The argument by which it is shown that the propaganda for coffee in Russia will only redound to the profit of Brazil and her ordinary coffees, while it is affirmed that the Java-coffee has more than a sufficient and certain *débouché*, seems to us rather futile and unconvincing. At any rate this argument is too restricted in sense, with reference to the movement set on foot in Brazil to extend the use of coffee as a beverage; a movement, as broad, open and generous as the proverbial South American hospitality. Brazil makes propaganda for coffee. The different sorts will recommend themselves on their own deserts, and no doubt the best products will be the most in demand and bear off the highest prices. If Brazil succeeds in opening markets for her coffees in Russia, and further extending its already great *débouché* in North America, do not then, as a matter of course, the other markets become freer for the Java coffees and other aristocratical sorts?

Not till ten or fifteen years hence shall we be able to ascertain whether the propaganda for coffee has effected anything, or not. Brazil will go on pertinaciously whether other countries co-operate or not. In the first place, Brazil wishes to gain consumers for the very probable and still augmenting increase of production, and in the second place, to be better covered against the disparity in the article itself, which, though of a transient nature, may possibly arise in the different markets, by an excess of supply over demand. It is desirable to aim at obtaining at least a constant maintenance of the present prices at least, and if possible a gradual rising of 10 à 20 per cent, which would completely satisfy the interests of the Brazilian planter. Can the same be said with respect to the Javan and other coffees? We have reason to doubt it. It is very true that Java is possessed of a certain *débouché* for her coffees, but does not Holland think of the possibility of a great extension of production, when probably the present labouring system in the Dutch Colonies shall have been modified, a system unfavourable to liberty and the improvement of the culture? The higher position that Brazil occupies herein, is in our opinion, that the improvement of the culture in America tends to the enrichment of industry, and not as in the Government culture in Java, to the filling of the treasury. No doubt the ancient and nefarious practise must be broken with, of dissembling the truth of the production and general exports, in order not to deter commerce and consumption. It is incontestable that the production increases more and more, and specially in South America, but do not let us be afraid of publishing the whole truth openly in the great and principal marts of the world; it is indeed still more generally acknowledged that the consumption increases in a still greater degree than the production. The main thing to attend to is—to regulate the stocks so as not to break the [illegible] supply and demand. The pro[illegible] and consumption has [illegible] *the latter*. It must not be [illegible] that the effects of the increase of [illegible] low prices since three years, are only as yet partially felt; but very soon this will clearly show itself. We may and must confidently hope so.

The position is not too bold, that in ten years' time the present exports from Brazil will probably hardly suffice for the consumption in North America; therefore the calculations are pretty securely founded; but notwithstanding this, Brazil is eager to find new *débouchés*, for it is also to be expected that, in the stated period, the general production will also have greatly increased. The milliard of K. G. or perhaps more, that the production of the world will yield in 1893, forces Brazil to look to Russia for new customers, and, at the same time, not to forget endeavouring to extend their custom on the existing markets.

Contrary to the Chamber of Commerce at Batavia, Brazil that occupies itself with contemplating the present in connection with the past, Brazil, in endeavouring to improve her present position. keeps her eye fixed on the future. This is the radical difference of the two points of view from which the same question is regarded. It must not be disregarded, that in South America the object is to produce cheaper and cheaper, in spite of the modification in labour, or, perhaps, just on account of these very modifications, while in general a visible progress in all branches of human labour in those genial regions, but especially of agriculture, is discernible.

The editors of the "Handelsbericht" offer very judicious observations on the equilibrium between the laws of production and consumption, on their mutual relations to the prices, and finally on the prices themselves in proportion to demand and supply on the markets. Over-production cannot be better compared than to a vase, the contents of which run over and are lost; the forcing up of the prices cannot be granted, but by thinking of the equilibrium, caused by competition, which allows neither of extravagant rising, nor continuous falling, and this point has been merely glanced at by the Chamber of Commerce, merely intent upon starting mitigating questions, such as the extent of the cultivated area, the vitality and product, ivity of the plant, involatarily reminds one of a man inquiring into the age of his uncle and the extent of his expectations.

This purely scientific inquisitiveness, based upon self interest. reminds us also of the computation made every year of the probable coffee crop in general. In Brazil, too, people are tempted to this—possibly meritorious, but yet inexact—attempt, and lately a very esteemed paper of Rio de Janeiro estimated the Rio crop for 1883 at 3 millions of bags, and the remainder of the preceding crop at 1,000,000 bags. Another paper agreed as to the last cypher, but evaluated the 1883 crop at only 2,400,000 bags. We make bold to say that such a computation. though made in good faith, must be entirely arbitrary; there is no means to gather the required date in a practical, correct maner, so as to be reliable. Whoever is any way acquainted with the real condition of the immensely extensive coffee-culture in Brazil, will not attach the least importance to such calculations, which look something like the famous *milliard* of coffee trees, said to be standing in the four Brazilian Coffee Provinces. Has any one ever been able to count them?

As to the average cypher of production, about which there has been so much dispute, there is indeed not much use in attending to it. It is almost acknowledged, and in a few years it will be duly acknowledged, that the general coffee-production in Brazil is balanced by nature. There exists no bad years; as there are no good years; what *can* happen, is a general progress or retrogression of production, which is quite a different thing. A culture extending over an area of more than 1,500 kilometres from North to South, and of more than 600 kilometres from East to West, is a very favoured zone, which is remarkably free from great meteorological changes, such a culture keeps its own balance. The intertropical climate of Brazil does not suffer from atmospheric disturbances, or only in a trifling degree, and then only for a part of the vast cultivated grounds.

Earthquakes, cyclones, severe frosts, and destructive inundations are almost unknown in Central Brazil. Besides this, another fact must be adduced to corroborate our assertion. It is known that in general the coffee tree only bears fruit regularly every two years. The new plantations on reclaimed soil of the first quality alone, can yield fruit every year regularly during the vigorous years of the plant. Now the variations in the production of adjacent plantations are often so great, that it is mostly very difficult, taking the crops of one or more districts as basis, to conclude to the goodness or badness of that year's crop. One plantation will yield more than another, while the latter yielded more the preceding year than the former; and then again, there are frequent late crops, that coincide with the new crops, and always considerable reserves, which, in consequence of several causes, pass from one season to the next. The crop season in the four chief Provinces of Brazil, and in higher or lower, or more or less southerly situations, differs too, so that, strictly speaking, the gathering goes on almost throughout the year, though the real and greatest crop is gathered from April to October.

However strange these purely practical particulars may sound, which are imparted without the least presumption by a person, who, more as one interested in the matter than as a tourist out of mere curiosity, has visited some hundreds of the great plantations in the Provinces of Rio, Minas-Geraes and S. Paulo, and therefore in a period of 20 years has travelled over some thousands of kilometres through those immense forests of coffee trees in Brazil; yet we transcribe them here and offer them to the reader, in order to co-operate in throwing more light on the question of the day.

A special circumstance has prevented till, very lately, the totals of the exports of Brazillian coffees being generally known; and this circumstance served casually the very blameable system of concealing the truth; the bad system we have already refered to. The statistics of this article of Rio-coffee run from January to December, and those of the Santos-coffee are reckoned after the financial year, being from July to June. Hence follows an isolated statement of the two most important cyphers of the Brazilian production, and although it is seemingly easy and a matter of course to have merely to add the two together to get the total, yet it is a fact that both in Netherland and elsewhere, people seem to have come for the first time this year to the cognizance that the exports of Brazilian coffee have reached the astounding figure of about six millions of bags.

As regards now the last argument of the "Handelsbericht van Rotterdam," we must observe, that the probability, as well as the prevailing tendency in Brazil, leads to an increase of production, a hypothesis which Brazil deems applicable to all the other coffee producing countries, and especially to those countries which are able, by their cost prices and general expenses, to compete with South America, where these expenses are diminished in inverse ratio to the improvements effected on the article, thanks to the new means of conveyance, the better system of management and the numerous machines adopted. Java, also, will and must obey the laws of progress, not only with respect to the quantity but also the quality, for are there not also other Java coffees besides superior?

But perhaps after all Java is not the most powerful rival of the Brazilian coffee of the future, but presumably such a mighty rival may appear in another part of America, and perhaps even within ten years or so. It is unnecessary to mention the new region opening to the coffee culture. A creditable writer, quite conversant with the coffee question, affirms that the consumption of coffee throughout the world might be tripled, compared with the present consumption.

The centro da Lavoura e Commercio at Rio de Janeiro, foreseeing all this, has taken upon itself to make every propagande for coffee, by more and more disseminating a knowledge of the effects, qualities, virtues of this beverage, by exposing the many adulterations to which it is subjected, by discussing the several statistics, by co-operating towards the adoption of the best system of culture, and towards a better economical condition of the planter, by measures of indirect protection, by contending for a diminution of duties, by organizing periodical or permanent, Exhibitions and scientific and practical conferences or meetings upon the question, and finally, by enlightening consumers everywhere as to the most practical, perfect and the simplest way of preparing the beverage, to which preparation in general, in Europe as well in North America much too little care is devoted.

The opening of some establishments for drinking and tasting coffee in the most populous centres of Europe and America, will be the necessary and also logical complement to the Exhibitions to be organized, and to the various measures for extending its use, of which we have already spoken.

Be it repeated here, that the "Centro" acts only from a sentiment of the *general good*. With a breadth of conception, inspired by the grandeur of the natural scenery of Brazil, this union labours for the improvement of the future prospects of Coffee in general, with the perseverance and courage necessary for the attainment of grand results, supported by the conviction of the real utility of their mission from an economical and humanizing point of view.

The Centro da Lavoura e Commercio do not demand the sincere co-operation of all those interested in this great cause, but neither will they contemn such aid. The "Centro" marches straight to its goal, without caring whether the road will be long or whether it will perform its mission alone or in company with others; all truly noble and useful ideas ever find a lasting support in themselves. We believe we tax the spirit of our age at its true value, when we express the opinion, that wherever the wonderful and creative power of so important a union as that of the "Centro" will make itself felt, that peaceful, but all conquering power, will ever gain sympathy and overcome opposition.

EDOARDO LEMOS,

Delegated Commissioner of the Brazilian section of the International Exhibition at Amsterdam.

—*India Mercury.*

BOTANY OF THE UPPER CONGO.—The handsome Hyphæne palms first appear here,—not H. thebaica, but some species akin to the Hyphæne of the Zambesi. This palm has orange-coloured fruit about the size of an apple, of which the elephants are intensely fond. There is a climbing palm, possibly a Calamus, very abundant in the Upper River. This in common with Hyphæne, is never found growing below Stanley Pool. On the lower river Hyphæne is replaced by Borassus flabelliformis. The genus Menensia exhibits an astonishing variety of species, many of them having developed large tracts (generally white) around the blossoms. These last range in colour from perfect crimson to pale yellow and white. Amomum and Canna are well represented and also Hibiscus and the Malvaceæ generally. The Mimosaceæ and Papilionaceæ present species varying from tiny herbs to giant forest trees. There are also many beautiful lilies, orchids, and Commelineæ, and altogether the flora of the Upper Congo can offer brilliant and almost unique displays of flowers.—H. H. JOHNSTON.—*Field.*

CULTIVATION OF CINCHONAS IN BOLIVIA.—If Mr. Sacc's information can be depended on, the cultivation of good forms of the fever plants has made more progress in Bolivia than we at all imagined: "Writing to the President of the Academy of Sciences, from Buenos Ayres (*Comptes Rendus* xcvii., 206), M. Sacc expresses his gratification at the extent to which during the last ten years the cultivation of the best species of cinchona has been carried on in Bolivia. In the mountains, he says, they are now sown by thousands in nurseries and afterwards transplanted, and he gives a list of seven villages which possess nearly four million cinchona plants between them. The trees are full grown in ten or twelve years and then yield 6 to 8 per cent of bark, the unscientific method of cutting them down prior to the removal of the bark being at present adopted. The Bolivian calisaya bark from this source is said to yield equal to 3 per cent of quinine sulphate."—*Pharmaceutical Journal.* [It is puzzling, however, to hear of the yield of trees which come to maturity in twelve years, while the cultivation is only ten years old.—ED.]

THE NEW ALKALOID, "CINCHONAMINE," is thus noticed in the *Pharmaceutical Journal*:—Some further information has appeared (*Comptes Rendus*, xcvii., 174) concerning the new alkaloid, cinchonamine, isolated by M. Arnaud from a "cuprea" bark (*Pharm. Journ.* [3], xii., 626) which he now states to have been derived from *Remijia Purdiana.* He states that he has again obtained the alkaloid in a state of purity from fresh samples of bark and that several of its salts have been prepared. He finds that it combines readily with acids, the salts formed being usually well crystallized and only slightly soluble in water, especially in the presence of an excess of acid; in hot alcohol they dissolve freely and upon cooling of the solvent crystallize out more readily than from an aqueous solution. The hydrochlorate crystallizes in two forms: from an acid liquid as an anhydrous salt, in very brilliant exceedingly thin prismatic laminæ, very slightly soluble in acidulated water, not efflorescing even at 100° C.; and these when redissolved in hot pure water recrystallize upon cooling in thick flat dull and opaque prisms, much more soluble than the original crystals in both hot and cold water, efflorescent, and containing a molecule of water of crystallization. This property possessed by the anhydrous hydrochlorate of crystallizing in acidulated water allows of the easy separation of cinchonamine from other alkaloids accompanying it in the bark of *R. Purdiana.* The observation has been made by Dr. Laborde that cinchonamine is exceedingly toxic, even in very small doses.

"PEPPER DUST."—Not long since, at the weekly spice sales in Mincing Lane, 609 bags (30 tons) of black pepper dust were sold to a single firm of brokers in two lots at 2d. and 1⅝d. per lb. respectively, the very worst pepper in the market being worth 4¼d. per lb and this in the face of a protest from Messrs. W. and D. Harvest, who had procured an analysis which showed the "dust" to be composed of sand and clay 44·2 per cent, leaves, husk, etc., mouldy and unsound 54·8 per cent and whole grains of pepper 1 per cent. When the question of the sale was put to the "room" only three hands were held up against it, and Mr. Harvest was threatened with legal proceedings for his disinterested interference. Where are the sanitary authorities?—*Sanitary Record.*

BITUMEN, JUDAICUM, OR ASPHALTE from the Dead Sea, is one of the numerous substances that have been put forward in France as a means of combating the phylloxera. According to some information furnished to the French Academy (*Comptes Rendus*, xcvii., 492), the Arab writers, in speaking of the use of this pitch as an insecticide, distinguish three kinds: first, the kind thrown up by the Dead Sea from time to time, which is solid and appears to be identical with the commercial substance; second, that which is found on the surface of the soil in the neighbourhood of the Dead Sea, which is also solid, and that which is obtained in the same locality from below the surface, which is liquid. A sample of the first kind having been examined by M. Delachanal, he found it to yield products of distillation analogous to those obtained from petroleum, together with more than 3 per cent of sulphur. As the substance upon incineration only gave 0·273 per cent of ash, the sulphur, or at any rate, the greater part of it, could not have been present as metallic sulphate. The presence of so much sulphur would appear to point to a mineral origin for this bitumen; and to separate it from those which are entirely of organic origin.—*Pharmaceutical Journal.*

The *Journal de Pharmacie et de Chimie* quotes a report from the French Consul-General at Calcutta, recently communicated by the French Minister of Agriculture and Commerce to the Comité Consultatif d'Hygiène de France, in which the cinchona febrifuge prepared in India under Government auspices from the bark of *Cinchona succirubra* is spoken of in not very favourable terms. It states that analysis has shown that quinine is present in the mixture only in small proportion, about 12 to 13 per cent of the whole, and expresses an opinion that in spite of the difference in price of this product and that of quinine the latter will continue to hold the exclusive confidence of medical men. A further contribution to existing evidence as to the unsatisfactory nature of the pharmaceutical preparations of cinchona has been made by M. Tanret (*L'Union Pharm.*, xxiv., 352), who has examined for alkaloidal strength, astringency and acidity a number of samples of soft extracts of cinchona prepared by himself from different kinds of bark such as are now met with in commerce, as well as other samples from the principal manufacturers of pharmaceutical products in Paris. The cinchona tannin principle was estimated in equivalents of tannin from nut-galls and the acidity in terms of acetic acid. M. Tanret found that some of the extracts, such as those prepared from Loxa bark, contained but little alkaloid and much tannin; those from Huanuco bark, on the contrary, contained five or six times more alkaloid and only one-third as much tannin. Two others, from "grey" barks not more distinctly defined, contained no more alkaloid than the Loxa bark preparations and only one-third as much tannin; whilst some preparations from "Indian barks" appeared to contain little tannin, but sometimes very notable quantities of alkaloids. The conclusion to which M. Tanret arrives is that the medical man cannot know exactly what he is ordering for his patient when he prescribes the soft extract of cinchona.—*Pharmaceutical Journal.*

SPICES AND THEIR ADULTERATION.

As spices in a ground state seem peculiarly subject to adulteration, it may not be uninteresting to note a few remarks of Professor Hilger on the subject.

Adulterations.—The commonest sophistications of broken and ground drugs appear to consist of (1) admixture with previously-exhausted spices from the preparation of essential oils; (2) admixture with roasted bread-crust, powdered wood, ground acorns, seeds freed from oil, malt, &c.; (3) admixture with mineral substances, such as clay, brick-dust, powdered porcelain, chalk, ochre, &c.

Detection.—In the first place, a microscopical examination is necessary, which can be followed by a chemical determination of the percentage of ash and extract, and in some cases of the essential oil and other volatile products, as well as of the alkaloids present in the substance under examination.

Percentage Composition of some of the Commoner Spices in an Unadulterated State.

Pepper.—Ash, 3 to 6 per cent; extract (by alcohol), 21 to 25 per cent. (Pepper is sometimes adulterated with mezereon.)

Cinnamon.—Characteristic for cinnamon is the presence of manganese, which in Ceylon cinnamon is about 1 per cent. and in other sorts goes as high as 5 per cent Ash, up to 4 or 5 per cent; extract (by alcohol), 23 to 29 per cent.

Cloves.—Ash, 4 à 6 per cent; alcaholic extract 32 à 50 per cent; volatile oil 9 à 21 per cent.

Nutmeg.—Ash, 4 à 5 per cent; extract obtained by sulphureted carbon 30 à 40 per cent. The *kanet* nutmegs, which are used for adulteration, consist of bread and clay, kneaded with oil of nutmegs and then dried.

Vanilla.—Ash, 4 à 5 per cent; vanilline (according to system Haarmann en Tiemann) 2 per cent.

Saffron.—Ash, varieable, to a maximum of 10 per cent. A special test of saffron consits in the blue colour, obtained by strong sulphuric acid. Saffron occurs adulterated with other flowers, especially with *arnica*, sandle-wood, saffron stalks, etc.

Ginger.—Ash, at most 5 per cent; extract by alcohol 24 à 28 per cent.—*India Mercury.*

SUGAR AND TEA IN FIJI.

The important item in this direction is the despatch to Sydney by the barque William Turner of the first of the season's crushing from the Colonial Sugar Refining Company's big mill. The cargo consisted of 6,150 bags, equal to 615 tons, valued at £18,450. The Hero also took up to Melbourne 1,601 mats, equal to 35 tons, from the Rewa Plantation Company's mills, owned by Melbourne proprietors. The Manhagen, a vessel of double the William Turner's capacity, is now loading from the big mill, and will take a full cargo to Sydney, so that the company is now reaping substantial returns for its large initial outlay. Throughout the group the crops are in splendid condition and promise magnificent returns. The Penang mill is well sustaining its reputation, and the quality of the product lately placed on the local market from that source is spoken of by judges as being all but unsurpassable. A better estimate may be gathered from the fact that it is bringing £44 per ton in Levuka, but it must be remembered that it has the advantage of a penny per pound protective duty.

The erection of the machinery at Navua, Serua, and Mango is going forward with all expedition, and there is apparently a perfect immunity from serious breakage. Even the Mango exception, mentioned in my last, has, upon fuller inquiry, dwindled down to inconsiderable proportions, and will not, in the managers estimation, entail a loss of over £200. He anticipates that the duplicate of the broken pan will be to hand, and the price be in perfect working order by the beginning of the new year, and there will then be at least 200 acres of ripe cane for it to commence on.

A small quantity of tea grown and manufactured on Mr. James E. Mason's Alpha Estate, Taviuni, has, during the past fortnight, been offered for sale, but that gentleman's town agent, and its strength and purity of flavour are very highly spoken of by those who claim to be judges. The favourable result of the several experiments which have been made at various places on that island leave no doubt as to its capability for tea culture, and the industry promises encouraging returns for its more systematic prosecution. That it will be undertaken at some future time, when the labour question has been placed upon a more satisfactory footing, scarcely admits of a doubt, though at the present rate of progress it will probably be many years before it occupies an important position on the list of exports.—*Australasian.*

CULTIVATION OF CHINA GRASS.

During the year 1882, a development took place of the interest attaching to the cultivation and use, in manufactures, of China grass, and, with respect to the supply of the raw material, it has been estimated that the progress achieved in 1882 was as much as had been done in that direction during the whole of the fifteen years immediately preceding.

According to a detailed statement, published by the *Central Blatt für Textil-Industrie*, the principal feature of the year was the extension of cultivation in Europe, the bulk of the supply having been received, previously to 1882, from China and the adjacent islands.

China grass has recently acquired a position of considerably augmented importance as an industrial product. This sudden advance of a textile substance, in the estimation of the manufacturing public, is not without precedent. Flax and cotton had, it is remarked, a long period of quiet utilisation before they became such important articles as they now are. The discoveries which gave an unexpected impetus to their employment for industrial purposes were, it is stated, Witney's machine for treating cotton in the raw state, and the flax-spinning machine of Philippe de Girard. In the same way China grass owes its present greatly increased favour to the Favier system of treating the fibre; the introduction of this process having been, in fact, a turning point in its industrial history.

In Italy, M. D'Humières has been for several years making experiments in its culture, and he has recently published the fact that, with suitable arrangements, a profit of 33 per cent may be made by the grower. Large plantations have now been organised in that country. Portugal has already planted a million roots; and Spain has also taken important steps in the matter. The plantations in Algiers and Egypt have, it would seem, been materially increased. In Java, companies have been formed to promote the culture; and it is stated that in various French colonies, as well as in America, steps will shortly be taken to introduce it. France seems, however, to have taken the lead in the new movement, and, during 1882, several million roots were imported for planting. In the southern departments, fields of China grass are constantly becoming more frequent. Favier's patent is owned, it is stated, by a company entitled La Ramie Française, which is located at Avignon, and has established nurseries in the departments of Vaucluse, Var, Bouches-du-Rhone, Gard, &c., occupying about seventy-five acres. This company intends to sell plants to the agriculturists, and to arrange for the purchase of the yield. It will also carry on, for its own account, the preparation of the fibre, and will be therefore able to offer it to the spinners ready for them to operate upon it.

The spinning of China grass is being developed upon a scale proportionate to its extended cultivation. Before the year 1880, it is stated that there were only two establishments in Europe where China grass was spun, and it would seem that these could only obtain their supplies from the London market. It is remarked that the establishments referred to have, since then, materially extended the scope of their operations. Six others are said to be now in working order, and, doubtless, others are in contemplation.

In France, many trials have been made as to the employment of China grass in various branches of textile manufacture, and from the successful results, it would seem that an important consumption of the article is assured. Its introduction in the trimming, hosiery, and cloth branches, has been well received. Some further modifications in the spinning of the yarn and a lower range of pieces would, it is said, place China grass in a prominent position as a textile material. The Ramie Française Company exhibited last year (at the Avignon Industrial Exhibition, and at the Colonial Exhibition, at the Palais d Indus trie in Paris) specimens of dress goods, cloths, and other materials, either entirely made of China grass, or into which it entered as a component part.

It is remarked, in conclusion, that the cause of the leading position held by cotton is the low price of articles made from it. A serious competition is not to be looked for, it is considered, on the part of flax, but it is suggested that China grass, if its price is reduced, may be found for certain purposes an important rival of cotton. —*Journal of the Society of Arts.*

THE QUEENSLAND SUGAR DISTRICTS.

Two years have not yet elapsed since the Colonial Sugar Company obtained leave, by a special act of the Legislature, to purchase certain lands at Mackay and on the Herbert River, whereon to cultivate sugarcane and erect sugar-manufacturing works. Since that date a large area of land has been put under cane, 10 miles of permanent railway laid down, two bridges constructed, and a large sugar-mill erected. For this year about 1,500 tons of raw sugar will be produced, and, all things being favourable, next season will see about three times that quantity manufactured; but the ultimate total production is to exceed 6,000 tons per annum. The manufacture of sugar on so extensive a scale by a single company naturally attracts a considerable amount of attention, and more particularly as several very important innovations in the system of manufacture have been made. The most important of these is the double crushing or milling. Hitherto all the Queensland planters have satisfied themselves with obtaining 65 per cent of the weight of the cane in juice, notwithstanding that large planters in other colonies have long since either made use of double crushing, or, as in the Mauritius, of the lately-patented Defribreur-Faure. The Honourable William Russel, of Demerara, is the man whose name is most intimately connected with the practical success of double crushing. At Homebush the cane is ground by a set of three 6 feet rollers, the megass from which is sprinkled by means of a jet with about 13 per cent of hot water, is then carried through a 5 feet roller mill, where it gives up 15 per cent more of juice, making a total of 80 per cent of juice for the total crushing. The megass finally ejected is naturally very dry, and contrary to the usual barbarous custom, it is not spread in the yard to dry, but is elevated into travelling bins, and thence thrown down shoots direct into the furnaces. In consequence of the thorough milling it goes through, there remains in the megass little combustible matter, and the deficiency has to be supplied with firewood. As yet the crushing (milling) is not up to the standard; the feeders at the rollers, being new to work, have not yet mastered the difficulty of regular feeding, but improvement in this direction is a mere matter of time. The mill and the greater part of the machinery are by Mirrlees, Watson, & Co. The juice is clarified by means of the clay (sulphate of alumina) process, and the water evaporated in the two sets of triple-effets—the first to work at Mackay. The scum and waste from the clarifiers and subsiders is put through the filter-presses, of which there are 10. The presses and triple-effets are by the Fives-Lille Company. The vacuum pans do their boiling in three hours and a half, the pumps being supplied by Fletcher & Co. The sugar is dried warm; it is not washed in the centrifugals, the object here being simply to produce raw sugar for the Melbourne and Sydney refineries. To save labour again the dried sugar is dropped from the centrifugals on to an endless band, whence it is raised in an elevator, thrown into a hopper, and from thence drawn off into the bags waiting for it below. The above gives a fair idea of the general arrangement and working in the mill, and shows how differently and in what a superior way the company are managing their works to what is usually done in Queensland.

No sugar-mill producing the large quantity of sugar Homebush is expected to turn out could be economically fed on the old system of carts and horses, and the Demerara system of canal-carriage being out of the question, a very effective substitute both for economy and rapidity has been found in the portable railway system known as Decauville's. This is a French system, invented and manufactured by M. Decauville at Petit-Bourg, near Paris, and of all the systems he or his assistants have tried, Mr. Knox, the general manager of the sugar company, considers this the best. By means of this tramway access can be had at a few hours' notice to the most distant fields of cane, and when once communication has been established, the cane is brought in faster than the mill can crush it. Arrived at the mill, the car carrying the cane is run on to rails which cross the carrier, and from that position the cane is drawn on to the carrier and taken up to the rollers. The saving of labour here is immense. To admit of continuous crushing—*i.e.*, crushing day and night—a set of sidings are being constructed. A sufficient number of cars with cane will be collected here during the day-time, and worked off during the night. In the yard and on the main roads this railway is a permanency, but on the fields it is portable. The points in which the Decauville Petit-Bourg system shines over the others are, first, that this railway is a speciality, the manufacturers producing nothing but rails, cars, and locomotives; that a set of rails come out wedded together in one piece, and hence acquire a stability which is not otherwise obtainable (where, as in a field, the rails are frequently taken up, and get knocked about, this is a consideration); that the set of rails fit together in the field without any bolting (which may be done if permanency is desired), which means a saving in time and labour, and as no bolts are used, none can be lost, and security against loss of bolts and stoppage of work are insured. The cars have the advantage of being low, so that they are not easily overturned; but the most remarkable point about them is their oil or grease box. This box, the Panama box as it is called, when filled with oil will lubricate the axles during a whole month's continual running. The cars are so light that a horse can draw 25 empty and eight when full. The buffers, however, do not appear to work well. The only objection in first cost is in the freight; the rails coming out in sets take up more room than ordinary rails do. The gauge is 2 ft., and there are many miles of this railway on this estate.

The erection of the works was carried on under the superintendence of Mr. Robertson, who is also the manager. He is a man of intelligence and great energy, and his hospitality is unbounded. His experience in Demerara, Fiji, and on the Richmond River has, together with his natural abilities, well fitted him for the important position he occupies.—*Australasian.*

ESSENTIAL OILS OF CINNAMON AND CASSIA.—Second report by Mr. A. H. Jackson on "The Differences between the Essential Oils of Cinnamon and Cassia." In his previous report Mr. Jackson dealt chiefly with the physical behaviour of the two oils and stated his opinion that, whilst there was some difference in their specific gravity and refractive energy, there was nothing sufficiently characteristic to supply a satisfactory method of distinguishing between them. In the present report more particular attention is paid to the chemical aspect of the question. The most promising experiment consisted in a comparison of the behaviour of the residues of the two oils after the removal of all the cinnamaldehyde by treatment with potassium bisulphite and either; but although some slight differences have been noted they are not sufficiently definite to encourage further work in that direction.—*Pharmaceutical Journal.*

A WEST AFRICAN BARK, called "doundaké," used by the natives of the Rio Nunez as a febrifuge, has recently been examined by MM. Bochefontaine, B. Féris and Marcus (*Comptes Rendus*, xcvii., p. 272). The bark is of a reddish-orange colour and is formed of superimposed lamellæ, which are easily detached from one another. The taste is strongly bitter. The plant yielding the bark is a shrub, and is supposed to belong to the natural order Rubiaceæ. An active principle of a bitter taste has been obtained from it, soluble in water and alcohol and possessing an alkaline reaction and the same physiological action as the bark itself. This substance the authors regard as an alkaloid, and they have named it "doundakine." The alkaloid possesses poisonous properties, producing in the frog and guinea pig a cataleptic state with gradual failure first of the respiration and then of the heart's action. In dogs the catalepsy is not so evident. A poison obtained from the natives of Rio Nunez and used in chase and in war produced similar effects, and is believed by the authors to contain the same active principle as the doundaké bark.—*Pharmaceutical Journal.*

LIQUID EXTRACT OF CINCHONA.

TO THE EDITOR OF THE "PHARMACEUTICAL JOURNAL."

SIR,—I have but now met with and read the paper by Dr. Paul, "On the Liquid Extract of Cinchona," reported in your issue of March 10, 1883. I have followed the discussion, and as I was the writer or "assisted" at the authorship of the paper read before the College of Physcians by Mr. Battley in 1838 and alluded to by Dr. Paul, I wish to add that I think Mr. Battley attained the object in view, viz., that of "separating and securing nearly the whole of the medicinal properties of the bark." Mr. Battley was aware that there was some quinine left in the residuum, but the preparation was a most elegant one, "leaving unchanged the medicinal qualities of the substance acted upon, separating and removing therefrom, as far as possible, every matter not possessing remedial virture." It was very highly esteemed by Dr. Farre and other distinguished physicians of that day as offering a means of administering bark under circumstances when the patient could not take quinine, and I have little doubt that if the successor of the late Richard Battley continues, as is presumable, the same process, the preparation will long hold its own against all comers. In justice to another, it is not for me to recapitulate the operations, but I may say that the finest cordifolia bark procurable was used, that the water employed was cold, that it was not a mere digestion and evaporation, but a process of manipulation and elimination, and that no spirit was added at the completion; the result being that it was as uniform a product as could be made. Analysis could not determine the mode of manufacture; criticism did not deter its use. It grew rapidly in professional favour, and was approved by the highest authorities, and if pharmacists could have kept to this one most valuable medicine, instead of purchasing cheaper and much inferior imitations, much time and much fighting would have been spared, and the profession would not have been baulked in the use of an admittedly valuable remedy, still admitted to take high rank. Mr. Battley never advertised it, yet it found its way both in public and private throughout the country and abroad.

One of the speakers at the meeting observered that "the pharmacy of cinchona bark is in a great muddle." He says that "he had always looked on the fluid extract of cinchona contained in the Pharmacopœia as a continuation of a preparation which was originally brought before the College of Physicians by Richard Battley about the year 1830." The framers of the Pharmacopœia have much aided this state of things. Did they apply, before completing their work, to those who were acquainted with the matter in all its details? Did they? In the year 1830 I was working with Mr. Battley in his laboratory, and I can certify that the extractum cinchonæ liquidum of the British Pharmacopœia has no more relation to the "liquor cinchonæ" introduced by Richard Battley, as then and there prepared, than has the extractum opii liquidum to the "liquor opii sedativus" of the same discoverer. I would not have intruded these observations, but having been a party to the work of 1830 and 1838, by the late Richard Battley, I venture to do so.

W. E. HEATHFIELD.

COFFEE AS A HOUSEHOLD ARTICLE.

Official and reliable cyphers prove:—

1st. That the production of Brazil-Coffee has alway been increasing;

2nd. That the use of it abroad has likewise increased;

3rd. That since 1879—1880 the price of Brazilian Coffee has been constantly falling.

What is the reason of this important and persistent deviation? Do the Brazil coffees suffer from foreign competition? Statistics do not seem to confirm this. On the contrary; every day the Santos and St. Paulo coffees supercede the St. Domingo; to these alone are the Brazilian parcels superior, above all other supplies. So the cause of this decline in prices must be sought elsewhere, and this is evidently in the *great disparity between* supply and demand. There is no longer an equilibrium between the consumption and the produce.

How to get out of this difficulty. There is only one way—to open new *débouchés* and to reduce the duties.

We hope that Government will at length apprehend all the advantages to health and general welfare, which would result from abolishing duties on a commodity so indispensable as coffee.

The excessive produce, the important extension given year by year to the coffee-culture, to the detriment of other cultures in South America, are also a cause of this crisis. Therefore the culture must not be diminished, but all obstacles must be removed that stand in the way of an increased consumption. Since Middle Europe and America use annually about 700,000,000 K. G. of coffee, and these regions might consume more than three or four times that quantity, it would seem more rational and more advantageous to promote a larger consumption than to restringe the produce,

Statistics coofirm that the use of coffee is most considerable where the duties are lowest; in other words: the higher the duties imposed upon coffee are in a conntry, the less the use of it is encourged.

Let us take a few figures and look at 1879.

In Netherland the use of coffee is the most considerable, in proportion, for it amounts to 8·12 G. K. per inhabitant. In Netherland there is no import duty on coffee. Yet in Java there are still export duties.

In Belgium, where coffee is only subject to an import duty of fr. 13·50 per 100 K. G., the consumption per inhabitant is 5·40 K. G.

In the United States, where coffee is subject to no import duty, and in Switzerland where the duty is only 3 francs per 100 K. G., the consumption is respectively 3·50 and 3·60 per inhabitant.

In other countries the consumption is considerably less.

In Germany, where the coffee is burdened with 50 francs per 100 K. G., it is only 2·47 K. G. per head.

In Austria where 16 florins per 100 K. G. is exacted, the consumption is still less, viz., 1·05 K. G.

In France, where the duty is almost equal to a prohibition—156 francs per 100 K. G. the population uses only 1·46 K. G. per head. A Frenchman imbibes consequently six times less coffee than a Dutchman, and nearly four times less then a Belgian. A Swiss, or an inhabitant of the United States, uses two and half times more coffee than a Frenchman, and a German uses double the quantity.

General rule: where alcoholic drinks produce much *delerium tremens*, there are few *Coffee-houses* in a good sense.

Where absinthe or gin begins, there is an end of coffee.

Temperance Societies ought to be foremost in insisting on a diminution of import duties, which are so oppressive in France and elsewhere.—H. JOH. SMID.—*India Mercury.*

QUININE AND OTHER CINCHONA ALKALOIDS AND THEIR SALTS.

Of the Cinchona alkaloids the U. S. P., 1870, included three: cinchonine sulphate, quinine sulphate, and quinine valerianate. No less than eight more have now been added: cinchonidine sulphate, cinchonine, quinidine sulphate, quinine, quinine bisulphate, quinine hydrobromate, quinine hydrochlorate, and chinoidin. The P. G., on the contrary, has dismissed quinine, quinine tannate, quinine valerianate, cinchonine and cinchonine sulphate, and retains only quinine sulphate, bisulphate and hydrochlorate, and chinoidin. It may be stated here that the method adopted in the P. G. for testing the strength of the bark in total alkaloids is the modification of Prollius's recommended by De Vrij. (*Pharm. Journ.*, [3], xii., 765). The following are the principal features in the characters and tests of the individual alkaloids and their salts given in the two works:—

Chinoidinum, U. S. P. (new); P. G.—This rather indefinite substance has pretty well dropped out of use in this country,—where indeed it has never been received with any favour,—but it has remained in use in Germany and some other countries, and has now been added to the U. S. P., where it is described as "a mixture of alkaloids, mostly amorphous, obtained as a byeproduct in the manufacture of the crystallizable alkaloids from cinchona." It is stated to be almost insoluble in water, freely soluble in alcohol, chloroform and dilute acids, and partially soluble in ether and in benzol. When triturated with boiling water, the liquid, after filtration, should be clear and colourless, and should remain so on the addition of an alkali. The P. G. requires that it should dissolve clear in an equal weight of a mixture of 1 part of dilute acetic acid and 9 parts of water so as to leave scarcely any residue; it must also form a clear solution with nine times its weight of cold dilute spirit. Both works limit the amount of ash to 0·7 per cent.

Cinchonidinæ Sulphas, U. S. P. (new).—The neutral sulphate of cinchonidine is made official in the U. S. P., and is described as occurring in white, silky lustrous needles, or thin quadratic prisms, soluble in 100 parts of water or 71 parts of alcohol at 15° C., in 4 parts of boiling water, in 12 parts of boiling alcohol, freely in acidulated water and in 1000 parts of chloroform, the undissolved portions becoming gelatinous. This salt crystallizes from a dilute aqueous solution with 6 to 7 molecules of water, but from a concentrated solution with only 3 molecules. It is the form with 3 molecules which is official.

Cinchonina, U. S. P. (new).—Sulphate of cinchonine was already official in the U. S. P., and now the alkaloid is included. It is described as occurring in white, somewhat lustrous prisms or needles, almost insoluble in cold or hot water, soluble in 110 parts of alcohol at 15° C., in 28 parts of boiling alcohol, 371 parts of ether, 350 parts of chloroform and readily soluble in dilute acids. A solution in dilute sulphuric acid should not exhibit more than a faint fluorescence, showing absence of more than traces of quinine or quinidine; it is distinguished from quinine by sparing solubility in solution of ammonia, and from quinine, quinidine and cinchonidine by being much less soluble in ether.

Cinchoninæ Sulphas, U. S. P.—Hard, white, shining prisms of the clino-rhombic system, permanent in the air, having a very bitter taste and neutral or faintly alkaline reaction. Soluble in about 70 parts of water at 15° C., or 6 of alcohol; in 14 of boiling water or 15 of boiling alcohol; and in 60 of chloroform; insoluble in ether and benzol. Heated to 100° C. it should not lose more than 4·8 per cent in weight (two molecules of water); melts with partial sublimation at about 240° C.—*Pharmaceutical Journal.*

TRANSACTIONS OF THE PHARAMACEUTICAL SOCIETY.

Meeting of the Council.

Wednesday, October 3, 1883.

Presentation of the Hanbury Medal.

The President said the next part of the programme was of a different character from the first, which had been more or less connected with the work of students and examinations. He now had to perform, in conformity with a trust which devolved on the Council of the Pharmaceutical Society, another duty of a very agreeable character, that of handing over one of the greatest honours which could possibly be offered in the domain of the particular branch of science included in the trust to a gentleman who was selected *without examination.* Before, however, handing over the Hanbury Medal, it would be necessary to state the circumstances under which it was founded. Mr. Daniel Hanbury, a distinguished member of the Society, and at the time of his death in 1875 probably one of the greatest, if not the greatest pharmacologist in the world, died at a comparatively early age, far too early for the work he might have accomplished. He had done so much work for the advancement of pure science, especially that of pharmacology, that it was thought only fit and proper that some memorial of him should be established in connection with pharmacy. Accordingly, a limited subscription was suggested and immediately responded to; the result was, that shortly after his death, a fund was raised, and the influential Committee that had charge of it, decided that the best way of perpetuating Daniel Hanbury's memory would be to award a gold medal biennially for high excellency in the prosecution of original research in the chemical and natural history of drugs. There was no limit as to country or place. It was a medal open to all the word. A trust-deed was drawn to meet the resolutions of the Committee and the Pharmaceutical Society was made the trustee. It was also decided that the adjudicators of the Medal should be the Presidents for the time being of the Linnean, Chemical and Pharmaceutical Societies, the President of the British Pharmaceutical Conference, and one pharmaceutical chemist, who should, prior to each award, be appointed by the Presidents of the Pharmaceutical Society and Conference. The first award was made to a distinguished German, who was Daniel Hanbury's coadjutor and friend, being the joint author with him of one of the works by which he was best known, the 'Pharmacographia,' viz., Professor Flückiger. This year the judges, having taken the matter into consideration and considered the claims of American, European, British and Irish competitors for the Medal, came to the conclusion that the person of all others deserving the award on this occasion was an Englishman,

MR. JOHN ELIOT HOWARD.

