the bark in London from January 1st, 1877, to January 1st, 1886?
5. What caused the great reduction in the price of the bark?
6. Do American manufacturers get supplies from Ceylon, Java, or South America, or all?
7. What was the duty per ounce on quinine when it was made free?
8. What was the duty on the bark, or raw material?
9. Was there a duty on the bark as well as the quinine, when the duty on the latter was removed?
10. How much quinine has been imported into the United States since the duty was removed, say since July 1st, 1879?
11. How much has been exported since then?
12. Can you give the foreign product per annum of quinine?
13. Also the American, before and since the duty was removed?
14. What is the tariff on imported castor oil?

We no these are quite a long string of questions, but we are anxious for the information and will certainly appreciate any assistance you can render us in the matter. M.

[1. The highest price of quinine in 1879 was $3 60 and lowest, $2 60. When Congress removed the duty in July of that year the price of American quinine was $2 25 per ounce in bulk.

2. Complete information on this point is not to hand. The duty was no sooner removed in the United States than large quantities of foreign quinine were shipped here and with this increased movement, prices advanced abroad. The lowest price in London during 1879 was 9s and the highest 14s.

3. Ceylon is one of the main sources of supply for bark, and it has only been during the past ten years that the shipments from that place reached any appreciable amount. In 1861 the first seeds were received in Ceylon and in 1869 the export of bark was only 28 ounces, but in the season of 1882-3 the exports were 6,925,595 lb. and in the season of 1883-4 the exports were 11,500,000. For many years previously South America supplied all the bark used by quinine manufacturers of the world, but through the active exertions and costly experiments of the British and Dutch Governments, the cinchona plant was introduced from South America into the East Indies, Java and Ceylon, so that large quantities of bark are now obtained from these more recent sources of supply. We are unable to give the actual figures of production. The Java barks are growing in importance while South American are not held in such high favor.

4. The price of bark in London on January 1, 1885 was 8d per unit and same date this year 5d per unit. We have no information as to the market in previous years.

5. While the removal of the duty has been an important factor in the cheapening process of quinine and barks, it has by no means been the only cause. Supply and demand have to a great extent led to the reduction. Quinine is cheap today in England and on the continent of Europe as well as in the U. S., partly because cinchona bark is cheap, and the bark is cheap because of overproduction.

6. Almost exclusively from Ceylon.

7. Twenty per cent ad valorem.

8. In 1861 the duty on bark was ten per cent. until August of that year, when it was increased to 15 per cent. In July of the following year it was changed to 20 per cent and in 1870 cinchona bark was placed on the free list. On June 22, 1874 a discriminating duty was imposed on East Indian bark which was repealed in 1882, the act taking effect Jan. 1, 1883.

9. Answered in preceding paragraph.

10. The total imports of quinine into the United States since 1866 have been has follows:—

	Ounces.
1867	40,675
1868	117,996
1869	35,550
1870	10,861
1871	34,723
1872	7,970
1873	114,814
1874	68,097
1875	12,279
1876	22,746
1877	75,804
1878	17,549
1879	228,348
1880	416,998
1881	408,851
1882	795,495
1883	1,055,764
1884	1,263,732
1885	1,390,126

11. The exportation of quinine has been so light that no record has been kept of the amount. Not long since the stock here of a German brand was shipped back to be recrystalized to give it the appearance of other makes, but outside of this there has been no exporting business if we may except two lots of domestic sent to London last year as an experiment.

12. As we stated in the *Reporter* last March, some parties interested in the quinine market have undertaken the laborious and unfruitful task of figuring up the world's production of quinine, which has been an enigma ever since the industry was

started. From a reliable London source we get the following estimate of production for 1885.

	POUNDS.
United States	70,000
Germany	70,000
England	50,000
France	40,000
Italy	30,000
India (febrifuge)	10,000
Total	270,000

These figures were shown to some members of the trade in this city and it is hardly necessary to state that they were characterized a ridiculous. We were volunteered another estimate as follows:—

	POUNDS.
United States	100,000
Germany	120,000
England	27,000
France	30,000
Italy	35,000
India	10,000
Total	322,000

In August 1884, the *Reporter* published an interview with a gentleman who placed the total production of the world at 4,500,000 ounces, forty per cent. of which was consumed by the United States. The production of the latter at that time was estimated at 1,000,000 ounces, or 500,000 ounces less than before the removal of the duty. From those statements some one may be enabled to strike a happy medium and arrive at a closer estimate of the world's production.

13. Answered in the preceding paragraph.

15. The duty on castor oil is 80 cents per gallon. ED.]

PARING AND BURNING LAND.

This method of clearing land is of very ancient date, and is more generally resorted to by the agriculturist than the gardener, probably for this reason—that in a well kept garden the soil is kept at such a high state of efficiency by continuous manuring and constant cleaning as rarely to require any such radical treatment, for one of the principal advantages of paring and burning is, that in one operation it not only cleans the land but also manures it. In the formation of new gardens, however, and especially where the ground is overrun with noxious weeds and the coarser kinds of grasses, such as *Oo'oo* (Imperata cylindrica) and *Mootho* (Cyperus hexastachyus), this is frequently not only the most effectual but also the cheapest and most expeditious means of clearing the ground.

In carrying out the system of paring and burning, we must first consider what soils are suitable for the work, and our experience teaches us that light, sandy soils are not adapted for it, nor is it so much required for cleaning this kind of land, because these soils work freely, and therefore the grass and weeds are easily separated from the earth, and besides soils of this description rarely become so foul as those of a more tenacious nature. It is also difficult in practice to burn these soils, because when turves or bunches of grass grown upon these soils are cast on the fires they settle down so closely that the air is impeded in its circulation through the heap, consequently the fire burns slowly or goes out entirely. The soils best adapted for paring and burning, in order to obtain the full advantage of the process, are those of a strong calcareous nature, and most other clays, the object being to obtain manure as well as the destruction of weeds. We obtain important results by the residue or ashes of the stronger soils of any description, and especially those yielding a large amount of potash and carbonate of lime, each in varying proportions according to the composition of the soil before burning. In the process of burning, valuable ashes are obtained from the coarse grasses and other weeds the soil may contain. These weeds and grass when left in undisturbed possession of the soil, are the resort of various sorts of insects inimical to almost every kind of produce, and although these insects may be greatly disturbed by the ordinary process of culture, yet their entire destruction is only obtained by the action of smoke and fire in the case of paring and burning. The enemies to crops are really so numerous that it would be simply impossible to enumerate them all, but the chief of them consist of wire-worms, grubs, slugs and snails; all these will be destroyed entirely by paring and burning the land, especially if it is done by turfing and burning with as little disturbance as possible to the turves after being cut. We strongly advise the plan of paring as compared with cultivating before burning which is sometimes adopted, because the latter plan during tillage would so disturb the insects in their haunts and holes that many would escape and again hide themselves in the loose earth before the clods could be placed on the fires, but it is ortherwise when the surface is cut over by paring say to a depth of four to six inches, because in that case they would be but little disturbed in their hiding places before the turves where placed on the fires. This is one of the strongest reasons why the old style of paring and burning is still most advisable. We must now refer to the record of experimental investigations made on the subject by Dr. Voelcker, one of our greatest authorities upon may points and practices in agriculture and scientific farming. He says:—"I am prepared to adduce reasons founded upon analytical evidence and well-established agricultural experience, in support of my conviction, that paring and burning on some kinds of soils is not only a profitable operation, but that it is under certain circumstances by far the most rational plan of cultivation which can be adopted in our present state of knowledge for raising upon some kinds of land the largest amount of produce with the least expenditure of money. In connection with the policy of paring and burning we must expect to meet objections, and to encounter some opposition from both practical men and theorists also, the former through want of experience, and the latter through misapprehension of the teachings of science. Various classes of objectors have arisen from time to time. There have been three principal ones which we shall refer to separately. The first objectors condemn the practice because they say it destroys the organic or vegetable matters in the soil, and that it causes a waste of a most important classes of fertilising constituents. In reply we do not deny that vegetable matters are soil constituents under all circumstances, and prove more or less valuable as fertilisers; in fact well cultivated and productive soils invariably contain much organic matter, which circumstance has led many to suppose that the productiveness of the soil depended upon their relative proportions found therein. Not many years past it was customary for agricultural writers to estimate the relative state of fertility of different soils by determining the amount of humus or decomposed vegetable matters in each. This it must be understood is clearly contrary to reason and well ascertained facts, for there are soils which, like peaty lands, contain a large percentage of vegetable matter and yet are comparatively sterile. On the other hand there are very many fertile clay soils which contain hardly any humus and yet are highly productive, and which for this reason may with much advantage be subjected to the process of burning. The last objection we have to notice is on the ground of expense, and maintaining that it is more profitable to lay out money in the purchase of Guano, Superphosphates or other artificial manures than to spend it in paring and burning. In reply we may observe that the opinions of practical men on this subject furnish most reliable evidence that paring and burning, as practised by the best farmers in England, proves, conclusively that it has been found to be the most economical means of culture for many descriptions of crops."

We quote from Dr. Voelcker's essay on the subject, who observes: that "Numerous personal enquiries lead me to confirm the opinion expressed by Mr. Caird,

who says that the best farmers burn the most, and he rests his opinion on the testimony of several practical men. Amongst others things he mentions a field that had been broken up from its natural state just fifty years ago; it was then pared and burned and so started for the first crop of turnips, which supported the other crops of the course. The same process has since been seven times repeated; no manure of any kind had ever been applied, and yet the crops in each succeeding rotation had shown no signs of decreasing. The soil which lies on the limestone foundation is very thin, but not more so than when first broken up." We have quoted this because it is so much in accordance with our own practice in paring and burning, for, after spreading the ashes resulting from burning, we have never had occasion to apply manure of any kind for a number of years when the soil burned has been of a strong loam or clay nature. In again quoting Dr. Voelcker in respect of the mode of burning, he says:—"A certain degree of heat is necessary to induce a proper chemical action; but, as demonstrated by my former experiments, an excessive heat should be carefully avoided, inasmuch as it has the effect of rendering burnt clay again less soluble. It is no doubt for this reason that practical men recommend stifle burning, * for this prevents the heat of the heaps of burning soil becoming too intense, consequently stifle-burnt clay is always very porous, crumbles readily to powder, and is more easily soluble than clay burnt at a higher temperature." In accounting for the advantages of paring and burning, the changes in the organic matters of the soil must not be overlooked. Soils which are regularly pared and burned often contain much vegetable an organic matter, and afford therein fuel for burning a considerable quantity of the soil itself. It must be understood that the destruction by fire of the organic remains in heavy soils, far from doing any harm, is the most available and economical way of preventing their undue accumulation. The fire, we would observe, also destroys insects, their eggs and larvæ, as well as the seeds of weeds, bits of underground stems which, like those of many species of grasses, are apt to grow again, and which therefore cannot be disposed of so effectually as by burning; in short, nothing cleans land so cheaply and effectually as paring and burning.† We must now observe that the excess of undecomposed vegetable matters are found to be injurious to vegetation. Peaty soils furnish familier examples of this. In conclussion it must be understood that the destruction of vegetable matter in soils adapted for paring and burning is not attended with any evil consequences. Inert vegetable matter is changed by burning into highly effective mineral food for crops. Burning improves materially the mechanical condition of the strong soils by rendering them more porous and more easily cultivated. The ashes produced by paring and burning are especially useful to green crops, because they contain a large portion of phosphates and also potash, constituents which are known to promote in a high degree luxuriant growth.—*Indian Gardener.*

TROPICAL FRUITS.‡

Amongst objects of productive industry receiving attention at presant in our Colonial possessions, tropical fruits are at once the newest and most interesting of all. Many of these fruits are practically unknown in England in a fresh state, and hence before tropical fruits are largely consumed here, it is necessary to diffuse knowledge respecting them, and to render them as familliar to English home people as they are to their Colonial friends.

* Smouldering: pieces of wood, weeds and rubbish slowly burning under a covering of clay. If the fire is too brisk, there will be danger of the clay hardening into the consistence of brick.—ED

† Where fire cannot be applied, a dusting of quick lime will be beneficial.—ED.

‡ Abstract of a Paper read at a Conference held at the Colonial and Indian Exhibition on Tuesday, July 26. Mr. W. T. Thiselton Dyer, F.R.S., C.M.G., in the chair.

At the present Exhibition, owing to the suggestion of the Council of the Royal Horticultural Society, fresh fruits are shown from nearly every part of the British Empire. Thanks to the Colonial Market established in connection with the Exhibition, Oranges Lemons, and Grapes are shown from the Australian Colonies; Oranges of several kinds from Natal, fresh Coconuts from the West Coast of Africa, Pine-apples from Antigua. Bananas from Jamaica, Naseberries (Achras sapota), Avocado Pears, Papaws, Bread-fruit and limes from British Guiana; Melons from Barbados, Prickly Pears and Dates from British India, and most luscious Pine-apples from Singapore.

Although not exclusively a tropical fruit, the Orange is found and flourishes throughout the eastern and western Tropics. Taking this fruit as an example, it is remarkable what a large increase has taken place in the consumption of this fruit in the United Kingdom during the last fifteen years. In 1870 the number of Oranges imported into the United Kingdom was 80,000,000. In 1885 this number had increased to 500,000,000, or at the rate of fourteen per head of population. Dates are consumed to the extent of 5000 tons per annum, while Coconuts are imported by the shipload.

Being the nearest to England, as well as the most productive in the way of tropical fruits, the West Indian Islands naturally supply, and should supply, the English market more readily than any other. At the present day in the West Indian Islands the value of the fruit exported is nearly £400,000 per annum.

In Jamaica alone fruit is annually exported to the value of over a quarter of a million sterling—consisting chiefly of Bananas, Oranges, Pine-apples, and Coconuts. The Bahamas export chiefly Pine-apples, both fresh and canned, to the value of £50,000 per annum. Trinidad grows and exports chiefly Coconuts. British Honduras, connected by a mail route with New Orleans, exports Bananas, Coconuts, and Plantains to the value of £15,000 per annum. Montserrat is chiefly interested in Limes, and exports Limes and lime-juice to the annual value of £11,000. Dominiac exports Limes, Tamarinds, concentrated lime juice to the value of £40,000; while flat and sugary Antigua exports only Pine-apples, but those, though small, of very superior quality. From their geographical position it is only natural to suppose that a large proportion of the fruit of the West Indian islands finds its way to the United States and Canada, where there are nearly fifty millions of people, with all of whom fruit enters largely into their daily food.

The Banana (Musa sapientum) is the cheap fruit at present cultivated in the West Indies, and this fruit is the one which in the future will be more largely offered in the English market than any other. There are numerous varieties of this fruit under cultivation, the Martinique Banana is found the most profitable to grow for export, although a smaller fruit, known as the Fig Banana, is more luscious and more highly esteemed locally as a dessert fruit. Jamaica exports Bananas to the value of nearly £200,000 per anum, and is capable of growing fully three times the quantity now exported without any diminution in the larger staples.

The Pine-apple (Ananas sativa) is no doubt indigenous in Jamaica, where an inferior kind, known as the "Cowboy macca," is still found wild. The Pine-apple is incorporated in the arms of Jamaica, and certainly nowhere, except perhaps at Pernambuco, can Pine-apples of such size and delicacy be grown as in some parts of this island. Antigua is noted for its Pine-apples, the pitch-lake Pine of Trindad has at least a local reputation, but the Bahamas export more Pine-apples in the fresh and cured state than any other part of the world. The chief supply of Pine-apples for the English market at present comes from Madeira, the Canary Islands and the Azores. Should the interesting experiments now being carried on by Messrs. Scutton & Sons, who have fitted up one of their ships with a refrigerating chamber, be successful, we shall before long have large supplies of Pine-apples direct from the West Indies, and at very moderate cost,

The West Indian Lime (Citrus medica, var. acida is a fruit which is not much known in England. It is possibly little grown anywhere else except in the West Indies, where a large industry is arising in connection with the preparation of raw and concentrated) lime-juice for the manufacture of citric acid.

The Mango (Mangifera indica) is the "Apple" of the Tropics, and is a most nutritious and wholesome food as well as a desert fruit. Originally an East Indian tree, the Mango has become thoroughly naturalised in the West Indies, and is forming large groves in waste places in Jamaica, where negros, horses, pigs, and fowls feed upon the fruits for nearly four months of the year. The West has given to the East the Anona fruits, known as Sour-sop (A. muricata), the Custard-apple (A. reticulata), Sweet-sop (A. squamosa), and the Cherimoyer (A. cherimolia), but practically only the second and third appear to have become established in their new home. The Guava fruits (Psidium Guayava) are very common everywhere, and utilised chiefly for making the well known Guava jelly, and for flavouring cordials and syrups. The Litchi, rambutan, and Longan of the East Indies are co-related by the Genip (Genipa americana) of the West Indies. The fruit of the spine-armed Zizyphus jujuba, allied to the "seductive sweet fruit"—the Lotus of the ancient Lotophagi, has become cosmopolitan in its distribution, and will soon finds its way to England from the West as well as from the East. The Passion-fruits are amongst the most delicate and refreshing of tropical fruits, and ome of them have been successfully introduced to England. The most common are the Granadilla (Passiflora quadrangularis) the Pomme d'Or or Water Lemon (P. laurifolia), the Sweet-cup (P. edulis), and the Calabash Sweet-cup (P maliformis).

Of tropical fruits known generally as nuts, we have a long list, some of which are seldom seen in England. The Coconut is too well known to need description. It is computed that over three million acres of land are under cultivation in Coconuts in tropical countries, and the annual export value of nuts, oil, copra, and coir is estimated at nearly two million and a quarter pounds sterling. The Brazil nut (Bertholetia excelsa) is obtained entirely from wild trees which, are of immense size; and the same may be said of the Sapucaya nut (Lecythis sapucajo), and the Souari or butter-nut (Caryoca nuciferum).

India is so badly off for fruit herself that she is not likely to be able to export any to this country; but the wild Apricot of the Himalayas, of the Punjaub and North-west Provinces, is produced in such immense quantities, and so easily cured by simply drying in the sun, that it might be imported at a very low price. It is the Prunus armeniaca of botanists, known in india as the Mish-mush or Moon of the Faithful. This latter appellation it has obtained from the fact that it is sometimes pressed out into sheets of "moons" and kept in that state until required for use. The delicious fruits of Singapore and the Malay peninsula, amongst which the Mangosteen and the Durian are the best known, are not likely to come direct from those countries. The former has, however, been fruited both in Trinidad and Jamaica, and large trees of the latter exist at these islands as well as at Dominica, Grenada, and St. Vincent. Hence West Indian Mangosteens and Durians are objects not impossible to be seen in England during the next decade —D. MORRIS, Assistant DIRECTOR, Royal Gardens, Kew, July 21.—*Gardeners' Chronicle.*

THE POTATO DISEASE.—We take the following from the *Journal of the Pharmaceutical Society*:—"Dr. A. B. Griffiths has lately made some interesting experiments on the effect of sulphate of iron on the Potato disease fungus (*Chemical News*, May 28, p. 256). He found that an aqueous solution of 0. 1. gram of ferrous sulphate in 100 grams of water causes perforations of the cellulose walls of the hyphæ and spores, while it does not attack the cellulose walls of higher forms of plant life, the cellulose of which appears to be of a different character, since it is coloured by reagents which do not affect the cellulose of fungi. He also suggests that potash salts in manures, while valuable for the potato, also stimulate the growth of fungi, since Chevreul has shown that fungi greatly flourish when watered with a solution of potassium nitrate.—*Gardeners' Chronicle.*

PLANTING IN TRAVANCORE.—Mr. Valentine of Travancore has been on a short visit to our Ceylon Tea districts, to note and compare progress. Travancore promises to be a very fine ea-growing district: indeed one report by a Ceylon planter says he has seen as fine tea growing there of its age as any in Ceylon. Very little in Travancore however is of a plucking age, and the extension of planting is not being pressed, but is carefully and gradually being attended to. There is no scarcity of labour, most of the coolies coming from Tinnevelly. As an outlying division of the Ceylon planting districts which we have always regarded South Travancore since the days of poor John Grant and his band of pioneers, we are interested to hear of progress such as Mr. Valentine reports.

A HINT TO CEYLON TANNERS.—A new use for Carbolic Acid has been discovered by an Australian inventor, namely for tanning leather. We had thought that Australia affords more than enough natural tanning material without this invention. In the process the skins, which have been limed in the ordinary manner, also haired and prepared if for the production of sole leather, are placed in a bath consisting of a mixture of 10 gallons of water, in which 200 pounds of soap are dissolved and containing 1 gallon of carbolic acid, the skins being left in the bath until tanning is complete. The process may be considerably accelerated by adding a pint of fresh carbolic acid to the tanning fluid from time to time. For a softer leather the raw, limed, and haired skins are for one or two days placed in a mixture of four parts carbon bisulphide and one of carbolic acid, and then washed.—*Chemist and Druggist.*

COFFEE up to 70s is indeed, good news for long-suffering planters who may have coffee to sell: and we may have the standard rate in the "eighties" before the end of the year. Brazil is rapidly getting into a bad way, witness the following new phase of their labour troubles recorded in the latest Rio paper:—

There is one serious problem in the social organization of Brazil which ought to be studied and solved—and that is: What is to be done with the freedman? Rare indeed is it that a planter is found who thinks that his ex-slaves may be retained upon his lands as paid laborers, and still rarer is it to find a legislator who contemplates the possibility of retaining them as a laboring force. The one great demand is for colonization or immigration, in which is to be found a substitute for slavery. Now, what is to be done with the ex-slave? It is thought by most men that the freedmen will all flock to the cities; but the cities are already overcrowded with them and can neither employ nor support them. Where, then, are they to go? They cannot camp in the highways, nor upon the lands of others. They can not live without food, clothing and shelter of some kind, nor can the charitable begin to provide even a tithe of these things for them. The cities, and even the country places, are already over-run with mendicants of every kind and description, and the number of idlers and vagabond dependents is even now grievously out of all proportion to the actual laborers. Out of a population of, say, twelve millions, there are probably not a quarter of a million of manual laborers outside of the slaves. The number of idle men among the poorer classes—men who actually do less than a week's work in the whole year—is simply incredible.

Correspondence.

To the Editor of the "Ceylon Observer."

SYNTHETICAL MANUFACTURE OF QUININE.

5th August, 1886.

DEAR SIR,—The July number of your valuable *Tropical Agriculturist* contained an article *re* Synthetical Manufacture of Quinine, your correspondent mentioning an advertisement in the *Lancet* according to which a "Syndicate for the above purpose was being formed." Have you not read any more of this interesting scheme? Quinine and quinine alkaloids possess a strong rotatory power, and as it has proved an impossibility as yet synthetically to prepare any substance which has the above property, planters and others concerned may take the medical men's Syndicate easy. Indeed a synthetical manufacture of quinine has to be looked upon as impossible for the presen t.—I am, dear sir, you s faithfully, M P.

We have heard no more of the *Lancet* advertisement.—ED.

ALL ABOUT TEA AND ITS PROSPECTS:

THE ALLEGED "DETERIORATION"; "PLUCKING FINE" *v.* MEDIUM PLUCKING; FINE QUALITIES FALLE; MOST IN PRICE; THE SYNDICATE TO APPLY THE REMEDY; NO "SECRETS" ABOUT TEA-MAKING NOWE THE "OBSERVER"'S FOUR HEADS OF ADVICE RECAPITULATED; THE NEED FOR THE DRAG ON THE COACH; "ECONOMY IN WORKING" REQUIRED; SAFE AVERAGE PROFITS R15 PER ACRE; THE FUTURE OF LABOUR SUPPLY; A WARNING TO PROPRIETORS.

5th August 1886.

DEAR SIR,—Some time ago you asked me to give you my ideas about things in general and especially Tea. I send you a rather hurried sketch for you to do what you like with.—I remain, yours truly.

The most serious question at present is: "Has Ceylon tea reached its lowest price or must we look for a further fall?" At present the fall is arrested, and we hope our produce will soon command better prices. Unless other markets are found besides Mincing Lane, later on, we shall probably see a still more serious and a permanent fall. How we are to meet this outlook is the point we have to consider. The reply of the London Broker is, "Pluck fine and send home superior teas." The Planter's answer, to this is, plucking fine does not pay me so well as medium plucking, which also tries the young bushes less, besides I find the teas specially affected by the late fall are the teas of better quality. To prove that this is correct we have only to refer to the weekly list of tea sales in London. Broken Pekoes and Pekoes formerly worth 1s 9d to 2s. now sell at 1s to 1s 2d, whereas Pekoe Souchongs formerly worth 1s 1d to 1s 2d still realize 10d to 1s: dust and broken teas have fallen very little in value. The complaint that Ceylon tea has fallen off in quality is not generally allowed by planters. One of them discussing this question with me lately said, 'My opinion is, an attempt is being made by London Brokers who are interested in Indian and China teas, to class Ceylon Tea as an inferior article, and rank it with Java produce and he suggested *first*, that for a short time all proprietors should pluck fine and thus compel an acknowledgment that Ceylon tea equally with Ceylon coffee and cinchona is second to none; *second*, that all proprietors should support the new Syndicate and show London Brokers that we can find other outlets for our tea and thus compel them to value our produce fairly.' I would urge the Syndicate not to forget to place Ceylon teas in London and all large towns in the United Kingdom and the United States, where, if proper agents are appointed and good teas (guaranteed by the Syndicate) sold large quantities of our produce will be absorbed and we shall be rendered less dependent on Mincing Lane.

That planters are anxious to know all about and to make as good tea as possible is shown by the way in which information is freely given in lectures, &c., and by the general exchange of opinions that is always going on. Mr. Gow's 'secrets" are the only ones that I know of in Ceylon. I hope they will turn out valuable ones and if he can without plucking finer, raise the price of tea on the estates he visits, he will benefit himself and the Island. I fear it is hardly likely he will divulge them—that is if they are worth having—in his paper to be read in Dimbula.

I believe Ceylon teas will improve as estates get older, and that possibly climatic influences may have caused a slight falling-off in quality; but that every planter has been less careful in manufacture or that the stamina of the tree has been affected I am unwilling to admit.

You have frequently warned planters not to be too sanguine and given them advice. It can do no harm to recapitulate some of your past advice, as even now it may be of use, as land is still being opened for tea, and coffee is being interplanted. It will also be interesting to see if you were correct. Advice No. 1 was, Not to put tea into worn out coffee estates or into land where soil was bad; 2nd not to use seed from young bushes or bushes of an inferior jat; 3rd, Not to rush estates into tea but to do the planting gradually and carefully; 4th, To have belts of gums and other trees to keep off wind and break the expanse planted in one product, thereby probably lessening the spread of disease if hereafter it attacks tea.

Inferior land has, no doubt, been planted by men unwilling to acknowledge that the estate they had sunk their money in and which failed in coffee and cinchona would not grow tea; and by speculators with a view to selling out when the rush comes (but the rush never has come and now prices are down probably never will). That tea from land of this description proves inferior is not surprising. Many have rushed tea into their places and been careless about seed because agents and mortgagees compelled them to plant large acreages at once and now in yield and quality their estates cannot come up to those of their more fortunate neighbours. It may be that advice No. 4, may yet prove to be sound but many belts put in for cinchona have been eradicated of late years showing that the advice is not generally believed in. I cannot believe poor soil will continue to give large crops of good tea without cultivation. cost of which may render keeping up of poor estates unprofitable. It is certain that prices will eventually fall to say, 40 to 50 cent for all round breaks and remain at that price. Only estates where the yield is high and quality good will then pay. If inferior land is abandoned when this occurs, those who have good land will benefit. The produce will be superior and prices less affected as the annual outturn will be less.

Economy in working must be the great aim of the Ceylon planter: the man who gets the highest average is not necessarily the best planter; but those who can combine cheap expenditure and a fair average price for their teas will show the best profits. When the question among planters is what profit did your last break show?

—instead of as at present what was your last average price?—the position of proprietors and the credit of the island will improve. The sooner the desire to raise the average price is coupled with the determination that it shall not be combined with increased expenditure the better. If high averages cannot be obtained without fine plucking, which means increased expenditure and is trying to our tea bushes it is far better to be content with our present rates. Without manuring, tea will cost in most instances not less than cents 30 delivered in Colombo and taking an average price of cents 45 and an average yield of 300 lb. an acre we have a profit of R15 per acre or on a 200 acre estate R9,000 per annum. It certainly cannot be safely calculated higher save in exceptional districts where soil and climate combine to increase yield and give a superior quality of tea. The above figures may be considered low but they are safe. Many estates are giving large returns, but will they continue to do so. After years of working?

Profits may be large now, but when the price of labor goes up, as I believe it will do, when Coast advances increase; and last not least when Superintendents are wanted and their salaries rise, I question whether my calculation of profits is too low. To prevent the cost of labor increasing we require, *first*, to have direct steamer transport for coolies to Tuticorin; *second*, the Paumben Railway; *third*, suitable Government *ambalams* for them at the ports of embarkation and debarkation; *fourth*, a direct service, *i.e.*, through tickets and European agents at each end who will not leave the cooly a prey to native peculation. Lastly, I much question whether the present kangani system could not advantageously be replaced by collecting agents. All who can grow coffee, cinchona and cacao successfully should put in tea only where the other products cannot succeed: this will pay them best in the end and others will benefit by their not increasing the output of tea.

I am of opinion that a large acreage of tea is pruned and plucked (probably in some cases owing to necessity) when very young, damaging the bushes and the future of the estate. It is necessary to warn proprietors that by this course they are not studying their own interests. The day has passed when agents and banks combined to help speculators to buy and sell estates at unremunerative prices. Proprietors must accept the fact that they are no longer birds of passage; they cannot as formerly plant up estates and sell. They must consider the future of their properties, which, if carefully tended from the first will yield them small and steady incomes. They are unlikely to effect a sale except to *bona fide* capitalists who will be careful only to buy the estates at a price that will be remunerative to themselves, that is, unless Limited Companies will help them out. They must remember also that estates, like everything else, after reaching maturity go back; that in many cases they are working on soil where cinchona and coffee have previously been grown: that disease may and probably will, later on attack their trees (for where a large expanse is in one product, disease is generally found). All proprietors should therefore lay aside at least half of their present profits and look on half only as income; then, in later years they will be able to enjoy a well-earned retirement in a temperate climate.

FOURTEEN YEARS A PLANTER.

TEA MACHINERY.

[We were invited by Messrs. John Walker & Co. of Colombo Iron Works, the other day to inspect some new tea machinery at their works, but owing to shortness of staff and a feeling that a practical authority would be able to give a more correct opinion we requested a well-known tea planter of large experience to inspect the machinery for us and we are indebted to him for the following.—Ed.]

Dear Sir,—While in Colombo having had occasion to visit Messrs. John Walker & Co.'s factory, I was enabled through the courtesy of Mr. Walker to see the new Jackson's Tea Sifting Machine put in motion and it seems to leave little if anything to be desired as regards strength, simplicity and general completeness. The machine, which is strongly built and works noiselessly, is about 3 feet by 12 feet. At the top end of the machine is a Cutter which also acts as a feeding-box through which the tea in bulk is passed; it then falls on to a 6, 8 or 10 mesh tray according to method of sifting and all teas that do not pass through this upper mesh go over the bottom end of the machine into another Cutter equalizing itself and forming pekoe souchong or souchong, according to mesh used. What teas go through this upper mesh fall on to a 12 or 14, the broken pekoe passing through these and the pekoe remaining above both discharging themselves at the lower end of the machine through separate hoppers, the different grades of teas being carried through the machine and evenly distributed on to the various meshes, by means of "rippled" metal plates. The teas are easily seen and got at, all the trays with meshes pulling in and out like a chest of drawers. At present there is no means of taking out the dust, but I suggested to Mr. Walker a slight alteration which should easily be made to effect this purpose.

The new "Economic Roller" is also worth a visit and is by far the best-looking machine at the money yet turned out in Ceylon, and I shall expect to find exceed the capabilities expected of it by the manufacturers.

At Messrs. Maitland & Co., I saw Mr. Gilruth's Packer, a recently patented machine, of which the public will hear more in the immediate future, there being no doubt from both local and London broker's reports on the trial shipment of teas packed by this machine that it will be the means of enabling planters to avoid rebulking charges in London. A few great improvements are being effected in this machine, and it may be a month or two before the public will be able to get delivery of it, as Messrs. Maitland & Co., as usual, want to turn out a thoroughly perfect article.—Yours truly,

PLANTER.

TEA MAKING AND THE CEYLON PLANTERS.

Sir,—I've been told by *experienced* Ceylon tea makers that they consider Mr. Gow's utterances anent our island manufacture "insultingly sweeping." No doubt there is *room* for *improvement* in every walk through life, and a friendly word of counsel, from an *authority* should not be discounted too harshly; at the same time, an utter stranger (may I say) to the country might have *paused* before thundering forth such "fiat."

The first question which arises to my mind on hearing that Mr. Gow had condemned the Ceylon mode of tea manipulation is, what experience has he had in this respect? Has Mr. Gow ever made a lb. of tea in his life before his advent to our isle of spice? Does he conscientiously believe that our manufacture of tea is entirely wrong? If so, what does he base his argument on? The recent poor prices no doubt! Supposing that the market went up with a "jump," as I hope it may; would Mr. Gow kindly publish his opinion as to the reason why?

The able and interesting letters which have lately appeared in print,—more particularly Mr. Spearman Armstrong's—give us an insight as to the recent falling-off in quality of our teas. My only objection to

his statements are, that he tells too much!—in fact is too honest towards our traducers. The planters of Ceylon are, as a rule, *quick at learning*, be it coffee, cinchona, cardamom or tea cultivation and manipulation. Mr. Gow's task therefore should not be a difficult one if he *really can* teach us to improve our teas, and enable Ceylon growers to double their present prices in the London market.

I trust I am not too stringent in my remarks, and that Mr. Gow will take them in the spirit in which they are intended; namely, to ventilate a discussion which day by day is growing in importance, and which some day not far off will, in my opinion, form the very foundation upon which Ceylon as an agricultural colony may be known, honored, and respected.—I am, sir, yours faithfully,

SHELTON AGAR.

ENEMY OF CACAO.

10th August 1886.

DEAR SIR,—Enclosed I send you a small piece of wood with chrysalides * attached. Will you kindly tell me what they are? I found them inserted longitudinally in the bark of the trunk of a cacao tree, and, as you will see, they had penetrated the cambium. As they exist in great numbers, I am anxious to know what they are?—I am, sir, yours truly,

A PLANTER.

P. S.—I have often been mystified, on reading the Monthly Market Rates given in your *Tropical Agriculturist* as to how different products are sold. I read this month, for instance: "Vanilla 14s to 24s" Is this per lb. or per kilo? Would you publish once a table of how these different products are sold? [We shall endeavour in future to give the measure opposite to each. Vanilla must be per lb.—ED.]

A BIG TEA LEAF.

Hunugalla, Elkaduwa, 15th Aug. 1886.

DEAR SIR,—What think you of this tea leaf from Elkaduwa? Its size when pulled was 11½ by 4½.—Yours very truly,

A. D. MOIR.

[The leaf is splendid, excelled only by a leaf of indigenous, fully a foot in length, sent to us a couple of years ago from Somerset, Dolosbage.—ED.]

THE RECENT FALL IN PRICE OF CEYLON TEA.

DEAR SIR,—Other eminent men have written about the late fall in value of Ceylon tea. Why should not I? I have planted tea, and I have made tea, and I have sold tea. I am a tea planter. Some say the cause is to be found in the fall of silver. I don't agree with them. It requires silver to make tea, but tea is not made of silver. Take a pound of tea, say B.O.P. for sake of argument. It is worth 60 cents. But you are up to snuff and get one rupee for it in Colombo. Next week the price of silver falls. But your pound of tea is exactly the same value if not exposed to rats and damp. Try to buy it back for less. You can't do it. This proves I am right. Some say it is faulty manipulation. Why manipulate at all? I don't manipulate. Pull your tea about and you get grey dust. Everycne knows that. Sieve it gently through 8 and 12, and blow your dust out. What more do you want? Some say it is over-firing. That 's absurd. Surely we have noses and can smell burnt tea? I can smell burnt tea at 100 yards' distance on the flat. A cooly who burns tea in my factory gets lifted out of it pretty smart. Some men burn their tea. But that does not prove that we all do it. I will give any man one rupee per pound for all the burnt tea he can find in my factory, if he agrees to give me 10 cents per lb. for all he finds not burnt. This will pay for damage done by his pulling my tea about in search of burnt stuff. I don't say I'll give him the tea for 10 cents. You bet I keep the tea! Some say it is young leaf. Ridiculous nonsense. We have not all got young leaf. Some of mine is very old, but it does not fetch higher prices than the young. Some say it is exhausted soil. Bunkum! Has all the tea soil in Ceylon suddenly become exhausted? The man who started that theory is in a bad way. He ought to consult Doctor White. Some say it is bad lead and rotten tea chests. Those men have lead and boxes for sale. Look out. Don't buy them. Some say it is bad stowage on board ship. Shipping with hides and other fragrant conserves. Rubbish! Does tea taste of everything it is shipped with? I hope not. Some say it is a fall in the tea market. Exactly so! I agree with them. An ordinary fall in the common or garden tea market. Nothing else.—Yours sincerely,

WOOLY WAG.

MR. SHELTON AGAR AND MR. GOW.

DEAR SIR,—I think that Mr. Shelton Agar's letter attributing to Mr. Gow, opinions regarding the manufacture of tea in Ceylon, which he never expressed, is not only unfair but written in very bad taste.

Mr. Agar acknowledges that he knows absolutely nothing about Mr. Gow's qualifications or whether he ever made a pound of tea in his life, and assumes at once that Mr. Gow like himself has expressed an opinion on a subject of which he is completely ignorant.

I know Mr. Gow has plenty of commonsense and I am sure that in anything he has said regarding the manufacture of tea here he has not condemned the good with the bad.

Mr. Gow was an Assam planter for seventeen years and manufactured from 150,000 to 200,000 lb. of tea per annum; he was afterwards, for several years, a tea taster and tea expert in London, and after years of study has invented a tea withering machine.

Surely if long practical experience in the cultivation and manufacture of tea, and thorough acquaintance with it after it is made, qualifies a person for endeavouring to correct mistakes which unexperienced planters may have fallen into, Mr. Gow is the man.

Mr. Agar says that his object, in his attack on Mr. Gow, "is to ventilate a discussion which day by day is of growing importance." It is a curious way of attaining his object by trying to shut Mr. Gow's mouth.—Yours truly, A TEA PLANTER.

[It is certainly strange that Mr. Agar should have been unaware of Mr. Gow's experience as a planter, but we fail to see the bad taste of his allusion to Mr. Gow's uncomplimentary opinion of the capacity of Ceylon planters to manufacture tea. If Mr. Gow never said that our planters were wrong from the first process to the last, he is truly unfortunate in his connection with the local "Times" editor, who has attributed such sentiments to him in the most explicit manner, sentiments which Mr. Gow has never personally repudiated. We beg to say that it is not enough that he should do so second-hand, through this correspondent. While the belief remains that Mr. Gow made the statement attributed to him, it is natural that resentment should be felt and expressed.—ED.]

* Eggs, probably of a cricket or locust, or perhaps those of a bug. The ones sent have been injured by pressure.—Our entomological referee.

RAINFALL AND TEA IN MASKELIYA.

Theberton, Maskeliya, 16th August 1886.

DEAR SIR,—As I expect weather reports will be of interest this extremely wet month, so far, I send you it, and also for August 1882, to the same date as that is the heaviest previously for comparison.

Date.	1886.		1882.	
1st ..	2·46	Days rain fell 15.	—	Days rain fell 14.
2nd ..	2·94		5·56	
3rd ..	0·35		2·40	
4th ..	0·85		4·31	
5th ..	1·33		7·21	
6th ..	1·80		0·63	
7th ..	12·42		1·05	
8th ..	3·45		4·42	
9th ..	1·12		1·64	
10th ..	1·32		5·25	
11th ..	1·29		2·83	
12th ..	5·18		0·12	
13th ..	3·32		0·01	
14th ..	1·45		0·35	
15th ..	0·90		2·35	
Total..	40·18		Total	38·13 for 15 days.

I believe Theberton, has the reputation of being the wettest estate in Maskeliya. I feel sure if the rainfall was taken on old Laxapanagalla, it would show an average of ½ to ¼ more per annum, particularly if taken close under the Laxapanagalla cliffs.

I would mention that the average for August for the whole month for 6 years is 37·47; so this year, we are above the average in 15 days.

Tea, this month, you may say, is at a stand-still, and no wonder, after such a fall of rain. The temperature has been low in mean maximum 66° mean minimum 64°. We ought, before long, to be in for a good spell of fine weather, as soon as this burst has blown its self out.—Yours truly,

T. J. GRIGG.

AN EXEMPLARY AGRICULTURAL STUDENT.

DEAR SIR,—You will be glad to learn that the scientific education imparted at the Agricultural School to intelligent boys is just beginning to bear fruit. That Mr. John Gabriel Atapattu of Dehiwala is making a proper use of his education and knowledge of botany is clear to anyone who takes the trouble to visit his vegetable garden in his own property in Dehiwala. Only the other day an English gentleman in high position condescended to visit Mr. Atapattu's garden, and, whilst he kindly promised to supply tomato and other seeds to Mr. Atapattu, at the same time expressed his pleasure at the way in which work is done there. Mr. Atapattu feels the suggestions made by that gentlemen valuable and of great encouragement to him. It is to be hoped that other agricultural students will follow in the wake of Mr. Atapattu and each of them will endeavour to spread a knowledge of improved scientific cultivation among his neighbours.—Yours faithfully,

AGRICULTURIST.

COCA CULTIVATION IN SOUTH AMERICA

SIR,—I should be glad if any of your correspondents through the medium of your paper could give me any information as to "Coca," what sort of soil is the best and at what elevation ought it to be grown because it would be worth trying as an experiment.—Yours truly,

INQUIRER.

To a German friend in Colombo, we are indebted for the following extract from the letter of a South American authority on "Coca":—

"With reference to the manner of raising, drying and preparing coca on the spot, he writes as follows:—Two-thirds of an acre is cleared about each cottage and planted with coca and bananas. During the first two years the workmen are paid regular wages for clearing the land and planting and caring for it, but during the second year only one or two workmen are needed. After the second year the gardens of the workmen begin to yield and no more wages are paid to them; they work three days a week for rent and have the other four days to themselves. The price of 12 pesos (about 3s 4d each) per sesto (? what weight) is as low as coca can be raised with any profit, and there is no probability that it will go beyond this point and remain there for any considerable time. The grade of coca raised on this land is very superior. With reference to handling and drying coca leaves I will state that Mr. C.'s remark concerning it has been anticipated in previous reports. Coca must be dried in the shade; it is impossible in that climate, artificial heat is ruinous. No process is superior to rapid sun-drying for, the reason that it is perfect. You will see from previous correspondence that I obtained same assayed results from a given quantity of fresh leaves, that I did from the same quantity after proper sundrying. The poorest coca assayed, that is the poorest grade of properly dried leaves, yields 8-10ths per cent of cocaine; the best yielded 1¼ per cent."

ED.]

TEA IN JAPAN.—The *Japan Weekly Mail* states:—Transactions in tea continue on a large scale, and a further decline is reported on all kinds of leaf on offer. Again the issue of June 26th, states:—The tea trade has again been extensive, and though prices were easy early in the week, a firmness has characterised later dealings which indicates that sellers have the best of the position at the close. The grades principally dealt in have been medium and below, and of these the shipments, both here and at Kobe, have been heavy. There have been but few complaints about the leaf sent in so far and the season bids fair to be a good one for growers.

BLUE-GUM OIL.—In Mr. Lawson's report on the Nilgiri gardens we find the following paragaph:—During the year 20 lb. of the oil of the leaves of the *Eucalyptus globulus* were sent to the Madras Medical Department. The last consignment was sold at hte rate of R3-3-0—5 shillings per pound being the wholesale English quotation. The processes required for the manufacture of the oil are very simple and inexpensive, and I think it is a pity that those who have large plantations of these trees should not endeavour to utilize them for this purpose as well as for fuel. The way to extract the oil is as follows:—The young shoots, having perfectly matured but not old leaves, are passed through an ordinary chaff-cutter and cut into chips not exceeding one inch in length; the smaller the chips the more readily is the oil extracted from them. These chips are then macerated in water over night and put the next morning into a still, which is kept boiling, till the greater part of the fluid has past over as vapor. This is then shaken up with a little common salt to cause the complete separation of the oil from the water; the oil is then decanted from the water and passed through a sheet of filtering paper, when it is ready for sale. Instead of passing the leaves through a chaff-cutter, it would be better to pass them through some crushing machine, as the object is to smash up the hard cells, which surround the cavities into which the oil is passed by the secreting cells. I do not know of such a machine, but I should think that some modification of the old-fashioned mangle would prove effective. *Eucalyptus obliqua*, *E. siderophloia*, *E. piperita*, and other sweet-smelling varieties, all of which are said to yield valuable oils, grow freely on these Hills; they are much more beautiful in their general aspect and their timber is greatly superior to that of the *E. globulus*.

PLANTING ON CEYLON HILLS.

THE ABNORMAL DISTRIBUTION OF RAINFALL THIS SEASON HITHERTO AFFECTED TEA AND 'FLUSHING' UNFAVORABLY —MINOR ENEMIES: THE GREAT BANDICOOT RAT—ON THE WHOLE, TEA NEVER LOOKING SO WELL AS NOW—ALSO CINCHONA OFFICINALIS.

Upper Lindula, 9th Aug. 1886.

As I telegraphed to you this morning this district seems about to receive compensation for the deficient rainfall of the first half of 1886. It is not so much the absolute deficiency we have had to complain of however, as the abnormal distribution of the rain which did fall in the early months of the year, and which affected so unfavourably tea which had been pruned in the closing months of 1885 and flushing generally. The fearfully rainy year 1882, when 30 inches beyond the average fell, being excluded, the averages for the first four months of the year at Abbotsford for the three years 1883 to 1885 compare thus with the figures for the same months in this year:—

1886.		Average.
January ...	6·07 inches.	2·11 inches.
February ...	0·92 „	3·76 „
March ...	2·27 „	4·04 „
April ...	2·80 „	3·38 „
Total ...	12·06 „	13·29 „

The actual amount of moisture precipitated is this year deficient by not much more than an inch. The defect was in the concentration of so much of the fall in the first month of the year, while February and March, the cold windy months of the year, had scarcely more than three inches amongst them, April also not getting much more than half its usual allowance. Deficient rainfall and cold winds checked tea flushing to a serious extent, but May and June together showed an average rainfall 10·32 + 8·14 = 18·46, bringing the total for the half-year up to 30·52 inches, or 5·46 below the average of the previous three years. July followed with 11·38 inches, less than three inches below the average, while August in its first eight days having shown 7·84 (the average for the whole being 11·99), promises fully to restore the equilibrium. If only a genial temperature accompanies copious rainfall, there can be no question that the collections of leaf in the latter portion of the year will atone for the deficiency in the earlier. In ordinarily favourable weather pruned tea ought to have recovered itself and to be yielding well in 2½ months, fully in 3 months, after the application of the knife. The abnormal drought in February, March and April, delayed the process in the case of our December and January pruned tea, by a month to six weeks, but the rains of May and June corrected the evil and now the bushes which so long hung fire are flushing luxuriantly. Our trouble at present, indeed, what with rain and mist, is to overtake the withering of the leaf which comes pouring in, laden with a good deal of the moisture by which it has been saturated. There is no sign of blossom on the pruned fields now come into full flush, but I suppose it is due to the abnormal season that so much more than we could wish of the fields pruned a year ago have gone off into flower and fruit; not merely China-hybrid, but many of the highest Assam hybrid jât. Some of the best seed is being gathered and after a few more leaf pickings, of course the knife will correct the tendency to produce blossom and fruit instead of leaf. In the case of a few bushes, so few as to be scarcely worth mention, this tendency to free blossoming and the appearance of dark spot on the leaves, have led to the shedding of the entire crop of foliage. Such trees, if pruned, will probably recover, unless, indeed, their roots have touched the fatal *symplocos* with its poisonous fungi. Black, or rather brown bug has been prevalent, in proportion, I think to the abnormal drought of February-April, but it is curious to notice how this blight affects certain fields and never appears on others. As far as my experience and observation go, this is the most serious affection to which tea in Ceylon is liable, for the moth, which comes and goes does little mischief. There have been occasional scares of *helopeltis* and "red spider," but neither of these pests has, as yet, done appreciable harm in Ceylon. The forest rats, which at intervals, made irruptions into our coffee fields and did much apparently wanton damage, in cutting off the primaries close to the stem, with a cut as clean as that of a pruning knife, have not as yet I believe, attacked our tea cultivation. But the gigantic member of the rat family, the bandicoot, has been giving us a little trouble here recently, in the ravine, curiously enough, where the big black *wanderoo* monkeys in former days devoured the tops of our cinchona officinalis plants, standing on their hind hands and pulling down the tops with their forehands. The bandicoots whose habitat is a belt of jungle left near the bungalow, do not seem to care for the fever plants or for the leaves or branches of the tea bushes. But they have discovered that the thick, succulent tap roots of the best jât tea bushes are delicacies and to get at these they have dug up several of our very best bushes. Traps having been set, a young bandicoot was captured and I requested it might be preserved for me to take to Colombo as I know there are many Europeans in Ceylon who have not seen this huge black rat. A carpenter was accordingly asked to construct a box for the safe keeping of the creature. He refused, saying it was contrary to his religion, the religion which teaches that there is no God, but that you must not take the life of any creature, however dangerous or noxious. In this case it was explained to the man that the object was not to take away life, but to preserve it. All in vain, and it is not worth while taking the man to Court for refusing to obey a lawful order. Tea, like every cultivated product has its enemies, but none of those I have named are formidable and on the whole I have seldom seen the great "new product" looking so well. The same may be said of the subsidiary cultivation of cinchonas (*C. Officinalis*, chiefly) amongst the tea. The cinchonas were put down long enough after the tea, to secure the thorough opening up and drainage of the soil by the latter. The result was an unprecedented success with the cinchonas, and now the coppiced plants are even more flourishing than were the original stocks. There is scarcely a coloured leaf to be seen, and the only question is whether the cinchonas will even pay enough for the elements of which they must deprive the tea. It is surely the very irony of fate that when bark is at its lowest, the trees are here and elsewhere at their best.

August 10th.—Since the despatch of my telegram yesterday morning the weather has continued wet and stormy, the south-west monsoon having asserted itself at last. The soughing of the wind last night was wild and the "blowing" continues, with mist and rain. The fall in the 24 hours to 6 this morning was ·33 inch. The most was made of the third of an inch, however, being well spread over the 24 hours.

A GRAND SUNSET AMIDST THE STORM—FIRE, FIREWOOD AND ARTIFICIAL FUEL—MR. GEO. WALL *v.* SIR SAMUEL BAKER ON CEYLON SOILS—THE IMPERIAL DUTY ON TEA—THE NATIVES AND LOCAL TAXATION AND GOVERNMENT—RAINFALL DISTRIBUTION ON THE HILLS OF CEYLON.

Upper Lindula, Aug. 10.

I ought to have mentioned that the storm of Saturday, which, in the shape of wind and drizzle, still continues, was preceded on Friday evening by one of the most glorious possible sunsets. Golden beams of light coming over the summit of Rillagalla, striking on the flanks of Great Western and illuminating the whole valley of Dimbula were set off by a perfect rolling sea of clouds floating over Dikoya and Maskeliya. First snow white and wintry looking, the masses of cloud slowly darkened and then as the sun was sinking, put on an indescribably beautiful cobalt blue. The whole circle of mountains by which we are here enclosed, from Pidurutallagalla round by Totapale, Kirigalpota, Elbedde, Talangkande, with the summit of the Peak, overtopping it, to Great Western, stood clearly revealed. We at first, naturally, anticipated a clearing up of the weather, but there were signs of anger on the horizon of the beautiful sky which too truly predicted what came to pass, the approach of a storm during which, for three days, (this is the fourth,) we have known of the existence of the central orb of our system, only by light struggling through wind-driven drizzle and canopies of dense mist. Better planting weather, barring the evaporating wind, which chills the poor coolies, there could not be. Any one visiting this valley or Nuwara Eliya in such weather would be very apt to go away with a very erroneous impression of the climate, which for a large portion of the year is most enjoyable. Indeed even in such weather as this, although the magnificent scenery may be hidden, healthy exercise can be taken, if only thick-soled boots, good great coats and umbrellas are put in requisition. When once the weather is faced, the discovery is made that both wind and rain sound worse when we are indoors than when in the open air we give them battle. The great point is, on return from a walk or ride in wet weather to obey the Scotch injunction of "change ye're feet," the change being carried further, but the additional injunction of "gang into the fire" being obeyed with some qualification. What a comfort a bright warm fire is; but how rapidly firewood disappears, when the requisitions of "the Factory" are added to those of the hundred-peopled lines and the bungalow. I cannot doubt that ere long artificial fuel will come to our aid in the shape of petroleum and other substances in which the greatest possible amount of caloric is compressed into the smallest possible space. Our forest up in this region is sparse beyond what any external and superficial view would indicate, the redeeming feature as to quality of soil being the dense and luxuriant undergrowth of *nillu*. We have found this all prevalent shrub a true index of fertility, but it is of little value for heating purposes. By the way what is to be said about Mr. George Wall's assertion that our Ceylon mineral soil is generally rich? Most authorities, hitherto, have recognized the paucity of phosphates as a serious defect, Baker attributing to this cause, the disproportionately small antlers of our elk or rather sambur deer, and the fact that, while in South Africa all elephants, females as well as males, bear tusks, in Ceylon only one in sixty of the males and none of the females produce ivory. Surely Mr. Hughes' analyses proved that our soils *were* somewhat deficient in phosphoric acid. Our wet but warm insular climate has been supposed hitherto to compensate for a soil, poor in comparison with the black free earths of India and the decomposed volcanic muds and ashes of Java. Mr. Wall's tendency has ever been to take sanguine views of the capabilities of Ceylon and we know how to the last he refused to believe in the decadence of coffee, although predicted by his friend "dear old Thwaites." Aided by our moist warm meteorological conditions, our soil generally, is excellent for tea, but inevitably, we must ultimately supply phosphoric acid, potash and nitrates to our soil, when exhausted by incessant harvesting of crops of leaves. It is true that those leaves are three-fourths moisture, but the remaining fourth—which leaves the land as dried tea, at the rate of 200 lb. to 500 lb. per acre per annum,—carries away a very appreciable amount of mineral matter. The question is, whether the consumers of tea will consent to pay the producers a price sufficient to enable them to manure their lands when manuring is, as the doctors say, "indicated." The sixpence per pound duty is a very serious consideration, in this light, and perhaps that heaven-born Chancellor of the Exchequer, Lord Randolph Churchill, may surprise and delight us all by a reduction of the impost to one-half its present incidence. As to Mr. Wall being a special sympathizer with the natives, this sympathy took the form of advocating the abolition of one of the very few taxes they pay, that on native-grown and imported grain, a bread-tax and, therefore, objectionable in theory; but, as the *Observer* ever contended and still holds, better a tax on grain (fruit, vegetable and root cultivation, including coconuts, being free), than no revenue wherewith to construct roads, irrigation works and all other improvements, including the extension of elementary education, on which the progress of a country and people, the natives of Ceylon included, depends. It is just as well to recall the fact that Sir Wm. Gregory, who gave Mr. Wall such special credit for sympathy with the natives, not only embodied in his dispatches views identical with those held by the *Observer*, but that he did us the honour to quote from our articles, the tendency of which was, "Better a moderate tax on one staple article, from all previous time a subject of taxation, than an acreage tax which would include every food substance from the sweet-potato and the pumpkin to the coconut and palmyra fruit." The best friends of the natives and of the masses everywhere are not those who tell them, "Base is the rogue who pays"—taxes. Mr. Wall is an able man who has done good work in his day, but we decline to recognize his efforts to sweep away a large portion of the revenue of the island, easily raised and lightly felt, as a service to the natives; while commonsense and expediency are simply outraged when it is contended that a Crown Colony can be governed on the principle that the Queen's representative, who is personally responsible, ought in all cases to allow perfect freedom of vote to the servants of Government who are members of the Legislative Council, even if his policy of necessary revenue, public works, education, &c. is as a consequence overset. Questions of religion and conscience being reserved, we hold that the Governor of a Crown Colony like Ceylon can demand from the servants of the Crown under his rule, the same support which the Prime Minister of the Sovereign has a right to demand from his associates in Government.

But I have wandered far from my subject which is the question of comparative Rainfall in various localities and at different elevations. We had a pretty heavy rainstorm here on Saturday last at an elevation of 5,800 feet and at a distance of

about a score of miles from the "cloud-compelling" Peak and its "rain-capturing" ranges, running down to 1,000 feet above sea level. You have no doubt, ere now, heard from Maskeliya, Dikoya and Ambagamuwa, that at places less than half our elevation, but in the teeth of the south-west monsoon, they have experienced rain deposits surpassing ours by two, three, four times. The rainiest station in the world, in the forefront of the Himalayas, Cheerrapoonjee, is only 4,000 feet above sea level, and the rainfall decreases as thence the vast Himalayas are ascended until at 14,000 or so no rain at all falls. Not giving due weight to this principle, I at one time calculated that if the late Mr. Heelis got an average of 106 inches per annum at 4,600 feet on Langdale, we might calculate on 110 at an elevation 1,200 higher on Abbotsford. I am now perfectly satisfied that the true average rainfall here is better represented by 100 inches (the figure also established for Nuwara Eliya by 16 years observations) than by our old estimate of 110. The truth is that if we commence with Theberton in Maskeliya, there is a descending scale of rainfall against an ascending scale of elevation, until the Nuwara Eliya tableland is reached. My good but thirsty friend Mr. Grigg, is not contented with absorbing less than from 200 to 250 inches of rain per annum. He kindly allows some of the rain clouds to pass on and so they get 150 in Dikoya, 140 in the Kotagaloya Valley, 120 about Talawakelle, 106 at Langdale, and 100 at 5,800 in the face of the south-west on Abbotsford. Nuwara Eliya is 440 feet more elevated and a rampart of mountains shelters it from much of the south-west wind and rain. But it is midway between the two monsoons, receiving an appreciable tribute from each, the result being, with striking inequalities between individual years, an average of 100 inches. This average, both for Abbotsford and Nuwara Eliya, requires the inclusion of the enormously exceptional rainfall of 1882. But the record for that year at Abbotsford being imperfect, (although we have good reason to believe that the rainfall was at least 130 inches,) I have taken the figures for the three years following, during which, of course, there was a reaction from the excessive fall of 1882, while in the case of Nuwara Eliya, so utterly exceptional a year as 1884 gave only 76·42 inches. The averages for the past three years of reaction from the abnormal rainfall of 1882, are considerably below 100, but for any period like 5 or 10 years that is the average, or perhaps 99 for Nuwara Eliya and 102 for Abbotsford. The figures for the 3 years ending 1885, were:—

	1883.	1884.	1885.	Averages
	inches.	*inches.*	*inches.*	*inches.*
Nuwara Eliya..	99·62	76·42	83·68	86·57
Abbotsford	100·10	85·13	89·70	91·64

In both places the rainfall is well-distributed over the year, no month shewing a lower average than 2·11 for January in the case of Abbotsford and 2·46 for the same month at Nuwara Eliya. The highest average figures are 15·15 for June at Abbotsford and 12·78 for July at Nuwara Eliya. But to shew the capriciousness of seasons, which must be calculated on, we need merely mention that while June 1884 gave only 4·88 at Nuwara Eliya and 9 at Abbotsford, the reaction in 1885 was to 23·43 at Nuwara Eliya and 28·54 at Abbotsford. *This* year June went down at both places to 12·49 at Nuwara Eliya and 8·14 at Abbotsford. Allowing for the fact that the north-east monsoon, as might be expected from the position of Nuwara Eliya, gives that place, appreciably more rainfall (3½ inches) in November and December than Abbotsford gets, the bulk of the year's rainfall at both places falls between May and October: about 65 out of 91·64 in the case of Abbotsford and 57·05 out of 86·57 at Nuwara Eliya. For the 3 years, 1883-1885, the Nuwara Eliya average was 5 inches below that of Abbotsford. It is curious to notice how in the first 6 months of this year, an attempt was apparently made to raise the rainfall of Nuwara Eliya and lower that of Abbotsford, so as to equalize the averages. The rainfall of Nuwara Eliya for the first half of this year was 39·09 inches or 6·96 above the average of the past 3 years, which was 32·13. The rainfall at Abbotsford, on the other hand, for the first six months of this year was only 30·52 inches, being 5·46 below the average for 3 years, viz: 35·98. It seems quite probable, therefore, that by the end of 1886, the average for both places will stand about 95 inches, another (the fifth) year bringing the figure for average up to the round 100. In February, March and April this year, (north-east monsoon months), Nuwara Eliya got 8·66 inches of rain, instead of the wretched 5 inches which fell at Abbotsford; Feb. and March getting little more than three inches between them, a quantity not equal to supply the evaporating effects of the north-east winds of those months. We have already noticed that the bulk of the rainfall both at Nuwara Eliya and Abbotsford falls between May and October. If, on the other hand we divide the year into halves, by far the larger portion falls in the second portion of the year. At Nuwara Eliya 32·13 inches only fall on an average between January and June, against 54·44 between July and December. For Abbotsford the similar figures are 35·98 in the first half of the year, against 55·66 in the second half. Of all the years on record, 1884 was probably that most distinguished by deficient rainfall at both stations. In that year the Sanatorium received only 76·42 inches, or very little more than three-fourths of its average supply; the proportion for the first half of the year being actually two decimals below 18 inches, so that the average for each month was only three inches. Abbotsford was better served by 8·71 inches, but the total 85·13 inches was fully two inches below the average of Colombo, while for the first half of the year the fall was only 23·59. The direct distances between the rain gauges at Abbotsford and Nuwara Eliya is less than three miles; but while Abbotsford faces the south-west, Nuwara Eliya is protected from that monsoon by the One Tree Hill and Kikilimaana ranges, is more exposed to the influences of the north-east monsoon, so that while Abbotsford receives somewhat more rain than Nuwara Eliya does in the south-west monsoon months, Nuwara Eliya receives compensation in the north-east monsoon months, which tends to equalize the average figures. As regards mean temperature, that of Nuwara Eliya is 58°, with minima going down to frost, the cold on the plain being intensified by evaporation of moisture and by radiation of heat into space, in the clear weather of the north-east monsoon. This refers to "THE PLAIN" proper, which is undoubtedly the grass-covered bed of an ancient lake. On forest land or land redeemed from forest, on the hills around, the temperature is much warmer, frost on such places being practically unknown. The mean at Langdale, 4,600 feet above sea level in the Dimbula Valley, being 65° against 58° at Nuwara Eliya, the difference is 7°, that being the fall of temperature for a rise in altitude of 1,640 feet. Were the conditions equal, this would mean a fall of 1° for every 235 feet elevation. At this rate the mean temperature at 5,800 on Abbotsford would be 60°. But as the estate has been entirely opened in forest and is surrounded by growing forest, the true figure is probably about 62°. As the lower portion of the estate is 4,600 feet altitude and the higher reaches

6,000 feet, the mean temperature ranges from 65° below to 61° above, the medium being 63°. It is quite probable, too, that a rain-gauge down at 4,600 feet, in the valley of the Dimbuldanda river, would show a few inches more rainfall per annum than occurs at 5,800 to 6,000. On the other hand, the occurrence of mist is rare below 5,300 feet, while there is a good deal at certain seasons of the year above that elevation and will be until more of the forest around is cleared for railway fuel and other purposes. The amount of moisture over the whole estate, therefore, is probably pretty equal for the twelve months. Apologies are doubtless due to the readers of the *Observer* for such large use of data connected with a property in which I am interested. But the data are available and trustworthy, while the meteorological conditions I have indicated apply with very slight qualification to many properties in this district; to Calsay, for instance, with scarcely any qualification at all. So with Mahaeliya, while the figures have a close bearing on Dessford, Clarendon, Edinburgh, Inverness and the whole group down the side of the Great Western. The publication of the figures I have collated may lead to the production of others and of valuable deductions drawn from them, establishing the suitability of exceptionally high altitudes in Ceylon for the culture of tea. Visitors to our Sanatorium in December, January and February, seeing the grassy plains whitened with hoar-frost, might naturally doubt the possibility of tea growing and yielding well at many hundreds of feet of loftier altitudes around. But the temperature of both air and soil on forest land is far warmer than on the damp grassy plain. Then Ceylon is an island and most of the tea estates are less than 7° from the equator. The comparative figures commented on are appended for reference.