He held in his hand the official award, which he need not read, signed by Sir John Lubbock, Dr. Perkin, Dr. Attfield, Henry B. Brady and himself. He regretted that owing in the one case to domestic affliction, and in the others to accidental circumstances, Sir John Lubbock, Dr. Perkin and Mr. Brady were not able to be present, but they desired him to express to Mr. Howard their extreme regret at not being able to assist at this award. It would ill become him to attempt to enumerate Mr. Howard's qualifications, but he might just say that his scientific work had been very largely, almost exclusively, in the chemistry and natural history of one single bark, the cinchona bark, the importance of which everyone present thoroughly recognized. He had before him three volumes with which Mr. Howard was more or less identified, and in one of them there were illustrations and a description of no less than forty-two species of cinchona. These, with many others, had been studied by Mr. Howard for many years at an enormous expense, for the benefit not only of those who were interested in pharmacology, but all mankind. For having regard to the value of the barks themselves, and the alkaloid quinine, it would have been impossible for the Government of India, and private growers of bark in Ceylon, to have carried on their operations with satisfaction and certainty if they had not been assisted from first to last by Mr. Howard, and the skill he had brought to bear upon the whole subject. Without saying more he would ask Mr. Howard to receive this medal and offer him most cordially not only his own respectful congratulations, but those of every pharmacologist in the world.

Mr. J. E. Howard said words would fail him to express the deep gratification which he experienced in receiving this proof of the appreciation of those for whose judgment he had so great respect. With regard to whatever he might have done in the way of scientific labour, he must say he considered himself still a student, and though he was happy to say he had not been subjected to an examination, he was a member of that Society. He was particularly gratified at receiving this medal, because it reminded him of the great assistance and sympathy he had received from the illustrious man in whose honour it was founded. His own love for science had sprung up spontaneously, and he followed it, not with any expectation of reward, but simply from the pleasure it afforded him. But he was induced and helped forward to publish the results of his observations more by Mr. Hanbury than any one else, and it was therefore to him very specially and exclusively that in looking back he might say he owed whatever advantage might have accrued himself or others—from the publication of his researches. At the late hour he ought not to detain the meeting longer, though he should have liked to say a few words for the encouragement of his fellow students. He trusted they would all find the same interest that he had found in the study of the works of the Great Creator, and that they would all feel that which he would particularly seek to impress upon them, that was no real contradiction between Christianity an Science. For himself he considered it the highest honour to be a Christian.—*Pharmaceutical Journal.*

COMPENSATION FOR UNEXHAUSTED MANURES.

About two years ago a series of papers issued from the pen of Sir J. B. Lawes, on the "Fertility of Soils," which appeared first in the *Agricultural Gazette*, and were afterwards revised and published in the form of a pamphlet. Now we have before us a similar publication, from the same eminent authority, on the "Compensation for Unexhausted Manures," in which the author maintains that the objection of the landowners to legislation upon tenants' claims would be considerably lessened if the value of the claim could be more correctly ascertained.

Dividing the constituents which exist in our crops into two portions, we learn that carbon and water are obtained from the atmosphere, while the nitrogen and mineral substances are derived from the soil. The atmosphere furnishes from 90 to 95 per cent, and the soil from 5 to 10 per cent of the dry substance of crops. The stock of fertility which exists in soils, though generally large, is for the most part in a latent form.

The nitrogen, for instance, which is in combination with carbon, does not appear to be available to any extent for the food of plants until it has been separated from the carbon, and by combination with oxygen has assumed the form of nitric acid. Its manuring properties we know are then very great.

The various mechanical operations which take place on the farm or in the garden—ploughing, digging, trenching, harrowing, rolling, hoeing—have for their one object the formation of nitric acid. A fertile soil is one competent to liberate and render available for the use of plants a considerable amount of active nitrogen from its store of organic nitrogen, while an abundant season is one in which the crops are enabled to take up an unusual amount of this active plant-food by means of their roots.

In an ordinary agreement Sir John supposes the landlord to say to the tenant:—"You may have unlimited powers to extract what you can from the atmosphere, as it is the common property of us all; but of the ingredients of the soil—which are my property—you must only sell such amount as is contained in animal products or grain. You must not sell hay, straw, or roots."

The reason of this restriction is obvious enough when we consider that in relation to the money value, grain, meat and milk remove the minimum of fertility, that is of nitrogen, from the soil; this is plainly shown in the following table:—

Number of Pounds of Nitrogen contained in produce that would sell for £10.

Milk	40 lb.	Roots	250 lb.
Live animal	28 lb.	Hay	428 lb.
Wheat	78 lb.	Straw	510 lb.

Hence the soil constituents removed in £100 value of animals sold off the farm could be replaced by an expenditure of about £5; while the same money value sold off in Swedes could not be replaced for less than £40.

In the pamphlet before us Sir John brings forward many illustrations from his experiments at Rothamsted to show that unexhausted fertility is to be found quite as much in the crops grown as in any substance still in the soil which has yet to be taken up by a crop. In a well-fed pasture it is quite probable that from 60 to 70 per cent of the nitrogen of the grass would be returned to the soil in the urine from the animals, and if the summer were not too dry, a considerable amount of this nitrogen would be available for the production of active growth in the same year. While a pasture may not produce more dry substance when fed than when made into hay, an equal dry weight of the fed grass would be much richer than hay in nitrogen, ash, and digestible food.

If, therefore, the stock of organic nitrogen in the soil is reduced by arable farming, with its constant tillage operations and absence of active vegetation during a considerable part of the year, we might naturally expect that the organic nitrogen would again accumulate during the formation of a permanent pasture; and we are told that it is quite possible for a tenant to divert the fertility from the arable part of his farm, and thus form a pasture by means of the inherent fertility which is the property of the landlord, and not from fertility which he has himself imported.

The following results give us some valuable evidence bearing upon this point:—

Table showing the Amount of Nitrogen per cent in the first 9 inches of dry soil in several fields at Rothamsted.

		Nitrogen per cent.
1.	Root crops grown continuously by mineral manures	0·0934
2.	Wheat crops grown continuously by mineral manures	0·1000
3.	Ordinary arable land just laid down to pasture...	0·1235
4.	Pasture laid down in 1872	0·1509
5.	Pasture laid down in 1863	0·1740
6.	Pasture laid down in 1858	0·2048
7.	Pasture laid down in 1838	0·1949
8.	Very old pasture, age unknown	0·2466

Multiplying these figures by $2\frac{1}{2}$, the product will represent the number of pounds per acre of nitrogen in the first 9 inches of soil. Thus No. 1 field will contain 2,335 lb. of nitrogen, and No. 2 field 2,500 lb. As No. 3 represents the composition of ordinary arable land, we see the reduction of fertility which has followed the removal of crops for a number of years where no nitrogen has been employed as manure. The various accumulations of nitrogen are not only interesting, but extremely instructive; more especially as they have taken place under the most opposite modes of treatment.

Field No. 6, for instance, which has received alternately either an annual application of purchased dung or of artificial manures, has been mown for hay every year since it was first laid down in 1858.

In field No. 5 stock has been fed with decorticated cotton cake, and no hay taken for the last eighteen years.

The analyses of No. 8 was made after twenty unmanured crops of hay had been removed.

Assuming that all these soils were originally virgin pasture, we are able to trace the reduction of their fertility during some centuries of arable cultivation by comparing the nitrogen of the old pasture No. 8, with that of No. 3, the land just laid down to grass. If, again, we compare No. 3 with the soil of the two experimental fields, Nos. 1 and 2, we see the loss which has taken place by a more exhaustive mode of cropping without the restoration of any substance containing nitrogen for a period of about thirty years.

In the composition of the various pasture lands we may trace the accumulation of nitrogen in the soil as the pasture approaches maturity. But in all the instances recorded, Sir John says, the pastures have been formed by large imports of both nitrogen and of minerals, and that the amount and cost of these would certainly form an important item if the value of an established pasture is made the subject for compensation.—*Gardeners' Chronicle.*

FIBRE PLANTS OF INDIA.

BY J. W. MINCHIN (OF OOTACAMUND, MADRAS PRES.)

The cultivation and treatment of fibre plants in India, has occupied the attention of the Society of Arts on several occasions. The great botanist, Dr. Forbes Royle, first suggested the importance of the fibre-producing plants of India in 1854; and Dr. Forbes Watson, in an exhaustive paper before the Society, in 1860, enumerated the most important varieties; having, with the assistance of the Indian Government, collected specimens, and prepared plates representing them, which were published in the *Journal* of the Society (vol. viii. p. 448). Mr. Leonard Wray read a paper on Indian fibres in 1869, and it was again the subject of an article by Mr. P. L. Simmonds, in 1873.

Notwithstanding these frequent discussions and the thorough knowledge that has been obtained of the value of the different principal Indian fibres, and of their cultivation and production, there has been no great commercial movement in the export of these fibres, and this is due to the difficulty that has been encountered in the treatment. The cost of preparing the fibre for the market by the native method of hand-scraping being prohibitive, and no machines or process for the economical preparation on a large scale having, until lately, been introduced.

For the valuable fibres strength and brightness of colour are essential. The ordinary process of retting or fermentation in stagnant water cannot be followed.

The *Corchorus*, or jute fibre, is used principally for coarse bags, and such purposes where the strength and colour of the fibre is not important. It can be produced at a very cheap cost; the cultivation of an acre of jute is estimated at R10 for the labour, and about half-a-ton of fibre is the usual crop; while by the retting process, one man can prepare for market about two cwt. of fibre in the day. The cultivation of jute has been taken up largely by the natives in India. The export stated by Dr. Forbes Watson in his tables, in 1860, at 88,000,000 lb., had amounted in 1874 to 560,000,000, or seven-fold in the fourteen years. For the more valuable fibres this retting process is not available; a man can prepare only 5 lb. to 12 lb. of rhea or Manilla hemp fibre in a day by hand-scraping, while the waste is enormous.

The necessity for some mechanical treatment has been long recognised. In 1872, the Government of India offered a reward of £5,000 for any machine that could separate rhea fibre in a green state, at a cost not exceeding £15 per ton. The conditions were not fulfilled, but a reward of £1,500 was given to Messrs. Greig, for relatively good results. The reward has since been withdrawn. The cultivation of rhea has now been successfully introduced into the South of France, Algeria, and the Southern States of America; and the attention of scientific men to some chemical or mechanical treatment has been continued.

There are now two machines and two processes that claim to treat green fibre successfully. This being accomplished, the golden hopes of Dr. Forbes Royle and of Dr. Forbes Watson, as to the future of Indian fibre, may be realised.

As the soil and climate of the hill districts of Southern India and Ceylon, with which I have been connected for the past twenty-five years, seem to me to be specially adapted to the cultivation of fibre plants; and as the introduction of any new industry is at the present time urgently wanted by the European planters settled in those portions of our Eastern Empire, I have ventured to bring the subject forward again, for the purpose of urging the adaptability of this cultivation to the circumstances of the hill planters; and the fact that lately invented chemical and mechanical processes have supplied the economical and commercial prospects of success which have so long been desired.

The following fibre plants are suitable for cultivation in the hill districts of Southern India:—Rhea (*Urtica utilis*), Neilgherry nettle (*Urtica heterophylla*)—these are dicotyledons, or exogenous plants, the fibres residing in their bark or bast—plantain (*Musa paradisiaca*), wild plantain, Manilla hemp (*Musa textilia*), aloe (*Agave Americana*), pine-apple (*Bromelia ananas*), wild pine-apple (*Bromelia sylvestris*, mooga, or bow-string hemp (*Sansevieria zeylanica*), mudar (or *Calatropis gigantea*)—which are monocotyledons, or endogenous plants, the fibres being embedded in the pulp of their roots, stems, and leaves. These, and other kindred plants are indigenous to India, and can be cultivated without difficulty.

Rhea (*Urtica utilis*), *Bochmeria nivea ramia*—China grass—is a perennial plant. In China, fields of rhea are said to last, with care and manure for 80 to 100 years. It grows in Sikkim and Nepaul at an altitude of 3,000 feet. It has been cultivated successfully on many coffee estates in India and Ceylon; but it requires rich unexhausted soil. It grows with the greatest vigour in damp warm climates. In the islands of the Indian Archipelago it is cultivated under shade. It requires a light but fertile soil, but it must be well drained. It is propagated from the separated roots, from layers, slips, or cuttings; in this way five cuttings of grown stems can be expected in the year after planting; from seed, no crop can be expected before the third year.

M. Favier describes the plant as giving out several stems, of which the number increases in proportion to the development of the root, which forms a kind of tuft or bush. The stems are woody, and have the appearance of thick strong rods, the height varying from 5 to 12 feet. The roots, slips, or layers should be planted 18 inches apart, and after the first crop the alternate rows should be transplanted into new fields, leaving the remainder, about 3,500 plants per acre, to spread and cover the ground. The yield in Java is said to be 44 stems per year from each stool, taken in four cuttings. Each stem in its green state weighs about 1 lb; 100 lb. weight of green stems yields 5 lb. of a raw fibre or filament, which, by Muspratt's analysis, as quoted by M. Favier, contains 66 per cent of pure cellulose. In the official reports to the India Office, with native hand treatment, the crop is said to be 1,000 lb. of raw fibre per acre, taken in four cuttings. M. Favier states that, in Algeria, 1,400 lb. of fibrous thongs was the crop per acre, as calculated by Mr. Hardy, ex-Director of the Botanical Gardens there, while in the South of France as much as 1,600 lb. of filament have been obtained to the acre.

Mr. P. L. Simmonds, in his article in 1873 (*Journal*, vol. xxi., p. 762), stated that the crop gathered in Jamaica amounted to 300 lb. per acre at each cutting, and that there had been five cuttings in the year, making the yield three-fourths of a ton per acre per year. While Mr. Bainbridge, in the discussion on Mr. L. Wray's paper, in 1869, stated that the result of his own experience in Assam was 750 lb. green nettles, which gave 45 lb. weight of fibre in each of three cuttings, making only 135 lb. per acre per year (*Journal*, vol. xix., p. 453). The yield appears to depend on soil, climate, and treatment. The properties of the rhea fibre place it in the first position among vegetable fibres; it is second to none in strength, while the fineness or attenuation of the fibre places it before flax, and it is equalled only by the pine-apple fibre. It can be used for any textile purpose, having been mixed with cotton, wool, and silk, to advantage; it is in special demand for sailcloth, table napery, curtains, and tapestry; but from the very limited supply as yet available, the applications of this beautiful fibre are yet in their infancy.

Neilgherry nettle (*Urtica heterophylla*) is an annual, and can be readily grown from seed, giving its crop in about seven months. It gives a strong white glossy fibre, and a sample, hand cleaned, was valued at £125 per ton. The cultivation has not been tried on a commercial scale; the difficulty will be in the cultivation and collection of the crop, as the leaves and stem are armed with a most poisonous sting. It has occupied the attention of planters on the hills for many years past, but no means of treatment was known.

Plantain (*Musa paradisiaca*) is generally cultivated for its fruit; it should be planted about six feet apart, and each stem will give about 4 lb. of raw fibre, and 50 lb. of fruit per year. The fibre is fine, white, and silky; long, light, and strong. The quality depends on the mode of cultivation and treatment; but it is not so valuable as Manilla hemp. The Government of India have constantly urged the value of this material for paper making; but no use has ever been made of the millions of trees grown in India for their fruit. The stems are cut down and left after the fruit is moved.

Manilla hemp (*Musa sylvestris*) has been successfully grown in Wynaad and other hill districts, since 1864; but hitherto to no commercial value, from inability to treat the fibre. It is grown extensively in Manilla, where 250,000 acres are planted with this staple; it has hitherto been treated only by hand, the natives preparing about 12 lb. weight of fibre per day, and receiving one-half its value for the work, the waste being so great that only about 1 lb. of fibre is obtained from each tree. Yet notwithstanding this, the exports have amounted to 35,000 tons annually. Manilla hemp is imported into Europe and America for rope-making only, and is worth £20 to £60 per ton, according to quality; the crop may be taken at from 10 cwt. to 2 tons per acre, according to successful treatment.

Aloe (*Agave Americana*) will thrive on any sterile waste land, and is now common throughout India. The cultivation is being extensively carried on in Mexico, where 5,000 plants may be found in an acre. It comes to full growth in three years, and can easily be propagated from suckers. The fibre is principally used for mixture with Manilla hemp in the manufacture of cordage, and is worth about £10 per ton less than Manilla hemp.

Pine-apple (*Bromelia ananas*) and (*Bromelia sylvestris*) produce a very valuable fibre. The former is cultivated for its fruit in all coffee estates, and the latter is found in large quantities in all the jungle swamps in the hill districts. The fibre is valued at £45 to £55 per ton.

Bow-string hemp (*Sanseviera zeylanica*) can be propagated on almost any soil, from the slips which issue in great abundance from the roots; it is perennial: the wild leaves are from 12 to 16 inches long, but under cultivation attain 3 to 4 feet. Dr. Roxburgh estimated that an acre of land would produce three-fourths of a ton of clean fibre.

Mudar tam. zercum (*Calatropis gigantea*) is common on all waste places in India. Mr. G. W. Strettel, of the Indian Forest Department, in his pamphlet, "A New Source of Revenue for India," published in 1878, urges the value of this product on the attention of the Indian Government. It comes to maturity in a year, is perennial, and requires no care. Mr. Strettel estimates the cost of bringing an acre into cultivation, planting four feet apart, at £2 9s. 8d., after which the only recurring expense would be for harvesting and treatment. He estimates that it will yield a crop of from five to seven hundredweight per acre yearly, and the fibre is pronounced equal to good flax, and therefore worth £40 to £50 per ton.

The treatment of green fibre has now been successfully accomplished by the following machines and processes:—

1. The machine of Messrs. Death and Ellwood, of which over one thousand are now in use, for extracting fibre from all kinds of aloe, plantain, and pine-apple, &c., in Mauritius, Canary Islands, Africa, &c. It is almost the only machine in use for extracting Henquin fibre or Sisal hemp, and Ixtle or wild pine-apple fibre, in Central America, of which 17,000,000 lb. weight are now exported annually. It is being tried in Manilla for the treatment of Manilla hemp. The jet of water which acts as an elastic cushion on which the fibre is beaten, to clear it of boon and useless particles, acting also most satisfactorily in removing the gummy matter which causes the principal difficulty in the treatment.

2. An ingenious invention of M. Roquet, a Frenchman, for crushing and scutching vegetable fibres at one operation, which has been patented by Mr. W. M. Adams in this country and elsewhere. It treats all kinds of dry fibres most thoroughly, and has also successfully treated green rhea fibre from Kew Gardens.

3. M. Favier, a Frenchman, has suggested a process of treatment for rhea fibre, by steaming the green stems in the field. This enables the easy decortication of the bast by cheap hand labour, at a very small expense, and saves the cost of carriage of the woody portion of the stems, these being used for the fuel of the boiler that creates the steam. The stem ashes can be at once returned to the field as manure, together with the leaves and waste, so that only the fibre itself is removed from the soil; by this process it is calculated that the fibre thongs can be obtained at a cost of 30s. per ton.

4. The process which is known as Ekman's patent, for the manufacture of cellulose or ultimate fibre from raw fibres, by treatment with the bisulphite of magnesia. This process consists in boiling the fibrous substance under a pressure of 90 lb. of steam, in water containing sulphurous acid, in combination with sufficient magnesia to prevent the oxidation of organic matter. This chemical treatment produces an ultimate fibre from the rhea plant, which is worth £168 per ton, or three times the value of the best cotton.

Seeing that it takes 100 lb. of green rhea stems to make 5 lb. of raw fibre or filament, worth at the rate of £45 per ton in the English market. M. Favier's steaming process, which saves the carriage of the woody portion further than the field in which it is grown, is an economical consideration of the highest importance.

This raw fibre or filament, after treatment in M. Ekman's boilers, is reduced from 5 lb., worth at the rate of £45 per ton, to 3½ lb. of ultimate fibre, worth £168 per ton. When this process is undertaken by the grower in India, as soon as possible after cutting and decortication in the field. the fibre is saved from the damage that is constantly going on from fermentation, as long as the tannic gum is attached to it; it being impossible thoroughly to dry the fibre while this gum remains. There is no trouble in at once drying and packing the ultimate fibre. The cost of carriage to the manufacturing market is reduced to a minimum, and the pure fibre is in no way damaged by pressure in packing under screw or hydraulic press. At the same time the cultivator obtains the full manufacturing value, which is otherwise intercepted by the mill men, who scutch, comb, and prepare the fibre for textile uses.

It seems that for dicotyledons, or exogenous plants, such as rhea and Neilgherry nettle, M. Favier's steaming process, in conjunction with M. Ekman's bi-sulphate of magnesia process, have attained the desired object, economical and thorough treatment.

For the monocotyledons, or endogenous plants, such as plantain, Manilla hemp, aloe, pine-apple, &c., the machines of Messrs. Death and Ellwood, or M. Roquet, are required. For the coarser fibre obtained from these plants, no further treatment is necessary; these coarser fibres are used for rope-making. The finer fibres, such as those obtained from the *Bromelias*, and the selected finer portions from other kinds, may be advantageously treated in M. Ekman's boilers; while from the waste and inferior stuffs a paper pulp may be obtained which will be an important item in the receipts of the estate. In the cultivation of the fibre plants I have enumerated, the planters on the hill districts of South India will have varieties suited to every exigence of their soil and climate. For their exhausted fields, which are no longer suited for the cultivation of coffee, cinchona, or tea, there is aloe, mudar, or moorga available, which will flourish on the poorest and most exposed hill-sides. For their low lying rich valleys, at elevations too low for coffee or cinchona, such as the lower slopes of the Ghats, the cultivation of rhea fibre can be carried on; on the level land, where ploughing is possible, the Neilgherry nettle can be sown to advantage. The undrained swamps can be planted with the *Bromelia sylvestris*, and the borders of the streams and steep forest hills can be cultivated with plantain and Manilla hemp.

The store houses and water-power generally found on the coffee estates that have been erected for the preparations of the coffee crops, and which are unused for nine months in the year, will supply the motive-power for the scutching machinery, and drying accommodation for the fibre. It is probable that the cost of Ekman's boiling and chemical process may be too considerable for each individual planter; but some convenient central factory established in each district, or on the coast, may enable the planters to obtain the benefit of this process, on the same principle as is now in use for the ultimate preparation of their coffee. It therefore seems that good hope is afforded, that the cultivation of fibre plants may relieve the Indian and Ceylon coffee planters of much of the troubles that have befallen them, from the persistent attacks of the *Hemileia vastatrix*, or leaf disease.—*Journal of the Society of Arts.*

GATHERING CAOUTCHOUC IN EQUATORIAL AMERICA.—The tapping of the trees they had discovered was being actively carried on. The adventurers, clad in ragged pantaloons, the body naked, were behaving like demons under the supervision of their chief round the gigantic Figs (Ficus), whose bark they were tearing off by slashing it off with their hatchets. The operation reminded me of the process of gathering resin in the Landes of Gascony. But here, instead of zinc cups to receive the resinous juice, the *caucheros* placed Heliconia leaves, on which the precious latex flowed, white as milk. The liquid was collected and poured into calabashes (*totumas*), where it soon coagulated and formed caoutchouc, ready to be packed and exported.—ED. ANDRE, "Le Tour du Monde," p. 399.—*Gardeners' Chronicle.*

TIMBER TREES FOR SINGAPORE.—The Government of the Straits Settlements has recently indented on the Government of India for a supply of seeds of various Indian timber trees. Sir F. Weld, the Governor of that Colony, intends to make experimental timber nurseries at or near Singapore, and the list of trees, amounting to nearly 50 kinds, includes most of the common timber trees, such as sál, sissú, chir, pine, the terminalias, tún, ebony, and others, but strange to say omits teak. Where it is thought that seed will not survive the journey, it is suggested that Wardian cases should be sent; but we fancy that the estimated cost (about R500) will not allow many Wardian cases to be sent, as they are rather expensive articles. The amount of seed asked for is more than 12 maunds. While admiring the energy of Sir F. Weld in endeavouring to procure good timber trees from Singapore, we should like to know more about the natural resources of the colony in that direction before awarding high praise to this measure, as the first step in rational forestry is to husband and utilize the indigenous material of the country. We hope to be able to place some account of the forests of Singapore before our readers at an early date.—S.—*Indian Forester.*

AN ANALYSIS OF TEA.

It has recently become the custom in selling teas in New York, to have a sample analysed as a guide to purchasers. The analysis given below was made from a sample of 164 packages of Indian tea, of good quality, sold in New York last summer; and, as it is quite full, we think it will prove of interest to our readers:—

	Per cent.
Hygroscopic moisture	5·980
Extract...	40·350
Total ash	5·200
Ash soluble in water	3·122
Ash insoluble in water	2·078
Ash insoluble in acid	·212
Insoluble leaf	53·670
Tannic acid	16·677
Theine...	2·090
Facing and coloring matter ...	None.
Foreign leaves	None.
Exhausted leaves	None.

—*Popular Science News.*

SOME OF THE CHARACTERISTICS OF SOILS.

In last month's number of *Forestry*, Mr. D. M'Corquodale calls in question a recent remark of one of your contributors to the effect that the annual growth of 'grass, brackens, and other weeds,' in plantations is liable to further the exhaustion of the soil in such places, and he slyly suggests that if the grasses and weeds bring about exhaustion, the growth of 100 tons of saleable timber to the acre must be a serious matter to the soil. But such short and close herbage as 'grass, brackens, and other weeds,' if allowed annually to wither and decay where it has grown, adds considerably to the fertility of the soil; and land under timber stores up each year in the surface soil the food constituents most required by our cropping plants. And this we shall endeavour to make plain. Out of the sixty-four yet known elements that together go to form our earth, sea, and air, only some twelve or so are found in the analyses of plants, and of course these must be present in company with other matter in all soils capable of sustaining vegetation. Of some, however, the plant requires but little, while of others it has to absorb a considerable amount. Those few elements combining one with another, or one with several, and in various proportions, go to form the many different compounds which are required to constitute a soil fit for cultivation: oxygen and hydrogen unite to form water, hydrogen and nitrogen to form ammonia, calcium and potassium each unite with oxygen to form respectively lime and potash; carbon, nitrogen, and phosphorus unite with water severally to form carbonic acid, nitric acid, and phosphoric acid; and these three with lime, potash, and soda to form the carbonates, nitrates, and phosphates of the latter three, and so on. And out of those few the vegetable kingdom elaborates innumerable substances ranging from simple starch to the subtle poisons of the alkaloids. The plant cannot lay hold of and assimilate to its substance any one free and uncombined element, unless perhaps we except the free oxygen of the atmosphere; when the plant is under certain conditions of growth it cannot avail itself of the free nitrogen of the surrounding air. Nor can it absorb any uncombined carbon—the element that forms the great bulk of the plant. Carbon when by itself is a solid and almost insoluble, but combined with oxygen it forms carbonic oxide, a gas, and plentiful in the atmosphere. Under certain conditions, owing to some mysterious action of sunlight on the green colouring matter of the tender parts of plants, the plant is able to decompose this oxide by which it is surrounded, and to turn the carbon to its own uses, and also to avail itself of the free oxygen if required. Thus carbon, and oxygen, and watery vapour too, which can penetrate the delicate outer membranes, are all the substances the plant is able to obtain by means of its leaves and other exposed parts. The rest of its food it must take up by way of its roots. The greater volume of the water it requires is taken up through those channels, and it carries with it what it is able to dissolve from the soil. But the active or absorbent parts of the roots have the property of so acting on some matters required by the plants which are insoluble in water that they can pass through the absorbing cells and vessels into the sap or general circulating medium of the organism. The potash, lime, soda, and magnesia required are taken up by the roots in the forms of the nitrates, sulphates, phosphates, carbonates, &c., of these bodies, and at the same time the requisite nitrogen, sulphur, phosphorous, and additional carbon to what it can otherwise obtain, passes into the sap. The plant's supplies of nitrogen, phosphorous, and potash, and perhaps lime as well, though to a less extent, are the most precarious, because these are the scarcest of the essential substances of plant food in soils. Enough of the other substances required by the plant are contained in all ordinary soils, and the agriculturist need not trouble himself over them. Of the four mentioned, nitrogen is the most valuable, it being the least available; in fact, the amount of nitrogen available as plant food in any soil is the measure of its fertility. The element is abundant enough, for our surrounding atmosphere is composed four-fifths of free nitrogen, but then it is one of the most inert of all the elements, and least inclined to combine with others. Under certain natural conditions, combination with others is brought about The intense heat of lightning flashes causes union between the nitrogen and other elements in the atmosphere. Thus it comes that ammonia and nitric acid can be detected in the air. These are extremely soluble in water, and rain carries them to the soil. From this source alone each acre of soil gets annually something like 7½ lb. of nitrogen. All organic matter—remains of animal and plant life—contains a large percentage of it, and this finding its way to the soil increases the latter's supply of nitrogen. Coal, peat, deadwood, leaves, dung, &c., contain it in abundance. But it is only when nitrogen is in combination as nitric acid that plants can assimilate it to themselves, and, as we have already said, by way of their roots. Plants cannot make use of the insoluble compounds containing nitrogen in the soil, but by a wonderful provision of Nature, the nitrogen of those bodies is made available to them. This is accomplished through the means of a minute fungoid organism, whose economy in life seems to be that of attacking the nitrogen of insoluble bodies, and of ammonia as well, and bringing it into combination as nitric acid. Given a due temperature, a fair amount of moisture, and sufficient organic or other matter containing nitrogen, and the presence of lime or some other base with which to neutralise the acid as it formed, and the process goes on untiringly. In early summer it commences with us, and continues far into autumn. The nitrates are so soluble that unless they are speedily taken up by growing plants they soon find their way to the drains, for ever to be lost to the fields from whence they originated. Phosphorous is rather scanty in soils, and though there is enough in the majority of them for the uses of natural herbage, the growth of cultivated plants necessitates the bestowal of large quantities of phosphates on land under tillage. Potash is not usually so scarce, for it enters largely into the composition of most of the rocks that form the basis of soils, and as disintegration and decomposition proceeds, fresh stores of it is being placed at the disposal of plants. Experiments on the absorbent powers of soils have revealed the strange fact, that when solutions of potash such as the nitrate, sulphate or carbonate, are poured on soil and allowed to filter through it, they have the property of arresting, as it were, the potash of any of these salts and substituting lime or soda in its place. Where, however, neither of these alkaline bases or any others are available to act the part of the potash in neutralising the acid, the solutions pass through unaltered, and the potash is found in the filtrate. Soils act similarly with solutions of ammonia, having the power of arresting this most soluble body and preventing its escape to the drains before it has taken part in the neutrifying process before referred to. Hence it follows that lime, besides acting directly as a supplier of food to plants, performs many useful offices in the soil. It acts as a base with which to neutralise the nitric acid produced by the minute fungus already mentioned, thus saving the less plentiful potash and ammonia for the uses of the plant; and in like manner it neutralises the acids of the soluble phosphates which are nowadays so much used by farmers, and enables the latter to obtain the full good of them. Before the plant has time to seize on the soluble phosphates freshly bestowed on the soil, the free acids they contain have attached more lime and once more become insoluble, but afterwards they are precipitated in such a finely divided state, that the rootlets of the plant can easily absorb them. Were lime not available, the accumulation of free acids in some soils would soon come to act prejudicially on the welfare of the plants which the farmer thought to encourage. Without its presence and use, the quickened decomposition of soils full of such inert organic matter as peat, is almost impossible. Other bases—potash, ammonia, or soda—may perhaps be available, but the first two are too valuable to be allowed to serve such purposes as the cheaper and more plentiful lime can even more efficiently perform. Comparing the composition or the analyses of the ordinary crops of cultivation with that of wood, we can at once see why it is that timber acts decidedly in the way of increasing the fertility of the soil and not towards its deterioration. Some tables in a recent little book on 'Agricultural Chemistry,' by Mr. Warington, which we have by us at present will sufficiently answer the purpose. From these we learn that a crop of wheat yielding 30 bushels to the acre, and with its straw included, requires from the soil within that area 45 lb. of nitrogen, 22·7 of phosphoric acid, and 27·9 of potash; and a 30-bushel-to-the-acre crop of beans, 99 lb. of nitrogen, 31·5 of phosphoric acid, and 81·1 of potash. A two-ton crop of clover hay will take from each acre 102 lb. of nitrogen, 25·1 of phosphoric acid, and 87·4 of potash. Seventeen tons of turnips, 22 of mangels, and 6 of potatoes, all with their respective leaves and stems, will absorb 120, 147, and 67 lb. of nitrogen, 33·1, 49·1, and 26·8 lb. of phosphoric acid, and 148·8, 262·5, and 76·5 lb. of potash from their several acres of soil. Unfortunately the amount of nitrogen in a season's increase of Pine and Beach wood quoted is not given, but Mr. Warington writes that a year's increase of Pine timber is 'produced with a consumption of only $2\frac{1}{2}$ lb. of potash and 1 of phosphoric acid per acre per annum; with Beech timber the quantities required are rather larger. The nitrogen contained in timber is very small in amount, but the actual quantity required by a forest has not been accurately ascertained.' From the foregoing data, we cannot be very far wrong in saying that a single moderate crop of mangels will extract from an acre of soil almost as much potash as can be required by the annual growths of a forest covering a like area through the long space of a hundred years; indeed, we may say for the lifetime of the trees. And during the same time an acre of forest trees will only require the use of twice as much phosphoric acid as will be needed to serve the purposes of a single crop of the roots in question on an equal plot of ground. The figures reveal also the necessity that farmers are under of manuring liberally in order to insure large returns, and show the advantages that result from a judicious rotation of crops, and the need there is in many cases to restrict the removal of certain crops to be consumed at a distance from the farm, unless some equivalent is to be returned in their stead to the soil. The nitrogen and phosphoric acid, and potash contained in growing trees are concentrated mostly in the leaves and twigs and tender branches—the parts that are seldom removed from forest ground. The roots descend far and feed on the subsoil, eating into and disintegrating the hardest rocks themselves, and they are independent of the surface soil for their nourishment. The leaves fall annually and decay, and thus they gradually come to enrich the surface soil of plantation ground; each year they are adding to it the bulk of the valuable bodies that the roots have extracted from the depths beneath. And at the same time they, and the decomposing parts of the trees that reach the ground, increase the soil's share of its beneficial organic or 'mould,' matter—spoken of by some as *humus*. The nitrates of soil occupied by trees are not nearly so apt to be washed out as they are from soil under tillage and underdrained. What of the rainfall in woods that is not carried away in the surface drains is eventually taken up by the trees and evaporated from their leaves. Any nitrates that may find their way to the subsoil will soon be seized on by the roots of the trees, and be once more transferred to the surface. And then again it is questionable whether the process of nitrification can go on in damp and shaded woods. At any rate, the more it is hindered, the less chance there will be of waste of the gradually accumulating nitrogenous matter. The thinner the trees on the ground, and the drier the soil, the greater likelihood there will be of its proceeding. And these are the places where we meet with 'grass, brackens, and other weeds.' Now it has been found, and we have it on the good authority of Sir J. B. Lawes, that there is far less waste of nitrates from soil continually covered with herbage than from bare soils or those that carry a crop during only certain seasons of the year; that, moreover, there is less waste from a badly cleaned field than from a well weeded one; but let that be no excuse for dirtiness. The grasses, and some of the weeds, are rarely altogether dead or dormant, even in the dead of winter, and their roots are ever ready to avail themselves of what is going in the soil. As the nitrates are formed they are made use of; and so with other plant food in the soil. The growth of each season being left to wither, the decayed matter gradually comes to be assimilated to the mould that gathers in the network of rootlets beneath such herbage, and which constitutes the great agricultural virtue of old sward—so full of matter that insures enourmous crops of corn. And thus the natural process of enriching the surface soil at the expense of the subsoil and the atmosphere may go on indefinitely so long as the trees remain unfelled, and the annual growth of herbage is not removed, but allowed to die and decay where it grew.—R. H.—*Journal of Forestry.*

SYRIAN SILK.—The *Central Blatt für Textil Industrie* gives some details as to a vegetable substance somewhat resembling silk, to which attention has lately been drawn by its having been exhibited in Greece. It is stated that this substance is a silky-haired portion of a tree-like shrub which comes originally from America, but is found in Syria and the South of Europe (*Asclepias Syriæ*), of the family of the Asclepiades. It is also known as the Syrian silk-plant. The substance in question is used for stuffing very soft cushions, when mixed with silk and wool. This Syrian silk is used in different tissues. The milky juice of the plant is said to be poisonous, and the tough stalks can be used in the same manner as the corresponding portions of the hemp plant.—*Journal of the Society of Arts.*

BAMBOOS.—In looking through one of the London parks some short time since, we were rather struck by the paucity of the efforts that had been made with the genus Bambusa in the decoration of those parts of the place called the subtropical garden, for with the solitary exception of one large group, and one or more small solitary groups standing near the water, there was nothing more to be seen. This is the rather to be wondered at, as many kinds are hardy enough to stand out with but little protection in the latitude of London. The Bamboos are capital centre pieces for sunny courts, formally arranged with some distinct large-leaved plant, as Gunnera scabra or G. manicata, Aralia papyrifera, cut down to a low height, not left with bare crooked legs of 6 feet or more, as they are sometimes seen; Polygonum cuspidatum, Bocconia cordata, or coloured-leaved Cannas, and Gladioli with bright flowers, or dwarf Ricinus, like Gibsoni. The above are all capital margin plants for a group. It need hardly be said that any of the Palms, hardy enough to endure our cool summers, will assort beautifully with the Bamboos—especially when the specimen is tall enough to show up from out of a dense thicket of the other. Aletris (Dracæna) fragrans, when grown to 5 or 6 feet high, and Costus imperialis grow well together with it. Panicum sulcatum is an effective plant to work in with Bamboos that attain a height of 7 feet or more, being capable of forming a foreground undergrowth—or surrounding belt—the pendulous foliage of the one contrasting well with the slender erect growth of the other. Among the sorts which are useful to plant in this country are B. metake, which will grow, when well established in good soil, from 7 to 9 feet; B. aurea striata, smaller; B. Fortunei, quite a miniature kind.—*Gardeners' Chronicle.*

THE CASTOR OIL PLANT.

At the last meeting of the Agri-Horticultural Society there was read a letter from Surgeon-General Shortt, dated Yercand, 28th September, 1883, stating that he sends some notes on the castor oil plant, which to make it a complete paper must be amalgamated with the printed note, most of which is extracted from "Drury's Useful Plants." Read the following notes of the subject by Doctor Shortt:—"The castor oil plant (*Ricinus communis*) being synonymous with *Palma Christi* and *Pentadactylon* (from the shape of its leaves) belongs to a genus of a *petalous dycotyledonous* plants, of the natural order *Euphorbiaceæ*. The Greeks called it croton, a name now applied to a closely allied genus. The Romans remarking the striking resemblance in the seeds to the vile insect known as the tick which infests living animals, named it *Ricinus*, which name in Entomology is used for a genus of *Acari* containing the creature called Tick.

"There are several varieties of castor oil plant. Recently some foreign varieties have been introduced from Italy chiefly. They may now be seen growing on the Government Farm, Sydapet.

"The known varieties at present are:—

1. Ricinus communis, fructus major (Lamp Oil).
2. Do. do. minor (Castor Oil).
3. Do. do. major Var. rubra.
4. Do. do. Var. Armata.
5. Do. do. ,, Sollinger.
6. Do. do. ,, Arcuatus.
7. Do. do. ,, Rugosus chunveanus.
8. Do. do ,, Subrisides.

"Of these several varieties the two first known as the small and large seeded castor oil, are in general cultivation all over the warm countries of the world, in South of Europe and the East and West Indies. In Southern India the castor oil is generally cultivated as an annual, with dry crops either of grain or pulse, and rarely alone, in almost every district, requiring no particular attention as a field crop. It thrives in the plains as well as on the hills to about 5 000 feet above sea level. It grows rapidly into a tall lanky plant from 8 to 15 feet in height, generally forming a large terminal spike about a foot in length, springing from the terminating branches at the summit, and sometimes two or more small side branches form, carrying smaller spikes of about 6 to 8 inches in length; each spike carries from 100 to 150 capsules which are armed with long flexible prickles and are trilocular or 3-celled, and about the size of a large marble when matured; the capsule bursts elastically expelling its seed usually 3 in number, to a little distance from the plant.

"There are two sub-varieties of the large seeded or lamp oil castor plant, differing in their coloration and size of seed. In one the stem petioles and veins are of a purplish red colour, and the seed larger than the other, in which the different parts of the plant are green and the seed somewhat smaller. As soon as a capsule on a spike ripens it is cut down with the green fruits before they have fully matured, to prevent loss by the bursting of the capsules and scattering of the seeds, and placed out in the sun to dry to separate the seeds from the shells.

"The small seeded variety grows into a large umbrageous tree 33 to 40 feet in height, with a sturdy looking stout stem. Trees on my estate now measure 4 feet in girth, one foot above the soil, and 3 feet, five feet above the soil.

"It is a handsome tree, and seeds freely yielding 15 lb. of seeds per tree per annum. The Sanscrit proverb in the 1st Book of the Hitopadesa says, 'That where there are no trees even the castor oil plant ranks as a forest tree.' It grows sufficiently large to produce specimens of wood, but is chiefly remarkable for the beauty of its large spreading leaves, and the value of its seeds which yield the medicinal castor oil. The stem suffers constant damage from white ants who are exceedingly partial to this tree, they eat through the heart wood of the living tree, leaving but a layer of new wood alburnum, and bark the hollow thus formed being filled with the debris of the white ant. The first blast of wind tears to pieces its branches or snaps off the stem. The bark is also constantly infested with insects which perforate it in all directions. The oil is chiefly used as a mild purgative in medicine, and its utility as such has been known from the most remote ages, and the seeds have been found with Egyptian mummies in Sarcophagi. In the arts it is used in the manufacture of soup, but its cost and smell preclude its general use. The clearness, limpidness, and absence of offensive smell can only be obtained, not from superiority of seed, but from repeated decolorization with animal charcoal and exposure to the sun's rays, but these qualities when obtained destroy its medicinal qualities and efficacy."