August 11th.

Yesterday the wind was stormy, and drizzle and mist prevailed. This morning is calm, but the drizzle and mist continue. The fall for the 24 hours has been ½ inch, so that the rainstorm has evidently worn itself out, up here at least. We have, of course, had a good many earthslips on estates, but none of much consequence. The paths show signs of "wash," but where the drainage is good, the amount of damage from this cause is not great.

Comparative Statement of Rainfall at Nuwara Eliya (6,240 feet above sea-level) and Abbotsford Estate (5,800 feet altitude) for the years 1883, 1884 and 1885, and for the first six months of 1886.

The rainfall at Nuwara Eliya for the 1st 6 months of 1886 is 6·96 inches over the average for the previous 3 years.

The rainfall at Abbotsford for the 1st 6 months of 1886 is 5·16 inches under the average for the previous 3 years.

THE WEATHER—TEA-MAKING AND MR. GOW—NUWARA ELIYA.

Upper Lindula, 12th Aug.

The compensatory process continues. The rainfall in July was 11·38, a total below the average considerably, but well distributed over the month, there having been only two days out of the 31 in which no rain fell. On every one of the 11 days of August concluded at 6 this morning, appreciable rain has fallen; the lowest record on any day being 16 cents. In the 6 days previously to the rainstorm of Saturday the 7th, the aggregate was 2·36 inches. From the 7th onwards the record has been:—

24 hours ended Aug.	8th	1·46 inches
,,	9th	1·00 ,,
,,	10th	0·33 ,,
,,	11th	0·50 ,,
,,	12th	0·82 ,,
Total for the 5 days		7·11 inches
Add for first 6 days		2·36 ,,

Total for 11 days of Aug. 9·47 inches; or close up to the total for July. The rain continues with but slight intermission, so that August promises to make up for the deficiency of June and July, which aggregated only 19·52 inches against an average of over 30. We should gladly hail a break of sunshine, however, to put an end to the present necessity of calling in the aid of artificial heat to further the process of withering. This species of heat is said to be systematically applied to the Loolcondura teas, so that the question arises whether Mr. Armstrong and the rest of us, who have built large stores to provide space at the rate of 6 feet for every pound of green leaf, to be withered by natural atmospheric air, have or have not gone to needless expense? The force of the question is intensified by the terms of Mr. Gow's patent machine for the combined withering and smashing of the leaves under the influence of artificial heat. No doubt the public here will soon have the opportunity of judging of the capabilities of a machine based avowedly on Chinese practice. Meantime the patentee, whom I have regarded as a sensible and courteous gentleman, is to be sympathized with for being represented (misrepresented, doubtless) by the journalist who specially lionizes him, as guilty of the exaggerated and offensive self-conceit, of denouncing the whole mass of tea planters and manufacturers in Ceylon as ignorant of their enterprise, from its alpha to its omega; as erring in every process from the plucking of the flush to the firing of the rolled and fermented leaf! The surprise is that Mr. Gow should not have protested against what must be so gross and injurious a representation of his character. If he *has* made any protest it has not fallen under my notice.

—Under the influence of the chronic damp, doubtless, a pretty emerald green, aquatic or semi-aquatic plant, of very minute foliage, has spread from the streams over the cultivated land to some extent in this district, giving at a distance the idea of moss, which is also beginning to show. The green plant does not seem of any consequence as a weed, but our staple weeds are, in this weather, giving work to the contractors.

A trip to Nuwara Eliya, yesterday, was very enjoyable, although a good deal of what the Scotch call "coorse" weather alternated with glimpses of comparative clear atmosphere. The forests were brightened by the profuse blossoming of white-flowered trees, purple nillus and white balsams, and Lake Gregory was a lively sight when the wind-squalls lashed the water into waves and produced the effect of a mimic sea. All round the plain, the presence of masses of slag here and there gives evidence of the former preparation on a rather extensive scale of metal from the ironstone which abounds. A piece of land near the bund having been cleared, two furnaces were revealed, one of them a well-built and very perfect furnace-pit, with ventilating opening at its base, in which doubtless a good deal of ironstone was formerly roasted. This pit will be preserved and good specimens of the iron stone and slag will be brought to Colombo for the Museum, as representing a native industry all but extinct, from imported iron and steel being obtained at prices so moderate.

PLANTING IN CENTRAL AMERICA: GUATEMALA.

A MODEL COFFEE ESTATE.

(*Extracts from the Letter of an ex-Ceylon Planter in Guatemala.*)

I will try to describe to you the estate of the late President (General Rufino Barrios) which may interest you. The estate is situated about 180 miles from the City (of Guatemala) immediately, next the Mexican boundary. There are about 15,000 acres altogether, situated at an elevation of from 1,000 to 6,000 feet. There are about 2,400 acres planted up with coffee, the oldest being nearly eight years, the rest all younger; so you see it is quite a young estate.

A little over 2,000 *acres* are laid down in grass for the use of cattle, mules, horses, &c. There are 2,500 acres of fine virgin jungle at about 4,000 feet elevation eminently suitable for coffee; the rest of the land is at high elevations, or the opposite, hot and low. There are 30 barbecues for drying the coffee on, 25 yards square, made of brick and cemented over (750 square yards of drying Patios). These barbecues are all very well arranged from the receiving or parchment cisterns; the parchment can be conducted to anyone of the barbecues by water. Eight Gordon Pulpers for pulping the coffee and eight wet parchment cisterns 6 by 8 ft. and 8 by 10 feet. The coffee is washed *by machinery*, two machines of the Guardiole patent, and one of Mason's patent. There is also a very large cistern for receiving the cherry straight from the field. The bottom of this cistern is a little above the level of the tops of the to ters, so that the cherry is conducted by water to he pulpers; then, by water, the parchment is conveyed pulpthe washers *after* fermentation, and from the washers direct to the drying barbacues or patios, as they are called here. So you see there is nothing lost to facilitate operations or save labour. After the parchment is half dried on the patios, it is *i* taken into the store and thoroughly finished by *artficial driers*.

These driers are patented by one Guardiole, a Spaniard, and very intelligent man. They are capable of drying 75 to 100 quintals at a time (one quintal = 100 lb). The drier is a round barrel-shaped machine which revolves very slowly; the heat is generated from a charcoal fire, and the heated air is forced into the machine by blowers of great power. (How would this do for tea drying?) El Porvenir (the name of the estate) has four of these driers. The next process is peeling and sizing the beans. There are *five* of these (one Gordon peeler, three Smoot's and one Mason's peeler?) also a complete set of the latest improved Gordon's sizers.

There are 400 oxen and 65 carts; and 37 mules and 15 carts.

There is also a saw-mill, lathes, and all tools and other implements connected therewith. The power to drive all this consists of one water-wheel 40 feet, one 24 feet, and one 12 feet in diameter. The building which contains all this machinery, also storage room for the coffee, and the selectors of bad beans (the same as is done in Colombo) is formed of two sides of a square, each side being 200 feet by 40 feet. For the accommodation of the extra labour force there are about 150 ranches of various sizes; besides these there are scattered throughout the coffee 18 large open houses 120 ft. by 24 ft.; these houses are for the accommodation of the extra labour required during crop time. There is also a large house for the managers and a *telegraph office*. There are 12 miles of good cartroads0 and two fine bridges to cross rivers

Last year 18,0t0 quintals of coffee were picked,. and from 8,000 or 10,000 quintals were estimated to have been lost fgom want of labcur to pick it; say 25,000 quintals altotther. This year 30,000 quintals were expected, but I suppose they will lose *one-half* at least.

The President, had he lived, would have made one of the finest fincas or estates in the world, but he died shot in battle, and so the place is almost lost for want of labour to pick the crops.

120,000 bushels of parchment is rather a big thing from an estate, the oldest coffee of which is not more than eight years of age. Can you match this in Ceylon or Madras? I guess not. I ought to state that there are 100,000 cinchonas planted along the roads and throughout the coffee: 10,000 Liberian coffee trees planted in the lower portion of the estate; also a small sugar mill and cane and a number of cacao trees, I don't know exactly how many.

The oxen and mules I mentioned are employed solely on the estate, carting cherry to the store and coffee to the railway.

THE CULTIVATION OF IRONWOOD.

Seeds of "the famous *Nahor* trees of Assam" having been lately advertised for sale, it may be well to state that the *na-hor* of Assam is the *na-gaha* of the Sinhalese, the true ironwood. Apart from its value as a timber, especially as posts for telegraphs and like purposes, the living ironwood tree is in every respect so exquisitely beautiful, that we are glad to see facilities afforded for its extended cultivation. The ordinary foliage, a dense covering of thin, green pointed leaves, covering the branches and stems in a pyramidal fashion, is strikingly elegant, while the scarlet hue of the young leaves and the large, white, sweet-scented flowers, with rich orange-coloured stamens, constitute truly "a thing of beauty." Very fine isolated specimens of this tree are to be seen near Buddhist wiharas in the lowcountry and pretty high up in the mountain

ranges of Ceylon. On the road from Awisawella to Ratnapura, and around Ratnapura itself, there are small groves of the tree. From Mr. W. Ferguson's notes on Mendis's list of timber trees of Ceylon, we quote as follows :—

Na-Gaha, Messua ferrea, Lin. Fl. Brit. Ind. I. 277. Under this name this work includes several supposed species of this famous tree. Our Ceylon tree is remarkable as an ornamental flower tree, grown invariably in the vicinity of Buddhist temples, and for having brilliant red leaves when young. The timber of this tree is the Iron-wood par excellence, and must not be confounded with that of Palu, No. 65. It is the best wood in the Island for piles and for the construction of bridges, and is very durable under water. It is straight grained, hard and difficult to work. A cubic foot of it when seasoned weighs about 75-76 lb. The result of trials with 9 pieces 1 inch in diameter, and 12 inches in length gave the following:— Lowest breaking weight 791 lb., highest 1,239 lb,, mean 1,049 lb., deflection ·15. Valuable for all purposes requiring strength and durability. The timber often breaks short and without warning.

Turning to Gamble's Manual of Indian Timber trees, we find amongst the native names, *Nahor*, Assamese ; *Nangal* and *Mallay nangal*, Tamil ; *Naga-kesara*, Telugu ; *Na* and *deya-na*, Sinhalese. Gamble's discription is :—

A large evergreen tree; bark ¼ inch thick, reddish brown, falling off in flat thin flakes, leaving a slightly roughened surface. Heartwood dark red, extremely hard. Pores moderate-sized, often in groups, scanty, often filled with yellow resin. Medullary rays extremely fine, uniform, equidistant, very numerous. Numerous fine, wavy, concentric lines of light-coloured tissue.

Eastern Bengal from the Monas eastward (though traces of its having formerly been found west of that river occur sometimes in the names of places, *e.g.*, Nageshwarbari, or Naksarbari, a town in the Sikkim Terai on the Nepal frontier), Assam, South India, Ceylon, Burma and the Andamans, often cultivated.

The weight and transverse strength have been determined by the following experiments: —

		Weight.		Value of P.
A. Mendis	Ceylon No. 59, with bars 2' × 1" 1"× found	72	lb.	994
Brandis	Burma No. 18, 1862	69	,,	..
Bennett	Andamans No. 4, 1872	70	,,	1053
Smythies	Assam (4 specimens), 1878	67·5	,,	..
	Kanara (1 ,,), ,,	62	,,	..
	Burma (6 ,,), ,,	70	,,	..

Several of our specimens, however, reached 74 to 76 lb., per cubic foot in weight. It is very durable. It has been found to answer for sleepers equally well with *Pynkado*, but the cost of cutting the hard wood, its weight, and the freight from the Tenasserim forests to Calcutta prevent its being much used, as the total cost is scarcely covered by the price (R5) per broad-gauge sleeper. It is used for building, for bridges, gunstocks and tool handles; but its more general use is prevented by its great hardness, weight and the difficulty of working it. In Ceylon an oil is obtained from the nut, and the tree is often planted for the sake of its handsome flowers.

Pynkado, classed above with iron wood, is *Afzelia bijuga*. The heart-wood is close grained, but the weight of the timber does not seem to be more than half that of the true ironwood. It is described as a valuable wood, used in the Andamans for bridge and house building. Mr. Gamble, still talking of this tree as iron wood, has several references to it and its value, in his recent report on the Madras forests. We quote as follows regarding another "iron-wood":—

In this strip the principal tree is the ironwood (*Xylia dolabriformis*), hitherto, so far as I can ascertain, considered of no account. The ironwood tree, better known perhaps under its Burmese name of 'Pynkado' and its Malabar name of 'Irul,' is really a most valuable tree. It has a hard, dark-red, very durable wood, is capable of being used for sleepers, for building, bridges, &c., and is in some localities much employed for telegraph posts. Where the sal forests of the Circar Hills end, there the ironwood begins—a most fortunate circumstance, though we may regret that neither of the trees have hitherto received sufficient attention in this Presidency. To show that the ironwood supply may be utilized as a source of revenue, I would mention that from information afforded by the office of the Inspector-General of Forests at Calcutta, 'Pynkado' or ironwood sleepers from Burma are now being sold in Calcutta, *ex* steamer, at R1-12-0 each for broad, and R1-15-0 for narrow, gauge. One of the most remarkable and valuable characteristics of the ironwood forests of Rekapalle and Rumpa is the abundance of reproduction; seedlings may be seen everywhere under dense shade and in the open, and there can be little doubt that the forests can be treated in a systematic manner more easily than almost any other kind in India except perhaps sal.

Again :

"The Conservator desires to put on record his experience of the wonderful powers of reproduction of the Konda Tangedu *(Xylia dolabriformis)* in the forests of the Upper Godavari and Rumpa. Whether under shade or in the open, seedlings are everywhere most abundant where the grazing is light, and he thinks that except perhaps the sal, he knows of no Indian tree whose new growth can be so easily obtained as that of the ironwood. It would be a thousand pities if the immense and valuable ironwood forests of the Rumpa country were to be carelessly destroyed unless it be for permanent cultivation."

On turning to *Xylia dolabriformis*, in the Manual we find that it is "the ironwood tree of Pegu and Arakan." There is no indication that it exists in Ceylon, but certainly it would seem to be a most desirable acquisition from what is stated about it. The Tamil name is *Irul*. It is described as follows :—

The wood is very durable—a property it doubtless owes in great measure to the resinous substance contained in it. This resin is more abundant in Burmese wood than in wood grown in South India. No. B 1451, which was brought by Dr. Wallich from Tavoy in 1828, is still so full of resin that it is quite sticky on the outside, and the resin may be scraped off with a knife. The substance is partially soluble in hot water, to which it imparts a reddish colour.

The wood is used for boat-building and for agricultural implements in Burma; also for carts and tool handles. In South India it is used for railway sleepers, posts, boat-building and carts. In Burma and Bengal it has been largely used for telegraph posts, for which it has answered well The large forests in Arracan, of which Dr. Schlich in his report on the ironwood forests of Arracan, dated 1st September 1869, says that "a third of the forest vegetation consists of Pynkado," produce large numbers of telegraph poles and railway sleepers. Major Seaton in his report for 1876-77 said that 10,000 such sleepers from Arracan had then lately been sold at Calcutta at R5 each, and Mr. Ribbentrop's Report states that Pynkado pieces and sleepers are brought out from the forests in Pegu. It is likely, however, to be found too hard, heavy and difficult to cut. It is a useful wood for piles and beams of bridges. It exudes a red resin, and the seeds give an oil.

The native name *Pynkado* is evidently applied to the two trees.

Turning to our own ironwood, the *Na-gaha*, we find that Mr. Vincent, in his Report on the Forests of Ceylon, gave figures showing that out of a value for timber exported from Ceylon in 1881 of R342,000, ironwood contributed R78,745, against R15,403 halmilla, R29,796 satinwood, and R135,509 ebony. It is possible, however, indeed pretty certain that palu was included in and perhaps constituted the bulk of the export. Recommending the extended use of Palé (palu) sleepers, Mr. Vincent said that the cutting of Na trees for this purpose should be

stopped. He wrote:—"The supply of na sleepers will, in any case, be small. With so much sapwood in na trees it appears a wasteful way of utilizing the timber, even if its durability is established." Palé sapwood, on the other hand, he said, was as hard as the heart. From Mr. Vincent's report we quote as follows:—

Failure of na sleepers supplied from the Northern Province.—In 1879 a considerable number of na* sleepers were sent to Colombo from the Northern Province. They were cut in a small temple grove in the Mullaittivu District, and having a good deal of sapwood were quite unsuited to the purpose. They were thought so bad that they were laid down only on an unused siding in Colombo, and are now nothing but touchwood. Na trees have always so much sapwood, that it is extremely doubtful whether they would ever give good sleepers; certainly not, if grown in the forest of the dry zone, where they are quite exotics.

Mr. S. E. Peal, of Assam, thus describes the *Nahor* (identical with our *Na-gaha*):—

Nahor, if well grown, is a fine wood; at times it is seen 10 to 12 feet in girth, and straight clean shaft for 45 and 50 feet. As a rule, in the Plains, the straighter ones are young, and the old ones more or less crooked. The forest, if properly studied, often yields information of a peculiar kind: thus, the above gives a clue to the density of population compared to what we see now. These large old and crooked-branching Nahors clearly indicate that, when young, the country (now forest,) was then open. They are often along the sides of old bunds, in dense forest, and evidently planted; and from the seed, the surrounding Nahor forest has sprung up, and it is generally as straight as the old trees are the reverse. As a tree, the Nahor is very ornamental: the young foliage, out in March, is a bright crimson, and the tree, in the open, a cone of foliage; and later in the year, about May, the blossoms, out in profusion, are like large white wild-roses, often in bunches, and perfume the air all around. The immense bunch of stamens in each flower are a deep golden colour, and contrast beautifully with the large white petals. No wonder the tree was a favourite in old times. It was mainly on this account that it was planted about. As a wood, Nahor is hard and cross; it is also fairly heavy, and the "heart" lasts well in the ground as posts, going for 16 to 20 years or so. For indoor and lighter work, Nahor is a very second-rate wood, on account of being comparatively difficult to work: there are so many much better. Its main use is for posts, in tea-estates at least, or where strength is needed.

Our readers will thus see that the chief value of the beautiful ironwood tree is for yielding posts to be put into the ground and for similar purposes. As an ornamental tree it can scarcely be surpassed. Palu or Palé, on the other hand is a specially valuable timber tree.

The Palu is indicated by Mr. Vincent as *Mimusops Indica*, and besides the large export of this wood he shows that railway-sleepers of the timber laid down on the Matale railway were very largely a success. In Mr. W. Ferguson's notes this form of "Iron-wood" is botanically indicated as *Mimusops Hexandra*. The description is as follows:—

This is the Pali of the Tamils, a common and abundant tree in the Eastern and Northern Provinces, and the timber much used for piles in bridges, &c. "The wood is very heavy, weighing 84 to 92 lb., per cubic foot when unseasoned. Its specific gravity is 1·120. It is close and even-grained, hard, compact and durable, of a purplish color when fresh turning to reddish-brown, and susceptible of a very high polish. It is used by natives for oil presses, building and a variety of other purposes; it is excellent for rulers, handles of instruments, and all articles of turnery, and for cabinet purposes." Beddome.

Economically, therefore, the beautiful-foliaged and blossomed *na* tree, is far inferior to the *palu*. The *na*, however, is valuable as posts for telegraph wires and like purposes.

*Owing to a confusion of names these have been called palu, and the latter wood has been needlessly condemned. A Sinhalese carpenter calls any hard-wood which he cannot recognize, palu, and some na logs were recently sold in Colombo as palu.

DETERIORATION OF CEYLON TEAS.

Ceylon tea is beginning to be placed in the Home Market, and already complaints are heard that it is of inferior quality. A distinction is sought to be made between the produce of old and of new estates, and in the case of the former, it is contended that no deterioration is noticeable, but on the contrary that the average quality is maintained, and in instances advanced. The brokers' unfavourable remarks are admitted to apply to young estates and new marks, and the inferiority of the teas is variously accounted for—want of experience, inferior or inadequate machinery, shortness of labor, or all combined. It must be borne in mind that the tea industry of Ceylon is in an incipient stage; the number of years since it grew to be a factor in the trade, can be counted on one's fingers; hence, the planters have all their experience to gain and all their hardships to encounter and surmount. An Indian planter who has been engaged in tea for sometime writes us:—"Tea cultivation and manufacture are not thoroughly grasped in a short time. I have been at it thirteen years, and every day almost, experience teaches something new." The unsatisfactory outturn in the Spicy island, is obviously the work of tyros, full of hope, laboring in the wrong direction. Everything was favorable up to the point of manufacture. Ceylon possesses a happy climate, a sufficient rain fall and suitable elevation, a combination of advantages, which sent up the hopes of the planters, and made them careless about the one thing needful, that is, manipulation and manufacture. The planters of Ceylon are, as a whole, men of energy and application, quick to seize upon points of vantage, indefatigable, and more than all, inured to reverses, and capable of overcoming them. With antecedents so distinguished it will be a surprise if the complaints so loud against the produce of their gardens continue to be made. If the causes of the inferiority of the Ceylon teas, now thrown into the London market are correctly stated, they are remedial, and the enterprising body of men engaged in this cultivation will not permit them to remain operative much longer. But we fear the evil is in another direction, and one not quite within the power of the planter to grapple with. The bulk of the large area under tea is used-up coffee land, land in process of abandonment as unprofitable, and about to be left to the recuperative influences of nature. Many years of constant cropping have deprived it of all the constituents of plant food, and it has consequently ceased to be capable of remunerative cultivation. Upon soil of this description tea has been almost universally planted. The shelter which the standing coffee afforded helped to establish the bush and impart a vigor promising great things. Appearances gave encouragement, and more desireable country was taken up day by day, until Ceylon can boast of a tea tract, twenty times larger than Southern India, brought under cultivation in one-fourth the time. The planter's knowledge and experience have not kept pace with his physical efforts. He has moreover not had time to ascertain the effects of an uncongenial subsoil, into which the roots of the young tea are only now finding their way, with the results we fear that have already been noticed. This same subsoil has done in Ceylon for cinchona and cherry, what it is now perhaps doing for tea. Indian planters of experience who have lately visited Ceylon, are of opinion that much of the land put under tea is quite unsuitable, and that progress is too rapid. Their adverse opinions, it is obligingly suggested are the result of jealousy of rivalry; we hardly think so. The Indian tea planter is flesh and blood of his Ceylon brother, and an Englishman is incapable of feeling animosity against a competitor. Fair play is a jewel

and the wonderful enterprise of Ceylon acts on him rather as an incentive to exertion, than as food to the green-eyed monster. He is justified in gauging the force and resources of his adversary, and assessing them at their true value. He does not believe he is to be overwhelmed in the contest, and perhaps he is correct in his estimate of the drawbacks of Ceylon as an abiding and formidable rival.—*Nilgiri Express.*

[Most of the coffee land planted with tea was not worn out but rather improved by tillage. Such tea as was planted on worn out land has not yet had time to make its influence felt. There is, in truth nothing new in our experience. Effects of pruning, of unseasonable weather and other circumstances have often baffled the best and most experienced tea-makers in in India.—ED.]

CEYLON PLANTERS' ASSOCIATION TEA SYNDICATE:—CIRCULAR.

[The following copy of circular has reached us, from which it will be seen that the Syndicate movement has already met with good support, and is likely to be a success. Even at the risk of some small temporary loss on sales, planters should join in sending supplies of tea to be sold in untried or little tried markets. No doubt the Syndicate will be glad of money subscriptions, but the great object is to introduce Ceylon tea and promote a demand for the article where it is not at present known. —ED.]

It has been decided to establish, under the auspices of the Planters' Association of Ceylon, a Tea Syndicate for the purpose of introducing our teas to, and pushing their sale in, markets other than that of Great Britain. The very favourable opportunity which the Colonial and Indian Exhibition affords the Syndicate of obtaining suitable agents in the Colonies will be availed of, Mr. J. L. Shand, the Planters' Association's Commissioner, has been instructed to take the matter in hand at once, and, with the aid of the various Colonial Commissioners, to obtain introductions to suitable Colonial merchants willing to become Agents for the Syndicate. Agents will be appointed on the Continent, in America, Canada, Australia, New Zealand, and in such South African, West Indian and other Colonies as may be found desirable.

Full information will be obtained as to the class of tea and size of package most suitable, quantity of tea required to open up connections, and the likelihood of success in the various new markets.

It is so manifestly to the interest of growers (however small their outturn may be) to extend the field for the sales of Ceylon teas, that it is hoped all growers will join this Syndicate.

It is by sending considerable quantities (which can only be obtained by every one contributing) that our teas will become known and obtain a firm footing; when that has been achieved, the Syndicate's operations may cease and the further development be left to individual enterprise and the usual course of trade.

The Sub-committee of the Planters' Association entrusted with the scheme proposes the following rules, but the Sub-committee will be glad to receive any suggestions calculated to promote the operations of the Syndicate:—

1. That members supply the Syndicate with such quantities of tea as they deem fit to foster the scheme of introduction into other countries.

2. The Secretary of the Planters' Association will become the Secretary of the Syndicate, receive the teas, arrange for their shipment and pay over proceeds of sale, for which work a charge of 1½ cents per lb. of tea will be made.

3. The Syndicate's Agents will (unless there is some special agreement) be paid by commission on sales.

4. Each member in forwarding tea will state to which country he wishes his teas consigned.

5. Great care should be taken by all members of the Syndicate to ship nothing but really good teas, which, before shipment will be examined, tasted, and reported on by an expert whose fees will be paid by the member shipping the tea.

6. If it be found desirable to bulk teas in Colombo so as to obtain an even tea in quantity, this method will be adopted.

7. The services of two Ceylon Planters, who are leaving the Island, have been offered to the Syndicate. Mr. McCombie Murray is prepared to work New York, and Mr. Hugh Mackenzie would push teas in Australia.

The undernoted quantities of tea have already been promised, and the Sub-committee requests that you will be good enough to intimate on the annexed form what quantity of tea you would be disposed to contribute during the next twelve months:—

Approved for the Ceylon Company's Estates, though I am not at present in a position to promise definite quantities.—(Signed) JOHN H. STAREY.

I approve of the scheme, but at present cannot say more than Mr. Starey.—(Signed) Jas. HILL, Messrs. CARSON & Co.

I desire to join the Syndicate on behalf of Ferndale estate. I would suggest that subscriptions should be received from those estates that prefer.—(Signed) H. W. HORNBY. A. PHILIP, Secretary.

Kandy, August 1886.

INDIAN TEAS this season, are being as severely criticised as those from Ceylon, to judge by the following report in the *Produce Markets Review* of July 10th:—

"The new imports are very disappointing, and the increased supplies show no improvements in quality. The small quantity yet arrived may not truly represent the quality of coming shipments; at the same time the Teas so far placed on the market are decidedly below the standard of the first shipments of some years past. Ceylon Teas have been freely offered, and have sold at steady rates, but Java Teas are less firm."

WEEDS AND WORMS.—A pretty common idea that the existence of weeds on cultivated lands presents insect attacks on the cultivated plants, is thus expressed in the Report on the Administration of Coorg:—

The teak plantations at Kootompolle are doing very well, they measure now 231 acres. An invasion of caterpillars after last monsoon did much damage. They appeared in crowds (8 or 10 different kinds) and devoured not only all the leaves, but the top shoots too in some cases. This plague retarded the growth of the trees somewhat. It is probably attributable to the surface of the soil being too clean of weeds and jungle vegetation, so that there was nothing else but the teak for the caterpillars to eat. This theory is borne out by the fact that the old plantations where the weeds are allowed to grow did not suffer. The cost per acre of teak plantation was R105.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, July 10th.

POULTRY farming at best can never be conducted profitably on an extensive scale. It is the natural work for medium sized or small farms. By common fowl is meant that which is usually kept for rearing and breeding and restricted to the genus *Gallus*—whose origin dates from the jungle fowl. Such fowl comprise several distinct races, but new varieties due to crossings and selections are constantly coming into notice.

The fowls of La Bresse in Burgundy are famous since nearly two centuries; they are short-legged birds having four toes. Their skin is fine, the flesh delicate and savoury. On an average a hen annually lays 170 eggs, and may rear two broods of chickens. For hatching many farmers prefer turkeys: they eat little, become fat while sitting, are ready for the market any day and cover double the number of eggs. There are farmers who breed stock for fattening and colts for rearing; so there are poultry breeders who only rear chickens to fatten off at two months old; or at five months if destined to be a capon or a poularde. All fowl fatteners prefer to buy only those chickens of a pure local breed. Crossings are estimated to diminish their value one-fifth. The next object is to know the rearer who does not hatch more than he requires, keeps young cocks and eschews egg-farming. The fattening season extends from September to March; the birds selected must be from three to five months old; the fattening is generally effected within four weeks. When chicken fattening—a special branch of industry is the object, the chicks are sent to market at two months old; they weigh then about 2 lb. and fetch between 2 and 3 fr. each. A fat cap on will sell from 10 to 15 fr., and a poularde, from 8 to 10 fr. The capon is emasculated with a scissors; the operation induces rapidity in fattening, and greater fineness and delicacy of flesh. If the operation be well performed the comb will augment in volume; if otherwise it will continue to grow. A poularde is a hen flayed. A fat capon weighs from 8 to 10 lb. The La Fleche capons are today in as much favor as they were in the fifteenth century; they are exported to London, Europe and even America, in cases like champagne. The process of fattening is nearly uniform for all breeds. Like mushrooms the development of flesh takes place best in the dark. About 150 are put up at a time to fatten; each bird has its own box sufficient to allow it to move in, but not to circulate. No light is allowed to enter the house where they are boxed, all chinks and crannies are stopped to exclude light, cold and free circulation of air. Some strew the bottom of the boxes with wood ashes, others do nothing at all.

Before being placed in their cells the fowls during eight days are accustomed to a moderately dark house. The diet consists of a paste composed of one-half wheat, one-third barley and one-sixth oat-meal, wetted with fresh milk. The mixture is made into balls about the size of an olive, and the man in charge takes three birds on his lap, ties their legs together, and administers their ration of paste, rubbing their throat if necessary to make it descend more rapidly. This process continues during four or five weeks. A fowl is known to be fat, if on being handled at the upper part of the back between the wings, or just under the wings, and on either side of the tail, it feels plump.

Before killing the bird is kept fasting for twelve hours. It is then held carefully, the mouth open and an incision made in the under side of the tongue with a scissors or a pointed knife, up through the palate into the brain. Or after removing the feathers on the left side of the head an incision is made just beneath the ear. The first spasms over, hang the bird up to allow it to bleed freely, as it is on this as in the case of veal, the whiteness of the flesh depends. Next pluck and wrap up in a piece of cloth kept moist with the milk. The fowl is fed twice a day and the crop ought to be felt to see if it be empty before another meal be allowed. Drink is given twice a day either of water colored with meal or milk. A fowl when plucked and trussed loses 18 to 21 per cent of its weight, and from 28 to 41 per cent more during roasting.

PRODUCTS AT THE COLONIAL EXHIBITION.

FIJI.—The products of these islands occupy a comparatively small space, and though there is but little of absolute novelty among them there are nevertheless, some of considerable interest. The Coco-nut and its products, as might be supposed, is fully represented, as well as Candle-nuts (Aleurites moluccanus), the oil of which is used for illuminating purposes; and Dilo-nuts, the kernels of Calophyllum inophyllum, from which an abundance of oil is obtained having a high reputation for the cure of rheumatism. Tapa cloths are also abundant, the entrances to the court being hung with curtains of this material, which, as our readers will know, is the beaten-out bark of the Paper Mulberry (Broussonetia papyrifera). Amongst the many valuable woods that are found in the Fiji islands the "Visa" and the Sandal-wood will attract most notice, for here is shown a canoe cut out of a solid "Vesi" trunk. The tree which furnishes it is a leguminous one (Afzelia bijuga), and the wood is heavy, close and even grained, and of an intensely dark brown colour. The natives use it not only for canoes but also for pillars for houses, bowls in which to serve kava, war clubs, &c. The Sandal-wood (Santalum yazi) was, it is said, "at one time plentiful in various parts of Fiji; but in the early stage of settlement its destruction must have been most indiscriminate."

Under the name of Bandina Boxwood some blocks are shown of a remarkably hard wood, which appeared upon examination to be suitable for engraving purposes. It is however, of a dark brown colour, which, it seems, unfits it for the better kind of work. Upon submitting a sample of this wood to an expert, he reported that the wood has no special claim in consequence of its dark colour. This, he says, considerably reduces the value, as it could only compete with inferior Box, which is at present supplied in sufficient quantity. He explains this objection by saying that "cutting upon wood is like drawing upon paper; if it is tinted, there must be a limit to the density of the tint, or your drawing will be absorbed by the tint upon which it is drawn. An engraver would have difficulty in observing his progress while doing his work." The plant producing this Bandina Boxwood is at present unknown, but it is stated that should it prove useful it could be had in any quantity up to two feet in diameter from Fiji, and the other outlying groups of islands in the Pacific.*

Some fine masses of Kava root (Piper methysticum) are shown, also powdered Kava root. This, it will be remembered, is the source from whence the Fijian beverage called kava is made by masticating the root and ejecting and fermenting the saliva. It is known to have diuretic properties, and has latterly attracted some notice for its medicinal value in this country. Quite recently, indeed within the last few weeks, a spirit prepared from Kava root has appeared on sale at the refreshment bars in the Exhibition. It is a colourless liquid and is sold in square white glass, capsuled bottles, with labels fully describing its virtues. It is called Yagona, the finest Kava Schnapps, or aromatic gin, and its value is set forth as follows:—"The active principle of this agreeable and splendid beverage is prepared from the root of the Piper methysticum, a species of Pepper. The root is called Yagona by the natives of Fiji, and from it they make their national drink, which is diuretic rather than intoxicating. Yagona has been the Royal drink of the Fijian and Samoan chiefs from time immemorial, and it is to its constant use that chiefs and people alike owe their robust health, in spite of the depressing influence of their tropical climate. This primitive and unsophisticated liquor regulates the action of the internal organs; it possesses remarkable soothing pro-

* Surely the colour could be dispelled by some chemical substance which would leave the texture of the wood uninjured.—ED.

perties; it is a health stimulant, an excellent brain-feeder, a wonderful restorer of faded energies and of exhausted nerve-power. It is a preventive to gout and rheumatism. To those engaged in heavy intellectual labour it gives renewed energy. It is a veritable Elixir of Life. As a diuretic it is unrivalled, and it imparts a purity to the blood."

If the general use of the "Vagona" should be the only result of the Exhibition, it will finally have fulfilled a great mission!

A little *Handbook to Fiji and Catalogue of the Exhibits* has been issued under the authority of the Executive Commissioner, the Hon. James E. Mason, M.L.C., and this contains some interesting facts on the culture of the Coconut, Cinchona, Coffee, Cotton, Sugar, Tea, Tobacco, &c. Of the latter we are told that though it flourishes in all the islands of Fiji, it is most largely cultivated, and reaches its greatest perfection in the "Colo," or highland provinces of Viti Levu, the largest island of the group. All sorts of Tobacco seed have been grown, including Virginia and Latakia. The natives smoke their tobacco rolled up into "saluka" or cigarettes, the wrapper used being the dry leaf of the Plantain. Connoisseurs are very particular in the choice of their wrappers, and will only use the leaves of certain sorts of Plantains. Tobacco is an important iota of native life. Without it and kava no important discussion can be conducted.—*Gardeners' Chronicle.*

DRUGS AT THE COLONIAL AND INDIAN EXHIBITION.

North Borneo.

The collections of articles contributed by British North Borneo are to a certain extent similar to those from the Straits Settlements. The chief products of the colony consist of valuable timbers, gutta-percha, india-rubber, Borneo camphor, edible birds' nests, sago, pepper, gambier and tobacco.

One of the timbers, named "billian," is remarkable, besides its durability and great strength, for being proof against the teredo or sea worm, a property that suggests the desirability of a chemical examination of the wood with a view to determine the nature of the constituent which proves obnoxious to these animals. It is perhaps still more valuable on account of being proof against the ravages of the white ant. Another timber called "kungas" is also not attacked by these insects. A third, known as "lakar" wood is a dark-red marbled and extremely hard wood, which gives off a fragrant odour when burned, and when scraped or rasped is used as an ingredient in incense; it is also employed as an astringent in medicine and for tanning fish nets. According to Professor van Eaden this wood is the produce of *Dalbergia Zollingeriana*, Miq. It is valued in Borneo at 6s. per picul, and in Singapore at 4s. per picul. The bark of the "Russack" tree (*Vatica Russack*), which is added to toddy to make it intoxicating, is one of the few barks exhibited. It is remarkable that a species of the same genus is used in Ceylon for a similar purpose. Under the name of "chindana," probably a corruption of the Hindoo "chandana," a handsome, yellowish, fragrant wood is shown, which might perhaps afford a volatile oil. It does not appear to have been botanically identified. A considerable quantity of mangrove bark forms a conspicuous object of the exhibit and perhaps deserves the prominence given to it, for according to an analysis of the bark made by Mr. W. W. Evans, of Bristol, since the Exhibition has been opened, it affords 41·398 per cent. of tannin.

Some very fine specimens of "dammar mata kuching" and of copal are shown, and several kinds of gutta-percha and india-rubber, including "gutta merah," "gutta hilang," or "elong," "gutta menoun," and "gutta liceak" (india-rubber).

Borneau gutta-percha and india-rubber, like those of Perak, are mixed articles. Thus, Mr. Burbidge states*:—

"That from the Larvas district is formed of the mixed sap of at least five species, the juice of *Ficus* and one or two species of *Artocarpus* being not unfrequently used in addition as adulterants. The Bornean "gutta soosoo" or rubber, again, is mixed sap of three species of *Willoughbeia*, and here also the milk of two or three other plants is added surreptitiously to augment the quality collected."

Mr. Burbidge further remarks that although the demand for caoutchouc from Borneo is a recent one, yet in many districts the supply is practically exhausted. He advises that the *Willoughbeia*, which grows quickly and may be easily and rapidly increased by vegitative as well as seminal modes of propagation, should receive the attention of the Government in India, where the plant might be expected to thrive.

Very little appears to be known concerning the trees which afford the gutta and caoutchouc of North Borneo, and in the 'Kew Report' for 1886 the Director expresses a hope that the North Borneo Company will employ a competent botanist to investigate the subject and to collect good specimens in flower and fruit of every tree yielding a product of commercial value, as it is to the interest of the Company to ascertain definitely the extent of the gutta-percha and india-rubber resources of the island, and how existing supplies may be best developed and husbanded,* since the same wasteful method of collecting gutta-percha that obtains in Perak seems to be followed also in Borneo.

In connection with these remarks it may be well to call attention to a very valuable paper by Mr. Leonard Wray on the great loss of gutta-percha resulting from the wasteful mode of extraction at present employed.† In some experiments made on the bark of a tree of "getah taban simpor" (*Payena Maingayi*) (see p. 5) from which gutta had been extracted, he found that the wet bark which is now allowed to rot in the jungle contains fully 5·7 per cent. of gutta-percha, or 11·4 per cent. when dry, and that by simple pounding or rasping and boiling the bark nearly all this gutta can be extracted. He calculates that, accepting the estimate of the export of gutta from the Straits Settlements and Peninsula as 10,000,000 lb. weight in 1875 the amount of gutta-percha lost to commerce, in the bark of felled trees, must have amounted in that year to no less than 300,000,000 lb., putting the price at 2s. 6d. per lb. to not less than £37,500,000. In other words, for every pound of gutta-percha collected 30 lb. are wasted. The gutta trees are of such slow growth that the tree planted in one generation cannot be expected to yield good gutta until the next, and according to Mr. Wray one-thirtieth of the number of trees that are at present felled could be saved.‡

The minjak (*i.e.*, oil of) tangkawang, a solid fat with a low melting point and which does not readily become rancid, is shown *in situ* in the bamboos in which it is moulded. There are two kinds of these fats, one of which is nearly white and used for culinary purposes, such as frying fish, making cakes, etc., and the other is of a greenish tint and is used for lubricating machinery and for purposes of illumination. The former is said to be derived from large seeds, probably those of *Hopea macrophylla*, and is known as tangkawang lingis. The green fat is prepared from smaller seeds, probably those of another species of *Hopea* and is distinguished as tangkawang mahjor or minjak kerapoh. A fuller account of these fats was given in a former number of this Journal.§

Two products, which also occur in the Straits Settlements' collection, viz, Borneo camphor and edible swallows' nests, can be more appropriately

* Kew Report, 1881, p. 44.

† *Journal of the Straits Branch of the Royal Asiatic Society*, 1884, p. 219.

‡ An attempt was made to carry out a project of this kind, some twenty years ago, in British Guiana. A very large outlay was made for the purpose, but the result was total faliure, the extract obtained consisting chiefly of astringent material with very little gum.

§ See *Pharm. Journ.*, [3], xiv., pp. 401, 481.

noticed here, since they are represented more fully in the North Borneo Court. Of the birds' nests three varieties are shown. The first and best are quite white and are said to be those which have been collected after they have been finished by the birds, but before the eggs are laid; the second quality appears to consist of the nests which have been used but in which young birds have not been raised; and the third contains adhering feathers. The two former are known as white and the last as black birds' nests. These appear to be made by different birds, for, as pointed out by Mr. Lowder, the feathers do not merely adhere but are imbedded in the salivary layers of which the nests are formed; portions of dried seaweed or lichens are also incorporated. The birds inhabit caverns near the sea or sometimes inland, as in Upper Perak, and the limestone caverns of Mount Gormanton, in Borneo, and the sandstone ones at Sandakan head.* They are collected, at great risk to life and limb, twice a year, in various parts of the Eastern Archipelago. There appears to be some doubt as to the exact species which build these nests. *Collocalia Linchi*, Horsf. being given in the Straits Settlements' Catalogue as the species. Mason, however, states that this bird makes a brown nest of moss glued together, while *Collocalia esculenta* makes its nest of repeated layers of glutinous salivary matter alone. The latter bird is called the "lawet" in Java, while the name "linchi" is applied to the smaller species named *Collocalia Linchi*. Possibly the white nests are the product of *C. esculenta* and the black ones of *C. Linchi*. Two other species, however, appear to produce edible nests and these are known respectively as *C. spodopygia* Peale,† and *C. fuciphaga* Horsf.,‡ which occur in the Andaman Islands, the latter also in Tenasserim.

The nests are often brown or discoloured at the parts where they are attached to the rocks, and have to be cleaned for the Penang market. The white nests are used by the wealthy Chines as an ingredient in soups, 120 grams being used for the litre of soup. The dirty nests are said to be employed to make a particular kind of glue. The first quality is valued at 2,500 dollars per picul, the second at 1,500 dollars, and the third at 1,000 dollars. It is calculated that as much as 242,400 lb. of these nests are annually exported to China from the Indian Archipelago. In some parts of China as much as £9 has been paid for a catty (about 1⅓lb.) of these nests. At one time it was supposed that the substance of which they are composed was seaweed collected by the birds, and some discussion has taken place in *Nature* on this subject.§ It appears now to be definitely settled that it consists of a salivary secretion similar to that used by the swallows in this country in binding together the clay of which their nests are made. Like another article highly prized by the Chinese, it appears to be considered a tonic and invigorating remedy, and is also used as a restorative by opium smokers; it is prescribed in consumption, and for convalescents after protracted illness. A detailed and interesting account of the commerce in these nests may be found in Simmond's 'Animal Food Resources,' p. 141.

Borneo camphor does not appear to have received the attention it deserves in this country. So astute a people as the Chinese have doubtless some good reason for their preference of this camphor to that which can be procured at one-twelfth of the price in Formosa and Japan. It does not appear to have been noticed that although the odour of the Borneo camphor is not altogether agreeable, the taste is by no means so disagreeable as that of Formosa camphor. Its physiological properties also cannot be said to have been fairly tested. For this purpose well defined crystals only should be used, since it is probable that the smaller crystals are frequently adulterated with crude Formosa camphor, because the large crystals do not appear to be volatile, while the smaller ones frequently furnish a crystalline sublimate at ordinary temperatures.

The high price of the drug is in part due to the fact that a large number of trees have to be examined before the collector can find one containing the camphor in a crystalline state. Many of the trees yield oil, but very few contain camphor. The presence of the latter is ascertained by making a hole in the tree with a native axe at about 14 or 18 feet from the ground, till near the heart, where a deeper incision with a smaller aperture is made; if the oil is present it gushes out and is received in bamboos or other vessels. Some hundreds of trees may be thus examined before camphor is seen. When a tree containing camphor is found it is felled and cut into pieces about 6 feet long, or less, and these are split open, when the camphor is found in the heart wood occupying a space about the size of a man's fore-arm. The produce of a medium-sized tree, *i.e.*, about 2½ feet in diameter, is about 1¼ pounds, and of a very large one, say 6 feet in diameter, about double that quantity. Camphor found in this way is distinguished as "se aaniong," and that met with in holes of trees that have been previously cut is known as "oogar," the scrapings of the wood being known as "belly and foot."* Trees less than two feet in diameter rarely produce camphor, oil being found in the younger trees, but sometimes a pitchy or resinous looking substance is found in the cavities in the trunk.

Probably on account of the uncertainty of finding camphor in the trees the natives and the Malays have very superstitious ideas regarding its collection. While searching for it they abstain from certain kinds of food, eat a little earth, and use an artificial language called the bássá kápor, *i.e.*, camphor language. It is beleived that if this language be not used great difficulty will be experienced in finding the trees, and when found the camphor will not yield itself.† There are some men who pretend to a special intuition as to the trees which will yield camphor. These are styled Toongoo Nyr Capoor. Fuller details concerning the commercial qualities of this camphor may be found in a former number of this Journal.‡

Some fine specimens of the camphor wood are shown in this Court. The tree is a very large one, and the wood is extensively employed for making boxes, furniture, etc. It is said to be abundant in the island called Pulo Bai, in Sandakan Bay, and in Padas district.

Another exhibit worthy of a brief notice is a kind of guano or manure, consisting of the excrements of swallows and bats. This is found forming a deep layer in caves, especially in East Borneo in the neighbourhood of Gormanton; it forms an important but, as yet, almost untouched store of this valuable material.

Hong Kong.

The Hong Kong Exhibit comprises but few objects of pharmaceutical interest, but these are well worthy of notice. The first object that strikes the eye on entering the Court from the upper end is a small collection of native remedies shown by Messrs. A. S. Watson and Co., but which is not mentioned in the General Catalogue. Several of the articles, such as chaulmugra oil, will be familiar to pharmacists in this country, but a few others, such as cypress seed and cypress oil, oil of coconut shell, bean oil (*Soja hispida*), oil of *Camellia odorifera*, wood oil (*Aleurites cordata*), and oyster oil and oyster cake, left after removal of the oil, strike one as articles hardly known in Europe.

The properties of the Chinese "wood oil"— which is very different from the oleoresin known in English commerce as wood oil or Gurgun balsam—have been

described in a former volume of this Journal,* and to the others there will probably be occasion to refer at a future time. Close to this exhibit may be seen the curious wedge press used in expressing oils from crushed seeds, the principle of which is to exert a gradual lateral pressure by the insertion of a series of wedges between the cake and the end of the press. In the immediate neighbourhood of this press may be seen also a large granite pestle and mortar for pounding rice, which is worked by the simple expedient of a foot lever or treadle. Opium smoking is illustrated by a series of the apparatus employed in preparing the extract, which, and not the crude opium, is used in smoking. The mode of preparation has been well described by Mr. H. McCullum, of Hong Kong (*Pharm Journ*, [3], vol. xi., p. 229). The apparatus used by opium smokers is also illustrated by various specimens, including opium pipes, spirit lamp, iron scrapers for clearing out the bowl of the pipe, and needles for inserting the morsel of opium in the orifice of the pipe, etc.† Specimens of these articles already exist in the Museum of this Society as well as at Kew Museum, and their use is fully explained by Mr. T. Sampson, of Canton, in a previous number of this Journal ([3], vol. xv., p. 22).

The next object to attract attention is an excellent model of a Chinese vermilion manufactory at Hong Kong, showing the complete process of preparation of the pigment from the raw material to the cases packed for export. This model was constructed under the superintendence of Mr. H. McCullum and Mr. H. R. Best, of the Colonial and Civil Service, and was presented to the Commissioner by the guild of vermilion merchants. From the descriptive account attached to the model it appears that 1 part of sulphur is rubbed with 5 parts of mercury, an operation which usually occupies about ten minutes. The mixture is then placed in an iron pan over a furnace, is covered with pieces of broken porcelain or white pottery, over which an iron cover is luted on. After this subliming pan has been subjected to heat for sixteen hours the furnace is allowed to cool, the iron cover removed, and the vermilion scraped off the porcelain. It is then powdered and elutriated with a solution of alum and glue, the coarse particles separated by this process being again powdered and elutriated. The object of the glue and alum is not stated, but the glue is probably to prevent the powder from settling too rapidly, the alum to prevent the decomposition of the glue. The details of the process have already been described by Mr. H. McCullum in the columns of this Journal ([3], vol. xii., p. 497). The first quality of vermillion is estimated at 8 dols. per picul, and the second at 750 dols. per picul.

A collection of raw materials used by the Chinese in the manufacture of the celebrated soy and other sauces is shown also by Mr. M. McCullum. Perhaps the most interesting exhibit to pharmaceutical visitors in this Court will be a very complete and truthful model of a Chinese druggist's shop, which is said to be faithful to real life in the most minute details. The roomy shop appears to be arranged in a most orderly manner, and by no means presents a "beggarly array of empty bottles," nor are there visible any of the disgusting animal remedies that are used in Chinese medicine. At the back of the shop and equally open to view at the other side of the model is the dwelling house, the appointments of which seem eminently comfortable, as might perhaps be imagined from the care with which druggist looks after the money, for in the shop he is represented as weighing the money of a customer to see that it is not short weight. This model is exhibited by Dr. Ho Kai, who has also sent a large collection of over four hundred bottles of Chinese drugs, the names and uses of which are written on the bottles. These consit for the most part of remedies which have already been described by Hanbury, Porter Smith and others, but are evidently highly valued by Dr. Ho Kai, since they have been heavily insured and are to be returned to him.

The only other objects of quasi-pharmaceutic interest are the exhibits of boxes, trunks, etc., made of the camphor wood tree, and a series of the woods of Hong Kong, including a few, such as *Liquidambar sinensis*, *Aquilaria grandiflora*, *Styrax suberifolium*, etc., concerning whose products some information might have proved instructive. Unfortunately, however, no special catalogue had been published at the time of our visit, and Mr. C. Ford, Superintendent of the Palace Garden at Canton, who might probably furnish valuable information concerning them, left this country soon after the exhibition had opened. The *Aquilaria grandiflora* yields, according to Mr. Ford, a kind of lignum aloes used in China as incense.—*Pharmaceutical Journal.*

† For figure of these see 'Encyclopedia Britannica,' 9th ed., Art. "Opium."

NOTES ON ECONOMIC PLANTS AT THE STRAITS SETTLEMENTS.

Appendix to Report on the Singapore Botanic Gardens, for 1885.

Enquiry was continued during the year into the source and extent of the vegetable supply of the colony, and experiments have been made with various seeds from Europe with a view to increasing and improving the general supply, with results as follows:—

I.—VEGETABLES FOUND IN CULTIVATION.—ORD. CRUCIFERÆ.—*Lobak* (Long Raddish), Raphanus sativus var.:—Native of China, largely cultivated throughout the colony. Supply plentiful. *Water Cress*, Nasturtium officinale:—Established in Singapore, but supply as yet very limited in the bazaars.

ORD. CAPPARIDEÆ.—*Mamum*, Gynandropsis pentaphylla:—Pods chiefly used. Common in a wild state not much cultivated. *Mamum Kechil*, Cleome viscosa:—A common weed, used in the same manner as the Preceeding, chiefly by Klings.

ORD. MORINGEÆ.—*Kelor* (Horse Raddish tree), Moringa pterygosperma:—Native of Madagascar Pods, root and leaves used. Supply plentiful.

ORD. PORTULACEÆ.—*Daun Gulung* (Purslane), Portulacca oleracea:—A common weed throughout the colony. Cultivated in England as a vegetable. Used in the Straits chiefly by the Malays and Klings, and seldom if ever taken into the bazaars.

ORD. MALVACEÆ.—*Kachang Bendie*, Hibiscus esculentus:—Cultivated all over the Tropics. Supply plentiful.

ORD. LEGUMINOSÆ.—*Kachang Kara Puteh*, Lablab cultriformis:—A good bean, but not plentiful. *Kachang Boty*, Dolichos tetragonolobus:—Moderately plentiful. *Kachang Prot Ayam*, Dolichos sesquepidalis:—Largely cultivated throughout the colony. Supply plentiful.

Kachang Prot Ayam Panjang, Dolichos sesquepidalis var.:—Plentiful. Canavalia virosa:—A good bean said to be in cultivation, but I have only seen one plant.

Kachang Parang, Canavalia gladiata:—A very large bean. Pods occasionally as large as a carving knife, hence the Malay name. Moderately plentiful.

Kachang Kara (Lima bean), Phaseolus lunatus:—One of the best beans in cultivation. Supply moderately plentiful. Also sold in tins imported direct from Brazil, its native country.

French Bean, Phaseolus vulgaris:—Cultivated largely throughout the colony, but brought to the bazaars at an advanced age in order to measure better, but only really good when very young and small.

Kachang Hijau, Phaseolus sp.:—Seed largely used in a germinating state. Supply plentiful. Pods also used after the manner of French beans.

Trong Merah, Agati grandiflora:—Leaves and flowers used.

Trong Puteh, Agati grandiflora alba:—Leaves and flowers used. Supply limited. Seldom reaches the bazaars.

Meng Kawang, Pachyrrhizus angulatus:—The root very much resembles a turnip, both in size and taste, hence called turnips by Europeans in the Straits, but it is in every way inferior to turnip. The supply is apparently plentiful.

Kachang Dahl, Cajanus indicus:—Pods used. Not much grown except by Klings.

Ord. Myrtaceæ.—*Nasi Nasi*:—The young leaves of a species of Eugenia, used by the Malays in Malacca as a vegetable in curries.

Ord. Pasifloraceæ.—*Grenadilla*, Passiflora quadrangularis:—Used chiefly by Europeans; the natives look upon it as unwholesome and dangerous.

Ord. Cucurbitaceæ.—*Timon*, Luffa petola:—Used as a cucumber, but good only when green. If used in a ripe state is said to cause violent purging. Plentiful in the bazaars everywhere.

Kelula Manis, Luffa acutangulus:—Largely used as a vegetable and for other purposes. Supply plentiful.

Kaundon, Cucurbita pepo and vars.:—Plentiful in the bazaars all over the Colony. Not much used by the Malays, who say that it creates cramp in the stomach when eaten raw.

Water Melon, Citrullus vulgaris:—Not very plentiful.

Lobu Ayer, Cucumis sativus flavus:—Very plentiful, and extensively used.

Pria Paddy (Bitter Gourd), Momordica charantiæ and vars.:— } Both extensively cultivated.
Pria, Momordica balsamina:— }

Cucurbita sulcata:—Not very plentiful.

Ketula Ular (Gourd), Lagenaria vulgaris, var. striata:—Very extensively grown. Bazaars constantly supplied.

Ketula (Pumpkin), Cucurbita Moschata:—Several kinds. Very plentiful.

Chocho, Sechium edule:—Established on Penang Hill; in general excellence this cucumber far surpasses all others grown in the Straits.

Ord. Umbelliferæ.— } Leaves only seen. Grown only for flavouring purposes. Supply plentiful.
Sadriea (Celery), Apium graveolens:
Do. do., sp.?
Do. do., sp.?
Do. do., sp.?

Pungga, Hydrocotyle asiatica:—A common weed, used by the Malay and Kling inhabitants only.

(Dill.), Anethum graveolens;—Used in soups, sauces &c. Supply very limited.

Ord. Verbenaceæ.—*Buas-buas*, Premna cordifolia:—Young leaves used in curries. Supply plentiful.

Ord. Compositeæ.—*Tang Ho*, Senecio chinensis:—Leaves used as spinach. Supply plentiful.

Saw., (Lettuce) Lactuca sativa var., } Boiled and used as cabbage.
Sawi Hitam Do. } Extensively grown and supplied.
Salad, Do. Used only as salad, and apparently a very good lettuce, but cut and brought to bazaar at a too great age in order to obtain as much leaf as possible. I have examined this plant very closely, and am of opinion that, if cut when young, it would be little inferior to lettuce grown in Europe. There is also a leaf commonly sold in the bazaar which I think belongs to this order, but no clue to its name has presented itself so far. It is said to be a good vegetable.

Ord. Solaneæ.—*Trong* (Egg Plant), Solanum melangena:—Very extensively grown. Abundant supply in all the bazaars.

Trong Manis, Solanum coagulans:—Plentiful. Used in curries.

Love Apple or *Tomato*, Lycopersicum esculentum:—Grown by Europeans in very limited quantity, and seldom if ever finds its way into the bazaars. The plant, especially the small variety, grows freely, and might be largely cultivated. Solanum nigrum, one of this order, is largely used in Mauritius as a vegetable with currie, but is not used in the Straits, although the plant is by no means uncommon throughout the colony. Its use requires some care, however, being poisonous if eaten raw, and regarded in England as highly dangerous. I have myself used it frequently as a vegetable and can testify to its excellence as such. It has a bitter appetitious taste and is a vegetable one gets much attached to after a time, and the Mauritians seem as fond of it as the Malaysare of Durians.

Ord. Phytolaceæ.—Phytolacca decandra:—Is so very scarce in the colony that it can hardly be said to be in use. It is nevertheless an excellent vegetable, when the young leaves only are used; the seed is noxious. Largely used in the Mauritius as a vegetable.

Ord. Basellæ.—*Tress*, Basella alba:—Somewhat extensively grown, but not nearly enough so. It is an excellent substitute for spinach and grown in England as such. It is better known among the Klings than the Malays. A small supply reaches the Singapore bazaars.

Ord. Euphorbiaceæ.—*Chekop Manis*, Phyllanthus reticulatus:—Largely used as a vegetable with currie by Chinese, Klings and Malays; not so much among Europeans. Supply plentiful. *Ubi Kayu*, Jatropha manihot:—Root largely used as a vegetable by all classes, but the leaves only by the Malays and Klings, especially the former.

Ord. Zingiberaceæ.—*Kunit* (Turmeric), Curcuma longa:—Root used in currie, and leaves as a vegetable, by the Malays.

Ord. Musaceæ.—*Pisang* (Banana) Musa, many vars.:—Pith and young shoot used as a vegetable.

Ord. Aroideæ.—*Kladi* } A small portion of the root used as a vegetable.
Klamomo, Calocasia esculenta:— } Grown extensively for leaves, which are boiled and pigs fed with them.
Kladi China, Calocasia esculenta var.:—
Kladi Hitam, Calocasia esculenta var.:—

Calocasias sp.:—Grown only in Padang. Largely used as a vegetable in Singapore. The Malays affirm that the plant will only grow in Padang. Not cultivated elsewhere.