"The oil is obtained by two methods, either by expression or boiling. Years ago an oil press was established in Stringer's Street, Madras, by the late Doctor Gay where the cold drawn castor oil was obtained by expression filtered through horse hair bags. The oil was considered good and was patronized by Government. The test of its purity is its being able to be dissolved completely in cold alcohol.

"The large seeded variety furnishes the lamp oil of the bazaars which is so expressively termed *velookoo yennie* in Tamil.

"The mode of extraction of the oil varies somewhat in the different districts. Boiling is the chief mode. In some districts the seeds are subjected to pressure in the common native wooden mill, known as *Checkoo*, to crush the oil out.

"Not only is castor oil used in medicine, but the juice of the leaves is given internally to increase the flow of milk. Cattle are fed with the leaves with the same object. Most cows eat the leaves freely and readily. Externally the leaves are applied to wounds and bruises, when it acts as a detergent. The husk of the capsule is used as fuel, and the oil cake forms an excellent manure, and is valued on account of its regenerating properties which it imparts when applied to plants.

"From my own personal experiments one pound of oil is obtained from three pounds of oil seed. The process consists in first scorching the seeds in an earthen pan over a fire, and then pounding them in a mortar to reduce them to flour. Two bottles of water are boiled, and into the boiling water the pounded castor seeds are thrown, and the mixture is well and constantly stirred with a wooden ladle for a time till the oil gradually rises to the surface, and is skimmed off. A fresh supply of boiling water is added to the mass in the vessel and it is boiled for the second time to remove any remnants of oil it may contain. The whole of the oil obtained is now boiled to evaporate any water it may contain, and the oil is then ready to be bottled for use. Care must be taken to see that the oil does not get burned in boiling."

A quantity of seeds of a large variety of *Ricinus* have been lately obtained for correspondents through the kind assistance of Mr. Gray, from Coonoor, where a large seeded variety grows into such a tree as described by Dr. Shortt.

Resolved that Deputy Surgeon General Shortt eb thanked for his interesting communication, and that a copy of these Proceedings be sent to the Government of India, Revenue and Agricultural Department, with reference to their letter.—*Madras Mail.*

RECENT DONATIONS TO THE MUSEUM OF THE PHARMACEUTICAL SOCIETY.

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society.

I. VEGETABLE TALLOW FROM SINGAPORE.

Mr. R. Jamie of Singapore, in a letter accompanying some interesting donations lately presented by him to the Museum, has called my attention to this substance as possessing the valuable property of not readily turning rancid He remarks concerning it—"The vegetable tallow never turns acid, and when the white kind is got, which is seldom, it makes very good ointment, simply with the addition of olive oil." At the ordinary temperature this tallow is a white friable solid, softening into a pasty condition when rubbed between the fingers and ultimately melting sufficiently to be rubbed in without leaving the hand very greasy. It has a very slight nutty odour and taste. It would seem therefore to be peculiarly suitable for camphor balls, suppositories and pessaries; for the latter its slowness in melting seems to peculiarly fit it.

Mr. E. Fielding at my request has made a few preliminary experiments as to its melting point and solubility in various solvents. He reports as follows: "At 65° F. it remains a little solid; between 82° and 104° F. it has the consistence of flour paste; it fuses at about 118° F., but remains transparent and liquid at 112° F. It is soluble in about an equal weight of cold ether; it is sparingly soluble in cold acetic ether and acetone, but very soluble in these liquids when heated, the greater part being precipitated on cooling; it dissolves in half its weight of cold chloroform, but mixes with one-third of its weight of the same liquid when heated. In bisulphide of carbon, either cold or hot, it is extremely soluble. In cold benzol it is soluble to the extent of about 1 in 4. In hot benzol and petroleum spirit (hexane or heptane) it dissolves in all proportions, but the solution gelatinizes on cooling. It is very soluble in cold turpentine and dissolves in it when heated in all proportions. In alcohol it is soluble to the extent of about 1 in 30 when cold or 1 in 20 when hot, and in isopropyl alcohol it dissolves to the extent of about 1 part in 25 when cold, and 1 part in 4 when hot" Mr Fielding thinks it may be compared in many respects with the fat of *Pentadesma butyracea* (*Clusiaceæ*), which should, however, judging from its natural order, be more nearly allied to kokum butter (*Garcinia purpurea*).

According to a cutting from the *Java Bode* newspaper, sent to me by Mr. Jamie, the vegetable tallow, known as Minyak Tangkawang, or Minyak Sangkawang, is obtained from the seeds of one or more trees of the genus *Hopea*, found in the S. and E. division of Borneo, chiefly in the neighbourhood of Qualla Kapuas, and on the west coast in the districts of Sambas and Mampawa. The Dyaks call the fat Kakawang and the tree which yields it Upu Kakawang. This tree is one of the giants of the forest. Several species of the genus appear to be used. Of these *Hopea splendida*, the Tongkawang Tonggul, is also called by the natives Dammar Tangkawang (because the bark yields a dammar?). The timber is used by the Dyaks for making their prahus, as it is proof against the influence of water. The bark also yields a red dye. This tree grows on alluvial flat clayey ground on the banks of great rivers. *Hopea aspera* grows on the higher mountain tracts, principally on the declivities of Mampawa, and is distinguished by the hairiness of the stems.

The preparation of the fat is very simple. When the ripe fruit falls on the ground, it is collected and allowed to germinate a little in a moist place. It is then dried in the sun until it becomes brittle. The fruit is then deprived of its shell and put into a rattan or bamboo basket suspended over boiling water. When it has been well steamed, the fruit becomes soft and plastic like dough. The fat is then expressed by squeezing the doughy mass in a cloth and is poured into joints of bamboos, by which it receives the cylindrical form in which it is met with in commerce. Some Dyak tribes press the fruit by means of two beams. But it is probable that by neither of these processes is all the fat obtained.

The trees begin to yield when they are about eight or ten years old and the crops are somewhat irregular, but every four or five years an extraordinarily large crop may be counted upon, the fruit being ripe in December and January. According to 'Spon's Encyclopædia' (p. 1413), about ten species of *Hopea*, yielding oil seeds differing much in size, are recognized by the natives of Borneo, three of these being common in Sarawak. The fat is also prepared in Java and Sumatra. By the natives the tallow is used for culinary purposes.

Although the tallow has not as yet been turned to account in pharmacy in this country, there is no reason why its fitness for medical purposes should not be experimented upon, the fat being a regular article of commerce. As far back as 1856, 651,586 kilos were imported into Singapore, and now several thousands of piculs go yearly to Singapore and are exported thence to England for use as a lubricating agent. For this purpose it has proved most valuable, especially for steam machinery, far surpassing even olive oil. In Manilla it has been employed in the manufacture of candles and found to be very valuable for this purpose. There are doubtless many other purposes in the arts to which the fat might be applied. It contains glycerine and about 65 per cent of saponifiable matter which has less oleine in it than animal fat. The tree is certainly also worthy of the attention of colonial planters since it yields fat, dye, timber and probably also resin, and the demand for the fat alone, when it is better known and prepared in a pure state, will probably far exceed the native supply.—*Pharmaceutical Journal.*

MODE OF CULTIVATION OF THE RHEEA PLANT.

(*Extracts from a report on the preparation and use of Rheea Fibre. By* J. FORBES WATSON, M.A., M.D., LL.D., *&c., in* 1875.)

(3).—*Cultivation of Rheea in Assam.*

With respect to the cultivation of the Rheea plant and the preparation of its fibre in Assam, I cannot do better than quote from Colonel Hannay's published observations, as well as from a communication received from that gentleman in 1859.

"The sole cultivators of this plant are the dooms or fishermen, who use it chiefly in making their nets; they cultivate it in very small quantity however; and as the fourth crop is that which bears seed, and they cut it down before the seed is formed, the plant is propagated entirely by dividing the roots. The ground is a small plot close to their huts, which they have great opportunities of attending to and manuring well with ashes and cow-dung, a quantity of which is essential to the proper growth of the plant.

"I have mentioned four crops; but as I have now a crop, the fifth, since planting, fit for cutting in February, and I see others belonging to the dooms in the same state, there will be five crops since planting, or six crops from April to April; the last or cold-weather crops, cut in February, being considered to produce the strongest fibre. However, as moisture seems so essential to the quick growth of the plant, generally speaking, after the early November or fourth crop, the dooms allow the cattle free ingress into their plots, and it is thus kept down till February, when some pains are taken in opening out the roots, heaping up the earth, and manuring them, as well as enclosing afresh the plot of ground. The soil, from repeated manuring, is of course rich ; and on this, and a good degree of shade and protection from storms, depends the luxuriance of the crops, which I have seen here eight feet high, and the extracted fibre six feet long. So much attention, indeed, is given to length of stalk amongst the Kakoos of the Chinese frontier, that the gardens are walled in (with wattling) like a *Pan* [*Piper Betel*] garden.

"From the roots thus dressed up in February a crop will be cut in April, another in June, another in August, and another early in November, the most luxuriant crops being those of June and August, as naturally receiving the greatest quantity of moisture. The fifth crop takes from early in November to February to come to maturity. Between the cuttings, all that seems necessary is a fresh opening up of the ground around the roots, which in a regular plantation is best done by hoeing between the rows with a spade-shaped hoe set in a long handle : the person, as he performs this, going backwards so as not to step over his work,—in fact, nothing can be more simple than the cultivation of this plant ; all that is required being a loose rich soil, and protection to the crop by a good strong fence. The roots throw up at least 12 shoots when in full bearing ; should they increase, and the crops get too thick, the roots require to be separated ; and by this means of planting out fresh ground and new plants from seed, the cultivation can be carried to any extent.

"The stalks are considered fit for cutting when they have become of a brown colour for about six inches above the roots. To cut them, the doom seizes the leaves at the upper end with his left hand, and passing the right hand down to the root, strips off the leaves. He then cuts the stem two or three inches from the ground."

(4).—*Notes on the cultivation of Rheea in India. By W. King, Officiating Superintendent, Botanical Gardens, Saharunpur*, 1869.

Limit of Growth.—The garden in Dehra Doon is about 2,500 feet above the sea-level, and the plantations in the Kangra Valley are probably higher. There are no exact records known to me showing the height at which the Chinese nettle thrives best. It grows, however, freely in the plains at very low elevations. At Saharunpur, which is about 1,000 feet above the sea, the plants are very green and healthy, and reach a height of five to seven feet.

Soil and Shade.—The Chinese prefer a rather stiff soil ; but I gather from a communication in the journal of the Agri-Horticultural Society that in Assam a loose rich soil is considered the best. That in the Dehra Doon gardens is of the former description, whereas the patch of ground planted with Rheea at Saharunpur is rather light and sandy. My own experience, which, however, is but limited, leads me to think moderate shade is an advantage. The finest plants in the garden at Saharunpur are a few grown under trees ; and shade appears to be the only condition of growth in which these differ from less vigorous plants near them.

Moisture and Manure.—A good supply of moisture is undoubtedly required, and regular irrigation would be necessary in the plains. But of all the requisites for successful cultivation, I believe the first to be manure, and this is the one least recognized in Indian agriculture. The Chinese manure extensively. They plant out in soil which has been carefully prepared and richly manured. They also use liquid manure, and in the cold season give a top-dressing of stable litter.

Propagation and Cultivation.—The plant being one of those in which the male and female flowers are separate, and situated on different parts of the stem, the production of seed is uncertain in localities where the insects by which fecundation is probably accomplished are not indigenous. In districts where Rhea has been *introduced*, propagation has therefore not been conducted by seed but by cuttings, and by division of the roots of old plants. By cutting it may be propagated very easily, as scarcely one fails to strike. During damp weather roots of old plants may be freely broken up into smaller ones, and these, if planted out into well-manured nurseries, thrive well. This is the favourite mode of propagation in China. Both cuttings and fragments of root should be planted about $1\frac{1}{2}$ feet apart. The soil between the plants should be frequently broken up so as to keep it loose, and should, of course, be kept free from weeds. Top-dressing with manure is strongly insisted on by Chinese cultivators.

GROUND-NUTS.

10th Dec. 1883.

SIR,—Enclosed is an extract from the London *Times*, about ground-nuts, showing that the villagers in the southern parts of India have an important article of export. Can you tell an upcountry planter—far from encyclopædias, &c.—what ground-nuts are? I cannot find them in the *T. A.* price-list.

The Sinhalese villagers in these parts sadly want some article of export, some product to take the place of their worn-out coffee which used to pay so well—something which will pay for pingo, tavalam, cart, railway and ship as coffee did ; for the cost of carriage (on anything but high-priced things) debars them from growing many useful products of the cheaper kinds ; and then the all-seeing, pandal-journeying civil servant writes them down as "apathetic," because they, so unlike him, do no more work than is absolutely necessary.

But look at the natives around: for instance, Wilson's Bungalow. Those near the cart-road still cultivate their coffee. Many have market gardens, onions, potatoes, &c., most carefully irrigated. Look at the processions of natives to any coffee estate bazaar, loaded with currystuffs, plantains, tobacco, eggs, fowls, &c., and then go further afield and look at the villager, who, having no market, has a paddy-tax to pay, whether his paddy is washed out or otherwise, spoilt or not. He is "apathetic."

They want a something to take the place of coffee, and so apathetic are they that our cinchona nurseries—and in lower places cacao nurseries—must be watched lest they should be robbed for the patch in the village which was so productive in the days of King Coffee.

What is the value of ground-nuts?

AN UPCOUNTRY PLANTER.

GROUND-NUTS.

The extract referred to by our correspondent, "An Upcountry Planter," is as follows :—

THE INDIAN GROUND-NUT TRADE.—A very large trade is being carried on this season in ground-nuts (*hypogea*) between Madras, Pondicherry, and Europe, and it is calculated that at least 500,000 bags had been shipped up to the end of August, and that the season's trade would be at the rate of over 700,000 bags. The principal demand for the ground-nuts and the seed comes from Marseilles and Genoa firms, while a considerable quantity of ground-nut oil is annually sent from Pondicherry to the Continent, there to be used for manufacturing purposes. Ground-nuts are a profitable industry, for they thrive well in sandy soil and do not require any care. The demand has been so great of late years that the ryots of the South Arcot district have largely increased their area of cultivation and the commercial aspects have never been so flourishing, as they are now.

The *Friend of India* of Nov. 27th had the following paragraph on the same subject :—

The Americans are seeking to obtain flour, it is said, from the pea-nut. In Virginia they are making flour from this nut already, of which about two million bushels are raised per annum. The pea-nut is the seed of the *Arachis hypogæa*, better known as the ground-nut, from the fact that, by a peculiar motion of the stalks (trailers), the pods are forced into the ground, as if the plant itself understood that its business was to sow its seed. Is the ground-nut of India the same plant as the *Arachis*?

This question is of course to be answered in the affirmative. We quote as follows from the "Dictionary of Popular Names of Plants' &c., by John Smith, F. L. S., published last year :—

EARTH PEA OR GROUND NUT (*Arachis hypogæa*).—It is an annual clover-like plant belonging to the family Leguminosæ, attaining a height of 2 feet. It is supposed to have been originally a native of America, but is now cultivated in most warm countries. It is curious for its seed-pod being perfected under ground. It is about 2 inches long, and contains two or three pea-like seeds of an earthy flavour, extensively used as food by the negroes. They contain an oil, and are imported in large quantities into this country, and the oil expressed by crushing is very sweet, and is largely used for adulterating olive oil. An allied plant, *Voandzeia subterranea*, is a decumbent annual, also extensively cultivated as an article of food in Western and South Africa, and has become naturalised in the warm parts of America.

Baron F. Von Mueller's "select extra-tropical Plants" has the following :—

The Earth-nut, Pea-nut, or Ground-nut. Brazil. The seeds of this annual herb are consumed in a roasted state, or used for pressing from them a palatable oil. The plant is a very productive one, and yields a very quick return. It ranks also as a valuable fodder-herb; the hay is very nutritious, much increasing the milk of cows. A light somewhat calcareous soil is best fitted for its growth. On such soil 50 bushels may be obtained from the acre.

In reply to the enquiries of our correspondent, W. F. furnishes the following :—

"Ground-nuts were grown in England under glass, in 1712, and grew in Ceylon in Moon's time (1824) but the plant (*Arachis hypogæa*) is a native of South America, though now cultivated in nearly all the inertropical (and some of the extratropical) parts of the world. The seeds of this plant are well known in Ceylon as the *rata* (foreign) *kaju*, and when roasted are sold along all the streets of Colombo. They are no doubt of a nourishing nature, but have a strong earthy taste. The plant grows readily in Ceylon and has large bright yellow broom-like flowers, but I am not aware that it has been cultivated to any extent in the island : indeed, the term *rata* indicates that the seeds used in Ceylon are imported, and no doubt, from Southern India where the plant is cultivated to a large extent. I question if we have the soil and the labor in Ceylon to make this a profitable crop to be cultivated in the island. The generic name *Arachis* is derived from a barbarous name used by Pliny for a plant without leaves or branches, with which our plant has nothing to do, and the specific name *hypogæ* is derived from the fact that the pods ripen under ground. Very large quantities of ground-nut oil is exported from Southern India to the United Kingdom, Bombay and Indian French ports, which is said to be an excellent substitute for olive oil, and makes a good soap. Your correspondent can, I doubt not, get seeds fit for growing from the nearest bazaar under their Tamil name *vayer* or *kilai-kadelai* or the Sinhalese *rata-kaju*. They are sold in the Colombo bazaars at the rate of R1·25 a bushel."

SUGAR.

TO THE EDITOR OF THE "INDIA MERCURY."

The sugar-industry in Java runs no risk, as many manufacturers have feared for a long time. The production is importantly increasing, and to the constant improvements in culture and preparation, will be owing—I have not the least doubt about it—that it will be able to bear up against the sister-industry,* which continues so vigorously to extend itself in Europe.

But then we must not be sparing of trials that may promise the best results ; then we must have an open eye to all the discoveries of science, and to examples given us elsewhere, and make the best use of them in our power.

In the December Number of this paper, 1881, we drew attention to the application of Salicylic acid in the manufacture of sugar. Since then the industry has gained abundant experience, and it seems to us in the interest of colonial manufacturers not unimportant to devote now a few lines to this important subject.—VAN GORKOM.

SALICYLIC ACID (KOLBE'S PATENT),

FOR THE IMPROVEMENT OF THE YIELD OF CANE SUGAR BOTH IN THE QUANTITY, SHAPE AND COLOUR OF THE CRYSTALS OBTAINED.

Salicylic acid is not a strong acid, but a white crystalline powder, chemically pure, free from odour and—when dissolved—colourless, and perfectly tasteless. It is universally recognized as the best preservative agent for articles of food, as it destroys all microscopic germs productive of false fermentation, acidity, turbidity and mouldiness. The *Juice of Cane Sugar* is effectually preserved by trifling additions of Salicylic acid, which is perfectly harmless ; and for the last few years, salicylic acid (Holbe's Patent) has been successfully used, and on an increasing scale, by many of the largest Sugar-cane mills for its material advantages in improving the yield, both as regards the quantity of the crystals obtained and their final colour ; as well as a flinty condition. Every planter knows from experience, that the fresh cane juice, as soon as it leaves the mill, and comes into contact with the air, begins to ferment, and that this even often happens to the juice while still in the cane. He also knows very well that the farther the fermentation has gone, the less good sugar is produced, and *vice versa.* The chief merit of explaining this process belongs to Mr. U. Gayon, whose researches on the cause of the spontaneous alteration of the raw cane sugar, which were laid before the "Académie des Sciences" in Paris on the 13th Dec. 1880, were verified by Prof. Ch. Pasteur. Mr. U. Gayon starts from the fact, that if the *raw juice of the cane* is left to itself, a great part of its sugar, which is capable of crystallization after passing through several stages finally turns into *Molasses.* By careful experiments M. Gayon proves that this change of the juice is a real *fermentation.* Though this process is not observable to the naked eye, as is the case with the fermentation of Beer and Wine, the action is set up by microscopic organisms, similar to the Alcoholic yeast, consisting of "Torulae" like fungi, the warm and moist atmosphere proving most beneficial to their growth.

Mr. U. Gayon found now, that this fermentation could be checked or prevented by the use of *Antizymotic* agents. To prove this, he used seven different neutral chemical substances,—neutral ones probably because by the large quantities which he applied to

* Quite lately we were assured, that in Italy a great Company has been organized, which purposes to establish some eighty beet-root sugar factories.

the juice, he wanted to be sure that the sugar was not changed by a free acid.* Among the seven agents chosen for the trial, sodium salicylate was the one which produced the best result.

The seven quantities of juice with their different Antizymotic agents were left for *a month* in coppers. After that the analysis showed the following results:—

Juice preserved with *Sodium salicylate* contained 90·24 *p. c. of the sugar capable of crystallization* and only 3·09 p. c. Glucose (Molasses). While some of the other quantities of juice only came up to 76·51 p. c. of the sugar capable of crystallization, and had 16·06 p. c. Glucose.

It must however be remarked that, as Sodium salicylate has *no* antizymotic virtues in itself, it must have been the *Salicylic Acid*, which it contained, that produced the great effect, the Sodium combining with those Acids, which are *naturally* in the *fresh cane juice*, and leaving the *Salicylic Acid in a free state*.

Already in May 1880, Dr. Phipson published in the "Sugar Cane Magazine" a short paper. On some points of cane sugar manufacture, in which he discusses the various qualities of the beet and the cane as sugar yielding plants. After showing that their cultivation in the field requires different treatment and different kinds of manure, he observes:—"But whenever we leave the field and come to the mills and boiling-houses, in other terms, when we are dealing with the expressed juice of the one or the other plant, then we find that the discoveries and appliances which have been found advantageous to the sugar beet grower may be safely turned to account by the West Indian planter. Now it has lately come to my knowledge that a considerable saving in the process of defecation has been obtained on the continent, by the addition of minute quantities of salicylic acid to the juice of the beet, immediately it is extracted from the roots, and it has struck me that the same results might be obtained in our cane districts, whether the *salicylic acid* be added as such, or as salicylate of lime, before the usual addition of milk of lime in the ordinary process of defecation."

The experiment recommended by Dr. Phipson has been first tried on a large scale in *Demerara*, and the results have been most successful, according to to the Monthly Magazine of Pharmacy, Chemistry, etc. (London), which in May 1881 writes as follows:—

"Although so short a time has elapsed, we have already received testimony of this in the following letter from Charles Williams, F. C. S., of the Plantation Bel Air, who writes on the 5th Febr. 1881: 'I have obtained beneficial results from the use of salicylic acid in the manufacture of sugar from cane juice. The quantity used varies of course according to the condition of the cane juice, but *three ounces* of salicylic acid (dissolved in two pints of alcohol per 1,800 *gallons* of cane juice, improves both the colour and the yield.'"

It is certain that much of the loss experienced by the sugar-boiler is due to the direct contact of the germ-loaded atmosphere with the juice of the cane *as it flows from the rollers. It is at this moment* that the salicylic acid in some form or other must be added, thereby preventing the development or the microphytes which determine a large yield of molasses at the expense of the cane in the juice.

Salicylic Acid can also be dissolved in boiling water, and, while hot, added to the juice as a spray. Do not use any iron utensils for the solution, because, as long as it is of a concentrated strength it would turn red from the contact with iron. Salicylic must not be expected to turn *fermented* juice into *good* juice. It only *prevents* and *stops fermentation*. The *defecation* (clarifying) with lime *cannot* be entirely dispensed with by the use of Salicylic Acid, though the quantity of lime required will be reduced. It has been noticed, that the sugar obtained from the salicylated juice, did not turn *deliquescent* on the voyage, and, therefore, kept a flinty crystalline shape superior to the condition of other sugar after the voyage.

* Mr. Kieldahl of Copenhagen ascertained in 1881, after careful researches, that the cane sugar does not suffer any inversion whatever from the application of Salicylic Acid, as long as certain proportions are neither exceeded nor reduced.

THE BURDEKIN DELTA SUGAR DISTRICT.

[Our visit, in its beginnings, to this district, which (if plenty of labour is available and irrigation systematically adopted) will be one of the richest sugar producing districts in the world, will ever remain one of the most pleasant reminiscences of our Australian experiences. With men like Mr. Jeffray of Sloane & Co., to provide the capital, and such men as Macmillan, Graham, Mackenzie and others to direct labour and machinery, the progress of the Burdekin Delta cannot but be rapid. There is not as much rain as could be wished; but the river and the lagoons provide an unfailing supply of water for the deep rich soil. It is curious to see names like Airdmillan, Seaforth, Drynie, &c., familiar in the Highlands of Scotland, reproduced in tropical Australia.—ED.]

Amongst the districts in North Queensland that have of late become of importance, the Burdekin Delta district has rapidly come to the front. Years ago a selection was taken up by Mr. Macmillan, the present managing shareholder of the Delta Sugar Company, with the intention of cultivating sugar. A company was formed, but owing to the great depression in Mackay, caused by a severe visitation of rust, prospects were so discouraging that it was thought best to suspend operations. In the meanwhile, Mr. Graham took up the now beautiful estate of Lilliesmere, containing 6,000 acres, which he planted with fruit trees, at the same time planting out a few acres of cane, the plants for which he obtained from the Pioneer Estate at Mackay. Whenever three joints had developed on these plants, he used to cut down and plant out again, until he had about 7 or 8 acres under crop, and also a nursery containing some 14 or 15 varieties. This patch of cane formed the nucleus from which the plants of the district have been obtained.

On changing the species of cane grown, the rust vanished from the Mackay district, and the returns were so encouraging from subsequent crushings that it was considered justifiable to recommence the formation of a company on the Burdekin. October next will be the third year of their operations, and since Mr. Macmillan became manager.

During '81 and '82 there was a great demand for sugar land, and the resources of the Burdekin Delta district becoming known, the country was rapidly taken up, and is now completely occupied. The extent of available land is about 250,000 acres, and the whole of this is admirably suited to the cultivation of sugar-cane.

The soil is an alluvial deposit of black loam, with a sandy subsoil; localities on which water has lain being somewhat clayey. This deposit is the result of the flooding of the Burdekin river, and which has been swept down from the ranges. Approaching the sea its waters have been backed up by the tides, forming comparatively still water and allowing the sediment to settle on the land. In all probability a universal flood is a thing of the past, owing to the bed of this river having deepened and widened, and having become more capable of carrying off its flood waters. At any rate, for the past fifteen years nothing of any consequence has occurred, although '81 was a year of serious floods in many parts of the country. In '82 there were partial floods over cane that was then growing, and the result has been that in such localities the crop is wonderfully heavy, and no harm whatever has been done to it. There is next to no current except in the channel of the river, but merely a gradual rise and fall; and it is evident that if floods could only be regulated they would prove of immense benefit to the district. Another important feature in these floods is, that it brings down with it quantities of lime from the ranges at its head, and also from the limestone beds that traverse the river; and the whole of the soil in the neighbourhood is strongly impregnated with this substance, which strengthens the land immensely. If the district could only reckon on a triennial flood, the planters might calculate on their soil being inexhaustible.

There are now eight estates, part of which are under cultivation. Of these, Airdmillan, the property of the Burdekin Delta Company, is now taking off its first crop; the Pioneer, Kalamia, Drynie, and Seaforth estates will have mills erected within the next few months, and take off their next year's crop; Maidasale and Norham estates will crush next year at the Pioneer and Seaforth Mills, and Ripley Estate will take its first crop off in '85.

At present, the cultivation appears to confine itself to those estates on Sheep Station and on Plantation Creek, the former being the western and the latter the eastern portions of the district. Airdmillan, Seaforth, Kalamia, and Norham estates emply Plantation Creek as a means of shipment, and the remainder Barratta Creek, which is considerably to the north, and debouches into Bowling Green Bay. The former has no roadstead, has an awkward bar, and the mouth of the creek is exposed to the south-east gales. At the entrance to the latter, Bowling Green Bay affords admirable shelter and anchorage, but it exclusively commands the western portion of the district.

A scheme is now on foot which, if it has successful issue, will enable the planters to ship direct to their various markets, instead of as, at present, being obliged to ship to Townsville and re-ship from thence. A sufficient depth of water is reported in Bowling Green Bay, under the Cape of that name, to float ocean-going vessels. This is being investigated, and Mr. Jefferies, of the firm of Sloane and Company, has offered the Government to consturct a line from this point to tap the district, in the event of being allowed certain concessions of land. The difficulties of the present communication, which is almost exclusively conducted by the fleet of small steamers belonging to Messrs. Aplin, Brown and Company, will be at once overcome; the planters will obtain direct shipment, and the district will, in all probability, become as independent of Townsville as Port Mackay is at the present time.

Of the plantations mentioned on Sheep Station Creek, the Pioneer, belonging to the Messrs. Drysdale Bros., is at present the most forward. It consists of 5,120 acres, two-thirds of which is available for cultivation. It has now under cane 40 acres of stand-over cane, 30 acres of ratoons, 500 acres under plants, and 200 more will be planted out this year, making a total of 770 acres under crop. The canes principally consist of Meera, Rose Bamboo, Striped Meera, Black Java, and Dupont. This latter is not a favourite in the district, and on this estate it grows badly, having a thin barrel, short uneven joints, and being a very hard cane. The principal objection, however, to it lies in the fact that it is very difficult to granulate, and lime does not appear to have the effect on it that it has on other canes. The favourites throughout the district are Rose Bamboo and Meera, of which a great quantity is grown.

The land under crop is laid out in 100-acre blocks, which measure about 40 chains long by 25 wide, and having roads between these blocks on to which the timber cleared from the land has been drawn, and which is now being cut for cordwood for the mill. Up to the present all this land has been cultivated by horse and bullock power, but steam is now being procured and is expected to arrive this month. No less than 110 horses are employed, that have splendid stable accommodation, and about 80 working bullocks are also employed in breaking up land, and hauling off logs. The ploughs used principally, are by Petersen, of Mackay, which are very highly thought of by the practical and experienced outside manager, Mr. Hoey. He qualifies them as being the best horse ploughs he ever used.

There are 116 Kanakas and 36 white men employed on the estate, all of whom, and more especiall the latter, have the best of accommodation and ~yons. The hours are 10½ per diem, and 9 for ploughmen; and the rate of wages given, being—for ploughmen 25s., blacksmith £2 10s., cooks £2 10s., and carpenters £3 per week, exclusive of rations. A mob of Chinamen were, failing other labour, employed in clearing, cutting up, and filling in the holes by contract. This cost the plantation £6 15s. per acre, and the labour was unsatisfactory. They tried every means to take advantage of their employers, and gave trouble in having to be watched. Chinese are grately disliked throughout the district, and the planters are getting rid of this class of labour as quickly as they can replace them.

The district being somewhat dry, and the supply of water being boundless, many plantations are about to systematically irrigate their fields. On this plantation some 14 wells have been sunk, procuring water at a depth varying from 14 to 55 feet, and steam power will be employed to throw 60,000 gallons an hour on to the land. This will be run down the drills, which can, if necessary, be puddled with the bare feet of the Kanakas. The gradient in most estates is regular and not too steep, and there is every probability of this system turning out an immense success. The only question appears to be as to whether the wells will supply the quantity of water required, but if not, the lagoons, containing an almost endless supply, will be utilised.—*Planter and Farmer.*

FORCE OF GROWTH.—The power exerted by plants in growth is something surprising. In the experiments by President Clark upon the Squash, this fruit in growing was able to raise 4,120 lb., and carried for ten days 5,000 lb. without injury. The frequent displacement of flagging stones, and the injury often done to pavements by the roots of shade trees, make it evident that growing roots of firm wood exert, under suitable conditions, a tremendous mechanical force. The power exercised by an annual root is also exceedingly great, as shown in the case of a long Blood Beet planted at the New York Agricultural Experiment Station, in an inch drain-tile set up on end and buried in the soil. This drain tile was split lengthwise with the greatest ease as the root outgrew its accommodation. The lifting force of fungi often excites surprise. A correspondent from Braintree, Essex, has lately sent us a specimen of a fungus, identified by Mr. W. G. Smith as Agaricus arvensis, and which is reported to have unheaved a flagstone measuring some 2 feet 6 inches by 1 foot 10 inches. Such statements are sometimes received with incredulity, or rather the phenomenon observed is attributed to other causes, the growth of the fungus not being conceived to be adequate to produce such an effect. This, however, is a mistake. If not in the case of the fungus, at least in that of some other plants, the lifting force has been not only observed but carefully measured, as in the case of the Pumpkin above mentioned.—*Gardeners' Chronicle.*

THE CINCHONA ENTERPRISE.

DEAR SIR,—In the present state of crisis in all that concerns bark growing, selling and manufacturing, it seems to us that a little information as to actual state of things, and an attempt, however crudely made, to disentangle effect from cause and to lay bare the actual facts of the case, will be useful to the planters of cinchona in your Island, and the facility you always give for ventilation and sifting of all matters in dispute, emboldens us to hope that you will assist us, by the publicity your columns give, in this our attempt.

We will try then and fathom the mystery of the rapid evanishment in Ceylon of the idea of cinchona growing being an Eldorado, and of planters accepting now prices which for some qualities must have ceased to be remunerative. We think we cannot begin better than by attacking the very widely-spread and too commonly received idea that the quantity of cinchona grown is absolutely and in itself beyond the requirements—in other words that the quantity of bark, now grown in the world, will provide more than sufficient Quinine and other alkaloids to supply the needs in these articles of the whole world.

Now we think that no fairly educated man, with a map of the world before him, with some slight knowledge of the area of inhabited land in tropical and swampy regions, will attempt to argue that the quantity of bark actually grown is sufficient for the *absolute* requirements of the globe.

Now that being the case—and who will dare to deny our assertion that the present production of bark is not nearly sufficient for the needs of the world,—we think that the growers have a right to enquire whether the manufacturers, whose only *raison d'être* is their turning out as much of the manufactured article as is possibly consistent with gaining a fair livelihood for themselves—we say the planters have a right to know whether these men as a body are fulfilling their duty, and we think that in pursuing this thought we shall come across the real root and cause of the present state of stagnation and crisis.

We should like to know where the Quinine trade would be now if the old-fashioned legitimate manufacturers of 14 years ago had argued on these lines, when, with a supply of bark only a sixth part of that which we receive now, Quinine was well nigh unsaleable at 4s per oz. Had they then acted in accordance with the same short-sighted policy as that being pursued now, and said that the then consumption represented the requirements of the world, where would five-sixths of those who now take Quinine get it from, or rather where would those manufacturers be who had as misinterpreted their work and its responsibilties? We venture to to think they would have been superseded by another class of men more in accordance with the requirements of the age and according to the inexorable and unalterable law that any species that ceases to serve some use or purpose dies out. But those manufacturers did not act so, they accepted their bad times, and were very soon rewarded by seeing the unvarying result of low prices, in increased consumption and they shortly reaped a rich harvest as a consequence of legitimate and reasonable trading.

For many years past during the period of prosperity, when the apparent consumption of Quinine advanced with those will-o'-the-wisp "leaps and bounds" that deceive so often in other matters besides quinine selling; in those days some large manufacturers turned out the manufactured article regardless of where it would find its real consumptive demand content to sell to speculators, who manipulated the markets so as to get their profit out of the real distributer, who alone really fulfilled a useful office in pushing the sale of the article in regions where it was not known or not fully appreciated.

But what is the state of things now? These large manufacturers (we are not for a moment speaking of the whole body, for there are still among them all those men of 14 years ago, who acted wisely then, and who nearly all pursue the same steady trade of supplying the demand and extending according to the requirements of the trade, discouraging speculation and encouraging all opening up of new districts, we are only speaking of such men as have acted rather as speculators than manufacturers), these men now find that their speculative buyers have no longer a trade, they, the speculators, could only live upon the work of others. The real distributers foresaw the drop in prices which extended production of bark must bring, and they advised all their under-buyers to reduce their stocks and wait for the low prices to increase their trade, consequently the speculators had a large stock in hand which they could not dispose of except at a very large sacrifice, but these large manufacturers, instead of allowing this logical effect to work itself out, intervened, bought back to a large extent their own make from the speculators, and proceeded to form a syndicate to keep up the price, and to enable them to get out of the mess that their own over-anxiety to produce had got them into, and the most extraordinary fact of the whole is, that they managed, by protestations of poverty, viz., the enormous loss they would have to make by saying that it would steady the market and that it would not reduce the consumption of Quinine, by threats of destruction to the timid, and by appeals to the mercy of those whose business they had much injured in the past, to get practically all the manufacturers to agree to form a syndicate.

And now let us consider the action of this syndicate. Not being in the confidence of the prime movers of the syndicate, we may not be exact in detail, and if so, we are open to be set right as to detail, but as to the main principle we believe we are exact.

The main provisions are these:

The manufacturers calculate the consumption of the world at an arbitrary figure fixed by themselves, and divide this among themselves pro rata of their previous make, no maker to make more than the quantity allotted to him, but with this important difference that those makers who had been overtrading had to reduce their make pro rata very considerably, whilst the legitimate manufacturers' make was not reduced.

No manufacturer to accept less than the syndicate prices.

Certain restrictions as to the members buying any large quantity of bark.

Certain members of the syndicate have deposited large sums of money to be forfeited in case they do not act up to their engagements, but with others their word has been considered sufficient security.

This being roughly the programme of the syndicate, we may now turn to the effects already produced by it. The planter has only to refer to the price per unit he obtained before the syndicate was formed, and when foreign quinine was selling at under 6s per oz., viz., about 9d to 10d per unit whereas now, when the syndicate has fixed an arbitrary price 7s 6d for quinine, it only pays the planter 4d to 5d and just at present perhaps 6d per unit. This will show you how much consideration you may expect.

We think it will be patent to anyone that (the manufacturers having agreed not to make more than a certain amount of quinine)—

They do not require a greater quantity of bark than that necessary to produce the quantity of quinine which they agreed to make.

That the quantity of bark actually produced contains a larger amount of alkaloid than the arbitrary amount fixed by the syndicate, and that consequently the syndicate does not want all the bark produced.

That the planters of Ceylon being mostly in want of money and all anxious to get in first and sell the syndicate has the Ceylon planters at its mercy so long as they each try to be the first to sell, and could, if it choose, compel them to take 2d instead of 4d to 6d per unit.

And most important of all that every pound of bark the planters sell to the syndicate at syndicate prices goes to strengthen the position of the syndicate, to enable them to make a fund of profit out of which they will later on be able to carry on their warfare which is alike against the interest of the grower of bark and the consumer of Quinine.

For example, all the large quantities of bark sold in the last year or two in Ceylon direct to the Continent enabled those manufacturers to depress the London market by abstaining from buying, and frightening London agents into accepting low prices; the London low prices re-acted on the Ceylon market and made it sell at again lower prices to the Continent, thus enabling the Continent to continue the abstention policy in London, and consequently a fresh drop in London, followed by a fresh drop in Ceylon, and so action and re-action following each other, all at the cost of the planter and to the profit, principally of that manufactory with which is connected the name of the man who is above all others answerable for the present deplorable state of affairs.

We say, then, and we cannot repeat too often or too earnestly, that the planters must not play into the hands of their enemies by providing them with the means to crush them. A new bark crop is just commencing. The speculator manufacturing part of the syndicate has not yet got rid of its stock of Quinine, costing high prices, and consequently there is no profit made yet. but let it be the planter's care that they do not provide them the sinews of war by selling 1884 crop at too low rates.

You will say, "What are they to do?" For obvious reasons we will not enter, in a public letter, into an enumeration of the steps to be taken by which even the smallest planters may be delivered out of their enemies' hands, and at the same time assist in promoting an antidote to the action of the syndicate; but we have gone very thoroughly into the matter with Mr. Felix J. Broun, of Abercairney, himself a planter, who is proceeding to Ceylon, and who will explain the position more fully to all those who are anxious to preserve the cinchona cultivation as a source of profit to Ceylon, and we hope some scheme may be adopted which will be found workable.

We may say that we shall be happy to act in concert with other houses who may be disposed to protect the real interest of the estates they have charge of.

Do not let any sophistry deceive you. Look at China with its hundreds of millions of people, with its rice fields teeming with the germs of disease—look at India, with hundreds of thousands of its natives dying needlessly, when cheap Quinine would mean life to them. Look at the interior of Africa! Look at South America! Look at the United States, where every westward bound immigrant to swampy virgin soils means a consumer of Quinine. Look at all the various islands in tropical climates—all the inhabitants of such places require Quinine, * and it is for the manufacturer to see that they get it; and once introduced, and we say it advisedly, both figuratively and literally these people would rather go without their shirts than without their Quinine, to say nothing of the hundreds of thousands of poor in our cities, who get advice, including medicine for 6d or 1s; how can they get expensive alkaloids like Quinine and the other alkaloids contained in bark. Reduce the price to a figure which would repay the cost of cultivation, shipping, manufacturing, and distributing, and you could then still sell at a price which would permit all and every of these classes and nations to become purchasers, and yet people are found who talk about over-production!

Do not accept the present state of things. Do not allow any class of men to stand between you and your market. Do not suffer any class of men to step in and say as this syndicate practically says to you:

"You have produced too much bark, you must consequently take low prices; but you shall not reap in the increased consumption of bark—which low prices of Quinine would cause—the benefit of the low price of bark you are forced to accept; for we will prevent that by keeping up the price of Quinine."