Ord. Liliaceæ.—*Bawang*, } Very extensively grown and largely in demand. Plentiful supply.
Allium ascolonicum:— }
Bawang Kechil, Allium ascolonicum var.:— }
Bawang Merah, Allium ascolonicum var.:— }

Allium cepa:—Not grown in the colony, but largely imported from China in a green state,

Ord. Commelyneæ.—*Tapak Itek*, Aneilema nudiflorum:—Used by the Malays as a vegetable with currie.

Ord. Boroginaceæ.—Cordia olitoria. Blanco:—The leaf of this plant is used as a vegetable by the Malays, who eat it with boiled rice.

Ord. Scrophularineæ.—*Bremis*, Limnophila punctata:—Used as spinach. Supply very limited.

Ord. Amaranthaceæ.— } Extensively used as a substitute for spinach. Largely grown and largely in demand.
Bayam Durie, Amaranthus spinosus:— }
Bayam, Amaranthus gangeticus:— }

Bayam Pasir, Amaranthus tristis:— } Used only by the Malays and Klings.
Kruma, Alternanthera sessilis:— }

Ord. Dioscoreæ.—*Kledek* Dioscorea batatas:—Extensively grown. Bazaars largely supplied.

Dioscorea bulbifera (?):—Grown more sparingly.

Ord. Convolvulaceæ.—*Kangkong*, Convolvulus repens:—Extensively grown for the leaves, which are used as a vegetable with rice and for feeding rabbits. Supply plentiful.

Ord. Artocarpeæ.—*Sekun* (Bread-fruit), Artocarpus incisa:—Fruit used by the Malays as a vegetable. The tree, however seldom produces fruit in perfection in the Straits, the greater number falling prematurely.

Nangka Artocarpus integrifolius:— } Young fruit used as a vegetable by the Malays.
Champedak Artocarpus polyphema:— }

Ord. Papayaceæ.—*Betek* or *Buah Papaya*, Carica papaya:—Extensively cultivated and used as a vegetable. Plentiful in the bazaars.

Ord. Filices.—*Paku Ruan*, Ceratopteris thalictroides:—Common in ditches. Used chiefly by Klings and Malays.

Anisogonium esculentum:—A fern not uncommon in ditches. Is a very good vegetable, used by the Malays, who also use the young shoots of the following ferns:—

Paku Akar, Stenochlaena palustris:— } All fairly plentiful in a wild state.
Paku Uban, Blechnum orientale:— }
Samber, Thamnopteris nidus:— }

Ord. Gramineæ.—*Rebong*, Gynotochloa aspera (?):—A bamboo the young shoots of which are extensively used among the Chinese as a vegetable and for preserves.

Juggong, (Maize):—Is grown to some extent and used green as a vegetable.

Ord. Palmeæ.—*Pinang*, *Klapa*, Areca and Cocos:—Heart or growing point used as salad. Supply very limited.

2. From the foregoing it will be seen that there are about eighty kinds of vegetables at present more or less in cultivation in the colony. Of that number, but few are exclusively Chinese, but a good deal of the seed from which they are grown comes from China. The cultivation is, however, much at fault, there being a tendency to produce quantity instead of quality, and some control over present system of cultivation seems necessary.

3. The following 45 kinds of vegetables of species cultivated in England have been tried, in Penang, at 1,000 feet elevation, and in Singapore at about 150 feet, with results as follows:—

II.—Vegetables Grown for Trial.

Giant Asparagus,	in Penang grew freely, but not to a large size.
Broad Windsor Beans.	Flowered in Singapore and Penang, but failed to set fruit.
Scarlet Runners, ...	Failed quite everywhere.
Egyptian Turnip, rooted Beet, ...	Did well in Penang.
Delt's Flower Garden Beet, ...	Grew fairly well in Singapore, not tried in Penang.
Broccoli, ...	Grew leaves only in the open ground, makes better centre when grown in Pots. Penang and Singapore experiments gave same results.
Brussels Sprouts, ...	
Cabbage, Large White Erfurt, ...	
Cabbage, Early Blood Red, ...	
Cabbage, Savoy, ...	
Carrots—Early short Horn, ...	Grew well both in Penang and Singapore, but of inferior flavour in Singapore.
Carrot Earliest French forcing, ...	
Cress, Curled, ...	All grew well in Penang and Singapore. Succeeded better in Penang.
Cress, American, ...	
Cress, Indian, ...	
Telegraph Cucumber'	Grew fairly well in Penang Failed in Singapore.
Sundringham Celery,	Grew fairly in Penang.
Cos defiant Celery, Williams' Matchless Celery, ... Major Clark's Red Celery, ...	Grew to leaves only in Singapore.
Dandelion	Grew well in Penang and Singapore.
Musselburgh Leek, ...	Grew well in Penang.
Kole Rabi, ...	Do Do. and Singapore.
Lettuce, Cabbage, ... Lettuce, Tom Thumb, Carter's Giant White Cos, ... Carter's Giant Brown,	Succeeded perfectly in Penang and fairly well in Singapore.
Melon, ...	Failed everywhere.
Mustard, ...	Grew freely everywhere.
Onion, The Queen, ...	Grew well in Penang.
The Student Parsnip,	Grew well in Penang.
Parsley, ...	Everywhere a success.
Peas, Ring-leader, ...	Grew fairly well in Penang.
Peas, Best of all, ...	Failed in Singapore.
Potatoes, Early Ash-leaf, ...	Grew to a fair size, but rather watery in quality.
Raddish, ...	All kinds grew well.
Horse Raddish, ...	Grew well.
Rhubarb.	Grew well for a time in Penang. Failed in Singapore.
Sea Kale, ...	Failed everywhere.
Turnip, Early French,	Grew well in Penang; not tried in Singapore,
Turnip, American Strap leaf, ...	Grew well in Singapore; not tried in Penang.
Tomatoes, ...	All kinds grew well, especially the small variety.
Jerusalem Artichoke,	Failed in Singapore.
Globe Do ...	Failed in Singapore, but produced a few flowers in Penang.

POT HERBS.

Sage, ...	All grew well in Penang and Singapore. Sage and Thyme best in Penang.
Thyme, ...	
Sweet Marjorum ...	
Spear Mint, ...	
Pepper Mint, ...	
Sweet Basil, ...	

4. It will be admitted that these results carry with them a large amount of success, and all that seems required to keep up a supply is the issuing of a standing order to a seedsman to send a regular supply of seeds of such as have succeeded and the appointment, for a year or two, of an intelligent person well acquainted with vegetable cultivation to superintend the distribution of seeds and regulate bazaar supply.

He should keep a register of all growers for sale and submit, for the information of Government, periodical reports on the progress of new vegetables, and encourage cultivators by liberal assistance.

5. By this means private enterprise would be stimulated and the object desired obtained without causing the injury to cultivators which the establishment of a Government, vegetable garden for bazaar supply would entail upon them.

III.—Other Economic Plants.

6. *Coca-leaf.*—The seed of coca was much in demand during the early part of the year, but the value of the leaf has now fallen so low that it would hardly pay to cultivate it in the Straits.

7. *Cubebs.*—There is at present but little cubeb pepper in cultivation in the Straits. Some plants lately received from Dr. Treub have been placed in the Experimental Nursery for trial. Samples of a large consignment from India of prepared cubeb pepper were received at the Garden from a Singapore merchant for botanical determination. The samples turned out to be only one-third cubebs, the remainder Piper nigrum, or some allied specimens. Cubebs can always be distinguished from Piper nigrum by the berries having little stalks.

9. *Black Pepper.*—The rise in the price of black and white pepper has stimulated the cultivation of the plant both in the colony and elsewhere. Several demands from other colonies have been made for the Singapore variety, which is acknowledged to be of superior quality.

10. I made a special visit to the Achinese plantations in Province Wellesley, where the plant is cultivated differently from the mode practised by the Chinese, but the difference only proved to be be what may be summed up in the word neglect, and bore no comparison to the better and higher cultivation as practised by the Chinese. The adoption of living supports by the Achinese (*Dadup*) is a point I would recommend, however, as in everyway more natural and economical than dead wood as used by the Chinese.

11. *Tea.*—The cultivation of tea is likely to prove a success in the Straits if handled with forethought and care. The chief drawback is the tendency the soil has to rent and fissure, even during a short period of drought, but this could be remedied by making special compost and planting in large holes.

12. *Cardamoms.*—Further experiments with Cardamoms show that the atmosphere in Singapore and Penang is apparently too dry for the proper cultivation of the plant, but it would no doubt succeed admirably in some parts of the Native States.

13. *Gambier.*—Observations have shewn that the gambier plant may be cultivated for forty or fifty years on the same land without the land becoming exhausted, if properly cultivated. This is the opposite to the general opinion. I measured the stems of some plants of the age mentioned and found them about 18 inches in circumference close to the ground and still bearing large quantities of leaves.

14. *Croton Oil.*—The Croton Oil plant produces seed freely in Singapore, and could no doubt be

grown with advantage. I would strongly recommend it to planters for trial.

15. *Cassia Auriculata.*—This is an East Indian bark which grows very freely in the Straits. The bark contains a valuable tanning principle, which would no doubt pay in cultivation.

16. *Cocoa.*—The new varieties of Cholocolate grow well, and the plant is now established in the Straits, but white ants, leaf insects, mildew, &c., play such havoc as almost to prohibit its cultivation in some districts.

17. *Nutmegs and Cloves.*—The protracted drought in Penang tried the Nutmegs and Cloves plantation very much, many young plants died, but the drought was of exceptional severity and has not discouraged planting.

18. *Hemp.*—Some plants of Mauritius Hemp, planted for experiment among rough lalang, have coped successfully with that troublesome grass, and although they have grown less rapidly, they have by means of their wide-spreading leaves, prevented the grass from covering them over and cutting off their supply of light.

19. *Rubber and Gutta Percha.*—The Foreign Rubber trees mentioned in previous reports continue to grow well, but in a country where the best rubbers grow wild, it is somewhat superfluous to refer to foreign species, the ultimate success of which may be doubtful. What is more required is the careful conservation and cultivation of native kinds, the growth and produce of which in our soil is not a matter of question. I believe a purley Gutta Taban forest, worked as they do timber forests in Germany, on say, a 30 years rotation would yield a good return in profit, that is to say, a certain area, however large, to be reaped (cut down if necessary) annually, and a corresponding area planted with young trees.

20. *Vanilla.*—The cultivation of Vanilla is being tried in the colony. There are some native varieties which fruit freely, especially in Penang, but I doubt the suitability of our climate for the cultivation of V. planifolia, the kind most prized.

21. *Mangosteen and other Fruits.*—The Mangosteen, which has hitherto been considered to fruit nowhere out of Malaya, is now reported almost simultaneously as bearing fruit in Jamaica, Ceylon, and India, and must be near bearing in the Mauritius and Seychelles Islands.

The cultivation of fruit pays well in the Straits, and orchards might be greatly extended with advantage.

22 *New Economics.*—Introductions during the year include Mimusops globosa, a famous West Indian Rubber tree; Chinese ginger; Chinese rice-paper plant; Yoroba Indigo. Canonball tree of West Indies, and West Indian fruits and medicinal plants the growth and properties of which will be detailed in next year's report.—N. Cantley, Superintendent.

TEA WITHERING.

Our representative paid a visit to Gillwell Park a few days since, and saw the new machine invented by Mr. Gibb's for withering tea. Until the blocks illustrating the machine are ready, we purpose holding our notice of the invention over. Suffice it to say that Mr. Gibbs, with his usual enterprise and skill, has made a clever attempt to solve the problem of withering tea in all weathers. *The Times* gives the following account of the invention:—

"One of the most important of the various operations connected with the preparation of tea for the market is that of withering. For this purpose the freshly plucked leaves are placed on trays on tiers in a building known as the withering house, where, by the aid of the dry, warm temperature, they are withered. This withering process has for its object the bringing out of part of the moisture contained in the leaf, so that every leaf is rendered soft and pliable, becoming to the touch like a thin piece of glove kid. In this condition the leaf is readily curled or twisted in the rolling mill, which is the next operation it has to undergo, withering being the necessary preparation for this treatment. It, however, sometimes happens that a damp atmosphere or a low temperature prevails, in which case the withering cannot be properly effected, and a considerable portion of the crop may be spoiled, thus entailing a heavy loss on the tea grower. Such cases are by no means of rare occurrence, as some of our Indian tea growers to their sorrow can testify. In these circumstances it is of course of the first importance to have some means of remedying this evil and of preventing this serious loss. Heat has been employed to dry the air, but we believe with indifferent success, for if the temperature cannot be perfectly controlled and regulated the leaves will become dried at the edges and in other ways rendered unfit for the subsequent process of rolling. To overcome this difficulty Mr. William A. Gibbs, of Gillwell Park, Chingford, has devised a machine which, in the opinion of those who are qualified to express one, is capable of effecting all that is desired whether the temperature be low or the atmosphere moist, or whether both conditions obtain simultaneously Mr. Gibbs' experience in desiccating machinery has enabled him to thoroughly grasp the difficulty and to provide the precise remedy, but this only after several months of careful study and practical investigation into the subject.

"The machine in question, which we were recently afforded an opportunity of examining in operation, is as simple in construction and operation as can well be conceived, thereby adapting itself to the degree of intelligence possessd by the class of operatives who will be intrusted with its working. It consists of one of Mr. Gibbs's fans fitted in an iron casing mounted on a pair of wheels, and having a small coke fire in a box in front of it. If we add a handwheel for driving the fan and a couple of handles for moving the machine about, barrow fashion, we shall practically have completed its description. There is, of course an air inlet to the rear of the fan, and there are two outlets in front of the firebox. Into each of these latter is fixed a light flexible hose, about 4 in. in diameter, for the distribution of the air from the fan. The work of turning the fan is very slight, and here Mr. Gibbs has met the requirements of Eastern labour, for after the fan has been once started, the slightest touch of the handle at each revolution will keep it going, as the friction is reduced to a minimum. The turning of the handle draws the air into the fan, and it is expelled on the other side; but on its way to the delivery outlet, it is made to pass through a chamber which is placed over the fire, and by which means the air is raised to the desired temperature. It will thus be seen that two streams of warm dry air, one on either side, can be delivered through the hose in to the tea which is laid out for withering. With regard to the range of temperature, we may observe that on the occasion of our inspection the thermometer stood at 63 degrees Fahr. at the inlet of the fan, and at 87 degrees at the outlet, thus giving a range of 24 degrees.

"So far, the question of temperature only has been dealt with. We have now to show how the machine acts in the case of a hygrometric atmosphere. To meet this case there is a small cage fixed in the front of the air inlet to the fan. In this cage are placed roughly broken fragments of chloride of calcium, and through this mass the air has to pass on its way to the fan. The chloride of calcium abstracts the moisture from the air, which enters the fan perfectly dry and is expelled from it in the same condition, the fire not being used if the temperature of the atmosphere be sufficiently high. The machine is perfectly portable, weighing only 1½ cwt., and measuring only about 7ft. in length by 4ft. in height and about 2ft. in width over all.

"The principle of this machine has been applied, or rather added, by Mr. Gibbs to the tea-drying cylinder which he devised for drying the tea as it comes from the rolling mill, and which was described by us towards the close of last year. This machine

consists of a revolving cylinder through which the tea is gradually passed: being exposed during its passage to the desiccating influence of a stream of heated air. In this case the air may have a temperature of some 450 deg. on entering the cylinder, and on leaving it will still be sufficiently warm to be serviceable in withering tea. The air, however, leaves the cylinder laden with the moisture which it has absorbed from the tea, and in this respect is of course quite unsuited for withering. But by placing a cage of chloride of calcium at the exit end of the drying cylinder and a small fan beyond it, the air is drawn through the chloride, in which it leaves all its moisture, and is delivered by the fan perfectly dry and of a temperature suitable for withering, as was demonstrated on our visit. Of course chloride of calcium, being a deliquescent salt, becomes dissolved as it absorbs moisture. In the case of the drier as well as in that of the witherer, however, it is caught in a pan placed beneath the cage, and is afterwards restored to its normal condition by evaporation. It is thus used over and over again, none being wasted, and, therefore involving no expense in this respect beyond the first cost. This simple method of obtaining dry air at moderate temperatures is applicable to many products where heat alone would be injurious, and Mr. Gibbs is now in treaty with a large inporter of timber to construct a building and provide large power-driven fans with calcium chambers for the rapid seasoning of damp timber. He considers that this more powerful arrangement will ultimately be adopted for tea-withering houses when the planters have satisfied themselves as to the value of the process by the use of the portable witherer we have described.

"We thus have a further extension of Mr. Gibbs's ingenious application of physical laws and mechanical principles to the saving of crops, an extension which appears destined to reflect on its inventor as much credit as those by which it has been preceded, and on which he has expended so much thought, time and money. Before concluding, we may refer to an improved apparatus, which we saw in model at Mr. Gibbs's, for desiccating fibrous substances. In this instance Mr. Gibbs has taken his hay-drying machine as the basis. Here he uses a series of forks or tines fixed on two horizontal bars to which motion is imparted by a crank shaft. The material to be desiccated is fed into a perforated floor through which hot air is forced, and the form and action of the times is such as to lift and separate the material under treatment as well as to gradually carry it forward over the floor from one end to the other of the machine, at any desired rate of speed. We thus have another useful appliance for the treatment of such fibrous substances as require separating during the process of desiccation, and which is specially applicable to certain new substances used in paper making, for which purpose, in fact, Mr. Gibbs has designed this model. A large machine, 35 ft. long by 12 ft. wide, is now being constructed, the cost of which as compared with the old-fashioned endless hand machine is less than one-half, while its greater efficiency in opening up the material is obvious to all practical men."—*H. & C. Mail.*

CASSIA LIGNEA AND THE CHINAMEN.—According to the report of the Superintendent of the Afforestation Department of Hong Kong for 1885, there is a great difficulty in growing this tree, as the following extract from the report will show:—"The plantations of Cassia lignea that were made on the hills north of Aberdeen would probably have been in a thriving condition by this time but for the persistence of the Chinese in breaking off the leaves and branches of the plants. They appear to attach some importance to the plant as a medicine, and despite the vigilance of the forest guards, they succeed in keeping the plants in an almost leafless condition. Even in the Botanic Gardens, where the plants are protected by iron tree-guards and wire netting, they have killed several plants by persistently defoliating them and wrenching off the branches."—*Gardeners' Chronicle.*

COFFEE PLANTING IN SOUTHERN INDIA AND CEYLON.—No. I.

(REVIEW OF THE "WRINKLES AND HINTS ON COFFEE-PLANTING" WITH DIAGRAMS AND SPECIMENS OF FORMS BY GEORGE WILDES; MADRAS, ADDISION AND CO., MOUNT ROAD.

By an Old Ceylon Planter.)

Had I been asked my opinion a little while ago, as to whether the Coffee planters of India and Ceylon needed another book of instructions, I should have answered with a decided negative. Behold, they have Laborie, Sabonadiere, Hull, Brown and all the information collected by the *Observer* Editors in the Hand books published by them! I will not now however say that Mr. Wildes' book is quite superfluous, or that it will not fulfil its promise of giving Wrinkles and Hints to the most experienced planters, rather narrow and local but pretty sound, and we cannot expect any one to deal with matters beyond their experience.

There are many things in the book worth knowing and not to be found in other works on the subject, which is sufficient justification for writing and publishing it, if the author and publishers saw their way to make it pay.

In the article on CLEARING, the author is intensely local, and not very decided in his views. He was evidently a rather dry climate to deal with, and he goes no further. Top knots and belts are recommended to be left, which are very unsatisfactory in all cases: get a good fire, and they will be destroyed by it running through them; if they escape this danger, they become nests of weeds and harbours for vermin; forest left on the tops of hills gives no more shelter to the leeward side, than the bare hill will yield. He advises the leaving of gorges where wind rushes violently, but how is any one to know where wind will come; even he himself admits that wind wrings patches of coffee that to all appearance should be free from it. We can have no object in leaving a belt across a hill facing the prevailing wind, knowing that the trees so left will break the wind to the coffee above, exactly to their own height, but belts are worse than useless where there is an inclination of surface on both sides. The shade question has long ceased to be a subject of controversy in Ceylon; we leave no shade trees when felling and we plant none afterwards. Even Liberian Coffee expresses its abhorrence of shade in an average temperature of over 80 degrees Fahr. and a correspondingsun heat. To get a good fire through fallen forest, is the planter's first object and to this end the under-wood should be arranged so as to carry the flame along the surface; and all branches of larger trees should be cut where they stand above the general level.

The author has a very proper idea of the importance of good LINING, and his method is as good as any that can be found. Bad work I have always found to be the result of trusting a measure to a native; not one of them that I have dealt with knows a level from an incline or the difference between a right angle and an acute one. My own method is one hundred and twenty feet squares, all the sides of which I measure and peg myself—the coolies lay coir lines across the squares; a moving line is carried over them from peg to peg and the pegs put in at the crossings. There is generally at least one cooly in a gang, who can lay a string straight, if he sees one end from the other.

From thirty-five to forty years ago, a great controversy went on, among planters about the proper size of HOLES for coffee plants. Some of us brought our opinions with us from Scotland, where twenty years earlier the subject of pits for forest trees had been copiously discussed by landed proprietors and practical men, Sir Walter Scott taking part as an ardent opponent of pits, and a firm supporter of the Spout. I do not know whether the one or the other method ultimately prevailed, but the dispute

was still unsettled when I left home in 1840. In 1842-43 some estates in Ceylon were planted in holes 3 × 3 × 3 feet and others 1 × 1 × 1 and all possible sizes between those extremes, but at no time afterwards could any one have told which was which. In process of time the dispute settled down to 18 × 18 × 18 in. which is now the general practice. In 1842 I tasked my coolies to 120 holes, 40 is now I believe the usual task. The object with the coolies is to get them to hole in the right spot, and make the regulation size. The superintendent must see to this on his own method, or may accept of Mr. Wildes, as suits him. In Ceylon holes are usually filled by taking the surface soil from the upper side, but I have lately had to deal with soil where no filling was needed, but to cut two small drains from the upper side of the hole, at an angle of forty-five with the line, and a few showers silts them full of the prime of the soil.

NURSERIES.

The rearing of nursery plants in baskets should supersede every other arrangement in the case of all delicate plants, but Coffee Arabica can hardly be classed as a delicate plant, where one hundred inches—or upwards—of rain falls in the year, but it is sufficiently perverse, where the temperature is much greater, the rainfall very much lower, and the droughts last for months. Of course, every one must study his own case, so far as climate is concerned. In some parts of Ceylon, no one thinks of making nurseries; they have only to send a gang of coolies into the jungle, to bring in whatever number of stumps may be required. In other parts, where rains are heavy and frequent and the soil soft, the best nurseries are made by clearing the underwood in a piece of forest, gathering the fallen leaves and rotten twigs into heaps, sowing broadcast, and then scattering the leaves, &c. over the seed.

PLANTING.

I have had occasion to remove many large and flourishing coffee trees in old fields in the course of my planting operations, and I do not recollect one of those with a single tap-root running straight down. I have seen many turned by a stone, and going horizontally along its surface, but the most common appearance is a plurality of tap-roots, from two to six, none of which go to a great depth, few indeed being a foot long, beyond the branching point. I have therefore long looked on the fuss so many planters make about the tap root, as mostly humbug. I do not indeed hold that it is a beneficial operation, to turn up the tap-root in transplanting, but I never saw a Tamil cooly, put in a plant without pressing it down, and however often checked he was always found at the trick again. For this cause I have always cut off tap-root at hard wood that is not easily doubled up. It is hardly possible to take up a nursery plant with the tap-root complete, to its deepest fibre, and if that is not done it will branch in the new situation, however carefully treated otherwise, and why should it not branch and who has proved, that a single deep tap-root belongs to a stronger and more fruitful tree, than the tree that owns a divided tap? Else, if we must have perfect plants, put down seed in baskets, and plant out in the field, before the tap gets through the bottom.

The best way of planting is to fasten two pieces of stick—long enough to cross the hole and rest on the sides together at one end, place the plant between the sticks so that it will hang with the root straight down in the centre of the hole, over the loose end of the sticks slip a loop of string so that the plant may be held in position till the earth has been filled in round it. By this plan there can be no possible turning up of the tap-root, or twisting of the lateral fibres.

CATTLE AND MANURE.

I know nothing about the keep of cattle in India, but in Ceylon the manure made will barely pay the expense of keep, when the planter has a tract of natural pasture sufficient for his herd all the year round. The planter therefore who has no pasture land, should limit his herd of cattle to such work bullocks as he can employ on or off the estate with advantage and such cows as may be necessary to supply his table with milk and butter. There is positively no market for any kind of Cattle but working bullocks. The small quantity of beef required is in the hands of the butchers, who purchase native cattle at from R6 to R15, and worn out cart bullocks for next to nothing, and any attempt by outsiders, to introduce a better article by systematic fattening, is resisted by their united might; the only thing a planter can do with his surplus stock is to shoot them and use the carcases as manure. I suspect matters are not much better in India, and the £950 Mr. Wildes recommends to be expended on stock keeping had better be directly employed in the purchase and transport of nitrates, phosphates and alkalies. Cattle manure is an excellent thing, but it may be purchased too high.

ROADS AND DRAINS.

The author has got the right view about the importance of roads, and his plan of tracing and partially cutting them as early as possible is a very good one. To make a drain as the first operation in making a road is the only way to get proper work, for when the Tamil cooly, gets a few shovel-fulls of loose earth to deal with, he scratches it up and down, and back and fore, and round about, and never leaves it till a kick or a curse overtakes him, and sends him forward to stiffer work; when he is set to cut a drain he has no loose earth to manipulate and must put some pith into his strokes to make any impression.

I do not like a road to be even so steep as one in 15, if it be possible to obtain a better gradient; of course they may be steeper where no bandy road can be made. I have before me as I write, a zig-zag, going up a steep face, sprinkled with mighty boulders and bounded by cliffs. None of the few gentlemen who had travelled it made any laudatory remarks on my engineering, but I compensate myself by looking on the work with unqualified admiration. In some recent road making I have involved myself in the necessity of some heavy blasting but that can be deferred till better times, and no one coming after me can improve on my traces, but I forgot I was asked to review Mr. Wildes' book and not to tell my own tale. Well, I agree with all my author says about roads, but I join issue with him about drains. He says "as a rule, and for a permanency, I do not approve of drains; I prefer renovating and and weeding pits, to stop the wash," I have no special objection to supplement my system of drains by wash-holes, but I dare not rely on holes alone, for dealing with the surface water resulting from exceptionally heavy rain; and be it remembered that it is the exceptional, that has in this case to be provided for. One twenty four hours in July 1878, Colombo was visited with a ranfall of eleven inches. Here where I sit twenty miles inland I have seen certainly not less than five inches fall in two hours. Five inches of rain gives upwards of 11 cubic feet of water, to every twenty-five feet of surface. I incidentally learn that Mr. Wildes' "renovation holes are 2 × 2 × 1½ feet, or a capacity of 6 cubic feet, suppose the earth to absorb one cubic foot, which is certainly as much as it is likely to do, the remaining 4 cubic feet must go down the hill, at the nearest to the first natural water-course. Then the surface is encumbered with the loose earth dug out of the holes: this the descending flood searches, and carrying off all the loamy portion in suspension, silts the holes up to the surface with the sand and smaller gravel while the water is forced out of them to augment the stream. This is the one serious objection to all systems adopted with a view of retaining the whole rainfall on inclined surfaces. The terrace, the embankment, the water hole may stand for years and answer the purpose satisfactorily, but the awful exceptional downpour comes at last and sweeps all away.

On a gravel surface there is no need of Drains, or of any other arrangement to save wash, for there is none. The same may be said of soapy clay, which may possibly benefit by deep tile drains, but yields little or nothing to surface wash. The cause is very different where there is a rich loose surface soil, several inches deep, from which every shower carries

off a portion, for the advantage off the neighbouring paddy fields. Such land I would drain from 400 to 800 yards per acre. The drains should be steep enough to keep themselves clear, running diagonally across the hills: they need not be more than a few inches deep. The drainage system generally practised on the tea estates is 440 yards per acre—15 inches deep and on the standard gradient of one in fifteen. It is contended in favour of this system that the 1 in 15 exactly hits the point of keeping the drain free of silt without wearing the bottom and that drains 33 feet apart are sufficiently near to prevent surface ruts. This may be true locally on many lowcountry estates, but I have had to deal with soils where easier gradients did not prevent bottom scouring nor more frequent drains prevent surface ruts.

It is the very foundation of what Monclare calls his system, that the more water sinks into the land the better for the planter. I deny the proposition *in toto*. There is a proper measure of moisture needful to mantain the growth of plants and any excess is injurious so long as it continues and is just as bad as too little; superfluous water very soon passes beyond the region of roots if compelled to remain till it sinks into the earth and therefore does little harm, as the earth only retains moisture as much as fills it, the same as a pint pot which if you keep on pouring after it is full merely runs over, and if more water than the earth can hold is forced on it, it merely filters away below. I am not aware that those who depend entirely on holes to get rid of superfluous water hold the notion that the land is thereby improved, but I maintain that properly arranged drains is the quickest and the most economical way of getting rid of it.

BUILDINGS.

Mr. Wildes is intensely local again in what he says about buildings. We do not even know the terms he uses, but it is little matter as he has nothing to teach Ceylon planters about buildings. This is however a subject on which I am not an authority, and will say nothing more.

WEEDING.

It appears that weeding is not so well understood or so carefully practised in the Wynaad as in Ceylon. The true rule is to keep the necessary labour to go over the estate once a month constantly employed and whatever else may fall behind, never take off the weeding gang to any other work, not even in crop, unless the precaution has taken to put on force enough to go over it in a week just before the heaviest crop comes on. Once let seed into the soil, and the cost of weeding cannot be estimated, and for my own part, I would rather sacrifice a little crop than allow my property to get into weeds. The Wynaad rates for weeding seem to be much higher than those of Ceylon. A recent correspondent of the *Observer*, states that he has weeded as low as 5S cents per acre, which extended to twelve weedings, gives R6-96 per annum, and I know that this may be done.

I cannot see the force of Mr. W's. objections, to burying the weeds as the work goes on. If the "renovation" holes, are of sufficient capacity to contain all the water and all the silt of even exceptionally heavy rains, then indeed, there will only remain the danger of the weeds thrown into them taking fresh root and shedding seed before the next weeding. But I have no faith in holes alone as a protection from wash, for if they ever overflow, they are certain to do more damage than would be done if neither hole nor drain existed. I used, when in charge of the only estate weeded monthly in Ceylon at that time, to give each weeder a small basket to be carried in the left hand for the weeds to be dropped into as picked, which were emptied on the roads, and a momattie went round and buried them in pits below I was in one of the wettest spots in Ceylon but never saw them washed out.

SUPERINTENDENCE.

All that Mr. Wildes writes on this subject, when stripped of details, amounts to this. The superintendent of a coffee estate should have brains enough in his skull to organize and administer a system, integrity enough to act justly in all his dealings, and firmness enough to exact the right from all employed under him. This is the man needed for all kinds of business, but is not the man most likely to be selected in this grasping and over-reaching age, the abilities by all means but moral qualities *be blowed*! We have arrived at the point, of giving our sympathy to every clever piece of roguery, at least till the clever one, has run his head against the laws of the land and come to grief. Smart men, as the Yankies call them, like to deal with smart men; as an edifying exercise of their own wits, it is the honest men who avoid them if they can, a piece of wisdom the stupid men never learn. The old Scotch proverb has it, "If he cheat me once foul fa' him; if he cheat me twice foul fa' me."

Smart or not, the superintendent of an estate, works under a disdvantage in dealing with his proprietor's agent; he stands on a different level than the man who can send him the sack any month in the year, while he cannot choose whom he will serve and may be left a long time without any service whatever. An honest man will at once refuse to do a dirty or dishonest act at whatever cost to himself, but a prudent man will not scald his mouth with other people's broth. If the system or no system of my neighbour is not pleasing to me, it is no part of my business to convey my views to his superiors. I may be conscious that the agent under whom I serve is working the oracle much more for his own interests than those of his principal; I am not called on to push in my oar between them. It is most probably a case of diamond cut diamond, and the proprietor knows more of the affairs between himself and his agent than I can tell him. Some proprietors insist on corresponding with the superintendent over the head of the agent: this no prudent man will undertake; it is unbusiness-like; it causes annoyance on all sides, and most probably leads to the dismissal of the superintendent who submits to it. The superintendent engaged by the local agent should have no official knowledge of any interested party beyond his immediate superior; to him all communications on the business of the estate should be addressed, and if he manipulates them to suit the digestion of his principal, it is no business of the superintendent. The superintendent stands in the same relation to his assistants that he himself bears to the agent, and the same rule should be observed.

One of the heaviest trials of a superintendent is when an agent who has never been a practical planter insists on directing the details of internal manage ment. It is true that in Ceylon the visiting agent is supposed to be a practical planter, but we are all aware that high professional attainments are not the sole or even the chief factor in their selection, and that their crotchets may be as troublesome in some cases as those of the desk planters who never set a pulper or pruned a coffee tree.

It appears to me that Mr. Wildes dwells much longer on minute details than on broad principles. Any youngster can master the details of working an estate in a few months but while he continues a planter, he is always learning something of the less obvious doings of nature, and if he undertakes to become a teacher of others it is not in minute directions about the daily routine that he can most benefit his fellows, but in opening to them the deeper results of experience that every observing man stores up during years of practice.

This book may be locally useful to new beginners but the author has nothing to teach to old Ceylon coffee planters.

PAY AND ALLOWANCES.

Pay and allowances will regulate themselves by the law of supply and demand; the employer will give as little as he can help and the servant will secure as much as he can get. It is the business of the employer to get the fittest man he can secure, and the servant to be fit for the place he seeeks to fill. A good character for efficiency and trust-worthiness will be certain to pay well sooner or later, and for the rest the parties will just act according to the view they respectively take of their own interests. I

either knows how or where, he can do better; the negotation will assuredly fail. It is best for both parties that there should be no unacknowledged perquisites.

Salary settled by mutual consent.

Cook house cooly—general custom.

Tappal cooly—general custom.

Horse keep or equivalent travelling allowance when it is a part of the superintendent's duty to travel on estate's business—general custom.

Keep of a cow.—Special where the estate keeps no cattle.

Cultivation of a vegetable garden—special.

The estate usually finds the heavier articles of furniture, as chairs, tables, couches, beds, almirahs, cash-box, &c, all other necessaries the superintendent finds for himself.

I would never give any sort of work on contract that I had labour enough to do myself. Contract work to get it well done needs even more supervision than day labour and with a properly organized establishment will in no case be cheaper. A contractor means scamped work, if he can possibly get it passed and a constant pressure for advances beyond the value of work performed.

ESTIMATES.

I have put no faith in estimates, since a time I remember in Ceylon when one very simple one served all intending planters the terms were. It will take £10 to plant and bring a coffee estate into bearing per contra. The average crops of a coffee estate will be 10 cwt. When the test came no estate planted during the Forties cost less than £30 per acre,—many of them much more,—and only a few favoured localities, ever yielded 10 cwt. per acre or over in rarely favourable seasons. So far as current expenditure is concerned it is easy for a planter who has the accounts of the estate for a series of years to tell now much money he needs for the next twelve months, but he who attempts to estimate crops before they are on the trees is certain to blunder; indeed it is only an experienced eye that can make a near approximation, with all the crop of the season before it. True the expenditure required to open an estate may be readily enough ascertained but practically, no man works on another man's estimate, unless tied down by stringent orders in which those who give the orders assumed the responsibility as for a cut and dry estimate prepared before the land is selected, setting forth the amount and value of the average crops it must range in trustworthiness with a present estimate, of the rainfall of 1885 in a given locality.

(To be continued.)

TEA AND THE EASTERN EXCHANGES.

The somewhat bewildering effects of the state of the exchanges with the East have a highly important bearing upon the Tea market. The increasing scarcity, or greater purchasing power, of gold, which tends of itself to lower the price of silver, and to lessen the quantity of commodities that can be bought by the latter, has been accompanied by a much greater production of silver. The result of these two causes has been that the silver rupee, the par value of which used to be 2s, as expressed in gold, has fallen below 1s 5d for some time, and has recently even been only 1s 4⅝d or 1s 4¾d. Without going into a tedious dissertation upon the various ways in which this remarkable change has come about, it is sufficient to say that it means that a sovereign, the exchange value of which was formerly 20s in India, is now worth 25 per cent more, or 25s. A price of 1s per lb. for Tea when paid in this country is worth 1s 3d to the producer in India, as compared with former times. It follows that the gain by the exchange has become a most important item, as a matter of account, in calculating the profits of the various Tea Companies, whose books are kept in rupees, and not in pounds sterling. Indeed, the *Indian Tea Gazette* says that there is now more profit from this source, than the difference between the cost at the gardens and the Calcutta sale price. In fact, with an average cost of something like 10d. per lb. for Indian Tea, as made by some of the chief Companies and laid down in London, the present exchange alone means a return of not far short of 2S per cent. It is to be remembered, however, that the greater portion of the Indian Tea gardens have been planted long since the rupee was at par, and probably at a time when its value was about 1s 9d or 1s 10d. Still, a fall to 1s 4¾d from those prices represents a great difference.

The first effect of such a remarkable state of things is to cause unexpected prosperity among the producers, at a period when they looked for bad times in consequence of the greater general production of Tea. The usual results, however, of a depreciated currency may be expected to follow. If so, the growth of Tea cultivation will continue till a point is reached, when the benefit through the exchange will be neutralised, partly by a fall in value here, and partly by a rise in the cost of production in India; for the greater demand for land, appliances, labour transit, &c., in the Tea gardens, will of course be reflected there by some rise in the amount of money which has to be spent in the manufacture of a given weight. It may at present be said that where there was formerly one rupee in India, there is now (judged by the exchanges) material in silver for a rupee and a quarter. In a country where the supply of the circulating medium is ample, such a state of things would immediately be followed by a corresponding rise in money values on the spot. When the United States issued a forced paper currency, it will be in the recollection of most readers how immediately prices, as expressed in paper rose, and how a similar change followed the fresh issues, and also how the reverse took place as the Washington Government paid off the greenbacks. Similar results, doubtless, are following in India in the veiled barter by means of silver, in which trade there is carried on. Indeed, though food and wages have apparently not recently risen in the Tea districts, one of the common subjects of talk among Anglo-Indians is the increased dearness of living in India at present as compared with twenty or thirty years back. In short, as the relation of the supply of silver to other commodities increases, money prices ultimately rise and wages follow.

The effect of such events in a vast empire like India is, however, immensely slower than in an European country. Suppose that in this kingdom all trading transactions were carried out, not by cheques, bills, bank-notes, or gold, but that they had to be transacted by carrying about florins, the equivalent of the rupee, in canvas bags; that the population was increased to 350,000,000; that the area of the country was increased twenty-fold; that there were few railroads, and, broadly speaking, no proper roads; that over a hundred different distinct languages were spoken within our borders, and that there were endless restrictions imposed by religion and by caste, on intercourse between man and man; and, above all, that our natural slowness to change, were indefinitely multiplied by the ingrained conservatism of the unchanging East—if all these causes were put together we should better be able to realise the length of time required to bring about a change in values, expressed in money, in India, as compared with the period requisite to bring about similar results in England or in other European countries. Why, till quite a few years ago, if the Government at Calcutta wished to pay a sum of money in the north of India, the actual rupees were packed in bags and sent in carts drawn by bullocks and guarded by sepoys, who marched on foot in charge of the treasure for some six months, before their goal was reached. The Government for the same reason—the scarcity of currency—even now only makes its own bank-notes legal tender within a limited circle from each of the issuing points. Further, the poverty of the people, according to our ideas, renders alterations in the relations of currency to values even slower, for a rupee almost represents wealth to a nation, where a rich man spends 4d a day on his eating, and where in some of the provinces the labourer gets 30s *a year* as wages and keeps himself. Where any currency at all is common, copper of course plays a far more important part than with us, and it is supplemented not only by the farthings and mites, of which we see so little in this

country, but by a circulation of cowries—shells worth twenty to the halfpenny, and used for small change.

Such a digression may seem to take us far from Tea, and yet brings us back to the point that, comparatively slow though they may be in their operation in India, yet the laws of supply and demand will, in the long run, if silver remains so low, raise prices in India till the present benefit of the Planters, through the exchange, is lost. It behoves them, therefore, not to forget economy in the hour of their apparent prosperity but to prepare for the worse time coming by cutting down expenses and by not letting fixed charges grow as the weight produced increases. Similar causes are at work in Ceylon, in Java, and above all China. The production of Tea is being immensely stimulated, and is increasing beyond the rate of increase of the consumption. This, of course, means constantly falling prices on our side, at a time when the cost of production in the East tends slowly to rise, and when, in addition to other causes, the increased scarcity of gold is tending to lower the prices of commodities in England and in most parts of Europe. While this is so, there appears, on the other hand, no apparent limit to the progressive decline in the value of silver. The actual cost of the bullion in the rupee is said to be about 1s at present, and it is probably a good deal convention and habit that keep it so much above that price. The planters will therefore continue to profit, if the rupee falls further, but by very slow degrees the cost of production would rise in proportion, while selling prices are likely to continue to drop here, through an opposite cause—the "appreciation," or rise in value, of the other chief circulating medium. The exactly contrary effects of these two currents in prices, are thus likely to deprive the tea planters of their present gains by the exchanges, sooner than they would have otherwise lost them.

Inevitable as they may be, these alterations in the values of gold, silver and commodities, while they are in progress, cause an enormous amount of inconvenience, and a good deal of actual loss in some branches of trade (for though the tea planters happen to gain, English exporters often suffer), especially as the causes at work are so difficult to discern or follow, that for a long time people are perplexed to know the reason for what is going on. An influential section of the mercantile community is greatly concerned at these fluctuations in opposite directions in the relations of currencies and prices of gold, silver and other produce. It thinks that the various governments of the world ought to intervene, and to decree that what is really worth 1s 5d is not worth that, but 2s—in short, that humanity at large should accept seventeen pence as being worth twenty-four. The task appears a large one, and of the character of that undertaken by Canute when he rebuked the sea for its progress. After all, it will be found that the main difficulty of the Eastern exchanges arises from the continuous fall in them, for once the rate is stable in mercantile transactions, calculations are readily made, and things equalise themselves. This instability in the relations between currencies and commodities no law could have altogether stopped. The part in favour of a regulation of prices by the Governments of the world, is greatly swelled by the Anglo-Indian official fraternity—a class that lose materially by the present state of the exchanges, because the Government has contracted to pay them so many rupees a month, and not so many sovereigns. It would be well for Indian officials to correct their ideas by asking any tea, indigo, or silk planters, or any exporters of corn, seeds, oils, or other Indian produce, whom they may know, what would be their opinion of the result of bringing exchanges to par, if it could be done at a blow, by an arbitrary law. The planters and exporters from India would probably point out that such a change would instantly ruin them. The views even of the Simla authorities may be coloured by the officials' sufferings through the loss on home remittances and pay. For instance, a despatch has recently been mentioned in the papers, in which the Governor-General's Council combat the assertion, that the recent amazing development in the exterior trade of India is due to the state of the exchanges, while, on the contrary, they put it down to improved communications. New railroads and so on have no doubt immensely facilitated this result of increased Indian exports, but Tea again disproves the assertion of the exchanges having no part in this result. There has been no particular improvement in the modes of transit of Tea from Assam, and yet the production increases rapidly, and is remunerative at prices in England that would formerly have destroyed the industry in a season.—*Produce Markets' Review.*

THE DETERIORATION OF CEYLON TEAS OR THE USE AND ABUSE OF THE KNIFE IN CEYLON.

No. I.

(By an Assam Planter.)

19th August 1886.

Before discussing this all-important subject, let us examine the different agricultural implements provided by the manufacturer for all sorts and conditions of growths, endeavouring whilst doing so to select that best suited to the requirements of the island and the subjects requiring to be operated upon.

First let us look at the Assam churri. Is it not a terrible-looking weapon, with its long, coarse and sometimes horney handle, its heavy back and crooked end? In truth it is as formidable as it looks. Made of the best tried metal, there is nothing that will turn its edge or break its point. When properly handled and a drawing cut given, it will sever with equal readiness a bambu stump or a *nahore* sapling. Unfortunately it is a trifle dangerous, the makers have neglected to provide it with a suitable sheath, thus it is always open and ready for use. Sometimes coolies cannot resist the use of it in the settlement of their disputes, so it may be found advisable to collect them at muster.

Next we come to a modification of the above. It will suit our purpose admirably, for in the first place it is inexpensive, whilst small and light it is very strong and handy and well suited for light work; it can give a big cut on the occasion: this is what we want, but of course it requires having the knowledge where to cut, how and when to do it.

Lastly we have that with a rough sawlike edge: let us dismiss this from our minds with the remark that, being unweildy it is too slow in its task, rough on the plant and tedious on the operator; its use could only be required as a last and very desperate remedy; in a new field like Ceylon it should not be necessary for many years. It will be my object to show your readers how they can best spare the knife with benefit to themselves. Much of the deterioration one hears of is due to its too liberal application; at any rate, this and the heaviest picking combined. Whilst repeatedly advising the abandonment of the barbarous style of plucking so conspicuous in the browsed bushes, the abuse of the knife is a still more crying evil. And now let me urgently impress the absolute necessity of giving the bushes a chance in the coming pruning season. If you have young trees let them run, it can do them no possible harm until they begin to crowd each other, then it will be quite time enough to prune them and there will be no occasion (more especially with high-class hybrid or indigenous) to do more than pass the knife across as nearly as possible at the joint of the main limbs, and as near the centre of the trunk as may be, the higher up one keeps with the knife the better: positively no cleaning out is ever necessary; some well-informed planters contend that for every single wiry twig removed, two come to replace it. The so-called cutting down cannot be too strongly deprecated: it kills many a

tree outright and (so to speak) ages the whole prematurely. With plants three to four years of age that have been cut across and plucked heavily there will be more scope for ingenuity by the careful application of the pruner.

But tea that has been plucked after the fashion usual here, will require a long letter to itself, which you shall have by and by. In the meantime let me enforce upon my brother planters that there is nothing which plays more havoc with a tea garden than the injudicious use of either the knife or the saw.

Assam Planter.

[A good deal of what is denounced as cutting down, has been advisedly resorted to in order to get bushes into good shape, with all possible breadth for plucking, present advantage being deliberately sacrificed for future benefits.—Ed.]

CHEAP QUININE.

Mr. John Hamilton (formerly of Dikoya) has taken a step in the right direction in order to make the cheapness of quinine known and appreciated. He ought to try and get at the people in the "fen" and other marshy districts of the old country where its use can be appreciated; also at the veterinary surgeons who promised to use it freely when cheap. Out here also it is a boon to get really good cheap quinine.—From an American journal we take the following:—

Quinine from the Retail Standpoint.

The daily papers of New York are taking unusual interest in the quinine market. The Reporter has already referred to an article which appeared the other day about adulterations, and we reproduce the following as the work of a reporter on the *Tribune*.

"It may be some consolation to sufferers from malaria to know that there is little if any impure quinine in the market at present. This desirable state of things is not due to any sudden spasm of virtue on the part of druggists, but arises from causes that are purely economical. Quinine is lower in price now than it has ever been; it is selling wholesale at 55 cents an ounce, and is so much cheaper proportionately than its usual adulterants that a loss rather than a profit would result from mixing these with it.

'People are almost certain to get quinine pure this season, no matter where they buy it,' said the proprietor of one of the large drug stores near the Post-Office. 'The most unscrupulous druggist has no incentive to adulterate it now as he did when he used $3 and $4 an ounce for it. Then it paid to mix it with cinchona, which sold for $1 or so an ounce. Yes, that is about the only ingredient used and it has the properties though not the strength of quinine. About the only fault found with a compound of this kind was that it lackedpower. Nothing injurious ever resulted from its use nor, in fact, do I know of any substance that would probably be mixed with quinine which might harm the system. The most despicable form of fraud practised with this drug, is the short-weight dodge. This is worked by some of the extreme 'cut-rate' stores and unprincipled dealers. They sell a pill that contains but one grain of quinine for a two-grain pill, thereby making just double the usual profit, which one would think large enough at present. An ounce of quinine costs the retail druggist a little over 50 cents. There are 480 grains in an ounce. At a cent a grain this gives a profit of over $4 an ounce, allowing for the cost of the rice flour and gum-arabic which form the body of the pills as well as for the time required to roll them. Some of the high-priced druggists charge two cents again, making a profit of about $9 an ounce, or something like 1,800 per cent on their investment. The cheap stores I referred to that give one grain instead of two to their customers, make almost as much as this and few of them are ever found out."

"How do you account for the cheapness of the drug at this time?" was asked.

"Quinine, as you are aware, is derived from Peruvian or Jesuit's bark obtained from various species of cinchona which grow in the Columbian, Ecuador, Bolivian and Peruvian forests of South America. The Countess de la Cinchona, wife of a Peruvian viceroy, was cured of a fever by its use, and when she returned to Europe introduced the medicine there about the middle of the seventeenth century. It derived the name cinchona from her. This bark used to be gathered by the Cascarillas Indians chiefly, who obtained it by cutting down the trees that produced it. This of course, soon thinned out the more valuable trees and such was the reckless stupidity of the Peruvian government that, though it put every obstacle in the way of the tree being planted elsewhere, it was never attempted by a system of forestry to renew the riches thus improvidently wasted. The result was that quinine became scarcer and scarcer every year; the price of it went to an extravagant figure, and at one time it seemed as if this most important drug was likely to become unobtainable. It was at this time that the East Indian government determined to try to naturalize the cinchona tree in India. To obtain seeds and young plants was a difficult task, but Professor Clement R. Markham, Dr. Spruce and others accomplished it, and in a short time a flourishing plantation was yielding large quantities of quinine on the Neilgherry Hills of Southern India. The tree has since become naturalized in Java, the mountainous regions of Jamaica and many other places, so that we are almost if not entirely independent of the Peruvian forests for this great febrifuge. It is this increased production of it all over the world, one might say, which is making the drug cheaper and cheaper every year as the demand for it becomes more widespread in this and all other countries where

"'Men shiver and shake.
Dose, swear and bake.'"

[Such is fame! No express mention of Ceylon which has simply revolutionized the world's trade in bark and quinine.—Ed.]

WYNAAD PLANTERS' ASSOCIATION.

Proceedings of a general meeting, held at Pookote Club, Wednesday, 4th August 1886.

Present:—Messrs. Abbott, Achard, Atzenwiler, Batty, Boosey, Imray, Jones, Jowitt, D. Mackenzie, W. R. Mackenzie, Tanqueray, vanReesema, Walker, Winterbotham, and Romilly. Honorary Secretary; Mr. H. B. Winterbotham in the chair.

Cinchona.—Read letter from Mr. Batty on the question of the approximate possible loss of weight in bark in transit from the estates to the coast. From the discussion which ensued and from actual results stated, it would appear that the loss from all natural causes, except theft, should not exceed three per cent under any circumstances.

Read an interesting paper forwarded by Mr. G. L. Yonge giving the following statistics *re* the renewal of Ledgeriana bark.

"*Hybrid.*—Bark analysed from the same trees for 4 years.

Original ..	1·81	Sulphate of Quinine.
Once renewed..	3·31	ditto.
Twice " ..	4·84	ditto.
Thrice " ..	5·20	ditto.

Ledgers.—Original bark from narrow-leaved Ledgers analysed last year gave 4·09 sulphate with total 5·97, renewed bark, 11 months later, 6·62 sulphate with total 8·49 *broad-leaved Ledgers.*

Original last year 2·90 sulphate with total 6·61.
Renewed 11 months 5·19 " " 8·51.

A broad-leaved Ledger recognised by Professor Lawson as C. Calisaya Hembra, yielded 5·96 of sulphate of quinine with total of 10·06.

The Honorary Secretary called the attention of the meeting to the Government Order in answer to the representations of the Madras Chamber of Commerce on the subject of their competion in cinchona cultivation, and asked whether the Association was prepared to take any further action in the matter. After

a long discussion it was decided that no further action need be taken as Government had pledged themselves not to increase their plantations; in the meantime the meeting regretted the inability of Government to assist us with cheap analyses in experiments with C Ledgeriana bark, as such help would only be in accordance with their expressed opinion for the "raison d'eter" of the plantations.

CORKS AND CORKWOOD.

THERE exists in the art of bottling no more prominent factor than the cork.

The Portuguese cork is inferior to the French in quality, but superior to the Italian, being lighter and whiter. Sardinia produces a kind easily distinguished by its color and weight, being pinkish hued, and heavier than many other varieties. It is considered by the English the best variety which can be obtained, but little, if any of it, comes to the United States. In 1861 it was reported that the cork forests of Sardinia and Corsica had been in a great measure destroyed by improper working; but this report, like the annual rumored failure of the peach crop in Delaware, seems to have made little difference in the supply.

France produces the finest grades of cork, especially in Languedoc province and the environs of Bordeaux. The peculiar velvet cork, so esteemed in the bottling of champagne, is the production of those places, and is becoming very scarce, it being feared it will, in time, become unobtainable.

Africa produces large quantities of cork, but of an inferior grade, although the soil and climate of its northern countries seems peculiarly favorable to its propagation. This is especially true of Morocco and Algiers. The causes of this are to be found in the uniformly high temperature and profuse nightly dews, while the dry, warm, open hillsides are covered with a sufficiency of light soil, peculiarly adapted to the growth of the trees, which attain to a large size here than elsewhere.

There are said to be 2,500,000 acres of cork forests in Algiers alone, of which about 300,000 are utilized. It is said to be capable of producing as much cork as all the rest of the globe, if the inhabitants could but be persuaded to remain peaceable, and give their attention to agricultural pursuits.

In 1859 an attempt was made to introduce the cork oak into the United States, Portuguese acorns being planted, with this end in view, in Wayne County, Miss. All grew, the largest trees, eleven years later, measuring thirteen feet in height, while the trunks had attained a diameter of eleven inches in thickness the cork bark being more than an inch in thickness. In 1872 the planting of cork trees was attempted in southern California, but with what success does not appear.

Among the conditions necessary for successful cork culture, climate and soil are of the foremost importance.

In the Mediterranean basin, where it is indigenous, the tree favors altitudes varying from 1,600 to 3,200 feet. It does not flourish beyond 45° north latitude, and the minimum temperature must not be less than 55° Fahrenheit.

It grows best on southerly slopes, which afford a freer circulation of light and air than do flat lands. It requires abundant sandy soil. Planting is usually performed from seed; as a rule the large, sweet acorns developing into the best trees, which yield the finest cork, the small, bitter acorns producing trees of a coarse and inferior nature.

The most approved method of planting, and that which is employed in France, Spain and Portugal appears to be the furrow or "hill" system, which consists in sowing the acorns twenty to forty inches apart, in a furrow between two or more grape-vines, placed at from five to seven feet apart. The sowing and planting are conducted simultaneously, the vines affording the shelter which is so necessary to the cork tree during its early growth. The young trees are thinned out as required so as to afford abundance of air and light to each. About fifty trees to the acre are recommended by the French cork producers, and the production is about eighteen pounds to each barking of the tree.

The distinguishing feature of the cork oak is that the parenchyma forms the mass of the bark, while the contrary is true with nearly all other trees. In the earliest state of its growth it is much more elastic than it ultimately becomes, owing to its containing in the first instance a large proportion of woody matter. The outer casing of the bark is formed during the first year's growth, and does not subsequently increase; but the parenchyma or inner bark continues to grow as long as the tree is alive.

In consequence of this phenomenon, the pressure of the growing inner bark beneath, forces the outer shell to split and peel off in flakes. The substance thus shed under natural conditions is known as "Virgin corks." It is very coarse and of woody texture greatly resembling the bark of the California live oak in appearance. Its uses, from its coarse nature, are very limited.

The removal of this outer bark from the tree is fortunately when performed in a judicious manner, unattended with any evil consequences to the tree; on the contrary, the operation seems to hasten and assist the growth of the bark, improving its quality, and at the same time the tree grows more vigorous, and attains greater longevity, trees which are regularly barked being known to live to the age of one hundred and fifty years and upwards.

The age at which the first stripping may be attempted varies with the locality, from fifteen to thirty years, the former being the most general.

The yield much resembles the naturally shed virgin cork, and is commonly included under the same term. Subsequently the barking is repeated at intervals of eight and ten years, the quality improving on each occasion. The second crop is also still too coarse for any but inferior uses.—*Independent Journal.*

THE COFFEE CROP-YEAR IN BRAZIL (says the *Rio News*, July 3rd,) just closed has shown no very marked features, but, so far as we can learn, has been fairly satisfactory to exporters. The estimates were very close to the actual out-turn, the estimates being from 4,000,000 to 4,250,000 bags and our receipts amounting to about 3,890,000. From 150,000 to 250,000 are probably carried over. The interruption of traffic on the Cantagallo railway during the early part of 1886 caused a sharp decrease in our *barra dentro* supply, which apparently has not since been overtaken. At the end of October a divergency of opinion arose among our brokers as to stocks, the estimates varying to the extent of 50,000 bags. This has since been reduced to about 10,000 bags by deducting local consumption, which is estimated to be 6,000 bags per month. As to the crop year upon which we are now entering, the extreme estimates seem to be that the Rio crop will produce from 3,750,000 to 4,250,000 bags, the drought in January, it is claimed having reduced the first estimates which were very large. We incline to the belief that the larger figures will more nearly approach the truth. As to Sao Paulo, all advices agree in stating that the crop will be very large. The May and June frosts were not general and even allowing for all damage, there are estimates that the crop will be one-half larger than that of 1885-86. The crop of 1887-88 will show greater prejudice from these frosts, but it is, claimed that new plantations are likely to counteract any probable decrease in the older orchards. In fact, there seems no reason to doubt that Brazil will export the usual average amount in 1886-87, which we consider to be very near 6,000,000 bags of 60 kilos from Rio and Santos.

Correspondence.

To the Editor of the "Ceylon Observer."

PALMS AND LIGHTNING: LIGHTNING CONDUCTORS.

Colombo, 4th August 1886.

Sir,—Though it is some time since you had *an article* on the above, I will act up to the saying "better late than never" and endeavour to explain why palms, which seem externally only slightly affected by a discharge of the electric fluid, be doomed to die.

What causes the discharge to come to earth? It is that the tension of the countrary polar electricity becomes so great as to overcome the resistance offered by the intervening air to their union. Now as electricity always takes the less resisting medium, and air (especially dry air) being the worst conductor, it is natural that high trees and buildings will be chosen in its passage to earth; then, as water (especially acidulated water) is the best conductor, the fluid will choose the most sappy trees though they may not be the highest. As coconut trees are the first high points which the monsoon clouds meet on striking the island it is natural that they should be the greatest sufferers, and as a single coconut tree is not sufficient to carry off the fluid other trees within a more or less extended radius according to the quantity of the discharge are also affected. A queer effect on a tree may be seen in front of Aitken, Spence & Co.'s office.

The reason that palms and *plantains* which have served to carry off the fluid are doomed to die is simply because their life lies in a single sprout in the most sappy, *i e.*, the best conducting portion of the tree, and the quantity of fluid which is sufficient to singe the outer leaves is quite enough to boil the life out of the tender shoot. Other trees, animals and human beings are only affected inasmuch as their life-sustaining properties have been injured.

While on the subject of lightning, a few lines about lightning-protectors (commonly called conductors) may be useful to dispel a few popular errors. The principal action of the protector is to neutralise the electricity in the clouds by discharging into the upper air fluid of a different polarity, thus acting as a "discharger." Its other important action is to act as a "conductor" to the electric discharge by offering to it the easiest passage to earth, *once* the discharge has taken place within its radius. Many persons, especially natives, believe that lightning-protectors act as lightning "attractors," and for this reason will not put up any on their buildings—a great error I should think.

It may astonish you to learn that there is only one thoroughly well protected building in Colombo and that is the Wharf and Warehouse Company's premises at the Wharf, which can be classed A 1. In the next class come the Colombo Club, the Clock Tower, and perhaps the Surveyor-General's Office. On the first of these, though the protector is well put up, there are portions of the building beyond its radius. In the case of the second a grave error has been committed by not metallically connecting the iron ladders and weight pipe in the nterior to the protector. As to the Surveyor-iGeneral's Office, with half the weight of metal used it might be twice as well protected.

There are many buildings, and mill chimneys principally, which might with advantage have their lightning-protectors refitted; and in the case of the barracks, the Military Hospital, De Soysa's buildings and a few more likely exposed buildings, their non-protection simply amounts to gross neglect, and I should certainly not like to find myself within an appreciable distance of the Ice Manufacturing Company's chimney even during the slightest thunderstorm, leaving, out of the question days like the 3rd and 4th of May last, the like of which for electric discharges I have never come across.

Apologising for taking up so much of your valuable time and space, yours faithfully.

Q. E. D.

[We have to thank our correspondent for his clear explanation of what to us has long, in regard to lightning-struck palms, been a mystery. The general information also, is valuable.—Ed.]

THE "TUMBA PLANT," AN ALLEGED CURE OF SNAKE-BITE.

Sir,—A native Indian medical practitioner, writing to the *Madras Standard*, declares that the juice of the "Tumba plant" is an antidote for snake-bites, and gives directions for its use. Will you kindly inform me by what name this plant is known to botanists, and whether it is to be found in this island?—Yours truly, INQUIRER.

No. II.

DON'T DIE IN THE HOUSE—THE "TUMBA PLANT"—A NEW PRODUCT—AN ANTIDOTE FOR SNAKE-BITES?

Kelvin Grove, Colombo, 20th July 1886.

Dear Sir,—Instead of adding a footnote to the letter of "Inquirer" on the subject of the "Tumba plant" as an antidote to snake-bite which you have submitted to me, I make you the following remarks:—When staying at the late Dr. Elliott's at Kollupitiya about 25 to 30 years ago, one evening after we had finished dinner "*John Colombo*" the head appu rushed in and said to the Doctor! "Sir, sir, the Sinhalese woman that you *cured* is *dead*!" We all joined the Doctor in a hearty laugh at his "perfect cure," the facts of which were that a mad dog attacked a Sinhalese girl close to the Doctor's house and bit her severely in several places, and when she was brought to the Doctor he at once did all he could to cauterize the wounds to prevent hydrophobia, but though the wounds healed, and the woman was so far cured, hydrophobia set in and she died. The application is obvious.

I cannot find such a name as the "Tumba plant" in any book at my disposal, but a very common plant in Ceylon is the Getatumba, Lin. Leucas Zeylonica, Br., but I do not believe that this or any other vegetable or mineral antidote has ever been found for snake-bite; that is for the regular injection into the circulation of the poison of a DEADLY SNAKE of mature age; therefore I do not believe in the cure of a cobra-bite by a Mudaliyar described in a late number of your paper. No such cure has ever occurred in all India or Ceylon as far as *true* records are concerned.

About the same time that I refer to, several grass-cutters and other natives used to come to Doctor Elliott to get cured of snake-bites, and the Doctor and myself believed that he was successful in his operations in this respect.

The patients used to come stating that they had been bitten by poisonous snakes and were in great pain. The Doctor searched for the part bitten and generally found it swollen, and he at once raised it by a hooked instrument and cut the piece out, and the patient soon got better; but these were from the bites of the small venomous and not deadly snakes, or scorpions &c., no doubt, and, as already stated, I do not believe in any antidote internal or external for the poison of a deadly snake, once it enters into the circulation, and no such antidote has ever been found.

Will your correspondent "Inquirer" mention the language from which the "Tumba plant" has been derived? How very strange it seems that most of the new and remarkable products have names not found in any native or European books.—Yours truly, W. F.

THE TEA SYNDICATE.

20th August, 1886.

SIR,—The Tea Syndicate circular is now being sent to all members of the Planters' Association and will be supplied to others on application. I would through the medium of your columns, desire to impress upon all those interested in tea the extreme desirability of supporting the scheme by contributing a little of their produce. The scheme is, I think, the only feasible one for increasing with some rapidity the number of our consumers while we are increasing our production, and for establishing the wholesome stimulant of alternative markets. Every one, I think, approves of the idea and recognises the benefits to be derived, but it should be clearly understood that barren approval is of no use, and if the planters of Ceylon are in earnest, and reay desire to see our teas consumed in the Colonies, and America, they must all help, for in such schemes, which at first may require a little sacrifice, there is a tendency to believe that others will make that sacrifice, and a desire not to interfere with their doing so. The syndicate cannot conclude satisfactory arrangements unless we know approximately what quantity of tea we will have to deal with during the coming season and I trust that the circulars will be returned with promise of some support, be it much or be it little, and that superintendents will obtain the necessary permission to contribute. The Syndicate will arrange that those who desire it can, on shipping their tea, obtain an advance of about three-fourths of its value, and this no doubt, will be a convenience to many—although the question has not yet been definitely settled. I do not think any bulking of the various teas will be attempted. Uniformity has advantages, but it would be difficult to obtain and has some drawbacks. It would do away with all the individual incentive, which in an enterprise like this is so necessary. Those shipping good teas will naturally desire that they should go under the estate marks, so that further orders for their teas can be handed to them. In this way I hope many, instead of sacrificing anything by contributing to the Syndicate, will derive individual gain. I should mention that the Syndicate has arranged for the advertisement and sale of packets of Syndicate Tea at the Colombo Hotels, so that all passengers will have Ceylon Tea brought prominently before them. The quantity so sold will of course be very small and unimportant, but the advertisement of Ceylon Tea and the Syndicate's Australian Agents given by these packets will be very valuable, and our thanks are due to those whose public spirit caused them to readily grant the privilege.—I am, sir, your obedient servant,

THOS. NORTH CHRISTIE.

THE WORKING OF THE CEYLON TEA SYNDICATE IN A BUSINESS POINT OF VIEW.

Kandy, 24th August 1886.

SIR,—I trust I will not be considered presumptuous if I venture to call in question certain assertions made by Mr. Christie in his letter appearing in your issue of 23rd inst. I quote the passage referred to:—(1) "I do not think any bulking of the various teas will be attempted. (2) Uniformity has its advantages, but it would be difficult to obtain and has some drawbacks. (3) It would do away with all the individual incentive (?) which in an enterprise like this is so necessary."

In answer to clause first, I do most sincerely hope that bulking *will* be attempted for the first reason given in clause No. 2, viz., that uniformity *has* its advantages. If it *is* difficult to obtain, surely the consignment of individual teas is the most unlikely of all courses to be followed in obtaining it. But again uniformity "has some *drawbacks*." Now this appears to me to be unreasonable. A certain amount of difficulty in obtaining the same I allow; but that *uniformity in tea*, which is expected to find a place in a new market against tremendous competition, has any *drawback* I do *not* allow. It is a power in itself, to my belief, INDISPENSABLE to our new undertaking.

The chief, and only drawback stated is that "it would do away with all the individual incentive."

Is *this* the case? Not necessarily, I think.

In the first place let it be remembered that proprietors are not supposed to send their *entire* crop through the Syndicate, but, as Mr. Christie has it, only "a *little* of their produce" in short a subscription from their crop returns to aid an undertaking which must materially affect every producer's future prospects.

Now, cannot the arrangements of the Syndicate be such as to allow a certain amount of the "incentive" element to remain in this subscription to the Syndicate, as well as in the bulk now shipped to London? Is it *necessary* that the comparative value of individual teas be overlooked, or that teas, up to and over a stated standard, sent to the Syndicate, should not be *fairly* dealt with in a fair division of proceeds, according to the valuation put upon them before shipment by experts whose decision is final?

Is there any reason why *local valuation* should be less powerful as an incentive to the producer than that of Mincing Lane? I can see no reason whatever, and I hold that the valuation of individual teas in Ceylon, before bulking, is a plan feasible in itself and unprejudicial to "individual incentive."

As regards division of proceeds: whatever the valuation put upon individual teas, the value of any individual consignment must form a certain portion of the value of the whole, and the proceeds as a whole must be divided accordingly.

By this arrangement, each consignor gets his dues according to the *value* of the produce he consigns, and I regret that Mr. Christie has expressed any opinion unfavourable to bulking as his opinion is influential. I am in hopes, however, that he will acquiesce with me in my opinion that the uniformity of tea properly obtained may not be altogether deterrent to "individual incentive."

Having considered this question from our own point of view, suppose we turn to the *buyer* and *his* incentive to continue dealings with an unhappy agent who NEVER CAN supply him with tea that he *so* liked at first.

Also the feelings of the agent who, bound to push Ceylon tea, is not in a position to give away a sample of tea to a likely customer (as is the general custom in America) without feeling that he is robbing someone to pay somebody else.

To attempt forcing the American market with one thousand small lots, is in my opinion as futile as the fire of one thousand rifles upon an armoured ship of war. One big gun and one big shot is the weapon to use.

"Those shipping good teas," says Mr. Christie, "will naturally desire that they should go under the estate's mark so that further orders for their teas can be handed to them."

"A house divided against itself cannot stand."

Individual brands may soon be in a position to claim superiority to other brands in America, but *this is not the time for them to do so.*

Hand in hand brothers! Waive local contention until your *market* is *secured*. Then and then *only* can you afford to force the sale of individual brands.

I trust my criticism may be taken, as it is meant, in a kindly spirit. If it leads to a full discussion of these points I will be only too glad, and if proved wrong will accept the opinion of of those who prove to me that they are right.—I am sir, yours faithfully,

J. McCOMBIE MURRAY.

FIBRES AND THEIR PREPARATION.—A London correspondent writes:—"Minchin is home now. and it has only just leaked out why he is here, He got to work on the Fremy process, but found that the chemical melted all the fibre in India. So I supplied the green stems of the China grass here, so that he could prove it in their own works. Cross & Bevan assisted by Johnston have agreed to test all the unknown fibres from India chemically and microscopically on the same scale as in Mr. Christy's book; there are also other departments in the Colonial Exhibition who are asking to be included for this fibre tests and classification."

WE see a claim advanced on behalf of Mr. E. Chasseriau, our leading agriculturalist, as the discoverer of Coffee-Brandy, or Cafeine. What may be the ultimate value of this new spirit remains to be seen, but it appears strange that nobody in Ceylon, Java, Brazils, &c. should have hit upon the idea before, and it, therefore, redounds all the more to the credit of our fellow-citizen should he have "struck ile," which we sincerely trust he has.—*S. F. Press.*—[For a generation past we have read notices of spirit distilled from the saccharine pulp of the coffee bean, but we have never heard of this being done for economic use.—ED.]

CEYLON TEA IN AMERICA.—We sympathise very much with Mr. McCombie Murray's view. In a country like the United States, it would be far better to present one good average grade of Ceylon tea before the consumers, at least until a hold was got of the millions whom we hope to convert to tea, from coffee drinking. We have had a long talk with Mr. Murray on the subject of his mission, or rather future business; he has most promising connections for pushing a big tea business where good tea has never been known, and we are hopeful of the result; but we say, do not let the Republicans be distracted at first with several classes and prices of tea, but let them have ample guarantees from the Syndicate of the purity of the article offered. Moreover, Americans even more than English tea-drinkers, will be glad to learn that in drinking Ceylon and Indian teas, they are discouraging the Chinese foreign opium trade.

TEA IN THE GALLE DISTRICT.—A well-informed correspondent at Galle writes:—"The production of tea in the south of the island has of late increased, and a good many gardens have been opened about Galle, chiefly by native agriculturists. Tea for local consumption is supplied from Morawak Korale and from several estates in the Galle district, viz.. Citrus, Castle, Wallahanduwe, Mount Pleasant, &c. Good pekoe season 1886 is retailed at R1 to R1·25 per lb., other grades from 60 to 80 cents. In the bazaars a fairly good leaf is sold at 50 cents per lb. The usual scented teas from China which were formerly so much in request are scarcely even seen in the market. We presume the local supply has completely put a stop to the trade in the imported article. The tea manufactured at Citrus and Castle estates at Narrawella, about six miles from Galle, is of excellent flavour and apparently much liked by consumers. Nearly all the land now planted with this product were originally either citronella or Liberian coffee estates. Land is also being rapidly opened up at Ratgama and Ganegama under European supervision, and there new clearings will be planted with tea during the next wet season."

STANDARD TEA CHESTS.—Mr. Horsfall advertises a reduction in the prices of his Nos. 1, 2, and 3 Tea chests from 95, 80 and 70 cents to 90, 75 and 65 cents respectively. All the sizes are of standard dimensions, so that nothing is lost by way of freight or dock charges.

JAVA CINCHONA PLANTING.—We give prominence to the following paragraph translated from the *Java Bode* for the *Straits Times*:—Cinchona plantation enterprise in Java seems to be going the same way as that respecting coffee and sugar, its future being also imperilled. The Government have become so convinced of the impending danger that it has directed official inquiries to be made into a disease which has put in an appearance in the eastern portion of the Preanger Regencies among the roots of cinchona trees, the latter dying within a few days after seizure.

COFFEE ON THE RISE.—It scarcely required the result of the Dutch salt at 30 cents (against 28 estimated) to show how Coffee is going to rise. Messrs. Rucker & Bencraft on July 22nd reported:—

A few months ago the question current was whether the low prices then existing were low enough, or whether when the pressure come on in the autumn of the year coffee would fall to a still lower basis. Now people ask themselves are the moderate prices current high enough? will there really be any pressure in the autumn? will coffee later on in the year rise to a higher basis altogether. July August, and often September, are dull months in the coffee trade. If the weather be fine people leave business and curtail rather than increase their liabilities. Again, coffee of course is not so largely consumed in the hot weather, and Brazil receipts run heavy as a rule in August September, and October. On the other hand the public will do well to remember that there are exceptional features current this year in the coffee trade, features which might easily upset the usual run of trade. One feature is this, that we have, existing prices which have been established by years of overproduction, and which, though stocks have heavily decreased, and though the over-production is possibly, some say certainly, a thing of the past, the trade, rightly or wrongly, still maintains will continue as the fair working basis. Another feature of interest is that 1885-86 crops generally were early, and it therefore appears probable that supplies from Honduras, Guatemala, Salvador, Costa Rica, Porto Rico, India Ceylon, and many other places. will be unprecedentedly small for the next few months. We have not time or space to go fully into the matter, but we reiterate that the article has seldom been in a more interesting position; we also note it as a fact that those who look for higher prices are daily adding to their number, though they still differ amongst themselves as to whether now or later on will give the better opportunity for buying. The whole position may be summed up very briefly. If the present reduction in stocks, a reduction which assuredly will for a month or two still further assert itself, is the result simply of poor crops, caused and produced by natural causes of a temporary and transitory character, later on the position will right itself, and stocks will increase again but, if on the other hand, as many experts assert, though the consumption of coffee is steadily increasing, the production is becoming a matter of more and more difficulty; if we are again to see not in one instance but in many countries profuse blossoms succeeded by poor crops, if the evil at work proves to be not above the ground, but below, then of coures overproduction will turn out to be a thing of the past. This digression, however is at present of no commercial value, the question the trade would like decided at the moment is whether current Brazil crop are to total about 5,500,000, 6,000,000 or 6,500,000 bags or higher. As regards the spot market in this port, supplies are and promise to be moderate. Plantation Ceylon coffees are again dearer, and quotations all round are well maintained in a market void of excitement.

GAMBOGE.

The Collector of Malabar reports that there are four species of Garcinia indigenous to the forests of his district:—(1) *Garcinia morella* grows on the Peria Ghat in the extreme north-west portion of the Wynaad taluq up to an elevation of about 1,500 feet. This species yields the tree gamboge of commerce. There is a considerable export from Ceylon, but none from the district. (2) *Garcinia pictoria* is widely distributed, and is found growing along the slopes of the Western Ghats, from 1,000 to 4,000 feet elevation. It is very abundant in the Chenat Nair forests, and fairly common everywhere. It yields an excellent pigment, samples of which were sent to the International Forestry exhibition, Edinburgh, last year; also to the Calcutta Exhibition. The gamboge is collected by lightly scraping the moss and the old bark of the stems of the trees, and then pricking them all over, with an instrument resembling a hair brush, with wire nails fixed in it at intervals of ¼ inch apart. The work should be done from December to March, when there is no rain. The gamboge collects in little tears, about the size of a small pea, in from three to four days, and is quite hard in a week, when it can be collected. The cost of collection amounts to about Rl-8-0 per pound, which is as much the product is worth in the London market; hence there is no trade in it here. A second way of collecting the gamboge is to clean the bark of the trees of all extraneous matter, and then to strip it off, pound and boil it. A yellow extract is thus obtained, which when inspissated yields a golden brown gamboge of inferior quality worth about 6d. a pound. The stripping of the bark, of course, kills the tree. The method is, therfore, a wasteful and expensive one. The fruit of both species are rich in gamboge, and the seeds yield an oil. 3 *Xanthochymus pictorious*.—This species is indigenous to the Ghat forests above Karimpoya in Nilambur. It bears a large golden-colored, thin skinned edible fruit of a pleasant sub-acid flavor, in bunches of 3 or 4 together. It is cultivated at Calicut and in the Wynaad, and is a tree of exceedingly slow growth. The gamboge yielded by it is resinous, and worthless as a pigment. (4) *Garcinia cambojia*.—A very common tree on the Western Ghats, up to 4,500 feet where, however, it rarely exceeds 20 feet in height. It yields a translucid resinous gamboge useless as a pigment. The fruit is ribbed, and of a bright canary colour. The aril is edible, being of a pleasant sub-acid like the mangosteen. The rind of the fruit when green is intensely acid, and is used by the Kurumbers and other wild tribes as substitute for tamarind in their curries. The seeds yield an oil. (5) *Garcinia purpurea*.—A very rare tree on the Ghats, but cultivated at Calicut for the sake of its edible fruit, which is of a bright purple colour. It yields a gamboge which might be used as a pigment. *Garcinias Travancorica et Wightii* are both said to yield excellent pigments, but they do not occur in this district.

The collector of the Nilgiris reports that the *Garcinia pictoria* tree does not grow in his district.—*Madras Mail*.

TYPICAL TEA, COFFEE, CINCHONA AND CACAO SOILS OF CEYLON, AND A FAVOURABLE SPECIMEN OF SOUTH AMERICAN CINCHONA SOIL.

have been analysed by Mr. John Hughes, the Ceylon soils for the Ceylon Planters' Association, the Secretary of which institution has sent them to us for publication, Mr. Hughes being good enough to send us his analysis of the South American soil for purposes of comparison. As Mr. Hughes has pointed out, the considerable proportion of alumina and oxide of iron in the South American soil shows that it can scarcely be so porous as Mr. Thomson represents. Indeed we have had accounts of cultivated cinchonas dying off in Andean plantations, just as they die off not only in Ceylon and India, but in the lava soils of Java. The statement that there are no winds on the Columbian plantation would seem to require equal qualification.

Mr. Hughes has accompanied his figures for the Ceylon and American samples of soil with such copious and exhaustive remarks, that we have little to add to the few notes we have made on the statements of Mr. Hughes. We would only say that the proportions of nitrogen, potash and phosphoric acid in most of the Ceylon soils, are so high as to suggest the presence of manurial substances added to the original soil and not exhausted. If this should not be the case, the proprietors of land showing such good results are to be congratulated on the possession of soils, only needing "a dressing of lime" to prove their fertility in the shape of teeming crops of leaf, fruit, or bark, in accordance with the nature of the plants cultivated.

For the following interesting paper we are indebted to Mr. John Hughes, so well and so favourably known in Ceylon as an analyst:—

CINCHONA SOIL OF SOUTH AMERICA.

The only practical way of ascertaining the chemical and physical properties of soils specially adapted to the growth of particular crops or trees, is to obtain reliable specimens of the soils in which these crops or trees are known to flourish. With this object in view and in order to get a sample of soil representing the natural forest land to which the better species of cinchona were indigenous, I had a correspondence some four years back with Mr. Robert Thomson, whose name has been deservedly associated with the now famous Government cinchona plantations of Jamaica.

At that time he was on the point of going out to South America, and he very kindly promised to procure the desired specimens of forest soil, but as time went on I was afraid I should hear no more about them. However, the other day, much to my surprise and pleasure, I received a note saying he had again returned to Helensburgh and could send me a soil that he had brought home with him according to his promise.

I have therefore much pleasure in sending you the enclosed results of a careful analysis of this soil and believe the figures will be interesting for comparison with those of the ten soils sent me by the Planters' Association, the analyses of which were forwarded to Kandy by last mail and will doubtless be published together with my official report on same.

I gather from Mr. Thomson's letter to me that this particular sample represents the soil of land originally virgin forest, but which has recently been planted with C. Lancifolia and other good species indigenous to the country. However I give his remarks as sent me.

"Soil from Central Cordillera of the Columbian Andes district of Chaparrel. The best varieties of Cinchona Lancifolia grow here. The soil is from an elevation of 8,000 ft; average annual rainfall about 100 inches, but you will see the details from enclosed register of rainfall. Entirely free from winds. One variety of Lancifolia gave 6·20 per cent of quinine 15 months old cultivated here, and several other indigenous species of cinchona gave 1 to 1½ per cent of quinine. The subsoil to a great depth is the same as sample sent except that it is more sandy and contains less vegetable matter, that is to say that it is extremely sandy and porous so much so that the soil immediately after heavy rains becomes perfectly dry. The sample is from the virgin forest exposed to the sun for about 3 years, and the soil

throughout the entire Cordillera is of the same character."

The above are Mr. Thomson's own words and I am sure Ceylon men will attach importance to the remark about the soil being so porous that the rain water rapidly passes away, and the trees consequently do not suffer from wet feet which has been a bad feature on many Ceylon estates and is the result of an impervious subsoil.

Indeed the dying-out of coffee in patches especially when *situated under* or in the immediate neighbourhood of sluggish water-courses is now fully recognized. As regards the analytical results it is gratifying to know that in the matter of the important mineral elements such as lime, potash and sulphuric acid &c., the Ceylon soils are certainly decidedly superior, at least those sent me by the Planters' Association in connection with the present exhibition and which are marked as growing cinchona. Notwithstanding what Mr. Thomson mentions about the soil being so porous I notice that there is 4·823 of water in the air-dried soil and also 21 per cent of oxide of iron and alumina together, which would suggest that the soil cannot be really so very porous or at least not more so than some of the best cinchona soils of Ceylon. In the matter of nitrogen it is above the average of your soils as you will see upon reference to published analyses in my report of 1879 but not above the average of the soils sent to me this year and which are known to represent some of the leading estates in the island.

In one respect this soil is peculiar, the amount of chlorine being unusually high. Whether this is due to exposure to saline rain I have no means of judging, but as the figures ·118 stand they appear quite abnormal for a naturally fertile mountain soil.

It will be seen from the particulars of rain registered, that rain falls pretty equally throughout the greater part of the year and that with a few exceptions which I have had copied out, the daily average is under an inch, although there are two or three inches recorded as having fallen in 24 hours.

March, April and May appear to be the months of greatest rainfall though October is always damp and tops the list in 1885 with the heavy record of 20·47 inches.

It will be interesting to compare these statistics with those of your best cinchona estates, and I will leave the figures for your consideration together with the analytical results of the soil.—

Yours very truly, JOHN HUGHES, F. C. S.

Analytical Laboratory, 79 Mark Lane, E. C.

CEYLON PLANTERS' ASSOCIATION: ANALYSES OF TEA, COFFEE, CINCHONA AND CACAO ESTATE SOILS FROM CEYLON, BY MR. JOHN HUGHES.

Planters' Association of Ceylon, Kandy,
27th August 1886.

The Editors, the *Ceylon Observer*, Colombo.

SIRS,—I beg to enclose for publication copy of interesting letters with reports from Mr. Hughes on the representative samples of soils from some leading tea, coffee, cinchona and cacao estates transmitted to him for analysis in connection with the Colonial and Indian Exhibition.—I am, sirs, yours faithfully, A. PHILIP, *Secretary*.

Analytical Laboratory, 79 Mark Lane, London, E.C.,
July 30th 1886.

A. Philip, Esq., Planters' Association, Kandy.

Dear Sir,—Yours of the 21st June giving information respecting the Rookwood soils 1, 2 and 3 arrived on Monday last, and I have much pleasure in sending you the results of the analyses of the ten Ceylon soils handed me about the end of May by Mr. Shand, to whom I have also sent a copy of same.

I am writing direct to Mr. Downall by this mail sending him a copy of the analyses of his soil from Dambatenne estate, and giving my opinion as to the kind of manure likely to be most suitable.

As regards these analyses it seems a favourable opportunity to have them printed for the general information of planters and those interested in coffee, tea, cinchona, cacao, &c., and as these results in many cases represent, or are at least supposed to represent as nearly as possible the average soil on certain well-known estates, it would be desirable that the air-dried samples of the soils themselves should be placed for reference in some museum either in London or Colombo.

I will see Mr. Shand on the subject in meantime.—Believe me, yours faithfully,

(Signed) JOHN HUGHES.

ANALYSIS OF CEYLON SOILS.

Samples selected by the Planters' Association and representing estates upon which Coffee, Tea, Cinchona and Cacao have respectively been planted.

The following analytical results represent the soils in the air-dried condition :—

JOHN HUGHES, F. C. S.,
Fellow of the Institute of Chemistry,
Member of the Society of the Analysts.

Analytical Laboratory,
79, Mark Lane, July 26th, 1884.

Analytical Laboratory, 79, Mark Lane, London, E. C.

6th August 1886.

A. Philip, Esq., Kandy. Dear Sir,—Mr. Shand as the representative of your Association called upon me this week to express his thanks for the analyses of the ten soils which I had sent him, and copies of which were forwarded you by last week's mails.

Mr. Shand is having these analyses printed in large type, so that when hung up in the Ceylon Court next week, they can be readily seen and read by visitors. He further informed me that he thought a few general remarks, by way of interpreting the analytical results, would be acceptable, and I have therefore much pleasure in contributing the following:—

Of course it will be understood that these remarks are made entirely upon the analyses themselves, and without reference to the respective elevation, rainfall, exposure (more or less) to wind and wash, the general physical character of the land, whether steep or flat, together with its situation, aspect and other matters which are naturally of great importance and demand careful consideration when reporting on the relative fertility of different soils.

1. For general convenience of future reference, as well as in order to arrive at the respective retentive properties of the ten soils, similar weighed quantites of each soil in an equally pure state of division were exposed for a fortnight to the air in a room, when the temperature varied from 60° F. to 75° F. The proportion of water still retained after being thus air-dried was then carefully determined by drying in the usual way at 212° F. and the whole of the different analytical results were accordingly calculated for the soils in this air-dried condition. By glancing therefore along the line of figures arranged under the heading of water it will be noticed that there are great variations: thus Dryburgh 4,244 stands highest; next comes Ragalla with 4.032; then Dambatenne 3,765; and so on down to Pallekelo which has only 1,218.

2. Next as regards the proportions of organic matter and water of combination it will be noticed that there are great variations also under this heading, sometimes, as in the case of Ragalla, Dambatenne, Rookwood No. 3, Dryburgh and Liddesdale; the high results are largely caused by the presence of an unusal amount of nitrogenous organic matter, as will be seen on referring to the column marked nitrogen which is an important element in the composition of such valuable fertilizing matter.

3. The variations of the oxide of iron and alumina in each soil are not very great, but there are notable instances, Rookwood No. 1 containing the most and Pallekelle the least. Generally high proportions of iron and alumina are associated with a more or less stiffness of soil.

4. The lime varies a good deal, Liddesdale having as much as ·743 while No. 3 Rookwood has only ·149, and as ·100 per cent is usually taken to represent one ton per acre of soil to the depth of six inches, it will be understood that these differences although only appearing in decimals really come to a question of tons when considered per acre. In soils originally formed from granitic rocks like those of Ceylon the relative amounts of lime found in each generally may be considered as indicative of its degree of fertility, and therefore its careful estimation is a matter of considerable importance in an analysis.

5. Passing over the items under magnesia which do not call for any remarks, as this constituent is not usually supposed to have any great effect upon the soil, we come to the proportions of potash which are very high in both the cacao soils, also in Dryburgh, and Dambatenne, and fairly high in most of the others, Dunedin in the Kelani Valley being the lowest ·081, but Rookwood No. 2 and 3 are only very slightly higher.

6. The proportions of soda, sulphuric acid, carbonic acid vary, but do not call for any special remark.

7. Chlorine is also somewhat various, but in Dambatenne the proportion is far above the average, though what the reason for such being the case is I cannot

of course say unless it be *exposure* to the monsoon.*

8. Phosphoric acid stands very well in many of the soils: thus Rookwood No. 3 has the most ·184, though curiously enough No. 2 next to it has the least of any, neither soil having been manured. From information furnished by Mr. Armstrong in reference to these two samples, it would appear that No. 2 represents a field of tea 10½ years old in virgin forest land, elevation about 5,300 ft., even lay of land; also that No. 3 represents a field of tea 10½ years old, *steep* lay of land, facing N. E never manured, elevation about 5,300 feet. With this information it seems remarkable that there should be so great a difference in the phosphoric acid which moreover is also followed up in the proportion of nitrogen, both being in favour of the steep land which is specially loaded with quartsz. I am inclined to think therefore that sample No. 3 may have been taken from some rich hollow in which a rather large proportion of vegetable débris had been previously washed down the steep face.†

9. Nitrogen stands very high in many of the samples and must be regarded as indicative of considerable latent fertility, which only requires time and a dressing of lime‡ to render available as plant food. How far nitrogenous organic matter is or is not in an available form cannot be absolutely determined by chemical analysis, but the fact that a soil is rich in nitrogen, at least, is certainly satisfactory, for it tells us that the element which is so important in all fertilizers is present and that it needs only proper cultivation to make it practically useful. A glance at the analyses will show which soils contain the most and those who know the situation of the several estates will be able to judge how far this richness in nitrogen is due to elevation, rainfall even lay of land and freedom from the exhausting influences of wind and wash.

It is noticeable, however, that both the soils upon which cinchona flourishes, are particularly rich in nitrogen: thus Liddesdale has 501, Dryburgh 496, and while Ragalla at present included under coffee has even more than these namely 521 and Dambatenne follows closely after with 411 which is far above the average of most coffee soils previously reported on by myself.

10. The proportion of quartz furnishes the last heading and varies from 7·89 in Dryburgh to 30·78 in Rookwood No. 3, the latter a soil that has already been specially alluded to when speaking of the high proportions of phosphoric acid. Generally a soil which contains much quartz is light and porous in character with low retentive properties and a general poverty in the important elements of fertility: thus Rookwood No. 2 is a fairly good illustration as we notice that the potash, phosphoric acid and nitrogen are all comparatively low and are associated with 25 per cent of quartz, and 1·549 only of water. On the other hand No. 1 the next above (?) with 15·74 of quartz has nearly twice as much nitrogen as No. 2 and is proportionally richer in the other important elements such as potash, phosphoric acid and lime. In fact I have every reason to suppose that No. 1 is generally a much superior soil to No. 2. § Again the Kelani Valley soil furnishes another instance in which with 11·02 of quartz the important elements above alluded to are also low, with the exception, however, of the lime ·302 which is fully high for the average Ceylon soil. At the same time we see two instances (Ragalla and Dambatenne) where the quartz is nearly as high as the last, and yet the nitrogen, lime &c. are certainly very far above the average.* The proportions of quartz must therefore only be considered in *conjunction* with the other items when forming a general opinion of a soil.

11. Taking then all these analyses as a whole, I certainly must consider them as very favourable, and they indicate in many instances a wonderfully fertile soil which under favourable climatic influences should be capable of producing highly satisfactory crop returns. The analyses representing as they do the soils on estates whose names already stand high in local reputation must be useful as a future means of comparison and as every care has been taken to render the results accurate I hope they may in this way be of practical use as well as of immediate interest.

In conclusion I have only to add that if any information is required respecting the particular manure for the respective crops on these soils I shall be happy to express my professional opinion as I have already been requested to do in one case.—Believe me, &c.

(Signed) JOHN HUGHES, F. C. S.,
Member of the Society of Public Analysts.

INSECTS AFFECTING PADDY CROPS IN TINNEVELLY.—The following is a letter from Mr. J. WoodMason, Superintendent, Indian Museum to the Under-Secretary to the Government of India, Revenue and Agricultural Department, Simla, dated 14th May, 1886:—I have the honor to report that the specimens of insects forwarded with the letter endorsed to me by you on 30th April last are no doubt referrable to the species of bug briefly described in 1837 by professor Westwood in his "Catalogue of Hemiptera in the collection of the Rev. F. W. Hope," under the name of *Leptocorisa bengaliensis*. This insect belongs to the family *Coreida* of the insectean order Rhynchota, the vast majority of the members of which live upon the juices of plants, a few only, such as the common bed-bug, attacking animals. The same insect has frequently been received by me from different parts of Assam and of Bengal, in both of which countries it has the same destructive habits. In the Sibsagar district of Upper Assam, where it is known as the "Gandi," it destroys the "Aho Dhan." Professor Stal, the leading authority on the system of the Rhynchota, who, however, had never seen the specimens described by Westwood, suggests that *L. bengaliensis* may be indentical with the bug previously described *L. acuta* of Thunberg. Some insects from Assam that differed, so far as I recollect, in no respect from the museum specimens from the same locality referred by me to *L. bengaliensis* have been named *L. vavicorinis*, Fabr. by W. L. Distant, also a good authority in this branch of systematic zoology. It is hence probable that the names *bengaliensis varicorinis* and *acuta* will prove all to refer to one and the same species, for which the last of these names, as being the oldest of the three, should be retained; in which event we shall have one species of extremely wide range, extending in its distribution, under slight variations of form, from India and Ceylon through Burmah and the Malay countries to Australia, wherein it affects low-lying lands (only occasionally creeping a short distance up contiguous hill-sides) suited to rice cultivation. It is not possible, in our present ignorance of the economy of this pest, to suggest any measures for stopping or mitigating its ravages, or even to form an opinion as to the possibility of any remedial measures. In determining the name of the insect and its place in nature, I have done all that is at present possible. The animal should now be studied in the midst of its surroundings.—*Madras Standard*.

---

* There can be very little doubt that the origin of the exceptional amount of chlorine on Dambatenne estate is to be traced to the not remote salt formations at Hambantota.—ED.

† Perhaps from the sheltered hollow which Mr. Armstrong described in one of his valuable papers, as giving an exceptionally large yield of tea.—ED. C. O.

‡ There is a general feeling that the application of lime is adverse to the flushing of tea; but we suspect that a moderate dressing of lime, would be as beneficial to tea land, especially if clayey and stiff, as to soils growing any other substance. The application of a dusting of caustic lime would seem to be especially indicated when moss grows on the tea bushes.—ED.

§ Unless the sample was taken from an exceptionally rich portion of the estate?—ED.

* Such being the case the question naturally arises whether the samples may not have been taken from spots containing unexhausted manure?—ED.

MARKET RATES FOR OLD AND NEW PRODUCTS.

CEYLON UPCOUNTRY PLANTING REPORT.

RESULTS OF THE LATE HEAVY RAINS—QUEER STORY OF A TEA AUTHORITY—"GOW SYSTEM" OF TEA MANUFACTURE—LAST BREAK OF AGAR'S LAND TEAS—COFFEE—THE WEATHER.

30th August 1886.

From the late heavy rains there have been many results: cooly lines washed away, tea stores flooded, big slips on the railway and roads, and little slips on estates, leaking roofs and damp bungalows, wrecked bridges and burst drains, besides many other things beneficial and otherwise. These were natural and to be expected. It was, however, rather out of the ordinary course of nature that planter's expectation, who in an answer to a store-keeper whose smile is not bland, and who expected some grumbling from his customer, said: "No, no, I have not come in to grumble; was just passing and wanted to see if the late heavy rains had washed down your prices any!"

By the way there is a queer story of a tea authority being employed by a local firm to sell or influence the sale of their "Boom Roller." He is not known to be in the swim, but as an authority, he is of the consulted: many men are anxious to get the result of his experience, to suck his brains in fact, and to these he yields of his stores willingly and in an innocent way. He will instruct you in tea from planting to packing, but is greatest in machinery. As to rolling, well, his universal advice is: "Go in for the 'Boom Roller,' two hand ones are much better than one of the large size; both are not likely to break down at once, you know, and *I* can recommend it." If this seemingly unbiassed opinion is followed he scores a commission, and this in a gentlemanly way, having no visible connection with trade.

It is rather a ticklish matter evidently saying anything about Mr. Gow, the tea authority. Around him there has been a good deal of dust kicked up, and I would like to keep out of it if I can. But "There is a Providence that guides our way." and when a friend of mine sent me a note of the "Gow System," I felt I was mixed up, and must take my chance with the others. This is how the matter is put:—"Take half the quantity of the full charge and roll from five to seven minutes; then take it out and do the same with the other half. Heap them both together and allow them to ferment for half-an-hour; then re-roll for thirty to forty minutes, complete the fermentation, and roll again for twenty minutes, then sift and fire." Tea which had been manipulated in this way, and which lately had been getting about 10½d a lb. when treated in the ordinary fashion was valued at a good deal over a shilling. The tea was said to have a fine black appearance and has a strong liquor. To keep this system going, two rollers are wanted, if there be much tea to manufacture, but the difference in price from what the estate had been getting before, and the valuation of the new tea manufacture on the "Gow Sytem" was so great as to make the buying of another roller a mere nothing.

I don't care to name the exact figure which was mentioned, it being something very fine, and a great deal less would satisfy. If Mr. Gow brings about such results, he will have unmistakably shown, that, although good teas can and have been made, still he can make better.

I have not seen any notice of the sale of the last break of "Agar's Land" teas which was disposed of the other day privately at R1·00 a lb. all round. That is a price which should surely satisfy the fortunate proprietor, and take a good deal to beat. The break, I understand, was not sold in grades.

Now that the price of coffee is rising almost daily, it is not a little vexing to see how the miserable sprinkling of crop which we hoped in time to gather is somehow disappearing. Whether it be the effect of bug or the persistent attention of leaf-disease or the sheer "cussedness" of things, certain it is that the lean promise—too scanty even at its best, either to cheer or to inebriate—which was held out of *something* in the way of coffee, this promise is again to be a disappointment. It is not much that any of us on this side hoped from it, as goodness knows; but when you have humiliated yourself to estimate a one-man-crop, and to find that *that* has to be reduced, it is then that you realize what it is to have your mouth in the dust. I heard, however, of more fortunate people; and with them I can rejoice, for it is not many good things which fall in the way of our planting brethren in these days.

The weather still keeps very favourable for the young tea plants, and several showers we had last week were specially welcomed, coming as they did after a few days' hot sun.

PEPPERCORN.

SPRING VALLEY COFFEE COMPANY, LIMITED.

DIRECTORS.—John Brown, Esq., Managing Director, Edward Conder, Esq., Leon Famin, Esq., Henry Hart Potts, Esq.

REPORT.—To be presented to the Twenty-first Ordinary General Meeting of the Company, on Wednesday, the 4th day of August, 1886, at 12 o'clock noon. The Accounts now presented to Shareholders comprise a Balance Sheet, showing the Company's Financial position on 31st May 1886, and Profit and Loss Account for Season 1884-85. Spring Valley Crop somewhat exceeded the estimate given in last year's Report the total weight of Coffee sold being 5,585 cwt. 3 qr. 3 lb., the net proceeds of which amounted to £15,845 4s 2d, equal to an average price of 56s 9d per cwt. Refuse Coffee sold in Colombo realised £663 0s 8d, bringing the total receipts from sales of Produce up to £16,508 4s 10d. The Ceylon Expenditure includes R22,923·20 spent on Tea clearings, and after providing for this, the result of the Season's working is a profit of £1,857 5s 5d which added to the balance of £1,450 9s 11d, brought forward from last year, makes a sum of £3,307 15s 4d at the credit of Profit and Loss Account. The average price obtained for the Coffee was 3s per cwt. below that of last year, and taking into account the sum expended on Tea planting the Profit secured is considered satisfactory. It will be seen that no Cinchona Bark is brought into the present account; this arises from the fact that early in the season the labour force was reduced it being then thought that crop was to be very short. The gathering of the larger crop secured, however, fully employed all the coolies retained, and no labour was available for Cinchona harvesting until after the close of the Company's financial year. The original estimate of the Coffee Crop for Season 1885-86 was 2,450 cwt., the latest reports, however, show that no more than 1,200 cwt. can now be calculated upon. The returns from Produce will be very materially augmented by the large harvest of Cinchona Bark; 25 tons of this Product being expected to come forward. The Coffee Market also shows signs of improvement, but it is not thought that receipts from that crop will be sufficient to meet the year's outgoings. Until the arrival of the last advices, the Board fully contemplated the payment of a dividend at the present time, but in view of the reduced crop as above, they now consider it prudent to carry forward the balance at the credit of Profit and Loss until the produce for 1885-86 has come forward and been sold, when they will be in a better position to see whether there will be any important deficit on that crop to be provided for.

TEA.—Shareholders were informed in last Report

that the Board had resolved on further extending the area under Tea. The extension decided upon has now been planted up, and the acreage under Tea on the Company's Properties is as follows :—

	Planted. Nov., Dec., 1884. acres.	Planted. May, 1885. acres.	Planted. Nov. Dec., 1885. acres.	Total. acres.
Spring Valley ..	271	—	230	501
Oolanakande ..	—	143	—	143
	271	143	230	644

The cost of planting the 271 acres on Spring Valley in 1884, and the 143 acres on Oolanakande in 1885 has been met out of the revenue of the Account now presented, and the cost of planting the 230 acres on Spring Valley in 1885, will be debited to Crop 1885-86. In face of the small crop to come forward during the last-named season, the Board are well satisfied in being able to report such a large area already under Tea. The Tea on Spring Valley is growing most satisfactorily, and the first small plucking is now being secured from the area planted in 1884. On Oolanakande, the Tea bushes are growing rapidly owing to the Estate being in the Low Country where the climate is very forcing; and preparations are now being made for the gathering of leaf. The whole of the Coffee on Oolankande has now been replaced by Tea.

Crop for 1886-87.—The planting of Tea, as above, has reduced the area of Coffee on Spring Valley to 990 acres. This is an exceedingly fine sheet of Coffee. Though leaf disease is still present, the Directors have hopes that this Coffee may yet give good paying crops, and they have resolved for the present to leave it intact. Several small blossoms have already set for Season 1886-87, and as far as can at present be seen that Season should show a good result, as a very considerable quantity of Bark will be available. The year will, moreover, be aided by a steadily increasing yield of Tea. The Directors, with the exception of Mr. Brown, whose fee includes the expenses of his visiting Ceylon, have resolved, in the meantime to reduce their fees by one-half. Mr. Brown returned from Ceylon in April, having visited the Company's properties. Mr. Leon Famin, a Member of the Board, retires on this occasion and being eligible, offers himself for re-election. Messrs. Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election.

By order, J. Alec Roberts, Secretary.

26th July, 1886.

OUVAH COFFEE COMPANY, LIMITED.

Directors.—John Brown, Esq., Managing Director. H. H. Potts, Esq, L. Famin, Esq., Edward Conder, Esq. Report.—To be presented to the Twenty-Third Ordinary General Meeting of the Company, to be held at No. 5, Dowgate Hill, London, on Wednesday, the 4th day of August 1886, at 1 o'clock p. m. A Balance Sheet shewing the financial position of the Company on 31st May, 1886, and Profit and Loss Account for Season 1884-85, are now presented to Shareholders. Crop 1884-85, estimated at 5,600 cwt., resulted in a total of 5,566 cwt. 0 qr. 17 lb. The value of this Coffee was £15,950 6s 10d, or, equal to a net average of 57s 3d per cwt. Refuse Coffee sold in Ceylon and proceeds of Cinchona bark brought the total receipts from sales of Produce up to £17,344 3s 8d. The Ceylon Expenditure includes R22,727·17 spent on Tea clearings, and after allowing for this sum, the result of the year's working is a Profit of £1,083 14s 6d. Adding this profit to the Balance of £1,109 6s 6d brought forward from last year, there is to the credit of Profit and Loss the sum of £2,193 1s 0d, and for the reasons which are given below, the Directors cannot recommend a distribution of any portion of this amount. In face of the low prices obtained and the small yield secured per acre, the Directors feel some satisfaction at having been able to carry out extensive Tea planting operations and yet leave a balance of Profit. It was at one time thought that Crop 1884-85 would amount to only 4,400 cwt. and the labour force was reduced accordingly; these hands were so fully employed picking the larger Crop secured, that it was found necessary to postpone any extensive harvesting of Cinchona bark until after the close of the financial year,—the sum of £443 11s 10d appearing as the proceeds of Cinchona bark in the accounts being derived from the sale of 4½ tons of this product. The Coffee Crop Season 1885-86, which was at first estimated at 3,000 cwt. is now expected to yield no more than 1,500 cwt. A very large harvest of Cinchona bark is however expected, but it is feared that the year's returns from these products will hardly be sufficient to meet the ordinary estate expenditure and also the expenditure on the large additional area of tea. The tone of the Coffee market is at the present time very firm. Tea.—The contemplated extension of this Product referred to in last Report has been very successfully carried out, and the area now under Tea on the Company's Estates is as follows:—

	Planted. Nov. Dec. 1883 acres.	Planted. Nov. Dec. 1884 acres	Planted. Nov. Dec. 1885 acres.	Total. acres.
Glen Alpin ...	9	55	118	182
Ballagalla ...	—	74	89	163
Grahams Land	—	16	—	16
Rockhill ...	—	—	65	65
Hindagalla ...	—	120	85	205
Narangalla ...	—	82	90	172
	9	347	447	803

The cost of planting the 347 acres in 1884, has been included in the expenditure of the past year, while the cost of planting the 447 acres in 1885 will have to be provided out of Crop 1885-86, and the small Coffee Crop to be obtained that year, fully upholds the policy of the Board in having accomplished the planting of this further large area of tea. All the Tea planted on the Company's Properties is reported to be growing remarkably well, and the first pickings are now being obtained from that planted in 1884. Crop 1886-87.—The planting of Tea has reduced the area under Coffee, from 1,992 acres to 1,273 acres, 89 acres of Tea having been planted in land formerly not under cultivation. The area of Coffee retained is mostly at a higher elevation and in stronger soil than that which has been replaced by Tea, and up to the present time the effects of leaf-disease have not proved so fatal to its crop bearing properties. It is not the intention of the Board to entrench on this area for the further extension of Tea, unless the ravages of the disease make it unprofitable to continue it in coffee. So far, several good blossoms have set for

Season 1886-87, and as the trees are said to be in a measure fr e from leaf-disease, a fairly good yield may be looked for; which, with the returns from Cinchona and the commencing crop of Tea above referred to, will, it is hoped, enable the Company to again enter upon the payment of regular Dividends. In the meantime, the Directors, with the exception of Mr. Brown, whose fee includes the expenses of his visiting Ceylon, have resolved to reduce their fees by one half. Mr. Brown returned from Ceylon in April, having visited the Company's properties. Mr. Leon Famin, a member of the Board, retires on this occasion, and being eligible, offers himself for re-election. Messrs. Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election. By Order. J. Alec Roberts, Secretary. 26th July, 1886.

Sarawak.—An ex Ceylon planter writes:—"Your *Tropical Agriculturist* is indeed a great boon, and is much appreciated in these parts. It is quite a treat to read of the improving condition of the planting enterprise, due, in a great measure, to the Old Rag. You will be sorry to hear of poor Tom Parry's death in North Borneo.

Fruits.—In the Trinidad court are large glass vases containing preserved specimens of the various fruits of the island—jak, breadfruit, sour sop, numerous cacao pods, some with the rind partly removed, &c. There are two good-sized coffee and cacao trees, to the trunk of the latter dried cacao pods are tied, showing how they grow; and a living specimen of vanilla creeper, showing method of cultivation. They seem to be ahead of us in Trinidad in the manufacture of such things as chocolate, prepared cocoa, arrowroot and soaps of various qualities, and I was surprised to see splendid samples of rich-looking comb-honey and to learn from a Trinidad gentleman that he found the keeping of imported bees entirely successful and the export of honey to England profitable. The bees have to be fed during the rains, against which period I suppose nature prompts them to store honey. Are the Trinidad rains more heavy and continuous than in Ceylon? or why should bee-farmers be successful in the one country, and not in the other?—*Cor.*

HORTICULTURE AT BANGALORE.

Bangalore is forging ahead in the cultivation of useful novelties for India. At the recent Agri-Horticultural Show held at the Salbagh Gardens on 4th August, some specimen of hop flowers were among the exhibits and attracted some attention. The hops were cultivated at the Eurasian Colony of Sansmora, in the vicinity of Bangalore, by one of the settlers, who had received the gift of some hop-vine slips from the Manager of the Murree Brewery Company, to be grown as a trial. Now that it has found a success it is probable the cultivation of hops will be largely carried out by the settlers at the Colonies and form a large item of supply to Indian Breweries.

The Exhibition of flowers at the Salbagh Agri-Horticultural Show at Bangalore on 4th August, is presumed to be below the average. This is attributed to the fact that the falls of rain have been unusually heavy and tended to damp off the blooms of roses and run many of the annuals to foliage. The number of exhibits were small compared with previous years; to account for this we have heard it stated that the issuing of Medals instead of small money prizes would make competition keener and create increased attractiveness for amateurs.—*Special Correspondent for T. A.*

THE CULTIVATION OF JALAP.

In December 1880 a Government Order was issued, directing that the report of the Superintendent, Government Botanical Gardens and Parks, on the cultivation of jalap on the Nilgiris for 1879-80 be printed with the order as a Supplement to the *Fort St. George Gazette*, and spare copies struck off for distribution; directing also, with remark, the Commissioner to arrange for the gratuitous supply of tubers sufficient for one-eighth or one-sixteenth of an acre, to persons willing to attempt it, and that the matter of experimental cultivation of jalap at the Lawrence Asylum be brought to the notice of the Committee of Management through the Educational Department.

On the 26th May last Mr. M. A. Lawson, Government Botanist and Director of Cinchona Plantations, Nilgiris, wrote to the Secretary to Government, Revenue Department:—"In reply to your demi-official asking at what cost jalap could be grown per pound on these hills, I have the honor to forward the following calculations. Every acre of ordinarily good soil ought to produce, at the end of three years, at least, 1,000 lb. of dry tubers; and the cost of raising this quantity may be detailed thus:—

	Rs.	A.	P.
Preparation of one acre of land ...	75	0	0
Planting and manuring	30	0	0
Cultivation for three years ...	55	0	0
Digging up and drying the tubers ...	35	0	0
Rates and taxes for three years ...	7	8	0
Total ...	202	8	0

This would make the cost of the *jalap*, as ready prepared for the druggist, annas 3, pies 2 per pound; but as the preparation of the land would be greatly reduced after the first crop had been taken, the cost per pound of every succeeding triennial crop would be considerably less. Taking the preparation of the land at R15 for each succeeding crop, the cost per pound would be annas 2, pies 3. The only person who grows *jalap* on these hills, so far as I know, is General Wilson. This gentleman bought a large quantity of the tubers about four years ago, and has been growing them in the neighbourhood of Kotagiri; and has, I believe, some 400 lb. to dispose of, an amount quite inadequate to meet the indent of 1,500 lb. send into this department. Allowing R50 per acre per annum for profit, the cost per 1 lb. would be annas 4, pies 8; so that, I think, annas 5 per 1 lb. should be the outside limit at which the drug should be sold *on these hills.*

On the 7th instant the following G. O. was passed:—"Government having definitely ascertained in 1877, that the jalap plant could be readily and profitably grown on the Nilgiri hills, endeavoured, between that

year and 1882, by the gratuitous distribution and, when a large demand occurred, the sale of tubers, to encourage the cultivation of this drug by private individuals, in the hope that the result would be that the supplies required by the Medical Department would be procurable in this country in sufficient quantity and at a reasonable price. In the current year, an indent for 1,500 lb. of jalap for the Medical Department was forwarded to the Government Botanist, with the request that information might be afforded as to whether he could meet it. Upon this, Mr. Lawson made inquiries from the different individuals who, from time to time, had procured tubers from the Government Gardens, and the outcome of these has been his learning that only 400 lb. of the drug can be supplied from this source, and that only by one grower. This being the case, and it being clear that private enterprise, to which every opportunity and ample time have been afforded, is unable to meet the calls of the Medical Department, His Excellency the Governor in Council considers it necessary, in the interests of economy, to resume the cultivation by Government of the jalap plant, which was discontinued some years back in order that there might not be interference with private growers. The Government Botanist will, accordingly, at an early date, arrange to begin planting operations calculated to meet an average demand of not less than 1,300 lb. per annum. Government, in issuing these instructions, desire it to be distinctly understood that they do so merely because private enterprise has been shown to be unable to meet the requirements of the Medical Department, and that, when private growers are in a position to supply Government with jalap of approved quality at a satisfactory price, the cultivation of it by the State will be discontinued. A notification will, early in every year be published, for the information of growers, stating the quantity of jalap which will be required by the Medical Department for the coming year and the maximum price per lb. which Government will pay for it. His Excellency the Governor in Council considers it desirable, as the growing of a large quantity of jalap would render the cost of the drug per lb. very small and much below the price in England, that the Government Botanist should address the medical authorities of other Governments in India in view to ascertaining whether they would be willing to draw their supplies of jalap from this presidency. If the total quantity annually required is approximately known, it will be easy for Mr. Lawson to state very closely the price at which he can supply the drug at Madras. It may at present be fairly estimated that this will not exceed 4 annas per lb. The Government Botanist should, when making the inquiries indicated above, forward to the officers addressed a copy of the Government Order embodying the opinion of Surgeon-General Cornish on the quality of the jalap grown on the Nilgiris. Government are of opinion that it would be advantageous if the Medical Department could be supplied from India with other drugs and with preparations which could be manufactured with the help of the Government Quinologist. They therefore resolve to direct Mr. Lawson to place himself in communication with the medical authorities in order to determine what can be done in this direction."—*Madras Mail.*

TEA BLENDING.

A correspondent, who signs himself, "Mincing Lane," writing to the *Grocer*, gives the following hints as to tea blending:—

First main point: Never use a coarse earthy tea.

SUGGESTED BLENDS.

For 2s. retail, to cost 1s. 6d., say:

		s.	d.
10 lb.	fine Ningchow moning (not too large a leaf; pure Pekoe flavour), about ...	1	0
10 ,,	strong plain Kaisow, "Saryune" or "Soomoo"...	0	10½
14 ,,	pungent Assam souchong, not coarse (if large leaf, should be milled to size)	1	1
6 lb.	rich, thick broken Assam or Ceylon fannings.	0	11
40 lb.	(If scent required, 3lb. fine Ouchain or Foochow.		

For 2s. 6d. retail, to cost 1s. 11d.:

14 lb.	choice small leaf Keemun or Ningchow...	1	5
10 ,,	choice first-crop Paklin or honey suckle	1	2½
10 ,,	finest Assam pekoe must be pungent —best if with a touch of autumn flavour)	1	5
6 ,,	very strong, heavy liquoring broken pekoe, either Assam or Ceylon with deep colour)	1	8
40 lb.	(For scent use finest quality only, if any.		

For 3s. retail, to cost 2s. 2d. to 2s. 3d.:

10 lb.	choicest Ningchow or Kintuck	1	8
10 ,,	choicest first-crop Paklin or Peceo congou	1	6
8 ,,	finest Darjeeling or Ceylon pekoe ...	1	8
6 ,,	autumn-flavoured Assam pekoe	1	5
6 ,,	the finest broken Pekoe obtainable, Assam or Ceylon (even small leaf).	2	6
40 lb.	(If any addition, 3 or 4lb. of the best Formosa Oolong, or 3 lb. finest Foochow pekoe.)		

All large teas should be milled being used, so that the general result is a uniform small leaf.—*Home and Colonial Mail.*

THE INDIAN TEA INDUSTRY.

A well attended meeting of ladies and gentlemen interested in the subject of Indian tea took place on Wednesday evening in the Conference Room at the Colonial and Indian Exhibition, when Mr. James Peter, of the Merfinga Gardens, Sylhet, read a paper. Sir T. Douglas Forsyth, C.B., occupied the chair. Mr. Peter began by stating that his object in coming there was to enlighten the British public as to the excellent qualities of Indian tea. He then gave the history of tea-growing in India, with which our readers are already familiar. It had been found that tea would "grow"—he said "grow" with emphasis—from 40 feet to 5,000 feet above sea level in almost any soil. Having given a description of the young plant, how it was first placed in the ground, Mr. Peter said attention was then turned to keeping down the jungle, and as soon as the plant was fairly established cultivation began, when all thereafter depended upon the nature of the soil. In regard to manufacture, he remarked that to this day the difficulty remained—indeed, it was the planters' greatest difficulty—of withering the leaf. It was, of course, in wet weather, when for weeks at a stretch the atmosphere was damp and muggy, that the worst difficulty was experienced. The tea had to be taken off, and the question that cropped up was "what could we do with it? This made the planter sad, and he could assure those present that planters would hail with delight the success of any inventor who would enable them to defy the elements. (Hear, hear.) Here was scope for the inventor. The man who was able to turn out withering machinery capable of withering in the worst of moist wether, would be sure of a fortune. Some speculation existed as to the yield per acre of tea in India. He found that the average yield was 360 lb. per acre. The present season's total crop was estimated at the large quantity of seventy millions pounds. The average price of teas now was 1s. 2d. and at this figure almost all the Tea Companies were able to pay good dividends. Now, he was anxious to put before the British public the advantages of tea as an investment. Would it pay, what were the best means to make it known, and, how were they best to enlist the sympathy of the people at home, with the view of increasing its consumption? To the first enquiry he replied, that tea as an investment would

pay, and pay handsomely. He had been met with the seemingly unanswerable statement that tea did not pay the investor when much better prices were obtained than could possibly be commanded now. He (the lecturer) said that no investment paid in which those responsible for results were persons not thoroughly acquainted with their subject. Planters in India were in this position at first, but by degrees they increased their knowledge of tea-growing, and at the present time there was no body of men more intelligently devoted to the task than India tea planters. (Cheers). Better communication existed between the tea districts and Calcutta, and facilities generally were greatly improved in the tea industry. The teas produced in Assam had found their way with the public up to this time owing to their intrinsic merits, and not by any combination either in India or at home. Indian tea might have forced its way sooner in the world had planters, plantation owners, and all those interested worked together. But no, in Assam it was the same now as at the beginning, no co-operation for the general good. Let them look at little Ceylon and its planters, who began after the Indian grower, and by dint of hard work, and working together, they had pushed their teas to the front of the tea industry. Tea-growing in Ceylon had, comparing it with India, entirely outstripped the larger country. A great deal had been written at various times on this question—a great deal of sentimental writing. The surest way to success was to give a better article, for less money than others. In this Indian tea planters could come to the fore. Indian tea generally, did not differ extensively from China, excepting in two great points—Indian tea was purer and gave a more pungent flavour. This being so, it was more economical—in addition to being better flavoured—because a smaller quantity of Indian tea would give an equal result as against a large quantity of China tea. Most housewives imagined that if the tea in the cup was perfectly black, they had obtained the best possible results (laughter) and had got good value for their money. One pound of Indian was worth at least 1½lb. of China tea. Indian tea was being sold in all the markets of the world. At first people did not take very kindly to it in Australia, but now a great demand existed. In America it had not made much headway, but a friend of the speaker who was in Canada, recently observed that the use of Indian tea had grown enormously fron the time he was in Canada, previously. Many private families were getting it direct, and the article was steadily advancing. When once India tea was used in a family, no one would revert to China—he had never known an instance. He knew of a case in which China had been imported, because some people could not stand the strength of our own growth of tea. (Laughter.) That was, however, very easily remedied. Now, he wanted to revert, for a moment, to the subject of finance. It seemed strange to him that it was so difficult to get money for tea planting, not for new plantations, but for those already established. The banks shielded themselves with the plea that tea was not known as an investment. One way in which the British public could very materially assist the planter was, by helping to remove the ridiculous legislation which encumbered him at every step. The labourer was fenced round with many absurd regulations. The houses must have a window and a door in a certain spot and of a size. These were to meet sanitary requirements. He had no objection to this; indeed he thought them very necessary, but when the coolie shut his window for ever, barricaded his door, and by way of company introduced his cow into the family circle, he (the speaker) entertained some doubts as to the wisdom of such legislation. What the planter wanted was freedom of action. There was so much that hampered him in connection with the laws affecting coolie labour that radical changes would sooner or later be necessitated. (Hear, hear.) There was no fear that planters would neglect the coolie. If only from self-interest the planter would see that his labour was properly housed and cared for. It cost a great deal to import the labour, and when once there it was not likely the planter would risk government interference through his neglect. It was only necessary to mention one absurd instance. If the death rate on an estate exceeded 7 per cent, the Government could step in and shut up the place entirely. No planter would object to this rule, provided labour was allowed to come and go freely. The extraodinary growth and importance of the industry, rendered it essential that all such rules shuld be relaxed. In conclusion, he assured them that Indian tea gave better value for money than any description of China tea produced.

Mr. Parker Thomson said he wanted to ask Mr. Peter a question or two. It seemed to him that Mr. Peter touched on the most important feature of the tea question only at the end of his paper; it was—Would Indian tea pay? That question was to him more important than any. Mr. Peter said they must lower the prices. That meant, that the cost of producing it must be lowered. He wanted now to ask Mr. Peter in what direction the cost of production *could* be reduced. There was no prospect of the quantity from China being materially diminished, and it was clear to everybody that the fundamental law of supply and demand must operate here as in everything. If Indian prices were lowered as suggested, the outturn must be increased, but before that increase could be utilised a market must be found, and it seemed to him that the market for Indian teas of the future would be discovered in the decline of China growths. (Hear, hear). He could imagine the answer Mr. Peter would give to his (the speaker's) enquiry as to the direction in which attempts to reduce cost of output would be made. Eleven years ago (1874) the Assam teas were sold in London at an average of 1s. 11¼d. per lb., and companies he knew of, paid on capital invested dividends as high as 22½ per cent. The average last season (1885) was just under 1s. 1d. per lb. Dividends amounting to 20 per cent, had been paid by the same companies; so that although there had been a decline in price of over 10d., they were in 1886 yet able to declare a dividend only 2½ per cent lower than in 1875. (Applause.) The cost of producing their tea had enormously increased during the eleven years named, and yet the tea was very much cheaper, so that he was at a loss to understand in what particular item of expenditure Mr. Peter hoped to reduce. On this side he could not see any chance of lowering. Duty and freight must be paid.

Mr. Peter said he was glad to be asked some questions. He could not, however, speak definitely at this moment as to the reduction or means of reduction now being contemplated. As one source from which personally he expected unusually excellent results he might mention Main's drier, which he understood would wither the leaf in any condition of the elements, which, as he previously stated, would be a Godsend to the planters. The process of withering was one of the most expensive, and if the consumption of fuel were smaller they would be able to do with fewer hands. The "Sirocco No. 3," one of the latest out, had withered more maunds per day than any other up to the present.

Sir D. Forsyth asked whether Mr. Peter would give his experience as to manuring.

Mr. Peter said his experience of manuring was not very great; when he found that one part of the garden was wearing out he added 15 or 20 acres of new cultivation to make up for the loss in the old ground. He had not, however, the slightest doubt that in the future as cultivation wore out they would have to take to manuring and condensing their areas. The subject of manuring had not up to this time, received any or very little attention from tea planters in India.

Sir D. Forsyth asked what kind of manures would be used

Mr. Peter said the manures would be those used on our English farms, bone dust and chemical manures. He had tried them all. His experience was that whereas bone dust would last well for two

years, the crops being equally good in both, the chemicals produced quite a different result. The first year the tea was good; but the effects of the manure the second year were scarcely felt—at least, advantageously felt. Besides this, the chemical manures, he discovered, made the plant more sensitive, and, unless they were constantly kept up—he might liken it to a stimulant—the bushes, deteriorated. A little had been done in the way of top-dressing, with excellent results. In cases where roots were washed and left exposed, the manuring he spoke of had been eminently satisfactory. He was in favour of top-dressing twenty acres of old cultivation, as against opening up twenty acres of new ground.