We say that is the practical language of the action of the syndicate, but do not for a moment imagine that all or even a majority in numbers of the members are in sympathy with the action of the syndicate. There are many men among them, we may say most of them, who would see with unfeigned pleasure the breaking-up of this unholy alliance.

You have no united foe to contend with, and if you are united it must break up, and break up to the benefit of the planters, to the benefit of the consumers, to the benefit of millions who will become consumers, and lastly to the benefit of every member of the syndicate, for this movement is ruining their own trade. It paralyses every distributer of Quinine who is not so foolish as to buy at 7s 6d Quinine which by the caprice of the same people who put it at that price, might any day be reduced to 5s, and stil yield a handsome manufacturers' profit. There is no inducement to the dirtributer to push the article; it is not likely he is going to work hard, to send out his travellers at great expense, on the chance of getting, in out-of-the-way places, 1s an ounce profit when the caprice of the manufacturer may at any time subject him to 3s an ounce loss.

This is not a question limited to today's aspect of it. If we are to submit to talk of over-production today, what shall we be told a few years hence!

* Russia ought to have been specially mentioned.—ED.

When all the immense planting of 1879, 1880, 1881, 1882 produce their bark.

When Java will send its millions of lb. of rich bark.

When South America shall send its fine cultivated Calisaya, growing on its native soil, and showing already results which promise wonders for the near future; and

When all the wild forests in South America, strengthened by their years of rest during the low prices, again send fine barks at small prices.

If you are going to sit down quietly now, what will you do then?

Why there must be at least one hundred millions of people in the world who require, and are able to pay for one hundred million ounces of Quinine, annually if only the Quinine be brought under their notice. Let the manufacturers get one tithe of these buyers, and where will be the talk of over-production! We say nothing about the consumption of the lower alkaloids contained in the bark, for which lower alkaloids the manufacturers at present do not pay you; our case being already so overwhelmingly strong, and as we have already gone to such a length that we fear you may not be able to find space for this letter, but the subject is so important and so absorbing, that it is difficult to know when to stop; we will therefore recapitulate.

Sell no bark to any member of the syndicate without your interest being protected by someone who knows all the bearings of the market and the requirements of the buyers, and who will see that they are forced to pay a fair value.

Consult with Mr. Felix J. Broun, who has been able to collect on the spot a very full opinion, from varied information, as to the proper course to be pursued.

When agreed on the course to be pursued, act together with the knowledge that you have the sympathies of all the consumers, of all the London trade, and of the greater number of the manufacturers themselves.

Trusting that, notwithstanding the length, you will find space for publishing this letter, we are, dear sir, yours faithfully, FRANCOIS LE MAIR & RIVERS HICKS.

DOMINICA AND ITS RESOURCES.

We have received from the Kew Gardens authorities a very interesting report by Dr. Alford Nicholls on the rich-soiled, well-watered and heavily-timbered Layon Flats in Dominica, the largest of the Leeward Islands. The island is of volcanic origin, and some of its mountains rise to 5,000 feet. The island is only 300 square miles in extent, and the Layon and Sara Flats in the interior of the island, which form the subject of the report are only 40 square miles, which is greater, however than the whole area of the island of Nevis Dominica was once a scene of prosperous cultivation; but first the Maroon War (waged by escaped negroes), then the effects of emancipation, and, finally, the destruction of the coffee trees by an insect blight (*Cemeostoma coffeellum*) brought the island down to depths of depression. The blight still affects the Arabian coffee, but, according to Dr. Nicholls, the Liberian species resists its attacks. Cacao (so Dr. Nicholls spells it) flourishes even when neglected, and Dr. Nicholls mentions a red pottery clay eminently suitable for "claying" the beans. But is the claying process necessary? Were a road or a tramway run through the rich central flats, Dr. Nicholls states there would be a mine of wealth in the fine timbers alone, a number of which he notices including the bullet-tree (*Bumelia retusa*) the trunk of which sometimes attains a diameter of 7 feet, which means 21 in circumference! Also the green-heart (*Nectandra rodiaei*) which is placed first class in Lloyd's list of timbers for shipbuilding. Also

Cacorier or *Mosia dasycarpa.*—This large tree is common in the forest, and its wood is most useful for house-building, and for any other purpose for which timber is employed. It is called in other West Indian countries the bead or necklace tree, on account of its seeds being used for personal adornment. These seeds are very hard and roundish, beautifully polished, and of a bright scarlet colour with a jet black spot at one end; they are considered of value in Europe, and they might be made an article of export.

Simarouba (*Simaruba amara*).—A tree three or four feet in diameter, the wood is used medicinally, and it is employed for making shingles and boards. It is much liked by the people for inside housework, as it keeps away wood ants and other destructive insects.

Dr. Nicholls further describes the properties of some of the trees :—

During the journey I did not observe any indiarubber yielding trees, nor am I aware of such being indigenous to the island, but a kind of gutta percha, known to commerce as "gum balata," is obtainable from the bullet tree (*Bumelia retusa*), and it might be made a valuable article of export from Dominica as it is now from British Guiana. I made a small incision into one of these trees, and the liquid gutta percha flowed out freely.

The Gomier (*Bursera gummifera*) exudes from the bark a fragrant gum in great abundance, and were it systematically collected it would soon become an article of export. It is burnt as incense in the Roman Catholic churches in the island, and it is employed as a disinfectant and deodorant at the Yaws Hospital and the Roseau Infirmary.

His lordship the Bishop of Roseau, who is ever ready to do all in his power to advance the material prosperity of the island, informs me that some manufacturing chemists in London think so favourably of this gum—which is unknown in England—that they are willing to buy a large quantity (at a price which will ensure the collectors against loss) in order to introduce it to the home markets.

The Mangue Rouge (*Tovomita plumieri*), and the Mangue Blanc (*Moronobea coccinea*), which belong to the natural order *Guttiferæ*, both yield a yellow resin resembling gamboge. This resin may become of commercial importance if it be introduced to the home markets. In Jamaica the resin of *Moronobea coccinea*, which is there called "hog gum," is employed as a substitute for pitch, and it is occasionally used medicinally in the stead of balsam of copaiba.

The Simarouba already mentioned amongst the timber trees is the source of the quassia wood used medicinally and for brewing purposes. The wood contains a bitter principle—quassine—which is sometimes employed as a substitute for quinine.

The Greenheart (*Nectandra rodiæi*), which as I have shewn is one of the most valuable woods known, is also the source of an important drug, for the bark of the tree is the "Nectandræ cortex" of the British Pharmacopœia. This bark is exported from British Guiana in large flat pieces from one to two feet long, and from two to six inches broad. It contains an uncrystallizable alkaloid called Beberia, which has tonic and ante-periodic properties. Both the bark and its alkaloids are sometimes used as substitutes for quinine, and the sulphate of beberia enters large y into the composition of the celebrated "Warburg's" Tincture, a medicine used in the treatment of malarial fevers.

The Angelin (*Andira inermis*), produces a drug which used to be largely prescribed in English practice as a febrifuge, an anthelmintic, and a purgative. The bark of the tree is the part employed and it is known in England as "worm bark" or "bastard cabbage bark."

If only capital and labour were available, the land, after the clearing and sale or export of the timber, would grow all tropical products from sugar to rice, one hundredfold return of the latter having been obtained from a swampy portion of the flats. Our readers will thus see that Dr. Nicholls' Report (which will be given in full in the *Tropical Agriculturist*) is very able and interesting, and that the small island of the Lesser Antilles has resources which only need developing in order to restore the colony to more than its former prosperity. A road or tramway of 20 miles would open Dominica from end to end ; and if English capitalists are not attracted by Dr. Nicholls' report, we shall be surprised if some go-ahead Yankees do not form a company to utilize first the fine timber and then the exceptionally rich soil.

A CURIOUS OMISSION.—Some little excitement has been created among importers of cinchona alkaloids and their salts into the United States by the discovery that when the Act was recently passed repealing the duty on quinine and its salts and cinconidine, sulphate of cinchonidinine—probably through an oversight—was not mentioned. The Act provides that all alkaloids and their salts, by whatever name known, if not specially enumerated as exempt, shall pay a duty of 25 per cent *ad valorem*. As the enumeration in the free list is limited to "quina, sulphate of, salts of, and cinchonidia." the collectors at the ports have decided that sulphate of cinchonidine is liable to pay the duty, and notwithstanding an appeal to the authorities they will probably maintain their ground.—*Pharmaceutical Journal.*

TEA AND COFFEE.—Dr. G. V. Poor, lecturing in London, with Sir Henry Thompson presiding, drew a comparison between tea and coffee, and said the effect produced on the human system was in both cases similar. Tea required less digestive power than coffee, and it did not "cloy" the palate. The latter, however, was a better stimulant, and there were but few beverages more refreshing than the cup of coffee. Tea was "the tobacco of women," and its ill effects were due to presence of much astringent matter, and this was one of the chief causes of dyspepsia. Coffee was a stimulant which would prove a good substitute for spirits, and as such its use should be encouraged by those who were trying to reclaim the drunkard. Since 1854 the consumption of tea in the United Kingdom had increased from 2lb per head, to an average of 4lb 9oz ; but the consumption of coffee, however, had in the same period decreased from an average of 1lbs 6oz to 15oz each person. If adulteration were stopped, the coffee planters of Southern India and Ceylon might be able to carry off a lakh or two of rupees, but with chicory and dandelion acting so prejudicially against fragrant berry they have not much chance.—*Madras Mail.*

THE squatting or grazing industry of Australia, and especially of Queensland, has only in the very slightest degree advanced beyond the condition occupied in the patriarchal and barbaric ages. This one exception is that now-a-days the employment of labour is avoided by fencing the country into large paddocks. Otherwise, we fail to see in what respect our wealthy, highly educated squatters, differ from those older squatters who flourished just before or after the Flood. The fact cannot be denied, so far as the grazing industry of Queensland is concerned. We are only just in advance of the wood-dyed savages who occupied Scythia or Britain in the days of Cincinnatus. We have retrograded two thousand years, and shall make no material advance until we learn to do what is done in all the civilised countries of Europe and America, and by the application of the art of agriculture to the soil, improve both it and ourselves by raising ten times as much stock, on a given area, as is at present done. It is little or nothing less than a sin, thus to relapse into a barbaric mode of life, and, because land is plentiful and cheap, throw overboard all the advantages of the age, and nearly all the amenities and sweetness of its civilisation. When our squatters throw aside the barbaric for a civilised condition, they will not only obtain larger and surer returns for their capital, but they will also open vastly more extensive channels for investment, while at the same time affording facilities for the spread of settlement and the improvement of society that are now entirely out of the question.—*Planter and Farmer.* [This is a true bill, but as population advances the wrong will be righted: farms will succeed to "runs," and where pastoral pursuits are followed lucerne and other forms of fodder will be cultivated as well as the native grasses.—ED.]

Correspondence.

To the Editor of the Ceylon Observer.

MR. HUGHES, AGRICULTURAL ANALYST, ON THE *TROPICAL AGRICULTURIST* AND ON CEYLON AS A TEA-GROWING COUNTRY.

Analytical Library, 79, Mark Lane, London E. C., November 30th, 1883.

GENTLEMEN,—I had much pleasure last week in paying your London agents my usual annual subscription for the current number of the *Tropical Agriculturist.* It is indeed a most useful publication containing the most recent information respecting the growth of tea, coffee, cinchona, cacao and other crops, in which planters are interested. I have had great pleasure in referring several friends, who wanted information on the above, to consult the pages of the monthly numbers of this really practical book, for the papers are for the most part written by thoroughly practical planters and experienced men. Such a book as the *Tropical Agriculturist* should be found in the library of all our large schools and colleges where so many young men who intend going out to the colonies are now being educated. Your agents might I think be recommended to bring this matter before the principals of such establishments. I am glad to see that Ceylon tea is making such satisfactory progress and is now favourably received by the brokers of Mincing Lane.

If you will refer to page 144 of my official report, published as far back as 1879, you will notice that I ventured to remark that "from the analyses of soils lately made, I should consider it extremely probable that when the curing operations were thoroughly mastered, Ceylon tea would be distinguished for its fine flavour." I believe that they will be valued chiefly for the *fine flavour* and not for *strength*, I am glad to say I am well in health and have my hands full of work.

Wishing you the compliments of the season, believe me, yours faithfully, JOHN HUGHES.

P. S.—I dare say you will soon get a copy of my recent report upon the analyses of the rainwater sent for examination by the Planters' Association.

TESTING AND DEVELOPING VITALITY IN SEEDS.

SIR,—In case there should be "anything in it" I send you copy of a memorandum of a process for testing and developing any vitality in seeds. The jotting is from an old scrap-book which has come into my hands and quotes no authority. Perhaps some of your readers will put it to the proof and report. It is a pity the formula is not more precise. —Your obedient servant, AN OCCASIONAL

(Copy.)

Torpid seeds if steeped in a diluted solution of oxygenated muriatic acid at a temperature of about 46° or 48° Fahrenheit, if not quite dead, will germinate in a few hours, and, if then planted properly in appropriate soil, will grow with speed and vigour.

NAVY CONTRACTS AND CEYLON TEA.

The Ceylon Tea and Coffee Agency, 4, Guildhall Chambers, 33, Basinghall Street, London, E. C., 7th December 1883.

DEAR SIR,—It has so often been said (without foundation) that this Agency is conservative in its sale of Ceylon teas, confining itself to certain marks and thereby benefitting the few without profit to the many, that I trust you will find space for the letter at foot.

Not one sixpence of profit will come to this Agency should Ceylon tea be chosen, but we have the satisfaction of knowing we are doing our part for the good cause and that tea-planters will reap the benefit.—Your obedient servant, A. HUTCHISON.

Admiralty, Whitehall, S. W., 30th Nov. 1883.

Mr. A. Ames, 4, Guildhall Chambers, E. C.

Sir,—On referring to your letter of 14th inst. submitting samples of Ceylon teas. I have much pleasure in informing you that instructions have been given to the Admiralty Brokers, that when next the department may be buying, no objection will be offered to their submitting samples of Ceylon teas, which they may consider suited to Navy Requirements.—I am, sir, your obedient servant, JOHN COLLETT, *Director of Navy Contracts.*

BUSHEL MEASURES: PRACTICAL ENQUIRIES.

Nuggur Division, Mysore, 12th Dec. 1883.

DEAR SIR,—I shall feel much obliged if any of your numerous readers can inform me *what* the average measurement of a box of palam is in Ceylon and what the average outturn in wet parchment should be: *that* is to say a struck Government bushel; what the measurement of a Government bushel is, and what is the difference between the wet and dry measurement of a bushel.

We have just commenced picking here. I think there is every prospect of crops being up to their estimates.—I remain, dear sir, yours truly, IGNORAMUS.

KINMOND'S TEA MACHINERY.

Calcutta, Great Eastern Hotel, 14th Dec. 1883.

SIR,—A copy of the *Ceylon Observer* of Nov. 14th has just been handed to me, in which when reviewing the latest edition of Col. Money's book on tea you state "Col. Money rather strains the English language by declaring that with recent improvements the machine (my patent tea drying machine) is very perfect," and you add "it ought to be for the prices for the different sizes are"—and then you give the prices of the different sizes of machines which are made. Now in order to test whether a machine is dear, its price together with the *quantity* of work it performs must be compared with other machines doing the same kind of work. The sirocco (which you also mention in your article), for instance, costs £85 in England and dries certainly not more than 5 maunds tea per day.

My No. 2 dryer dries 2 maunds tea per hour, or 20 maunds in a day of 10 hours—that is it does the work of *four* siroccos and it costs only £220. Whereas the cost of four siroccos is £340—or a difference in favour of my dryer of £120—that is the sirocco is a little more than 50 per cent *dearer* than my dryer. I may also state that this season I am allowing a special discount of 5 per cent on single orders and 10 per cent discount when not less than 4 machines are ordered. The latter discount reduces the cost of the No. 1 machine to £135, and that of the No. 2 machine to £198. JAMES C. KINMOND.

[Mr. Kinmond makes out a good case for his drier, but two questions arise: would not several smaller sized driers spread over a tea house and diffusing heat, be better than one large machine, and is it a fact that, unless great care is exercised, the fanners which send forward the hot draft will blow away some of the tea?—ED. C. O.]

TEA CUTTINGS.

Beruwala, 18th Dec. 1883.

DEAR SIR,—In your issue of the 12th inst. I read that "Short of Plants" requires some information with regard to tea plants raised from "cuttings." As far as my experience goes on this subject, I give it.

I have tried cuttings largely, both in Assam and the Himalayas, and also in this island, in the districts of Laggala, Rakwana and Morawak Korale, and I have always found them thrive very well indeed. In India, I generally put the cuttings out as hedges round different fields to distinguish them from each other, as a help to the pickers, and numbered my fields accordingly. The yield is not so large as plants grown from seed, and the liquor not so strong, but as seed-producing plants they are unexceptionable. There is not the slightest harm in filling up vacancies with them, if required, for seed, and where the vacancies are not too high, but in any other case I would not plant them, as where you have a good jât of plants as "Short of Plants" evidently seems to have, it would deteriorate the quality of his teas by mixing them. I would, however, recommend planters, planting up a few a acres of land with tea cuttings and reserving them for seed which will be of service to them in times, when there is a want of seed and where nursery plants are scarce. In planting tea cuttings, I would do so in hedges, in the same way as rose or shoe-flower cuttings are put out, and each time three feet apart from the other. It is generally understood that you cannot get both leaf and seed from the same garden and, to get a better quality of seed, cuttings are the best for this purpose, as the percentage of good seed is larger than in the other case where you have weakened your plants by "plucking."

I give my opinion here from several years' experience in tea planting in Assam and Darjeeling,—I am, &c., C. ACLAND RYVES.

TOBACCO CULTIVATION IN TAMANKADUWA.

Topare (near Pollonnaruwa), Dec. 1883.

DEAR SIR,—I send you (accompanying my letter) a small packet of tobacco, prepared from plants grown in the Tamankaduwa district on the banks of the Mahaweliganga. It is, I believe, of good quality, and is said to have been sold in Negombo (where native tobacco of the best kind is grown and cured) at the rate of R48 per thousand, the standard price there being, I think, R50. It is well to mention that an attempt was once made by some energetic planters to open out a tobacco estate a few years ago in the same locality; an experienced man was brought from India to supervise the processes of growing and curing; but, on the whole, the enterprise seems to have proved a failure. The sample enclosed has been picked from a crop gathered from a few acres which were planted for trial. I do not quite know the cause of the failure of the former attempt, but certainly this one has been very successful, for the land cultivated has yielded an ample profit to its very enterprising and energetic owner. Should a fair trial be given to the cultivation of this plant here, it is not improbable that the wildest, and in some respects poorest, district in Ceylon will advance to a flourishing condition. I write this to point out to enterprising spirits what might be made a new (and perhaps well-paying) field. Hoping that you will be kind enough to express an opinion as to the quality of the tobacco I forward. I remain, yours etc., J. H. B. F.

[We have submitted the tobacco to Mr. C. E. H. Symons, who reports as follows:—"The leaves, I think, have, been left on the stem too long, the ribs being too coarse; color is too dark and uneven. Character of leaf good."—ED.]

CANKER IN TEA PLANTS.

DEAR SIR,—By this post I send you a number of tea plants taken this morning from a nursery within 3 miles of Nawalapitiya. You will observe they appear to be cankered much in the same way as cinchona plants, round the collar. Kindly say if you have seen this disease before and whether it is likely to prove as fatal to tea as it has to cinchona.—Yours faithfully, H. M. E.

[We cannot say that we have ever seen the disease before as shown on these plants, but we know that some nursery beds in an elevated swamp in Abbotsford were killed out by apparently the disease which attacked gums and cinchonas so severely in 1872. Some of the adult trees were also affected, but they speedily recovered, and for long now there has been not a trace of disease—only flourishing growth. We trust the present case is owing to some peculiar conditions of seed, soil, or climate, and that the affection may not spread. Of course tea, like every other product, has its enemies.—ED.]

TEA SEED IMPORTED AND THAT GROWN LOCALLY.

SIR,—Before writing on the first subject, I will ask my readers to make a little allowance for any discrepancies they may find in my figures from what they have experienced practically. I have exported large quantities of seed from Darjiling to Assam and the consignments have invariably turned out well: yielding from about 30 to 35 000 plants per maund: and this was at a time when the tea mania was on, and seed was selling at a fabulous price. Again, I have myself visited selected and picked seed off two estates in Ceylon one in the Laggala district and another situated in Dolosbage, and this has yielded me from 35 000 to 40,000 plants per maund. The local seed I found somewhat smaller in size than that sent to Assam from Darjiling. I have invariably packed my seed in well-sifted soft earth and moss and have (immediately on arrival) separated the germinated seed and put them out in prepared beds in a nursery: and the rest I have pitted and as they germinated removed them to the nursery. If planters follow this plan, they will find that a larger percentage of seed germinate than by immediately putting them out in nurseries as I have seen done here in Ceylon.

More again. C. A. R.

PLANTING TEA AND COFFEE: DIBBLING VS. HOLING.

27th December 1883.

DEAR SIR,—I was under the impression that I was the only planter in the country who was bold enough, or fool enough as some would say, to plant tea with alavangas. I have just finished 60 acres without having made *one* of those tea-cum excavations called "holes." But I see that Mr. Mullens has had the courage to urge the practice, as not only being the most economical (in these hard times), but also the best, or *better* than holing. Both these reasons should cause earnest enquiry, and to help to give sorely-pressed planters confidence in this cheaper and more efficient process, I will, sir, with your permission, give my own reasons and experience.

Now, six months ago I had never even seen a tea-plant, so that I am not trying to pose as an expert in tea. But I have planted as much coffee as, perhaps, any planter now in the country, and I may claim, therefore, to know something about that? I could point to hundreds of acres of the finest coffee ever seen, in *all* the Uva districts, planted by me with alavangas only, the roots having spread themselves out everywhere throughout the soil. Some months ago I paid a visit to an old friend of mine in Dikoya, and assiduously trudged with him through his own and his neighbours' fields of coffee; and what did

I see? Along the roads, every now and then, the holes that had been cut when planting up the estates were exposed in vertical section in the bank. With few exceptions the roots of the coffee were to be seen *hole-bound*, i. e., they never got beyond that hole, the thick *surface* roots of course excepted.

Well, when later I began to think about planting tea, I studied all the papers that were written by the various experts, visited several estates, and became intimate with Messrs. Cameron, Daly, and others; and I was not long in finding out one great fact about tea, viz., that it is a much hardier plant than coffee, and far better able to hold its own against other plants growing with it, owing to its stronger and more vigorous roots. To argue, therefore, that what coffee will stand, tea will more so, was an easy process, and reasonable enough; and in old coffee land, pitted with old manure holes and with passages made by coffee roots, it seemed to me to be the height of folly to waste labour on more "holes," which, however, I should not have cut even in new land. Properly done alavanging *is* cheapest *and best*.—Yours, R. W. J.

COFFEE AND LEAF-DISEASE.

DEAR SIR,—I have to express my obligations to "An Old Coffee Stump" for his very interesting letter published on the 10th Dec. in answer to mine. The information he affords is more than I dared to hope for, and, what is of more importance to me, bears me out strongly in the opinions I have expressed, even further than "A. O. C. S." seems to be aware of.—Yours faithfully, SWADDY.

CURIOSITIES IN CACAO AND COFFEE.

Maria, 5th Jan. 1884.

DEAR SIR,—In going over this estate today to select certain cacao trees from which to pick pods for nursery, I came on a very healthy large tree which to my surprise had three varieties of fruit of all sizes:—

(1) red when very small, and up to ripening;

(2) green when small, gradually as i colour, then ashy red when ripe;

(3) green when small, then yellow when ripe;—each kind on a different branch.

I have two Trinidad trees in bearing about 300 yards from this tree: the fruit is green when young and gets yellow when ripe. How to account for the tree giving three varieties without grafting or anything done to the tree I leave to a scientist to describe. I have also a coffee tree now four years old bearing the last two years, grown out of a kitul tree about 15 inches above ground; the kitul tree is now about nine years old. This has been shown to many visitors. —Yours faithfully, J. HOLLOWAY.

LIFE IN SOUTHLANDS, NEW ZEALAND.

DEAR SIR,—I sent down the letter of your correspondent from Southlands, a Ceylon man, to a relative of mine, a young man who has been nine years in Southlands and now having sufficient capital has taken up land on his own account.

I send you full extracts of his reply, if you think it would be of interest to your readers your are at liberty to publish it. Though for my own part had I three thousand pounds, and were I young and healthy, the uplands of Ceylon would be good enough for me. —Yours faithfully, H.

Mossburn, Elbow, Southlands.

My dear ——, I have carefully read the letter by "Ceylon Planter" and with one or two exceptions can find no fault with it; it shows the writer has thoroughly observed and understood what he saw. Prices, etc., are so very different, in different places, that it is very hard to give any fixed price for ploughing, harrowing and other works, but in my district they are 20 to 25 per cent higher than quoted in your paper.

I also doubt if in any part of New Zealand, land can be bought for the price quoted.

The price for unimproved land near a railway station, except direct from Government, under the deffered payment system and under stringent conditions of residence etc., ranges from £4 to £8, and improved land near a railway from £5 to £15; nearly all the D. P. lands that are any good here are already taken up.

The want of society, of course, is keenly felt by those of better education and will continue to be so if people make that a reason for not coming to New Zealand. It is easily explained: 99 per cent of the farmers have come to *make* a living; not to live comfortably on what they already possess, and for the first few years there is sure to be a hard struggle and a great many go to the wall, and often by the time they have made a comfortable income they have got into the way of hard grinding and do not care to get out of the old way of living. Every year the condition of farmers is improving, and a better class of people taking to farming.

"Ceylon Planter"'s estimate of the amount of capital required is very true; also his account of the willingness of Loan Companies to advance, which often ends in the Loan Company taking everything.

With the rest of the letter I thoroughly agree, everyone should see for themselves, no one's experience will be exactly the same. Exactly opposite advice is given and there is truth and reason in both ways of looking at a thing. One thing is certain: a clear-headed, hard-working man will get on perhaps better in N. Z. than elsewhere, and a thriftless, careless one is perhaps more likely to lose what he has.

Drink and gambling are the two great curses of this colony among all classes.

Fixed deposits in the banks just now receive 6 per cent, loans on freehold security 7 per cent to 10 per cent is easily obtained.

With regard to the estimates given at the end of "Planter"'s letter. my experience is very different.

It is very seldom that a man picks up a block of 1,000 acres that he can plough the whole of the first year.

The best land generally takes a great deal more than 3s 6d per acre to clear it, and no allowance has been made for draining.

And even if he could plough the whole the first year what would any stock he might have do for *tucker*?

One would not be justified in depending alone on cropping, for in this, as in other countries, there are good and bad years. And the same with regard to sheep feed must be grown for them therefore a certain rotation in cropping is necessary one would not find sale for 1,000 acres of turnips in one district, though two or three hundred acres are always marketable.

In my district (Wallace country) the prices range somewhat as follows:—

	s. d.		s. d.	
Clearing ...	3 6	to	20 0	per acre.
Ploughing ...	6 0	to	10 6	„
Sowing ...	0 10	to	1 0	„
Harrowing...	0 10	to	1 0	per time.
Rolling ...	0 10	to	1 0	„

Draining may cost from nothing to almost anything according to the nature of the ground.

With regard to sheep, I think the average clip would be nearer to them 9lb. Though, perhaps, after many years careful breeding it might be raised to 11b. No one could expect to pick up sheep for sale that would clip that amount.

The climate here is very changeable, and at times cold. We have a great deal of moderate weather, a little very bad, and a little exceedingly charming.

I believe no country in the world is more pleasant than N. Z. when it really is fine. Of course, my experience is confined to the Wallace country, and I have been here now 9 years, and I can speak confidently of its resources, which only want men who will work, and capital to develop them and I am for my part pretty confident, that a man can do well here.—Believe me, yours truly, A. B.

AMENDED REGULATIONS FOR THE WEIGHING OF INDIAN TEA TO COMMENCE 1ST JANUARY 1884.

(*From Messrs. Stenning, Inskipp & Co.*)

The weight of Indian tea for duty, may, if desired by the Importers, be ascertained under the following regulations:—

1. The packages on arrival to be weighed to ascertain the gross weight of each package.
2. With each entry the Importer to give and endorsement or statement of the net contents of each package.
3. To test the accuracy of the endorsement or statement of the net contents, 10 per cent of each break to be turned out and weighed net, but in no case should less than 3 chests be turned out.
4. If the variation in weight of the test packages be found to exceed 1 lb., the whole parcel to be weighed net.

When the average of the packages weighed net amounts to so many pounds and a half, or more, the half or more will be charged as a full pound; when the fraction is less than a half pound, it is to be rejected and disregarded.

29, Mincing Lane, 20th September 1883.

NEW PRODUCTS IN UDAGAMA.

SIR,—The excellent growth of the Tea plant on Oodigama estate and other properties proving the district to be pre-eminently well suited so it—no place better in the island probably. A moist, humid climate, represented by over 150 inches of rain evenly distributed throughtout the year, and a deep free soil impregnated with iron, and rich in alkalies, reads something like pefection, and the bushes where pruned, have (as might be expected) shewn a marked tendency to flush very rapidly. We may fairly hope to hold our own with other low-country districts regading the generality of new products—but certainly as regards tea, for the facilities for cheap production are all that could be desired. Cardamoms are now a proved success, with a considerable acreage under cultivation; and arecas likely to develope into a very extensive and highly profitable industry in the district. We know I think now about all that can be urged it its (the latter's) *favor*—and this no little,—but cannot hit on any arguments *against it*. Can any of your readers suggest any, say that no appreciable crop can be expected till the 5th to 6th year after sowing the seeds at stake? If so they will much oblige OODIGAMA.

[NOTE BY EDITOR.—We believe arecas will, in suitable localities, prove a most remunerative cultivation. The demand is large and steady, whilst the upkeep is very small. As regards tea, there is undoubtedly a splendid future before Udugama and Kalutara in the cultivation of tea, for all the elements of success are there, and we shall always be glad to hear of the progress of tea or any other product from our correspondent.—Local "Times."]

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, December 8.

Sorgho has never really taken in France; it was in 1851 that the French Consul at Shanghai sent a number of the plants for experiment. It was introduced with too many flourishes of trumpets. However, it was from the industrial, not the fodder point of view, that its culture was advocated. It was thus brought into competition with maize, and beet. Sorgho requires rather much care, and is cultivated as maize. The soil must not be poor, nor made too rich; the climate must have at least a mean temperature of 60 degrees for 150 days; associated with these conditions, must be a fair amount of humidity or irrigation, for sorgho is a tropical plant. The plant grows to and 11 feet high, in a tuft of 8 to 10 stems, of which two or three bear the seed. Dr. Sicard has discovered, that the saccharine substance disappears from the summit of the plant, pending the maturation of the grain, while it continues to accumulate in the stem. The experiments of Biat and Soubeiran confirm, that on removing the ears of maize before their maturity, this did nor increase the secretion of juice in the stem more than 2 per cent. The same remarks apply to sorgho. Bear in mind, the maturation of the plant must not be confounded with its natural desiccation, a process quite distinct, and taking place at a different epoch. In France, the yield of sorgho is about 25 tons per acre, giving 25 per cent of its weight of juice, that which represents about 19 cwt of crystallized sugar. But this corresponds to the yield of beet sugar, and the latter can be worked more easily, and above all, more surely. For forage—tilled like maize—50 tons per acre have been reaped; the plant must be cut before the stems harden and the knots get woody. It is chaffed and mixed with bran. Some suggest to dry it like hay. Its great competitor, however, is maize.

THE ADVANTAGES OF SHADE.

The farmer or planter has only one method of shading open to him, and that is mulching, or protecting the surface of the soil with dead litter of any kind from the sun's rays. The material burnt off the land every year on many farms would more than pay for the extra labour it would entail in saving and storing it, if it were reserved and applied for mulching purposes. Although and unusual practice, it is a quite natural one, for in nature the young seedlings of any kind are invariably protected with a mulching of dead vegetable matter, which shades the soil and conserves the moisture, thereby helping the seed to germinate, and afterwards in decomposing adds to the fertility of the soil and invigorates growing plants. For some plantations, such as coffee, mulching is not only desirable but quite practicable, and it has this further merit, that while it encourages the growth of any cultivated crop it has the very opposite effect upon weeds, which it tends to smother and keep back. It is questionable whether coffee will ever be cultivated to profit in Queensland under any living shade; but mulching the soil may probably prove a very sufficient substitute for the shade afforded by trees in more humid climates.

It is in market gardening and floriculture, as well as in orchard work, however, that shading in various ways will prove most effective. As in cold countries protection is constantly sought from bleak winds and the severest cold, so in hot countries shelter is desirable from the fervour of the sun's rays, and from drying and withering winds. Breakwinds may be living, if far enough away from growing plants not to rob them of moisture or nutriment, and that means a long distance if the breakwind consists of large and strong growing trees. For shade purposes only, however, nothing living is admissible. Only mulching is available for the orchard, and it would be well if all who cultivate an orchard regarded this method of shading as indispensable.—*Queenslander.*

QUALITY OF THE NEW COFFEE CROP.

The effect of leaf-disease on the constitution of our coffee trees has been a subject of frequent discussion in our own and our contemporary's columns; and it was by no means unnatural that, looking to the much smaller crops of late years, the inference was drawn that leaf-disease had prejudicially affected the health and strength of the trees, and in this way prevented them from setting their blossom, and maturing all that did set. This being the view generally taken, it is exceedingly gratifying to note, as we have done during the present early months of the new coffee season, the superior quality of nearly all the coffee arriving from the interior, whether low or high-grown. It was noticed some weeks ago that much low-grown coffee fully equalled in quality high-grown parcels of last year, and now that some of the produce of the higher estates has arrived in Colombo, we find that the quality of these far surpasses that of parcels that had reached Colombo during last season; and, in fact, is quite as good as any that we remember in the palmy days of coffee.

Now that coffee such as this is produced on our estates, we are naturally led to ask: can it be inferred that the constitution of the trees has been seriously weakened? If it were so, they would not mature such a sample as that to which we have alluded. It is true that the past season has been one favorable to the growth of all vegetable matter, having been moist in the extreme; but we have had previous wet seasons. Last season was certainly not a dry one, but we saw nothing approaching the Wellington sample of coffee during the whole of last year. The fact augurs well for the future outlook of coffee, as we cannot help feeling that the trees are still vigorous and healthy, but are prevented from yielding large crops as in former times from some cause as yet beyond our knowledge. There is still hope that we may see good crops, if not the crops of former days, at any rate on such estates as have been well cared for. As regards the estate in question, we are not aware that it has had any particularly high cultivation. It has, of course, been kept clean and well tended, but we suspect that is has not been highly favored in the matter of manure, or we may have been led to look to that as the cause of the superior quality of the coffee. The Matale, equally with the Pundul-oya, crops are this year of very fine quality, a good deal above the average; and we are informed that the quality on estates in the former district, which have not been named for several years, is in every respect equal to crops from regularly named estates.—Local "Times."

SORGHUM CULTIVATION IN THE UNITED STATES.

Mr. Henry Stutniczka, of St. Louis, a genteman having a thorough practical knowledge of the beet sugar industry of Europe, in an open letter addressed to Prof. Silliman acknowledging the receipt of a copy of the report of the committee appointed by the American Academy of Sciences to investigate the sorghum interests in this country, speaks most hopefully in regard to its future.

Since 1871, when first I landed in this country, it has been incomprehensible to me how this singularly enterprising people could import more than one hundred millions of dollars worth of sugar per annum. The consumption in this country in 1882 being of home and foreign product 942,890 tons, an increase of 120,000 tons over that of 1880. These figures will be found suggestive, when we realize that our domestic supply is not more than 100,000 tons, or about ten per cent of the consumption. Hence the outcome to this home production may safely be said to be unlimited. On the strength of my seven years' experience in the beet sugar industry of Europe, I am convinced that it is far inferior to the northern cane as a sugar producing plant, and if this beet sugar industry has since 1811 grown to be the only dangerous rival of the cane sugar industry of India, and has thus far increased to almost two millions tons annually, what may not be the outcome to that of our northern cane?

The only doubt I ever had of the success of this cane industry in the north, was the possibility of its maturing in sufficient season to secure its crystallizable sugar before frost. There is no difficulty in the manufacture of the juce of any sugar plant into crystallizable sugar, if the juice, on ripening, contains from eight to twelve per cent of crystallizable sugar, and the impurities not more than from two to three per cent.

I can produce many letters from northern farmers enquiring how they may separate their sugar from the melado, and how to prevent their syrup from crystallization. Now, if their difficulty is to prevent this crystallization with the crude and imperfect agencies at hand, what, it may be asked, is to prevent the successful production of sugar in the hands of experienced men and with the latest and best machinery; and the well-defined manipulations of perfect extraction, improved defecation and boiling under vacuum!

Much of the success attending the cultivation of this northern cane and its susceptibility to the production of a marketable syrup or sugar depends, I am satisfied, on the use of proper fertillizer; that barn yard manure, guano or any other ammoniacal manure producing a rank, fibrous plant with little crystallizable sugar is uncalled for and used to no advantage, but that if any fertilizer is used it should be a superphosphate of lime with small portions of potassa combined. * * * There is no occassion for disappointment in the failures experienced either in the beet or northern cane industry. Europe expended millions before reaching success. Still, I am of your opinion, Professor, that beet sugar cannot be as profitably cultivated as the northern cane, but may do in some sections, especially as an appendix thereto, susceptible as it is of occupying the factory several months longer. * * * I conclude then, finally, that this northern cane sugar industry needs, with such fostering care as I have hinted at, proper land, good cultivation, the right kind of fertilizers, to ripen fully the cane. Second, the extraction, as much as possible, of the juice you cultivate; third, not to be discouraged with apparent failures; and last, to induce the state and general government to give it such aid and encouragement as so important an industry is entitled to.—HENRY STUTNICZKA.—*Farmers' Review.*

A TOUR IN THE LAMPONGS, S. SUMATRA.

BY H. O. FORBES.

Among the wonders of the vegetable world, apart from flowers, few will draw forth the admiration of the traveller more than the gigantic waringin and kawat trees, as the native calls them, which are to be found in the second growth as well as in the virgin forest, though naturally greater in the latter. They belong to the fig family, a tribe the botanist falls in love with at once, not only from their striking character, but also from the general beauty of their foliage, and what would be popularly called their fruit; but the fig is in reality a hollow, almost closed cup or receptacle, within which minute flowers, and by and by small fruits, are produced. The kawat and waringin belong to the genus Urostigma, and often overtop the highest giants of the forests; but they are among its most relentless parasites and tyrants. As a tiny seed they are brought by some bird, or fruit-eating creature, to the cleft of some tree, great or small. At once they germinate, sending down their rootlets—tiny rootlets at first they are too—and for a time they seem, with their dark green glancing foliage and their long cord-like roots running down, around, and upon the trunk of their host, anything but ungraceful ornaments. After a few seasons, however, these roots will have interlaced, annealed, and almost closed in the tree that gave support to the seedling. Here and there only, through lattice-like apertures, can its stem be seen, like some Inquisition martyr built into the wall, till it rots away and disappears. The seedling grows, shoots out its top higher and higher, spreads out its arms wider and wider, dropping down on all sides, farther and farther asunder as it grows in height, long slender cords that only longed for the touch of the genial earth to start into all the vigour of as it were a double life—life of a branch from the parent, and life of a root with insatiable feeding powers—and develops into a giant stem itself. The shade beneath gets deeper and deeper, and all that grows under it, feeling the chill and gloom, withers and dies. Year by year it widens its base and enlarges its stem till it casts its shadow over thousands of square yards—we describe an individual under which it has been our fortune to stand with awe and admiration—its broad buttresses and sturdy supporters looking like the pillars of some ancient Moorish temple, among which the wanderer may almost lose himself. In its season of fruit it harbours legions of skipping squirrels, great apes, and troops of monkeys, which, to the eye surveying them from below, look like pigmies fitting about amid the branches, and from which the spectator is so far off that the most timid is not afraid, even at the report of his firearms. Immense flocks of the large fruit pigeons, and also of the smaller members of that numerous and beautiful family, crowd to this rendezvous, their wings keeping up a constant whirring in the air by their coming and going; scores of the great hornbill (Buceros galeatus), with their 5 ft. expanse of wing, and myriads of smaller birds, whose varied calls and notes alone indicate their presence, flock from far and near to this inexhaustible storehouse (and its produce cannot be estimated at less than tens of thousands of bushels of figs), and yet the vast assemblage but sparsely peoples this single magnificent specimen of the vegetable kingdom. Of course, it is well known that these trees belong to the indiarubber producing family, a true caoutchouc coming from the sap of the Urostigma caret. All the species of the family produce more or less gutta as a white milky sap; but only a few species produce any of commercial value. All are more or less climbing and epiphytic in their nature. The smaller members are among the most beautiful of shrubs in habit and in form of foliage, and, during their season of ripe fruit, the figs, with which they are literally studded, are often of the most brilliant hues of lake, purple pink, or orange.

The waringin is a favourite tree with the native; in Java, in most villages there is one aged waringin in some open space, where the natives may collect in the heat of the day, and under which travellers may rest, and the lazy lounge. Its shade takes very much the place of the Balai in Sumatra. Under its funeral gloom, in some quiet forest spot, is generally to be found the last sleeping place of the villagers. Here it was our fortune to meet, for the first time, with specimens of the giant Aroideæ, which in this island are not infrequent. Everyone is acquainted with the "lords and ladies" or "cuckowpint" of our hedge sides, a small plant with a white spathe or collar, about 4 in. or 5 in. in height, surrounding a central stem or spadix, one of our English representatives of the order. Think, however, of its congener here, more than 12 ft. high and 31 in. round the stem. One who greatly dislikes unpleasant odours should examine this plant in the early part of the day, and it will appear to him a beautiful object, with its tall stem handsomely marbled, its cream-white spadix, surrounded by its dark lake-purple spathe, full of grace and symmetry in contour and curves. Towards five o'clock in the evening he will not, however, we fear, bestow a benison on it, when he learns that that intermittent, sickly, rotten-flesh odour emanates from the elegant Arum he so admired in the morning. It is a singular circumstance occurring in many species of this family, that towards evening the temperature inside the spadix rises several degrees, followed by the discharge of the pollen and the emanation of a powerful and disagreeable odour, developed to attract insects, especially beetles, which, by carrying pollen to other plants, assist in their cross fertilisation.—*Field.*

QUICKLIME.

SIR,—I fear, to be of any great use, it is rather late in the day to record the results and particulars of experiments I have had the opportunity of witnessing in this district with quicklime, in the double capacity as a check to leaf-disease and as manure; but there are still, and I hope with sound reason, believers in the bearing capabilities of good coffee, if fairly treated, to whom they may be of some interest.

One great objection to any extended—rather I should say, universal—trial as regards carbolic acid and sulphur applications and, though perhaps, not expressed, that must have weighed heavily in the minds of the more cautious—has been that their possible, or *professed*, merit has had relation only to the destruction of the disease, and, if they failed in this—as failed they have, one and all, signally—it could but represent a total loss of outlay, which, if not, perhaps, more wisely kept in pocket, it was felt would at least give some return in manure. Now, to say nothing of the infinitely lower cost, this I maintain, not on theory only, cannot be urged against the use of lime, similarly applied; and further, as the result of the trials in question, I believe the effect at each application to be equally potent—apparently far more so—though of course the great point gained is in the continued frequency with which, as as cheaper and *self-paying* remedy—as I certainly regard it—it can be repeated. I must not at all be supposed to imply that, in the present instance, it has proved, or is likely to prove, a perfect cure—leaf-disease is still sufficiently to the fore to require but little search for—but I do say that on the majority of trees it is far less conspicuous, and their health and appearance, though many of them carrying a heavy crop, so vastly improved that I firmly believe, had but a little of the money now hopelessly sunk in manure (for though, in some instances, the balance on manuring has continued on the right side, haw many are there not to the contrary? and remedies that have proved abortive, been spent in the systematic and careful application, say twice a year, during the past decade, on quicklime—well, that leaf-disease would have been kept within comparatively harmless bounds, and the balance then spent on other fertilizers would in most cases have proved a remunerative outlay, as of yore. I may be taken up here by a reference to the numerous trials made in Mr. Morris's time with *lime and sulphur*, and also subsequently I daresay with lime *alone;* but this I maintain is but to afford a good illustration of one of the advantages possessed by the low-country over the majority of up-country properties, in their near proximity to, and quick and cheap transport from, the coast, for it is in its (artificially) primary form only—namely as quicklime—that good results can be hoped for; and but little has really in this form been applied, or I am mistaken, even though so professedly, when despatched from Colombo, the mere moisture in the air being quite sufficient within a few days in damp weather to largely destroy its specific value; to say nothing of increasing weight and consequent cost of transport. Though I doubt not known to most of your readers, it may not be out of place here to recall to mind the different stages lime, after burning, passes through: (1). As *quick* (caustic) *lime* a very light fine powder (strictly speaking, to reduce all the burnt stone to this, it may have become slighly *hydrated.*) (2). As *hydrate of lime*—in which form, by absoption of water, it is increased immensely in weight and volume. (3). As *carbonate of lime*—or its original condition prior to burning, *chemically* (the water in turn having been driven out, and replaced, on long exposure, by carbonic acid gas) but in a finely divided state—in other words *powdered chalk*—as which, save directly in itself as a manure, it is, if I mistake not, valueless, having lost its active qualities and become *inert.*

It is not its caustic properties merely—possessed more or less by hydrate of lime—but its great lightness *and extreme affinity for water* that evidently constitutes the merit as an antidote of quicklime over the latter (*hydrate*). Throw a handful over the tree, and, if the slightest breeze be on, much will float away like mist (eventually of course to settle), so much so, that still days only should be chosed in applying it; whilst the balance falling on the leaves is in impereeptibly minute particles, drawn as to a loadstone into every crack and fissure where there happens to be the slightest moisture; thus, so it seems to me, forming a very *searching* remedy to the disease, death being inevitable—I think it will be everywhere admitted—to every spore that caustic lime comes in contact with. Not so *hydrate*: if the leaves happen to be wet with dew or rain, it becomes plastered on, but I cannot believe, am sure it is not, to the same extent, or anything like the same extent, effectual. Having become *hydrated*, it has no longer any affinity for moisture, and can only become attached to the leaves, as implied—virtually, in the form of mortar. Taken as a manure, a more correct mode of applying lime could not be, as it thus become evenly distributed over the whole surface, and from its peculiar tendency to do so, soon sinks into the soil, and, as the majority remains on the trees, if the leaves are fairly moist at the time of applying, till slacked, any objection that can be raised against the direct use of quicklime is thus avoided. Quicklime, as far as leaf-disease is concerned, it must be. I myself consider this at least a *desideratum* and to obtain it "fresh and fresh"—*it must be* burnt on the estate, or very near at hand. After having become, owing to any unforseen delays in applying, slacked by exposure, it can be reburnt. A suitable limekiln stands in but a few pounds.

Now, as to cost, I may best state what this actually amounts to here per ton, and let others modify the figures given according to their own circumstances:—One ton of coral stone at Galle R5; cost of tranport per cart R10; cost of burning R2 to R6 according to the amount of suitable firewood available, say, R5 (figures as to cost and cart-hire are higher than need be on a large scale, and I fancy that coolies could be easily taught to burn well enough, at a saving); cost of application R4, the which might be reduced by using Walker's blowers. The above amount does 2½ to 3 acres Liberian coffee (10 ft. × 12 ft.) well, at, say a cost of R8 to R10 per acre. I fancy half a ton at each application would be emple for *C. Arabica*, so that, if the above figures can be kept to, for a double application annually representing a two-fold purpose, R24 per acre will suffice.

That the frequent, regular, application thus of lime would be some check on grub—perhaps tend to send the bettles elsewhere—is not impossible; and that apart from any good results from it as regards leaf-disease it would be, on good coffee, likely to add sufficient crop to pay expenses, though the above outlay be doubled—in other words add about 1 cwt. per acre, I believe. Did it not sound too sanguine a hope now-a-days, I should be inclined to add "and more!" Anyhow I think but few practical men will be inclined to characterize it as a *wild statement*, to say that the soil is scarce in Ceylon that would be injured by any amount of lime, judiciously applied, they could for any purpose desire to afford the trees. QUICKLIME.

—Local "Times."

LIBERIA COFFEE.

The Netherland Cousul at Monravia in Liberia in his annual report, dated 16th February 1883, specially treats of coffee-culture. His views are mainly the following:—The coffee-crop has been very good, the export amounted to about 500,000* lb., 100,000 of which to Netherland. Yet the quantity exported is not so great, as, in view of the mild weather and particularly appropriate soil, might reasonably have been expected. This culture dates only from a decade since, and though there be already some large plantations, yet it is only practised as yet in smaller and recently established places.

There exists not in Liberia any bank-establishment which might enable the planters to take up money for extensions, and for a more profitable method of culture. The simplest way would be for the natives to plant coffee themselves, but their manners are too unsettled and irregular to allow of their doing more to the peaceful cultivation of the ground, than what is needful for their own support. The Liberian government lacks the necessary money to keep up an effcient police among the various native tribes, who are now in constant warfare, and thus allow the fields to lie fallow. They likewise lack the means of awarding great premiums to the best coffee-planters among the natives, as could formerly be done to the Liberians. The coast tribes prefer roaming the sea, and those who dwell further inland, would have to return home to their own field-labour just at the time they were most wanted in the plantations. For foreigners it is exceedingly difficult to set an enterprise on foot. The Liberians cede no land in fee-simple to whites, they at most lease it out for 40 years. Besides this, the white man would soon suffer from the prevailing agues, and so have to leave a great deal to the care of a coloured manager.

Formerly it was supposed that the Liberia coffee-tree, which exceeds all other known sorts in size, was either introduced from India, or centuries ago by the Portuguese. It is now generally held to be of native growth, on account of its never attaining its original size when transplanted elsewhere, and that it is never found in any other part of Africa. It is found only between 4° to 7° North Lat. and it grows spontaneously from the sea-coast to the luxurious grassy plains of Abandingo-Land.

The climate of Liberia seems unequalled for the culture of coffee. The temperature varies in the shade from 74 to 80° Fahrenheit, but rises in the dry season from 90° to far beyond 100°; the lowest point, 62° at sunrise, was observed at Monravia in January, during the prevalence of the harmattan-winds. The difference in the interior is not so great, because the ground rises so rapidly; 25 miles from the coast the land is already 500 feet, and at a distance of 198 miles as much as 2,200 feet above the level of the sea. Yet the coffee is everywhere the same. Even in a wild state, there are splendid trees from 10 to 12 inches in diameter; the cultivated plants are not much smaller. For laying out a plantation, the best land would be a wooded, rocky, hilly country, a few miles from the sea-shore; there are found those loose loamy soils, with a rocky ground and the manure of decayed leaves, which are the most appropriate. The water absorbed by the porous ground, keeps, even in the dry season, the coffee-tree fresh and verdant. A sandy soil with a bottom of a few feet of loam would also do very well. The lower grounds are of easier tillage, and yield larger fruit and more plentiful crops, but the more elevated tracts yield by far the best coffee and of the finest aroma.

The fruit stript of their pulp are planted at 3 or 4 inches from each other in rows, in the rainy season one foot, in the dry season two feet deep. The annual or bi-annual plants must be transplanted in May or June, in the beginning of the rainy season. Only the roots of the very young plants must be guarded against the sun. In planting out the gardens, the plants must be set at mutual distances of at least 12 feet, in paralled rows, at the commencement of the rainy season, without the ground's being dug or ploughed up, after the burning of the trees that had stood there. Generally they are first topped when 5 feet high, and then new shoots are constantly plucked off, till the new ones are set at intervals of about eighteen inches from the old ones, by which sufficient space is provided for air and sun-shine. For manure fine clay from the hills is preferred, but offal of cleared coffee, mixed with dung is also good. Guano may only be used now and then; if used regularly the trees would grow too rank and soon get exhausted. On older soils, ashes mixed with a little lime is also used. Of disease there are very few traces in the Liberia coffee bean. Only occasionally are small yellow spots seen on the leaves of some trees. The fear that this would prove the so-much dreaded *hemileia vastatrix* of India has not been confirmed. The spots do not change colour, nor does the tree suffer by it. Only in the neighbourhood of great forests they sometimes turn black, and then the fruit dries up before maturity on the tree, which however does not suffer further damage. Only now and then are the trees infested by the larvæ of a fly, or a kind of winged beetle—the borer. This insect usually bores its way into the stem, a few inches from the ground, making a passage as if with a bore. The tree then soon begins to pine, and dies down to the spot where the larvæ first entered the tree. Sometimes the rind too is infected, while now and then a branch, or one-half of the tree becomes diseased. The tree will often pine away long before it dies, and sometimes proper manuring and judicious nursing will effect a complete cure.

As no statistics are extant in Liberia, it is very difficult to calculate the expenses of laying out a plantation there. Immigrants from America receive 25 acres of land gratuitously from the Government, while the inhabitants of the Republic can buy land of Government at the low rate of 1 dollar or 50 dollarcents per acre. To prepare the land, about 10 dollars per acre are required; wages for planting 6 doll., labour 3 dollars.

If the fields are well burnt out, then the weeding begins only in the second year, at 5·50 dollar per acre, at least by following the Liberia practise. If the planter has the grass and thistles removed immediately on appearing, he will find the greater expense fully compensated for, by the greater fruitfulness of the trees. The topping, generally begun in the third year, costs 1·5 per acre, and the pruning the same. The manure is not an article of commerce, so cannot be evaluated.

The costs of machinery, plant, etc., vary, of course, according to the views of the owner and the extent of the estate. The gathering costs fully 1 or 1·5 Amer. cent per lb. On account of the imperfect manner of working, and the primitive tools or instruments, the charges of cleaning are as much. Little is known for certain about the produce of one tree. One between 8 and 12 years old, will yield, it is said, 3 pd. on an average; but others pretend 5 pd., while from one old tree as much as 38 pd. were brought clean to market. It is thought that, if every thing is well attended to, the average yield would be 1,500 pd. per acre. A planter of Ceylon affirms that the Liberian tree, with careful treatment, would yield ten times more than the Ceylon tree. However, it blows not till the third year, and in the fourth, only a few ripe fruit are gathered.—*India Mercury.*

* Less than 5,000 cwt.—ED.

NEW AND OLD PRODUCTS IN TRINIDAD.

(From a Report by Mr. H. Preston, Government Botanist.)

LITCHIES (*Nephelium Litchee*). In the Philippines and Mauritius, where this neat yet handsome fruit tree is largely grown, the fruit is esteemed as one of the most delicious in the dried as well as in the fresh state, and the fruit grown in the Gardens here is pronounced by persons who have eaten the East Indian fruit in a fresh state, to be in all respects equal. Only a few trees exist in the Island till now, these not having been so much propagated as usual, owing to the failure of the seeds produced. This want of vitality in the seeds I find, however, to arise from the popular but erroneous notion that all seeds should by some means be dry before being sown—the condition really being fatal to the vitality of the majority of tropical fruit tree seeds. Further, the tree is not so prolific as fruit trees usually are here. This arises in a great measure, however, from want of full light or exposure, and thorough drainage; these conditions being present the tree will well repay by its fruitfulness any trouble taken to promote them, or otherwise expended in its careful cultivation. It should not be forgotten also that the fruit is here as readily dried and made suitable for after use, or exportation as in the East Indies. Indeed, it may be regarded for a tropical country as perfect a fruit as the grape is for more temperate regions.

LACOOCHA (*Artocarpus Lacoocha*).—This, as its botanical name shows, is an ally of the Breadfruit tree; but, unlike the fruit of that tree, is suitable for dessert. It averages about 5 oz. weight; is of an irregular form, rich orange colour, and of a pleasing sub-acid flavour. The tree develops rapidly from seed, and bears the third year.

TONGA-BEAN (*Dipteryx odorata*).—There are large examples of this valuable tree in the Botanic Gardens, which afford evidence of the habit of growth of the tree and its requirements under the usual conditions of soil and climate here, and which in some districts appear to be exactly similar to those of the Tonga-bean districts of Venezuela. In the face of the commercial value of the Tonga-bean—arising from a widespread and ever-increasing appreciation of its use in Europe and United States, as a flavouring in articles of enormous consumption which come under the head of indispensable luxuries as well as the more necessary food product—cacao. The price has already reached $2 per lb. Its cultivation in this Colony may be regarded as of the highest prospective importance and value; the more so as the tree will thrive in land altogether too poor for cacao or sugar, and the forming of plantations (as with cacao) would have the great attendant advantage of maintaining the climatic and other conditions characteristic of full afforestation (without its attendant drawback of malaria) so important in tropical agriculture, on land which once cleared is very liable to lapse into useless "bush" or "jungle" overborne with malaria. The cultivation of the Tonga-bean tree is therefore such as may be regarded as eminently suitable for the lowlying and sandy (and for sugar or cacao) unproductive lands of the upper Caroni, Couupia, Carapichaima, Chaguanas and Valencia—established by a process of successional development to annual crops of plantations, corn, peas, &c., which the land would bear (as affecting the surface stratum) for 3 or 4 years, after which the Tonga-bean trees would themselves be sufficiently developed to be productive and profitable. The stock of plants of this important tree is as yet limited, extensive demands having already set in, but as there is every probability that a stock will be acquired in the course of the next few months, sufficient to meet all probable requirements, attention is specially directed to the subject in view of extensive planting next season. Meanwhile, it is strongly recommended that a few trees be planted by way of experiment on estates presenting the conditions of soil alluded to in the districts mentioned. Plants being put in at once would indicate by their condition at the end of the next dry season what extent of land it might be desirable to devote to the cultivation as well as in great measure the method of planting to be adopted. It should not be laid down, however, that the condition of the plant at the end of the dry season be accepted as a definite and certain augury for the future, for the phases and effect of the dry season are so varied that in respect of plants not deeply rooted, while one year the condition of drought might prove fatal to many plants, the next year it may not be attended with a casualty.

COLA-NUT (*Cola acuminata*).—The Cola-nut till quite recently has been confined to West and Central Africa as an article of commerce, where it holds a position of immense importance as an article of consumption by the inhabitants. It has at length, however, attracted the attention of chemists and the commercial world, and is found to possess properties analogous to, and attractions—as an article of food—not less important than those of Tea, Coffee or Cacao. As may be expected, the price of the article has lately taken a sudden rise, and there is active enquiry from tropical agriculturists as to the characteristics of the tree bearing the Cola-nut and its prospective value as a subject for cultivation. As such it may be regarded only second in importance to the Tonga-bean. The general character of the tree is that of a strong growing Cacao tree—attaining the height of 30 or 40 feet with proportionate spread, and beginning to bear at about the same age. Unlike the Cacao as to requirements, however, it flourishes in comparatively poor soil and in exposed situations. The Cola-nut tree has been long grown in these Gardens, the original tree being now sixty inches in girth, and from young trees put out during the last few years, a very good idea of the disposition and habit of the tree as well as its requirements may be gained by those desirous of attempting its culture. The young plants progress satisfactorily without shade, if planted in moderately good soil, but in poor soil or dry situations, the usual shade afforded by plantain cultivation is advantageous or even necessary. The cultivation of the Cola-nut tree will therefore be of the simplest possible character. Not particular as to soil, bearing full exposure, growing quickly from the large seed, the only care required will consist of suppressing native bushes of more rapid growth than it, and when matured and fruiting, to clean off the surface growth to facilitate the collecting of the seeds as they fall on the ground. Briefly, it will be a cultivation of a similar character but of much less cost than that of Cacao, and suitable for land that may be too dry or poor and exposed for that valuable cultivation. The process of planting up land abandoned as too poor for provision or other cultivation, or indeed any "rastro" land would be the same as recommended for the Ceara-rubber tree; only, the Cola-nut would not thrive in such a poor condition of soil as that tree. There are a few Cola-nut trees in the island from which are obtained small supplies of seeds which are brought to the market, and are appropriated in the same manner as in Africa.

VANILLA (*Vanilla planifolia, var.*).—The cultivation of Vanilla continues to be one of the most profitable pursued. It is moreover of a nature to require so little physical effort that the proprietor may be regardless of the condition of the labour market, and however limited the cultivation, it may be regarded correctly as a highly intellectual occupation—for intelligence is specially required both in the management of the plant and the proper preparation of its fruit—or Vanilla. The value of the produce of Vanilla from a few square yards is so considerable, that the rental of any house may be realised by Vanilla culture in the court yard, provided there be means for, 1° maintaining a chequered shade or a diminished sunlight—to one-third of that it usually is: 2° a few hard wood posts and bamboo laths for horizontal trellises, and such vegetable matter or rubbish as is usually met with in yard or street—including, specially, horse droppings; the trellising being of course for support, and the rubbish—mixed with the surface soil—being the compost for the nourishment of the roots, and through them the sustenance of the plant. Fortunately Trinidad possesses in her forests a variety of Vanilla of the very best kind, both as to size and flavour, and of this plants can be obtained in quantity to meet all possible requirements.

CEARA-RUBBER (*Manihot Glaziovii*).—This rubber-yielding plant, which is really only a gigantic form of Cassada, is specially adapted for cultivation in dry gravelly hillsides. It has enormous power of root development and penetration, growing luxuriantly during the wet months, and becoming dormant and leafless in the dry season when the milk-sap is of great density. It thus shows its adaptability for poor soils and arid situations; indeed, the production of a satisfactory "rubber" very largely depends on these conditions, for with trees in the Gardens on moderately good and moist soil, under rapid growth as occurs in the wet season, the sap is watery and shews scarcely a trace of rubber globules. The cultivation of this tree is therefore a prospectively valuable one for the poor gravelly soils of the north-western hill slopes. No preparation of the ground will be necessary beyond the reduction of useless and encumbering vine or bush growth: such trees as may be useful as timber or otherwise being left as shelter against the squalls of the wet season—the Ceara trees being somewhat heavy headed and brittle when in full growth. The young Ceara trees can then be planted —by labourers using ordinary grubbing holes—singly wherever a space of 12 feet occurs amongst the indigenous trees left.

PRODUCTION OF PRIVATE AGRICULTURAL ENTERPRISES IN JAVA IN 1882.

Products for the great marts are cultivated and prepared:

On Private Estates.—On lands ceded by Government in rent or lease; On enterprises exclusively dependent on agreements with the population, and lastly, by enterprises on rented land, in the Principalities of Soerakarta and Djokjokarta.

COFFEE.

281 Concerns producing 273.324¾ piculs of coffee.

Most of the Plantations are still very young; very many have not yet any fruit-bearing trees. The coffee yield may be doubled within a very few years, when all the new Concerns are in full swing. The best results are anticipated of East Java; the production per unity of ground is on the whole greatest there, and the gardens there seem, as a rule, to be of longest life.

More and more it is growing tho custom to send the coffee to Netherland *in the parchment*. The opinions as to the results are not unanimous: but the custom shares in the struggle to which all novelties are, and will ever be, exposed.

For Java it is a thing of the greatest moment to spare labour. This also saves time and hands, for the better watching and tending of the crop. If the prices of ordinary and inferior coffees were not encouraging these last years, yet experience has proved, nevertheless, that superior coffees hold their prices tolerably well. The producers have therefore chiefly to apply themselves continuously to the improvement of the quality. Whatever may be thought or said about the menacing and overpowering competition of South America, we ourselves are convinced that Java, as to the burning question of labour, holds a much more favourable position, and that just this question—especially in South America—will become more and more critical.

TEA.

39 Conserns producing 5,674,176 lb. of tea. Besides which 101,350 lb. were bought up by the population.

If we cannot exactly say that the tea industry in Java languishes, still less cause have we to boast of progressive improvement. It is undeniable that the young concerns are burned with heavy charges, quite disproportionate to the low prices of the product. Any idea to increase these charges, either directly or indirectly, should therefore be seriously combated, and if the Dutch Legislature should increase the high duties on tea, then there is no doubt that both the producers in Java and the commerce in Netherland will be great sufferers. Seven years ago this consideration withheld the Legislator from resolving on an increase of duty. The circumstances did not improve afterwards. The producers in British India work under much more favourable conditions. Yet they did their best to push their products into notice, and to make them appreciated. It is indeed much to be regretted, too, that the enterprisersi n Java have not made a better and larger use of the Amsterdam Exhibition, were it only to conquer the prejudice or the aversion still prevailing against their article.

Though the tea-industry in Java is restricted to a few districts, yet it binds great capitals, is a blessing for the local population, and of great significance for commerce.

The productions of cinchona demands a serious word in conclusion. Allured by high prices, it has been thought for about six years that planting cinchona was like opening an inexhaustible goldmine. The culture has been carried to a lamentable excess, both in Java aud in British India, without minding that the demands for a remedy, however specific, have their limits that may easily be overstepped.

Contrary to all former expectations and fears, the production in the mother-land of the cinchona does not decrease; on the contrary, in South-America they are applying themselves seriously to the regular culture. A production of six millions kilogr. of bark amply suffices for all requirements, and whilst South America remains competent to furnish this demand, Ceylon alone yields already more than one million, and the production of Madras and Bengal is not less. Should all the cinchona concerns in Java only see a portion of their great expectations realized within six years, as to production, then it is evident that Java's production on the market must exercise a preponderating effect, and the prices be so much depressed, that, for establishments that are not free, there can be no questions of profits.

At present the market is already overstocked, and the prices stand no longer in proportion to those on which the planters based their calculations.

Coffee is giving way to cinchona, because the former is mistrusted, but inconsiderately and inconceivably enough, no account is taken of the limited requirements, of what has been effected outside Java, and of what is already so amply produced. K. W. VAN GORKOM.

GUTTA PERCHA.—An article which may be termed French gutta percha has been patented in Paris by E. Mouriot fils, and is described as follows:—He boils birch bark, especially the outer layer, in water over an open fire, and concentrates the extract by evaporation. After which there remains in the evaporating dish a black liquid mass, which, on exposure to the air, quickly becomes solid and very compact. This mass possesses all the properties of gutta percha, and may be applied to the same uses. It has further this advantage, it does not crack on exposure to the air, it is more solid, and its production is cheaper. It may also, if desired, be mixed with gutta percha and with India rubber.—*Monthly Export Prices Current.*

ARBORICULTURE IN THE N.-W. P. AND OUDH, 1881-82.—While mentioning the success obtained in rearing jack seedlings, the report says that there are two devices for bearing seedlings that will not bear transplanting, either of which is almost certain to answer. The first is a basket of very thin strips of bamboo lashed together with bark, which is put into the ground with a sufficiently wide aperture in the bottom to permit of the exit of the tap root. The second is an earthen pot rather smaller at the top than at the bottom, and open at both ends. This is put on a board or flat basket, and put with the plant in the hole intended for it. A few taps are said to disengage the earth inside, and the pot is withdrawn bodily to serve for another occasion. It is believed probable that either of these plans would succeed as well with jacks, as they do with coffee plants. A third plan recommended is the use of small pots made of clay and cowdung, and of a consistency and thickness which would ensure their decomposing rapidly when buried.—*Asian.*

GOVERNMENT FARM AND ECONOMIC GARDEN, HYDERABAD (SIND).—The Report on the Government Farm an Economic Garden, Hyderabad (Sind) for the half-year ending March last, shows that good progress was made during the year, and that both these institutions are already doing much towards producing upon the zemindars and agriculture of the country side, those direct and indirect beneficial effects which must be regarded as their chief object. It is satisfactory to find that the agricultural class attached to the farm is reported to be making good progress. It comprises 13 young zemindars, who are spoken of as well-behaved young men, attentive to their duties. Half of the number are well up in the subjects taught; the rest having joined later are more backward. Mr. Strachan adds that a report as to the behaviour and studies of these pupils is sent to the Collector every week, and as any one of them would consider it a great disgrace were the Collector to see a bad mark against their name, these reports have a very wholesome effect in keeping them to their work. We observe that it is intended to build quarters on the farm for the pupils attending the farm class, and when these are ready, the Superintendent thinks that they will be able to devote more of the morning to field work, and the afternoon to theoretical work in the class room.—*Asian.*

COLEMAN'S PATENT CANE PLANTER.

After the trials made at Kaueohe and Sprecklesville last year, Mr. Coleman has devoted himself to improving his invention. For the purpose of facilitating the working of the machine, the drum which feeds the cane has been placed at right angles to the wheels instead of parallel to them, as in the first experiments; the drum is worked by a chain passing around the axle and communicating with the drum by means of an ingenious set of moveable pulleys. The cane, in pieces about a foot long, is placed on a shelf and fed by hand to the drum, it is dropped by the drum into the delivery spout, which lays it regularly into the furrow. The furrow is made by a plough placed between the two hind wheels, while just behind the delivery spout are the coverers which close the earth over the seed cane. Recently Mr. Coleman made some practical experiments on a piece of land just beyond Mr. Ward's residence. Very few people were present; among those on the spot were His Majesty, the Hon. C. N. Castle, Messrs. Atherton, A. P. Baldwin, and A. T. Atkinson. The working of the machine was clearly shown; as to time, it was impossible to estimate, for the six yoke of oxen employed were inferrior animals not up to their work. A good furrow, however, was cut, the cane regularly laid and neatly covered over. Three men suffice to manage the machine, one to attend the plough and coverers, and one to feed the drum, and one to supply cane from the box to the feeder. We have little doubt that Mr. Coleman's machine will be a success, and will be used not only by our own planters, but by planters in other sugar-growing countries.—*Pacific Advertiser.*

FARMING IN BURMAH.

The Moulmein correspondent of the *Rangoon Gazette* gives the following account of an interesting farming experiment:—

I went a few days ago to the farm at Toungwine which is being carried on by Mr. Addis, junior. He has a grant of 200 acres, of which 35 have been brought under cultivation, which is carried on scientifically. As it is about the first of the kind undertaken for the past thirty years, by private enterprise at least, in these parts, perhaps it would not be uninteresting if I give you some particulars of what I saw. The land is plotted off in squares of an acre, each having its allotted number; and for the convenience of cultivation there is a gravelled pathway of 6 feet in width between each plot, which appears to me an unnecessary waste of good land. There are a comfortable teak and tiled bungalow which might house a family easily, cooly quarters also built of wood and tiled, for 20 men: fowl-house and yard surrounded by wire netting seven feet high (with a tank adjoining for ducks and geese), containing about 100 head of poultry: a piggery which boasts of 7 or 8 pigs, large and small, English and Chinese, and cowsheds accommodating some 40 head of cattle. The latter seem to be allowed a great deal too much liberty as could be seen by a number of plantain, mangoe and other trees being denuded of their leaves or shoots. The work of clearing, up-rooting and ploughing must have been no small job, but I understand some contractor undertook it at R30 per acre. If the work of up-rooting was conscientiously carried out, the figure mentioned was a low one. The ground is laid out in long beds four feet wide and manured with oil-cake and bats' dung obtained from the caves. As you pass the places where the oil-cake is most utilized, you cannot help exclaiming "Sweet Edinbro' I smell thee noo!" but Mr. Addis does not seem to mind it, and he smilingly informs you, to your surprise, that it is only decomposing oil-cake. I certainly thought that Maulmain sewage had been freely indented upon, and for fear of any cholera germs floating about and seeking their nidus in my internal economy I thankfully accepted, as an antidote, av coorse, a large 'drop of the crathur' which the hospitable planter offered me a short while after. However, don't suppose that the atmosphere of the whole farm was like that, it was only a small portion that was objectionable. Now for the nature of the cultivation; there were 4,000 young orange trees, 2,500 coffee plants, 2,000 custard-apple trees which, strangely enough, are scarcs in Tenasserim, 7,000 plantain trees of good qualitiee, 1,000 areca palms, 100 cocoanut trees, 300 doorians, 200 grafted mangoes from the Horticultural gardens, Calcutta, 100 guavas, 50 loquatz from Bangalore and 50 rose-apples. In addition to this there are, or were, six acres under tapioca cultivation, 2 acres of yam, 3 acres of all sorts of English and country vegetables, 4 acres of paddy, 2 acres of Chinese pan-leaf which, unlike the indigenous variety, lasts for 5 years, one acre of Burma roses and about half an acre of roselle or sorrel for purposes of fibre extraction. Every form of cultivation looked in a thriving condition. Besides all this, which is most creditable for 7 or 8 months' work, Mr. Addis has dug two large wells, 30 feet deep and 20 square, and he is also bunding up certain natural hollows which, when finished, will give him a tank of water covering 3 acres. There is ground quite suitable for a lake of 13 acres, but Mr. Addis feels that the large sum this would cost could be better employed in other directions. A windmill pump is being got out from England for irrigation purposes. There is also about a mile of portable railway with several tilt trucks, on the premises, which will come in useful by and bye. It will thus be seen from what I have written, and what you yourself know of the labour difficulty, that no little capital must have been embarked in this concern, and Mr Addis has received little or no aid beyond obtaining the ground free. He cannot recoup himself to any great extent for the next few years, while all his crops or the greater portion of them may at any moment suffer from the effects of blight, insects, or other such well-known pests like the coffee borer. Let us hope, however, that care and attention may avert the danger, for certainly Mr. Addis deserves a better reward.

PINEAPPLE.

(*From the Proceedings of the Agricultural and Horticultural Society of India.*)

The following information was given by the Deputy Secretary regarding Pine-apple in answer to enquiries thereon:—Though the Pineapple is so thoroughly naturalized in Bengal and other parts of India, it is native of South America and some of the West Indian Islands, where it is largely cultivated for export. Particularly in the Bahamas, where all that is considered requisite for its successful cultivation is that the soil should be at least two feet in depth and capable of retaining moisture; a rough and ready way of testing this latter requisite, is to thrust a long knife into the ground in the dry season, and if earth adheres to the blade, the soil is considered suitable. The best pines are grown on a reddish clay rich with decayed vegetable matter, remains of shell fish, &c. In the West Indies only two varieties are considered profitable for export, the Sugar loaf and the Scarlet. The former are planted somewhat closer together and have a longer time of life, about five years, while the Scarlet variety lives about three years, but the fruit comes to maturity a month or two earlier than those of the Sugar loaf. As all the fruit in a field do not ripen together, they have to be gone over two or three times; the people employed in plucking them have to protect themselves with leather gloves and leggings from the sharp thorns with which the leaves are armed. The cultivation is of the simplest, the under growth is cut down and rooted out, and the land grubbed up, the plants are then put down about 2 feet apart, in some places 2½ feet, and 3½ feet between the rows. In dry localities the spaces between rows might be utilised for water channels, as both quantity and quality of crop is injured by drought. Once planted the only cultivation necessary, is to keep the soil free of weeds. Should it be contemplated sending the fruit to a distant market, they must be cut green, and in the West Indies where the fruit is exported, a large portion of the plants are taken as well. Ships are fitted up for the trade with tiers of shelves on which the fruit is packed, this arrangement allows of the passage of air, and the lowermost pines are not crushed and spoilt, as would otherwise be the case, with the weight of those above. The business is found very profitable in a good season, but ruinous in a bad; too much, or too little rain, armies of rats, land crabs, and bush fires, are a few of the ills the cultivator has to fear. As regards growing the plant for fibre only, the fruit should not be allowed to form, and the leaves will then grow larger and broader. The well known pine-apple cloth is made from this material in China, and the fibre has been sent there from Singapore. In Eastern and Lower Bengal where the soil seems particularly well adapted to this plant, the fibre is not apparently appreciated though its strength and fine quality seem to be well enough known. In 1836 Dr. Wallich presented the Society with a bag which he had "purchased for a trifle at Cherra Poonjee" made of this material, he says the natives used the fibre for the manufacture of such small fancy articles. In his letter to the Society, Dr. Wallich says:—"Considering the enormous quantities of pines grown in that region, the plant appearing as if it were quite a natural production, the fibre of it is worthy of attention." An allusion is made to it in a paper by Lieut.-Col. Walton in the Asiatic Society's Journal for 1832, alluding to the great abundance of the pine-apple plants in the adjacent valleys to Cherra Poonjee, "the sanitary station recently occupied by the East India Company," and that the natives use the fibre as a material for bags and pouches.

In 1839 Miss Davy in answer to an advertisement published by this Society, submitted some thread made from pine-apple leaves, of which she remarked that it was "equal to the finest flax thread manufactured in Europe," and considered it comparable with the best cambric thread. Miss Davy thought a beautiful table linen could be made with it, and a lace resembling blond. This lady eventually, though with some difficulty, owing to the conservative objections of the Dacca weavers whom she tried to induce to make some cloth from this fibre, manufactured handkerchiefs, cuffs, and some cloth which are alluded to in the proceedings as "elegant specimens." Some thread was sent home but the English spinners seem to have been as prejudiced against this fibre as the Dacca weavers were.

The method employed for extracting the fibre in Manilla, China, and the Khassia Hills seem to be identical, the leaf is spread out on a board and scraped with a blunt knife which removes the pulp, and exposes the fibres which are then raised taken hold of at one end and pulled off the leaf with a jerk, the pulp which underlies the fibre is again scraped and the operation repeated, finally the fibre is combed and dressed like a handful of woman's hair.

I imagine the implement used in Mauritius for extracting the fibre of the Aloe leaf would be very suitable for the pine-apple too, and as there is less pulp to deal with, the operation should be much quicker.

In this Society's Journal for 1853, some trials of various fibres made by Messrs. Harton & Co., of Calcutta, are published; a 3½ inch in circumference rope made of pine-apple fibre easily bore the Government test of 42 cwt. and eventually broke with a weight of 57 cwt., more than the Government breaking test.

INDIGO IN THE NORTH-WEST PROVINCES.

[As the question of indigo cultivation in Ceylon has been started, we take a few extracts from an article in the *Indigo Planters' Gazette* shewing that the plant needs first-rate soil and the most careful tillage.—ED.]

The soil best suited for Indigo in these districts is one neither too dry and sandy, nor too stiff and clayey, with a light free subsoil, one that does not retain water: in a wet subsoil the young plants either die off, or, if they do live, they grow up sickly, stunted plants. As a general rule, the safest plan is to follow the classification of the village revenue papers, which divide the land into 1st, 2nd, and 3rd quality, and to take for Indigo sowings nothing but lands down in the village papers as first quality, only being careful that such lands are not liable to be swamped by heavy rains; and that there are no tanks adjoining the fields, for when these tanks are full, they are apt to keep the subsoil very wet and waterlogged, the plant on such fields never comes to anything. The Indigo plant revels in a moist atmosphere and a moist soil, but cannot stand a wet soil, especially a wet sour subsoil.

Neither Manager or Assistant can go far wrong with regard to the quality of the lands, if he takes *goind lands*, that is, lands about the village; these lands are always well manured, and will produce heavy crops of indigo when well cultivated. Fields that are sites of old ruins, no matter how thickly they are covered with brick-bats, broken pottery, and old mortar, also produce heavy crops of indigo; such fields invariably have a trace of *noona*—nitrate of potash—in the soil

During the *bundobust*, and more so when the lands are being measured for the *zillabundie*, great care is necessary, and a sharp look-out kept that no poor lands, or lands that hold water, are taken; more especially the latter, for by good cultivation you may get a fair crop off poor lands, but no amount of good cultivation will give a crop off water-logged lands, or lands with a wet sour subsoil.

Indigo can be sown, and will germinate, in every month in the year, provided the ground is well prepared, and contains the requisite moisture: as a matter of fact, it is sown in every month, except December and January.

The sowing season "must very often, and to a great extent, be made to depend on climate." The season for Bengal will not be the best for the North-West. Then again, though the indigo may be sown all the year round, there is no doubt that there is only one season that will give the best results, and the maximum yield, and what that season is, can only be found out by careful records being kept of the different months in which the indigo has been sown, and of the produce from such sowings, both in plant and *mál*. It is a well known fact, that the indigo plant cannot stand much moisture; the conclusion then is obvious, that to make it a rainy whether crop is a mistake: there then remains the *October*, *Spring* and *Jamawah* sowings, all these three sowings do not give the same result, the one that gives the best results, taking into consideration "conditions of soil and weather, which vary so greatly, that what is best one year, is not best another" should be the one fixed on: accurate records should be made for several years, "so as to hit wet or dry, cold and hot, bad and good years."

It is of the greatest importance that lands for an indigo crop be well ploughed, and the surface soil be brought to a fine tilth. It is not absolutely necessary that the soil be turned up to any great depth, practically, four inches is enough, but it is absolutely necessary for full crops, and good healthy plants, that the subsoil be loosened and stirred, and that as deep as ever it can be done. An iron plough followed by a *nugra* country plough would do this. "Shortly before sowing, the surface soil should be brought into as fine a tilth as is possible, to receive the seed. When the requisite degree of fineness has been obtained, the surface should be rolled down in order to render it sufficiently compact and even, to prevent the seed, which should always be sown in lines to admit of after cultivation, from being buried too deeply; in fact, probably half an inch deep is amply sufficient for so small a seed, and were it not that the sun is, whenever it appears, so powerful, scorching, and destructive to young plants, it might be sown with advantage on the surface and only covered, as clover is, with a brush harrow."

No hard and fast rule though should be adopted as to the proper depth to sow the indigo seed. It should depend on the nature of the soil; a quarter of an inch deep in some soils, would be equal to an inch in others; as a rule, the indigo seed is sown much too deep. In sowing indigo, as well as other small seeds, it should never be forgotten that the nearer the seed is to the surface, and kept moist enough to germinate, the stronger as a rule will the plants be. "To know just the depth the ground will be moist enough to sprout the seed requires more than an ordinary amount of intelligence. On light sandy loam it is safe to plant much deeper than if the land be low, and moist, and heavy. The smaller the seed the nearer the surface" should be the rule. Indigo seed planted too deep exhausts a large portion of its vitality, and will not make that vigorous growth it would if planted at the right depth, or even on the surface. No rigid rule should be made, the condition, texture, and nature of the soil, and the state of the weather, should be taken into consideration, and the seed be sown just deep enough to germinate; just deep enough to keep the seed sufficiently moist to germinate.

W.

INSECTICIDES.

Notwithstanding the immense variety of substances known to be destructive of animal life, and the large number of preparations offered as insecticides, the gardener, the orchardist and the farmer remain very much at the mercy of their numerous insect foes; they have the means of killing them, but the difficulty lies in the application of those means; the materials for the warfare are sufficiently abundant, but the foe will not "come and be killed," he lives and increases in all sorts of out of the way places, and frequently a large amount of time and ingenuity have to be expended before an opportunity is found of coming to close quarters; even when the insects are visible in thousands on plants or trees, it is an almost endless task to get rid of them. The only principle of action that is efficient and economical of time and the munitions of war is to take them early, if possible, in the first stages of their existence, or, if that is unattainable, then before they have had time to breed and thus increase their numbers.