Mr. Wyllie, formerly an Assam planter, said it was nearly twenty years since he was connected with tea planting in Assam. The great difficulty then—and gathering what he had from the remarks of the reader of the paper, he discovered that the great difficulty now—was withering. He desired to ask Mr. Peter whether from his own personal knowledge, he could name any machine or any contrivance which had dealt successfully with withering tea or was likely to deal in a practical form with it. He had been in Cachar, Sylhet, and Assam provinces, and could himself testify to the tremendous loss in every way which the withering process entailed.

Mr. Peter replied that he had seen Mr. Gibbs's machine for withering purposes which was most excellent. The Main machine, manufactured by A. and J. Main, Glasgow, was a magnificent drier, and he had every reason to believe that Mr. Main's machine would meet with the success it deserved.

Sir D. Forsyth said he wanted to make a remark. He had been connected with tea for a long time. His experiences in India, however, were not in the tea districts of Assam. Now Mr. Peter placed his average yield per acre at 300 or 350 lb. In his (the speaker's) experience they had never attained to anything like that, except in a few very exceptional instances. The greatest difficulty, perhaps, they had to deal with was the shortness of yield. He wanted to know how they were going to reduce their expenditure and increase their yield. The climate was responsible for a good deal, but there were other agencies at work besides the climate. Indian tea was, in his opinion, making its way exceedingly well. Everybody who cared anything for good tea knew that Indian tea was pure. It was not adulterated like China tea, and people were beginning to find that fact out. If the objects mentioned by Mr. Peter as to increase of yield and reduction of cost could attained, he prophesied that before long Indian tea would stamp all inferior teas out of the English market. (Cheers.)

The usual vote of thanks having been carried with acclamation, the company separated.—*Home and Colonial Mail*

THE BLACKMAN AIR PROPELLER.

The Blackman Air Propeller Ventilating Company, Limited, of 57, Fore Street, London, E.C., exhibited at the Norwich Show six of this firm's air propellers of different diameters, as well as a model of George Greig's patent fan all these of their own manufacture. These air propellers have already earned the world-wide reputation of being the most efficient, most convenient, and most economical form of punkah yet brought out for use in cases where it is desired to really remove from, or supply large volumes of air to large apartments or buildings. The old-fashioned punkahs merely cause an oscillation of the air contained in the room or building, whereas these air propellers are capable of changing the whole of the air contained in the building, either by the supply or the exhaust process, as may be desired. Over and above its mere utility as the best means of ventilating ships, public and private buildings, &c., for sanitary purposes or for the sake of comfort, and by using a *kuss kuss tattie* in connection with one of these air-propellers the air can be cooled to perfection, it is worth while to point out to our readers that it is a peculiarly opportune invention for removing the saturated damp atmosphere of tea-houses in cases where no exhaust fans are used for getting rid of the moisture evaporated during tea-drying. It has lately been repeatedly pointed out that the saturated condition of the atmosphere in tea houses is most prejudicial to tea manufacture, inasmuch as it prevents rapid drying and tends to "stewing." Were these propellers brought into use in *pucka*-built tea-houses, we have no hesitation in saying that a great improvement would be noticed in the tea manufactured, and a considerable economy in fuel would certainly be effected inasmuch as the constantly renewed air itself would be so much more absorbtive. A 48-inch propeller, fitted with the lately applied multiplying gear, is capable of propelling or removing 5,000 cubic feet of air per minute, and only requires one coolie to work it. It is easily packed for shipment, and weighs under a hundredweight complete.—*Home and Colonial Mail*.

CINCHONA AND TEA IN MADULSIMA AND HEWA ELIYA.

This District, so far out of the ordinary beaten path of Ceylon travel, is one of the most favoured in the Island for the growth of Cinchona, and Tea is now growing as luxuriantly and flushing as freely at an elevation of 4,000 feet and upwards as in the most favoured of Kandyan districts. Few strangers and only at long intervals, visit the Estates, and the first impression on entering the District is not pleasant, owing to the wretched-looking fields of abandoned Coffee the road passes through. The feeling, however, rapidly gives place to surprise at the luxuriant fields of Cinchona and equally fine fields of still rich green Coffee which rapidly replace the abandoned desolation of the first part of the journey. Much of the soil is poor to all appearance, but it is this apparently poor quartz soil which has proved so fertile to Cinchona, whilst the heavier and richer soils are shewing a cover of Tea, which for its age cannot anywhere be surpassed. In no district in Ceylon has there been more attention paid to the planting of Cinchona, and what were at one time considered the most valuable varieties were reared in nurseries on which neither money nor supervision was spread: but unfortunately the Ledgeriana, Calisaya, Officinalis, &c., have not given the returns so confidently expected. Many varieties never reached maturity, others cankered and died off, whilst in almost every case the percentage of Quinine was found to be far lower than in the original or parent trees in Java or India; and it is the at one time greatly despised Succirubra and its acclimated sprouts or Hybrids, commonly known as Robusta, which have covered our hills with the present luxuriant growth of this valuable tree. The average extent now under Cinchona in this small District may be placed at 2000 acres in various stages of growth, and although the axe and the shaving knife are making inroads on the plantations, a large portion of the coppiced trees are growing from the stools. Far more serious, however, is the insidious disease known as canker, which, once established, is like the leaf-disease in Coffee and cannot be eradicated; but we find that healthy, self-sown seedlings are not only less liable to canker, but are hardy and thrifty growers, and the analysis is also good, so that planters are now at a nominal cost planting hardy, natural Cinchonas in sufficient quantity to replace the trees destroyed annually in harvesting the bark. Already about 800,000 pounds weight of bark has left the district, and shaving and harvesting are still going on. Next year the harvested bark may reach a milllion pounds weight, and it will be some years before there is any appreciable dimunition of the crop. The planting of Tea and the consequent necessity for uprooting the Cinchona will be the first cause of a material falling off in the yield of bark, but the fact that Cinchona grows best on the poor quartz and gravel soil, whilst Tea luxuriates most in the deep rich brown loam of Uva will show a distinct and well-defined limit for the cultivation of the two plants. In Tea cultivation we are several years behind the Kandyan and low country districts; in

fact, the oldest Tea in Madulsima is only two and a half years old, but so rapid has been the extension of this cultivation, that there are now 2,000 acres under Tea, and 600 will be added this season. On Uva Estate there are 400 acres of Tea, and here the first planting only, 18 months old, is as fine a cover of Tea as any in the Island, and the question of flushing may now be finally set at rest, as growth during the dry months of June and July has proved to be fully as good as anything in Kandyan country. The flush on trees 18 months old cut down to the hard wood in June, in one month from cutting, gave a growth of ten to fourteen inches. On Galoola Estate the Tea is even finer and more luxuriant and stronger in growth at the same age. I have mentioned these two Estates without disparagement to other Estates, simply to shew what may fairly be expected from Tea in Madulsima and Hewa Eliya. Much of the Tea is quite equal to a yield of 600 lb. made Tea to the acre, and when the ground is not too steep to fork in manure I see no reason why the maximum Ceylon yield of 1200 lb. should not be obtained. The character of the plant in Uva is essentially different from the Tea shrub raised from the same jât of seed at a similar elevation on the Kandy side. The growth is much stronger and thicker, and lateral branches are thrown out with more regularity from every eye on the stem; the foliage is denser, and the leaves remain longer on the bush and are of a darker colour; the stems of the young shoots are thicker, and the brown or ripe wood follows more quickly on the flush; the leaves are also thicker and heavier, and it will be found in practice when plucking, although I have had no opportunity as yet of fully verifying the correctness of this statement, that a given number of tips, including the Souchong leaf, will perhaps weigh as much as 20 o/o more than lowcountry grown Tea. It will probably be found necessary to pluck what usually termed fine plucking, and there may be found some difficulty in the manufacture at first, but the samples of made Tea I have tasted and tried, although only roughly made, bear me out in all I have previously said as to the value of Uva Tea—they have both strength and flavour. Several Tea factories are being erected in the District, and before 1886 closes, Uva, or at least Madulsima, Tea will have proved itself in the market. Most of the Estates have a small reserve of forest which will last some time, and charcoal may be had from the low country in any quantity, but a cart road is much wanted from end to end of the District, that is from Passara to Roeberry Estate. There are no bridges of any size required, and a good gravel road might be constructed for say R12,000 per mile. At present length and difficulty of transport are the great drawbacks to this District. No Estate will be able to send down full chests of Tea, and even half-chests will be difficult of transport to the cart road.—Local "Advertiser."

THE COLONIAL EXHIBITION.—NO. VII.

CEYLON.

From all points of view the collection from Ceylon is one of great interest. Tea, as might be supposed, occupies a prominent position, numerous samples being exhibited, some apprently of excellent quality. The preparation of Tea for the market is well illustrated by a series of photographs. In the course of ten years the Tea industry has marvellously increased in Ceylon. In 1876, 282 lb. only were exported, and in 1885 it had reached 3,796,684 lb.—this increase being the result of a high quality Tea, the distinguishing characters of which are described as richness of flavour combined with strength—"the results of most careful cultivation and systematic attention to every detail of manufacture." In the excellent *Illustrated Handbook and Catalogue for Ceylon*, which has recently been published, it is said that "On a Ceylon Tea estate the leaf is never allowed to be handled from the moment it passes into the factory to the time it is bulked in a huge heap preparatory to packing in chests; every stage in the delicate operation is passed automatically, and thus the most rigorous cleanliness and freedom from possible taint is secured."

Amongst spices, Cinnamon takes the most prominent place. Magnificent bundles of this bark are shown, together with chips and clippings. These chips, it seems, are largely used in the manufacture of Thorley's cattle food, as well as in perfumery, and in the distillation of Cinnamon oil, a good deal of which is also made in the island. Jaggery, which is a coarse description of sugar obtained chiefly from the Palmyra Palm (Borassus flabelliformis), was exported from the Northern Province of the island during the past year to the extent of nearly 7,000 cwt., valued at £2,000. Besides this large consumption of Jaggery in Ceylon, the trade might be made one of great importance, as there is at present an active demand from Europe.

Under dyes and dye stuffs we find Jackwood, the wood of Artocarpus integrifolia, which, it is said, "dyes an extermely useful yellow, and is used by the natives for dyeing house mats, fibres for ornament, as well as for giving to cotton and silk cloths the peculiar pale canary colour which is required for the robes of the Buddist priesthood. It is not exported."

Of Anatto, of which there are some fine examples, both of seeds and paste, the Handbook says:—"This useful and rather delicate orange red dye is obtained from the pulp surrounding the seeds of Bixa orellana. This dye is largely used in Europe and India in dyeing silks and also for colouring cheese and other articles. The pulpy matter is separated from the seeds by boiling, and when dried pressed into cakes and shipped. It is imported into England chiefly from French Guiana, where it is native; but the plant is an ancient introduction to Ceylon and is now semi-wild."

Besides a large collection of small wood specimens, of which there is published an excellent list, there are some remarkably fine examples of the choicer cabinet woods such as Calamander, Tamarind, Satinwood, &c. Of the first of these, obtained from Diospyros quercita, it is unsatisfactory to known that it is becoming extremely scarce. The tree is of slow growth and the forests in the south of Ceylon are now denuded of all their Calamander trees of a size suitable for furnishing cabinet wood. Of Satinwood the produce of Chloroxylon Swietenia we also learn from the Handbook that the "trees are common enough in the northern, eastern, and north-western forests, but the proportion of these which yield "flowered Satinwood" is very small, and this description of wood is therefore comparatively high in price. One would not think there was any scarcity in Satinwood when one sees such elaborate show-cases made of it in which the Ceylon Teas are exhibited, and the use to which it seems to be put in Ceylon for carriage building.

The Ceylon court is well arranged, and the Handbook and Catalogue is one of the best of the Exhibition Series. *John R. Jackson, Curator, Museums, Royal Gardens, Kew.—Gardeners' Chronicle.*

COFFEE ROASTING.—"It is a nice task to brown coffee just right," said a New York coffee-roaster the other day. "Nearly everybody browns coffee too much. It comes out burned instead of browned, although it is greatly to the interest of the wholesalers not to brown it too much on account of the loss of weight. When the berry is roasted until it becomes red, instead of chestnut colored, as is customary, it preserves its maximum weight and aroma. One hundred pounds of berries roasted properly lose but fifteen pounds in weight. As usually roasted they lose twenty pounds. If roasted long enough the berry glazes over and turns dark brown. It loses a fourth of its weight in the process." "Why does the grocer overroast his coffee, then?" was asked. "The trade demands it. The coffee that is made from over-burned berries is black, and the flavour is rank. The popular taste is educated to choose black coffee, and would find the light-colored liquid made from the reddened berries rather insipid at first, and would refuse to buy enough to learn to admire the rich flavor of the reddened berries."—*American Paper.*

Cassia:—The attempt that has been made by the afforestation Department of Hong Kong to grow *Cinnamomum Cassia* appears to have met with an unexpected check. According to the report of the Superintendent of the Department, the Chinese persistently break off the leaves and branches of the plants, and notwithstanding the vigilance of the forest guard they manage to keep the plants in an almost leafless condition. The reason assigned is that the Chinese use the leaves in medicine. (*Gard. Chron.*, July 17, p. 82).—*Pharmaceutical Journal.*

Coffee as a Disinfectant.—Years ago some studious German made the observation, the correctness of which he endeavored (and to a great extent also succeeded) to establish by statistical data that coffee, if taken early it the morning on an empty stomach, acted as a preventive against infectious and mainly acute epidemic diseases. He quoted a great number of cases where individuals accustomed to drink a cup of hot coffee for breakfast had either escaped an epidemic of typhoid then ravaging the part of Germany in which the observer lived, or if attacked by the disease contracted it in a much milder form, while all those who died from the disease had not been in the habit of taking coffee in the morning. This was a good number of years ago, at a time when in many parts of Germany coffee was still either an unknown or so costly a beverage as to be looked upon as a luxury that only the rich could enjoy. We have forgotten the name of the physician, but remember that the medical profession did not take kindly to the idea of coffee being a disinfectant, or, as they then said, an anti-zymotic, and those who could not deny the correctness of the observation itself ascribed the apparent immunity to other causes, many to the hot water with which the coffee was prepared. That the physician, however, has not been so wrong has been but recently proved. During the last meeting of the Prussian army surgeons in Berlin, Medical Director Oppler reported that after extensive investigations, which he related in detail, he had discovered that we possess in coffee an antiseptic remedy of no mean value, but one which could well serve for the purposes of a first dressing of a wound received in a battle. If employed at once it totally prevented suppuration, but if used after pus has already accumulated in the wound, it leads to the formation of a scab, beneath which the wound heals with asepsis. The coffee should be employed in the form of powder, and as it might entail the loss of valuable time to have to grind first the roasted coffee bean, which in Prussia every soldier is bound to carry about him, O. recommends the use of coffee-tablets, which have been recently discovered by a Hamburg firm, and which answer their purpose admirably well, as it is only necessary to rub these tablets a little, when they at once assume a powder form.—*American Paper.*

Agriculture in Coorg was thus reported on in the Administration Report for 1884-85:—The area of land held under grants for coffee &c., and denoted in Statement I. E. Fiscal (2) as "Zamidari" was computed at 73,199 acres in 1884-85. Of this area 37,544 acres bearing an assessment of R67,602 were held by Europeans, and 35,655 acres with an assessment of R65,591 by natives planters. The area of European estates has been diminished by 699 acres since the previous year, and by 2,910 acres since 1882-83. The average size of European Coffee Estates, is estimated at 163 acres, and Native Plantations and of at 7·8 acres. A considerable area of unassessed Bane land (the wooded pasture land) attached to farms under rice cultivation) is cultivated with coffee, and it has been for some years past in contemplation to survey and assess these lands. It is expected that a commencement will be made during the ensuing working season. *Labor* for the coffee estates, though late in coming, was plentiful at the end of the season. The Cooly Maistries are no longer stimulated by the high rates formerly paid by the estate owners, the heavy losses sustained of recent years having led to a disposition to curtail expenses in every possible manner. The monthly wage now offered varies from R6 to R7½ for a man, and R3½ to R4 for a woman. *Prices.*—Allusion was made in last year's report to the sudden fall in the price of coffee which took place early in 1884. The price had fallen during that and the previous year from R40 to R26 or R25 per cwt, and in the English Market from 100 shillings to 61 shillings per cwt. The local price has with occasional slight fluctuation been maintained at the former average rate of R26 per cwt. The season was on the whole fairly good. The South West Monsoon rains were lighter than usual during the usual June and July, the rain-fall gauged for those months at Mercara was only 16·55 inches and 29·61 inches respectively. The fall during August, however, amounted to 42·94 inches, and thus a fair average was maintained. Notwithstanding the late period at which the rains commenced, the outturn of the cereal crops was fully equal to the yield of former years. The coffee crop was somewhat affected by the untimely occurrence of the blossoming showers, as well as by the circumstance that the yield of the previous year had been in the most instances large. The cultivation of cinchona has not received the same attention as in the previous years as it is feared that the enterprise will prove a failure owing to the low prices for the bark now ruling in the English Market.

The Colonial Exhibition.—The literature pertaining to this Exhibition is not unnaturally extensive, and for the most part it is excellent. Each colony has caused to be prepared a short account, which generally includes a summary of the history, foundation, government, physical and natural features, as well as commercial products of the colony. In this way an amount of authentic information has been got together which can rarely if ever have been made so accessible before. Adverting more especially to matters in which our readers are more directly concerned, we note an excellent descriptive and classified list of the woods of Queensland, by Mr. F. Manson Bailey, the Colonial Botanist. The Ceylon catalogue, in addition to a mention of raw products generally, has a list of the drugs and of the timber trees of Ceylon, to occompany the specimens exhibited by the Director of the Royal Botanic Garden. The New Zealand catalogue also comprises a list of native woods, but not so usefully arranged as in some other cases. New South Wales issues a general statement of the progress and resources of the colony, but no list of products. The Cape of Good Hope catalogue includes descriptive lists of medicinal plants and of woods. The official handbook of Natal deals with generalities, and the same may be said of Fiji, a special feature of which, however, are the elaborate meteorological details, which will be useful for future refcrence. South Australia furnishes an excellent general account of the nature, history, and products of the colony. The Victorian handbook is remarkable for the copiousness of its illustrations. Canada has an admirable summary of its history, productions, and natural resources, accompanied by two large sized maps, which enable us to realise the extent of the Dominion, and the splendid prospects in store for it. The special British Guiana catalogue is very interesting to peruse, and the notes on timbers instructive, though here, as elsewhere, the use of popular names, compulsory in this case, is a great drawback. The notes on the Straits Settlements contain an interesting history of the colony, but little detail as to its products. The West Indian courts so far seem least well represented in this enumeration of literary exhibits. Tasmania, for some reason or other, does not appear to be represented at all in this Exhibition. We are frequently asked to give information and advice to intending emigrants—a task which, at least so far as the counsel goes, we rarely comply with, for reasons that will be sufficiently obvious; but since the opening of the Colonial Exhibition we have referred all applicants to the Exhibition and to the official reports. We allude to this matter because in our judgment it shows the desirability of securing a permanent Colonial Museum, where every applicant may find the information he is in search of.—*Gardeners' Chronicle.*

THE NORTHERN TERRITORY OF AUSTRALIA.

Port Darwin, July 6th.—The Government nursery is now (July 9th) located at the new site about a mile and a half from town. All buildings, fences, and the most valuable plants have been removed and work at the new nursery is now on a firm footing.

A late visitor to Cox's Peninsula says it is disheartening to see the rapidity with which the two abandoned plantations in that locality are reverting to their primary condition of tangled jungle. Nearly every vestige of the trees and plants introduced at the cost of so much time and labour on Erikson & Cloppenburg's holding have vanished, one of the buildings has been destroyed by a bush fire, and the remaining erections are on their last legs, prematurely decaying for lack of a caretaker; the doors are falling from their fastenings, and the interior of the dwellings have been monopolized by white ants, who have riddled every article of furniture left lying about, displaying a special weakness for Scripture, for they have gone for several Bibles with such vigour that little remains but the bindings. Shovels, hoes, wheelbarrows, coils of wire, blacksmith's tools, and several other once useful articles are mouldering away in the vicinity and quickly being dissolved into their original elements. Harris & Head's plantation, which has not been abandoned very long, is in a better state of preservation. There are numerous papaya-trees and banana plants loaded with fruit, but there is also a thick crop of tall grass growing right up to the dwelling-house, which only needs a careless spark to afford food for a fire which would sweep away every trace of what took so much toil to produce.

CINCHONA IN JAVA.

The following translation of M.Van Romunde's Report on the Java Gardens for the 2nd quarter of this year—recently received,has been made for the *Observer*. The most noteworthy fact is that there is not the slightest reference to "canker" in the Report extending up to 30th June, but of course the Government Gardens may have escaped the trouble so far. The Government crop of bark does not increase:—

Report on the Government Cinchona Plantations for the 2nd quarter of 1886.

The rains continued to about the middle of May. The latter half of the month was very dry, as was also the beginning of June, after which a few rainy days were again registered. Planting out in the open ground from the nurseries was pushed on as much as possible, when the state of the weather was favorable.

The dry weather had a beneficial influence on the young plantations, this influence was particularly noticeable on such plantations as had been highly cultivated at the latter part of the wet monsoon. The harvest of this year amounts to fully 100,000 Amsterdam pounds of bark, of which 85,106 pounds were sent to Batavia by the end of the quarter. This harvest was almost exclusively obtained by thinning out close plantations, and consists chiefly of C. Ledgeriana. On the 15th April fully half of the produce of the harvest of 1885 was disposed of by public sale at Amsterdam. The gross proceeds amounted to 190,000 guilders (gulden) being an average price of *f* 0.79 per half kilogram. The highest prices were obtained for a very fine lot of C. Calisaya bark in long quills which fetched up to *f* 3·86 per half kilogram. The highest price offered at this sale for C. Ledgeriana bark was *f* 1·85 per half kilogram. The inquiry respecting the influence of succirubra stems on the bark of the Ledgeriana grafted thereon, is steadily pursued. The results of the chemical researches shall, if possible, be made known during the coming quarter.

The original Ledgerianas as well as the old Succirubra plantations produced such an insignificant seed-harvest, that only a very few sales of cinchona seed could be held, which produced a gross result of *f* 552·75. The graft-plantations of Tortasari promise in the course of the third quarter an abundant harvest of valuable seed, so that important sales will then be held.

(Signed) Van Romunde,
Director of the Government Cinchona Plantations.
Bendoeng, 5th July 1886.

TEA IN UVA.

Everything concerning the practical development of the tea enterprise in the Province of Uva is full of interest at the present time, and we have been much pleased with a series of reports from diverse hands, which we have had the privilege of looking over. When a Colombo Agent with a considerable experience of tea writes to a Manager in almost the *ultima thule* of Uva as follows, "The teas you send down are first 'chop' and leave nothing to be desired; if you can send us teas like these from Uva in quantity, the enterprise cannot fail of success," it is evident that the district is to take no second place in its quality of tea. Madulsima 'broken pekoe' has been valued lately by London experts at 1s 10d and upwards; while here is a local report on another series of samples from the same district:—

"Your tea is excellent and bears favorable comparison with about a dozen tea samples we tried with it. The report written on your tea was as follows:—

'Sample No. 4.—Broken Pekoe.

Appearance:—Fairly well twisted, slightly greyish, good display of tip.

Fermentation:—Good and even, bright.

Liquor:—Strong, dark, good flavour, somewhat rasping.

'Sample No. 4.—Pekoe.

Appearance:—Twist uneven, evidently hand-rolled, somewhat greyish, grading defective, some red leaf and congou present.

Fermentation:—Even and bright.

Liquor:—Strong, dark liquor, slightly metallic taste.

"For commercial purposes you should grade as we are doing elsewhere. Pluck out tea leaf, pass through a No. 8 sieve, then break all save congou through the No. 8 mainly by gentle pressure of the hand, not against the metal. Take out dust by a 30 or 32.

"Your B. P. is beautiful and have a splendid liquor, only two on the table were better, a B. P. of Kerr's and old Taylor's.

"The pekoe has too much tip, I think, and is rather disfigured by congou and a little red leaf. It liquors splendidly. What you want is a roller, and you could look over most men."

The Galoola Tea Factory, we learn, was opened on the 1st September. Machinery will doubtless be required on a good many other estates erelong.

CEYLON TEA.

The pamphlet issued by the Ceylon Planters' Association, has at length reached us, a copy having been courteously posted to our address by the Secretary. The coloured lithographs, when looked at closely are more patchy than artistic, but they give a very good idea of what is intended to be illustrated, viz.:—

A Tamil Woman Plucking Tea Flush;

View of a Tea Estate and Factory;

Weighing in Green Tea Leaf.

As a large portion of our readers are interested in the subject, we quote the text which accompanies the illustrations. The writer certainly does justice to our new staple and turns the tables effectually on those whose "vested interests" in the inferior teas of China and Japan led them to prejudice the public mind as far as they could against the stronger and purer competitor as if it were a dangerous poison. But it ought in fairness to have been mentioned that Indian Tea and its producers bore the chief burden and heat of the day in the fierce and bitter controversies which once raged in England around the competing teas of India and the Far East. By the time Ceylon tea came on the stage, many of the old enemies of Indian tea had been converted into friends and had contracted vested interests in that product, which the tea-drinking public had come gradually to appreciate for themselves. Ceylon tea, therefore, apart from its merits as combining in an unmixed form delicate flavour with strength, had less prejudice and selfish opposition to contend with than was the case when "Ind of Great Mogul" first entered the lists as a competitor with "Far Cathay" and its world-renowned "Thay." This might have been generously mentioned; but the object of the writer was to recommend Ceylon tea, and this task has certainly been well performed. We trust the circulation in tens of thousands of this pamphlet, the show and sale of Ceylon teas in the Exhibition and the efforts of the Syndicate will be to increase consumption in markets already open and secure favour for our product where it is as yet unknown, or only partially known; so that consumption may be in proportion to the increased production which the writer of the brochure correctly anticipates:—

TEA IN CEYLON.

In the minds of the British public the name of Ceylon has been chiefly associated with the production of Coffee and Spices; the latter in poetry, but in poetry only, imparting their fragrance to the very air.

While Ceylon Coffee and Ceylon Spices are of superior quality and remain most important articles of trade, it is Ceylon Tea that is rapidly becoming the staple product and the one for which the island will soon be most celebrated.

Seldom or never has an industry made such progress or a new article of consumption overcome by its intrinsic merit the opposition of vested trade interests as has Ceylon Tea.

In 1873 the exports of Tea from Ceylon were 23 lb.; in 1885 they have been 4½ million lb.; in 1886 they will be about 10 million lb.; and in the near future 40 million lb will be exported.

The area under Tea in the island is rapidly extending, and already about 120,000 acres have been planted. Over 700 European planters and 150,000 Indian and Sinhalese laborers are engaged in the cultivation. Some of the plantations are but little above sea level, while others run up to an elevation of 6,000 feet. The average altitude of the larger districts is about 4,000 feet above sea level, an elevation at which the climate is pleasant and most healthy. A railway runs up into the hills and a good system of cart roads exists, so that most of the estates are already within a day's journey from Colombo—the capital and shipping port.

At a time when dietetics has almost become a science, when purity and cleanliness in food and beverages are so strongly insisted on, it is strange that greater attention has not been called to the more than doubtful nature of much of that which is consumed as Tea.

It has been said that, if to be an Englishman is to eat Beef, to be an Englishwoman is to drink Tea. True it is that the article which in the sixteenth century was a luxury, costing ten guineas a pound and consumed by a hundred people, has in the nineteenth century become a necessity, costing two shillings a pound and consumed by millions.

Did the people of Britain thoroughly understand the difference between British-grown Tea—such as Ceylon's—and that of China or Japan, it is certain that those who could get the pure, clean, machine-prepared leaf which is turned out from the planter's factory, would never touch the far from pure article prepared by the hands and feet of the unwashed Mongolian.

In China and Japan Tea is mostly cultivated in small patches by the peasantry, who gather the leaves and prepare the Tea in their huts in a very unfastidious manner. The Tea, either in a half-

manufactured or finished state, is sold to petty dealers who in turn sell to larger dealers.

The large dealer mixes and manipulates Teas, packs and sells them to the European Merchants for shipment to England, Australia, or America. The manipulation of Tea is an art in which the Chinaman excels, and in many of the inferior kinds the quality is infinitely deteriorated—thus, "the dust of the leaf is mixed with clay and manipulated into the form of the ordinary leaf"—this is with appropriate philological coincidence termed "lie" Tea. "Tea leaves which have been already used are again manipulated and rolled into shape and sold as genuine Tea."

The Teas of Japan, which are almost entirely consumed by our American cousins, are frequently and admittedly "faced" with a mixture of Prussian blue and soapstone.

The Ceylon estate cultivation and manufacture are very different, and it may not be uninteresting to give a brief account of how *pure Tea* is made. Visitors to the Ceylon Court in the Colonial and Indian Exhibition will find an interesting series of photographs from life, attached to the exhibits of Tea, illustrating the various operations

The Tea bushes are planted in lines at regular distances over hundreds of acres of carefully roaded and drained land, which is regularly weeded every month. Once a year the bushes are pruned down to a height of about 2 feet; and eight weeks after the pruning the first "flush" of young shoots is ready to be plucked, and during the height of the season the flushes reoccur every ten days. Coolies, having a small basket attached to their girdle, then go round and pluck the bud and a couple of the tender half-developed leaves. At mid-day, and again in the evening, the leaf is weighed and taken into the factory. The leaf is at once spread very thinly on trays or shelves to wither. The time which the leaf takes to wither—to become soft and pliable without drying up—varies with the weather, but as a rule the leaf gathered one day will be sufficiently withered the following day.

The withered leaf is [then] placed in the rolling machine; an ingenious and effective machine which is driven by water or steam power. The rolling lasts for nearly half-an-hour, at the end of that time the leaf has become a moist mass of twisted and bruised leaves, out of which the expressed juice freely comes, technically called "the roll." The roll is then placed in trays to ferment or oxidise; during this process it changes from a green to a copper color. The subsequent strength and flavor of the Tea depend, to a great extent, upon the fermentation—a chemical process, the success of which is not entirely within the control of the Planter, but depends greatly on the weather and takes a time varying from two to six hours.

The next process is that of firing. The roll is thinly spread on trays, and placed either over charcoal stoves or in large iron drying-machines, and at the end of half-an-hour it is thoroughly crisp and dried and has become Tea. The Tea is then sorted or sized, by being passed through sieves of different mesh (see working model of a Tea-sifter in the Ceylon Court) giving the varieties of broken pekoe, pekoe, souchong, congou, and dust. The broken-pekoe, which consists chiefly of the opening-bud of the leaf, gives the strongest Tea, perhaps too strong a Tea to be infused by itself; and a mixture of pekoe and souchong makes the most pleasant drinking Tea.

The final process is that of weighing and packing. When a sufficient quantity has been manufactured the Tea is again slightly fired, to drive off any suspicion of moisture, and packed while warm in lead-lined boxes carefully soldered down to exclude air.

Such is the mode of careful, cleanly preparation in the specially erected factory of the Ceylon Planter; and every drinker of genuine Ceylon Tea may be certain that it is *absolutely pure*.

Specimens of the various classes of Tea, above named and also of fancy Teas, from all districts in Ceylon and grown at all elevations (from sea level up to 6,000 feet) may be seen in the Ceylon Court. And every information regarding the industry may be obtained from the Planters' Commissioner at the Exhibition. Ceylon Tea, in packets guaranteed by the Planters' Association and also as a beverage, is sold in the Tea Room attached to the Ceylon Court as well as in the Ceylon Tea Kiosks in the Exhibition Grounds.

Ceylon Tea stands unrivalled for its combination of strength and flavor; and the pure Tea gives a beverage pleasant and beneficial to those who drink it. One cannot doubt that, were the well-meaning evangelists in the cause of temperance to realize the difference between pleasantly-strong well-flavored stimulating Tea and the "wishy-washy" decoction infused from the cheaper China Teas, their efforts to substitute "the cup which does not inebriate" for that which does might be made much more successful.

In addition to the other good qualities Ceylon Tea possesses that of being economical; for it is generally admitted that two pounds of Ceylon will go as far as three pounds of China.

The Tea you drink should be—1.—Pure. 2.—Wholesome. 3.—Pleasant. 4.—Economical.

And Ceylon Tea justly claims pre-eminence on these grounds.

Would-be purchasers of Ceylon Tea must be warned that there is danger (just as there is with everything which has earned a good name and become popular) of a spurious or admixed article being sold instead of what is genuine.

French Walnut Wood.—The finest and most costly of veneering woods is the French walnut. This is imported from Asia Minor and Persia. The burr is the valuable portion of the tree, and sometimes as much as £100 to £200 was obtained for them while one at the Paris International Exhibition in 1878 realized the enormous sum of £1,000, or about 8s per lb. weight. The use of this wood is now limited to pianofortes. For a particularly fine piece of ebony £1 the pound has been paid, as it is difficult to get large pieces which can be used without cutting.—*M. Mail.*

Natal and Mr. Angus Fraser.—The O. B. C. sold their branch at Port Elizabeth to a local establishment, which has since had to write off half its capital, and our old acquaintance, Angus Fraser, having taken shares in the concern, was naturally somewhat irate at having a hint that his salary would be reduced in like proportion; so he gave the Bank notice to quit, making the fourth O. B. C. man now in London "on the staff," the others being J. B. Morphew, A. Carmichael, and J. D. Dawson. In reply to my enquiries about Natal tea. Mr. Fraser laughed consumedly, and said the severe and long droughts to which the district was subject rendered tea cultivation out of the question, and what he had seen of it had convinced him that nothing would ever come of that industry in any part of the Cape territory.—*Cor.* Local "Times."

The "Tropical Agriculturist" is the means of bringing us some curious requests and enquiries. Here is a letter received by the last mail which we publish in the hope that it may come before the eye of the writer of the valuable paper referred to which we took over from the pages of the Melbourne *Leader*, as duly acknowledged at the time:—

Surinam, Plantn. Gagtlust, 25th June 1886.

To the Editor of the *Tropical Agriculturist*, Colombo, Ceylon.

Dear Sir,—By reading your novelles, 1st Jan. 1886, vol. V. No. 7, p. 505, "Management of Fruit Trees," the few lines had such effect to me as amator of fruit trees, that I contain to pleas you to bring me in transaction with the writer.

In this case you will oblige to give me the address of the writer, if it is possible,—I am your obedient servant,

S Crench,

Old President of the Agriculture, &c. Society, Surinam.

A TRIP TO CHIRIQUI: CACAO, BANANAS, VEGETABLES, COCONUTS, &c.

From an article so headed in the *Gardeners' Chronicle*, we quote as follows:—

Leaving Kingston, Jamaica, on November 8, we entered the lagoon of Chiriqui on the 14th by a zigzag course between an island and a point of the mainland through a passage known to navigators as Bocas del Drago, or Mouth of the Dragon, but locally known as "Boque's Mouth." Once inside, a broad expanse of water was before us almost deserving the term of inland sea, for certainly the term lagoon, as it is generally understood, is not an appropriate name for these waters.

In the provision fields we found Plantains, Bananas, Pumpkins, Cassava, Sweet Potatoes, Yams, &c., growing in the greatest profusion; the only enemy they appeared to have to contend with being the "We-we," or Umbrella Ant. This insect—although very destructive, it is true—did not appear to effect the general results of the cultivation, and the groves of Cacao on the outskirts of the field were in most instances untouched by it. We found large colonies of this insect in every part of these islands, and it is without doubt in a great measure due to the labours of these little creatures, assisted by the numerous land crabs, that the probably once barren coral rocks which form the foundation of these islands are raised from sea-level to become fertile fields adapted for the production of food for the human race.

Plantains and Bananas produce large bunches, which meet a ready sale on the spot, at the hands of captains of trading schooners running to and from the Isthmus of Panama. "Sarse," the roots of a species of Smilax, known to commerce as Sarsaparilla, also meets a ready sale, large quantities being grown at various places in the lagoon, and not a little is produced and brought down by the Indians from the mainland.

The varieties of Cacao (Theobroma Cacao) were numerous. The most commonly cultivated were the white and red-skinned varieties, the green-skined is a very heavy cropper, and produces beans of excellent quality.

Chocolate of good quality is manufactured locally. The beans are first roasted, then deprived of their skins, and afterwards ground on a small, flat, porous stone, the crushing instrument, also of stone, being of a shape similar to a housewife's rolling-pin. We had frequent opportunities for testing this preparation, and often declared that, if travellers of the olden time tasted as good a mixture as it was our fortune to drink, it was no wonder that they described it as being "Food for the Gods."

Another distinct species of Cacao was met with, which, though of doubtful value as an economic plant, was of sufficient botanical interest to induce us to spare no pains to introduce it into Jamaica, in which endeavour I am glad to say we were primarily successful, as growing plants reached Kingston in safety, and are now contributed to the Castleton Botanical Garden. The plant has not as yet been scientifically determined, but I may venture to state that it will probably prove to be Theobroma bicolor.

The tree itself is of a stout spreading habit, its trunk and branches being much thicker than those of the ordinary kinds; but it is not so erect in its mode of growth.

In the Cacao groves we saw many trees of the ordinary kind reaching a height of over 40 feet while the "Tiger Cocoa" seldom reaches more than 15 or 20 feet.

Several plants of a tree locally known as the "Wild Cocoa" were met with in the forest, and botanical specimens duly secured, which will probably prove the plant to be, not a Cocoa at all, but a species belonging to the allied genus Herrania. The plant has but a small single stem, its leaves resembling at a short distance those of the common Papaw (Carica papaya). The pods are small, ten-ribbed, with roundish seeds, covered with a thick sweetish pulp, much sought after as a "bush" delicacy by the juvenile members of the community.

On our return from the morning's outing we examined the locality around the settlement in which we were residing, and it was found that little cultivation was attempted near the dwellings, but that groves of Cacao and Coconuts abounded everywhere, while many of the inhabitants took great pride in showing me their "Soopa" trees. This is a palm well known under the name of Gulielma speciosa, Mart., but now referred by the authors of the *Genera Plantarum* to the genus Bactris. Wallace in his *Palms of the Amazon* thus describes it:—"This most picturesque and elegant Palm has the stem slender, cylindrical, and thickly set with long needle-shaped spines disposed in rings or bands. It reaches 60 feet in height, and grows quite erect, though in exposed situations it becomes curved and waving. The leaves are very numerous, terminal, pinnate and drooping, forming a nearly spherical crown to the stem; and the leaflets growing out of the midrib in various directions, and, being themselves curled and waved, give the whole mass of foliage a singularly plumy appearance."

"The fruit is the size of an Apricot, of a triangular oval shape, and fine reddish-yellow colour. In most instances the seed is abortive, the whole fruit being a farinaceous mass."

"This palm appears to be indigenous to the countries near the Andes. On the Amazon and Rio Negro it is never found wild." It is most commonly known as the 'Peach Palm,' from the similarity of its fruit, in size and colour, to some species of the genus Amygdalus, to which the Almond, Peach, and Nectarine belong.

The fruits are eaten either boiled or roasted, and have a flavour, to our taste, somewhat combining that of roasted Spanish Chestnut and Sweet Potato. As they are very wholesome I ate several, which I particularly enjoyed. They are said by Wallace to be "also ground up into flour, and made into cakes, which are roasted like Cassava bread, or the meal is fermented in water, and forms a subacid creamy liquid. Parrots, macaws, and monkeys, eat them greedily, but the latter gentry are prevented when in a wild state from obtaining them by the prickly nature of the stem.

The trees were growing at sea-level, and as the temperature is similar, I believe it would be an excellent plant to introduce for growing on the plains of Jamaica. As an article of food it would certainly be a valuable plant to the poorer inhabitants of this island, provided they could be induced to overcome their invariable prejudice against "Buckra tings." The fruit will stand transport with great facility when ripe. I had a single one which I kept for some twenty-five days, and that it was found in a comparatively sound condition on my arrival in Jamaica.

THE RED SPIDER.

(TETRANYCHUS TELARIUS.)

The red spider is not correctly speaking an insect, though it is commonly spoken of as such, neither is it a spider, as its name would imply, but an acarus or mite. Whether its name is correct or not, it is a most destructive and troublesome pest wherever it makes its presence felt; it by no means confines itself to one or only a few kinds of plants, as many insects do, but it is very indiscriminate in its choice of food, and it attacks both plants grown under glass and those in the open air. When these pests are present in large numbers the leaves on which they feed soon present a sickly yellow or schorched appearance, for the supply of sap is drawn off by myriads of these little mites, which congregate on the undersides of the leaves, where they live in a very delicate web, which they spin, and multiply very rapidly; this web and the excrement of the red spider soon choke up the pores of the leaves, which, deprived of their proper amount of sap, and unable to procure the carbon from the atmosphere which they so much need, are soon in a sorry plight. However promiscuous these mites may be in their choice of food plants—Melons, Cucumbers, kidney Beans, Hops, Vines, Apple, Pear, Plum, Peach trees,

Limes, Roses, Laurustinus, cactuses, Clover, Ferns, Orchids, and various stove and greenhouse plants being their particular favourites—they are by no means insensible to the difference between dryness and moisture. To the latter they have a most decided objection, and it is only in warm and dry situations that they give much trouble, and it is nearly always in dry seasons that plants, &c., out-of-doors suffer most from these pests.

Sulphur is one of the most efficient agents known for killing them; but it will not, however, mix properly with water in its ordinary form, but should be treated according to the following recipe:—Boil together in four gallons of water 1 lb. of flowers of sulphur and 2 lb. of fresh lime, and add 1½ lb. of soft soap, and, before using, 3 gallons more of water; or mix 4 oz. of sulphate of lime with half that weight of soft soap, and when well mixed, add 1 gallon of hot water. Use when cool enough to bear your hand in. Any insecticide containing sulphur is useful. In hot-houses one of the best ways of destroying these creatures is to paint the hot-water pipes with one part of fresh lime and two parts of flowers of sulphur mixed into a paint. If a flue is painted in this way great care should be taken that sulphur does not burn, or much damage may be done, as the flues may become much hotter than hot-water pipes. During the earlier stages of growth keep the atmosphere moist and impregnated with ammonia by a layer of fresh stable litter, or by painting the hot-water pipes with guano made into a paint; as long as the air in the house is kept moist there is not much danger of a bad attack. If Carnations are attacked, tying up some flowers of sulphur in a muslin bag and sulphuring the plants liberally, and washing them well in three days time has been recommended.

Tobacco water and tobacco smoke will also kill these pests, but as neither tobacco nor sulphuring the hot-water pipes can always be resorted to with safety in houses, by far the better way is to keep a sharp look-out for this pest, and as soon as a plant is found to be attacked to at once clean it with an insecticide which it is known the plant will bear, and by this means prevent other plants from being infested. These little mites breed with astonishing rapidity, so that great care should be exercised in at once stopping an attack. A lady friend of mine had some Castor-oil plants growing in pots in a window which were badly attacked, and found that some lady-birds soon made short work of the mites and cleared the plants. The red spider lays its eggs among the threads of the web which it weaves over the undersides of the leaves; the eggs are round and white; the young spiders are hatched in about a week, and they very much resemble their parents in general appearance, but they have only three pairs of legs instead of four at first, and they do not acquire the fourth pair until they have changed their skins several times; they are, of course, much smaller in size, but are, however, in proportion just as destructive as the older ones. They obtain the juices of the leaves by eating through the skin with their mandibles, and then thrusting in their proboscees or suckers through which they draw out the juices. These little creatures are so transparent, that it is very difficult to make out all the details of their mouths accurately. The females are very fertile, and breed with great rapidity under favourable circumstances all the year round.

The red spiders, as I have already stated, are not real spiders; but belong to the family Acarina or mites, a family included in the same class (the Arachnidæ) as the true spiders, from which they may be easily distinguished by the want of any apparent division between the head and thorax and body; in the true spiders the head and thorax are united together and form one piece, to which the body is joined by a slender waist. The Arachnidæ are followed by the Myriapoda (centipedes, &c.), and these by the Insectæ or true insects. The red spiders belong to the kind of mites called spinning mites, to distinguish them from those which do not form a web of any kind. It is not quite certain at present whether there is only one or more species of red spider; but this is immaterial to the horticulturist, as their habits and the means for their destruction are the same. The red spider (Tetranychus telarius) is very minute, not measuring more than the sixtieth of an inch in length when full grown; their colour is very variable, some individuals being nearly white, others greenish or various shades of orange, and red. This variation in colour probably depends somewhat on their age or food—The red ones are generally supposed to be the most mature. The head is furnished with a pair of pointed mandibles between which is a pointed beak or sucker. The legs are eight in number; the two front pairs project forwards and the other two backwards; they are covered with long stiff hairs; the extremities of the feet are provided with long bent hairs, which are each terminated by a knob. The legs and feet appear to be only used in drawing out the threads and weaving the web. The thread is secreted by a nipple or spinneret situated near the apex of the body on the underside. The upper surface of the body is sparingly covered with long stiff hairs.—G. S. S.—*Rural Australian.*

MINOR INDUSTRIES FOR THE WEST INDIES.

The following letter from Mr. D. Morris, formerly Government Botanist of Jamaica to Governor Robinson of Trinidad, will be read with interest:—

Royal Gardens, Kew
21st May, 1886.

Dear Sir William Robinson,

On my arrival at Kew, Mr. Thiselton Dyer was good enough to place in my hands correspondence and papers bearing upon the prosecution of Minor Industries in Trinidad, which are of a very interesting character.

The Island is to be congratulated upon the able and energetic action you have taken in this subject: and possibly no time is so suitable as the present for drawing attention to small industries, which in the aggregate, would go far to make up the difficiency in the larger stables of Trinidad, and of the West Indies generally. I am not sure how far I can help you, but I shall be happy to give the results of my experience and knowledge in Jamaica and other places known to me: and it is quite possible that indirectly, if not directly, suggestions thrown out in this manner may be capable of being utilized as local circumstances may allow.

As regard the utilization of Trinidad-grown Corn Meal and Sweet Corn, a letter from Kew was sent a few days since to the Colonial Office, which no doubt will be duly forwarded to you. The weak point in papers received here was the absence of numerical results in Mr. McCarthy's Report. The general impression all round was good: but in these days men require a substantial and reliable basis on which to rest their conclusions, and unfortunately in this instance it was not supplied. I wrote Mr. McCarthy on the subject but, as was natural, he had not brought his books with him to England and hence could not give me the detailed analysis of the two corns. He has promised to supply them on his return to Trinidad and I would recommend, that they be published as soon as possible. If it can be shown by actual analytic results that Creole-grown corn is richer in food products than American imported corn, the superiority of the former will be established beyond question.

Tea will grow in Trinidad at elevations above Cacao and the Hybrid-Assam variety is specially suited for a warm, moist climate such as exists in Trinidad. It is essential to have a trained experienced manager from Ceylon or India, and such a man might be obtained for about £250 a year. In addition to supplying local wants, I should think a good quantity of Tea might be supplied to the Mainland at renumerative rates. A plantation of say 50 acres, might be established at the rate of £10 per acre. The first crop would be available in

3 or 4 years, and the results, even on an experimental estate, give a good return on the capital invested. If started in connection with a cocoa estate the expenses would be reduced to a minimum regards buildings and Offices.

The Ground-nut (*Arachis*) will only thrive in light sandy soils which however require to be fairly rich. In Virginia and Kentucky the "Peanut" is very important crop, and if it could be established at Trinidad, and the "nuts produced at a price to compete with the States," there is a large market open there for them. An experiment tried in a few districts at Trinidad would soon show what prospects the industry would have. Seed nuts can be had in any quantity.

Among Minor Industries to which attention might very well be directed, I would mention a few here, in the hope that my remarks may stimulate inquiry and lead to some practical result.

Limes, I know, are cultivated in Trinidad, and the export of crude lime-juice may have been already attempted. The most acceptable form however for presenting lime-juice in the market is as "Concentrated Juice." This is prepared by boiling the crude juice down to the consistency of thick molasses. The proportion of concentrated juice to the raw juice should be as 1 to 16. Just at present concentrated lime-juice is selling at very high rates, viz:—about £30 per pipe. I commend this cultivation within certain limits: and I have no doubt that there is plenty of scope for it at Trinidad. In some Islands I find that a trade is arising for the seeds of the Musk Mellow (*Abelmoschus Moschatus*) which are used for perfumery purposes. I believe the chief market for this "Vegetable Musk" is in France. The plant itself is a common weed in Tropics, and might be grown in the rows between Sugar cane, Indian corn or other field crops. The parts used are the seeds cleaned from the husk, which, when crushed have a strong flavour of musk.

It is a matter of surprise that the cultivation and preparation of Vanilla has not taken a larger hold in Trinidad than it has done. At Martinique and Guadeloupe, Vanilla, exactly similar to what is found at Trinidad, is sucessfully cultivated and the exports are considerable. This is an Industry suitable to old and somewhat feeble people and requires no laborious effort or exposure to the sun. Black pepper is another small industry capable of being carried on successfully at Trinidad and at an outlay that is purely nominal.

Annatto (*Roucou*) is just now in large demand. Thisis produced by a shrubby tree of a hardy character, not browsed upon by horses or cattle and capable of being established on rather poor savannah land. Seeds may be planted a few in each hole 12 feet apart and in three or four years the plants will begin to bear.

There are various drugs and spices which might be successfully introduced into the Island, but it is impossible to enumerate them here.

Bee-keeping with Italian or other good strains might be greatly extended in the West Indies. In Jamaica, Bees-wax appears as an important item in the Exports.

I have thus far only given general hints and offered suggestions which might be hereafter devolped.

At to the best means of promoting the growth of minor industries, there is nothing better than the system of Agricultural Boards which you have already organized to act as local centres. These Boards might very conveniently distribute seeds and cuttings of economic plants and give practical information respecting their proper treatment. To aid in this latter work it is important to prepare and distribute all over the Island leaflets or bulletins, couched in simple and clear language, giving directions to the people how to proceed with industries the details of which are new to them. The preparation of such leaflets will require at first some care and attention, but they are invaluable if rightly worked.

In the West Indies there is an unfortunate absence of publications dealing with agricultural matters and to this fact in a great measure is due much of the doubt and hesitation which exists respecting new industries. I know of no better publications on miscellaneous tropical cultures than one published monthly in Ceylon called "The Tropical Agriculturist" and for which Messrs. Trubner, 57, Ludgate Hill, London, are Agents.

The plan of offering prizes through the Agricultural Boards is an admirable one. The prizes might consist of seed, plants, agricultural tools and implements, or purely a money prize. Annual shows, trials of tools and implements, friendly contests in agricultural tasks, are all means for exciting the interest of the people in progressive ideas and in eventually bringing about an improvement in habits of thought and life as bearing upon agricultural matters.

I shall be happy to give any further information in my power and shall at all times take a deep interest in your efforts to infuse life and energy into the agricultural interests of the West India Islands.—I am, believe me, very sincerly yours,
D. Morris.

His Excellency, Sir Wm. Robinson, K. C. M. G. Governor of Trinidad.—*Trinidad Chronicle.*

BALATA INDUSTRY.

In the *Journal of the Society of Arts* for Nov. 20th, 1863, a list of subjects for premiums was published, amongst which was one "For any new substance or compound which may be employed as a substitute for India-rubber or gutta-percha in the arts and manufactures."* This was responded to in the *Journal* for February 26th, and March 4th 1864, letter being published in the latter from Sir William Holmes, from British Guiana, advising the despatch to the Society of a box containing samples of balata, both in the fluid or milky, as well as in the dried or coagulated state. In the letter referred to, Sir William Holmes speaks of the small specimen which was exhibited in tbe International Exhibition of 1862 as attracting a considerable amount of atteution, and further says, so far as he could judge, balata was not to be rivalled either by India-rubber or gutta-percha, possessing "much of the elasticity of the one, and the ductility of the other, without the intractibility of India-rubber, or the brittleness or friability of gutta-percha." Sir William Holmes further expressed a hope balata would, ere long, be included as an important item amongst the exports of the colony. Notwithstanding that this was written so far back as 1864, little or nothing has been done since towards making balata a regular article of import; occasional notice has been drawn to it from time to time, and tbe subject as frequently allowed to drop. As a poof of the truth of Sir William Holme's statement as to the ductility of balata it may be mentioned that a sample of that exhibited in the Exhibition of 1862, and presented to the Kew Museum at the close of the Exhibition, is still in a fairly ductile state, and shows no such brittleness as is the case with gutta-percha.

In connection with this subject of the development of balata, Mr. G. S. Jenman, Government Botanist, and Superintendent of the Botanical Gardens in British Guiana, has just drawn up a very exhaustive report, the result of which, it is hoped, will be to bring the substance into a regular commercial channel.

The title of the report is "Balata and the Balata Industry, Forest Laws, &c.," and it commences with a very interesting description of the bullet tree region, including its inhabitants, character of the vegetation, &c. Coming to the immediate subject of the report, Mr. Jenman describes the bullet tree, from the bark of which balata is obtained, as a large forest tree

* In a paper on "Gutta-percha in Surinam," Professor Bleckrode described balata as the product of a tree named by him *Sapota Mulleri*. *Journal*, vol. v. p. 625, Oct. 9, 1857. See also vol. viii. p. 713, and vol. xxxii, p. 14.

ranging from Jamaica and Trinidad to Venezuela and Guiana. He refers it to *Mimusops balata*, and says—"The vernacular name appears to be applied to two species or sub-species which are united by Grisebach, in his 'Flora of the British West Indies.' Young plants of *Mimusops globosa*, of Jamaica and Trinidad growing in the Gardens, seem to be distinct from the Guiana type. The tree grows to a height of 120 feet, and has a large spreading head. The trunk is nearly cylindrical. The bark is about half an inch thick, with deep paralled fissures an inch or so apart. The hard reddish-coloured wood is one of the densest in the colony, and is used for all sorts of purposes where great strength and durability is required. The tree is more plentiful in both the eastern and western parts of this colony than in the intermediate region. From the east bank of the Berbice river to the Corentyn is the region of its greatest plentifulness in the colony, but its distribution extends still eastward beyond the Corentyn into Dutch Guiana, where a grant of several hundred thousands acres has recently been required by an American firm for collecting balata. The trees are more plentiful in this region in the depths of the forest than near the rivers, hence the creeks form arteries to the balata grounds. Several of the creeks on both sides of the Canje are instances of this. The wood cutters of this district regard the tree as inexhaustible; in the interior of the forest it exists in profusion and abundance, and lies beyond the reach of the balata collectors as they at present conduct their operations. As the trees near at hand become exhausted, they will no doubt alter their habits, and make clearings as drying places in the heart of the forest; but now they are under the obligation of returning to the settlements on the creeks with the milk they have collected to dry. Under this necessity they can at most only penetrate about two days', journey, but, so far as they have explored, they report there is no diminution in the abundance of the trees. The forest at this depth, of course, has never been touched by woodcutters, as, for convenience in getting their timber out, they have to confine their operations to the banks of the river and creeks, rarely going in more than a mile or two."

Regarding the character and value of balata, Mr. Jenman says its strength is very great, and as it does not stretch under tension, for special appliances, such as bands for machinery, it is unequalled. It has recently been pronounced by an American firm of manufacturers as "the best gum in the world."

Dr. Hugo Müller, F. R. S., in a report on the substance says: "It seems that balata is by no means neglected, and in fact it would find ready purchasers if more of it came to the market; as it is, the supply is very limited, and generally it comes only once a year. It commands a higher price than gutta-percha, and this in itself is a proof of its usefulness. It is used almost in all cases in which gutta-percha is used, but on account of its higher price only for superior purposes. It seems that balata is treated by the manufacturers simply as a superior kind of gutta-percha, and, therefore, its name disappears when manufactured. Nevertheless, balata is distinctly different from gutta-percha, and this is especially manifested in some of its physical characters; for instance, it is somewhat softer at ordinary temperatures, and not so rigid in the cold.

"In one respect balata shows a very marked and important difference from gutta-percha, and that is its behaviour under the influence of the atmosphere, whilst gutta-percha, when exposed to light and air, soon becomes altered on the surface, and changed into a brittle resinous substance, into which the whole of the mass is gradually converted in the course of time. Balata, on the other hand, is but slowly acted upon under these circumstances. The electrical insulating quality of balata is said to be quite equal to that of gutta-percha."

Mr. Jenman says that the collecting of balata is an open and recognised business, is carried on only in Berbice, but he proceeds to show that the greater part of that so collected is not obtained from trees on Government grants, but surreptitiously from Crown lands; and Mr. Jenman further says that much damage is done to the Crown lands by the depredations of collectors, and "that it is desirable, in the interest of the colony, till effective rules are devised for the protection of the forest and preservation of this valuable wood, that the trade should be discontinued."

The life of the balata collectors is a very hard one. The ground they have to traverse is generally very wet and swampy. In many cases the traveller sinks at every step up to his knees, and this continues for miles, and water often has to be waded through up to the armpits. When the collecting ground is not too far distant, women sometimes accompany the men, and cook or assist in laying out the calabashes, and collecting the milk while the men fell and ring the trees. The collectors connected with a grant sell the milk they collect to the agent on the grant, and never dry it themselves. The price for pure milk is four shillings per gallon, or occasionally a dollar, and for clean well dried balata one shilling per pound. Considering the circumstances of the people who follow it, balata collecting, if pursued with Industry, is a paying business. The calling pays better, while the season lasts, than the best mechanical trade; with fair weather, a man can earn from one to five dollars a day at it, and an exceptionally expert collector has been known to make twenty dollars in three days.

The instruments used in collecting the milk are an axe for felling the trees,, a cutlass for making the channels in the bark to cause the milk to flow, and two or three gourds in which to collect the milk. The collector commences operations by chipping a piece of the bark from the selected tree, and if the milk runs well he quickly shaves the moss and rough bark from the side he intends to tap, then stooping down with his back to the front of the tree, but on one side of it, he cuts from the base of the tree obliquely upwards towards himself, in the bark, a narrow channel, then moving round the other side, a similar one. These grooves are generally about eighteen inches long; they form an acute angle at the base, just below which a niche is cut in the bark and is slightly lifted with the end of the cutlass, and a calabash inserted by the rim under it. Occasionally a piece of palm or maranta leaf is inserted under the bark, and the calabash is placed on the ground, the leaf conducting the milk into it. The channels are then quickly cut upwards parallel to each other on the opposite sides, about ten inches apart, the operator continuing them as far as he can reach, which is about eight feet from the ground. The milk trickles from cut to cut down this zig-zag line into the calabash beneath. The best collectors cut the bark with much neatness and precision, and do not injure the trees; but little care is usually taken, and the wood is injured with every stroke of the cutlass, the result being that numerous trees are killed, and left standing. Large trees are always tapped on the opposite sides, careful collectors leaving the intervening spaces or subsequent years. It takes from five to ten minutes to cut the channels in each tree, and the milk runs from forty to sixty minutes; at first it forms a little rivulet, but after about twenty or thirty minutes, it only drips. After a little use, the gourds become so coated on the inside with dry balata, that they have to be occasionally soaked in water, when it peels off freely, leaving them perfectly clean again. The yield of a tree varies according to circumstances. If favourable, a tree 15 inches to 20 inches in diameter, bled 8 feet high, will yield 3 pints of milk. Trees are often felled, and then tapped by ringing the bark in parallel transverse lines, at intervals about a foot apart.

To dry the milk, it is poured into shallow wooden trays, the insides of which are previously rubbed over with oil, soap or grease, to prevent the balata sticking, and the substance is exposed to as much air as possible, and sometimes to the sun. In fine weather it takes two or three days to dry, and in wet weather a week or more; when it is sufficiently dry to be removed from the boxes, the sheet is thrown over a line or bar to drip and become hard.

A good deal of foreign matter is found in the milk, and Mr. Jenman says adulteration is systematically carried on, and the agents have at all times to be on their guard against it.

The report concludes with a consideration of the damage done to the forests, and some remarks on their better conservation.—*Journal of the Society of Arts.*—[We have carefully read the Report of which the above is a summary and the conclusions we have arrived at are that Balata gum is not equal to India-rubber, and that the prices received for it do not justify the destruction of the noble forest trees which are felled simply for the sake of the bark juice. Ed.]