Insecticides are found in both the mineral and the vegetable kingdoms, the latter being much the more numerous. Among the former, arsenic is a deadly poison to all insects to which it can be applied; it is generally used as a preparation known as Paris green, which is infused or partly dissolved in water and applied with a syringe or watering pot. It is much used in the United States on potatoes infested with the bug, for which it is a perfect remedy. In that case, being applied only to the tops of the potatoes, its use is not at all dangerous; but there are many cases to which, on that account, it could not be applied. It has been recommended as a preventive of or remedy for the Codlin Moth, though we have not seen a statement of how the effect is produced. The recommendation is that it should be syringed over the trees when in blossom, but whether that prevents the parent moth from laying her eggs in the blossoms, or poisons the worms after they are hatched, does not appear. At any rate, it would be well if some of our orchardists would try it by way of experiment, and probably they may deem it prudent to dress some of their least valuable trees, though we do not anticipate that any harm would ensue from an outward application, while the quantity would be too small to have any effect upon the roots; neither is there likely to be any danger of the poison remaining on the fruit till it is fit for use, as the quantity that falls on the incipient fruit would be infinitesimal. Sulphur is another mineral that exercises a deleterious influence upon certain insects, though not in its crude state, in which it has no more power than as much sand; but a slight degree of heat suffices to cause decomposition, when sulphurous acid is produced, and that is a deadly poison to both animal and vegetable life, therefore requiring to be used with caution; fortunately a proportion in the air that is destructive to red spider and the lower vegetable parasites—fungi—has no perceptible effect upon plants, though a slightly larger amount would prove very injurious, as many inexperienced persons have found, when, in their anxiety to produce a sufficient amount of the gas, they have placed the sulphur on hot smoke flues in their vineries or other houses, to the destruction of both plants and insects. In the open air and merely under the influence of the sun the amount of gas generated, though sufficient for the desired purpose, produces no ill effect on the vines or others plants to which it may be applied. Petroleum, either crude or in the refined from of kerosene, is quickly and entirely fatal to insect life, and is of such a nature that it searches into every crevice where an insect can penetrate, and also takes instant effect upon the mealy bug and others that are covered with a downy substance impenetrable to many other liquids. Though this substance produces little or no ill effect upon the bark or other hard parts of plants it is destructive of nearly all young or tender parts, and therefore requires to be used with great caution and to be washed off immediately, which, fortunately, can be done without its efficacy being at all impaired, for a touch of it is death to any insect of whatever kind. It is difficult to apply with moderation, as it will not combine with water, but an emulsion, soluble in water, may be made with soft soap or milk. Professor Riley, the celebrated American entomologist, gives the following recipe for its preparation:—Refined kerosene, two parts; sour milk, one part; or, if milk cannot be obtained, then condensed milk is employed, as in the following formula:—Kerosene, one gill; condensed milk, a pint and a half; water, three pints. First mix the milk and water, then add the oil, and churn till a sort of butter is produced. When required for use this is diluted with twelve to sixteen times its bulk of water, so that the emulsion resembles milk, and it may in this state be employed with safety. Ammoniacal gas is also thoroughly destructive of insect life, and may be at the same time beneficial as a manure. Ammoniacal liquor from gasworks forms a powerful insecticide.

Of all vegetable substances, tobacco is one of the most potent, whether used in powder or as smoke; still there are some insects, such as mealy bug, upon which it produces little or no effect. Pyrethrum powder has recently obtained a great name as an insecticide and but for its liability to adulteration would probably be more worthy of it than it is supposed to be. It is, however, even in the condition in which it is offered, an effective substance, especially for domestic use, and may be frequently used for gardening purposes, especially in the destrucion of aphides, to which it may be applied either as a dry powder, or mixed in water and laid on with a syringe, as may be most suitable or convenient. The powder, which is merely the flowers of Pyrethrum roseum ground to dust, might be grown and prepared by anyone, now that the seed can be obtained in the colony; and we trust the experiment will be tried, as there appears a great probability that its virtues may be brought out to the full in this climate. The flower-heads are gathered when fully expanded, dried in the shade, and finely pulverised. As the powder soon loses its properties when exposed to the air, it requires to be immediately packed in air-tight vessels. Its wants of permanency is, of course, a draw-back, for if applied to the insects on a particular plant it will destroy them, but has no effect on any others that may alight on the plant half an hour after the application; neither does it produce much effect except on those with which it comes in actual contact; nor any upon the eggs or pupæ of insects. It is also harmless to man and other of the higher animals, as well as to plants. It may be also used in fumigation, as it burns freely, giving off much smoke, which suffices to kill or paralyse flies or mosquitoes in a room, and is likewise efficacious in the case of furs, feathers, herbaria, or in greenhouses; and when used in that way pulverisation would not be necessary. An alcoholic extract may be also made, and is useful for application to insect infested plants in houses. The powder is, however, of no service in the case of hard shelled insects, as beetles, scale insects, or hairy caterpillars.—*Leader*.

THE CULTIVATION OF FERNS AND LYCOPODS.

As fern cultivation is becoming general with all who aim to make their homes attractive, the following paper upon the subject, read by Mr. P. Somerville at the S. A. Gardeners' Mutual Improvement Society, will be of service to many of our readers.

"In laying before the members of the Gardeners' Mutual Improvement Society a few remarks on the cultivation of ferns and lycopods it is not my intention to give a scientific description. It is no wonder that within the last fifteen or twenty years such a love for ferns has taken place. Flowering plants were at one time all the rage, but plant houses could not always be kept in bloom, and so, by degrees, a desire for something different set in, and, as all are aware, ferns came in for a large share of patronage. I think their presence is as necessary to embellish the flower stands as it is indispensable in a well made up bouquet. Although ferns often succeed well in a mixed collection of plants, there is no doubt to have them in perfection, like orchids, they require houses specially for themselves, and more particularly in such a climate as that of South Australia, as there is nothing more destructive to their tender fronds than hot winds and high temperature. Ferns are naturally reproduced by spores, and I think on this point it is necessary to give extra prominence, as it seems to me not to be so well understood as it ought to be so well understood as it ought to be. There is just one remark I have to make with regard to the difference between a spore and a seed. The seed is the body from which the young plant springs, and so is a spore; but in the seed the root comes from a fixed spot; in the spore it does not. The part of the spore which is downmost produces the roots, and that which is uppermost produces the stem; and, as it has been said, it is as easy to find out the end of a circle as to find out the spot of a spore where the root springs from. When the spore germinates it produces what is called a thallus, and at one time it was thought and believed that the thallus was analogous to the cotyledons of dycotiledonous plants; but recent investigations prove the fallacy of this belief, and show that it is after the thallus is produced that fertilisation takes place. But I must refer you to books for full information on this point. Every one seems to have his own way in saving and sowing the spores, but I shall simply describe the way I have found them succeed best. Now, the first thing is to get the spores in proper condition. The majority of people are too long in gathering them, and what they suppose to be the 'nice brown ripe spores' are very frequently nothing but the cases which contained them, and are just the same as if a farmer would let the grain drop, then gather and sow the chaff. I thought it advisable to bring specimens to illustrate what I have been saying, and submit them for your examination. When I consider the spores are ready for gathering (and a little observation will soon make anyone acquainted with the time), I take off so much of the frond as I want, and wrap it up in a piece of paper and put it in a dry place for a few days. On opening the paper again the frond will be partly shrivelled, and the spores lying in the paper in the shape of the finest dust. But before doing this, if you intend sowing them, have the pots prepared, and I certainly would advise the sowing as soon after the spores are collected as possible. I am (I dare say you all are) partial to fresh seed of any kind. Now about preparing the pots for sowing the spores. We are generally told to crock the pots well, fill up with some rough stuff, placing some *fine* sifted soil on the top, and, to crown all, stand them in saucers of water, cover with glass or bell glasses, &c., &c Now, if you have a nice close pit flat in the roof and sunk in the ground a little, no such manipulation will be required. Have some peaty soil, such as we get in the gullies, chop up a little of it, taking out any of the long grassy roots. The only sieve I use is a very fine one to get rid of the fine particles of the soil. It is not necessary to put crocks in the pots; simply fill them up to within half an inch of the rim, giving the pots a few taps on the bench, and genntly pressing the soil down. The only bit of trouble I go to is to dip the pot, soil and all, into some scalding water. This destroys all seeds, and any spores of native ferns which may have been in the soil; and I think it has another effect—namely, swelling out the small dried pieces of peat, and so forming a suitable bed for the spores to germinate on. As you are anxious now to get your spores sown, water the soil with cold water through a fine rose; and, if the soil is of the right description, the water will pass through it as fast as you pour it on. Take the paper which contains the spores, and carefully shake it over the pot; rub the frond between your finger and thume over the pot also, and the operation is complete. Stanb the pots in a shady place, and in three weeks maud of the varieties will be showing themselves. Of course the soil must not on any account be allowed to get dry. When I see it getting dry I generally dip the pots in water. I consider autumn the best time to sow—the soil can be kept in much better condition, and the young plants grow stronger. When once the soil begins to get covered with the thallus of the future plants, it is well to 'prick' them off into pots or pans prepared as for the spores. With a sharp-pointed stick lift them out, and distribute them over the surface of the soil, pressing them gently with the hand so as to make them adhere to the soil. These must be kept very close and shaded for a few days, until they get established in their new quarters. Some little time will elapse before they are ready potting, and I think it is better to let them have a little strength first; on the other hand, it is not wise to delay too long in potting, as the roots get matted, and cannot be separated without injury to the young plants. If a proper pit is not to be had, and only an exposed or airy house is at command, a close case or bell glass must be used in raising the spores.

"Some ferns produce young plants on the fronds. A familiar example is *Asplenium bulbiferum*, and also *Doryopteris palmata*. Part of the frond can be taken off with the small plants attached to it; if the cut end of the frond is inserted in the soil and covered over with a piece of glass the young plants will soon root, and can be potted off at pleasure. Some other varieties can be divided or pieces taken off. Some of the Adiantums and Davallias can be treated this way, but plants raised from spores give the most satisfaction. Where a collection of ferns is grown, two houses will be required, one for those requiring a cool temperature, and the other for those requiring a warm one. For the former I would advise a house facing south or south-east, and for the latter north-east. Perhaps a few points are immaterial, other points being attended to. If grown in pots they should stand on a cool moist surface such as common bricks. These absorb and retain moisture, and part with it slowly. Nothing seems to be more injurious to ferns than standing the pots on open stages, over hot water pipes or flues. In a house without artificial heat the case is different, and some latitude may be allowed. The houses, I should have mentioned, should be well protected from prevailing winds and flat in the roof, and I would recommend a 'lean-to,' as a much evener temperature can be maintained; so, also, with regard to humidity. Of course ventilation must be provided and airing judiciously applied. Cutting winds are injurious, and so are hot ones. Shade is absolutely necessary, and ferns will stand a heavier shading than most plants. The soil I use for potting is chiefly peat from the swamps. After having lain in a heap for some months it will be fit for use. I generally shake out the long grassy roots, but use it otherwise in a rather rough state. A little coarse sand and a few small pieces of charcoal make up the compost. I like to be rather particular in having the pots well crocked—not half filled, but carefully done—as on this depends a good deal the maintaining the soil in a healthy condition. I am not a great advocate for syringing ferns over head, and it never should be applied to Gymnograms of the gold and silver class In the winter season it causes many of the fronds to damp off. Of course all ferns do not require the same treatment, as some grow on trees, others amongst rocks, and some in swamps. It is always desirable to have a knowledge of the places where they are found growing, and under what conditions.

"As a rule, ferns are singularly free from diseases; their principal enemy is the brown scale. Thrips, too, sometimes play havoc with them, and occasionally the green fly. Slugs, too, give sad annoyance, eating off the young fronds, &c. Fern growers know how difficult it is to get good fronds on *Pteris tricolor*, owing to the slugs eating them. Just one word about getting rid of these pests, or rather keeping them down. I have no better plan for getting rid of the scale than destroying them with the hand. If the plant gets very bad throw it away and bring on a young one. Occasional fumigating is the best remedy for thrips and green fly, and nightly visits must be paid it slugs are attacking your favourites. They are rather nice in their tastes, and are particularly fond of the best varieties. The grand secret in growing ferns, as in other plants, is to grow them vigorously and without check. There are a great many points connected with growing ferns not touched upon in this paper, neither would it be possible in the time allowed for reading it."—*Queenslander.*

INDIA CROP AND WEATHER REPORT.

For the Week Ending the 25th December 1883.

General Remarks.—Rain continues to fall generally in the districts of the Madras Presidency, where harvesting of paddy, ragi, &c., is in progress and standing crops are in good condition, though partial injury has been done in one district by excessive rain.

There has been no rain in any other province except slight showers in Dharwar, Bombay Presidency, and Sandoway in British Burma. The rabi crops in three districts of the Bombay Presidency are suffering from blight, otherwise prospects are good. In Mysore rice is being harvested and standing crops promise well. In the Berars and Hyderabad cotton is being picked and the kharif harvested, and the weeding of rabi crops has commenced. Prospects continue fair in Central India and Rajputana, but cotton has suffered from frost in Ulwar, and rain is needed in that State. In the Punjab and the North-Western Provinces and Oudh the rabi crops on unirrigated lands require rain, but prospects are on the whole favourable. In the Central Provinces prospects are excellent.

In Bengal the outturn of the rice harvest is very poor and will, it is expected, fall short of the estimate even in Eastern Bengal and Orissa. The rabi has much benefitted by the last showers, but more rain is much wanted. In British Burma the rice harvest is reported to be well advanced and the prospects generally excellent.

Cholera still lingers in the Southern Presidencies, and small-pox and fever are generally prevalent though not severe.

Prices continue to rule high in Bengal.

Madras.—General prospects good.

British Burmah.—Public health generally good, but small-pox more or less prevalent in Akyab, Rangoon and Shwegyeen; health of cattle good, except in Akyab, Pegu, Bassein, and Thyetmyo; crop prospects for the most part excellent; reaping well advanced.

Assam (Gauhati.)—Nights and mornings foggy and cool; reaping of sali crops in progress; public health fair.

Mysore and Coorg.—Rainfall slight in four districts; standing crops reported unfavourably; harvesting of grain general throught the province; prospects and public health good; prices unchanged.—*Pioneer.*

Red Spider.—Amateur, Footscray.—Sulphur may be considered a specific for red spider; it is certainly one of the most efficient agents for killing them. It will not mix properly with water in its ordinary form, but should be treated according to the following recipe:—Boil together in 4 gallons of water 1 lb. of flowers of sulphur and 2 lb. of fresh lime, and add 1½ lb. of soft soap, and, before using, 3 gallons more of water. Use at a temperature of 140 or 150 degrees, according to the tenderness of the plants to be treated. —*Leader.*

The Annual Report of the Superintendent, Botanical Gardens, Gunesh Khind, for 1882-83, shows that very satisfactory progress has been made in grafting mangoes of the best varieties. Fair progress was also made in the planting of oranges, but we should like to know whether the Malta species, which thrives so luxuriously at Lahore, has been tried at Gunesh Khind. The Nagpur orange has long had a great reputation, but it does not come near the Malta by a great way. *Taraxacum* yielded a profit of R50 per acre. *Rhea* has grown very well, but is still waiting for the machine which is to render it of real importance. Tapioca was a failure financially. Of the potatoes, Sutton's *Magnum Bonum* and *Red Emperor* grew well. We do not, however, find that any trials have been made towards the all-important question of experimenting with grains which are of rapid growth. Had the ordinary crops been largely destroyed by locusts, it would have proved of the first importance to point to other food-grains which could have been planted and brought to maturity before the extreme effect of the destruction of the ordinary crops could have been felt. Such grains exist and are known to the Punjab Botanical Society, and we would commend the matter to the attention of Government, as relief works are not the only resource that may be resorted to, and more strings than one to one's bow is a distinct advantage.—*Bombay Gazette.*

JAMAICA AND CINCHONA CULTIVATION.—In the opinion of Mr. Morris, the Director of the Government Plantations in Jamaica, who has recently visited British Guiana, the cinchona plant is very unlikely to thrive in either British Honduras or British Guiana, and, as he has not much faith in the systematic cultivation of it in its natural home in the South American States, whilst all attempts at its naturalization in the United States have failed, he thinks it very likely that for many years to come Jamaica will remain the site of the only successful cinchona plantations in the New World. In that island plantations are now being laid out by private persons on a large scale, and during the last two years the Government has sold twelve patents, or runs, of high forest land, containing about five thousand acres, under conditions which require that at least one-sixth shall be planted with cinchona at the end of five years.—*Pharmaceutical Journal.*

TEA IN CEYLON.—I consider that eighteen months' growth in Ceylon is equal to 3 years in India; consequently it is better to begin a gentle course of plucking (which is really pruning) at 18 months old, so as to form the bush, than to allow the trees to run up, say, eight to ten feet, than ruthlessly prune it down, and by so doing throw away what really ought to be in tea boxes. I consider the damage done to the tree by this method of treatment incalculable; in fact, in one or more gardens that had been allowed to run up, as described above, I feared to prune the trees to the required height, knowing the shock might prove fatal. Again, if early plucking is carefully carried out, the bush receiving a check on top, throws out laterals and so forms itself. In India, a tree pruned and allowed to run, for one year without plucking, would make between three and four feet; in Ceylon it would make near ten. If we do not pluck our trees here, they will simply run away from us, and, in proof of this, I could mention more gardens than one. Indian tea planters, and Ceylon men also, ridicule the idea of our getting 700 lb. of dry tea per acre all around. From what I now see, I have come to the conclusion that 800 lb. is nearer the mark for carefully planted estates in the low-country. I have no fears of the bush being injured by his so-called "close plucking," if it gets a good start after pruning. The tea tree in Ceylon is always growing, both above and below ground, and I have not on any estate noticed the bush receiving a check, unless where it has been sufficiently pruned.—(THE LATE W. CAMERON). —Local "Times."

OILCAKE—WHAT IS IT?—I am now writing of cotton and linseed oilcakes, as, in practice, I have little knowledge of other oilcakes. In almost all cases the actual value is based on the comparative number of percentage parts of oil which a sample of cake contains. Round this central figure of "oil" all the other component parts are grouped in various degrees of lesser value or of no value at all—*e.g.*, on p. 248 of the last issue of the Royal Agricultural Society's *Journal*, in the report of the Chemical Committee, Dr. Voelcker, in giving 4'07 as the percentage of oil in a sample of decorticated cotton cake, says that "the cake is poorer in oil than good undecorticated cotton cake." Again, on p. 372 of part 1, 1882, of the same journal, Dr. Voelcker reports of two samples of linseed cake sent to him for analysis that No. 1 contained 7'75 and No. 2 11'05 percentages of oil. To use Dr. Voelcker's words, "No. 2 was a good linseed cake. The cake marked No. 1, it will be seen, was poor in oil." In actual fact, compensation was paid to the purchaser of this No. 1 cake by its vendor because of such deficiency. In the good time coming, when oilcakes will be sold by guaranteed analysis, no cake will fetch a high price unless it is not only pure, but rich in oil. Meanwhile, for myself, I do the best I can with what I find on the market, and purchase both linseed and cottonseed oilcakes, just as each seems for the time being better worth its quoted price. Just now decorticated cotton cake is scarce and not fine. Unfortunately also our best and purest linseed cakes have less oil than they had a few years ago. When I bought, a few weeks since, E. and K.'s linseed cake and the best decorticated cotton cake I could find, I regretted that neither sample had as much oil as I like. Perhaps it is right to say that by a preference, founded on long use of both, I like decorticated cotton cake for all purposes, better than linseed cake.—T. C. S.—*London paper.*

WHY DO ANIMALS NEED SALT?—The Prof James E. Johnston answers this question. "Upwards of half the saline matter of blood (57 per cent) consists of common salt, and this is partly discharged every day through the skin and kindeys. The necessity of continued supplies of it to the healthy body becomes sufficiently obvious. The bile also contains soda (one of the ingredients of salt) as a special and indispensable constituent, and so do all the cartilages of the body. Stint the supply of salt, thereafter neither will the bile be able properly to assist digestion nor the cartilages to be built up again as fast as they naturally waste. It is better to place salt where the cattle can have free access to it than to give it occasionally in large quantities. They will help themselves to what they need if allowed to do so at peasure, otherwise when they become salt-hungry they will take more than is wholesome.—*Mark Lane Express.*

I FIND it is the almost universal experience in these parts that a cow will, if turned out to graze, require at least 1½ acre for the summer; and my own experience agrees with my neighbours', that for the long winter of this district, the hay of another 1½ acre is required. It will be seen that by only using half acre of ground for the summer months, my plan is 1 acre to the good for every cow kept; and, as this will give 13 acres for my whole herd, it enables anyone working on this method to keep just 50 per cent more stock than by the old-fashioned plan. Against this is to be placed the extra labour, which it does not need great calculation to prove is much more than covered by the increased return. Every day in the year each cow receives 2 lb of decorticated cotton cake, and during the winter, when tied up and fed on chopped hay any straw, and a few roots, they get 3 lb. each of meal, composed of equal quantities of maize, rice, cocoanut and palm nut, which, combined with the decorticated cotton cake, forms a food of, I believe, unsurpassed nutrition and manurial value.—*London paper.*

PEACHES.—I planted a peach orchard, writes M. Siroy, of the Society of Horticulture, and the trees grew well and strongly. They had just commenced to bud when they were invaded by the circulio (*pulyon*), which insects were followed, as frequently happens, by ants. Having cut some tomatoes, the idea occurred that by placing some of the leaves around the trunks and branches of the trees, I might preserve them from the rays of the sun, which are very powerful. My surprise was great upon the following day to find my trees entirely free from their enemies, not one remaining, except here and there where a curled leaf prevented the tomato from exercising its influence. These leaves I carefully unrolled, placing upon them fresh ones from the tomato vine, with the result of banishing the last insect and enabling the trees to grow with luxuriance. Wishing to carry still further my experiment, I steeped in water some leaves of the tomato, and sprinkled with this infusion other plants, roses and oranges. In two days these were also free from the innumerable insects which covered them, and I felt sure that had I used the same means with my melon patch, I should have met with the same result. I therefore deem it a duty I owe to the Society of Horticulture to make known this singular and useful property of the tomato leaves, which I discovered by the merest accident.—*Indian Agriculturist,*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, December 20th, 1883.)

IMPORTED FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White	Slightly softish to good hard bright	£7 a £8 10s

THE EXHAUSTION OF SOILS.

SIR,—In your October issue, p. 452, 'N. N.,' in his criticism on Mr. Paterson's views on pruning, says,—"If, on the other hand, the covert of unmixed Oak be very open, the soil is liable to be exhausted by heavy annual crops of grass, brackens, and other weeds.' Now if grasses, &c., which may grow and decay on the same soil year after year for many years, exhaust the soil, how great must be the exhaustion where, along with the production of this grass, the soil produces, say, 100 tons of saleable timber per acre. As 'N. N.' is not singular in the opinion he thus expresses, perhaps he or some of those who hold the same views, will be so kind as to tell us how they became aware of this exhaustion. D. M'CORQUODALE, Dunrobin, Golspie, N. B.—*Journal of Forestry.*

THE DWARF PALM (CHAMÆROPS).

This plant, referred to in the issue for Nov. 2nd, has some properties which I think are peculiar to itself, and although of no commercial value, they greatly increase its use for ornamental purposes. We have had one of these planted out in a drafty corner of a garden for three years without any protection; in one winter all the large leaves were broken down with the weight of snow accumulated on them, and that winter was exceptionally severe. It is almost the only plant which is absolutely uninjured by the fumes of burnt gas, and it will keep in perfect and robust health in badly lighted rooms in which gas is constantly used for lighting purposes. The plant which stood three years in the garden has been now standing twelve months on the floor of an entrance hall with a north aspect, and at some distance from the window; it has had no attention, except to occasionally wash the accumulated dirt or dust off the leaves, and is now as perfect and handsome a specimen as could be desired. It has stood, without injury, fourteen years of knocking about in an ordinary dwelling-house and garden, and thrives under the treatment. If its hardy nature were better known, it would become one of the most popular ornamental plants in existence.—THOS. FLETCHER.—*Journal of the Society of Arts.*

PAINTING TAR ON FOREST TREES: AN ENQUIRY.

SIR,—My son now rents a moor in a lovely part of this county, called Blanchland, which is on the borders of Northumberland and Durham. The former tenant having a dislike to adders, &c., supplied himself with goats to destroy them (which these animals are very clever in doing). The lovely woods being found to suffer from such unsuitable inmates, he (I conclude in ignorance) painted the suffering kinds of trees with coal-tar as a preventive! The Planes, Rowans, Willows and Beeches, are all victims, and up to the height of eight or ten feet are encased in this black band, and evidently dying. I notice where Nature has made a strong enough effort to split *down* the bark the trees look more hopeful; but in dozens of cases the entire bark is falling on to the ground, leaving the wood bare, and, of course, dying. Will anything save these *treasures*, as trees must ever be considered? I have thought that perhaps oil, well rubbed into the injured bark, might do good, since it seems so burnt. Can any of the readers of *Forestry* suggest a remedy?—THERESA T. LAING, Thornhill, Sunderland.

We fear that irremediable damage has been done to the trees referred to, except in the instances mentioned, where Nature is rising superior to the injury which has been done to her. But if any of our readers could suggest a remedy, we shall be glad to publish it.—ED.]—*Journal of Forestry.*

[We are all familiar with the band of coal-tar painted by the Sinhalese round their coconut palms to prevent, it is said, rats from climbing to destroy the young fruit. We suppose the coal-tar rings are too narrow to have any injurious effect on the trees, such as tar is described as having on English forest trees.—ED.]

THE GERMINATION OF SEEDS.

Dr. Sturtevant, the Director of the New York Agricultural Experimental Station, reports that:—

It early came to our attention that seeds which responded well to the test for vitality in the germinating apparatu did not equally respond under circumstances of garden planting. Hence a few investigations have been made, in order to decide what relation might exist between the germinating and the vegetating power. By germination we mean a vitality in the seed sufficient to put forth the radicle. By vegetation, in our tests, we mean that vitality which enables the seed planted under the favourable conditions of a testing apparatus to form the cotyledons, or seed leaves. Thus far we have found no constant relation between the perceutage of seeds which germinate and those which vegetate. In some exceptional cases seed which gave 100 per cent of germination were unable to vegetate a single plant. These exceptional differences were, however, found only in the case of some seed which required quite an extended period for vegetation, and, therefore, was more subjected to accident than other seeds whose habit was to vegetate more quickly.

Some seeds will germinate when quite immature. Thus, Sweet Corn kernels, while in prime edible condition, if carefully removed from the cob, will germinate perfectly. The same fact is true of Peas while in the edible state. In some trials with unripe Corn it was found that immaturity of seed hastened the germinative processes, and it is certainly worthy of trial whether by the use of immature seed we may not attain earliness in our crops through a series of successive selections. If earliness be gained, even at the expense of some other quality of growth, it may be possible, through a series of selections, to attain earliness in varieties and yet retain qualities which may be sufficient for the purposes of the grower.—*Gardeners' Chronicle.*

THE CHINESE SABAH LAND FARMING COMPANY.

Latest advices as to the progress of operations are:—The result of the Experimental Planting of Tobacco and Sugar is so far satisfactory that we have full confidence in the success of the planting on a larger scale for next season. There are 48,000 fine trees on one of the estates. Cutting will begin shortly, and paddy will be laid down as an after crop about October. The Marine lots purchased by the Company are now worth \$5,000 for immediate realization, adjoining lots having sold at these rates. We are forming a township on the Sibooya estate as a field for the immigration of Chinese Agriculturists. In the centre of this is a nice fresh water stream about 40 feet wide, we will be ready for settlers in two or three months hence, and would prefer married people and their families, there will be comfortable houses prepared for them, with gardens, piggeries, and fowl houses attached. The land will grow all tropical produce, and there are at present near the township Pepper, Gambier and Coffee nurseries all looking well. A road will shortly be completed to the Settlement of Elopura, thus securing a profitable return for the cultivation of fruit and vegetables. The land in the neighbourhood of this estate is now valued at \$10 (ten dollars) for acre. The cultivation of Lanoot or Manilla Hemp has also been commenced, the preparation of which will be an additional source of income to the wives and children of immigrants. Neighbours on the spot remark that we have stated on the two principals of planting and opening estates that our method of experimenting is undoubtedly a good one, being both practical and economical, and that we are right in giving our first attention to the cutting of roads.

Elopura—Agency of the Chinese Sabah Land Farming Company.—*N.-C. Herald.*

USEFUL HINTS.

A tablespoonful of turpentine, boiled with your clothes, will greatly help to whiten them.

Clear boiling water will remove tea stains, pour it through the strain to prevent it from spreading.

Salt fish are quickly freshened by soaking in sour milk.

Kerosene will polish your tea kettle like new, if well rubbed in with a rag.

A little gum arabic dissolved in boiling starch is a great improvement.

Salt and beeswax will make rusty flat irons clean and smooth. Tie a lump of wax in a rag, and when the irons are hot rub them with it, then scour with salt.

Kerosene will soften boots and shoes that have been hardened by water.

Buttermilk and bathbrick mixed together is the best thing for scouring copper boilers.

Salt will curdle new milk.

Before scaling fish, dip them in boiling water for a moment; it saves half the trouble.

Half a teaspoonful of common table salt, dissolved in a little cold water, will instantly relieve heartburn or dyspepsia.

Soap rubbed on mildewed linen, and afterwards fine chalk scraped on the spots, will remove them after two or three times.

Spirits of salt will remove ink stains from mahogany.

A teaspoonful of oxalic acid, dissolved in a teacupful of hot water, will remove ink stains from a coloured tablecloth.

Cream of tartar cleans soiled white kid gloves.

Shoes may be rendered waterproof by being rubbed over at the seams with a little beeswax and mutton suet melted together.

Charcoal, finely powdered, gives knives a splendid polish.

Before using a brass kettle clean it with salt and vinegar.—*Leader.*

THE QUEENSLAND SUGAR DISTRICTS.

The great event of the week among sugar planters has been the sale of one of the largest plantations in Mackay to a Melbourne capitalist. The plantation known as the River Estate, the property of Messrs. Spiller and Brandon, was sold on Saturday to Mr. Robert Bruce Ronald, for the sum of £80,000 cash, as on the 1st of June. The plantation commences at about three miles from the Mackay wharves, and consists of 2,411 acres. At the present moment 1,430 acres are under cultivation, and of these the cane from 901 acres will be crushed this season The estate also crushes cane from 560 acres belonging to farmers located in the neighbourhood. By the end of the season the output at the plantation is expected to exceed 2,000 tons of sugar. There are two mills on the estate; the older and larger mill produces the usual sugars manufactured in the district generally, but the new mill, which is just approaching completion, is intended for crushing purposes only, and will forward its juice by means of piping to the older mill, there to undergo the usual process for final production for sale. A railway runs through the whole plantation, and by means of the portable rails the furthermost portions of the land are brought within a few minutes of either of the mills. The rails and locomotive are by Messrs. Fowler & Co., of Leeds. Altogether, the length of the line amounts to three miles. The one mill is lighted up by a Gramme electric light. The plantation, besides the usual implemants, &c., is worked by 130 draught horses; it employs 65 Europeans and 250 kanakas. This number of white and coloured hands is in about the usual proportion of such labour in this district, namely, one to four. By the time the crop is taken off and sold the purchaser will have received £20,000 back again, this sum being the balance of the amount estimated to be realised on the sale of the sugars, less the expenses of taking off the crop, &c.

The property has undoubtedly been sold cheap. There are several reasons for this, not the least of which is the very unsatisfactory state of the coloured labour question. During the last week two labour schooners the Fanny and the Emily—certainly arrived with full complements of kanakas, but previous to that several vessels like the Sparkle, the Lavina, and others, came in only half full, and that after six or more months' recruiting. The declaration of the Premier that he *will* introduce Indian coolies is not of much value in the face of an impending dissolution, and the planters are experiencing more difficulties than they expected in the introduction of Chinese labour.

Planters regret much that the failing health of Mr. Spiller has caused the retirement of one of the chief pioneers in sugar production in the north of Queensland.

A plantation newly formed on the Burdekin has also changed hands. The Pioneer estate on that river, the property of Messrs. Spiller and Brandon, has been purchased by Mr. G. R. Drysdale, a Riverina squatter, for £42,000. It consists of 5,061 acres of splendid forest land on the Burdekin delta. A 2,000-ton mill is now on its way out from England, and the estate is further to be supplied with a set of Fowler's powerful steam ploughs. There are 600 acres under cane planted for next year's crushing. This estate took first prize and special cup at the late Townsville show for the best exhibit of sugar-canes. —*Australasian.*

DESPATCHING OF COFFEE IN THE PARCHMENT TO THE NETHERLANDS.

The question whether the despatching of Coffee in the parchment and the peeling in Netherland be recommendable or not, has not yet been satisfactorily answered. Many planters and brokers laud the results, while others object to it, and in this case too, the right will be on the side of those who neither recommend it absolutely, nor dissuade it, but bespeak the matter conditionally.

It is therefore desirable to watch carefully this still tender industry. Nobody will deny that, if it is of great importance for producers in India to save time and labour, it is on the other hand becoming more and more a grave problem for Netherland, to create or preserve industrial enterprises, that secure to thousands who desire it, useful and remunerative labour.

The 17th October last, the Netherland Handel-Maatschappij sold by auction 112,102 bags of Java coffee, 265 chests of Padang Coffee, and 1,921 bags of Macasser coffee. The lots No. 17 — m 30, sold at Rotterdam were of the same origin, *i.e.*, from the Residence of Tegal. The Nos. 17-22, together 1,439 bags, were peeled and treated in India, Nos. 23/30, together 1,170 bags, in Netherland. (Chavot & Andres at Rotterdam).

A rough computation taking the bag for convenience sake at 60 kilos) demonstrates that the coffee peeled in India realized about 56,509 guilders—*i.e.*, plus minus *f*0.65 per kilogr. and the coffee peeled in Netherland about *f*56,600 *i.e.*, plus minus 0.80 cents p. kilo.

We have for convenience neglected the fractions; they can never be of much important significance.

However, this example proves so evidently the advantage of the coffee peeled in Netherland, that it must attract the attention of those interested in it. For, if the greater produce be compared to the greater costs of sending it in the parchment and preparing it here in the parchment, even then the account closes with a surplus of 5 cents per half-kilogr.

Could these cyphers allow of being applied to the doctrine of equations, then we should come to the conclusion, that the despatching of the government coffee in the parchment and the peeling in Netherland might yield the government a profit of 6 or 7 millions of guilders. We do not go so far, however, but we do believe that the producers, especially in the Eastern part and in Central Java, would run no risk, if they were to make serious trials of shipping off the coffee in the parchment.

Opportunities for peeling are extending more and more in Netherland, and this circumstance gives us the right to suppose that the supplies of Coffee in the parchment are increasing, and must therefore have proved profitable to a portion of our growers.

Where less favourable results are supposed to be observable, it will always be reasonable and advisable to examine closely whether there may not be adventitious or natural causes to account for this. It has only been our intention to point out to those interested in the matter the facts proclaimed to us by the auctions of the 17th instant.—VAN GORKOM.—*India Mercury.*

THE IMPROVEMENT OF AGRICULTURE.

Rothamsted Experiments. These experiments are stated to have produced evidence that:—

1. The Turnip plant can no more grow without phosphorus than without water or air.

2. It must have the phosphorus applied in an unhurtful form (that is to say, it must be neutralised by oxygen and lime, or a substance similar to lime; this triple compound is termed a phosphate).

3. A full crop of Turnips (say 30 tons) contains only about 30 lb. of phosphorus.

4. Bone is an effective manure, mainly on account of the phosphorus it contains.

5. The more thorough the pulverisation by grinding (or "finer the division" of bone, the earlier the action on the growing plant.

But the work by which this Association is more particularly known and individualised is that abundant evidence is now at hand to prove the following statements:—

6. Undissolved phosphate in finely ground coprolite acts almost identically with phosphate in crushed bone—that is to say, the action is slow, but lasting, and the crop produced is healthy.

7. Dissolved phosphate acts more quickly than undissolved phosphate, and gives usually a rather heavier crop, but a less healthy one.

8. Too quick action, resulting in rapid early growth, tends to produce ultimate disease in the plant.

9. Steamed bone-flour possesses nearly the same rapid action as the dissolved manures, combined with the healthy and lasting action of the undissolved manures, and produces heavier crops than either.

Seven years ago steamed bone was unknown to farmers as a manure. By boiling or steaming bone its glue is extracted, and grinding then brings it down, not to a coarse sawdust-like state, but to a state of division like Wheat-flour; it is recommended on account of its cheapness, as each pound of phosphorus in steamed bone-flour can be purchased for about 6*d*. It is further stated to possess the advantage of keeping the Turnip free from the "finger-and-toe" disease.

Nitrogen on Root Crops.—"Plants can no more grow without nitrogen than without water or without air."

"A full crop of Turnips (say 30 tons) contains about 100 lb. of nitrogen."

"Ten to 15 lb. of nitrogen per acre appears to be a sufficient quantity to apply for Turnips grown in granitic (siliceous or clay) soils generally."

(This applies probably to most soils that are not exposed to prolonged hot seasons, and that are cultivated in a similar manner to those in Aberdeenshire, *i.e.*, receiving during a short rotation, a fair dressing (12 tons) of farmyard manure per acre, and grazed one or two years; 10 to 15 lb. nitrogen would be supplied by about ⅔ cwt. of nitrate of soda, and in many cases much less would do.

"Larger applications of nitrogen than 15 lb. per acre retard ripening, and produce large watery bulbs, without much, or any, increase in solid, nourishing matter."

"To such an extent may this happen that 20 tons of watery Turnips may not contain more nourishing matter than 12 tons of imported Turnips."

Nitrogen on Grain Crops.—"Nitrogen influences grain crops more than phosphorus. The reverse in the case with root crops."

"A full crop of Oats (say 8 qr.), contains about 80 lb. of nitrogen."

"It is probably unsafe to have less than 100 lb. of nitrogen at the command of the grain crop."

"The soil farmed as indicated above, and aided by the nitrogen in rain, may be depended upon to provide, in suitable form, by far the larger proportion of the nitrogen required."

"The manurial application may, as a rule, be limited to 25 lb. of nitrogen.

(This would be provided by about 1½ cwt. of nitrate of soda, or 1¼ cwt. sulphate of ammonia, or by 2 cwt. of Peruvian guano.—*Gardeners' Chronicle.*

THE TREES YIELDING BENZOIN.

BY E. M. HOLMES, F.L.S.

The benzoin which enters into English commerce includes four varieties, named respectively Sumatra, Palembang, Penang and Siam benzoin. These exhibit certain characteristic appearances by which they are easily recognized, and three of them, namely, Sumatra, Penang and Siam benzoin, are probably derived from three distinct plants. The botanical source of Sumatra benzoin was determined by Dryander, and an account and figure of the plant were published by him in the *Philosophical Transactions*, for the year 1787, lxxvii., p. 303, but the trees which yield the other varieties have as yet never been identified with certainty. The Penang benzoin is similar in appearance to the Sumatra kind, but it has an odour which is quite distinct and resembles that of storax. It is in all probability not produced by *Styrax benzoin*; but we have as yet no accurate information concerning the botanical source of Penang benzoin. The authors of 'Pharmacographia' point out that it may perhaps be the produce of *Styrax subdenticulata*, Miq., since this tree, which occurs in West Sumatra, has the same name, "Kajoe Kéminjan," as *S. benzoin*, and Miquel remarks of it *an etiam benzoiferum?* That these two species should receive the same native name in Sumatra is not surprising since the leaves are very similar in shape and appearance and the fruit of *S. subdenticulata* apparently only differs from that of *S. benzoin* in being obovate instead of globular and depressed.

Palembang benzoin resembles the Sumatra sort in odour and differs from it chiefly in its much greater transparency and in yielding, as I am informed, a larger percentage of benzoic acid. It frequently contains moisture, and if recently imported specimens are placed in a bottle they soon become mouldy. Concerning the tree which yields Siam benzoin, nothing definite has hitherto been ascertained, although as long ago as 1859, Mr. D. Hanbury wrote to Sir R. H. Schomburgh, asking him to investigate the origin of the resin, and to find out whether the tree which yielded it was really *Styrax benzoin*. Nor have subsequent inquiries been more successful. The only account extant of the mode of collection of Siam benzoin is that given by Sir R. H. Schomburgh, who was British Consul for some years at Bangkok. He, however, never visited the region producing benzoin, and could therefore only give information at second-hand. He represents that the bark is gashed all over, and that the resin which exudes collects and hardens between it and the wood, the former of which is then stripped off. The authors of 'Pharmacographia,' remark that it is evident that all Siam benzoin is not thus obtained. Schomburgh adds that the resin is much injured and broken during its conveyance in small baskets on bullocks' heads to the navigable parts of the Menam river, whence it is brought down to Bangkok.

The state of our knowledge of Siam benzoin being thus imperfect, it occurred to me to write to Mr. R. Jamie, of Singapore, to ask him for information on the subject. This gentleman takes great interest in all that relates to pharmacy, and has, I believe, been a liberal contributor to the Museum of the North British Branch. A few weeks ago I received from him a box of specimens for the Museum of the 'Pharmaceutical Society,' containing amongst other interesting and valuable donations some sections of the trunk of the Siam benzoin tree, and herbarium specimens of the leaves, but unfortunately neither flowers nor fruit; also specimens of the Sumatra benzoin tree with leaves, flowers and fruit. In addition to these specimens he has contributed some interesting information, which I have taken this early opportunity of laying before you. With regard to the Siam benzoin plants Mr. Jamie writes:—

"My friend, Captain Hicks, of Bangkok, kindly procured them after very great difficulty from his friend living in the district where the gum benzoin trees are found, and he writes as follows:—'According to your request I had fifteen gum benjamin plants brought over from Suang Rabang, one of the northern Laos states tributary to the King of Siam, but after a deal of shifting and removing baggage on bullocks, twelve of them withered up; however, I have succeeded in getting three of them brought to Chung-mai; these I now send you. The one in the flower pot seems to be thriving remakably well, but the other two in bamboo joints I have my doubts about. I also send you some sections of wood with the bark attached, and here and there you will find the gum sticking on the wounds and incisions made by the natives. The flowers, I am sorry to say, I could not get, as the trees have already flowered. From reliable information the tree is indigenous in all the northern Laos states, but grows luxuriantly in Suang Rabang and all along the belt of mountains in this province.'