The "Whistling" Tree.—In Nubia there are groves of acacia extending over 100 miles square. The most conspicuous species, says Dr. Schweinfurth, is the *Acacia fistula*. Its Arabic name is "soffar," meaning flute or pipe. From the larvæ of insects which have worked their way to the inside, their ivory white shoots are often distorted in form and swollen out at their base into a globular bladder-like gall, about one inch in diameter. After the insect has emerged from a circular hole, this thorn-like shoot becomes a sort of musical instrument, upon which the wind as it plays produces the regular sound of a flute. On this account the natives of the Soudan name it the "whistling tree."—*Indian Gardener*

Green Manuring.—Vegetable substances in their green and succulent state are powerful fertilisers when thoroughly incorporated with the soil. A great portion of the bulk of green crops is obtained from atmospheric sources; and after a green crop is ploughed in, the soil necessarily contains more of the organic elements essential to vegetable nutrition than it did before that crop was grown; it is richer, in fact, by the carbon, oxygen, hydrogen and nitrogen, which the green crop has obtained from sources independent of the soil. In like manner, the crop grown after a green crop has been ploughed in has the advantage of a regular supply of mineral elements, which have been worked up by the roots of the fertilising crop from the soil and subsoil, and which in many instances, owing to their sparing solubility, are with difficulty obtained under ordinary circumstances. —*Morton's Cyclopædia.*

Mica Mine in Groton, N. H.—The ledge is really a large hill of solid rock, composed in the regular order, after the covering of schist is removed—quartz mica, feldspar, again through the hill to an uncertain depth. The work of blasting has been carried forward there until an open drift has been cut 300 feet long, at least forty feet wide, and not much less than fifty feet deep. Branching off from this cut is a tunnel now about seventy feet long and twenty feet high, drilled horizontally into the ledge. Small iron tramways lead to the dump, and little cars, pushed by hand, carry the refuse rock out of the way. The mica crystals of all sizes, from an inch across to more than two feet in their larger axis, protrude from sides and from above and below, with their planes at every conceivable inclination, waiting for some well placed charge of giant powder to free them from the mass of worthless rock in which they are imbedded. These crystals vary from the size of one's hand to blocks two feet in length and from six inches to a foot in thickness, and are rapidly split into sheets by a group of men seated on low stools. The thin sheets are carried from this group to a long line of men standing at benches, who cut them to the largest possible patterns with tinman's shears. The market value of mica depends on the size of the sheets.—*Rocky Mountain Mining Review.*

Bones.—It is well known that bone dust is a first class fertiliser where sufficient farmyard dung is not available. But it is sometimes advisable to supplement it with some other materials containing important elements, such as potash, in which it is deficient. It is a great pity that the German potash salts are not to be procured here. The discovery some years since of large deposits of potash salts in Germany has led to an enormous demand in Europe and America for agricultural purposes. Good muriate of potash, which is one of the salts above alluded to, contains about 50 per cent of pure potash, and is most valuable to use in combination with bone dust. Then to add to the stimulating quantities of the fertiliser, some salt containing ammonia or nitric acid should be added. Soot, containing a large percentage of sulphate of ammonia, is excellent, if only to be obtained in sufficient quantity. Nitrate of soda, another agricultural salt largely used in Europe and America, will also supply nitric acid. It is very soluble and is most valuable in dry seasons, as a very little rain will wash it down to the roots. Supposing we have these at hand, we might apply to an acre of land, five cwt. bone dust, two cwt. muriate of potash and one and a half cwt. of nitrate of soda. This would be a first-rate fertiliser for ordinary farm land.—*Rural Australian.*

Boxes for Young Plants.—These are of different sizes—from 15 inches to 20 inches wide, 16 inches to 30 inches long, and 2½ inches to 3½ inches or 4 inches deep. I buy empty soap and other boxes at grocery stores at the price grocers are allowed by the manufacturers for returned empties. I cut these boxes lengthwise into three parts, and in this way get two complete plant boxes (one from the top and one from the bottom), and all except the bottom of a third one. The bottoms of these third boxes are supplied from factory strips, or a few boxes laid aside for furnishing bottoms only. Of course, the boxes got from the top and bottom cuts are close-bottomed, and that will not do for plants, but that is soon altered. When young plants are raised in pots, their roots become root-bound, or twisted into a tight mass; if at planting time we undo these balls of roots, it will for a short time materially check growth, and if we set out the plants without unfastening their roots, the roots never become uncoiled, and although the plants may wilt less at the time of setting out, they do not afterwards grow as thrifty as those do whose roots are not coiled into a mass; and they also are more susceptible to injury by drought. For all one-season plants, such as Geraniums Coleuses, we should avoid pots. Plants in boxes need less care in watering than do those in pots, and in moving boxes from one place to another, we move 100 plants with as much ease and as quickly as we would six or seven in pots.—*Ibid.*

The Value of Salt.—Severe pains in the bowels and stomach are often speedily relieved by the application of a bag of hot salt. A weak solution of salt and water is recomended by good physicians as a remedy for imperfect digestion, and for a cold in the head it is a complete cure snuffed up from the hollow of the hand. We have known severe chronic cases of catarrh entirely cured by persistent use of this simple remedy every night and morning for several months, when the best efforts of the best physicians failed to do any good. It should be used milk warm. A good handful of rock salt added to the bath is the next best thing after an "ocean dip," and a gargle of a weak solution is a good and ever-ready remedy for a sore throat. As a dentifrice, salt and water is very cleansing and also hardens the gums. It will also prevent the hair from falling out. When broiling steak throw a little salt on the coals, and the blaze from the dripping fat will not annoy. A little in starch, boiled or raw, will prevent the irons from sticking. If the irons are rough, put a little salt on thick brown paper, lay a piece of thin brown muslin over it, and rub the iron over it till perfectly smooth. Ink stains are entirely removed by immediate application of dry salt before the ink has dried. When the salt becomes discoloured by absorbing the ink, brush it off and apply more; wet slightly. Continue this still the ink is all removed If new calicoes are allowed to lie in strong salt water for an hour before the first washing, the colours are less likely to fade. Damp salt will remove the discolouration of cups and saucers caused by tea and careless washing. A teaspoonful of salt in each kerosene lamp makes the oil give a much clearer, better light.—Katherine Armstrong in *Farmers' Review.*

SELECTION OF LAND FOR TEA GROWING IN JAPAN.

Mr. T. Futatszzi, a member of the Committee of the Central Tea Industry Association, Japan, having inspected the cultivation of tea in China, some of the estates in Ceylon and Darjiling in India, has, with a companion, spent a few days in Ceylon on his homeward journey. Gathering the materials for an exhaustive report upon what he has seen, this gentleman expressed himself much gratified with the attention paid him in his journey in British territory and the readiness with which all information was afforded him in response to his inquiries. He was good enough to supply a paper on the soils of Japan, entitled "The Mode of Selecting Land for Growing Tea in Japan :'

1. The red lime soil, partly black and mixed with a little sand, is quick to grow tea, is free from the invasion of insects, and the tea grown on it has an excellent flavour and taste.

2. The same kind of soil as above, only not mixed with sand, is almost equal in capacity for tea-growing to the first, but is more liable to devastation from insects; besides the tea grown on it is not pungent.

3. Light black soil, partly red, is very quick to grow tea. It wants, however, to be fully manured or the tea bushes are apt to die away. The tea leaf contains very little of tenacity and is hard to twist, and consequently produces a large quantity of fannings. Gardens on such soil pay the owners well for first nine or ten years, but not beyond that limit. The tea made from it is not good (superior ?)

4. The red lime soil is slow to grow tea for the first nine or ten years. It is liable to invasion of insects, and heavy oily manuring must not be done for the first six or seven years. It is recommended to bury in only green grass and leaf, until a change is effected in the soil. Although the crop of tea for the first nine or ten years is not so large as from other gardens, it eventually produces the largest quantity, and the tea will be found to be the best in quality.

5. White yellowish lime soil mixed with sand requires manuring to the utmost. Tea is slow to grow in it, but in other points equal to that of other gardens.

6. Pure black soil is not preferred in Japan, as the cold and frost in winter and early spring kills the bushes.

These statements are generally admitted in Japan to be the actual condition of tea gardens, but first of all it is very important to have a deep soil—say eight to ten feet as the main root of the tea plants grows straight downward. Therefore we choose the poor deep soil rather than that which is shallow and rich, if there is hard lime soil or rocky sand below 3 feet of its surface.

The crop of tea made per acre in Japan is as follows :—500 to 735 lb. per annum in the districts of Kioto, Kanagawa, and five others; 417 to 490 lb. per annum in Osaha, Hiogo, and nine other districts; 139 to 390 lb. per annum in Tokio, Nagasaki and seventeen other districts. The average yield of all these districts is 438 lb. per acre, and the average size of the tea gardens belonging to each proprietor is only about three and three quarter acres. It must be mentioned that most of the tea growers do not depend solely upon tea for their livelihood, but mainly depend upon rice growing and other agricultural employments.

There are one or two interesting items in the above report, principally as showing the conditions under which tea cultivation is carried on in Japan. There are but few of us in Ceylon who can afford to look forward for nine or ten years as a preliminary period in which cultivation and growth must be subservient to profit, though doubtless from a purely agricultural point of view it ought to be so. In some of the districts mentioned the rate of produce per acre is considerably more than we have hitherto seen stated, and it must not be lost sight of that to arrive at actual correctness with figures from so large a number of very small gardens, must be an extremely difficult task, and it does not appear from what source these returns have been compiled. In all probability the smaller and more carefully cultivated gardens produce a much larger quantity of leaf than the larger estates. There are one or two questions to which Mr. Futatszgi would like to have the answers if any of our readers will be good enough to supply them :—

(1) What is the largest break of Ceylon tea sold locally ?

(2) What is the largest break of Ceylon tea shipped from the island ?

(3) What is the cost of opening tea land up to the 2nd year. 1st Forest-land ; 2nd land turned from a coffee into a tea estate (details are not wanted except as to cost of tea plants.)

(4) What is the cost of transport of tea from Darjiling to Calcutta ?

As regards the third question we may at once say that while R110 to R130 is not too high to bring forest land into cultivation, with planting and two years' expenditure; in the case of coffee estates transformed into tea, the expense would probably not exceed R70 to R80. The "Tea Planter's Manual," to be ready in a few days, will however supply the needful information on this point and many others.

The Amsterdam Quinine Works.—The *Pharmaceutish Weekblad voor Nederland* states that the Amsterdam Quinine Works may soon be compelled to stop working; but that efforts are being diligently made by the directors and a few gentlemen interested in the cinchona trade to avert the threatened disaster. If the works are closed it is feared that the Java bark would be consigned to Germany instead of to Holland, and the latter country would thereby lose an important and growing branch of commerce.—*Chemist and Druggist*, Aug. 14th.

The Production of Heat in Flowers has often been observed and measured, and the general chemical explanation given of the phenomenon is no doubt true in the main. It depends upon oxidation or the union of oxygen gas with the tissues of plants or their contents, and to the "combustion" or destruction that goes on in consequence, accompanied by the emission of carbonic acid gas. [This statement, from the Gardener's *Chronical*, seems to have a direct bearing on the discussion respecting the so-called "fermentation" of tea.—Ed.]

The Crisis approaching in Brazil.—The *Pall Mall* has the following remarks in the course of a review of Mr. H. C. Dent's "A year in Brazil":—With regard to slavery, the slaves are gradually being emancipated, and slavery will soon have ceased to exist, besides which, the lot of a slave in Brazil would appear to be very bearable one, and cases of cruelty seem to occur but very rarely. Slaves are worth up to £200 sterling. The financial position of the country is a chronic state of borrowing more than it can pay, and of thereby getting more and more hopelessly into the mire of bankruptcy. Stockholders should beware in time.

THE LONDON "TIMES" ON THE "CEYLON COURT."

There is nothing very striking in the following Report, but it is of importance simply because it is the view presented of Ceylon to the reading world by the leading English journal:—

THE COLONIAL AND INDIAN EXHIBITION: CEYLON.

The very varied and highly attractive exhibits of this most charming of islands are appropriately placed at the end of one of the Indian Courts. The whole arrangements and decoration of this court reflect high credit upon the Commissioner, Sir Arthur Birch, and his able assistant, Mr. Davidson. On entering the court through the richly-carved Kandyan porch, we do not think that it suffers in the least from comparison with the splendour of India. The visitor sees at once a likeness and a dissimilarity, and experiences a sense of relief at the compactness and methodical arrangement of the court, after the confusing superabundance which he has just quitted. In the colouring and design of the walls and the roof the main object has evidently been to adhere as closely as possible to the arts of Buddhism, of which the traditions and sites have been maintained in the highest purity among the mountains of Ceylon. The most notable colour, therefore, in the decorations is that shade of yellow which is the sacred colour of Buddhism, and this yellow is blended in the other shade constantly depicted in the Kandy temples. The attractive and handsome entrance gateway has been erected with the same object of reproducing the traditional features of the country's art. It is a Kandyan porch flanked on each side by a loop-holed wall, the whole copied from portions of the King's Judgment Hall of the Buddhist Temple in Kandy. The carving was executed in Kandy by Sinhalese workmen. On passing through the entrance the eye is attracted by the decorations on either side, especially the frieze, which is the production of Kandyan artists, and which describes the Perahera, or grand annual procession, and other phases of Buddhist worship; and those on the west wall facing the entrance and terminating the portion of the building assigned to Ceylon. High up on the wall is seen a coloured bronzed figure of the Gautama Buddha, modelled in high relief, seated in the attitude of contemplation. Below the Buddha the passage westward is made through a gateway, elaborately carved in ebony, coconut wood, and coromandel, faithfully copied by Sinhalese workmen from a stone gateway found at Gapaboo, an ancient capital of Ceylon. On either side, at the base of the west wall, is arranged a very fine collection of all the woods of Ceylon, numbering over 250. Some of the finer woods are further exhibited in slabs of timber affixed to the wall. These include the special cabinet woods—satinwood, coromandel (or colomander) tamarind, ebony coconut wood, and a number of others whose names are not familiar to English ears.

The cases near the entrance porch are devoted to a display of the arts and wealth of Ceylon—tortoise-shell work (in which Ceylon stands pre-eminent), lace, ebony carving, and ivory in all stages from the tusk to the most minute carvings. The jewels include a very choice collection of Ceylon gems—the cat's-eye, ruby, sapphire, and many others of minor value, and some good strings of pearls. Native jewellery has been largely lent for exhibition, and can vie successfully with that of the Indian Empire in quality, though not in quantity. The same remark applies to the exquisitely beautiful silver work, the Kandyan goldsmiths specially excelling in their *repousse* work. The Kandyan pottery exhibited deserves attention from its unique colouring and its astonishing cheapness, which, we believe, disposed of the whole collection a few days after the opening of the Exhibition.

The second half of the court is devoted to the exhibition of the native and European industries. Among the former the collection of pearl-oyster shells and the models illustrating the method of fishing for them are instructive; while the native agricultural interests in cinnamon, the products of the coconut and palmyra palm, are adequately represented. Plumbago, the only mineral in Ceylon which it has yet been found profitable to work, is shown as befits an industry in which Ceylon takes the lead in the world's markets. The European enterprise which has made Ceylon wealthy and prosperous in the past is more fully represented than at any previous Exhibition. Prominent among all are samples of tea of all qualities and from gardens at all elevations from sea level to an altitude of 6,500 feet. Arrangements have been made and are daily carried out with Messrs. H. S. King and Co. for the sale of this tea both in the cup and by retail in the gardens, in order to give the public an opportunity of judging of the quality and price of this now, and that only within ten years, the foremost industry in Ceylon. The Ceylon tea-house between the court and Old London has become one of the favourite resorts of the Exhibition for wearied afternoon visitors and dangling couples, who enjoy their tea all the more that it is served by white-robed Sinhalese, with their jet-black heads coronetted in a crosscomb. Ceylon coffee (a fading industry), cinchona, and cacao, are also well shown, as well as paddy and rice in various forms, grain of other kinds, cardamoms, indiarubber, and many other products from this exuberant island. The scenery of the island is well illustrated by numerous pictures by Miss North and Mr. Gordon Cumming, and a good collection of photographs by Mr. Skeen, of Colombo. A view of Kandy in the principal entrance hall of the Exhibition is worthy of notice. It is from the brush of an amateur, but from an art point of view will compare favourably with the views representing the other leading colonies. The Ceylon Court, like the Indian and Canadian Courts, has its sporting trophies, foremost among which is the huge stuffed elephant, surrounded by other trophies of elephant shooting. Some well arranged cases of leopards, deer, &c., are shown, and enough is to be seen to remind sportsmen that there is no country as accessible as Ceylon in which big game can be found with equal ease. The elephant taming scene near the gateway is particularly instructive and interesting.

Such is a running summary of the leading features in a court in which every exhibit has some special interest attaching to it, and in which there is no padding, if we may be allowed the expression in this connexion. Some of these exhibits, however, deserve a little further notice. First of all comes tea, now the leading industry of an island which only 10 years ago could export no more than 1,400 lb. In 1885 the quantity exported amounted to 4,350,000 lb. Along the side of the court are three long cases of satinwood, containing samples of teas as prepared in Ceylon from 30 different estates and sorted in the various grades of broken Pekoe, Pekoe, and Souchong. Besides these there are also samples from about 150 estates shown in the exhibits of Messrs. H. S. King and Co. (Tea Trophy) in the North Court. In the catalogue attached to the entries of most of the samples the rainfall in the estate is given; it is always high, ranging from 100 to 200 inches. Tradition says that tea was introduced into Ceylon by the Dutch during their occupation of the island, but we only know for certain that the first plants were brought from China somewhere in the forties. It was not, however, till 1865 that the low price of coffee drew the serious attention of planters to the possibility of successful tea cultivation. Seeds were brought from Assam, where the indigenous tea plant had apparently not been recognized until after it had hybridized with the introduced Chinese variety. It is this hybrid variety which is now most generally used in Ceylon and is known as the Assam hybrid. Still, it was not until the devastation of the coffee estates by the ravages of the *hemeleia vastatrix* that tea planting was undertaken on a large scale. The scepticism incidental to an agricultural novelty caused much wavering, until it became an indisputable fact that the moist climate of a great part of the island, its abundant labour supply recruited from Southern India, and its exceptional transport facilities by road, rail, and river, were specially favourable to tea cultivation, that Ceylon teas could be placed in the market

at a less cost and command a higher average than those of India. As the plant is now being cultivated with successful financial results from the sea-board to an altitude of 6,000 ft. it is impossible to say where the limit of production may lie. It is estimated that in the present year 140,000 acres are under tea, and this area is rapidly increasing, for coffee planters are making all haste to turn their estates into tea plantations. There seems, however, to be some danger in all this haste. We believe that the plant may be shorn of its leaves in Ceylon much more frequently in the year than in China; but is there not some danger of exhaustion in this rush, and that in the course of a few years both the plants and the soil may be exhausted. However, with so competent an adviser at hand as the Government botanist, Dr. Trimen, dangers of this kind need not be blindly incurred. Ceylon teas may be had in retail at all prices from 11d up to 20s per lb. The average price of the tea sold in Mincing-lane in 1885 was 1s 3¾d per lb. But the comparatively high duty on tea and the extortionate profits of retail dealers increase the wholesale price in bond largely before the tea reaches the consumer. However, we believe that an excellent Ceylon tea may be had for 2s per lb., and what the Ceylon tea-grower should do is to take some means of securing agents in this country who will be trusted to give Ceylon tea when asked for. The following figures as to area and export may be interesting:—

—		Area under Cultivation.	Export.
1875	...	2,700 acres	1,438 lb.
1880	...	9,000 ,,	162,575 ,,
1885	...	100,000 ,,	4,353,000 ,,
1886	...	140,000 ,, (probable)	8,300,000 ,,

For 1887 it is estimated that 14,000,000 lb. will be exported, and for 1888, 25,000,000 lb. Still Ceylon has a long way to go before it can compete with either India or China. The value of the tea exported from Ceylon in 1885 was about £250,000; that of China was about seven millions sterling, and of India over four millions.

Though coffee is in danger of being put into the shade by tea, still the many fine samples shown in the Exhibition prove that it still remains one of the most important, if not the most important, cultures in the island. How it has declined may be seen from the fact that in 1877 the quantity exported was 971,000 cwt., while in 1885 it was only 310,922 cwt., and the estimate for the current season is not more than 200,000 cwt. Still, the value of the export in 1884 was £1,106,000, by far the highest export item, though the lowest value for coffee since 1853. It would surely be a pity to let it lapse entirely; there must be some means of preventing the plant from utterly deteriorating. Next to coffee, hitherto the most important export has been cocoa-nut oil, of which, as well as of copra, a good many excellent samples are shown. The export of oil has risen from 134,000 cwt. in 1876 to 423,830 cwt. in 1884, though it fell to 274,990 cwt. in 1885. The value of the oil export in 1884 was £448,000. Another oil, an essential oil, which has rapidly increased as an export, is that known as citronella, used by soapmakers and perfumers. The quantity exported has risen from 1,760,000 oz. in 1881 to 5,721,000 oz. in 1885. Next to products of the cocoa tree cinchona is the most important economical exhibit in the Ceylon Court, and, indeed, it bulks more largely, as the product is shown in all states, from the broken bark to the tree. It was only in 1872 that planters seriously turned their attention to it, but the progress was so rapid that in 1884 the value of the export was over £389,000. The quantity exported increased from 18,730 lb. in 1873 to 11,678,360 lb. in 1885, the result being to greatly reduce the price of this invaluable bark in the market. Still, there have been disappointments in its culture, arising from extravagant expectations. One familiar method of collecting the bark is to strip it from the tree in alternate layers, a new covering rapidly taking the place of that stripped off. Whether this method is deleterious to the tree, as one would expect, results have not yet proved. Specimens of the tree so stripped are shown in the court. As will be seen from the many samples exhibited, Ceylon has many other drugs and spices to show; the production of these by natives could be increased to any extent required, and certainly should be encouraged. Dr. Trimen exhibits a collection of over 360 native vegetable drugs from the Central Province. The tobacco exhibits remind us that a considerable quantity is sent across to India to be made into cigars; while the native cheroots of Jaffna can be had at from 4s to 20s per thousand, cheap enough smoking surely for those who care for it in this form. Cane-sugar, though shown, is of little importance, though the Jagghery, or sugar of the Palmyra palm, is in some demand as an export, and is capable of development. We have, of course, specimens of the famous arrack of Ceylon, and, besides these, a pot arrack still, Government derives a large revenue from the licences to arrack shops—£153,500 in 1885. A good many specimens of cacao will be found in the court, and of this £32,000 worth was exported in 1884. The export has grown from 122 cwt. in 1880 to 9,863 cwt. in 1884, though it fell to 6,758 cwt. in 1885, mainly, we believe, owing to the attacks of an insect pest, combined with prolonged drought. Paddy and rice, the staple food of the people, have, of course, their place in the Exhibition, but although over 5,000,000 bushels of rice are produced annually, as much more has to be imported. Cinnamon, of which some bales are shown, has not now the importance as an export it once had, the price having fallen tremendously; still 1,574,022 lb. in bales and 629,000 lb. in chips were exported in 1885. It would be useless to go over all the other food products, spices, and drugs, which have been sent from this productive island. Over £81,000 worth of cinnamon was sent to England alone in 1884.

Although nearly four-fifths of the area of Ceylon is still a forest country, still timber has not that importance as a commercial product which it might have under an intelligent and energetic forest department. In the Exhibition, heavy timbers are particularly prominent, and some of the woods are marvellously beautiful. A Forest Act has recently been passed. It is only in the extensive and thinly-inhabited dry plains of the northern parts of Ceylon that any extensive forests remain, and even here in most places the good trees have been cut out. But all that is needed is demarcation of the best portions and rigid protection and proper conservancy of them for a few years to render them a permanent source of valuable timber.

The exhibits of wood in the Ceylon Court consist, first, of an extensive series of hand specimens—*i. e.*, blocks about 15 in. high, illustrating no less than 255 species of Ceylon trees. These have been prepared with the bark left on, and exhibit, besides transverse sections, vertical, tangential, and oblique ones, thus fully showing the character of the wood. The native and botanical names are painted clearly on each specimen, and much pains have been taken in the accurate determination of the latter by Dr. H. Trimen, the director of the Botanic Gardens, Peradeniya, who prepared and exhibits the collection; secondly, a series of handsome planks of the best or most ornamental timbers arranged to form a panelled wall or dado. The woods employed here are satinwood, ebony, jack, nedun, tamarind, sapu, wa, suriya, suriya-mara, pumburu, and calamander; thirdly, a series of discs, including, besides some of the above, also kumbuk, del, palu, goda-kirilla, &c., many of large size; fourthly, miscellaneous specimens, including several palms, as the coconut, kitul palm, areca palm, and four entire palmyra palms from the north of the island surmounted with carved capitals of the same wood.

Out of the great number of woods many of excellent character, growing in Ceylon, only a very few sorts are exported—ebony, satinwood, halmilla or Trincomalee wood, and wewerane or ranai. Teak is not native to the island, but grows well in the southern parts and ought to be extensively planted. India is the principal market, but ebony goes to England and also largely to China. This is a very hard wood, but the Sinhalese carpenters turns out highly-carved furniture, of which fine examples are shown in the Court. Satinwood is a heavy, strong and beautiful timber, well-known and generally admired, especially

the "flowered" variety. From its durability it has been lately a good deal used for railway sleepers in the East. The handsome table cases containing the planters' exhibits of tea, coffee, &c., were made at Colombo of this wood. Trincomalee wood is of a light reddish-brown colour, and remarkable for its combined strength and lightness. It is a wood which should be more widely known. Of the timbers and cabinet woods used in Ceylon itself one of the most interesting and curious is calamander, a word corrupted from the Sinhalese name Kalumediriya. This is obtained from a slow-growing, rather small tree of the wet low-country, which has become extremely scarce, and, unfortunately, is entirely confined to Ceylon. Being very peculiar in appearance it is much sought after by wealthy natives for furniture, and some very handsome and highly-carved cabinets are exhibited. The ordinary furniture woods of Ceylon are jak and nedun. The former is a very common tree, though not originally native; its wood; when first cut, of a crude yellow colour, seasons into a fine chestnut, and is scarcely to be distinguished from mahogany when old. It is, of course, a well-known tree also in India. Nedun (*Pericopsis Mooniana*), on the other hand occurs only in Ceylon. It is an attractive wood, easily worked, and has a good deal the appearance of walnut. If it could be obtained in sufficient quantity it might become a favourite wood for furniture in Europe. Another very ornamental wood is Wa, dark brown with small black lines, but it is small and rather coarse in texture, and is actually chiefly used in Ceylon for fuel on the railways. Na and palu are both called ironwood, but have no relationship to one another. Both are extremely hard, heavy, and durable, and much used for piles of bridges, the latter also for railway sleepers. The light cedar-like wood called hulankik is much used for furniture and carving, being close-grained easily worked, and durable, presenting much similarity to teak. There are many other Ceylon woods deserving of notice as furniture or cabinet woods, such as the suriya (used in carriage building at Colombo), the mendora, the lunu-midella (of which the outriggers of native boats are always made), the tamruana, and the lujan, some of which it might be worth while to export on trial.

The importance of Plumbago, of which such fine specimens are shown, may be seen from the fact that in 1884, £46,000 worth was sent to England, which was only half what was sent in 1882. The Ceylon like most of the other Courts, has its show of fibres, and here they are of substantial importance. The leading feature is no doubt coir, the product of the coconut palm, and was exported to the extent of 84,000 cwt. of yarn in 1885 and 12,700 cwt. of fibre. To England alone the export of cordage and twine in 1884 was valued at £177,500.

The Gems of Ceylon would require an article to themselves, but here we can only draw attention to the many beautiful exhibits of sapphires, rubies, cat's-eyes, moonstones, amethysts and other beautiful gems, both mounted and unmounted. One very rare Alexandrite cat's-eye is specially worthy of notice. With them may be classed the native gold and silver work, the fine *repoussé* objects, and the exquisitely beautiful gold and silver filigree work. The brass work also deserves attention, and especially the many beautifully-carved objects in ivory, ebony and other woods, and cocoanut shells. The tortoise shell exhibits are also many of them exceedingly beautiful, and the pottery is a study in itself. The finely-chased swords and knives and the other weapons in cases and on the walls attract much attention, while the models of natives, though few, are instructive. Specially interesting, in our estimation, is the very valuable collection of objects from the Maldive Islands, in case M. lent by Mr. C. W. Rosset. The portraits of these islanders show them to be a dignified and self-possessed people, while their weapons, silver and gold jewelry, cloths, and other manufactures show them to be well advanced in art and civilization. Not the least interesting exhibit in this case is a primitive telephone, consisting of a string between two drums, and which is perfectly good for short distances

Every traveller agrees that few islands of the world are richer or more beautiful than Ceylon. Haeckel's descriptions are scarcely less glowing than those of Tennent. The very fine map of the island on the wall of the Exhibition shows that the rainfall is below 50 in. over but a small area. It varies in other regions from 75 in. to 200 in., though about 100 in. may be taken as the average. Its insular character renders Ceylon remarkably healthy for a tropical country, and the richness of its soil is shown in the great variety and luxuriance of its products. Notwithstanding its long occupation by Europeans, Portuguese, Dutch, and English there is much yet to be done before the island is developed as it might be. The population in 50 years has increased from 1,000,000 to 2,760,000. Its revenue and expenditure in the same period have trebled, rising from £400,000 to about £1,200,000 respectively. During the same 50 years the trade (exports and imports) has been multiplied eight times, rising from £1,000,000 sterling in 1836 to £8,000,000 sterling in 1885. This surely is significant enough of progress under British rule. Should the Government continue a judicious expenditure on public works and useful institutions, and planters and natives work together to develop all the possible resources of the colony, "this beautiful island, from its geographical position, its excellent harbour accommodation, and healthy climate, is destined to justify its Brahmin title of 'the Pearl in the brow of India,' or Lanka, 'the Resplendent."

COFEEE; HOW IT IS SOLD IN ENGLAND.

Writing to the London *Times* Mr. Shirley Hibberd says:—

Coffee deserves the importance it has acquired as a subject of publice discussion, and the more so because it is but little understood. At good tables poor coffee is too often seen, and it may be said that on the world's table (in these parts) it is never seen at all, but in its place appear various nauseous and injurious imitations. Valuing coffee as a great aid in hard work, I made a resolve to have the real thing on my table daily or "perish in the attempt." Thereupon, I entered upon a series of experiments that were at least amusing if not particularly profitable. I bought every kind of coffee I could see or hear of, and tried every possible (and some impossible) way of making it, having the assistance therein of a diligent and clever cook. One striking result was the discovery that all ready-ground coffees sold in canisters, packets, and other "convenient" parcels are bad; some very bad, a few infamously bad. After trying innumerable samples without noting one that was worth trying again, I concluded that canister coffee is an unmitigated cheat—consisting usually of a mere shadow of the real thing, with a great bulk of chicory and more or less of what is termed "colour," this being simply burnt sugar to give factitious strength. What may be termed "chandler's coffee" is so bad that I strongly recommend a trial of it to respectable people who love good living, for they ought to know, by a taste of real agony how the poor are robbed and poisoned, and have as it appears, no protection from law, gospel, or the customs of society. It is not good policy to purchase coffee ready ground, but if it must be done the supplies should be small and frequent. Any one may test the purity of ground coffee by shaking a little over a tumbler of clear, bright cold water, and leaving it for an hour or so. Pure coffee communicates its colour to cold water slowly and when the colour has been imparted the infusion is still bright and clear, and the colour is never deep. But chicory and other adulterants quickly produce an opaque and dark infusion. The difference is so striking that for ordinary purposes

a better test is not required. To place good coffee on the table daily is a simple and inexpensive business, but it cannot be done at a penny a cup, as some folks are in haste to aver. At for 12d to 20d. per pound a good coffee in berry is always obtainable, and 16d. may at the present time be considered a fair family price. It is best to roast and grind as wanted, but the grinding is the one important point because ground coffee quickly parts with its aroma, and there is a great charm in having it made immediately from the mill. In some houses the trouble of grinding is thought much of, but as a matter of fact, it is almost nothing and a mill costing only a few shillings will last a lifetime. Coffee should never be boiled; it should be made with soft water at boiling heat but if hard water must be used it should not be made to boil until wanted, for boiling augments its hardness. A common tall coffee-pot will make as good coffee as any patented invention, but a *cafetiere* is a convenient thing as it produces bright coffee in a few minutes, and thus enables us to secure a maximum of the aroma and dispense with the use of any rubbish called "finings." Every one to his taste, we will say, but as careless people make the coffee too strong one day and too weak the next, the ground coffee and the boiling water should be both measured, and it will always take as much as four cups of water to make three cups of coffee. For the breakfast-table the addition of about one-eighth of chicory is an improvement, but for the dinner-table coffee should be made without chicory, because it dulls the piquant flavour of the genuine article. Two points in coffee-making deter people from using it—the trouble of grinding and the boiling of the milk. The grinding however, must be done, and it is really nothing, but the boiling of the milk may be advantageously evaded by using Swiss milk, which harmonises perfectly, and by many well-trained palates is preferred to fresh milk heated.

PLANTING IN NETHERLANDS INDIA.

BUITENZORG GARDENS—JAVANESE COOLIES—SUGAR—CINCHONA.

(Translated for the *Straits Times*.)

The yearly report on the Government Botanical Gardens at Buitenzorg for 1885 has just been published. The particulars given of the improvements made and work done last year in keeping up and increasing their usefulness show satisfactory progress, especially in the determination of the Netherlands India Sapotaceae or family of plants yielding gutta-percha. Dr. W. Burck, assistant Manager of the Gardens, commissioned by Government to investigate the subject, has determined the existence of 94 different varieties of which no less than 24 were represented in the gardens. Dr. Burck has drawn up and brought out a monograph on Gutta Percha plants describing no less than 55 new species of which 11 were discovered by himself. Another family of plants forming a subject of investigation in the Gardens, was that producing Minyak Tinkawang or vegetable tallow. From many quarters, as well from Holland and the Netherlands Indian possessions as from Britain and the British Colonies, inquiries were made into the Botanical characteristics of the so called Minyak Tinkawang, a tallow exported from Borneo, and in great demand throughout Europe and America for industrial purposes. Research soon disclosed the fact that the tallow in question was obtained from a great many different kinds of trees belonging to the Dipterocarpeæ and Sapotaceae families of which but little was known botanically. Owing to the cultivation of these plants being of great importance from the demand for the tallow the yield, it was decided upon by the Garden authorities to set to work make a thorough investigation of the subject, by first of all undertaking systematic research regarding the Dipterocarpeæ to be found in Netherlands India. The first steps taken to carry this through were directed to calling in the aid of Major General Haga, the then Civil and Military Governor of West Borneo, and of the Resident of that Division. Their co-operation resulted in the securing of a large collection of dried specimens of tallow yielding trees from West Borneo, besides a piece of Minyak Tingkawang from each tree specified. Dr. Burck has been since actively engaged in these researches. The results will be made public in the next annual Gardens report.

The Batavia *Dagblad* comments as follows on the description of Javanese coolies as being full of arrogance and false pride given by a Johore correspondent in a recent number of the *Straits Times:* "It is rather amusing to find a British writer complaing that Javanese of the lower classes who go to other lands in search of coolie work or have been recruited by crimps for the purpose are in fact too proud and too arrogant in nature to make good coolies. It is especially instructive to the British to find their cherished belief, backed by natural jealousy of another colonial power in neighbouring countries, that the Netherlands colonies are the scene of tyranny, oppression, and extortion, meeting with little confirmation when they come in personal contact with the people of Netherlands India, especially with the lower orders. Instead of a submissive slavish sort of people they meet with fellows of whose arrogant air they complain, and who do not show that submission to discipline indispensable for coolies to be serviceable.

It is to be hoped that the so-called arrogant air of our Javanese coolies will give the British in some way another idea regarding the oppression and slavery under which the Netherlanders in the Far East bring the people under their sway—so at least the British persuade not only themselves but also the world whenever they can." The *Dagblad* points out that the substitute system under which while the number of a gang of Javanese coolies continues the same, the faces are continually changing, is also known in Java, the substitutes being called *orang ganti*. This is accounted for by the Javanese coolie being perhaps too honest to abscond and fancying that his employer has nothing to complain of when he takes upon himself to substitute some other coolie in his stead.

Java sugar shows no signs of improvement in value, quotations ruling now under 8 guilders per picul. So near are planters being drawn to the brink of ruin that the Home Government has been alarmed into promising to do something to alleviate their lot. Meanwhile, notwithstanding the deadness of the times, enterprising individuals are casting about seeking fresh outlets for speculative energies and unemployed capital. Paper mills and cement works started at various places will yield little to make up for the certain loss resulting from the scanty outturn of staple articles, when plantation enterprise not longer pays remuneratively. The moment all is over with sugar and coffee cultivation, it will be hard work to keep new industries going.

Several influential persons interested in the cinchona trade have forwarded a memorial to the Netherlands Minister for the Colonies in favour of increasing the number of bark action sales at Amsterdam to eight a year. They urge this course on the ground that Java cinchona has of late been shipped by holders more and more to London

where auctions of bark are held every fourteen days. In their opinion, the Government, from its being the greatest importer of the article, is fully abel to prevent the larger portion of the Java bark shipped on private account from finding its way to London.

NOTES ON INDIAN AND CEYLON PRODUCTS FROM THE OLD COUNTRY.

(*From Our Special Representative.*)

CEYLON TEA—CEYLON AND INDIAN COURT AT THE "COLIND" EXHIBITION.

I saw in a grocer's window a printed bill which stated in large letters that "the finest tea now imported was from the mountain gardens of Ceylon, grown at from 4,000 to 6,000 feet above the sea," and another smaller one, of which I enclose a copy:—

CEYLON TEA.

The climate and soil of Ceylon have proved themselves peculiarly adapted to the successful cultivation of Tea, and the product of many of the Estates possesses all the richness and flavour of the old-fashioned China Souchongs, combined with the strength and fulness of Indian Teas, but without their excessive astringency. Such Teas are perfection in themselves and need no blending.

It is now about ten years since the Ceylon Planters first turned their attention to the culture of Tea, the export in the years 1875—6 being only 482-lb which had increased in 1882—3 to 1,522,882 lb. and still further in the following season, to 2,263,000 lb. According to the *Grocer*, a correspondent, writing from Colombo under date August 1st, states:—"Already our export for the new product, Tea, has doubled itself within the year, and during 1886 it will again double itself, with an ever-increasing value of the article." There are now 35,000 acres under cultivation, which will be in full bearing 1887—8, during which season it is estimated the export will reach Ten Million Pounds.

Prices—2s 6d and 3s per pound, in original leaden packages only, weighing 1-lb and ½-lb nett.

Sold by—E. J. WILLIS' Tea Dealer, Boscombe

But there is another link with Ceylon in a house not five minutes' walk from here, the name of which is *Talawakellie*! It has only just been finished, and is at present to let furnished: the owner, I learn, is a Rev. Mr. Godson; what is his connection with our island? As might be expected, the name is popularly mispronounced with the accent on the first syllable.

I notice from your last *Overland* that Dr. Watt's story about the jungle of 50 to 100 feet tea trees is regarded by many of your readers as well as yourself as a 'pull at the long bow.' But though he learned doctor may have exaggerated a little, perhaps unconsciously, may not trees of at least 50 feet high exist in their wild state? You are mistaken in supposing that the Indian planters who visited Ceylon were astonished at the *height* of the 'giant' trees on Abbotsford and other estates: it was the immense lateral growth of the branches to which they had never seen anything equal in India. As to height, Mr. Tod of Assam told Mr. A. M. Ferguson, Jr., that he had on his own estate a clump of trees exceeding 50 feet.

I have already given a pretty detailed description of the Ceylon Court, and will only add that when I visited it last week I found that on each side of the porch had been placed tubs with tropical plants, such as *Cycas circinalis* (Sinh. *Madu*), &c.; also that Col. Clarke's map of the mountain district has been now hung where its details can be examined minutely and justice done to its workmanship. The Ceylon tea houses seem to be as well patronized as ever. With regard to the complaints of correspondents in your columns as to the quality of the tea served there, I cannot offer an opinion as I never drink tea; the coffee and the chocolate are, as I can testify, excellent. Closely connected as our island is with India, it is natural that it is to the Courts of this empire that I should first take your readers. The space allotted to India is divided into (1) the Indian Hall; (2) the Art Court; (3) the Imperial Court of Economic Products; (4) the Court of Private Exhibitors; (5) the Tea, Coffee, and Tobacco Court; (6) the Administrative Galleries; (7) the Indian Palace and its adjuncts; and lastly (8) the Indian Jungle and Kuch Bihar Trophy. To begin with the last, it is naturally a great attraction to visitors, but the thought that must strike an Indian *shikari* would be, I should think, "C'est magnifique; mais ce n'est pas la—nature": at least, I should imagine one could hardly find so many animals congregated in such a limited space in their native wilds. In the Indian Hall (1), which is hung with rich chintzes and guarded by portrait models of the various types of the Indian soldier, are cases in which are models of some of the P. & O. Co.'s latest vessels while an illustrated pamphlet giving the history of the Company and details as to its fleet &c., lies handy for visitors to take away. To the general public the Art Courts (2) are, I imagine, the most attractive, with the magnificent Jeypore entrance arch, the courts of the different states, presidencies and provinces with their varied and often elaborately carved screens, and the thousands of articles of value and beauty therein displayed. But these I must pass over and come to the Economic Court, (3) which is entered by an archway thus described in the Official Catalogue:—

The Forest Trophy.—The massive archway which forms hte entrance to the Court is constructed entirely of I dian timbers, and designed by Mr. F. B. Manson, Deputy Conservator of Forests, Chutia Nagpur, Bengal. The middle portion is 22 ft. broad, and rises to a height of 15 ft.; the side parts are 12½ ft. high. The total breadth of the trophy is 46 ft., and it is 5 ft. in thickness. It contains 3,000 specimens of useful timbers.

The timber specimens used in its construction belong mostly to the Bengal Economic Museum, and have been lent by the Government of Bengal. The trophy includes also the greater part of Mr. J. S. Gamble's collection described in his "Manual of Indian Timbers." The specimens so described are marked with a letter followed by a number; the letter denotes the region from which each specimen was obtained. In addition to these collection a large number of new blocks of wood, furnished by the Inspector-General of Forests, have also been built into the trophy. The very extensive series of timbers thus brought together has been arranged on the trophy in geometrical patterns, and on either side of the arches are placed fretwork panels of teak wood in arabesque design. A border of alternating dark and light woods surrounds the entire framework. The pilasters are supported by large slabs of timber, bevelled to show the grain of the wood. For the construction of the ornamental arches some of the principal Indian timbers procurable in Calcutta, viz., teak, sál, sissu, and pine have been used. The geometrical tracery of the panels forming the plinth on either side of the middle arch is of teak and sissu; whilst that of the pilasters on each side of the smaller arches of teak.

Immediately close to the arch are articles of furniture carved from the wood of the Padouk or Andaman redwood tree. The table constructed of one complete section shows the enormous size which this dark red, close-grained and hard wood attains.

On entering into the court the first object that strikes the eye is

The Bamboo Trophy.—Occupying the centre of the Court, and conspicuous by its height, the great object of attraction will undoubtedly be the Bamboo Trophy, which consists of an arch over the central transverse path leading from the Art Ware Courts, and contains one of the most perfect collections of bamboos ever

exhibited. This familiar name of the gigantic grasses has, like so many other terms, come to us through the Portuguese pioneers of European trade and settlement in India. The Trophy consist of a platform raised 12 ft. above the floor on four columns. The steps on either side are covered with split bamboo arranged in geometric patterns which are continued on the floor of the platform. The forty steps of the two staircases exhibit forty different designs and ten species of bamboo. In all, thirty species of bamboo are exhibited in the trophy, for full explanation of which the curious are referred to the index set on the adjacent walls. The number of objects made of bamboo which are hung over the trophy far from exhausts the uses and applications of this, as it may be called, most versatile gift of nature to the Indian and Indo-Chinese peoples.
The solidity of this structure has been well tested by the thousands of visitors who have ascended its steps and descended on the other side. The third trophy in the court is the

Grain Trophy.—All these grains are combined in the structure of the Grain Trophy, the idea of which is taken from the famous tomb of *Itmád-ud-Dowlah* at Agra, the beautiful marble geometric mosaics having been imitated by glass panels of coloured grains. On the outside elevations there are large panels, two of which are devoted to rice, two to wheat, two to Indian corn, one to barley and oats, and one to millets and Job's tear's a curious grain which is cultivated in Assam and among the Eastern frontier hill-tribes. Sixteen smaller panels are filled with the pulses, and the remainder with other edible grains and oil seeds. The interior is filled with grains in ear, and Indian corn cobs. In the four corners of the room are shown commercial samples of the grains, and in the centre a group of three women modelled in clay "grinding at the mill." Near it are cases containing special displays of wheat exhibited by the Bombay Commercial Committee, and collections of rice from Bengal and Burma.

Near the timber trophy are specimens of Indian furniture carved from the wood of the Padouk or Adaman (the Official Guide says 'Cinnamon') red-wood tree, one table being constructed of a complete section of this enormous tree. The rest of the body of the Court is occupied with specimens of fruits and vegetables, nuts, pulses, grains, wheat, sugars, narcotics and stimulants, drugs, fibres (cotton, jute, rhea), paper, oil seeds, oils, extracts and inspissated saps, lac, and models to illustrate the official life and industries of India. From the Official Catalogue I may quote a few extracts regarding some of these:—

Fruits and Vegetables.—A collection, partly of models made at the Botanic Gardens of Saharanpore, under the supervision of Mr. J. F. Duthie and by the Krishnagur moddlers employed by the Government of India, and partly of actual fruits, such as will bear the transport and keep good in the glass cases, is supplemented by a very large collection of preserved fruits, jams, and pickles. With regard to the fruits, it will be a surprise to many to hear that the fruits of the East are, it is believed much overrated in Europe. Many of the best of Indian fruits have been introduced from Europe, Chena, the West Indies, and America. The most characteristic modern fruits of India are the mango, guava, litchi, pine-apple and plantain. Of these the mango is far the most popular fruit in India. Colonel Yule in his Glossary says that theroyal fruit, the *mangifera indica*, when of good quality is one of the richest and best fruits of the world. The origin of the word is Tamil *Mán-kay*, *i. e. mán* fruit. The Portuguese formed from this *manga* which we have adopted as mango. Numerous varieties of jams, pickles, and chutneys, prepared from this celebrated fruit are to be found amongst the exhibits.

Nuts.—Together with the fruits are samples of nuts, a term which in India includes ground nuts and the seeds of the edible pine. The true almonds, which are a sacred offering common to the Hindoo and the Jain, as well as a regular ingredient in cookery, especially in a savoury *pillao*, are imported by the traders of Afghanistan and Persia. The Afghan traders also supply the hazel nut, the walnut, and the pistachio nut, from Afghanistan and Kashmir.

The Singara nut (647) which is grown on an aquatic weed, forms in some parts of the country an important article of food. It is stated that in Kashmir 30,000 persons are dependent upon this wild plant for food, during certain months.

Coconut.—Near the bamboo trophy is a most interesting collection of objects made from the common coconut palm (properly called coco and vulgarly coker), exhibited by Mr. Pereira of Bombay. Eighty-three articles are enumerated. The origin of the name of this well-known and useful palm, which to the early travellers and mediæval writers was known as the Indian nut, is suggested to be the old Spanish *coca*, a shell, although the Portuguese and Spaniards say that it was called *coca* because it looks like the face of a monkey or some other animal.

Vegetables.—The vegetables met with in India are readily divided into two sections of indigenous and introduced. Of the latter it may be said that European fruits and vegetables, though often growing luxuriantly, rarely attain the same flavour as their European congeners. Of these, however, the cabbage, the cauliflower, and radish, alone are eaten by the natives of India, but not until they are over-grown and coarse. From America, the potato and the egg-apple or *brinjal*, have been introduced. As to the indigenous vegetables, India may be viewed as the region of the cucumber and the melon, with a large series of allied plants, all of which yield valuable fruits and vegetables, and furnish a great proportion of the food of the people. It is almost impossible to arrive at any definite idea as to the extent of the internal trade in vegetables. Nothing is more characteristic of the Indian village than its bazaar or market-place, and it would be difficult to find a bazaar where the egg-apple, the melon, the cucumber, the pumpkin, and the radish were not offered for sale alongside of rice, plantains and chillies. The foreign trade in vegetables has increased in the last five years from about £20,460 to £21,963; the bulk of these exports go from Bombay. Nearly the whole of the pot-herbs are wild plants which require no cultivation, and they illustrate one of the most striking features of India, for in few countries in the world are so many edible products to be procured for the trouble of collecting, edible products too which enter largely into the dietary of the mass of the people.

Pulses.—By themselves under the head of "Pulses" will be found the various leguminous seeds which under the name of *dál* and *gram*, the lentils (which furnish the vaunted and really beneficial food for invalids known as revalenta), and others occupy an area of cultivation of forty-eight millions of acres. The grain merchant's shop, in which the varieties of this collection are shown, reproduces one of the most curious and interesting features of an Indian bazaar.

Grains.—One of the most important collections is that of the grains, which may be popularly described as rice, wheat, barley, oats, Indian corn and the various forms of millet. Of these, rice is the most valuable of all the cereals to the inhabitants of India. It is the principal food in Bengal, Burma, Orissa and the eastern portion of Central India, the southern parts of Madras, and the western districts of Bombay. In the Punjab, the North West Provinces, and Oudh, Behar and the northern parts of the Central Provinces, and Gujerat, the poorer classes live chiefly on millets, supplemented by barley and gram, while the rich only use wheat and rice. In the southern part of the Central Provinces, Berar to Bombay, Deccan and the northern part of Madras, the *juar* and *bajra* are the staple foods, and in Mysore the small millet known as raggy or *ragi*, furnishes the principal provision. In Assam rice is the staple with the addition of Indian Corn and Job's Tears. The estimate of the total area of land annually under cereals is 119 400,000 acres, of which nearly sixty millions are devoted to rice. As there are many forms, so there are several crops of this essential grain which is, in truth, the staff of life to at least one-third of the Indian population. For the Foreign trade, which, however, may be said to have been almost ruined within the past few years, the chief supply comes from the

abundant harvests of that most prosperous province British Burma, while Bengal supplies a small proportion. Where rice cannot be cultivated the millets invariably take its place as the staple food crop of the mass of the people. Even in wheat-producing districts this is true. Dr. Hunter is of opinion that, taking India as a whole, it may be affirmed that the staple food grain is neither rice, nor wheat, but millet. Excluding the special rice tracts, varieties of millet are grown more extensively from Madras in the south, at least as far as Rajputana in the north.

Sugars.—The raw and refined sugars exhibited by Messrs. Turner, Morris, & Co., of Calcutta, and Messrs. Carew & Co., are examples of a cultivation and a trade which are more important at present for Indian internal commerce than for the prospects of increased exportation. The 1,922,000 acres of sugar-cane cultivation may be said to yield two million tons of coarse sugar. Besides sugar-cane, sugar is obtained from the date palm, or toddy palm, of Bengal, and the *palmyra*, or toddy palm, of South India, Bombay, and Burma; but the exports, in which the sugar-cane produce cannot be discriminated from other produce, only amounted to one million cwt. as against the two million tons just mentioned. Improvements in the present defective method of expressing the juice, and gradual removal of the prejudice against refined sugars amongst the natives of India, who chiefly consume *gûr* or raw sugar, will doubtless give a large stimulus to the internal trade. A model prepared at Poona in order to show the method of crushing the sugar-cane in the Bombay Presidency, is exhibited in the Agricultural *annexe*. The primitive pestle mill is still the machine most generally used over the greater part of India for the extraction of cane juice. The method of working it is shown in the model village.

Narcotics and Stimulants.—* * * Attention is called to the exhibits of beer produced by the hill breweries, the more important of which are in Madras and the Punjab, and whose ale and beer are of an excellent quality, as may be seen by the fact that the import of foreign beers in 1884-85 was 194,531 gallons less than in the previous year. Another novelty is the exhibit by his Highness the Maharaja of Kashmir of the wines and spirits prepared in his kingdom. The white wine obtained at Calcutta International Exhibition, a gold medal for its purity and superior quality.

Drugs.—There are over thirteen hundred plants reputed by the natives of India to possess remedial properties; and as in all popular herbals which exist unwritten as having been handed down from unknown antiquity by tradition, a great number even of the most highly-esteemed are valueless. The Sub-Court devoted to drugs and medicines contains examples of over one hundred indigenous drugs, which have almost all attained a European reputation, and which most thoroughly deserve to be more extensively used. From Nepal a large series of aconites, accompanied by botanical specimens of the plants from which the roots were obtained, has been sent by Dr. Gimlette. The monkshood or wolvesbane, which grows on the Himalayan heights, from an altitude of 10,000 feet to the highest limits of vegetation, is equalled if not surpassed in its poisonous and its curative powers by its congener the Indian or Nepal aconite. The specimens of cinchona or Peruvian bark numbered 780, bear their silent witness to the success of an enterprise undertaken by the Government of India to acclimatise if possible this invaluable tree, and so to bring within reach of the population of India what up to that time had been too costly a remedy. This was primarily due to the travels and labours of Mr. Clements Markham, C.B., devoted to the examination of the cinchonas of Peru in their native forests, and their importation to and ultimate establishment in India in 1860. The produce of the Government plantations at Darjiling and on the Nilgiris amounted together in 1884-85 to 457,218 lb., most of which was manufactured into febrifuges. Extensive private plantations also exist in Southern India, and the exports in 1884-85 were valued at nearly £100,000.

The specimens of cinchona bark referred to above are good, but of course not equal to the display from Ceylon. Next regarding

Fibres.—We now come to the vegetable fibres of India. The more important of these, such as cotton, jute, rhea, and other commercial fibres and paper materials, are exhibited in separate sub-courts, and require separate notice. But besides these there is an extensive series of fibres which are regularly used by the natives of India, though the large majority are unknown to the textile manufacturers of Europe. The Indian flora contains over 300 fibre-yielding plants, one-third of which afford strong and useful fibres. Some of these will be found illustrated in the 'Rope Trophy,' near which are excellent samples of stair-carpets and door-mats made of the well-known *coir* or coconut fibre.

An article on which a good deal has appeared in your columns and in those of the *T. A.* is:—

Rhea.—One of the first and most important of the commercial fibres, not so much in its present as in its probable future utility, is rhea. The prize offered by the Government of India for the most perfectly successful machine for separating this fibre was, it is true, not awarded, no single machine being deemed able to comply at the time with all the requirements; but strenuous endeavours have within recent years been made to overcome the difficulties of dealing with rhea grass, and the difficulty of the separation of the fibre has been overcome. The high price of the fibre itself, together, with its exceptional strength and durability, unfit it for many purposes. The Glenrock Company, Limited, of the Wynaad, Madras, exhibit an interesting collection of their fibres, showing not only rhea but also two or three of the allied rhea fibres, including the so-called wild rhea of South India. The wild rhea of Assam, and various Nilgiri nettles, and, in addition, pine-apple fibre and Manilla hemp, together with a large assortment of aloe fibre, are also on view.

Regarding paper, I quote the following:—

The art of paper-making in India dates from the time of the great emperor Akbar, and was first practised in Kashmir. Rapidly it spread all over India, displacing the birch bark used by the hill-tribes, and the palm leaves which served the people of the plains as the vehicle on which they incised with a stylus their accounts and written records, and of which examples are shown in the Education exhibits. It is probable that the inhabitants of the Eastern Himalaya, long previously to that era, derived the art of paper-making as practised in Nepal from China. The Nepal papers, of which extensive collections are exhibited, are prepared from the bark of two sorts of daphne, and from the fibre of a plant which grows along the Himalaya, and has recently been found plentifully on the mountains of Manipur, extending to the northern frontier of Burma. The paper manufacture of India, like the paper trade of England, is still seeking for a new material. The paper trophy, as well as the special show case contributed by the Bengal Exhibition Committee, shows the paper materials; the half stuffs, the manufactured papers from all parts of India. The Bally Paper Mills of Calcutta, and the Upper Indian Paper Mills of Lucknow, are the chief contributors; but besides, a large collection of jail and native-made papers from all parts of India is exhibited.

Under oil seeds I read:—

The trade name of the sesame seed, which comes next in importance, is another instance of commercial nomenclature derived from the first Portuguese traders. In Colonel Yule's "Glossary" it is traced step by step from the Arabic *al-jaljulan*, corrupted by the Spaniards into *aljonjoli*, and so gradually transformed into *jinjali* or *gingeli*. It is used in India for culinary purposes, for anointing, and also in soap furniture, and as a lamp oil. It shares with the ground nuts the reputation of being employed by European importers to furnish a sham olive oil. Of the latter the cultivation may be described as a modern industry, the trade in oil as a substitute for olive oil having within the past thirty or forty years developed in an almost unprecedented manner. The value of the exports of ground nuts from India rose between 1879 and 1885 from nearly £17,000 to something over £360,000; and the exports from the French ports in India were but little short of the same amount, the total value being thus just over half a million sterling. The bulk of this seed is shipped for the continent, prin-

cipally to France and Italy. France is said to import from all countries 33 million francs worth of the ground nuts, of which India only supplies 2½ millions, but it is believed that the oil expressed from these nuts, as well as that from *gingeli* seed, finds its way into the markets of Europe as olive oil.

I might quote further extracts regarding oils &c., but refrain from doing so, merely mentioning that a model of an indigo factory shows the process of manufacture of this important product.

Among other objects shown in the Court are ornaments and other articles of rock-salt, a collection of snakes exhibited by Col. Beddome, and some very amusing life-like models of Indian villages. Throughout the Court are grouped life-size models of the various races of India, the different types being admirably shown. Round the walls are many interesting objects, the most important being the index collection in little tin boxes with glass fronts. Then there are the grain and drug bazaars above referred to, cases of stuffed birds and colored drawings of birds, and a collection of very fine photographs and drawings by Col. Lockhart (Mission to Gilgit and Kafiristan) and Col. H. C. B. Tanner of the Survey of India, the latter being chiefly representations of the Himalayan range. The printed labels on these have not been carefully corrected, for on one, "The Yaccam Kunga Mountains" (it should be "Yassana i Hunza"), one reads :– "Behind the peaks in the left of the pictures, is situated the great Ab-i-Nil, or Sar-i-chasma-i-aba-sind, the northern source of the *Trans* river *decorated* in 1881 by Pin Mukhtar Shah, *Emperor*." The three words I have underlined should be *Indus*, *discovered*, and *explorer*! In this Court are also shown a fine collection of minerals and ores exhibited by the Geological Survey of India, and illustrated by maps; and in an adjacent annexe are a large number of maps shown by the Survey Department, there being also an 'over-flow' assortment of models, grains, &c. In the adjoining Burma Pavilion the Bombay Burma Trading Co. have a fine exhibit of teak logs and manufactured articles, including lattice archways made of small pieces bolted together, showing how such 'waste' bits can be utilized. The Court of Private Exhibition (4) is separate from the Ceylon Court by a passage running north and south and contains a variety of articles, mostly of the class well-known to your readers as sold by the 'Delhi men' such as jewelry and carved work, shawls, &c., and also jams, pickles, chutneys, curry-powder, &c. The Crown Brewery Company of Mussoorie show samples of their beer in bottle and cask. Down the middle are specimens of native and European carriages, a handsomely carved billiard table, and Baroda pigeon-house. Lastly, I must not omit to mention that at one of the ends nearest Ceylon is shown the method of reeling silk from the cocoons by the 'Tavelette Consono,' an ingenious invention, which is a great improvement on the native method. The Tea, Coffee, and Tobacco Court I have before referred to in connection with the Ceylon Tea trophy, so I shall pass on to the Administrative Court, (6) which is situated in the galleries to the right of the Indian Hall and the southern part of the Eastern Arcade. Here, to quote from the succinct description in the Official Catalogue :—

The Survey of India Department contributes illustrations of the various processes by which the results of the surveying operations are transferred to maps, and the maps themselves, in which are made accessible to every one the exact knowledge collected by the labours of science, and the observations of dauntless and patient explorers. The Revenue Settlement Maps and charts showing the internal trade and the emigration are both worthy of study. Everyone will be interested to learn of the large and constant emigration of Indian labourers to the tea-gardens of Assam, the Island of Mauritius, and to the distant labour fields of the West Indies and Demerara, and even to our young but vigorous colony of Fiji. Some return after their contract of service expires, with their savings. Others remain as settlers.

In the divisions of the Department of Finance and Commerce, besides the printed reports, there are exhibited specimens of the coinage of India, and the processes of the Mints. Patterns of all stamps used which make up a revenue of over three million pounds, are shown by Messrs. De la Rue. The Post Office shows from the different Presidencies models illustrating the peculiar means of carriage which are needed in distributing the 184 millions of letters, cards, &c., delivered throughout India in one year, models of mail runners and riders, &c. Specimens of buffalo horns sounded to scare away wild beasts in Assam, or bows and arrows carried for defence in Rajputana, carts, coaches, boats and rafts are ranged according to the particular provinces. Our printers and bookbinders can compare the tools and work of their Indian fellow-craftsmen.

The Home Department sends a most curious and complete illustration of the means and appliances employed in the 111,237 schools with their 2,790,061 pupils inspected in 1882-3. The indigenous schools of the Punjab, and all schools not inspected are of course omitted. The model of an indigenous school in Bombay is well worthy of examination.

The models shown by the Public Works Department, illustrating the Indian railway carriages, the public buildings, and the great works constructed for irrigation, on which the lives of millions constantly depend, can only be pointed out as claiming much more than a passing glance.

The Military and Marine Department, in addition to the portrait models which stand round the vestibule, contributes, not only descriptions but various models illustrating the internal economy of the army, and the soldier life and work in barracks. The medical ambulances, the war material, elephant *kheddahs* for catching the wild elephants, which become the most useful and docile servants, and other instructive exhibits, will be found illustrated in the somewhat confined space available.

Besides the objects specified above, I may mention a case of books published by the Christian Vernacular Education Society, and one of Messrs. Trubner & Co.'s revolving book-cases, containing their latest publications relating to India, including a volume of the *Tropical Agriculturist*. I now come to the Indian Palace (7) and its connected courts. Of the Palace itself I need say no more than that it gives an admirable idea of the Indian style of architecture. The little bazaars, where weaving, metal work, confectionery &c. are carried on, prove sources of great attraction to the crowds who are always to be found in front of them, and I expect a good trade is carried on in the articles manufactured. Round the bottom of the Garden Vestibule of the Palace is the Silk Court, which is hung all round with silks of various hues, while in cases are shown moths, worms and cocoons of Tusser and *rcnia trifenestrata* from Ranchi, Chota Nagpore, the latter new to Europe. This completes the Indian section, and I must leave the other Courts for future letters.

THE WEST INDIAN, JAMAICAN, TRINIDAD AND BARBADOS COURTS.