"In the months of April and May the leaves begin to wither and fall off, and the natives then make incisions in the bark, and after a short time a lot of milky substance exudes and soon hardens; the gum then dries on the incisions and falls to the ground, which is swept daily and watched so that no earthy matter gets mixed up with it.

"The tree attains from 3 to 6 feet in circumference, and has a long trunk throwing out branches on the top; after six years' growth it can be bled. The flowers are attached to the small branches close to the leaves and begin to flower in June. The tree throws out shoots from the roots, and can be propagated by cuttings. The natives also say that after the flowers fall off, in a short time a lot of young plants spring up.* The gum is a considerable article of traffic, in fact a monopoly, fetching a good price in the Bangkok market. It is used generally for fumigating sick rooms and making scented water. Large quantities generally find their way to Bangkok, being brought overland on oxen to Sawaryaloke, Pitchai, and other Siamese provinces, and are exported to Europe by several mercantile firms."

Of the three young plants above mentioned, one was given by Mr. Jamie to the Curator of the Singapore Botanical Gardens to forward to Kew, a second was planted in Mr. Jamie's own garden, and the third died. The twig which I now exhibit was taken by Mr. Jamie from the young plant in his garden. The specimen sent to Kew is still living and seemed to be in a healthy state when I saw it a fortnight since. Judging from the appearance of the plant at Kew and from the leaves sent by Mr. Jamie, the Siamese benzoin tree is probably a distinct species, although nearly allied to *S. benzoin*, Dry. The leaves are rather thinner, the lateral veins are fewer in number, and the veinlets more prominent beneath, but it is necessary to wait until flowers and fruit are obtained before the exact species to which it belongs can be ascertained. Mr. Jamie has now the two growing together in his garden, and remarks in his letter, "Judging from what I have seen of the two kinds growing together, they are different."

I have compared the specimens of the Styrax benzoin tree from Mr. Jamie's garden, with Dryander's original specimen in the British Museum, and they correspond exactly.

Concerning this tree Mr. Jamie writes:—"The Singapore grown tree is thought to be from Palembang,† it is about 30 feet in height, and the branches are all at the top. The circumference of the trunk is from 14 to 16 inches. It flowers in March and the fruit does not take long to mature, then it falls off, producing seedlings in abundance at the foot of the tree. How old this tree may be is rather difficult to determine, but it must be over thirty years at the least."

The tolerable certainty that in a short time flowers and fruit of the Siam benzoin tree will be obtainable, and that the source of the drug can then be definitely set at rest, must be my excuse for bringing incomplete information before you. I need none for bringing the admirable specimens presented by Mr. Jamie under your notice.

FRESH WEEDS (FIELDS) AND PASTURES NEW.

(*From "Through Madagascar" by the "Standard" Correspondent.*)

Although Mojanga is the chief seaport on the west coast of Madagascar, and the second in importance in the island, there is no regular communication between it and the capital. Mojanga is on the borders of the Sakalava country, and beyond furnishing the customs officials and their protecting garrison, the Hovas of the interior province of Imerina have little interest in that portion of their dominions. The trade of Imerina for the greater part finds an outlet at Tamatave, on the east coast, so travellers to Mojanga are few and far between. Frequently raiding parties of Sakalavas on "cattle lifting" expeditions are to be encountered, and other dangers of the road, fancied more than real, interfere with the opening up of traffic. Our way for the first dozen miles lay along the banks of the Ikopa river, whose stream we were again to strike some two hundred miles lower down. Here the river was near its source, and its waters spread out on the fields on either hand in broad glistening sheets. The Hovas irrigate extensively, and long fields of green rice, and some of sugar-cane, bounded our road as we went. There is probably no country in the world where provisions are so cheap as in Madagascar. We passed large flocks of geese and turkeys on their way to market at Antananarivo, where they would be sold at the ridiculous rate of from twopence to fourpence each; and droves of huge pigs were met, whose price per head would not exceed a dollar, or four shillings sterling. For a piece of silver equal to about eightpence I purchased more water melons, mangoes, and pineapples of delicious flavour than my score of men could eat and carry away. For the first forty miles of our journey we passed through numerous villages, the inhabitants, apparently, all well-to-do and flourishing. But the population perceptibly grew more sparse the further we left the capital behind; and the country soon assumed that empty and silent aspect which is characteristic of nearly the whole of Madagascar. Only Imerina, for a distance of two hundred miles long by from fifty to eighty broad can be described as inhabited. The rest of the island is an empty though fertile wilderness, where one may travel for miles, almost for days, without seeing man, bird, or beast. Mr. Stribling's station (40 miles from the capital) was the last European's residence I met with on the journey. For the remaining two hundred miles I had either to sleep on the open veldt or in the native villages. But, day by day, the latter grew fewer and further between. The road from the east coast to the capital, as I described on a former occasion, lies through dense forests and over precipitous mountain ridges. But on the western side the descent from Imerina to the sea is much more gradual. Fifty miles from the capital I reached the edge of the plateau, and thenceforward journeyed down gentle slopes, descending some four thousand feet in one hundred miles. The last eighty miles of these lay through what is known in Madagascar as "The Wilderness." It is a kind of "No Man's Land," lying between the Hova territory and that of the coast Sakalavas, wherein, in the days of strife only a few years back, neither Hova nor Sakalava dared permanently to dwell. But the grasses in this wilderness are sweet, and water is plentiful. It contains the best feeding ground for cattle in the island, and the Hovas have consequently built across it a few scattered stockaded military posts, around which immense herds of kinee graze. This tract of country would form a Transvaal Boer's paradise. Rolling veldt for hundreds of miles, with bubbling springs in every kloof, and firewood plentiful, represent conditions seldom found in South Africa; whilst in Madagascar neither cattle nor sheep are subject to epidemic disease. Hence the startling cheapness of bullocks, to which I referred in a former letter. Sixteen shillings to a pound would, at any village on my journey, purchase me a whole fat bullock, and the hide generally returned more than one-third of the cost. And there is this advantage both over South Africa and South America, that the grazing grounds of Madagascar are within easy reach of the sea. Eight days my porters took in traversing the one hundred and fifty miles to Mevotanana. They journeyed on untiringly across the grass from daylight to dark, and at night, while we camped out, there was little rest. For it rained incessantly every evening, and the thunder pealed overhead. Four nights I passed in Hova villages, but my recollections in connection with them are not pleasant. I observed that on many occasions my servants were asked whether I was a French or an English Waza—or foreigner —and satisfaction was always expressed upon my nationality being made known. Looking down from the stockade of Mevotanana on the broad valley underneath, the Ikopa river again met my view. Very different it was from the modest stream at Antananarivo, for now a mighty flood, interspersed with islands and half hidden rocks, it roared down in a succession of rapids to where I could see it subside in the distance into a long snake-like streak that led on to the ocean nigh a hundred miles away. Here the navigable portion of the river began. Up to the capital, except for short intermediate sections, it is impracticable even for canoes. Down to the sea, river steamers might easily ply. The country behind us rose

* This evidently means that the seeds quickly germinate, as is the case with those of the Sumatra benzoin tree.

† If so, then, it supports my supposition that Palembang and Sumatra benzoin are produced by the same tree.

in a grand succession of mighty green terraces to where, high up in the distance, we could see the loom of the lightning that nightly lights up the upland moors of Imerina, across which we had journeyed. Before us stretched a tropical country, where the numerous subsidiary hills were clad with dense forests, and the valleys with jungle underneath and fields of tall, reed-like grass. This was the Sakalava country, over which France has raised her claim of protection—a claim which was weighing everywhere in Madagascar where I have been, upon Hovas and Sakalavas alike, with a sense of coming calamity. At Mevotanana I embarked on board a canoe, provided for us by the Governor. We had four negroes for a crew, Mozambique slaves formerly, but who, under the Queen of Madagascar's recently promulgated law, became free men. Paddling down a sluggish creek, between tall reeds, from which at every few yards a huge crocodile plunged, we reached the broad river itself. It was in flood, and our negroes, resting on their paddles, permitted the craft to float swiftly down with the current. Ten miles brought us to a junction with another majestic stream—the Betsikoba—under whose name the united waters rolled on to the sea, a full half-mile broad, and on which our tiny canoe seemed but a speck. In two days we had in this easy manner covered sixty miles, and reached the point, at a town called Maroway, where the tides from the sea are met. Both nights I passed in Sakalava villages near the river banks, where the inhabitants, notwithstanding the allegations of Sakalava disloyalty to Hova rule, honoured the Prime Minister's commands to pay me attention as faithfully and as willingly as did the Hova villagers themselves. At Maroway, I met several Indian traders, whose astonishment was great—first, at seeing a white man come down the Betsikoba; and, secondly, at being greeted by that individual in their own tongue. From what I have written above it will be seen that the road between Mojanga and the Hova capital may be divided into three sections. First, there are one hundred miles of river, on which steam launches can be utilised. Then there are some eighty miles of unihhabited country, but offering no natural obstacles to the easy march of an army. For the remaining eighty miles of their march the invaders would have to count on meeting a nation, mustering eighty thousand fighting men in arms. Mojanga I found to be a town of about twelve thousand inhabitants. It is placed at the entrance of the noble arm of the sea into which the Betsikoba flows, and the anchorage affords good shelter for shipping. Down by the sea beach are the Indian, the Arab, and the Sakalava quarters. The Sakalavas dwell in wattled huts, but the Indians own numerous substantially built houses and warehouses. They number, all told, some seven hundred souls, and constitute the most important and the wealthiest section of the population. There are also many Arabs of Zanzibar, who have maintained a settlement at Mojanga for many centuries. There are only three Western firms—one French and two American; but these transact their business mostly through the Indians. All along the coast, at every village, Indian traders have established themselves, and these must have suffered severely from the recent proceedings of the French fleet. The entire coast was covered as far inland as I could see with dense forest. It was hilly, too, and did not seem so suited for cultivation as the long reaches of magnificent alluvial country on the eastern side of the island. The Sakalavas received me in a friendly manner. They are a fine race physically, the men strong and lithesome, but evidently far inferior in intelligence and in civilisation to the Hovas. The Sakalavas are untutored savages pure and simple, which the Hovas certainly are not. I coasted round Passandava Bay, the possession of which the French covet so much. It is a splendid stretch of land-locked water, with numerous creeks and inlets, in which the navies of the world might all ride with ease. Coal has been discovered close to the coast, and beyond doubt Passandava Bay would form a first-rate station for a naval Power.

SOME ECONOMIC PLANTS.

Some plants take curious names. There is, for instance, that growth in Jamaica known as "John Crow's Nose," and the vegetable "Gingerbread" of Egypt. "Aaron's Bread," "Old Man," "Mourning Bride," "Fresh-water Soldier," and the like, are familiar appellations in our own country. It is easy to see how such names were given originally. Suggested by the appearance of the plant or by its exudations, they were readily adopted in folk-speech, and they have survived not because they are odd, but because they seem appropriate. Common words may not outlast scientific terms, but they will always enjoy popularity; and in the case of plants, they may be made botanical stepping-stones to a more learned nomenclature. So far they have a value, apart from the attachment people who enjoy simplicity have to them. This, however, is not the opinion of Mr. John Smith, the ex-Curator of Kew, who, in a "Dictionary of Economic Plants" (recently issued by Macmillan & Co.), deprecates the prepetuation of names like those here mentioned. He admits that as they have long been familiar, we are left no alternative but to adopt them; but he can point to cases in which the scientific names have also become familiar, as the geranium, pelargonium, hydrangea, calceolaria, chysanthemum, and many others. And yet, reduced to their roots, those terms, like "love-lies-bleeding," or "Job's tears," show that they are not the result of arbitrary choice. They are used because they are more or less suggestive of the appearance or characteristics of the objects described. Mr. Smith's observations on the point, it should be explained, are entirely prefatory. In his Dictionary he draws largely upon the terms that are justified by common usage. The book is a valuable one. It is not a Dictionary of Names in the ordinary sense, but it is encyclopædic in all that relates to the history, products, and uses of those plants that have a distinct economic value. The "gingerbread" plant, to which reference has been made, merits the name. It is a species of palm, growing to a height of twenty feet or more, and bearing large pendulous bunches of fruit. There are about two hundred nuts to a cluster. A fibrous mass surrounding the fruit has the flavour of gingerbread, and forms part of the food of the lower classes in Upper Egypt. A more curious specimen of vegetation is the cow tree, or Pala de Vaca, described by Humboldt. This tree is a native of Venezuela, where it grows in forests and attains a height of from eighty to hundred feet. It gets its common name from the sap that is drawn from it, which, being copious and nutritious, is used by the natives as a substitute for milk. Europeans have also made use of the fluid and been benefited by it. A speculative Englishman who took note of this made up his mind to introduce the tree to Great Britain, and so once and for ever stop the draughts made by the milk-dealers on the iron-tailed cow. It would be a grand thing, he reasoned, to give every English family the opportunity of possessing a vegetable dairy, whose strong, oblong leaves would be a shelter from rain and sunshine, and whose trunk had only to be tapped to yield a lacteal supply, about whose purity there could be no manner of doubt. It is said that the speculator shipped over enough young trees to start a forest. He brought a thousand with him, and asked a guinea each. It was a losing venture. The owner had forgotten climatic considerations; but even had the temperatures of the two countries been reconcilable, the plants would have been useless for the purpose intended. They turned out not to be true cow trees at all. There was more sense in the experiment the Government made a century ago to naturalise the bread-fruit tree of Otaheite in the West Indies. Captain Cook brought this tree into notice; and it was the ship *Bounty*, of mutineer notoriety, that was despatched to the South Seas to get the trees. Captain Bligh was in command of the expedition. Everything went well on the outward passage, and the trees were successfully shipped. The vessel had not long left Otaheite, however, befor the mutiny broke out. The captain, the officers, and the members of the crew who remained loyal to the ship were put into an open boat and sent adrift. The island of Tunor, 3,618 miles distant, was the nearest point where European aid could be obtained, and this place was eventually reached. Captain Bligh went out again to Otaheite in the ship *Providence*; and this time had the satisfaction of seeing the trees safely transplanted in the soil of the West Indies, where they have continued to flourish. The Otaheitean bread-fruit, when ripe, is shaped like a melon, is about a foot in length, and consists of a large number of nuts embedded in the mass. Africa has also an indigenous bread-fruit tree; but this must not be confounded with the Baobab or monkey bread, which is found over a large extent of the African continent. This tree and the Dragon tree of Orotava are mentioned by Humboldt as "the oldest living organic monuments of our planet." The Baobab reaches a height of some forty feet, and in maturity is nearly as broad as it is long. The natives hollow out chambers in the trees and use them as tombs, and the cutting-out process does not appear to impair the fruit-bearing properties of this extraordinary plant. As may be surmised, the growth of the Baobab is slow, and the tree consequently lives to a great age. How long it retains its vitality has never, in fact, been ascertained. Some have been found with dates of the fourteenth century cut into them, and the calculation has been made that the trees so marked are upwards of five thousand years old. As an example of the slow growth of the Baobab, Mr. Smith mentions one at Kew, which, though more than eighty years of age, was in 1858 only 4½ feet high, consisting of a slender erect stem, bearing a few leaves at the apex only. As the wood is soft and spongy, the task of hewing a chamber out of the tree is not a very formidable one. The fruit is a capsule, eight to twelve inches long, containing a large number of seeds, which the natives use for food. Clothing is also obtained from the Baobab, the bark being convertible into wearing material. It was natural that some of the food-plants should have been named after the miraculous daily provision made for the Israelites in the desert. Mr. Smith describes several varieties of so-called "manna," and he mentions an edible lichen found in many regions of Western Asia and also of North Africa. This litchen losses its attachment to the surface on which it grows, and being light is carried by the wind to a great distance It sometimes falls like snow, forming a layer several inches in thickness. Sheep eat it, and the inhabitants use it in times of scarcity for bread. Specimens of this and other varieties of manna may be seen in the museum at Kew. There are numerous plants from which products that are rather a bane than a blessing are obtained by man. This is particularly the case with a member of the mushroom family (*Amanita muscaria*), a native of this country, but regarded by us as poisonous. The *Amanita* is also found largely in the north of Europe. It is common in Siberia and Kamschatka, and there it is collected, strung up, and dried —a process that is said to divest it of poisonous properties. Thus prepared, the fungus is used as an intoxicant. It is rolled up and swallowed at gulp, like a pill. The effects are experienced about two hours afterwards. Pleasing emotions are first produced, and then come actions that are involuntary, and that suggest somnambulism. In moderate doses the fungus is a stimulant to exertion, but it often acts in a curious way. The partaker, for example, will, when once affected by it, take a long spring to jump over a straw in his path, fancying he sees before him a log of wood; he gets, in fact, very much into the condition described in one of Dean Ramsay's anecdotes, where some friends, returning home after an evening out, take off their shoes and stockings to wade across a brook, and are amazed to find themselves on the other side dry-footed. They had mistaken a streak of moonlight for a running stream. It is strange that so simple and familiar a plant-name as "apple" should have an unknown origin and a doubtful meaning. Mr. Smith gives Dr. Prior's opinion that it is an Anglo-Saxon word derived from the old Danish "Appel"—a name which, in turn, is supposed to have been derived from the more ancient word "apalis." The Celtic word "Abhal," meaning a round body or ball, is as good a derivation as any. The Romans are credited with the introduction of the apple into Britain, but the testimony on this point is doubtful. There is proof that the fruit was introduced into Rome itself in the time of Appius Claudius (149 B.C.), and that in the time of Pliny there were many varieties of it, and that it was grown in orchards. There have been many different varieties of apples in our own country from an early period. A sort called "costard" was sold in the streets of London in the reign of Edward I., and it seems likely that here we have the origin of the word "costermonger." According to the catalogue of the Royal Horticultural Society, there are some 1,500 sorts of apples. Of oranges the variety is by no means so great; but the orange tree has an advantage over the apple tree in its greater productiveness, and in the venerable age it attains before any serious diminution is noticeable in its fruit-bearing qualities. In some parts of Spain there are orange trees six centuries old. One at Versailles, growing in a box, is said to have been sown in 1421. As to the productiveness of this tree, Mr. Smith speaks of some individual trees that have been known to produce as many as six thousand fruits in one year. Several tropical and sub-tropical fruits brought to this country have, when cultivated under glass, attained a flavour and a size surpassing that of the countries where they are indigenous. This has been the case particularly with the pine-apple, the grape vine, the melon, and even with the banana and plantain. Bunches of bananas, weighing from 50 to 60 lb. each have been produced at Kew. It is impossible, however, in this country, to obtain any adequate idea of the prolific growth of either the plantain or the banana. Common in all tropical countries, ooth plants grow under favourable conditions in weed-like profusion, and yield a weight of fruit that seems out of all proportion to the space of land occupied. Mr. Smith gives the calculation that the same area required to yield 33 lb. of wheat or 99 lb. potatoes will yield 4,400 lb. of plantains. The phrase "economic plants" is a wide one, and Mr. Smith gives to it its fullest interpretation. Every plant that in any way is found useful to man, be it as food, as clothing, as medicine, as timber, or even as an object of adoration, is described in his book. In every case the popular as well as the scientific name is given to the plant, and it is the popular name that forms the key-word throughout. Probably not a single herb referred to in this Dictionary is without a representative at Kew, and a connection of more than forty years with that finest of botanical gardens has given Mr. Smith an insight into the nature and growth of plants of which his book bears ample testimony. About sixteen hundred subjects are mentioned in the work.—*Leeds Mercury.*

TEA: ON THE RED SPIDER "ACARUS," LALL MAKEE.

As it is called, resembles a mite, one of the greatest pests that the tea plant suffers from, throwing back gardens at the commencement of the season from long drought, and even deficiency of rain. This contagious pestilency predominates. But it is not so fatal or so injurious as the "Leprosy" or "Mildew Blight."

The red spider is a very diminutive insect, reddish colour on the back, and white on the under part of the body. It lives and feeds on the sap of the leaf. Its eggs resembles white dust or very fine *soojee*. The eggs have a very slight adhesive feeling by which it adheres to the leaf; the numbers that are to be found on the leaves are sufficient to extract all sap, after which the leaf withers, showing in bad cases a resemblance as if the leaf had been scorched by fire, leaving white stains. The red spider, as I have generally seen it, is worse to tea without shade on flat land, but bushes along the slopes of hollows where jungle is growing, are rarely bad with it.

Causes.—Excessive drought, sterile, water-logged, and partially-exhausted soil; deep hoeing too near the stems of the bushes, thereby cutting away runners, feeders, and young shoots, which comes forth from the main root of the plant, thereby weakening it.

Remedy and prevention against these pests, is to have good hoeing between the lines of the bushes, and avoid hoeing any depth within 18 inches of the stem, thereby not running the risk of cutting any suckers or feeders, which supply the nutriment of the bush, which, if done, each lateral root cut away weakens the bushes (same as bleeding would act on the human system), and exposes it to various diseases. Drain all stiff land where it is necessary, leading the drains into hollows or any other outlet. When pruning, thin out all superfluous twigs and wood, *i.e.*, non-bearing old wood, attacked by Lichen, &c., and allow free ventillation through the bush; retain a fair height with all breadth attainable. The average height as mentioned in my articles in the *Tea Gazette*, "On the Cultivation of Tea." I have considered, after seeing the way manuring has been done on a very extensive scale at several friends' gardens who I have been staying with, instead of the manure being placed close to the stem of the bushes, placing it so as to be hoed in between the lines; it would not have the effect of being too powerful in heating the bush. I quite agree with all who manure, that it revigorates the soil, adds fresh vigour into bushes which have had previous hoeing promiscuously, plucked year after year, nothing put into the soil, but all taken out, thereby gradually impoverishing and making the land quite sterile, laying it open to the attack of all pests. What would be the consequence to farmers at home if they tried to take crop after crop off their farms, and not fertilize their lands either by manuring or draining. The result would be downright failure. *Drain only such lands which require it*, and have good cultivation, and there is little chance of being much troubled with the red spider, "Acarus," Lall Makee.—*Indian Tea Gazette.*

ORANGE TREES.—Mr. William Saunders, in an official report to the United States Department of Agriculture at Washington, mentions having seen a large tree in Florida, from which as many as 10,000 Oranges had been picked in one season; the crop for this year, which had recently been taken from it, amounted to 7,800 oranges.—*Gardeners' Chronicle.*

VEGETATION OF THE ISTHMUS OF PANAMA.—The following description of the vegetation of the Isthmus of Panama is given in a recent report from that country. The isthmus is covered with thick vegetation, the wonderful verdure grows pell-mell, the variety and luxuriance are marvellous. Great trees overshadow an interminable and impenetrable jungle of lesser growth, made up of an endless number of nameless plants and vines, all pushing, struggling, clambering towards the light. The flora is perfectly gorgeous and bewildering in beauty and variety. The solar rays cannot penetrate such layers of thick foliage, and the soil always remains saturated. Emanations and effluvia which arise from the surface being debarred of the sun (which extracts dampness and destroys decayed vegetable and organic matter) are the main cause of the various kinds of fevers in the country, such as yellow, typhus, malignant, remittent, and intermittent. The only specific used by medical men is quinine; the natives use a bitter Tamarisk (?), of which they make a febrifuge. There were 130 lb. of quinine used last year on the Isthmus.—*Gardeners' Chronicle.*

THE COCHINEAL TRADE OF TENERIFFE.—The old proverb that "What is one man's meat is another man's poison" was never better exemplified than in the cochineal trade, which has been nearly ruined since the discovery of aniline dyes. Until very recently this trade was the mainstay of the island of Teneriffe, the cochineal depending upon the cultivation of the cactus plant (*Opuntia Ficus Indica*), which, since the supersession of the trade by aniline, is no longer the remunerative business that it formerly was. Cochineal consists of several kinds and qualities, the first and second qualities being called black *aronchada*, the others being *madres buenos* and *plateada*. The export trade is principally in the latter kinds, the first being less abundant and having to be more carefully picked and sorted. The *madres buenos* is seldom exported, but is principally used for propagating the cochineal insect by sprinkling them on the thick fleshy leaves of the plant, which flourishes equally well in indifferent and rocky soil and requires little or no care or irrigation. The sowing or sprinkling season of the insect is during the month of May or June, and the gathering is made in October, when the commercial operations commence and continue until the following May. During 1882 the shipments of cochineal were 1,840,316 lb., showing a diminution of 791,339 lb. on the export of the previous year. Of this quantity England took 2,715,983 lb., America 868,813., and France 952,460 lb., the remainder going to Germany, Spain, and Morocco. That the trade was of great value is shown by the price in 1880 of 2s. 4d. per lb. in England and 3f. the kilo in France, which produced a return of £600,000, or four-fifths of the whole trade of Canary Islands. The trade might have continued in a better state, had not the cochineal farmers glutted the markets and refused to see the necessity of lowering their prices, in consequence of the discoveries of fresh colouring matter. Consul Dupuis says that the failure of the trade has effected all classes of society, and has brought great distress not only into the homes of the working men, but of the wealthier residents, who were all more or less interested in cochineal. It is now proposed to limit the growth of the cactus and to substitute that of the sugar cane, for the cultivation of which, and of tobacco, the island is extremely well fitted.—*London Times.*

THE MANGO SEASON IN INDIA.—In a letter dated Sept. 5, Mr. C. B. Clarke writes:—"Mangoes lasted this year from May 1st to September 1st—the finest Mango season in the memory of man. Mangoes on the railway 40 miles down would not pay carriage to Calcutta." So the good Mango season coincides on this occasion with our good Apple season.—*Gardeners' Chronicle.*

THE FIELD RAT on the hills is becoming a formidable enemy to garden cultivation. The scanty potato crop has been robbed wholesale, and root crops and vegetables also suffer severely from the depredations of these rodents. The fine turf walls which protect the sides of our thoroughfares are being riddled and destroyed. Last year our Municipality waged war in the bazaar against the rats, and this destruction furnished remunerative occupation for youthful idlers; but the nuisance is growing in magnitude, and should be combatted in an effectual way. The Government of India, some time ago, allotted fifty-thousand rupees to be disbursed in rewards for rats destroyed in the hill tracts of Chittagong. French agriculturists adopt a successful plan for the destruction of field mice which might be effectually tried for the rats here. It is the construction of small stacks of straw which are below the level of the ground and securely packed and covered in, after being first stored with poisoned beetroot, turnips, and carrots. The mice resort to the stacks in myriads, and die after partaking of the poisoned food provided.—*Madras Times.*

VEGETABLES.—The following notes on vegetables are from Mrs. Reeve's book on cookery:—All vegetables have an effect on the chemistry of the body, so that we cannot speak too highly of their importance at table. We will mention a few of these matters first, and dispose of this aspect of the subject, so as not to seem to mix pharmacopœia with the kitchen. Asparagus is a strong diuretic, and forms part of the cure for rheumatic patients at such health resorts as Aix-les-Bains. Sorrel is cooling, and forms the staple of that soupe aux herbes which a French lady will order for herself after a long and tiring journey. Carrots, as containing a quantity of sugar, are avoided by some people, while others complain of them as indigestible. With regard to the latter accusation, it may be remarked in passing that it is the yellow core of the carrot that is difficult of digestion—the outer, a red layer, is tender enough. In Savoy, the peasants have recourse to an infusion of carrots as a specific for jaundice. The large sweet onion is very rich in those alkaline elements which counteract the poison of rheumatic gout. If slowly stewed in weak broth, and eaten with a little Nepaul pepper, it will be found to be an admirable article of diet for patients of studious and sedentary habits. The stalks of cauliflower have the same sort of value, only too often the stalk of a cauliflower is so ill-boiled and unpalatable, that few persons would thank you for proposing to them to make a part of their meal consist of so uninviting an article. Turnips, in the same way, are often thought to be indigestible, and better suited for cows and sheep than for delicate people; but here the fault lies with the cook quite as much as with the root. The cook boils the turnip badly, and then pours some butter over it, and the eater of such a dish is sure to be the worse for it. Try a better way. Half boil your turnip, and cut it in slices like half crowns, butter a pie-dish, put in the slices, moisten with a little milk and weak broth, dust once with bread-crumbs and pepper and salt, and bake in the oven till it gains a bright golden brown. This dish, which is the Piedmontese fashion of eating turnips, is quite unsuited to cows, and ought to be popular. What shall be said about our lettuces? The plant has a slight narcotic action, of which a French old woman, like the French doctor, well knows the value, and when properly cooked it is really very easy of digestion, but in our country, though lettuces are duly grown in every garden, you often hear the remark, "I can't eat a salad;" and as few cooks know how to use a vegetable which has been refused in its raw state, the lettuces are all wasted, and so is the ground on which they were grown.—*Indigo Planters' Gazette.*

HYBRID MOCHA is a variety of coffee growing at Trinidad. It is suitable for low elevations, like the Liberian coffee, but produces a very small bean, much smaller than the *Coffee Arabica*, but in greater profusion. The plant is vigorous, and would be much improved if crossed with the Liberian. Such a crossing might possibly get over the objectionable flavour of the latter description of coffee.—*Madras Times.*

OUR correspondent, F. G. S., is mistaken in assuming, with reference to our article on the subject, that the Nilgiri wattle "is not that of commerce." Last year the local Forest authorities sent a quantity of bark, abtained from the trees of this place, to some Madras firms for despatch home, where, we learn, it was very highly spoken of. We may also indicate that the well known Perfumers, Messrs Piesse and Lubin, manufacture their "Essence of Australian Wattle" solely from the flowers of the *Acacia Dalbeata*, which, under the name of Yellow Blossom, is so well known on the Nilgiris.—*Ibid.*

WE learn from a Home paper that two companies have been formed on the continent to work the new variety of cinchona bark found in Columbia and named *Cuprea*. One thousand seven hundred people are daily employed in collecting the bark, which, at the rate of eight and a half pounds of dry bark per hand, ought to amount to four hundred thousand pounds in thirty days. The business is therefore large and ought to prove remunerative. *Cuprea* bark yields two per cent of quinine sulphate. It was a large importation of *Cuprea* bark into the London market lately that effected the price of quinine.—*Ibid.*

TEA CULTIVATION in the Andamans appears to be a success. In February 1878, tea was planted at Port Blair and in January 1882, or just four year after, manufacture was commenced. In that period some of the bushes are reported to have grown eleven feet high, and pruning was then adopted. From three acres under plants, twenty-one thousand and fifteen pounds of tea were made, averaging seven hundred and five pounds an acre, which is an excellent yield. The climate of Port Blair is said to be admirably suited for tea, having an annual rainfall of one hundred and twenty-six inches. With such results, tea planting ought to increase in the Andamans.—*Ibid.*

PICKLED TEA forms a common article of consumption in Burmah, but the method of preparation will perhaps be new to many. The leaf, after picking, is first steamed and then spread out on mats to dry. When dry it is deposited in a pit lined with bamboos and pressed down layer after larger until the pit is filled up, when it is covered over with branches and leaves of trees, and earth heaped over it. The tea is left thus for a month or six weeks, when it becomes fit for use. It is then tightly compressed into bamboo baskets, which are submerged four days or a week before being finally taken up. The great secret is to keep the tea wet. The leaf is eaten in its moist state and undergoes no process of cooking. The Burmese flavour it with a sprinkling of salt and coconut scrapings, and then prize it above all other pickles—*Ibid*

THE *China Mail* predicts the partial extinction of the China tea trade in five years, and its total extinguishment within ten years' time, owing to the competition of Indian teas. A reduction in the export duties on the leaf is suggested as the only means of saving the trade. This should be good news to Indian tea planters, whose prospects are far from cheering. The very best plantations on the Nilgiris are not paying, it is said, at present, and investors will not look at a tea estate or break land to plant the shrub. The two hundred millions of the population of this country consume three millions of pounds of China tea, and if, say, two millions of Indian produce are likewise locally absorbed, we have the comparatively insignificant consumption of five millions of pounds in India, or an average of a fortieth of a pound per head per annum. Recently a taste for Nilgiri tea has sprung up among the Mahommedan population. Petty dealers are purchasers of the article, and, from enquiries made, we think that for inferior sorts an increasing demand may annually be expected. Tea planters here would do well to encourage this demand and propagate a taste for tea among the natives by even a sacrifice in price, as native consumption is certainly a healthy sign for the future.—*Ibid.*

THE BOTANIC STAND.—Under this heading Mr. Twining publishes an account of a stage which he has constructed with a view to cultivate in pots representatives of the various natural orders of plants. A "botanic garden" may thus be formed and tended by ladies and others to whom stooping and other discomforts attendant upon gardening are serious objections. The stage is set up in some convenient spot in the garden, supported on an iron fence or otherwise. Most of the plants are grown in 32-pots, and provided with labels. On a stand 90 feet long Mr. Twining manages to cultivate about 120—130 representatives of some eighty natural orders of British plants. An amateur with a turn for botany might clearly secure to himself much pleasurable occupation by this method, and even be enabled to throw light upon the constancy or otherwise of certain "critical" forms. In the Florence Botanic Garden a similar plan was adopted on a large scale on the terraces of the garden.—*Gardeners' Chronicle.*

ST. HELENA.—The authorities of the Colonial Office are to be congratulated upon a plan they have lately adopted, of sending specialists to various colonies with a view to affording the residents information in cultural matters. Mr. Morris, ofter doing good service in Ceylon, was drafted off to Jamaica, where he still holds the post of Director of Public Gardens and Plantations, and latterly he has been despatched to St. Helena to report on the agricultural capabilities of the island. Mr. Morris, among other things, recommends the culture in that island of Fourcroya gigantea for the sake of the fibre produced by its leaves, which is worth, when prepared, about £37 per ton. The plant grows luxuriantly in wild rocky parts of the island; its cultivation, therefore, need not encroach upon the more valuable parts. Aloe vulgaris, which also grows plentifully in waste ground in the island, might be utilised for the supply of bitter Aloes. The soil and climate of the island are adapted for the culture of Coffee, Tobacco, Oranges, Sorghums, Carob tree (Ceratonia Siliqua). The introduction of the Guango (Inga Saman) was recommended, for the sake of the nutritious fruit, said to be the basis of "Thorley's Food for Cattle." The Cushaw (Prosopis juliflora) is so valuable in times of drought that Mr. Morris recommended its introduction into St. Helena. The visit of Mr. Morris is the direct result of those efforts to promote the practical application of botany in the colonies which were made by the late Sir William Hooker, and which have been continued with such signal success by his son and successor, Sir Joseph Hooker.—*Gardeners' Chronicle.*

NILGIRI TEA, like every other manufactured article, is of many and different qualities. We have tasted the *Congou* of estates enjoying a high reputation for the excellence of their tea, and found it poor, not to say vile, stuff. Planters are in the habit of disposing of tea damaged in the manufacturing process, to local tradesmen and petty dealers. This is frequently palmed off on consumers as the genuine article, and the former thereupon form a bad opinion of all hill tea. Even the very best tea becomes mouldy in a climate like Ootacamund if not carefully kept, and then yields a most objectionably flavoured fluid. It is a common practice to see tea, that has become mouldy in packets, dried in the sun and re-packed, to the great detriment of the leaf. Teas, however, of reputed brands, obtained from respectable dealers, are simply perfect in flavour, strength and wholesomeness. The China tea is not nearly so good in any respect as the Nilgiri teas; it has, however, the siuple recommendation of imparting a milder flavour to the strongly-tasting varieties of the latter, and is therefore frequently mixed with local teas. For this reason planters cultivate small patches of the China variety on their estates, and, after manufacturing it separately, mix it in the proportion of one to ten with the leaf of high class hybrid. The separate manufacture seems necessary, as China leaf is hard and does not roll or ferment as rapidly as the leaf of Assam hybrids. The prospects of tea planters are not very bright at present. Tea estates appear a drug in the market, but an improving future is before them, and a re-action will inevitably set in. With expanding consumption, increasing markets, and depression in the China trade, all the conditions exist for the future prosperity of the tea industry of the Nilgiris.—*Madras Times.*

THOMPSON'S TEA ROLLER.

We quote from the local "Times" details of the trial of Mr. Thompson's "Challenge Roller," and since Mr. Greig tested his machine with cabbage leaves we do not suppose that a machine was tested under greater disadvantages. As we read of leaf thrown on the floor and left all night thick and wet, the leaves sticking together with water between them and the fine leaf discoloured we cannot help asking if the superintendent of Mariawatte was on the estate, and, if so, whether he took any interest in the trial of the machine; because, if he did, the interest seems to have been a hostile one, or, if favourable, his people seem to have but badly seconded his good intentions. And where was Mr Thompson or his representative that he did not see the leaf, to be experimented on in the morning, spread out thinly on shelves so as to wither properly during the night? It is truly remarked that leaf in the condition described is simply unworkable and "*cannot*" be made into good, even tea. And yet we are left to infer that from such a beastly mess, well-rolled, well-fermented, well-fired tea was evolved! "Extremely handsome teas full of pekoe ends." It is thus claimed for Mr. Thompson's roller that it *can* make first-rate tea out of leaf described as being so neglected and in such condition that it was unworkable and *could not* be made into good even tea! That is, the "Challenge," roller has accomplished an impossibilty, the result being 74 per cent pekoe, 22 pekoe souchong, 4 per cent souchong and good broken mixed, exclusive of a fine showy "dholie." Of a machine which has accomplished what the narrator himself declared to be impossible we are prepared implicitly to believe that it will turn out 90 per cent of pekoe when ordinary care is taken to free the green leaf of moisture and wither it properly. Mr. Thompson's roller may be a very excellent machine, but if so its inventor is to be condoled with on the appearance in the local "Times" of an account of its performances which is simply an insult to the common-sense of intelligent readers. We can only express the hope that Mr. Thompson personally is not responsible for an article which "doth protest too much." If the description was written by "a goodnatured friend," Mr. Thompson has certainly not much to thank him for. Had the desire been to throw ridicule on the "Challenge" roller, that object could not have been more effectually accomplished. The machine must have great merits if it survives the preposterous claim to perform impossibilities preferred on its behalf.

THOMPSON'S TEA ROLLER: THE "CHALLENGE."

The trial of this simple, but effective machine on Tuesday last, 15th instant, in the presence of some fifteen gentlemen, showed it to be of even greater capacity than previously claimed, inasmuch as it takes 2 maunds of green leaf at a fill and works most efficiently when filled right up, so long as the leaf is turned up occasionally by the man superintending. Mr. Thompson's intended progamme was to have rolled off two or three fills in the early morning, so that those who came should not have to waste time by waiting for colour and firing. This, however, was quite impracticable, as, by some mischance the leaf in the morning was found to have been thrown on the floor and left wet and thick, a great number of the leaves sticking together, three and four thick, with water between them, while some of the fine leaf was discolored. It was endeavoured to separate these wet leaves from one another, but the attempt was unsuccessful, as the leaf was found to contain a lot completely stuck together when placed in the machine, an instance of which Mr. Thompson showed to Messrs. McKenzie, Scovell, Inglis and others. It is needless to remark that leaf in such condition is simply unworkable and cannot be made into good, even tea. Such leaf is raw and brittle, and cannot but remain so. It also prevents other leaves from receiving proper manipulation, mostly coming out green even after firing.

At 12-15 p. m., however, the machine was started and kept going till 3-35 p. m., simply stopping to discharge and reload six fills, consisting of about 11 maunds=880 lb. The first and last fills being small ones were worked off in this time, each fill being from 30 to 35 minutes in the machine. 3 coolies were at the handles, and Mr. Thompson attended the hopper. At the end the first two rolls were put in the machine together and given another few minutes with marked success, some few gentlemen remaining to witness it. For leaf in such condition it was evident thet a double roll was beneficial, but, on properly even withered leaf, it is better worked right off, as is done in India with these machines. On the 16th Messrs. Thompson and Inglis found there were 216 lbs of tea made exclusive of Dholie. They then put some of the bulk through the sieves without any hand-picking whatever, and turned out extremely handsome teas full of pekoe ends weighing as under:—

Orange pekoe	... ...	33 per cent.
Pekoe	... ...	41 „
Pekoe souchong	... ...	22 „
Souchong and good broken mixed	...	4 „
		100 per cent.

These are exclusive of a fine showy Dholie samples assorted and packed in the presence of Mr. Inglis can be seen at the G. O. H., Messrs. Davies, and Messrs. Forbes and Walker. Mr. Thompson has no hesitation in saying that, even with the best of leaf perfectly withered and manufactured by the most careful manipulation, the teas would be hard to equal, and with careful manufacture the "Challenge" will give from 80 per cent to 90 per cent of pekoes, as it has done on some of the gardens in India during the past season. Mr. Thompson has samples of the leaf worked at the trial, and will be happy to show them with teas produced.

REMINISCENCES OF A VISIT TO THE CALCUTTA EXHIBITION, WITH A TRIP TO DARJILING.

(*By Mr. A. M. Ferguson, Jr.*)

I was able to see three or four various sets of tea machines. Jackson's without doubt carry off the palm for magnitude and perfection. Mr. Dalgarno, their able representative, told me that a steam engine that had only been erected two days had been bought up at R2,000; a large "Excelsior" roller, capable of doing four maunds of leaf at a fill, was also sold, and negotiations were going on for others. Their "Eureka" sifting and sorting machine, capable of doing 20 to 25 maunds of tea per day, consists of 3 sieves, each 11 feet long and 2 feet wide, placed over and parallel to each other acting upon 4 strong ash laths fastened down by brackets at each corner. One can be seen at work by anyone interested on Abbotsford estate (Ceylon). The price of Jackson's machines exceeds that of some other makers, but their work is far superior, I believe. I visited two estates at Darjiling, Tukvar and Happy Valley, and at both the machinery was all Jackson's. I was told it had done exceedingly good work, and both the managers declared they preferred it to any other make. Mr. Curtis of Tukvar told me that he had had a roller at work for nine years without a hitch, and I believed he could work it 9 years more equally well.