The Handbook and Catalogue to the West Indies and British Honduras, issued under the authority of Sir Augustus Adderley, K.C.M.G., the Royal and Executive Commissioner, is, as you will see from the copy I send you herewith, a work on the preparation of which a good deal of labor and considerable expense have been spent. It is hand-

somely bound in cloth with a design in gold on the cover showing some of the typical vegetable products of the West Indies, while the contents are as follows:—

Principal Entrance to the Court (Coloured Illustration) West Indian Gallery; Picture Gallery—West Side (Coloured Illustration); Picture Gallery—East Side (Coloured Illustration); Jamaica (with illustration); Trinidad (with illustration); Barbados (with illustration); Sugar Canes by Anglo-Continental Guano Company (Ohlendorff) (illustration); Grenada (with illustration); St. Vincent (with illustration); Tobago (with illustration) St. Lucia (with illustration); Antigua (with illustration); St. Christopher (with illustration); Dominica (with illustration; Montserrat (with illustration); Virgin Islands (with illustration); British Honduras (with illustration); A Group of Exhibits (illustration); The Bahamas(with illustration);Diagram showing the respective Values of the Imports to the United Kingdom, &c. &c. List of Exhibitors Map of the West Indies and British Honduras.

The account of Jamaica is written by Sir A. Adderley; that of Trinidad by Mr. C. A. Harris; Barbados by Hon. C. C. Knollys, Colonial Secretary; Grenada by Mr. J. Wells, editor of the *St. George's Chronicle*; St. Vincent by H. E. A. F. Gore, C.M.G.; Tobago by Hon. L. G. Hay; St. Lucia, Antigua, St. Christopher and Nevis by Mr. C. A. Harris; Dominica by His Honor J. S. Churchill; Montserrat by Hon. J. S. Hollings, C.E.; Virgin Islands and British Honduras by Mr. C. A. Harris; and the Bahamas by Sir A. Adderley, who contributes an introduction to the work as a whole. But, besides this, Mr. Eugene Rimmel, the well-known perfumer, has taken the opportunity to advertise his wares by getting up a little brochure in colored cover, which is sold in the West Indian Court, and which contains, besides a reprint of certain details given in the Handbook and Catalogue, some interesting remarks (with illustrations) on "The Fragrant Products of the West Indies." I send you a copy of this, as it contains matter which will be useful as well as interesting to the readers of the *T. A.* Proprietors of land in the lowcountry of Ceylon should take a hint from what is said regarding the distillation of "rose-apple water" from the jambu and "oil of ben" from the murungai. The illustrations in the Handbook will give you a fair idea of the artistic and tasteful manner in which the West Indian Courts have been arranged, but, as has been said above, some of the effect is due to the employment of articles which have little or no connection with the West Indies. I would only instance the portraits of the royal and other notable personages in the Picture Gallery and especially the fountain in the centre, which attracts so much attention but which has, so far as I know, not the slightest connection with any of the West Indian colonies. (Perhaps it has been placed there to counteract the effect on teetotal minds of the numerous bottles of rum in the adjacent courts.) But lest I should be thought to be trying to depreciate the West Indian Court I shall at once say that a very considerable part of the artistic effect is due to perfectly legitimate means, For instance, to quote from the Handbook,

In order to fully illustrate the Flora of the West Indies—indigenous and acclimatised—Mrs. Blake, the accomplished wife of the Governor of the Bahamas, has most kindly painted, expressly for the Exhibition, a series of 104 large water-colour drawings, copied from nature. These drawings are nearly all life-size; they are very carefully finished, and are, for the most part, without being botanical studies, faithful representations of the plants they illustrate, besides being artistically beautiful. Mrs. Blake, in the majority of her pictures, shows us the plant, its foliage, fruit, and flowers. Sometimes she adds, as a background, a landscape; and now and then she has included one or two specimens of insects, butterflies, and moths.

The picture which appears to attract most attention is that shown in the colored illustration in the Handbook of the west side Picture Gallery. It is thus described in the catalogue:—

In the centre is an immense painting of "A Wave breaking upon the Bahamas Coast." The transparency of the water, the brilliance of the colouring, and the perfection of every detail reflects greatly upon the exceptional powers of the artist, Mr. Bierstadt.

Mr. Albert Bierstadt is called "the Millais of America": whether this title is deserved or not I cannot say; but certainly to the unartistic eye the painting seems wonderfully well done, and I should not be surprised to learn that it has been sold at the high price (£1,000) affixed to it. The old maps and books and specimens of Carib pottery &c. shown in cases in these Courts are all very interesting, especially to the student and antiquarian. The Jamaican Court shows "the touch of a vanished hand," that of Mr. Morris, whose labors on behalf of Ceylon, St. Helena and Jamaica have been recognized by his appointment as Assistant Director at Kew. To his energy are largely due the various exhibits of the Botanical Department, including cinchona, spices and drugs of all kinds, oils, woods, &c. Some very fine samples of coffee and cacao are shown, among the former being several from Arntully estate, with which Mr. W. Sabonadière is connected. Mr. J. Hart exhibits some "Assam tea, prepared from plants growing on the Government Cinchona Plantation, Jamaica:" of course this is simply an experiment, and Ceylon planters need not fear rivalry in that quarter. In the Trinidad Court the chief exhibits are the products of the sugarcane, cacao coffee and chocolate and asphalt bitters. There is a large collection of wood by Mr. S. Devenish, who has compiled a list giving the English, French and Spanish names as well as the scientific names and families of each. A model of a cacao-curing house is shown, illustrating the mode in which the beans are dried in the sun. Before passing on, I should note, that, as the Handbook states,

Opposite the Trinidad Court the Anglo-Continental Guano Works (late Ohlendorff's) exhibit a collection of Sugar Canes from all parts of the world. Here, side by side, may be contrasted the different varieties from West and East. Statistics of production and imports, tools used in sugar cultivation, and specimens of the rat-killing mongoose, cane-borers, &c., make the exhibit a very attractive and interesting one In the Barbados Court the predominant feature is sugarcane and its products. Samples of bituminous coal are shown, which testify to volcanic action in this coral island; and the sight of a model house with 'hurricane cellars' makes one appreciate being out of the range of such destructive natural agencies in Ceylon. The exhibits from the other Windward Islands are of much the same character as those above specified. I would only mention plantain meal, as it struck me that a profitable industry might be created in Ceylon in this direction, as well as in dried plantains sliced. Of the Leeward Islands, Dominica has some interesting exhibits, especially those of Dr. N. A. A. Nicholls; and from Montserrat the lime-juice industry is well exhibited, not only in this Court but in the eastern gallery where there are 'tasting bars' at which this refreshing drink can be had gratis (by a certain number) and lime juice cordial, tablets &c., can be purchased. British Honduras has a fine collection of woods, fibres, fruits, arts and manufactures as well as natural products, and also some Indian antiquities; and the exhibit from the Bahamas is small but interesting, the bonnets made from gorgonas or sea-ferns being very attractive to the lady visitors.

A NEW INDUSTRY—MINOR BUT USEFUL FOR THE NATIVES OF CEYLON.

We learn that there is a good demand in England for "crocodile leather," which is being used for fancy bags, purses, &c. In view of the large number of crocodiles to be found in our Eastern, Southern and Northern tanks and on the margins of other waste waters extending from Anuradhapura to Jaffna, it is a question whether their capture and the conversion of their skins into leather would not pay handsomely.

The skins, as exposed for sale, are stripped of the hard scaly covering and present the color of ordinary leather stamped with the figuring of the outer scales. The price offered per skin is at present we are told enormous, and none but the choicest articles are made of this newly developed material. We think therefore that the authorities of the Colombo Museum should prepare a few specimen hides as used and sold in England, and that the Government Agents in the districts concerned, should exhibit the same with a view to the development of an industry which would put a good many rupees into the hands of the poor half-fed villagers of the Vanni districts as well as prove a benefit to many natives in the Eastern, Southern and perhaps North-Western provinces.

THE ORCHIDS OF CEYLON.

A friend writing from home tells us that on the occasion of a recent visit to the magnificent Botanical Gardens at Kew, he was struck by observing that there was an absence in the houses there devoted to *orchideæ* of many specimens with which he had become acquainted while resident in Ceylon. So much attention is now directed—not by botanists alone—but by home floriculturists to this family of the plant world, that it is certainly desirable some effort should be made to have every member that can be discovered, represented in the national collection.

Not very many years back, while travelling through the dense forest towards Batticaloa, the gentleman already referred to, saw for the first time forms of orchids which had, to that time, been altogether unknown to him. Of one of these varieties he sent specimens to Kew, where it was pronounced to be of a new kind and was gladly accepted and propagated. There is no part of Ceylon where orchids grow in such profusion, or in such variety, as they do on the forest trees in the neighbourhood of the Rugam tank, only a few miles distant from Batticaloa. Doubtless great havoc has been made thereabouts by the clearing of the land recently brought under cultivation through the execution of the irrigation works, but it is exceedingly improbable that having once flourished in the district, there should not remain many undisturbed spots where these lovely eccentricities of nature do still abound. We are asked to suggest that those whose business or pleasure take them into the recesses of the forests we have referred to, or to others equally favourable and remote, should endeavour to secure specimen plants of any varieties which may appear to be new or rare. Their value as regards their transportation to Kew can be determined by a reference to the *savants* of Peradeniya; but so great, is the production and wealth of orchid life in the forests between the foot of the hilly ranges and the Batticaloa lake that—notwithstanding all that has been done by the plant collectors of Dr. Thwaites and Dr. Trimen—it is just possible that careful search will reveal varieties which may not yet have been named or catalogued. In the paper which Dr. Trimen read before the local branch of the Royal Asiatic Society a few months ago, he mentioned that there were in Ceylon of *Orchideæ*, 155 species of which 74 species (or 47·7 per cent) were endemic, that is orchids peculiar to Ceylon. It ought to be an object of interest and ambition—apart from profit—with travellers, sportsmen and others to add to this list.

The wonderful and endless changes in form and colour which the family of the *orchideæ* present to us are, to a great extent, the results of hybridism. This, which is artificially induced in the greenhouses of England, may be presumed to go on naturally among surroundings specially favourable to growth such as are presented in favorite localities in Ceylon. Now in England it is no uncommon thing for sixty or seventy guineas to be paid for a single new hybrid of special beauty or eccentricity in form or colour. It might prove far from unremunerative therefore, for search to be made in the favorite *habitat* of the plants for such hybridism as may have occurred naturally. It may not be far-fetched to assume that by encouraging hybridism in such a vast storehouse of the plants as we possess here in Ceylon, a new and paying form of industry might be opened out. We are all accustomed to laugh at the tulip-mania which wrought through the speculation to which it gave rise, so much ruin among our countrymen in the time of William and Mary, and again also at that for 'crotons,' favorite kinds of which sold in Java a very few years ago for from £10 to £20 cash. But the craze for orchids is scarcely less strong in its present development than was that for the flashy bulb of the Hollanders and more permanent than that for crotons could be. If, as we learn is the case, any new and strange variety of orchids bring prices running up almost to 100 guineas the plant who can pretend to say whether our eastern forests might not prove well worth a careful examination. There, at all events, the plants abound among conditions most fostering to their growth. A little art employed to aid nature, and there need be no limit to the fantastic forms and brilliant colours which a skilful operator might produce and if he can bring these under the notice of the connoiseur at home, he will scarcely fail to reap the fitting pecuniary reward of his labour and skill.

CINCHONA IN JAVA: OPINION OF THE CHAMBER OF COMMERCE OF BATAVIA.

We present our readers with the first answer received to our several enquiries addressed to well-informed quarters in Java. The following letter is a formal one from the Chamber of Commerce, Batavia, the office-bearers of which have promptly and courteously responded to our enquiry. It will be seen that these gentlemen consider the estimate (in our "Handbook and Directory") of a total of 15 million cinchona trees for Java as above the fact, while they very properly remark on the discouragement to cultivation in the prevalent low prices for bark. Altogether this report will be regarded as reassuring by cinchona owners in Ceylon who ought

to say to Messieurs the President and Secretary of the Batavia Chamber of Commerce,

For this relief, much thanks—

(Kamer van Koophandel en Nijverheid, No. 45. Getal der Bijlagen:)

Batavia, 4th Sept. 1886.

Messrs. A. M. & J. Ferguson, Colombo.

In reply to your letter of 26th July, we beg to inform you that, according to the Colonial Report issued by the Dutch Colonial Department in September last year, Government's plantations of cinchona for the year 1884 amounted to 1,516,500 plants in the nursery-gardens and 1,753,900 trees is the open air.

Private planters are very much against giving publicity to their operations and therefore we regret not to be in a position to give you any reliable informations regarding the area under cultivation with cinchona trees on private estates.

We suppose, however, your estimate of 15 million trees of all ages given in your Handbook, as you say, as the extent of the cultivation in Java, is rather more than the real quantity. At all events when prices remain as low as they are now, many plantations, in so far as they are not of the best kinds of Ledgerianas, will hardly cover the cost to gather the bark.—The Chamber of Commerce of Batavia:

W. Suermondt, *President*,
F. Ader, *Secretary*.

TEA CULTIVATION AND LAND REGULATIONS IN NATAL

are thus noticed by the London correspondent of the *Indian Tea Gazette*:—

At last the Natal samples promised some time back have come to hand, but they have yet to be soldered up I see, which means that they will not arrive at your end till possibly a fortnight after this. I send them merely as curiosities of interest from a new tea growing colony which has already 400 acres under tea and is planting out 200 more. The climate, or rather climates, for with their hills in Natal they have several climates, are excellent, and altogether the life is enough to tempt anyone, who has had enough of jungle life and discomfort, to start for Natal to begin afresh. To do so, however, upon no capital and without a certain appointment to go to, is to drop the bone to snap at the shadow, and a very long march to disappointment, which may be found at far less cost close at hand if sought for. The following extract from the land regulations of Natal, dealing with lands likely to be required by a tea-planter, as there are other regulations for grazing and other classes of land, may not be amiss here. All Crown lands otherwise unappropriated are open for sale in freehold (except those referred to in the regulations) in lots of not over 2,000 acres each, payable in ten annual instalments without interest, but subject to certain servitudes connected with roads, railways, minerals, and outspan, and subject also to compulsory occupation. The definition of occupation is expressed as follows:—"To constitute such beneficial occupation, there must be continuous personal occupation by the purchaser or by his agent, duly approved of by the Surveyor-General, during nine months in every year of the period for which the occupation certificate is issued, and the erection of a suitable homestead or dwelling-house, and the cultivation, where the lands purchased are 100 acres or more in extent, of not less than one acre in every 100 acres." The process laid down is as follows:—A person having selected the lands he wants, makes application to the Surveyor-General, depositing certain fees. The survey (at purchaser's expense) is then completed and the lot is advertised for sale by auction at an upset price of ten shillings per acre. The intending purchaser must watch this: if he buys the lot, he must pay down one-tenth of the purchase price in each, and a further tenth each succeeding year till the whole is paid, but is charged no interest. He can then obtain clear title, having first satisfied the Surveyor-General that the conditions of occupation have been complied with, and on payment of a further sum of 40s. Should any purchaser wish to pay for a lot, not exceeding certain limits, at once, he can do so; but an auction sale must take place. The upset price in that case is 20s per acre, and the occupation clause is inoperative. I need hardly add that the purchaser of land in a country of varied soils and diversified physical conditions as are to be met with in Natal, needs to take every precaution, and should bear in mind that a small estate of good soil and aspect, well looked after, is far more profitable than a large, unwieldy property, though bought at a cheap rate. Over and above the large amount of Government lands still available—though not by any means all suited for tea—there are doubtless numbers of private owners of grants in excess of their needs, who would be willing either to sell land to new comers on terms of credit, or to lease it with right of purchase at a date to be fixed. At the present time the usual prices are, on the coast, where sugar and tropical products are raised, from £1 to £5 per acre; in the midlands from fifteen to thirty shillings; and in the up-country or pastoral districts, capable likewise of producing cereals, from 12 to 15s per acre.

CEYLON UPCOUNRY PLANTING REPORT:

A NOVELTY IN TEA: MANUFACTURING THE FLOWERS—THE NEW PRODUCT COCA.

13th September 1886.

I have been shown a novelty in tea. The sample was made from the flower instead of the leaf, and while it had all the fragrant aroma common to high-class, well-made teas, the color was bright orange. This, I should fancy, would prove a delicate enough article, and meet the wants of the most fastidious. As to how it tasted that I cannot say. I question if, up to the time I saw it, it had been liquored: my opinion is that it had not. Perhaps the owner of this dainty article was not quite sure what its effects might be—in the tea seed there is said to be poison, so there may be also in the flower—and it is possible that he was waiting for a friend to come around on whom it might be tried. If the selection were judiciously made, that friend might remember him all his life. I knew of one manager whose memory will ever remain green in consequence of his zeal. He was so determined to get a strong liquor for his teas, and succeeded so well, that a cup of it—taken in ignorance when it was new—almost killed the wife of the proprietor, and was likely to lead to a change in the management!

Whatever may be the effects of the flowery tea, there is no doubt it would be a boon to estates with a bad *jat* if the flower could be utilized, and it has been utilized. I heard of one place where the flower has been regularly plucked with the leaf rolled together, and the tea has realized a fine price. Whether it be that the high average got by this estate has been owing to the presence of the leaf of the flower having been mixed with the other, or in spite of it, I cannot say, but that the flower can be manufactured, is something to know. It is a puzzle what to do with those plants which *will* flower, few finding that to pluck the flower off is a thing that pays. To get however some return for that labour, would put a different complexion on things, and benefit in more ways than one.

The new product Coca which was run after a year or so ago, is not receiving much attention, although there are some people who are now planting it. That the export of its leaves from Ceylon will ever be very great is not a likely thing, but those who know about it, and what weight of leaf it is likely to yield, incline to think that even at the present price—8d. a lb., I believe—it will pay to grow. If I remember aright,

when we first had a trial of this plant and agonized over the few seeds supplied by the Royal Botanic Gardens, Peradeniya, seeing in them the potentialities of future fortune, the price for the coca leaf was said to be 13s a lb. and now,—well it is down to 8d. I suppose it was because we threatened to grow it, that there was this truly characteristic Ceylon decline. Had we done it, we would have had to give the leaves away for nothing. PEPPERCORN.

MANILA NEWS.

(*Translated for the Straits Times.*)

In the Philippines, too, the prospects of sugar growers are far from encouraging. The future gloomy enough already owing to low prices has become more unpromising still by the Home Finance Minister directing that sugar imported from the Philippines into Spain should be saddled with a duty amounting to seventeen *pesetas* and a half on every 100 kilogrammes. This rate comes to $1·61 per picul. The average price of the sugar forwarded to Spain is $4 per picul, so that the duty is almost 40 per cent on the value. Under these conditions, the sugar trade with the mother country will become impracticable. A congress of sugar-growers is shortly to meet in Spain. It is expected that they will take steps to secure greater liberality to their Philippine fellows in fiscal matters.

PLANTING IN THE WYNAAD.

Rain, rain, rain for six continuous weeks, and still rain, and yet all the difference one notices is that the streams run through the *sholas* a trifle more noisily, and the cataracts leap down the distant Neilgherries a trifle more furiously, so that one ponders as one paces the verandah, how many inches might have been registered during those memorable forty days some six thousand years ago. Still this weather is not to be grumbled at, for up to now it has been perfect for planting, but as nearly all the young plants are out, a few warm, sunny days would be most acceptable. Another great advantage of this weather is the necessity for fires; for what is more pleasant than after a hard day's work trudging about ankledeep in slush and mud, with water spouts bursting over you and a bleak sou'-wester howling round you, than to throw yourself into a long arm-chair before a blazing fire and give yourself up to the pleasures of a cheroot and the latest *Indian Planters' Gazette*. At such time the most truculent coolie might cheek you and fear not, and the distant belling of a sambhur, as he invites his mate to come and browse off your choicest child cinchonas, merely causes you to remark with the Newmarket tout, "Another little trial sent for my good."

Coffee is beginning to look up again, the latest quotation being M. P. 70s. and lucky are they who have not yet sold. Though some of the first shipments fetched good prices, one small lot of twelve tons we heard of averaging 71s which means at the present rate of exchange R600 per ton net on the estate. The estimates for the coming season are in the majority of districts below the average, owing to the failure of the early rains, but the bushes themselves are in good fettle, so if the clerk of the weather will only prove propitious next March and April, 1888 ought to find some of us smiling

Our cinchona trees continue to grow and grow fast but alack a day (wish we had one) the unit eve, sinks, sinks faster, but being planters we hope for better times, for a planter without hope is as a preacher without charity, and besides Peruvian bark has lately been discovered to be an antidote to alcohol, and forty-two diseases, and they are daily discovering more, are attributable to alcohol, therefore if the statistics given at Blue-Ribbonite meetings are the truth and nothing but the truth, the demand for cinchona in some form or other ought to be on the increase.

A young planter of an enterprising but economical turn of mind is opening out an estate this season on a rather novel plan. He has planted up fifty acres thusways,—cinchona, six by six, coffee five by five, tea four by four. Where to put each plant causes the thoughtful coolie more heart searchings than would the puzzle 15. When last heard of, our friend was meditating, seeing there are still some five inches of bare soil left, whether it would not be as well to put down ground nuts or ginger to keep down the weeds; and as he pursues his trivial round, his daily task, he may be heard chanting this roundelay:—

Weeds, weeds indeed!
I am going to do without them;
Won't have them any more,
I am going to do without them,
As none have done before;
I am going to be a planter
On a very novel plan,
And agents and neighbours all will say
Oh! what a 'cute young man!!!

May we for weeds never have to read coffee, tea, cinchona, ground-nuts, &c. &c.—*Indian Planters Gazette.*

THE SIKKHIM CINCHONA PLANTATIONS.—We find the following notice in the *Madras Mail* :—"The Government cinchona plantations in Bengal now contain upwards of five million trees, of various ages, of which the red Succirubra and the yellow Calisaya Ledgeriana are the most numerous. A considerable addition was made to the number of plants last year, upwards of 400,000 of the yellow varieties being planted out. The yield of the plantations amounted to 205,410 lb. of dry bark, principally red, and the bulk of it was made over, as usual, to the febrifuge factory. The expenditure on the plantations amounted to R79,728, and the receipts to R93,476. The capital account now amounts to R10,96,255, but this has been recouped by the saving effect by the substitution of cinchona febrifuge for quinine in medical institutions."

GERMAN EAST AFRICAN PLANTATION COMPANY.—This company has been formed in Berlin, the promoters including Count Behr, Dr. Grimm (Karlsruhe), Rear-Admiral Count von Hacke, Karl von der Heydt (firm of von der Heydt-Kersten and Sons, Elberfeld); Dr. Otto Kersten, Vice-Admiral Livonius, Captain von Luck, Dr. Karl Peters, Herr Paul Reichard, Dr. Schroder, and Dr. Zentzytski. The capital is to be 2,000,000 Mks., of which only a quarter will at present be called up, the remainder being called up at the rate of 25 per cent. yearly. The company will cultivate tobacco on lands to be acquired for the purpose in East Africa. German growers, trained in Sumatra, and coolies will be employed. The German East African Company grants to the company 25,000 hectares of land, receiving shares to the amount of the purchase money, viz., 4 Mks. per hectare.—*Kuhlow's German Trade Review.*

THE PLANTING OF GUTTA-PERCHA.—We hear that the Netherlands Government has caused experiments on a large scale to be made in the gardens of Buitenzorg in the cultivation of the plants which yield Gutta-percha, and thus far the planting of the following varieties has been attended with favorable results. Palaquium Gutta (Isonandra Gutta Hookerii) from Singapore; Palaquium Oblongifolium and Payena Leerii, of Sumatra; Palaquium Treubii and Palaquium Parrifolia, of Banca and Palaquium Borneese, of Borneo. The plantations are at an elevation of about 2,000 feet above sea-level; where fully 1,000 plants are growing so well as to leave no doubt as to the success of the experiments.—We have had the above translated for the *Observer* from the *Indische Mercuur* of the 18th August, 1886. Have experiments been made in Ceylon with these varieties?

THE TEA PLANTER'S MANUAL.—The publication of this book has been somewhat delayed but we are happy to state it is now nearly ready and the 14th of this month will we hope see copies in the hands of those whose orders have been registered. We may mention that the two large factory plans have been lithographed at the Surveyor-General's Office, Colombo, and they are as well done as they could have been in India or even the old country. The way in which this work has been executed speaks very highly for the quality of the work turned out by the Surveyor-General.

MANGOSTEEN TREES IN CEYLON.—I learn that there are several very fine mangosteen trees at Galle which have been in bearing for at least 20 years past. Durians also bear at Galle. I hear at Baddegama there are mangosteens planted on a cabook hill, but these probably have been manured. They are bearing heavily this season. A day or two ago I heard of a lot of trees at Ratnapura doing well, and if my recollection serves me there used to be mangosteens on the old Nillambe nutmeg estate which was abandoned over 20 years ago. Some of your correspondents might tell us the history of those nutmegs and other spices which were tried at Nillambe, I think, by Sir John Cheape.—*Cor.*

VALUE OF TEA PROPERTY.—Our Upper Lindula correspondent—an old and experienced planter both as proprietor and superintendent,—starts a discussion on this subject, by showing that a certain favourite property if it gets 600 lb in tea per acre as is expected, should at seven years' purchase, be worth over R900 per acre when in full bearing. We do not at all quarrel with the calculation in this particular case; but if we were asked for an average valuation of tea properties coming into bearing in Ceylon, we should be inclined to fall back on what was at one time the old standard rate for coffee namely R400 per acre—basing our estimate on an average crop of 400 lb per acre and 10 cents per lb. profit at 10 years' purchase. Of course a very much better return can be shown, and is expected, from the majority of tea gardens in Ceylon; but there are exceptions already and these will probably increase as tea fields on old coffee land begin to crop.

THE CINCHONA OF NETHERLANDS INDIA.—We had occasion some time ago to notice a paper read by Mr. Brady at a meeting of the Pharmaceutical Society, in which he gave an account of a visit he had paid to the Government Cinchona Plantations in Java. We gathered from his remarks that, for some years to come no considerable exports of bark was to be expected from that island, as nearly all available trees had been uprooted to make room for the more valuable kind of "ledgers," to which species the local authorities had decided to devote all their attention. The fact of old ground having to be cleared to make room for the new plantings did not look as if suitable land was abundant, and the total extent of the Government's estates, which have usually been supposed to be the principal source of the Javan bark export, was then only 1,200 acres. * * * Mr. Mundt's 175,000 acres of cinchona will probably come into yield about the same time as that right good fellow Allan Quatermain revisits Leu, and swamps the diamond market with his discoveries in "Solomon's Mines." One phase of this question has apparently escaped the attention of the Ceylon planters, who by the last accounts, are still somewhat alarmed about the Javan ledgers, namely, what effect the approaching largely increased Indian export is likely to have upon them. Hitherto the bark trade from this country has been comparatively insignificant, but were statistics available, it would be found that the five years' exemption from taxation conceded by Sir M. E. Grant-Duff's Government in 1882 has startlingly increased the acreage under cultivation. Our planting districts cannot show 175,000 acres of cinchona; and the Forest Department will probably see that they never do so, but there is enough growing—and growing remarkably well too—to make a very fair show even besides the Ceylon export of the last two years; not that that inflated state of things is likely to be maintained. Even if the 20,000 acres which it is just wildly possible may be in existence in Java, should ever come, into maturity, the competition will not be enough to hurt the Indian planter. It appears that in Java the custom is not to harvest bark from trees less than six or seven years of age,—a fact that will perhaps raise the old controversy as to the relative profits from growing these expensive and delicate varieties as compared with the commoner sorts which yield less quinine, but can be worked earlier, and give more bark. On the whole, the opinion of large owners who can afford to wait some time is in favour of planting ledgers.—*Madras Mail.*

TEA IN UPPER DIMBULA: VALUE OF TEA PROPERTY.—Upper Lindula, 11th Sept.—No change in the weather: it still continues to rain every hour of the day. The sun peeps out between the clouds for a few minutes at intervals to let us know he is there, and to let us know he will "give it us hot" by and bye. Everyone is taking advantage of these September rains to get another round of tea supplying done, and splendid weather it is for that work. I had the pleasure yesterday of a long walk with the proprietor, over one of the most promising, perhaps *the* most promising of the young tea estates in the whole of this district. Lippakelle is well-known to be a property of exceptionally good soil, good aspect, and very favourable in lay of land. Its grand expanse of coffee in days gone by encouraged its former proprietors to pay £18,000 sterling for it; that figure was not considered too high in those days when prices of coffee were good and the estate gave regular crops. That coffee is gone, and the beautiful fields of young tea springing up where the coffee used to be, give promise of giving as good returns as the old product did in its former days. Every care has, and is being taken to have none but the best jât of plants in the ground. The great advantage that this estate and most estates in this district have, is, that the soil is not worn out, and no wash of soil has occurred, the land having been well drained from the year of clearing the forest. On the property I am referring to, the rotten bark of the old forest-trees and stumps is still to be seen scattered on the surface of the ground. Mr. Maciver, the lucky proprietor of Lippakelle, is commencing the conversion of the coffee store into a tea factory. In another eighteen months' or two years' time, this fine property will be in full bearing, and judging from the vigorous growth of the bushes, a regular return of 600 lb. the acre will not be too much to expect from it. It is not easy to get at the value of a tea estate. How many years' value to place on it? Say seven years after the fourth year from date of planting. At seven years' purchase, giving 600 lb. the acre at 62 cents a lb. and say 40 cents for all charges would leave 22 cents profit or R132 per acre value of estate R924 per acre. But how about those who take their estates at ten years' purchase and calculate a yield of at least 800 and 1,000 lb. per acre? It makes one's hair stand on end to think of such figures, and to make such calculations will do more harm than good to the tea enterprise of this island. The lucky owner of Lippakelle need not fear short returns from such fine soil and fine jat of tea. Beginners in tea would do well to take a walk over this property. I will undertake they will get a hearty welcome, and, what's more, a rare glass o' whiskey into the bargain.

AUSTRALIAN FORESTS.

BY HENRY F. MOORE, FROME, SOMERSET.

So much of the Australian continent remains unexplored that the approximate area of its forest lands cannot be even conjectured. One thing is certain, however, and that is, that a much smaller portion of its surface relatively speaking is wooded than was the case on the North American continent when it was first colonized by Europeans. Nevertheless, it and the neighbouring islands of Tasmania and New Zealand contain immense forests of valuable timber for both constructive and ornamental purposes. These are described in a recent report to the American Government. There are 150 varieties of the *Eucalyptus* or gum tree, some of them attaining a gigantic height, as, for example, the *Eucalyptus amygdalina*, which has been known to reach an altitude of 480 feet. The specific gravity of the *Eucalyptus rostrata*, or red gum, which is largely used for railway sleepers, nearly equals that of the oak, while it is capable of sustaining a much greater pressure to the square inch than either oak or teak. In point of durability the harder varieties of the *Eucalyptus* will last four times as long as the former. Many of the Australian trees, as, for example, the *Eucalyptus botryoides* the *Cedrela toona*,* the black-wood, and the *Frenela endlicheri*, or Cypress pine, and the numerous indigenous cedars, are beautiful in grain and colour and take a fine polish. The Kauri pine of New Zealand, which, with a diameter at the base ranging from 10 to 20 feet, attains to the height of 160 feet, and often presents a columnar trunk of 100 feet without a branch, is much prized for its timber by the shipbuilder, the miner, the railway engineer, and the cabinetmaker. What renders it exceptionally valuable is that it exudes a gum almost equal to copal, the choicer qualities of which will sometimes command from 584 to 730 dollars per ton in the London market. The *rurin* or red pine, an ornamental as well as useful timber, some of it resembling rosewood, though of a lighter brown colour, is largely used in the manufacture of furniture. With the *totara*, a durable and clean-grained wood, not unlike cedar in appearance, the Maoris made their largest canoes, and almost invariably constructed the palisading of their "pahs." The forest trees of Western Australia claim special attention on account of their useful and valuable properties. Among these may be mentioned the tuart (*Eucalyptus gomphocephala*), an extremely hard heavy, and close-grained wood, which furnishes the strongest timber known, its transverse strength per square inch being 2·701 as compared with the English oak, which is 2·117, or the Indian teak, which is 2·203. Hence it is extremely valuable for shipbuilding purposes. The karri (*Eucalyptus diversicolor*), also highly prized for its timber, attains to colossal dimensions, sometimes measuring 60 feet in circumference at the base, while its tall and shapely trunk rises to the height of 300 feet without a single limb. The jarri† (*Eucalyptus marginata*), which resists successfully the attacks of both the white ant and the Teredo navalis, is unsurpassed for the durability of its timber. Specimens of jarrah piles, after being exposed between wind and water for over forty years, are still found to be in an almost perfect state of preservation. According to the Director of the Botanical Gardens at Sydney, no country has been favoured by nature with a greater variety and abundance of trees yielding strong, beautiful, and durable timbers, than the colony of New South Wales. Its magnificent forests contain woods valuable alike to the cabinetmaker and the shipbuilder, including such timbers as the different species of the *Eucalyptus*, the red cedar, turpentine, rosewood, mountain ash, and tulip-wood, most of which are beautiful in grain, rich in colour, and susceptible of a high polish. Queensland is richly endowed with immense tracts of forest lands, furnishing large quantities of valuable timber, and indirectly supplying the soil with an abundance of rain.* The enormous fig trees and gigantic *Eucalypti* tower aloft and spread out their great arms, festooned with vines and flowering parasites, which throw themselves over every spreading branch, and deck it with their varied and brilliant colours; the tall pine trees, the cedar, the myrtle, the rosewood, and tamarind trees are also forest representatives.—*Journal of Forestry.*

* What is known in India and Ceylon as the Toon tree.—ED.

† Jarrah.—ED.

THE CULTIVATION OF TOBACCO IN IRELAND,

In an article on this subject in the *National Review* Mr. R. Staples says that upon the revolt of the American colonies, for the double purpose of punishing the Virginia planters and trying to win the affections of the Irish, the Government of Lord North made it lawful to grow and cure tobacco in Ireland. There can be no question that in certain districts where the soil was suitable large profits were earned. The county of Wexford, and the neighbourhood of Enniscorthy in particular, was the most favoured spot in this respect. A young man from Enniscorthy had been over to Maryland, and on his return brought with him some seed, and encouraged his brother to venture on it, and from half an acre 100*l.* had once been produced. Holding a farm of sixteen acres this man made a profit of 1,200*l.* in seven years. It is frequently asserted that the climate is unsuited to tobacco, and that it cannot be profitably cultivated, but in face of the weight of evidence existing to show that a profit used once to be obtained from its growth this objection cannot be considered of much value. In any case, the abolition of an artificial restriction would soon prove the truth or fallacy of this assertion, for, if it cannot be produced at a profit to compete with foreign tobacco on equal terms, tobacco, like wheat, would again cease to be cultivated. The farmer would soon prove to be the best judge of the profit or loss derived from the transaction. One objection, no doubt, is that it is an exhausting crop to the soil; but the same objection, only in a lesser degree, applies to flax, which has been for many years past the mainstay of industry in Ulster. And, as tobacco can now be cured by steam, the influence of the weather on the process of curing is of less importance than formerly. The climate and soil appear to be as well adapted to it as they are to the potato, which was introduced at the same time and from the same source. Some short time since an interesting paper on the subject of the cultivation of tobacco was read in Dublin by Mr. J. A. Walker, at a meeting of the Statistical and Social Inquiry Society of Ireland. The writer of that paper, who, like many others, is fully alive to the necessity of finding some new employment for the unoccupied agricultural population, had taken the trouble to communicate with several gentlemen, both in Ireland and America, who are intimately acquainted with the conditions necessary to the successful growing and curing of the plant. According to the testimony of one of his correspondents a statute acre should produce two and a half tons of dried tobacco, and if, after paying all expenses, the farmer should only realise a profit of 2*d.* per pound, it would amount to over 40*l.* per acre. Another estimate placed the profit to be derived at not upwards of 25*l.* per acre, but all accounts agree that a good and substantial profit would be realised. In France the expense of cultivating a hectare of land, nearly two acres, with tobacco, is stated by M. Joubert (Tabac) to be about 32*l.* 1*s.* 8*d.*, and the average produce to be 86*l.* 5*s.* leaving 54*l.* 3*s.* 4*d.* for profit to the French farmer, while even more can be made in successful seasons. The collection of the excise duties in France is not surrounded with any special difficulties, and it is not easy to see why it should be otherwise in Ireland. In the year 1870, the latest for which there is any

* The mountains have more to do with the rain than the trees, amongst which the Toon (red cedar) and the *Auracaria Bidwillii*, the latter preserved for the sake of the cones, on which the natives fatten, ought to have been specially mentioned.—ED.

special return, the importation of unmanufactured tobacco into Ireland amounted to 634,632 lb. This is of unmanufactured tobacco alone, and mainly for the use of the poorer classes, and exclusive of cigars, which are a luxury for the rich.—*Overland Mail.*

AUSTRALIAN WATTLES.

AN INDIAN POSSIBILITY.

It is not long, since the planting craze throughout India was "*divi divi*" as a source of tannin destined to bring wealth to some and benefit to many by creating a planting industry which it was asserted would meet a world-wide demand. Time, however, has nullified these expectations, and now the question often asked is "what has become of the *divi divi*." This negative result has been simply induced by exaggeration, which did harm by raising hopes through promises purely speculative and outside domain of the feasible and practicable. There can be no doubt that there are various part of India well adapted by nature for the production of this variety of the botanical family called "Coriaria" and the pity is that they have not been utilised for the production of a commerical substance of great value in the arts, commanding a high price everywhere as tannin matter. Had *divi divi* received three or four years back the attention it needed for development as planting industry, with rumunerative aspects, the Australian Colonists would not at the present period be going in for the cultivation of wattles for bark which likewise yield the same material as the *divi divi* pods, and for which, owing to the falling off in the supply of tannin barks, there is a brisk demand in the markets of Europe. It is stated on good authority that the Australian wattle yields the best material in the world for the purposes of the tanner. The trees known as "wattles" in Australia are indigenous species of *acacia*, and it is only since past improvidence in regard to this natural product has commenced to tell unfavourably upon the present supply that attention has been devoted to the physical predelections of the plants with a view of cultivating them on a commercial scale. We learn from a Government Report issued under the auspices of the Executive of South Australia—which is the principal habitat of the wattle—that two species are available for cultivation, and that outlay in this direction would give a return for in excess of that which is realized in ordinary industrial channels. The first of these—*Acacia pycnantha*—commonly known as the broad leaf or golden wattle, is the best of the many varieties. It is hardy and quick-growing, flourishing in localities where the rainfall averages 15 inches per annum. According to the South Australian Official Report—due to Mr. T. E. Brown, the Conservator of Forests—"this species will grow readily in almost all kinds of soils, but its rate of growth is most rapid in those of a sandy character while at the same time the largest trees and the best bark is produced on sites where the soils is sandy on top and of a good retentive clay in the sub-soil. Mr. Brown adds, that "with this tree we have the means of making our poorest soils yield valuable crops, instead of their lying idle and worthless." For of all the *Acacias* the bark from this variety yields the largest percentage of tannic acid. The other of two species referred to *Acacia decurrens*, called the Black Wattle, "delights in sandy soil with clay sub-soil; but it attains its largest dimensions upon a black alluvial soil of great depth, and where there is great percolation of moisture." It will even grow in situations where the soil is almost pure sand. The cultivation of this variety can, however, only be recommended in more moist and temperate regions than those which favour the growth of the broad leaf or golden wattle. In other words, it will not grow satisfactorily and as a payable crop in places when the rainfall is below 15 inches annually. This variety is not so rich in tannin as the broad-leaf wattle, yet it is three times more valuable as a tanning agent than English oak bark. These two species of the Australian wattle, therefore, offer the best recommendations for Indian cultivation. The broad-leaf wattle only attains a height of 25 feet and 12 inches in diameter, whereas, the black wattle grows to a height of 40 or 50 feet and to diameter, of 20 inches. The latter is therefore sooner available for stripping, which, in either case, should not be attempted before the expiration of seven years from seeding. The bark now sells at £87 per ton; and, since 10 lbs. of bark is the lowest yield per tree, and 1,000 trees may be easily planted to the acre, the profits derivable from wattle cultivation are therefore found to be highly remunerative. We have no doubt that wattles might be profitably cultivated in India. Considering the vast extent of wasteland suitable for the purpose in the country and facilities it affords generally for this class of industry, the possible becomes very probable that not only the European planter but the Indian ryot would find this a good field for investment.—*Indian Agricultural Gazette.*

Surface Culture in Fruit Farming.—According to Mr. Kruse, of Yew Tree farm, near Maidstone, fruit-growing best succeeds when the roots not interfered with are left to multiply and interlace, and so take advantage of the upper and more nutritive soil. So he practically uses only the common garden hoe and the pruning-knife, aided by an abundant top-dressing, mainly of bones crushed to quarter-inch size. As much as from £10 to £13 per acre is yearly spent on manure which is simply placed on the surface of the soil. According to a correspondent of *The Field*, the results have this year been very gratifying, as regards strawberries, gooseberries, black currants, as well as apples, cherries, and damsons.—*Journal of Forestry.*

Lord Tollemache's Estate Management.—On these extensive domains in Cheshire and Suffolk extending to about 33,000 acres, there are 250 cottages each with three acres attached, so that the occupant may keep a cow. There are also fifty-one farms averaging 25 acres, some of which are in the hands of carpenters, blacksmiths, and other artisans residing on the property. There are besides fifty houses built by other resident tradesmen on ninety-nine years' leases. This admixture of large and small holdings yields the happiest results.—*Journal of Forestry.* [And will continue to do so while the tenants are intelligent, sober, provident and industrious, conditions which would beneficially affect even the wretched Hebridean crofters. —Ed.]

Coconut Toilet Soaps.—Some interesting information on the preparation of *cheap coconut toilet soaps* comes to us from Herr Eichmann, who discusses the so called "filling" of soaps made from coconut oil. Soaps charged with soluble glass, although at first presenting a fine, transparent appearance, gradually dry up to and become coated with a solid crust. Moreover, he assures us that such soaps are apt to act rather injuriously upon the skin of the persons who use them. Salt solutions, having a specific gravity of 15° to 20°, Baume, are occasionally used in conjunction with soluble glass. The behaviour of potash solutions is similar to that presented by soluble glass. Talc is used either alone, or in admixture with soluble glass, for the "filling" of inferior toilet soaps. Where it is employed, it is mixed with a small quantity of coconut oil, and then added to the whole charge of oil. The same writer offers some remarks on *curd soaps*, from which we glean that for the preparation of a good curd soap with a silvery fracture, we should boil 700 kilogrammes of tallow with soda-ley of 15° B. to a clear jelly, and introduce 450 of palm nut oil, and 100 kilogrammes of coconut oil with the requisite quantity of caustic ley at 23° B. The mixture is then boiled until a clear jelly, free from froth, is obtained. After the laps of two hours, any scum that may have found its way to the surface is removed, and the product is salted or precipitated respectively with salt solution of 20° B., or caustic soda-ley of 40° B.—*Burgoyn & Co.'s Monthly Export Price Current.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(Special Letter.)

PARIS, Aug. 7th.

M. Peligot announces some interesting facts about sugar beet, and the influence of atmospheric humidity and rains, on the quantity of sugar contained in the bulb. According to him, M. Girard experimented with beet from the 19th June, to the 1st October last. Every twelve days he analysed roots, simultaneously recording the meteorological condition of the atmosphere. Excepting the water and sugar contained in the root, the other matters never changed; the water varied from 83, to 89 per cent, while the sugar fluctuated from 5, to 18 per cent; but the water and sugar together, strange fact, uniformly represented 94 per cent of the bulb. The sugar augmented, as the water declined, both compensating exactly. However, once the sugar became deposited in the root, that is, stored up, it there remained unaffected by the conditions of vegetations or the action of rain.

M. Gagnaire confirms his experiments, that sulphuret of carbon is efficacious in the destruction of wire worm, moles, beetles &c., whether in garden or field; half an ounce per square yard dug in the soil with a spade, will get rid of the vermin.

ERYTHROXYLON COCA.

BY J. B. LILLIE MACKAY, A.K.C.

Formerly Professor of Materia Medica to the Birkbeck Institution, London.)

Coca, or the "narcotic of the Andes," as it has been called, has for some time past created a good deal of interest both to medical men and pharmacists, who in late years have devoted no little attention to the properties and uses of this remarkable drug.

It consists of the leaves of the *Erythroxylon coca*, a plant, indigenous to South America, which thrives most in the valleys to be found on the eastern slopes of the Andes chain, in that continent. It grows best at an elevation of from 5,000 to 6,000 feet above the sea level.

The plant belongs to the natural family *Erythroxylaceæ* nearly allied to the *Malpighiaceæ* or Barbadoes cherry tribe; and must not be confounded with *Theobroma Cacao*, which yields cocoa, nor with the coconut tree (*Cocos nucifera*), species of palm. It is, however, from the cultivated shrub, and not the wild plant, that we obtain the sun-dried leaves which constitute the *coca* of commerce.

Some description of coca plantation may prove interesting to the readers of this journal. The plant, a bush attaining a height of seven or eight feet, abundantly covered with green foliage, and bearing small white flowers, is raised from seed sown in December and the early months of the year, just before or after the commencement of the rainy season which prevails in these tropical regions. A mean temperature of 66 deg. Fahr. is most conducive to its healthy development. During growth the young seedlings require much watering, as well as protection from the sun's rays. The latter is frequently secured by the erection of thatched roofs over the nursery grounds where the plants are reared. Sometimes, however, shade is procured by the interplanting of palms or Indian corn. The plants are generally grown in terraces on the slopes of the hills in a similar manner to that carried out in the vineyards of Palestine and Southern Europe. After eighteen months the harvest begins, and may be continued at the proper season, for forty years, from the same plant. The average crop from each bush is about 2½lbs., or 30 *arrobas* (800 lb.) from an acre. Three pickings are got from the shrubs in the twelvemonths, but if irrigation is well carried out, no less than four harvests *per annum* may be obtained.

Almost as much care is required in the selection and drying of the leaves as in the case of tea plant cultivated in China and India. If the gathered leaves are too moist they are liable to decompose, while if over-dried they lose their agreeable aroma and peculiar flavour.

The exact time for collection is when the green leaves are mature enough to break on bending. They are then pulled from the branches by native women and children. The subsequent exsiccation has to be gradual, and is effected by exposing them in thin layers to the heat of the sun.—*Chemist and Druggist.*

COFFEE PLANTING IN SOUTHERN INDIA AND CEYLON.—No. II

(REVIEW OF "WRINKLES AND HINTS ON COFFEE-PLANTING" WITH DIAGRAMS AND SPECIMENS OF FORMS BY GEORGE WILDES; MADRAS, ADDISION AND CO., MOUNT ROAD.)

(Continued from page 205.)

ESTIMATES.

An experienced planter can make a pretty accurate estimate of the expenditure necessary under his own system for any given operation, and he may make a tolerable approximation to the quantity of crop on an estate he knows well if he takes pains, but no dependence can be put on any estimate that proposes to go deeper.

I recollected a case in which the necessity of local experience in estimating crop on the trees, was clearly illustrated. Two estates were situated on each side of a dividing stream. The older of the two had always been pretty-well cultivated and the other had been awfully neglected, but under a new agency and a new superintendent a change was wrought that brought out latent powers of the soil, and the repressed vigor of the trees which developed in heavy and brilliant foliage. Planters from other districts passing through remarked that the old *shuck* place was greatly improved, but had gone too much to leaf; but every one talked of the magnificient crop on its neighbour. The two superintendents both estimated 10 cwt. The agent for both (no red tape planter, but a sound experienced man) added one to the estimate of the one, and deducted two from that of the other. When the crops were despatched and cleared out, the one that made the noble display had given 44 parchment bushels per acre; the one that had modestly hidden its treasure in its foliage, gave 55.

On the first occasion I had to estimate a crop, I confessed to my superior, my distrusted powers and he undertook it himself, mentioning as a proof of his ability, that his estimate of the crop of another estate the pevious year had turned out correct within *three bushels*. His estimate was made and booked, and would have turned out very nearly the truth if he had not omitted to divide it by two. I suppose no such wild estimates of crop takes place nowadays, yet we do hear of crop estimates being revised after the gathering has been going on for six weeks, of longer.

ACCOUNTS.

In Ceylon forms are generally supplied, so that it is no part of a superintendent's duty either to make or select a system for himself. Weekly reports never have taken root in Ceylon, and are not likely ever to do so, being to those who send and those who receive them alike a bore.

I never knew a really good planter, who loved desk work; who did not work with dislike on the materials of his monthly accounts; and who did not defer the uncongenial labour to the last moment. It is sometimes, but not generally, incapacity or self distrust that lies at the root of the planter's reluctance to tackle the accounts, and that renders the time devoted to them the most disagreeable of his month, but the same habit seems to grow even on those who were good accountants, before they became planters.

The planter of earlier times contracted rust from paucity of social intercourse, and plodding in his own groove till any change of habits or duties became a terror to him. He would do his possible to avoid meeting strangers, and, alas! in too many cases he took to solitary tippling ending in D. T. and death. The old Ceylon planter can tell many a sad tale of the neighbours, acquaintances and intimate friends of from thirty to forty years age, and can never feel thankful enough that he himself escaped the dangers to which the life he was obliged to lead exposed him in common with those who succumbed.

Yes, truly, it is an unmanly and ignoble thing for one who has been taught some tincture of letters and the habits of the civilized society to become degraded into a sloven or a sot or even one who defers as long as possible a disagreeable duty. But send society's brightest ornament into the jungle five miles from a neighbour, and compare him with his old self at the end of four or five years: you will probably find that he has deteriorated not a little. The planter's safeguard in a new country or a new district is a taste for science or literature, or art, or a good stout Hobby on which he can mount at will and gallop away into the brightest regions of Utopia.

FRUIT AND VEGETABLE CULTIVATION IN THE WEST INDIES: A TRIP TO CHIRIQUI.

On reaching that portion of our route where the surrounding districts consisted of flat alluvial, we noted several extensive Banana plantations. I was informed on reliable authority that from the time of planting to the production of fruit only some nine or ten months were required, and the plants from their thriving and luxuriant appearance would assist to bear out this statement. They were planted in straight rows some 10 to 12 feet apart, and were producing enormous bunches of splendid fruit at the time of our visit. So productive are these plantations becoming on this and other rivers in the locality that large steamers begin to come in regularly to load for the American market, and when it is considered that the depth of water in the lagoon is sufficient to allow them to come to within easy distance of an hour or an hour and a half's journey by canoe, it will easily be seen what a profitable business it is likely to become in the near future. The transit of the fruit from the plantations to the steamers is all performed by large Cedar canoes similar to the one in which we were travelling, or in larger ones dug out from the enormous Cotton trees. Rice was growing wild on the river banks, and appeared to be of good quality. Several large Cane fields were also seen, and Canes 15 to 20 feet high were common objects.

Near the house was a large leguminous tree, which was here known as the "Guanga," but though it bore considerable resemblance to the tree known under that name in Jamaica, it was not the same. It is a tall umbrageous tree, with bijugate leaves and brown hairy pods, somewhat falcate in outline, and 6-8 inches in length. These, when open, are found to contain a sweet mucilaginous pulp, which envelopes the seeds, which when freed from their covering were of a chocolate colour. The pulp much resembles that covering the seeds of Theobroma, and has a pleasant sub-acid taste. There were also plenty of Coconut trees, which found a congenial home in the sandy soil of the beach, but on tasting them as "water Coconuts" we found that they were much inferior in flavour to those grown on the islands in the lagoon, but the ripe nuts are equal in size and quality to those grown in other places.

We also procured seeds of "Samba Gum" tree. These were about the size of small Nutmegs, and, like them, were covered with a reddish arillus, or fleshy covering, much resembling the Mace of commerce. The "Samba Gum," when first produced from the tree, is a yellowish creamy-looking liquid, which after a time becomes hard and somewhat resinous, and when in that condition resembles the "Hog Gum" of Jamaica, the produce of Symphonia globulifera, if, indeed, it is not the produce of the same tree, for it has not yet been our fortune to obtain seeds and botanical specimens of the Jamaica plant.

The remaining days of our visit were spent mostly indoors, on account of the very inclement weather which prevailed at the time; but even during this time I was fully occupied in drying and properly preserving the specimens I had already secured. One of the specimens thus brought to us was the fruit of a Passiflora, called the "Wild Granadilla" locally. It was a ripe fruit 1 inch in diameter, bright scarlet in colour, having a very thin papery pericarp with light coloured transverse and longitudinal markings. It contained a very pleasant sweet pulp, and, being fully ripe, seeds were duly secured, and I am glad to say safely transported to this island, where they are now growing freely. It is a pretty species, and was found on a small island called Careening Cay, forming the tongue of the Bull's Mouth. Another plant of interest of which seed was brought to us was Elais guineensis, or the African Oil Palm, which has probably been introduced in a similar manner as it was into Jamaica from the coast of Western Africa. We also had a fruit of the true Passiflora quadrangularis brought to us under the name of "Granadilla." I had not seen the fruit of this plant for some twenty years, but it has often occurred to me that the name "Granadilla" was probably applied indiscriminately to the two kinds, *i.e.*, Passiflora macrocarpa and P. quadrangularis, the former of which is known and grown in Jamaica as the "Granadilla." The difference between the two varieties is not so much in the size and shape of the leaves, which are very similar, but in the different form, size, and flavour of the fruit [and specially in the construction of the flower. Ed.]. The fruit of P. quadrangularis is in size about one-third less than that of P. macrocarpa, more oval in shape, and of a darker green colour. It is much superior to the ordinary fruit known as the "Granadilla."

The fruit of Bromelia pita was also brought to us. This is the "Silk Grass" of the district, and is the plant from which all the Indian hammocks, bags, &c., are manufactured. It has leaves sometimes over 10 feet in length, in appearance not unlike those of the "Penguin" of Jamaica, but the fruit of the plant is much more like the Pine-apple, as it rises on a stem 3 or 4 feet long from the crown of the plant, and the pips, are aggregated together, in a similar manner to that fruit. The bracts are much more distinct, bright scarlet, and close together, and the pips are much smaller than those of the Pine-apple, and not of such succulent nature. It is very handsome, and were it not for the somewhat unwieldly proportions of the plant producing it would be of some interest as an ornamental fruit.

The bread-fruit was a tree we found abundant in all the islands, and was tended in every place with much care, as it is one of the favourite plants selected by the "We We" and for the display of its depredatory powers. It nevertheless thrives well, and produces fruit in abundance. "Cassava," as a rule, is not so prolific as in some of the drier districts in Jamaica, but it is generally cultivated by both Creoles and Indians. Tobacco is grown, but is of very inferior quality. Limes are plentiful, but Oranges are scarce, rendered so by the constant attacks of the "We-We" upon the leaves of the tree.

The Star-apple was fairly common, and several trees of Blighia sapida, the "Ackee," were in cultivation near the settlements.

There is one variety of Coconut which is deserving of special mention. It is called the "green-skinned," and though to all outward appearance it is smaller than the ordinary kind, it is found that when denuded of its husk the nut is very much superior in size. It is apparently quite as prolific, the trees are as quick in growth and quite as hardy as the ordinary variety. The nut when ripe is about one-third larger, and is much handsomer than the common one. As water Coconuts they contain a very large quantity of liquid; one we had given us produced sufficient to fill a soda-water tumbler once and a half, and we were informed it was not selected for its extra

size. It would be well for those who intend cultivating the Coconut in Jamaica if they were to seek a supply of this special kind, as without any doubt it is very much more valuable than the common variety, and would command a much higher price in any market.

A destructive animal in the provision grounds is the sloth, which is fairly numerous. It is a disgusting looking creature, and specially adapted in form for living in the branches of trees, &c. It is to be seen occasionally at mid-day perched upon the top of a bunch of Bananas or Plantains, leisurely eating them without any apparent regard to external objects, never leaving the bunch until it is entirely consumed.

Pine-apples of the several commoner kinds are in cultivation on the provision grounds; but just as we were leaving we were presented with two enormous fruits of a superior variety. I immediately recognised this as being the true Smooth Cayenne, a variety which I have not as yet seen in Jamaica. Inquiring into the history of its introduction into the islands, we were told that the plants were introduced from Jamaica. It is one of the best varieties that can be grown, and is highly esteemed, even when produced under artificial cultivation in English hothouses. I cannot take leave of this district without mentioning the immense tract of land on the interior mountains, which without a doubt possess a climate somewhat similar to the Jamaica hills. Hence it follows that there is plenty of room for the cultivation of such products as Cinchona, Coffee, Tea, &c., while the coast districts are suitable for the growth of nearly all tropical products, &c. Cacao is at home in the tracts near the coast, and produces much finer beans naturally than can be exhibited by many other countries which expend a large amount of capital and labour in its production.—J. Hart, Jamaica.—*Gardeners' Chronicle.*

INDIAN AND CEYLON TEA AND COFFEE, AND THE TERRIBLE ADULTERATION OF THE LATTER.

[A mercantile correspondent in expressing the wish that the following article should be republished, says that Messrs. Gladstone and Bright are largely responsible for the adulteration of coffee as sold to the English working classes, but so, in fact, are all M. P.'s who are silent under the present iniquitous system of allowing mixtures of coffee and foreign substances to be sold.—Ed.]

Nature has prepared, in Ceylon and Southern India, a special home for the plants from the leaves of one of which and from the seeds of the other come an average Briton's morning and evening draught. China may be proud of her Pekoe and may set aside her choicest Bohea for the cultivated throats of Mandarins, but events seem to hint that it is no longer her destiny to fill the breakfast urns of "foreign devils" with those sun-dried leaves that have for so long formed her staple trade. In Assam, to the South, and farther down yet in Hindustan, where the black Deccan soil dips away in noble terraces, to the teeming plains of the Madras lowlands, there are districts where the tea shrub can be, and is, as well and successfully cultivated as it ever was beside the canals and willow trees of the Celestial kingdom. Ceylon, again, a little thrown back by her short coffee crops, now finds she can grow good tea, and, what is equally important, can dry and cure it to suit the curious and difficult tastes of Europe. The industry is rising rapidly within the limits of that brightest jewel of the English Crown, and the island hillsides, where the disease-swept miles of coffee bushes stood a year or two ago, have now put on a new livery of verdure and prosperity, and the "flush" of new leaves which marks the commencement of each season finds a counterpart, we must hope, in the cash-account of Englishmen who have been down to the very bottom of the well of despondency till this new enterprize rescued them.

This Ceylon tea is not a mere fancy article. It is good sterling "stuff," commanding a high price in the open market, of recognized strength, cured with the best knowledge of modern times—as regards the best samples, at least—packed judiciously in well-chosen wood, and to be had for the asking in a steady and constant stream. Only two things are necessary to exalt Indian tea to the pinnacle of good repute and fashion—the stern suppression of adulteration in every form and an encouraging initiative patronage by all those who wish well to British trade and enterprize. While dark arts are in certain quarters practiced to a lamentable extent in disguising and weighting teas, coffee suffers even more from this cause than the alternate drink. It is an open secret that consumers at home very rarely obtain a genuinely good cup of coffee untampered with and prepared as it should be. Here, in these stalls at South Kensington, may be seen the bean in its natural state, just as it comes down Indian Ghauts on the backs of a long file of white bullocks, when the "pulp" and "parchment" that composed the cherry-like fruit have been crushed and washed off. Again, we see it here roasted as it should be and ground finely, an operation that should not take place until just before the coffee is needed, as if kept roasted and pulverized long, much of the delicate strength and pungency is lost. When visitors have had a hasty and superficial education in the variety of beans from Mysore, Coorg, the Wynaad, the Neilgherries, Travancore, or whatever territorial designation the sample may bear, they may put their ideas of goodness to a practical test by stepping down to the neighbouring coffee-stalls and sipping there with judicial acumen a genuine cup of coffee, such as that with which Fatima solaced the thoughtful moods of the Prophet, and which to-day serves Afghan and Arab, Nubian and Turk, for meat and drink combined. Coffee is an invigorator for work and a restorative for strained nerves and faculties. It must be owned that the sovereign good qualities of this coffee, grown under the shadow of the British flag, may not strike every one as a happy revelation. English taste is vitiated by long abuse. People have drunk noxious compounds so long that they hug their delusions and hardly recognize anything but a foreign smack in the genuine article when the allied planters and the Exhibition thrust it under their unappreciative noses. In the United Kingdom its consumption hitherto, unfortunately, has been hindered to a great extent by many and shameful adulterations, carried to such lengths that large classes of the population hardly know the flavour of genuine coffee. Chicory is the chief ingredient in the cheap mixtures, because it soon makes hot water black, thick, and bitter, and so gives apparent strength to what may contain little of the coffee-berry. Among many other substances used to adulterate coffee are burnt sugar, roasted and ground roots of dandelion, carrot, and parsnip, together with beans, lupin and other seeds. These are mixed in varying proportions, the only "vegetable matter consistently in the minority" being the substance that gives a *nom de guerre* to the miserable preparation. An analysis of forty-three samples of coffee and coffee mixtures purchased in London during March and April, 1886, shows an average proportion of coffee in these samples of just fifty per cent., added to fifty per cent of burnt sugar and various vegetable substances. Nine of those samples contain from 62 to 93 per cent of chicory, &c., averaging 70 per cent of other substances than coffee. Those mixtures are sold at prices ranging from 10d up to 1s 4d per lb. The price of the pure Indian coffee sold in packets at the Royal Commission's stalls is 1s 4d per lb. Upon a moderate calculation the vendors of many of the compounds just mentioned must be realizing profits of something like 100 per cent., and the worse the mixture the greater the gain; but from the report of the Local Government Board for 1884-5 on this subject we may call a story which shows adulteration *in excelsis*. Coffee, says the evidence, continues to be one of the chief subjects tampered with, and about one-fifth of the samples examined were condemned. "The peculiarity

in one case was that the berries were actually shown to the inspector and were ground in his presence, so that there seemed to be no likelihood of an adulteration. Chicory, however, was found on analysis to be present, and the vendor was fined. It is possible that this fraud was due to the revival of an old practice of compressing chicory by machinery into the size and shape of coffee berries. These sham berries are mixed with real ones, and the purchaser who sees what he believes to be coffee being ground before his eyes, is hopelessly deceived. As chicory only costs threepence or fourpence per pound, the fraud is very profitable. It is no rare thing for so-cal'ed "coffee" to be sold which proves on analysis to be composed of one-fourth part of coffee added to three-fourths of chicory,"

There is no reason whatever why such deleterious stuff should be drunk to the enrichment of unscrupulous dealers and the prejudice of a fine industry; a real article is perfectly accessible if we go to the right quarter for it, and all that remains to be done when we have qualified ourselves to judge by a cup of the Commissioners' coffee is to secure our "Ceylon plantation" or "Mysore"—the older in bag the better, for coffee improves with keeping—and then roast it with skill. A modern Brillat Savarin is, however much needed to teach the true manipulation of the bean. The main care should be to roast the material freshly, as it is needed, and the work may well be done in a dry, shallow frying pan, afterwards storing it only in stoppered glass bottles; having it ground according to the prevailing fashion, or better still to pound it in a mortar as Turks do just before using. Then if the Briton allows himself two ounces to a pint of boiling water poured upon the crushed stone —to boil coffee at any stage is rank heresy—he will have a beaker of healthful and dietetic drink such as too seldom graces the table of any but a wise and select few, and of which Pasquet Rosee himself the first who made and sold good coffee in London, would not have been ashamed.

Half an hour may very well indeed be spent in this Indian room, containing not the least worthy of the many curious and varied collections of this year's show, epitomizing, as all do, the wealth, industry, and endless capabilities of that realm upon which the sun never sets. It matters little that one branch of planting has suffered and succumbed under a widespread blight in Ceylon. Already its place is taken and filled by more than one new and promising enterprize. In India neither tea nor coffee is yet within measurable distance of the limits of production; both stand high in the world's favor, and, though appreciated today, ought to be still more popular to-morrow. With their success is linked a wide field of usefulness for adventurous younger sons, as well as the very desirable flow of English capital to English territories, and the securing of a wholesome and cheap drink to replace the decoction of the cabbage-stalk and burnt sugar, which has hitherto passed by the name of coffee. For many reasons "the planters" corner of the Indian and Colonial Exhibition and the moral it teaches deserve, therefore, public attention and reflection.—*Daily Telegraph.*

TOBACCO CULTIVATION IN LOWER BURMAH AND JAVA.

We are indebted to Mr. H. Caine for the following interesting report, dated 1st June 1886, submitted by him to the Chief Commissioner of the Andaman and Nicobar Islands on the cultivation of tobacco as pursued in Lower Burmah and Java:—

I have the honour to submit the following report on the cultivation of tobacco as pursued in Lower Burmah and Java.

Leaving Port Blair on the 23rd of February, I arrived in Rangoon on 26th instant, and having a little time at my disposal, pending the departure of the Straits steamer, I decided to go further inland, and visit the tobacco districts under the charge of Mr F. Cabaniss, Assistant Director of the Agricultural Department. With this object in view, I left Rangoon as soon as I had informed Mr. Cabaniss of my intended visit. I met this gentleman at Myanoung, on the Irrawaddy river; we started together for Thayetmyo, from which place we proposed dropping down the river in a small boat to see the tobacco on the banks of the river. The following is a summary of the tobacco cultivation which I noticed in the Prome and Thayetmyo districts.—

The tobacco grown by the Burmese in Lower Burmah is usually planted in alluvial deposists without any preparation of the soil. The seed is sown broadcast on the damp mud, and thus allowed to germinate, which usually takes about eight days. When the plants are well up, they are thinned out here and there where crowded, and the surplus plants disposed of at the rate of R1 per hundred plants. The remaining plants are left pretty much to themselves; very little (if any) hoeing or harrowing is done.

Mr. Cabaniss has instituted nurseries for transplanting at his own farm. A better crop could be secured if the same plan were resorted to by the Burmese themselves. The plants could then be planted out at regular intervals, each would have its own area of land to grow upon, and a more regular crop would be the result. Where village upland is used for tobacco cultivation, the soil is ploughed up three or four times, also partly broken up by wooden rollers and five-pronged wooden harrows; in these lands the seed is also sown broadcast, the plants coming up very irregularly. The soil is not pulverized as in Upper India, but broken up into small nodules or lumps.

Curing.—I saw some of the tobacco cured by the Burmese themselves after their own method, which, however, does not differ materially from that of the natives of Upper India, only less care is taken over it: the plants are cut when ripe and left to cure in the sun, exposed to rain and night dews. The samples I saw were dirty and badly cured. Mr. Cabaniss has induced a few of the Burmese to try shade-curing, which would greatly improve the quality of the leaf; he also says that shade-cured tobacco fetched R. 40 to 50 per 100 viss, about 350 lb., which would be one anna and ten pies to two annas three pies per lb. Sun-cured tobacco fetches some R.10 less per 100 viss.

The seed is sown in December and January, and takes about eight days to germinate.

I much regret that owing to my time being limited, I was unable to visit the curing sheds at Myanoung under the supervision of Mr. Cabaniss. However, there was no tobacco-curing at the time. I left Rangoon on the 13th of March and arrived at Singapore on the 20th instant; from thence I crossed over to Batavia on the 23rd instant, arriving at the latter place on the 25th instant. From information received from the British Consulate at Batavia, I decided to go to Sourabaya to see tobacco grown in the Probolingo and Passoerean districts. I arrived at Sourubaya on the 4th, and from thence set out for Probolingo on the 7th. I received letters of introduction to one or two planters from Messrs. Fraser, Eaton and Company, of Sourabaya; these gentlemen were very civil and obliging. I engaged a native cart of Probolingo to take me to Lomadgong, a distance of 40 miles. The roads were in fairly good order, lined by teak and tamarind trees. There were vast tracts of land under rice on each side, also a good deal of sugarcane planted some four feet apart in ridges, allowing free currents of air to circulate between the rows. A fine grade of indigo is also grown in this district. Jack fruit and rambutans (a sort of lichee with a shell like a horse-chestnut) grown in abundance. I arrived at Lomadgong on the 8th, and left this place for the tobacco districts on the following morning. The first planter I visited had finished curing, and was engaged in sorting his tobacco leaf for the Amsterdam market. He showed me his sheds and system of bulking and prising.

Curing sheds in Java.—These sheds are built very large and roomy, made up of bamboos and palm-leaf thatch with plenty of space, so as to permit free circulation of air and to prevent house-burning,

while allowing the plants to hang free of each other These sheds are 300 feet long, 60 feet high in the middle, by 60 feet broad, and would contain 30,000 lbs. of leaf hanging up. In this part of the district the planter grows his tobacco on much the plan as that pursued by the tobacco farm at Poosa, Tirhoot, namely, the cultivator receives so much advance on his land which he cultivates himself receiving the seed from the planter. The seed beds are 30 feet × 3 feet in size. The exact proportions for sowing the seeds are as follows:—

With 1 ounce of seed mix 4 ounces of ashes (wood) and 1 ounce of dry sand, then scatter over the beds and rake over. When the plants are ripe, they are bought by the planters at rates of 9 to 10 guilders, and sometimes when very fine plants, as much as 20 guilders are given for 1,000 plants. These rates vary according to the weight, size, and texture of the leaf.

Planting.—The seedlings are planted out at a distance of $2\frac{1}{2} \times 2\frac{1}{2}$ feet apart from each other, they are topped when 8 to 10 feet high. The plants grow tall with long narrow leaves, and about 20 leaves are allowed to remain on each plant.

In the Kedirie districts the planters in most cases possess the land, and then can make their own arrangements about growing their crops. 4 to 500lbs. is the average turn-out per beegha.

Curing.—When the plants are ripe they are cut off close to the ground, and then hung up in the sheds with twine or some fibrous roots. No splitting of the stalk is permitted, as the object of the planters is to cure slowly.

The curing of the leaves usually takes about 24 days if the weather is moist and favourable. The colour turns out a light brown which becomes a darker shade through fermentation. If the weather is hot and dry, the leaves cure quickly and become more or less yellow which is a bad colour, and unsuited for the manufacture of cigars. Otherwise the curing process is the same as pursued in shade-curing in India.

Fermenting.—When ready cured, and when the leaves come in order, *i. e.*, become moist and limp, the tobacco should be taken down and bulked, the leaves having been first of all stripped from the stalk. The leaves are bulked in three bulks of some 4,000 lbs. each, ends outwards. Some planters fasten a thermometer on to a thin stick, which they insert into a hollow bamboo previously placed, so that the thermometer reaches and remains in the centre of the bulk. When you require to test the temperature, the stick is drawn out, the hollow bamboo remaining fixed. There can be no fixed rule as to the number of degrees you should allow the tobacco to ferment, as some leaves are of finer texture than others and should not be allowed to heat so much as leaves of a coarser kind. However, leaves of the finest sort should not be permitted to exceed 105°, and those of a coarser texture might rise up to 107° or 108°. The object of the thermometer is to let you know the degree of heat, so that the bulk may be opened in time to prevent the leaves from over-fermenting and rotting.

After the tobacco has been bulked a few days, it will have to be cooled. The bulk is then opened, and the hands of tobacco well shaken and cooled. After the cooling process is finished, two of the bulks are made up again into one, taking care, however, that the hands of tobacco forming the outward sides of the first bulks should now be placed more in the centre, and those previously inside now form the outsides. In a few days the bulks will heat again, and must be opened and treated nearly the same way, except that the light colors should be placed in the centre, and darker ones bulked all around them. Three bulks of as near as possible the same degree of temperature should now be made up into one large bulk of 10,000 lb. or so. Some of the bulks I saw contained as much as 40 to 50,000 lb. of tobacco. Each bulk receives as it were three heatings. The bulks are raised three feet off the ground on platforms; this is to keep off the damp as much as possible.

Several of the planters in Java dispense with the thermometer altogether, and simply ascertain the heat by thrusting their hand into the bulk.

Sorting.—The tobacco seldom heats after the third time, if it should, however, still continue to sweat, the bulks must be opened and treated as above explained. As soon as the fermenting is over, the bulks are opened and the leaves arranged for sorting. These leaves are sorted into:

Brown—clear, light, and dark.
Red—light and dark.
Black—light and dark.
Fahl—light and dark.
Streaky.

These are again divided into five different lengths for each colour. Scrubs, which are very small, and poor leaves, are sold locally.

The tobacco costs about 30 cents shipped (5 annas) per lb., and fetches about 50 cents (8 annas) per lb. in Amsterdam.

The tobacco after sorting is baled into square boxes lined with palm-leaf matting, and when the tobacco is well pressed, the bale is made by sewing up the sides and tops. A ratchet screw with four handles is used for prising.

Cultivation.—In Sumatra tobacco lands are used once in ten years; after having once had a tobacco crop, they are left alone untouched for nine years. In Java owing to all the land being under some sort of cultivation, the planters grow on the three-year rotation system.

Seed.—I received two bottles of Manilla Kadow seed from a Dutch planter, which seed I intend sowing this year.

I left Java on the 15th April and arrived at Singapore on the 19th. Left Singapore on the 21st, and reached Penang on the 24th. Seeing that I should not be able to catch the steamer leaving for Port Blair from Rangoon on the 24th, I took advantage of a Government steamer leaving Penang for Taipeng (Perak), at which place I arrived on the 28th. I went up a hill in Taipeng, where there was both coffee and tea. The coffee, planted some 3,500 feet high, seemed very flourishing, good report of its quality having been received from England. There is no tobacco grown here, the soil I saw was not at all suited for it. I believe some tobacco has just been started further inland, but unless they have an experienced curer to look after it, no good result can be expected.

My travelling expenses being very limited, I could not see Sumatra. However, the seed of Sumatra and Java were originally identically the same, *i. e.*, Manilla Kadow. It is the virgin soil which gives that texture and gloss which is so much admired in the Sumatra leaf, the color is obtained through judicious fermenting.

I arrived at Rangoon on the 8th of May, and drove out with a gentleman there who is given to agricultural pursuits, and saw some of his tobacco, about 7 miles out of Rangoon. It was planted much too close, and otherwise badly attended to. None of the tobacco lands of Burmah can compare with Java for tobacco. This gentleman had grown some wheat, which requires a good deal of watering, and cost him a great deal of trouble.

I left Rangoon, on the 19th May, and arrived at Port Blair on the 21st instant.—*Indian Agriculturist.*

Kulu Peach Crop.—The Kulu correspondent of the *Delhi Gazette* writes quite recently:—"There is a simply amazing peach crop, some of my best trees being simply broken down by the weight of the fruit."

Hops, when introduced into England from the Netherlands in 1524, were regarded only as a means of "spoyling good beer," and in 1529 the city of London petitioned against coal from Newcastle on account of the stench, and against hops "because they did spoil the national drink." It was not until 1771 that they became subject to duty.—*Rural Australian.*

TOBACCO CULTURE IN ENGLAND.

The August number of the *National Review* contains an article by Mr. A. G. F. Eliot-James on the culture of tobacco in England. He says that since the cultivation of tobacco in this country was stopped the difficulties besetting the renewal of the industry have materially increased. The English climate, always to a certain extent unfavourable to tobacco growth, has altered for the worse, its variability is more pronounced, the rapid changes of temperature, especially of late years, being against not only vegetable but animal life. The soil, though still very fertile, has less of virgin freshness, and would require, for such an exhaustive crop as tobacco is proved to be, high manuring, which means money an article which our farmers, more particularly our small farmers, are found at present sadly wanting. Manuring is, however, by no means the only expensive outlay needed for a profitable growth of the plant. And, besides the disadvantages of bad climate, unsuitable soil, and want of capital, there are other conditions now attached to the opening up of a home trade which formerly did not exist. Foreign competition is incomparably more severe, the tobacco-grown area of the world has been enormously extended, and the freight charges on the foreign supply so greatly reduced since the time the plant was raised in the United Kingdom, and the cost of transmission consequently so trifling, that it would give our cultivators little or no advantage, certainly no really appreciable advantage, over the numerous foreign growers who would contest them the sale of inferior tobaccos.

Mr. Eliet-James goes a little into detail as regards the disadvantages. First of all, unfavourable climatic conditions. In a warm climate possessing a certain amount of humidity, a tobacco, by ordinary means, can be raised that yields a profit; a warm and moist climate allowing the selection of these fine sorts of leaf which command a high price. Can this be described as a warm climate? The tobacco plant is not hardy; on the contrary, delicate. Frost is most injurious to it in the early stages of growth, and the seedlings cannot be transplanted into the plantations from the beds in which they must be carefully protected until all danger of frost is over. Sown in March and planted out in May, the plant should arrive at perfection in September, and the leaves be gathered before there is any danger of frost, as a single white frost would spoil the whole crop and cause it to rot. Hail-showers at certain periods of early growth are absolutely fatal and high winds very detrimental, as they tear the leaf. Heat, sun-heat, is an essential to the well-being and proper development of the tobacco plant both to ripen it for harvest and to dry the leaf.

Taking soil, the difficulties, though great, are far more easily met than are those of climate. Tobacco requires a friable and sandy soil, rich in those ingredients on which the plants thrive. It draws from the soil, for the proper formation of its substance, carbonic acid, ammonia, lime, potash, magnesia, oxide of iron, chlorine, silica, sulphuric acid, and phosphoric acid. In most soils these essential ingredients are present; not only must they be present, however, but in proper proportions to the wants of the plant, as regards quantity and quality, or else it will not thrive. Tobacco needs a soil rich in humus from the fact that its development must be both rapid and complete. If the soil is not, therefore, naturally rich it must be made so artificially, by high and constant manuring with well-matured manure, carefully prepared for the purpose, and not of too heating a nature, or else blighting of the roof, dust, and consequent failure will be the result. Nitre is one of the principal ingredients tobacco extracts from the soil; and some tobacco-growers, particularly when they crop the same land successively with tobacco, counteract this drain by sowing rye on the land directly the tobacco is cut, and ploughing it under the next May, scattering the tobacco-stalks, cut into two or three inch lengths, over the land the sowing of the rye takes place, and ploughing them in also; both rye and tobacco containing nitre it is thus, as it were, returned to the soil. High manuring, without which even in suitable soil, no good results can be looked for, must be set against probable profits, as also the rent of the land, and the price of labour—no small consideration at the present time. Tobacco is a crop requiring incessant looking after, and a very large amount of hand labour from the time of seed-sowing to the outturn and delivery of the cured leaf into the manufacturer's hands. The number of persons employed would naturally depend on the amount of land under tobacco. The amount of seed required to raise plants for an acre of ground depends very greatly on the vitality of the seed. There are about 100,000 grains of tobacco-seed in an ounce; but the percentage of vitality is low, so from three-quarters of an ounce is usually sown in India to raise enough plants for an acre. Allowing the plants to be two feet apart in each direction, some 10,890 would be required and 4,840 if set 3 ft. apart. The medium distance is often observed of 3 ft. apart in one and 2 ft. in the other direction, and then 7,260 plants are needed. Anyhow, a reserve stock must be kept, as many plants die in the seed-beds or after they are transplanted into the plantations and such gaps must be kept filled up. In America less plants are set to the acre—1,613, if broad vigorous leaves are wanted. Such plants will each yield half a pound of prepared tobacco, or about 800 lb. to the acre; this average of produce to the acre being what the Indian Government farms are estimated to yield; the natives put the production considerably lower. In England the probable outturn may be roughly estimated at 600 lb. the acre.

In cultivation, the following numerous operations are followed:—The land is prepared by manuring, ploughing, harrowing, rolling, the ploughing and harrowing being repeated at certain intervals. The seed-beds are most carefully prepared, sown, and protected; the seedlings thinned out and transplanted in favourable calm weather into the plantations; weedings and light hoeings are given as needed, and followed by heaping, nipping, and topping (some few plants being saved for seed,) and when the crop is ripe, leaf-gathering; all this being hand-labour, the operations having to be conducted with care and delicacy of touch to avoid injury the plants or leaves. With the gathering of the leaf, the incessant labour is not over—indeed, the processes to follow are of a much more delicate and critical nature. Drying-houses will have to be provided, not of a very expensive character, perhaps, but still fulfilling the requirements of shelter and ventilation; wilting-sheds, too, must be built, unless there are unused barns or out-houses handy. If the plantations are far removed from the farm-house it is more convenient to have the buildings close to the standing crop, as the wilting, or withering, and sweating processes are carried on with less risk, as also the stringing of the leaves on a cord, or rather threading, for a needle is used for this purpose. When strung, follows the close suspension in the drying-houses, the outside drying in the sun, or by flue-heat if sun-power is not sufficient; the return to the houses and second suspension, farther apart this time; then what is called the final suspension; and lastly, the sorting, making into hands and packing for the market. It will be seen from the mere mention of these various operations, without dwelling on their intricacies, that tobacco is not simple but an extremely troublesome crop to grow; not an enterprise to be rashly and unadvisedly undertaken by any farmer, even supposing the experiments about to be made point to a favourable decision.—*St. James's Budget.*

The Transit of Tea.—A tea train is now running from San Francisco to New York, the object of it being to demonstrate that the railway transit can be accomplished more quickly than the sea journey by the Suez Canal.—*Home and Colonial Mail.*

COFFEE-GROWING IN MYSORE AND SOUTHERN INDIA.

('From Paper Read in Conference Hall, of Colind Exhibition, July 22nd, 1886, By Colonel Campbell, Formerly of the Mysore Commission.)

The coffee districts of Mysore are the furthest north on the line of the Western Ghats; next to them on the south lies Coorg; then Wynaad and the Neilgherries, and further south again Travancore.

The altitude at which coffee is grown varies from 2,000 to 3,500 feet above the sea, and the rainfall from 80 to 150 inches per annum. The months of heaviest rain are June, July and August. This is the period of the south-west monsoon, which begins to die away in September, and is succeeded by the north-east monsoon in October and November. The rains of this monsoon are not heavy in a locality so far to the west, and fortunately so, as rain is by no means acceptable at the time of picking and drying crops. In December rain sometimes falls. In January and February seldom or never. In March occasional showers are expected, and if none come till the middle of April the coffee tree begins to droop, except on well-sheltered estates, and anxiety is felt about the blossom and the setting of the fruit. At this time the heat is considerable, and thunderstorms towards evening are frequent. But no period of the year is in any special degree unhealthy, as compared with other parts of India, and the mere discomfort of hot weather is mitigated by the sea breezes from the western coast at night, the distance from the sea as the crow flies being not more than fifty or sixty miles. The rainy season is well known to be the healthiest time of the year, and as there is plenty of estate work to interest and occupy the planter out of doors, little regard is paid by him to the weather.

As was mentioned above, the three head-quarters of the Mysore coffee districts are—Koppa, Chicmugloor, and Hassan.

The oldest coffee estates in Mysore—some of them established between forty and fifty years ago—are to be found on the slopes of the Bababooden Hills, which project, in horse-shoe shape, towards the east. In Munzerabad there are estates upwards of thirty years old, and in Koppa, a few of nearly equal age. But numerous estates near Koppa, and in the Sullibyle portion of that talook and elsewhere, to the number of about thirty, have been opened out within the last ten years, and are growing trees, the seed for which was obtained from Coorg, the Wynaad and other places. The coffee from these plantations is distinguished in Mincing Lane from that known as "Old Mysore," and although more than rivalling the prices fetched by other Indian coffees, the "Coorg kind," as it is sometimes called, does not reach the figures obtained for some well-known brands of the "Cannon" description. But there is hope that prices will level up, and that as it is found necessary to fill up vacancies in the old estates by plants of the new kind, the distinction between them will, in process of time, be obliterated. At all events, the satisfactory conclusion may be drawn, that the coffee plant can be made to renew the promise of its youth in a green and productive old age.

The pay is four annas a day for a man, and two annas for a woman. It would be unwise to attempt to lessen it. As the coolie's native village is seldom more than three or four days' journey from the estate on which he works, there has been no necessity to burden the Mysore planter with rules and regulations intended to protect natives of India, who are tempted by large advances and high pay to emigrate to places far distant from their homes.

There is not very much land suitable for coffee cultivation remaining in the Mysore country, which is not either occupied or secured by grant; but there is room—much room—for the profitable employment of a great deal more capital than the majority of planters possess. Nothing is more certain than that in return for capital wisely laid out, coffee will pay handsomely. It is doing so in individual instances in which money and skill enable the fortunate owner to force a fair return in spite of all the well-known drawbacks, which is neighbour, for lack of sufficient means, is unable to overcome. In one word, judicious manuring is the secret of success, not, of course, neglecting the important operations of pruning, digging, &c. Without liberal manuring, the large returns of former years are not now obtainable. But perhaps these returns, if regarded per acre, were not so heavy as is often supposed. The yield from large estates of from 500 to 700 acres was not, as a rule, calculated at so much per acre. The ordinary yield being well-known to the owner and his neighbours, it was sufficient to quote the number of tons more or less in any particular year, and these were obtained sometimes from one block and sometimes from another. But in the more modern estates of from 200 to 300 acres, the calculation is per acre, and large blocks out of this comparatively small area cannot be allowed to remain fallow. It is not economy to open out an estate of less than from 150 to 200 acres, although the question is sometimes asked, why not restrict the area to 80 or 100 acres of choice land cultivated in as nearly a perfect manner as possible? But this risk, for reasons not difficult to imagine, no one is disposed to run.

Take an estate not less than six years old, of average quality in all respects. The outlay in up-keep, including superintendence, but excluding all crop operations on the estate, may range from R50 to R80 per acre. Under the head of crop:—

	R.	
The cost of picking and pulping is .	56	per ton.
Transport to coast	26	„
Curing, shipping, and insurance . .	78	„

Total expenditure on crop, from R150 to R160 per ton.

For R50 per acre spent on careful cultivation, but with little manuring, a return of 3 cwt. per acre, or 30 tons, may be expected in good years. But for R70, or R80, which means liberal manuring, at least 5 cwt. per acre, or 50 tons, on an average, should be obtained. Prices are now showing a tendency to recover from the depression of the last three seasons, and may for present purposes be quoted at £65 per ton net (a reduction of more than 20 per cent. on the prices of 1882-83).

At R50 per acre, the yearly expenditure under all heads in India would be—

	R.
Cultivation and superintendence . .	10,000
Crop expenditure at R160 on 30 tons .	4,800
Total . .	R14,800

The price of 30 tons at £65 would be £1,900, or R25,350, at 1s. 6½d. exchange. Profit, R10,550, or £811.

At R80 per acre, the figures would be—

	R.
Cultivation and superintendence .	16,000
Crop expenditure on 50 tons . .	8,000
Total . .	R24,000

Price of 50 tons at £65 = £3,250, or R42,250. Profit, R18,250, or £1,103.

An income of, say, £1,400 a year, when capitalized at 5 per cent, would be £28,000. But for money embarked in a distant land, with attendant risks, from 15 to 20 per cent. should be looked for with some confidence, and from £7,000 to £10,000 would therefore probably be the approximate valuation of an estate in full bearing, such as has been now described.

The value of a property brought into paying condition, after years of labour, anxiety, and residence in a foregin land, represents, of course, a sum much larger than the actual outlay upon it. An individual intending to open out an unfelled forest, and to bring gradually into cultivation an estate of 200 acres, should have at his disposal at least £4,000, to be expended during the first four or five years. Out of this money he would support himself at the rate of £150 a year. But if he were possessed of no experience in planting, or had not the help of an efficient partner, he would do well to go into training by working as an assistant on some well-managed estate, for, say, two years. Many men have

begun a planter's life with much smaller capital, and by the exercise of great self-denial, coupled with special aptitude for the work, have met with fair success. But such are exceptions, and in these instances the hour of success has to be patiently waited for beyond the ordinary period. On Indian plantations, as elsewhere, young men are received as assistants on payment of a premium, and may eventually gain a living as managers. But without capital it will be a living only, and the life is not to be recommended.

The calculations which have been given above have special reference to Mysore, where, although the conditions slightly vary according to the positions of estates, the supply and the price of labour are more favourable to planters than in most other districts. The figures which follow refer to coffee estates in Coorg, which is a British province lying to the south of Munzerabad in Mysore, and is administered by a Commissioner under a Chief Commissioner—namely, the Resident at the Court of the Maharaja of Mysore.

The present Acting Chief Commissioner of Coorg, Mr. C. E. R. Girdlestone, made a tour in that province in January and February of this year, and inspected a number of coffee estates, one of his objects being to inquire into the state of the coffee cultivation, and to ascertain whether local circumstances were such as to justify a request for a reduction of assessment which had been submitted to him by the Coorg Planters' Association.

The full assessment being R2 per acre, leviable only after the twelfth year, the Association urged that it should be reduced to one rupee for coffee in full bearing, and to eight annas on the remainder of the estate. The Chief Commissioner, in declining to comply with this request, pointed out that, while the relief applied for would be hardly perceived by successful planters, it would not avail to retrieve the fortunes of those who, for a variety of reasons, for which the Government was not responsible, had failed to make their estates remunerative. At the same time, he admitted that the planters had some cause for complaint in the state of the roads, and he promised to arrange that they should be placed in a proper condition.

The result of the Chief Commissioner's inspection of coffee estates, both in North and South Coorg, tends to confirm what has been said above—namely, that coffee may be relied upon to give a fair return for capital liberally and judiciously laid out. One estate of 225 acres is said to give in a good year 50 tons of coffee, or 4½ cwt. per acre, and the average net price last year was £62 a ton. The outlay was about R20,000 on the estate, or nearly R90 an acre, and if to this be added curing and shipping charges, with insurance at R80 per ton of crop, the result will be R24,000 or £1,846 for expenditure, against £3,100 purchase-money, or a profit of £1,254. Allowing for slight differences in rates, these figures are in near correspondence with those which have been quoted for Mysore.

In another estate of about 500 acres, the average yield was 150 tons, or 6 cwt. per acre, and the net price per ton about £65. The expenditure is not given but, taking rates in proportion to those stated above the profit must have been more than £5000. A third estate of 130 acres, yielded last year about 45 tons, or 7 cwt. per acre. Other estates are referred to as flourishing especially some in South Coorg, in what is called the Bamboo District, but figures are not given.

The concluding remarks of the Chief Commissioner, as coming from a disinterested observer after careful local examination, deserve attention and are as applicable to Mysore and other districts as to Coorg. Mr. Girdleston says, "I am by no means singular in the opinion that the success of the coffee industry depends, humanly speaking, on refraining from extravagant payments for land already stocked, on avoiding loans at high interest, on restricting the size of estates, so as to ensure close personal supervision, and on economical and scientific management. If these conditions be observed there is a fair competence attainable by European planters even though prices should remain comparatively low."

A CEMENT very much used at the present day in China and Japan is made from rice. It is only necessary to mix rice flour intimately with water and gently simmer the mixture over a clear fire, when it readily forms a delicate and durable cement.—*American Grocer.*

PLANTING GLADIOLI.—In lifting a quantity of Gladiolus bulbs of various kinds lately, I came across one of the largest I have ever yet seen, and all were as plump and fresh as could be desired; those that were lifted and replanted last season had for the most part two large bulbs with the old decayed one still under them, and others that had remained undisturbed for three or four years had increased into large clumps. The finest bulbs of all were on a raised bed of rather poor soil, and although last summer was excessively dry, and other plants on this bed nearly scorched, the Gladioli produced very fine spikes of bloom, and branched out into several side spikes when the leaders were cut off. I may remark that our soil is light and stony, and that the Gladiolus grows freely in it without the aid of manure. I feel sure that the bulbs are sounder and less liable to disease if grown without gross stimulants of any kind.—*Rural Australian.*

RATS.—Some years since (writes a correspondent of the *Queen*) I took a house in Ireland which had been untenanted for a considerable period; but very shortly after my arrival there it became infested with rats. For a period I submitted to the nuisance, merely allowing a terrier to visit the ground floor during the night; but the advent of an invalid relative caused food to be taken upstairs, and the vermin soon followed, overcoming my patience. Finding the rats behind the skirting board, I had it removed and a liberal coat of gas tar placed there, and, seeking closely, I found the run leading from below, into which I also caused some to be poured. I found this effectually stopped their raid to the upper storey, and then I determined to adopt the same plan on the ground floor, though, I had to take down a dado in my dining-room and entrance-hall. However, after this had been done, I neither heard nor saw a rat in my house for the remainder of my occupancy, which was about twenty months. The gas tar should not be too thick, so as to remain soft for the longest period possible, as the efficacy of the remedy depends on the feet and coat of the animal becoming soiled on passing it.—*Rural Australian.*

THE RESULTS OF THE LAST INDIAN TEA SEASON.—Most of the leading Indian Tea Companies have now presented their report for the past year, and a weekly contemporary has compiled an interesting table which exhibits at a glance the results accruing in regard to 25 of these as compared with those of the preceding year. From this analysis, which will be found at foot, it will be observed that although season 1884 gave good results, 1885, or last season, gave still better returns. Higher values were in most cases obtained for the teas of 1885—the highest average price realised last season for the crop of any garden in Assam, viz., 1s. 5¾d. per lb. was scored by the Jhanzie Tea Association. Among Cachar gardens Borokai Company still bears the palm, the average price obtained for that mark being 1s. 6¾d. per lb. The Darjeeling Company's average 1s. 5¾d. per lb., is also a handsome one. Larger dividends, consequently, were paid to shareholders on the results of 1885. In 1884, as will be seen, dividends ranged from 1 to 15 per cent. per annum. In 1885, however, they range from 1¼ to 20 per cent. per annum, and only four concerns out of twenty-five pay no dividend, while in three of these profits were made, although circumstances rendered a division of the profits inadvisable. It is somewhat surprising that with such handsome results tea is not a more favourite investment among English Capitalists. The shares it is true, quoted on the Stock Exchange, and for this reason probably little is known among the general public of the advantages of tea as an investment.—*Planters' Gazette.*

THE BANANA TRADE: AS IT IS AND AS IT MIGHT BE.

Under these headings a writer in the *Fiji Times* discusses thus the question of the disposal in fruit which cannot be exported:—

Roughly I estimate that six tons ripe bananas make one ton of dried fruit (if my memory does not play me false it takes only five tons). Well let us take the low estimate of 20 tons of fruit per acre, suppose half this fit to ship, green, the remaining half from various causes, such as defective size or appearance of bunch, or surplus over and above carrying capacity of vessel, or the ripening of large quantities between arrivals of steamers, or low price of green bananas in foriegn markets, or possible causes I have not enumerated, the grower sells to be dried, for which I believe it possible to pay him £1 per ton and still leave the driers a sufficient margin for profit and working expenses. Now the question is, Will it pay to raise and deliver them at Levuka or other curing centre at such a price? I believe it will, it pays to deliver cane or river banks for 10 per ton, surely it will pay to deliver and carry a reasonable distance a much hardier crop than cane which is liable to ferment in a very short time. He has also to the good all those bunches fit to send direct to a foreign market; also the advantage of such a case as is now before me where I am informed 1,000 bunches, which if of marketable size, ought to weigh at least 22 tons, have arrived too late for the steamer, and unless another steamer arrives will have to be thrown away which amounts to this, that £22 worth of raw material or its equivalent of £103 manufactured do, will be thrown over-board. This is only a case of many in point. I suggest no royal road to wealth. I greatly doubt its existence except in stock gambling, but I certainly think money might be profitably saved which is now utterly lost. It has been objected to me that it would cost more than the article was worth to place the first instalment on the market; well the only part of the premier transaction which I perceive to be non-rumunerative would be the cost of the travellers' wages and expenses. This difficulty I opine to be unavoidable, but I cannot at all see that so slight a one need crush the industry, and this of course would be a matter of after detail.

There is another use for the banana, viz:—the manufacture of jam. It makes a first class jam and being free from stones and seed is admiraby suited both for the table and culinary purposes; and also I believe the fruit to be suited for canning purposes, though in that I have not practically tested it. In fact to sum up, we are only at the beginning of the banana trade and have only developed one branch of it; the other features are not to be projected without an effort, at least.

OLIVE CULTIVATION IN SPAIN.

Consul Oppenheim says that there are many varieties of the olive tree cultivated in Spain, the better known descriptions being the *Manzanillo. Sevillano, Gordal, Beliotudo, Redondillo, Lechin, Nevadi'lo blanco, Varal blanco. Empeltre, Racimal, Verdejo, Madrileno,* and the *Cornicabra.* Each of these varieties can be reproduced in several ways, but the method of propagation generally adopted is either by *estacas* or by *garrotes.* Both these methods are followed throughout the whole of Spain, though in the central provinces the second process is more general, while the contrary holds good for the south and the extreme north. The time chosen for planting is from January to March in the maritime zone, from January till April in the central provinces, and from January till May in the north. The *estaca,* which is a stout limb of the parent tree about three yards long, is planted immediately after being cut from the tree; a hole is dug to a depth varying between one and two yards, the depth increasing with the severity of the climate. Square pits, about three quarters of a yard each way, are considered to be the best for the purpose. At the bottom of the pit a layer of manure is first deposited, upon which a layer of soil is placed; the limb is then placed in the centre of the pit, and earth is then put in, thoroughly broken up, and pressed down with the feet. In Andalusia it is usual to pile up moist clay against the protruding part of the *estaca,* until no more than about a foot of its length is visible; and this is considered to be very efficient in hot, dry regions, as otherwise it often happens that the limb produces shoots from the lower part only, while the upper part becomes dried up. The moist clay is piled up in the form of a slender cone, and at half its height an opening is left for supplying the limb with water, which in dry weather is done plentifully. The *garrotes* are cuttings of from two to three feet long, and for these the pits are dug somewhat less deep than for the *estacas,* and two of the *garrotes* are planted together, leaning towards each other in such a position that the two cuttings and the bottom of the pit form a triangle, of which the apex is even with the ground. In regard to manuring and filling the pit, the process is the same in both methods of planting, only the upper part of the smaller cuttings must be covered with a little loose soil. The sprouts from these smaller cuttings are more exposed to damage by frost and by animals, and the bearing age is also reached some four or five years later; but it is considered that the trees cultivated in this way are more hardy and productive. During the first eight or ten years after planting, the orchard is ploughed three times a year, and the soil immediately surrounding the plants hoed three times the first and second year, and later twice a year. Manuring is usually effected once every three years, and the autumn is the period generally chosen for this operation. Plaster from old walls is considered to be a beneficial addition to the stable manure ordinarily used, and calcined bones are known to expedite the growth and increase the yield of oil. It has been stated that one hundred kilogrammes of manure increase the product of each tree the first year by over two kilogrammes, the second year by three, and the third year by two kilogrammes again. Artificial irrigation is restored to only in dry regions, or in times of drought; as a rule the grown trees thrive very well without it. In Saragossa irrigation is largely resorted to, as is also manuring, while in Seville there is very little of either. The time at which the olives ripen varies considerably, according to locality and the species cultivated. In Andalusia, when intended for pickling, they are picked usually about the middle of September, and the pickling lasts until the middle of October; at that time the fruit has reached its full development, as far as size is concerned, but is yet green and hard. When the fruit is required for the extraction of oil, the harvest commences in November and sometimes last until January. The usual mode of gathering is by knocking the fruit down with sticks, but careful growers pick by hand, which is less expeditious but more profitable, as the fruit is obtained in a better condition. For pickling there are two methods employed, the first, which is a very slow process, being as follows:—The freshly picked olives are placed in water, which must be changed every day, and allowed to remain a fortnight; at the expiration of that time the water is quickly drawn off and promptly replaced, not leaving the fruit exposed to the air more than is absolutely necessary. The water drawn off is at first very bitter, and this bitter taste will go on decreasing day by day, the taste being taken as a criterion as to when this process is to be considered as completed, a fortnight being the time usually required. The olives are then placed in a solution of salt and water, generally in barrels, in which wine or brandy has been kept. At the bottom a layer of olive twigs and leaves is first placed, which protects the olive from injury by pressure, and on the top of the fruit another similar layer is placed, care being taken to have this layer well covered by the brine. The whole is kept down by oak staves weighted with bricks or stone. all of

which are kept scrupulously clean, as any noxious taste or flavour imparted to the brine will effect the olives, and the vessels are then covered with a cloth or tarpaulin in order to exclude the dust. Olives thus treated will be in good order for boiling or for consumption in about four months, and will keep sound for two years. For pickling by a quicker process, a solution of caustic soda is prepared, and the fruit placed therein. After remaining in soak about one hour, a few olives are sampled by cutting, in order to ascertain how far the solution has penetrated the pulp; the depth of such penetration being easily seen by the colour, and it should not exceed half the thickness of the pulp. When the olives are in proper condition, the solution is immediately drawn off, and replaced by fresh water, which must be changed quickly three or four times, the fruit being allowed to remain in the last water for twenty-four hours. During that time the brine is prepared, and the next day the olives are placed in it. By this method of pickling, the olives will be ready for use within thirty days. In both processes the olives, after once being wetted, are never exposed to the air more than a few minutes at the time, and in handling the fruit, ladles of wood or tin are used invariably. The extraction of oil is effected in many ways, some of them being very primitive. The first pressing is generally done by means of a mill, and the mass, when reduced to a pulp, is soaked in hot water, and is then subjected to a second pressing, which in the Seville district is usually accomplished by means of hydraulic machinery. The refuse of the second pressing is used as fuel, and in some cases as cattle fodder. Recently a new process has come into vogue, whereby a further quantity of fatty matter is extracted which is used for making soap. Where it is not thought advisable to utilise the refuse in any of these ways, it is employed as a fertiliser for the olive groves. It is estimated that the yield of oil generally averages from about 16 to 25 per cent. Consul Oppenheim states, in conclusion, that a considerable export trade both in olives and in olive oil is carried on in Spain, the amount of the former shipped in 1882 exceeding 1,722,000, and of the latter 13,730,000 kilogrammes, the principal countries of destination being the United Kingdom, France, and Cuba.—*Journal of the Society of Arts.*

THE COLONIAL AND INDIAN EXHIBITION AT SOUTH KENSINGTON.

CANADA.

A trophy of fruits shows what may be done in preserving the appearance of fruits. Mr. W. Saunders, of London, Ontario, a pharmacist whose name is as well known in this country as it is as an entomologist in Canada, after many unsuccessful experiments has at length hit upon a fluid which itself remains uncoloured while preserving the plumpness and a good deal of the natural colour of these fruits, and it may be hoped that he will publish some information respecting the preparations employed. Some idea of the fruit trade in Canada may be gathered from the fact that 200,000 barrels of apples are annually produced in Nova Scotia alone. Among the chemical and pharmaceutical products it is interesting to note that there is a collection of chemicals exhibited by the North American Chemical Co., and presumably manufactured in the Dominion. Hemlock bark extract, obtained from bark of *Tsuga canadensis*, is also placed in the same class of products, instead of, as might have been supposed, amongst tanning materials. According to Mr. H. B. Small's pamphlet on Canadian Forests, the manufacture of this extract is assuming large proportions, the export of extract having risen from 190,068 dollars in 1881, to 305,426 dollars in 1883, exclusive of the bark, which amounted in 1883 to 321,291 dollars. According to the census of 1881 there were at that date four factories employing 140 hands engaged in this industry. In a Report of a Committee of Parliament in 1868 it was estimated that an extent of 10,000 acres of the best hemlock land was stripped every year for the bark, the timber being left to rot on the ground. This wholesale destruction threatens to diminish the future supply of a wood that will become more and more useful as the pine disappears. The mineral exhibits are far too extensive to be noticed at length here. Among the more striking exhibits in this class are a large mass of graphite, surmounted by a gigantic plumbago crucible, a fine block of crystalline sulphate of strontian (celestine), magnesite, sulphate of barytes, a very large crystal of apatite (native phosphate of lime) for which £50 is asked, and a case illustrating the manufacture of asbestos; also some good specimens of mica shown close by.—*Pharmaceutical Journal.*

AGRI-HORTICULTURAL SOCIETY OF INDIA:

A Bifurcated Bamboo.

Mr. H. C. Spry, of Dhoolie Tirhoot, writes regarding the very unusual circumstance, which he had recently observed, of a bamboo branching. The following is his description of the phenomenon:—"The bamboo shoots up some thirty feet high, and then divides off into two separate perfect bamboos: the measurements are as follows:—From root to where the bamboo shows signs of dividing 22 feet; at 32 feet it divides, each fork measuring 25 feet; the total length being thus 57 feet. The circumference of the stem at the root is 10½ inches, and the same where it divides: the forks shortly after separating are each 7 inches in circumference." The Deputy Secretary stated that he had not found any record of a similar freak, and had consulted Dr. King of the Royal Botanical Gardens, who had in reply stated that he was not aware of such a case being recorded, and thinks it must be of very rare occurrence. He suggests that the specimen would be valued at Kew. Dr. King remarks that "there is not more reason why a bamboo should not bifurcate than why a palm should not, but palms occasionally do. We have a fine bifurcated specimen of *Dictyosperma Alba* in the garden here." There is also, or was, a branching date-palm at Indore, of which a drawing is given in Vol. IV., New Series of the Society's Journal.—[A seven-branch coconut palm which was one of the great sights of Colombo, was destroyed in the burning of the Racket Court building recently.—Ed.]

Malta Lemon.

Dr. E. Bonavia has frequently, in letters to the Society, alluded to this fine fruit. Some lemons grown by Mr. Stalkartt, of Goosery, were recently sent to him. He writes as follows:—

"I have received the lemons you kindly sent me and which were grown in Mr. Stalkartt's garden, Goosery. Please tell him he has the finest lemon in the world. It is neither more nor less than the *Malta lemon* (*citrus limonitum vulgaris* of Risso). It agrees in every possible way with that lemon—scent and shape of leaf—scent of rind, and shape of fruit; abundance and purity of the acid juice, bears a heavy crop, *heaviest* in cold weather. That is the spring crop, (*sets* in spring). Those you sent me are '*Dumrez*,' or after crop, which ripens in the hot weather and rains. With *mnageium* this lemon tree can have ripe fruit all the year round. The *Dumrez* is smoother, and varies often in shape from the Spring crop, which is rougher. There is no one point in which Mr. Stalkartt's lemon does not agree with the Malta lemon. I should like to learn the history of it. I introduced the Malta lemon in Lucknow in 1863. Last year when I sent your Society some Malta lemon trees, you stated that there were some old trees in the Society's Garden of the same kind, and it was not known they were Malta lemons. Probably your old trees came originally from Lucknow, and Mr. Stalkartt may have got his from your Society. Anyhow I have been sending Malta lemon trees to Assam, and Devikulam, South India, from here, and you have lots of them in Calcutta, from which you could supply both East and South India. This lemon is the *best* for *decoction*, for fever and spleen. More-

over, it makes the best *jelly*, for which I send you a recipe. If Mr. Stalkartt will try it, he will never eat English or Scotch marmalade again. It is, in addition, a fine antiscorbutic; I mean the lemon-jelly. This fine lemon tree is easily propagated by cuttings in the rains in the shade of trees. This is also the best time for *layering* it. In two months the layer's roots fill the pot. The layering is done as follows:—Take a lower branch fit for layering; tie a bit of twine tightly below a joint, so as to cut slightly into the bark, and knot the string. Then bend the part tied, U-fashion into a pot of good soil well drained, cover it with soil, and put a heavy brick over the surface to prevent the branch from springing out. In two months or less, in the rains, the pot will be filled with roots. This can be easily known by lifting the brick, and seeing the roots under it. Then it is fit to separate from the tree, and should be kept in the shade and watered, till planted out. Lime in any form is a good and essential manure for all Citrus trees. Anybody who has a tree of this kind would do a good service by propagating it, and widely disseminating it. It propagates by *seed* and *bud* also. Seeds sown now will be fit to plant out next rains.

"Now for the jelly recipe:—Cut up the lemon very finely, removing all the seeds. To every pound of lemon allow 3 pints of water, soak the lemon in the water for 24 hours (in the rains perhaps less) then boil in the same water in a *glazed vessel*, till quite tender, and let it stand another 24 hours (in the rains may be less.) Then weigh 1½lb of Cossipore crystallised sugar to each pound of the boiled lemon and water. Boil sugar, lemon and water till the marmalade, *on trial*, will *set*. When cool, eat it with toast and butter. According to taste, more lemon juice and less rind can be used.

"I am glad to find you have this lemon tree well established in Calcutta."

Mr. Stalkartt, on being referred to as to the age of his plants, stated that he has known them to exist at Goosery for some fifty years; so it is probable that the Society obtained their grafts from him. Firminger, at page 226, Edition 1874, alludes to lemons distributed by the Society as "the common Spanish, so much used in England," though he adds: "this is not altogether similar in shape to the European fruit," *Kurna Neebo* is given in Firminger as the native name, and under this name the *Citrus medica*, common lemon," is given in the *Hortus Bengalensis*, or a catalogue of the plants growing in the H. E. I. Co.'s Botanic Garden at Calcutta (1814) and the date of its introduction is given as 1796. Mr. Stalkartt's lemons are probably grafts from these plants, which may themselves exist at the Botanical Garden.

Dr. Bonavia, again writing on the subject, mentions that he calls the Lucknow lemon "Malta lemon," as he introduced them from that island, but it is indentical with those grown in Sicily, Malta Spain, Portugal, &c. He adds: "In the olden times the lemon was *C. medica*, then Risso and Poiteau called it *C. limonum vulgaris*; Hooker and Brandis have now called it *C. medica var limonum*."

In a subsequent letter Dr. Bonavia asks for samples of the different limes and lemons obtainable in Calcutta, and these will be sent to him to assist him in the preparation of his book on this useful family.

Mr. Sturmer, of Khaja, Ghazipore District, mentioned at the meeting that he had in his garden plants of lemon exactly similar to those placed on the table by Mr. Stalkartt, and they had been in existence for some thirty years to his knowledge.

Rhea.

At the last Meeting of the Society a letter was read from Mr. C. S. Bayley, Under-Secretary to the Government of India, submitting a sample of Rhea fibre prepared by M. Legros, an engineer attached to the Public Works at Cairo. The following reports were kindly furnished by Mr. W. Stalkartt, of Goosery, and Messrs. Birkmyre Bros.:—

Report.—"Sample of Rhea fibre from M. Legros, Cairo, said to be prepared by a chemical process of little cost,

"Parts of the sample are well cleaned, and the fibre retains its full strength, unlike other samples I have seen chemically prepared; while in other parts of the sample, the gum and bark adhere to the fibre; save for this, the process appears to be efficient. The important consideration is that the strength of the fibre does not seem to be in the least deteriorated by the process, as is unhappily so often the case with chemical treatment."—W. Stalkartt.

Report.—"In reply to yours of 1st instant, we beg to report upon the sample of Rhea fibre, from Mr. Legros, Cairo, said to be prepared by a chemical process of little cost, as follows:—

"The fibre retains its full strength, and does not appear at all injured by the chemical used, but we cannot say that the bark and gum have been effectually removed.

"We enclose you a sample of Rhea prepared by Messrs. Death and Ellwood's machine, and also return you your own samples and letters appertaining thereto."—Birkmyre Bros.

ROOTS AND THEIR WORK.

Uses of Roots to Plants.—*Special Uses.*—We have in considering the various forms of roots spoken of the probable uses for which many of them would be suitable—the strong root for the tall growing plant the much branched fibrous root for the grossly feeding, plant, the wedge-like root for such as need support and grow in crevices, &c. Some plants require long roots to reach to considerable depths, as in many alpine plants where a stem and leaves 1 inch above-ground may have "40 inches below." This is to ensure that the plant gets a supply of water when the soil and surface of the ground are deeply frozen, and which the sun's heat would not affect, whilst the leaves of the plant would soon wither under its heat, no fresh supply of water coming into the tissues. A Statice incana measuring some 9 inches to the top of its leaves actually measured 7½ feet from the neck to the extreme end of the roots. Six of these plants were grown round the edge of a pot, their roots had coiled round and round at the bottom, squeezing the crocks into the "ball." Here, doubtless, the length of the root might be abnormal—it might have grown at the expense of the plant, but evidently the root attains great lengths in its natural home, perhaps enabling it to penetrate among rocks to a fairly depth.

Functions of the Roots.—But we have other than mere variations in the size of roots likely to be of aid in meeting special ends; we have general uses which roots fulfil, which we will briefly mention here:—They support or fix the plants, as we have elsewhere alluded to, and as it is so evident a fact we will not further consider it here. They are the means of supplying most of the [liquid] food necessary to the growth of the plant. We notice that the leaves wither and dry up if they are severed from the root; they may last for a considerable time if placed in water; but it is evident by this that roots are the means by which plants obtain the large amount of water required by them. If we take a leaf of Eucharis amazonica and place it between dry pressing papers we find, after drying it, that instead of being about one-eighth of an inch in thickness, it will now be less than one-hundredth of an inch. This shows how large a part of most plants is water alone. The solid part left after drying might be burnt to an ash, and we could learn what chemical substance it was composed of. It is very evident that these solid ashes could never travel up the plant or enter into it in a solid form, and they must have either got there [in solution] from the air or from the earth.

Action of Leaves.—We learn that there is not enough of the substances required for the plant's food in the air, even were the plant capable of taking it in. Carbonic acid gas, however, is plentifully taken up by the leaves, a very large amount of the ash being carbon. The greater part of the other constituent matter is dissolved in water, and so

passes from the roots through the cells of the plant, and is so carried up to the leaves, &c. Water may also be taken in by the leaves, as we know is the case when they are cut off and placed on the surface of water; also one use of a very damp atmosphere in some of our houses for young plants is to supply them with water, or at least not to allow the water already in the leaves to drain away by evaporation. We might just note here that roots seem to have the power of turning towards moisture or to substances they seem to like to grow in, where also they are generally found emitting more root branches. We learn also that roots have the power to secrete fluids [when in contact with particles of] the soil; at times these secreted fluids are said to aid in dissolving solid matter (as marble even) which may be taken into their tissues when so dissolved. Some roots store up starchy or other matter for the future use of the plant. We may see the swollen growth of the preceding year decaying away as the leaves form, and another reservoir for such starchy matter is built up. There are good examples of this to be met with among biennials, as many Campanulas with a thickly developed "first-root" or tap-root. Dahlia also is a good example, and I expect that Oxalis hirta has its root developed for a similar purpose. Potatoes are about the best example one knows, however, and it is a really marvellous sight to see the innumerable starch granules when exuded from a cut piece, under a powerful microscope; but we have considered Potatoes as branching from (underground) stems, though capable of emitting root fibres as well as buds; they also absorb fluid matter through their exterior which bulbs and corms of Hyacinth and Gladiolus are, I should imagine, unable to do, by reason of their "coat." We might by "stretching a point" consider that roots, as the word is understood by horticulturists, of Drosera, Primula (and Dodecatheon?), had another use to perform, that is, to continue the species by budding.

The Manner in which Roots Perform their Work.—Bearing in mind the remarks made as to the structure especially, but also of the external features of roots, let us discuss how they perform their varied works in aiding the life of the plant. 1. It is not difficult to see how they act as anchors or supports. The few fibrous roots noticed in the Pinguicula and Drosera, the swollen tap-roots of Astragalus or Hippocrepis, the huge branching roots of the Oak or Elm, all plainly tell us by their construction and direction that they support or fix the growths above them. Often the roots of a tree will extend underground as far as the branches do above. There seems a mutual dependence of one upon the other, causing them to grow more profusely, or stretch for further distances as required. 2. As to the absorbing of food by roots. We have seen that the external tissue of all young roots is soft, and that this young tissue, either of cells alone, or of hairs and cells, is present everywhere in roots, from the moss to the highest tree. As any soft substance will absorb water when placed in it, so we might assume the soft tissue of the root would do so. We can indeed see coloured water entering into the root-hairs when these are placed in it. Most plants are not surrounded by very evident supplies of water, and it is here that the longer root-hairs become most useful. They stretch among the particles of soil, and abstract the watery films which we learn enclose all but the very driest particles. All the solid food elements needed, if dissolved in water, would thus be able to enter into the plant. We have next to see how such are taken from the root to the leaves, where we know the fluids undergo necessary changes upon their distribution throughout the plant. If we consider—1st, the action of a sponge or piece of sugar when placed in water; and 2nd, the effect produced by sucking the air from a straw held in water, we shall have a partial clue to the *modus operandi*.

Capillary Action and Pressure of the Air.—We know that in both the cases referred to water will rise above its level in the dish in which sugar and straw were placed. This rising of fluid is due to simple physical laws, depending in one case on the closeness of the particles of sugar for its effect, the water rising up the thread-like openings between the particles, and in the other on the partial vacuum which would be caused by suction necessitating that the water should rise [by atmospheric pressure].

Osmosis.—The cells of a plant, as we saw, are so arranged that watery fluids would rise in or between them as in the sugar, and would be much helped by the evaporation going on from the leaves, compelling its rise, as the suction of water up a straw does. But we often have, as in winter-pruned Ivy, a great surface to be supplied with nutriment, and no leaves to aid in drawing fluids up the stem. Clearly we have great need for another process by which it shall rise, and this has been found by botanists to be indentical with a well-known physical process termed *osmosis*. Roughly this process of osmosis takes place wherever a denser fluid is separated from a lighter one by any thin-walled substance such as parchment, when a current will be set up from one to the other until the densities of the fluid on either side are similar. With the cell wall instead of parchment the cell's denser contents might pass out into the earth, whilst water would be taken in were it not that the evaporation from the surfaces of the plant keeps up a continual inflowing, whilst the currents from one part of the plant to the other are stimulated by the denser contents of cells from evaporation takes place, drawing lighter fluids towards them. This ascent of sap is naturally much more vigorous and *vice versâ* in summer, and nearly ceases in winter. Experiments have shown its force to be very considerable.

Stem Cuttings and their Roots.

These are mostly fibrous. At times, however, some are specially developed, and grow much in length, and harden very considerably.

If we place a suitable piece of stem in the earth, so that it produces roots, various changes take place at the cut end, as follows:—

1. The pith cells shrink slightly and become discoloured, owing to the decay of the damaged cells.
2. The cells forming the ring around the pith cells grow so as to produce a ring of warty structure. This is called "the callus."
3. From below this ring or series of worthy growths are given off in an ordinary manner a greater or less number of roots. In some cases these roots penetrate through the warty cells, but generally I have observed that they spring from below them.

Probable Reasons For These Changes of Tissue.

1. We can understand that the pith cells should decay back where broken—possibly they harden a little—in some cases where a stem is cut at both ends one end may dry.
2. We see the necessity for the woody and fibro vascular cells to be sealed up by some means—as they are by the callus—or else the sap in them would not be properly subjected to the influence which would cause it to spread through the cutting.
3. We have seen that in all root-branches or roots such as these are that there is necessity for some of the denser central tissue entering into their structure. We should then expect that they would (as we saw in Strelitzia) start from the thickened layer of cells. These roots push through the surrounding cells in the ordinary manner.

I believe that before much or any root-growth takes place there must be some pressure of the fluid causing tension in the cells of the plant, and this state cannot well be if they are open in the ground or "bleeding."

A knowledge of the preceding facts will, I think, show us why in many cases we should not expect cuttings to strike.

What will Strike.

1. We should not expect any stem destitute of a fair band of the harder (fibro vascular) cells, either to "callus" or subsequently to emit roots.

2. We should not expect plants having a very thick or hard epidermis to root, as the necessary absorption through thin-walled cells could not take place. Nor would the root branches be well able to pierce the epidermis did they commence to bud.

3. We should not expect portions of the stem in which there was a great amount of woody or thickened tissue (in addition to little outer absorbing tissue) to callus readily enough to allow much change of growth before the cutting decayed.

Naturally we ask ourselves, Can we formulate any rules which will be fairly correct in regard to the chances of cuttings of roots "striking"?

We require the formation of leaf-buds here in addition to the formation of feeding roots. The giving off of fibrous roots we may consider even more likely as were they in a slightly undeveloped state I believe they might grow without callusing of the cutting.

But it will be considerably more difficult for stems or leaves to be given off.

1. A stem requires a pith or central medullary tissue as well as woody tissue. This we have seen is generally absent from roots.

Could the stem-buds, if present or dormant, find enough woody tissue, and also obtain pith perhaps from the outer layer, as they do when branching off from a root-stock, as in Lysimachia, we might fairly consider that our root cuttings would generally succeed. That they sometimes callus without producing leaves is a known fact.

Leaf Buds from Roots.

An examination of Primula cashmiriana and Drosera has led me to think that the reason why these roots [stocks] give off leaves so readily, is because there is no central pith required; the growths are "stemless."

Dodecatheon will produce little rosettes of leaves from every root stock if once the crown has decayed away after flowering. This may not be a fair example of root-propagation, as it may be thought that some portion of a very slightly developed stem would be attached to the upper part of each root and from this leaves were given off.

Rhizomes.

Wherever there are dormant leaf-buds, as on the rhizomes of Helleborus and Dracæna, there is no difficulty in getting plants from small cuttings, but these are not true "root-cuttings." There are cases, as in Ipecacuanha, where stems are produced from annulated root-cuttings, where also there is no pith. It seems rather that we may take it as a fairly correct rule, that where stems are required from our root-cuttings there must be pith. In Dandelion and Dock when cut accross we know there is the power to give off leaves.

We might consider here how universal in the vegetable kingdom is the readiness of certain tissues to emit roots. There must be a trace of a harder tissue than that which exists as an absorbing agent at the exterior of all roots. They are given off:—1, from scales, as in the Lilium auratum, Pinguicula caudata, and many others; 2, from bulbils borne among the flowers (in allium) or from the axils of the leaves, in Lily or Banunculus Ficaria; 3, from soft leaves, as Begonia or Kyophyllum: from succulent leaves, as in some species of Echeveria, &c.; 4, from almost any part of the stems and branches if treated carefully, from the end of Fern fronds, as in Adiantum Edgeworthi; these organs, developed especially to feed the plant, are very freely given off from the other organs of vegetable growth.

Places from whence Roots grow out.

We are not surprised to see, then, that from many lower parts of stems roots and stems (the latter either ascending or creeping) are given off one above the other very indiscriminately. This can be seen in hosts of examples, from palm (Phœnix) to bog-loving creeper.

Roots prefer to grow out from places as in the swollen nodes in stems, where there is more fibro-vascular tissue, and as in the Philodendron, where, though having most of its bundles scattered through the softer tissue of the stem, there is yet a concentric layer below the epidermis of more substance, therefore more really giving off roots.

I may mention that Lysimachia verticillata is an excellent example, showing the roots growing from the dense woody ring in the lower part of the stem if cut across, whilt the branching stems have a growth from the seemingly much-coloured pith (resin in the pith?) passing into them in the centre of the woody tissue.

The Distinctions between Stem and Roots,

Lastly, before passing on to consider the bearing of these facts upon cultivation, we will roughly try and note whether we find any distinction between stem and root, so nearly, as we have seen, do they resemble each other.

1. The growth of the stem upwards away from the more damp earth towards the light, stands out in great contrast with the tendency in all roots to grow towards moisture, and as a necessary consequence towards shady or dark places.

This growth in different directions is in direct relation to the differing functions of the two organs—stem and root. The one bears flowers and leaves spread out to all the influences of air and light—the other as a general thing chiefly developed to absorb water and food which may pass into the whole plant.

2. As to whether there is any difference in external or internal structure I believe is an undecided point. Internally the cells are, to all less thorough investigation at least, just the same. We certainly find that pith is oftenest present in stems and absent from almost all roots, except as in some trees where they branch from the trunk, the pith being present because growing as continuation of that in stem. This pith (though useful in giving more bulk to the stem, from which the leaves may more readily pass off) is needless to the root.

We can all see that the root is colourless generally though when growing in the air at times, as in Chlorophyton, it becomes green, or hard, brown, and stem-like, with bark on it. The epidermis in many stems whilst green has also breathing places, or "stomata." It is sufficiently evident that there would be no need for these in terrestrial roots, although botanists point out among aërial roots, as in some Orchids and in Mangrove, the marks of similar stomata.

3. As to the power in stems, and the absence of this power among roots, to give off leaf-buds, which we have already referred to somewhat fully, I may add that according to the functions of a root we do not need the presence of leaf-buds, and they are never present in true absorbing roots as we should perhaps restrict the term though whether present in storage roots at all frequently I cannot yet make out.