I saw Kinmond's machines being put up and painted, but only one was finished, and no one was by to give instructins or explanations. The dryer is described in the catalogues as a patent dryer and green-leaf witherer: it was a machine of about 3 feet by 8 feet wide by 10 feet high, and contained nine trays on each side. There was also a "Kinmond's Commpressed Action Centrifugal Rolling Machine," but it looked altogether as complicated as the name itself. The dryers are said to be capable of drying one, two, and three maunds of pucka tea, and the rollers of rolling from 6½ to 10 maunds of leaf, per hour.

I unfortunately did not see any of the machines invented by Messrs. John Greig & Co. of Edinburgh, but close by Kinmond's exhibits I noticed a "patent tea sorting and winnowing machine" by C. W. Ansell, Woodcot, Kurseong. This was much on the same plan as Jackson's, except that it had the addition of a revolving fan at one end to blow out the dust and red leaf after the first sieve had taken out the pekoe and broken pekoe—a great improvement, I think. The dimensions of this machine are about 20 feet by 5 feet; the extra length of 3 feet over Jackson's sifter is accounted for by the box containing the winnowing fan. There were one or two tea cutters, but they are so little used now-a-days and are withal so like grown-up coffee-mills that there is no need to describe them. I saw a tea roller at Messrs. Burnand & Co.'s works, one of which had been ordered for Ceylon, but as the inventor had withdrawn it from the Exhibition in order to add something that would make it (as he hoped) perfect, it could not be fully described to me. The action of this machine was sideways, the leaf being picked up by cogs as it were, and falling down to the bottom of the box by its own weight. Unfortunately none of the tea machinery was in action, so any description must be a good deal from appearance.

Messrs. W. W. and R. Johnson exhibited very fine specimens of tea-lead plain and stamped, thin and thick. Messrs. W. Avery & Co. displayed with great taste weighing machines of all sorts and sizes, just the things for an ounce packet or a 100 lb. chest. The celebrated firm of Nettleford had a capital collection of nails, screws, mamoties, kodalis, etc., and willingly gave anyone interested a sample packet of the smaller articles on application. Among the objects of special interest to tea planters, I must also mention the "Willesden Paper Stand," adjoining what is to be the Ceylon court. There every article from a house to a water trough is shown made wholly of this wonderful paper, which is really a composition of rope and copper and is said to be absolutely waterproof. It is certainly light, and if cheap would be invaluable for running up stores, tool-rooms, etc., on estates where timber is scarce. Another object of use and beauty was the Metall-Gewebe (of Gottlieb Hebrandt), for which Messrs Balmer, Lawrie & Co. are the agents in Calcutta. This, as its name implies, is *wire mesh* of every description, and the specimens were really things of beauty as well as usefulness.

The Tea Syndicate, I hear, had a separate little building in the ground. It was not erected when I left for Darjiling, and when I returned having only one day at my disposal I unfortunately missed seeing it. I am told that the specimens of tea shown by them were very fine, and were made additionally attractive by being arranged in very neatly got-up boxes and packages. In the exhibition itself I found, scattered through the various courts, samples of teas from the Nilgiris, Kangra Valley, Darjiling, Java, etc.

Mr. W. L. Kirby of Brookwood estate, Nilgiris, had a good assortment of both tea and cinchona: of the latter he had specimens of Ledger seed as well as of Ledger bark; of the former he was not content to exhibit merely Pekoe, Souchong, and so on, but he gave us samples of Mandarin and Gunpowder tea. Brenton & Co. exhibited Darjiling teas in tins covered with extremely pretty paper. There is no doubt that outward appearance tells a good deal with the work in every branch of industry and knowledge.

H. J. Myers & Co., Calcutta, had many good and one or two awful samples. The Gold Tip Flowery Orange Pekoe, the Fl. O. P. and the Fl. P. were very handsome, but the Assam Pekoe was enormous, and the "Unassorted" looked very repelling.

The Holta Tea Co. (Kangra Valley) were very ambitious in their display. The following is a list of sorts and prices affixed :—

Assam Indigenous Pekoe, nominal value		R 5	per lb.
Namuna Souchong	"	R 1-4	"
Do. Pek. Souch.	"	R 3-8	"
Assam Ind. Fl. P.	"	R 7	"
Namuna Fl. P.	"	R 6	"
O. P. (Golden Pek. ends)	"	R15	"
Pek. Souch.	"	R 1 6	"
Souchong	"	R 1	"
Fl. Pek.	"	R 9	"
Brok. Fl. Pek.	"	R 8	"
Pek.	"	R 5	"
Brok. Pek. (O. Pek.)	"	R10 to R12	"

In the Malayan court a capital assortment of teas and coffees was to be seen. There was tea from Dramaga, Nangoeng, Sinagar, &c., in Java; Liberian coffee from Samarang; besides Arabian coffee from Java, Johore (by the Maharaja), Samarang, Sumatra, Celebes, Timor, Bima, Soio, &c., &c. This Malaya court and the Autralian courts were the most tastefully got up in the whole Exhibition. In the latter I noted a case containing all the products of the Eucalyptus—oil, gum, lozenges, soap, pastilles, powders, &c., &c. Baron Von Mueller on behalf of the Victorian Government sent specimens of Australian woods made up as little books, the title on the back consisting of the name of the wood. This was a most beautiful exhibit. On an adjoining table were arranged the various sort of implements and pieces of furniture into which these woods could be converted—table-leaves, legs, spade and other handles, rakes, and so on, and these were flanked by noble sawn and polished slabs of Eucalyptus, Melanoxylon, Acacia Dammara, and other woods. One plant I measured was 6 feet long and 34 inches wide. It had been taken from a tree in Gippsland, an Acacia, Melanoxylon (Blackwood), 4 feet in diameter. There was also a "Red-Gum" plant 10 feet long by 4 feet wide.

I find I have omitted to notice the beautifully perfect narrow gauge engines and carriages of Messrs. W. B. Dick & Co., whose genial representative Mr. Fleck was the presiding genius of the St. Andrew's dinner we had on board the "Peshawur." After seeing what the wonderful little Darjiling railway can do, it is no exaggeration to say that there are very few estates in Ceylon which could not have one Messrs. Dick & Co.'s trains running from their lowest to their highest elevation. Finally and in conclusion with regard to machinery I may say that at Messrs. Burn & Co.'s workyards I was shown a very handy little "patent sugar mill," that was guaranteed I believe to squeeze 50 per cent more juice out of the cane than any other mill; and to be sure it squeezed juice out of an apparently dried up stick. The natives buy it up as fast, as it can be made at the rate of 30 a day often, and willingly wait while they are being made so that they may only get them. The simplicity of the wooden framing renders its construction easy in districts where skilled labour is not procurable. The mill is frequently bolted to the stump of a jungle tree, the top being cut off, and the trunk left growing in the ground. By the introduction of strong steel springs between the sliding bushes and the frame, breakage of any portion of the mill is prevented as the springs yield and allow the hard knots of the cane or any other undue obstruction, to pass between the rollers without injury to the mills The price is from R80 upwards.

It was a bitterly cold evening when I arrived at Darjiling. In the morning I rode down to Happy Valley estate, and Mr. Balmer kindly showed me all that could be seen. Of course, in this winter season, no tea-making was going on, but I saw the bins, machinery and stores. I was struck by the great scale on which the stores are built. No use is apparently made for withering of all the wall space, the whole work being done on the two lofts. Mr. Balmer told me what a very heavy item in expenditure the cost of fuel and charcoal formed. I think the figures were R1-4 and R1 per maund of made tea respectively; the wood supply being thirty miles distant. I was agreeably surprised to see both here and at Tukvar what a very even appearance the tea bushes presented. I imagined from what I had heard that vacancies would be the order of the day, but, on the contrary, they were noticeable by their absence. The jat is China, but all supplies latterly put in are of the best Assam hybrid. I was told of one estate that was being opened up, and only the very best seed at R200 per maund was being put in, and my informant exclaimed, "It will pay." I was fortunate enough to see the women hard at work pruning, and the men apparently the same at digging. I say "apparently," for Mr. Balmer told me that a short time before he had probed the ground with his stick and not finding the depth dug up to the standard he had refused to give the men their names till it should be redug to the proper depth, upon which the whole force struck work. He took no notice, and for two days no one turned out; on the third day three men put in an appearance; and the day after all submissively returned to their duty. So human nature is the same all the world over. I examined the pruning, and found that only an inch of new wood was left for starting the next flush upon, but Mr. Balmer took me to another portion of the estate to show me an experiment he had tried and was to continue year by year till the whole estate should be gone through, of leaving the bushes a whole year without pruning, so as to get a good strong six-inch shoot to work upon. I do not think we have cause to be ashamed of any of our tea work in Ceylon.

In the afternoon, I walked out to Tukvar estate, 5 miles beyond Darjiling, through the grandest tree ferns imaginable. I found the able and courteous manager, Mr. Curtis, at home, and though an utter stranger he placed his time at my disposal and gave me much interesting information. Of course, his turbine was his pet hobby, and it is a wonder. It is at the bottom of a ravine, half-a-mile away from the store, but as it stores water to the extent of 80 horse-power, it not only turns all his machinery but is capable if necessary of generating enough electricity to light Darjiling (two miles in a direct line). The wires travel at such a rate (52 miles per hour) that birds often alight upon them with the idea that they are stationary, and are at once thrown violently into the air again. One day an unfortunate dhobi tried to save himself the trouble of stooping by lifting up the wire. He was next seen 50 yards up the hill among the tea-bushes, having let go just in time to save himself from being mangled by a set of wheels that help to carry on the wire. A man with a cold would have called this a "terrible *turbination* to one's existence." Mr. Curtis's bins were a sight to behold, one being capable of holding 20,000 lb. of tea at least, I should think. It extended from the floor to the top loft. Almost the whole of the ground floor was taken up by charcoal furnaces. On my asking the reason for so many, Mr. Curtis said it would be impossible to wither the leaf in wet weather without them. As Tukvar tea fetches some of the best prices in the market, the idea that heat is injurious to the leaf must be an utter fallacy.

Moral to Ceylon planters:—If you take to machine-drying, do not pull down your furnaces, but have both.

TEA MACHINERY.

Since writing my notes on the Calcutta Exhibition I have received the following further information respecting some of the tea machines there exhibited.

Mr. J. C. Kinmond of Leamington, who can be personally consulted, as he is staying at the Great Eastern Hotel, Calcutta, has two specimens of tea driers at his stand, one specially for coke or charcoal and the other for any kind of fuel. The result of certain improvements lately made by Mr. Kinmond is that more tea is turned out at a less consumption of fuel. It has been, and is still, claimed for these dryers that they are the only ones which can keep up with the largest rollers. As these machines are very largely used, the sole complaint we have heard being that some of the small tea is liable to be blown away by the fanners, this claim must have very good foundations. During the final firing before packing, a piece of fine gauze spread over the tray will effectually prevent the dust from blowing out.

One important point to be noticed about the coke burning tea dryer, is that it is nearly one-half less in weight than the wood-burning dryer, [illegible] one-half saving in freight [illegible] requires no [illegible] brickwork of any kind. The prices f. o. b. in England are:—

Coke [illegible] two maunds of [illegible] tea			per hour	£170
No. I Dryer one	..	,,	,,	1[illegible]0
.. II. .. two	,,	,,	,,	220
.. III. .. three	,,	,,	,,	300

With Nos. I. II. III. [illegible] any fuel can be used.

Mr. Kinmond also exhibits one of his centrifugal rolling machines. The [illegible] against this roller was that it cuts the leaf. [illegible] that now the machine is being made after an improved patent, the rolled leaf comes out in a comparatively short time unusually fresh and green, and consequently takes an even and better fermentation, and *is not broken*, and the tip comes out brighter than by the best hand-rolling. Mr. Kinmond's agents in Calcutta (Messrs. Williamson, Magor & Co., 4, Mango Lane) keep a supply of duplicate wearing parts for these machines, so that Ceylon planters investing in them could easily get repairs done when necessary.

We come next to the world-widely known dryer of Messrs. Davidson & Co., the "Sirocco." This also is made in two forms, No. I to burn any fuel and No. II to burn coke; but only where fuel is scarce should No. II be used, for Messrs. Davidson & Co. confess that No. I produces finer tea, besides having the advantage of burning any kind of coal, wood, bamboo or grass that may be handy. The "Sirocco," like every other machine, human or otherwise, was not considered absolutely perfect, and so it is stated:—

"In addition to the improvements made in our No. I 'Sirocco,' during last year, we have, this season, added to its general efficiency by further detail modifications, the principal of which are:—

"1st. The lower section of the Air-Chimney widened, by which its power on the Drying-box is considerably increased.

"2nd. The Air-Chimney is now made in 3 lengths, so that it is much more easily erected than formerly, and it packs into a shorter case (12 feet long), rendering the package more convenient for transit up country.

"3rd. The Smoke-Chimney shortened, with the advantageous results detailed in our Circular, No. 55.

"4th. An improvement in the Back Plate of the Stove, which effects a considerable economy in fuel, and maintains the outer back casing much cooler, preventing its buckling and scaling.

"5th. A new and more durable make of Fireclay Tile than those first introduced for the lining of the Fire-place.

"6th. An improved make of Tray, the woodwork being bolted together so as to render the frames capable of being tightened up, if required, after being in use for a time, and all four corners are brass-bound. We have also special Trays of finer mesh for final firing, and these may be had to order.

Very extra attention is being given to packing, and we now feel confident that the risk of breakage in transit, if not altogether removed, is at any rate reduced to a minimum."

Some idea of the popularity of this dryer may be gained from the knowledge of the fact that 600 siroccos are at present in use, and that about *one-third* of the total crop of Indian teas was sirocco-dried, and we believe that had the process of final roasting, as recommended, been properly carried out in these teas alone, they would have been increased in value (taking say, the minimum of 1d per lb. while an enhancement of 2d to 3d per lb. often takes place) to the large extent of £80,000 *sterling*. To effect such an annual gain, the first cost of the necessary apparatus and more careful and increased supervision on the part of managers are as nothing when compared to the result. When one looks at 1d. per lb. on 20 millions of lb. bringing a total of £[illegible] as the increased value of the crop [illegible] season, and compares this increase alone with the whole original cost of the 600 siroccos now in the field (only a little over £50,000), it is important that attention should be drawn to a point which, if observed, would *in one single season* pay, probably, *twice* over, for the whole cost of the drying machinery on the tea estates.

Mr. Davidson asserted that not only did the sirocco turn out more malty teas than other machines, but that it was capable of giving this malty flavour to, and so enhancing the price of inferior teas which had already reached the London market. This assertion was put to the test by two firms, who sent him several chests out of bulks which had just been sold at the London auctions in the beginning of October last, and which were then reported on as "flat, characterless, and wanting in flavour." [illegible] were siroccoed, and samples of them were submitted to Messrs. Wm. J. & H. Thompson and Messrs. Gow & Wilson, from whom reports were received showing that a [illegible] malty flavour had been developed upon these teas by the process, and that they had gained an addition to their value of from 1d to 2d per lb.

We cannot close this notice of the sirocco better than by giving in *extenso* Mr. Davidson's

DIRECTIONS FOR DEVELOPMENT OF MALTY FLAVOUR AND FOR GIVING "GOOD KEEPING" QUALITIES TO TEAS.

It is now an ascertained fact that, with the 'Sirocco' apparatus, the much wanted 'malty' flavour can be developed upon any ordinarily well manufactured tea, and, at the same time, its 'keeping' qualities be improved.

"It is in the final 'Siroccoing' of the tea before packing, that this flavour is developed, and the apparatus can produce it even upon teas which have received their primary drying over charcoal.

"Careful attention to this process may easily effect a difference of 2d to 3d per lb. in the value of the teas for the London market; although if disposed of in Calcutta the relative difference might be less noticable, as properly 'Siroccoed' teas actually improve by a few months keeping in well closed chests; whereas teas which have been imperfectly treated before packing 'go off' and depreciate in quality before arrival in London, and continuously get worse if kept afterwards.

"The process is really a 'roasting' more than a drying process, for, at low temperatures, the tea could be made perfectly and absolutely *dry* without in the slightest degree producing the richness of flavour that a suitably high temperature will develop, just in the same way that coffee beans, until they are roasted to an exact degree of temperature, do not yield a proper flavour; although, with coffee, the degree required is far beyond that which is most suitable for tea, but the object of the process is analagous.

"It is the chemical action of hot air upon the tea which produces the rich flavour referred to, and air at about 260° F. develops it better than at any other temperature.

"Pure hot air has a more energetic and perfect chemical action on tea than air which is impregnated with fumes off coke or charcoal fires, even if same be quite free from taint or smell, and consequently, though the No. 2 B 'Sirocco' (using a mixture of air and coke or charcoal fumes) may be employed for this roasting process, its results are not equal to those obtainable with the No. 1 'Sirocco,' the pure, and continuously fresh, hot air from which, in passing through the tea, develops the richest malty flavour and best keeping qualities that can possibly be produced upon it.

"It is absolutely necessary that the hot air should get at every leaf properly, so that the tea itself be raised to the requisite temperature; and it will not do, therefore, to hurry this roasting process, as a certain amount of *time* is required for the heat to thoroughly permeate into the leaf, as well as a proper temperature, in order to produce the desired result, but so far as my present experience goes, a fair outturn per machine would be something near a chest per hour, *properly* roasted for packing, and the apparatus, should be used as follows:—

"The temperature should be maintained at about 260° F. and about six to seven pounds weight of tea should be spread upon each tray, though 'with fine brokens less should be used,' because they lie so close that they offer a much greater resistance to the passage of the hot air through the trays, than is the case with open lying teas like Pekoes or Souchongs, 'and consequently the broken teas require to be spread more thinly.' At 260° F. I recommend that each tray of tea should have about four to five minutes exposure in the last or hottest place, which means, that in order to properly develop the requisite flavour, a tray should occupy, altogether, from sixteen to twenty minutes in passing through the apparatus from it is put in at the top till it is removed from the bottom space, although, to some extent, the time required depends on the condition of the tea when it is put in for the roasting process.

"A temperature of 300° F. *can* be used if the teas have been kept a length of time before packing, and have become somewhat flat and soft flavoured; but at this temperature very careful attention is required, together with thin spreading of the tea upon the trays, and quick removal the moment the necessary flavour is attained, because, if the tea be left long in a temperature of 300° F., discolouration of the infused leaf would be the result, whereas, at 260° F. the leaf is scarcely perceptibly darkened in colour, no matter how long it may be subjected to that degree of heat.

"Care must therefore be taken that the roasting be not carried to too high a temperature; but, at the same time, the higher the temperature employed, without touching too much upon a burnt flavour, and without discolouration to the infused leaf, the better will be the character of the flavour developed, and the tea also will have better keeping qualities.

"This process has such a direct and important bearing upon the market value of tea that it should be attended to as a *specialty*, and carried out in a separate department of the tea house to that in which the primary drying is done. It ought to be worked regularly from day to day and always in charge of careful and reliable men.

"It is advisable to have one 'Sirocco' for this process to each three employed in the primary drying, and to keep the *same men regularly* at this work, as experience soon enables them to judge the exact amount of roasting to give the teas, so that the whole outturn of the estate may be up to an uniform standard of aroma, and they should be required to show infused samples of each day's work in order to check results.

"The infused leaf of the roasted teas should be a degree (but only *just* a perceptible degree) darker in colour than the same teas before being roasted, and in the dry tea the leaf should be a some what more glossy black and the pekoe tips a shade yellower.

"Tea coming direct to the London market, can with safety, be a little more highly roasted than the Calcutta trade might fancy in dealing with it for sale there inside a month from packing, as that tea, when three months packed, will have mellowed down considerably, and what might seem, perhaps, a degree highly roasted if reported on immediately after packing, will, by the time it reaches London, have assumed a very desirable flavour.

"A tin lined bin or box, of suitable dimensions, to hold about ten chests of tea, should be provided alongside the 'Sirocco,' and each trayful of tea, as finished, should be emptied into it.

"A full day's work of one 'Sirocco,' ought to fill this bin, and, before packing, the tea should be well bulked together, for, even with practised hands, it is almost impossible to get every trayful roasted exactly alike, and much variation in value, on this account alone, might exist in the different layers of a chest were each trayful put direct into it from the 'Sirocco.'

"The tea will be found to remain hot enough in the bin to be suitable for bulking and packing in the evening, as above recommended."

The next candidates on our list are Messrs. John Greig & Co., who have invented a "patent green leaf tea cutter," a "link and lever tea roller," an "improved tea sifter," "the Greig patent or cyclone green leaf withering, self-acting [illegible] and [illegible] winnowing machine combined," and "the [illegible] all in uno." or "economic tea drier."

The following very intelligent report on the above machines appeared in the [illegible] newspaper of 22nd September 1883:—

"On [illegible] the representatives of the press, along with several [illegible] connected with tea-planting in Assam, were [illegible] a private view of machinery which has been [illegible] in India by Messrs. John Greig and Co., Engineers, [illegible] Works, Edinburgh, and will be forwarded next week to the international exhibition which opens in Calcutta in December. The machinery is designed to perform the various processes which are required to prepare tea for the market, and will effect a considerable saving both in time and labour. From the fact that the article [illegible] on Wednesday was cabbage-leaves, the [illegible] in [illegible] not exhibited to the best advantage; [illegible] general satisfaction was expressed with [illegible].

"The [illegible] is placed in what is called a [illegible] which consists of [illegible] and [illegible] fan working in [illegible] the interior. It is stated to be [illegible] the kind in existence, and is [illegible] present slow process of drying in [illegible] the heat of the sun, or in a hot [illegible] of the drum are two doors and [illegible]. The tea having been placed in the interior, the doors [illegible] fastened. As the leaf is constantly turning over, the hot air from the fan plays upon it, exposing each separate leaf to equal heat. To avoid friction, and at the same time obviate the necessity of using lubricating oil, the fan revolves on a packing of asbestos and plumbago. When, in five minutes, the leaves were taken out, they had that kid-glove feeling which indicated that the withering process is completed. The leaves fall out from the bottom of the drum, and are conveyed to the 'green withered leaf-cutting machine,' which possesses the great advantage over chopping with a knife, that not only is it much quicker, but cuts every leaf into small squares, so that whatever position the cut pieces lie in the machine, they will roll up to the length required for the market, and when dry are sifted more rapidly, and preserve the bloom on the tea, as it does not require to be rubbed by hand over the breaking sieve, and there is a saving of between 40 and 50 per cent in the amount of loss through broken tea and dust. The leaves fall from a hopper over a feeding roller, and in between two metal cylinders, which cut the leaves into the requisite size of square. The leaves gathered from underneath are placed in a canvas bag, and thrown into what is designated 'the link and lever tea-rolling machine,' where the bag revolves between a ribbed central drum and sides.

"The exterior of the latter is composed of staves, which, by an ingenious and powerful application of the lever principle, can be drawn tight or expanded, in order to produce the desired pressure. About eighty pounds of tea can be rolled at one time. Emptied out of the bags, the leaves are placed in galvanized wire bottomed drawers, which are fitted into tight-fitting grooves in a chamber exposed to hot air. The stove is of a novel design, and six or more stoves can be added at a nominal cost, and all heated by one fire, thus utilizing all the heat of the fire before the smoke enters the chimney. Any kind of fuel can be burned, as the smoke arising therefrom does not penetrate to the interior. The atmospheric air entering from underneath is conveyed through perpendicular pipes, which throughout their length are alternately contracted and expanded, giving them the appearance of a turned pillar. By the heat from the fire being directed so as to strike on the upper end of the pipes a thorough draught is created, while, by an economical arrangements, the heat after passing through the leaves, is conveyed in a pipe, and serves as the hot-air supply of the withering machine, or hot air can be got from a charcoal Tullah, independent of stove.

"For the sorting of the dried leaves the inventors have provided an unique circular motion sifting machine, now much improved and strengthened, which, while it occupies less room than any of the existing machines, possesses the advantage of being self-delivering, and of separating the tea into the various qualities. There are four sieves. The tea, after being rubbed over the upper sieve by hand, falls, by the action of the machine, into No. 2 sieve, where the souchong is deposited, while on the two lower sieves respectively pekoe souchong and pekoe and tips remain, the dust falling through beneath. After having been again dried, the tea is packed for the market. The inventors claim for their patents originality, combined with simplicity and cheapness, and that both space and motive power are economized."

The agents in Calcutta are the Planters' Agency, 10, Hare Street

We quote also from the Calcutta *Statesman* a notice which was given of the machinery now being shown by this firm at the exhibition. Who are the planters in Ceylon, who are using these machines "with great satisfaction?"

"MESSRS. JOHN GREIG & CO., REGENT WORKS, EDINBURGH.

Tea-preparing Machinery.

"Messrs. John Greig & Co., the well-known engineers, of the Regent Works, Edinburgh, have forwarded to Calcutta several specimens of their tea-cutting, rolling, and sifting machinery. These various processes are, of course, absolutely necessary for the proper preparation of the article which the Dean of Bangor so unsuccessfully attempted to denounce the other day, and their arrangement is such as to effect considerable saving both in time and labour. The Greig patent green-leaf tea-cutting machine is one of the leading exhibits at the firm's stand. It is claimed for it that it is the only machine which can separate the pekoe nibs from the other leaf, while it is the only machine which can cut the leaf rapidly into regular squares. The use of this machine saves enormously, as the production of broken tea and dust is prevented, while the saving of time in sifting, as compared with the usual method of pressing by hand through sieves, to make the tea of uniform size, is very considerable. By the use of these machines the tea is enhanced in value, and the bloom preserved. They can be driven by hand or steam power, as desired.

"We now come to the link and lever tea-rolling machine, which has the advantage of possessing few frictional parts, can be driven at any speed, and is easily worked. The finest nibs can be rolled to any degree of nicety without breaking them, and the coarsest teas crushed into broken black at will. The bags are, by their own centrifugal force, thrown out of the machine, and they are put in by simply lifting up the table. A point of importance is that the firm manufacture a small machine of this sort, which is specially adapted for driving, with the aid of cattle-gear. This will roll from six to eight maunds per hour, and machines of this size have been working upon a large number of estates, both in India and Ceylon, with great satisfaction to the proprietors. The machines are all of first-class workmanship: they can be erected by unskilled workmen, and occupy but a small space.

"The third machine exhibited is the Greig tea-sifter, which, while it occupies less room than any of the existing machines, possesses the advantage of being self-delivering, and of separating the tea into the various qualities. There are four sieves. The tea, after being rubbed over the upper sieve by hand, falls, by the action of the machine, into No. 2 sieve, where the souchong is deposited, while on the two lower sieves respectively pekoe souchong and pekoe and tips remain, the dust falling through beneath. Some recent improvements have been introduced into this machine which possess great strength, and is arranged to sift from six to ten maunds per hour. The makers claim that this is the only machine in the market on the right principle, and certainly the numerous testimonials which they have received from several large planters seem to point in this direction. The inventors claim for the patents originality, combined with simplicity and cheapness, and that both space and power are economised by the adoption of their machines. Certain it is that they have sent out to Calcutta an exhibit which is likely to be inspected with the greatest interest, and seeing that one of the chief sources of Indian wealth in the future promises to be the further extension of the tea industry, we are gratified to see this eminent firm so well represented."

USP AND DOWNS IN NORTH BORNEO.

(*By an ex Ceylon Resident.*)

Sandakan, North Borneo, 1st Dec. 1883

We are not getting on so well in Borneo as I could wish, but I fancy we have passed through a crisis and things look better. The early part of the year saw a great spring, people bought greedily, and 150,000 acres were applied for and partly paid for, $1, and $0·30 being the total and 1-3rd down. It was easy to buy 1000 acres, say at 30 cents, paying $100, and we became a landed proprietor at once, a little hard up at the moment, it may be, but our account at the store for liquor was not paid, and that was the only difference, meanwhile we had 1000 acres and could *talk* Most of the officials, and a good many Chinese, followed the fashion, and the total sold looked booming.

Time runs along, there were no surveyors and the land was unsurveyed, of course we "could not think" of opening land whose locality existed on an application form and had been selected for us by a friend who knew someone who said, land at such a river would soon turn over its money, "when the rush began." How nice it all looked, and it was only last February we felt so buoyant, so awfully jolly, you know! *so* careless! A big Chinese Company bought land, ten square miles (I must say there is something unctuous in describing land by the square-mile, it has the same effect on the mind as "those tarts" had on the fat boy's mind in "Pickwick)" adjoining ours and "By Jove, sir, I said to my partner, well make them buy us up at a good figure"!

Those celestials bid us up for a town block, but carried away with the hopes prevailing we thought nothing of it.

The Company's agents left in March to report to their board of directors. I believe they never had any, they left and their applications, unpaid for even to the 1-3rd, lapsed, and left us wondering somewhat doubtful. We'd had such a lot of [illegible] on it all. I'll defy any one to attend land sales or to move about among one's fellow men in the hope of gaining information (or in other words "[illegible]" your friends) without liquoring up a good deal. Oh! those bills, those bills.

This is December, and I understand the Commissioner of Lands has declined to cancel the applications made by one or two fellows (who thought they would try it on), or to return any money, and politely added that the 2nd instalment, *i. e.* 2-3rds would be due in February. Polite indeed, I call it *unfeeling*.

How can a fellow open the land? Why, it's 170 miles away from here, and there are no steamers going there and no coolies living there. How is a fellow to open land at such a place? I think it's a monstrous injustice for the Government (Government indeed) to have sold land at such a place without at once organizing means of communication. I think of leaving the country. I see little hope of getting on. There's a want of organization throughout the country. The natives get all their own way. The Resident here gives blocks of land to every hadji or cooly who asks for it. They have only to remind him that they knew him four years ago and met him up such and such a river, and now wish to settle at Sandakan, and he immediately gives them ten or twenty acres for nothing. In fact, these given lands are the only transfers made for sometime by the Government, as I believe the Survey Office cannot undertake the survey of lands that would sell, as orders have been received from home not to sell any more land. My partner says so, and he ought to know. He's just got the sack—because they are reducing expenditure, and he wants me to buy his half share. I said "I'd see!" It makes me perspire to think of it. Was not there a poet who said something about no money improving the mind. Some of us here ought to be "improved;" the Government seem hard up too, reducing the staff all round. Some of the reductions commend themselves—every service imports a lot of "Queen's bad bargains," and although the number may have been reduced, I question whether the efficiency of the staff has been. It's a curious thing that as soon as some men get into a Government service they keep hours. With a diligence that is charming, 10 o'clock to 4 finds them in office. They dress neatly, and that [illegible] society affords their brain all the scope they are capable of.

They accept work from the heads of their department in the same spirit that a young lawyer receives a chancery suit, with the hope that it will last, and they linger it out until in despair it is taken from them and put through by someone else. These men are not wanted in a new country. A surveyor who thinks that because the office hours in town are so and so he can carry them into the field with him is apt to find he is not wanted. An office man who pigeonholes his papers at 4 o'clock and talks despairingly at the [illegible] of the accumulating mass of correspondence [illegible] by the public and his superiors. And [illegible] sometimes takes [illegible]. Sometimes something valuable [illegible] to the rubbish.

The Governor, the Hon. W. H. Treacher, as head of the family, does not [illegible] day. I believe he wanted to leave [illegible] the colonial service to which he properly [illegible] the board in London have obtained leave for him to stay another year, and Mrs. Treacher is coming out to join her husband after a visit to England.

Australia has lately been investigating the resources of Borneo, and a syndicate started by Sir Julius Vogel, and some leading men of Australia, have just bought 100 000 acres and paid the first instalment. They seem to have a good thing, as I hear they have found minerals and fought over the mineral clause until they got it all their own way. They propose to plant sugar, but also look to tobacco and the Ceylon products. An Anglo-Chinese Company here are planting tobacco, and have two Deli planters superintending operations; unfortunately both these gentlemen complain of ill-health. As you found it unhealthy in Ceylon to open land, so we find it here, and our soil is richer; of the latter I have no doubt. Our lowcountry soil is equal to your hill soil, and I argue that our hill soil will, when it is opened by future planters, be found richer than anything you can boast of.

The climate at Sandakan, Kudat and Gaya, our chief settlements, is delightful. Much cooler at night than Colombo, and not so painfully hot in the day.

The Australian representative accustomed to Fiji frankly allowed, at leaving, that the climate here was preferable to anything Fiji could show, and the growth (they were here from May to Oct.) was remarkable.

The question of labour will have to be solved. We did look to get from Hongkong all the labor and more than we could possibly use. That idea is passing away, and the Straits Chinese will probably be the cooly of Borneo. They are agriculturists accustomed to the work required, and their pay is less than those of Hongkong. Sir W. Medhurst, our Immigration Commissioner in Hongkong, has retired and is understood to allow that the native Chinaman is not so suited to our requirements as the Singapore-born cooly, a great admission for the Cantonese-loving Sir Walter to make.

The Australians hope to get labor from Madras on the Mauritius terms. At the back of this Company, I hear, a New Zealand company is waiting, to go in if Sir Julius and his friends show the way. Of course there is plenty of land, from the sea-port to the next down south it is 170 miles; to Kudat it is somewhat less. This immense seaboard is partially unexplored. "I have found a new river and been up it twenty miles" is a common enough statement. Of course some of these rivers turn out mythical, but it gives you an idea of the large area of land waiting to be taken up, when such statements can be made and believed. What is to be the future of Borneo? In spite of the present coldness, which is merely the result of a few speculating men finding their little attempt at a "big thing" has failed, I believe with economy of administration a wonderful future is before North Borneo, dependent on the agricultural interests.

This is really getting too long so I close.

MR. W. CAMERON'S PAPERS ON CINCHONA AND TEA DRYING.

Our planting readers will peruse with interest the papers prepared by Mr W. Cameron for the meeting of the Dimbula Planters' Association. We regret that we cannot accompany them with the plans referred to. Mr. Cameron suggests for the slow drying of cinchona bark at a moderate temperature is a modified Clerihew apparatus, originally the invention of the superintendent on Rabaluagoda of the late Mr Hay Cameron. We well remember Mr. Clerihew's learned preliminary lecture on "Eremacausis or Decay" delivered in Kandy some time in 1847, we believe; that is thirty-seven years ago. The main object of the invention was to keep coffee sweet in damp weather by forcing a current of hot air through parchment spread on lofts. In utilizing the idea for dispelling moisture from cinchona bark Mr. Cameron suggests alterations which would economize fuel. We do not suppose that any patent rights survive in the case of the Clerihew, but we are not quite so certain that Mr. Cameron may not be trenching on the domain of some patentee in his suggestions for manufacturing and applying dry air for the withering of tea leaf. We hope not, however. A practical trial alone can decide the real value of the means proposed, but we believe that moderate, diffused artificial heat helps the process of withering in damp weather, while there can be no question of the value of as much light as can be secured in tea-houses by the liberal employment of glass.

REMARKS ON HOT-AIR CINCHONA BARK DRIER.

(*From the Proceedings of the Dimbula Planters' Association.*)

22nd November 1883.

Mr. Chairman and Gentlemen,—Being unable to be present at the late meetings, when cinchona statistics, modes of harvesting the bark, &c., were discussed, I promised our Secretary a few remarks on curing bark, as soon as I had completed a new drying apparatus then in progress. I now redeem my promise.

It is almost superfluous to notice that for drying cinchona bark and most other products of the kind, there is likely no way so good as laying the substance to be dried in the sun. It is equally so, to remark, that in our wetter districts for months on end, there is no sun-drying available—rain, mists and clammy damp prevailing.

Such being the conditions under which some of the products of this prolific island have to be harvested, it becomes an important consideration, how curing may best be done by the use of fire heat, which can be employed for this purpose efficiently in a variety of ways. Dismissing all other considerations for the moment the matter resolves itself into the simple question of economy: first, effective performance of the work, second, the cost. This granted, we have now to go directly into the subject from a mechanical point of view. Fire-heat employed directly will not answer our purpose. It is all very well for drying our clothes or boiling our kettles, but in the case of bark and other products, bulky masses of material have to be dealt with, and it is not mere heat or stewing that can be effective; but for the purposes of conservancy, the moisture must be driven off or removed as completely as possible. To do this properly, we must expose the largest amount possible of the surface of the materials to be dried, to the drying influence. As this could be but small at an ordinary fire, we are thus led to using air already heated, *or dried indeed*, if the arrangements are sufficiently elaborate.

Without at all attempting to go into this subject deeply, or from a purely scientific point of view, I would trust to the intelligence of my fellow members of this Association, to always keep the laws of nature so far in view as not to go against them, otherwise the common punishment of failure may and is certain to result, even in the construction of a chimney, when dealing with heated air.

The conditions necessary to secure control of the movements of heated air, in, say, a common fire-place, are, first, a supply of atmospheric air sufficient to furnish oxygen for *combustion*, and a flue or channel of proper capacity to contain and carry off the expanded gases, products of the combustion. To secure the movement of these gases in one direction, a difference of level is necessary more or less according to circumstances. This arises from the law that heat expands all gases, but they do not naturally rise—only do so from the mechanical pressure of the atmospheric air being greater below than above. The slightest difference of level or pressure is sufficient to determine the movements of a volume of heated gases or air, and, unfortunately, this is often painfully experienced in the heating of large buildings, churches, theatres, etc, where numbers of the audience are in one part of the house, being half-suffocated with heat, others in another part are starving in chilly draughts. This will always be the case in such structures more or less. Now there is a lesson for us in this—how to construct drying apparatus. We are thus led to deal with small quantities of heated air, or in other words to use it in as small spaces as possible to gain economic effect. A perfect drying machine should have little waste space. The whole of the heated or dried air should just have room enough to play freely through and around the materials to be dried, till its drying powers are exhausted.

Here I would direct your attention to the "Sirocco" tea drier, not as an economical machine for substances that may be dried slowly (of course a brisk heat is here required to check fermentation in the tea at a certain point), but the principle of the construction of this drier is beautiful and simple. The hotter the fire the stronger the current of heated air rises, this being supplied from the ordinary open air of low temperature. Comparatively the apparatus is thus nearly self-regulating, at all events safely workable and admirably adapted for the purpose. It is just on the same plan as one of the best modes of house ventilation in use in cold countries, where an aperture is made into the flue at the highest point of a room to carry off the overheated and vitiated air.

The "Sirocco" is perhaps a model of a self-acting drier, for certain purposes. The principle of construction is correct. Let us consider how far the laws embodied in the construction of the "Sirocco" can be availed of in the work of drying such substances as cinchona bark, or those which may be dried slowly and not requiring any particular temperature. Well, I have for the last year or two used a drying-house, constructed on the same lines as the "Sirocco." It works well, and a large quantity of bark has been dried in it in the wettest weather, but at a great sacrifice of fuel. The construction is simply this. A furnace with brick horizontal flues with air drains alongside occupy the floor, and so a current of heated air is maintained to carry off the moisture in the bark, resulting in the complete drying of the article. It works well but as noted before *not* profitably, although, indeed, it is a great improvement on hot plates or other impervious material, which only dry by radiating heat.

You will observe at once, that in the case of the Sirocco, or the drying-house just described, it is a question of temperature, whether circulation is kept up at any given point or at all, and that when it is maintained it is at a loss of heat. So this being the case we are driven back to the old "Clerihew" idea, a beautiful one in all respects, if properly carried out. It consists essentially of the providing of a discharge of heated air into the material to be dried, and the forcible removal of the air after it has done its duty, by the use of fans, or other mechanical appliances. I have seen but few of these "Clerihews" at work, but lots of remains of them. The idea is faultless, but the construction seems to have been improperly carried out. It consisted of a large square furnace, with a perpendicular chimney at one end of the drying-house, and the suction fans at the other. The furnace contained a battery of cast iron pipes to heat the air discharging into the house. The discharge or volume of heated air would thus flow at a rate in proportion to the partial vacuum caused by the fans.

So far good, but the fault lay in the upright chimney, which caused a great loss of fuel, the pipes taking out a fraction of the heat available in the furnace. Now, we purpose to improve on this particular, keeping always hold of the beautiful original idea, not inventing but adapting. We know that if properly constructed a flue for heating purposes may be laid nearly horizontal, for a long distance. Now let this be done, for a bark drying-house, keeping "Clerihew" fans; let the air be heated and dried by playing over the furnace, and along the sides of a series of flues, so that all the heat may be abstracted, and you have a perfect drying-house, the only lost heat being that required to keep up the draught in the chimney, which need be very little. The mechanical force used in the removal of the steamy air, is equivalent to so much fuel saved as compared to the "Sirocco" plan, while the management of temperature could if needful, be adjusted to a nicety. If all these particulars are carefully carried out in designing a drying-house, the full value of the fuel will be obtained, and the work done speedily and to a certainty. The arrangement of trays, shelves, etc., or travelling webs of cloth (as for tea withering), will always depend on the nature of the products to be dried. But, as I have noted before, all waste spaces must be filled up in such a drying-house. Passages there must not be, as heated air, like almost every other body, certainly will move in the direction where the resistance is the least,—it would take an open passage instead of going through your drying shelves. Passages can be entirely filled with moveable trays. So not an inch of space need be lost; and by working the heated air in this manner a uniform movement is secured.

To save time I must now refer you to the rude plans which I have here.

1.—The ground plan shows the position of furnace, flues, and air drains.

2.—Another, part of the longitudinal section of the heating apparatus, with drying-house above.

3.—This plan shows an end view of the whole.

4.—Plan of air drain (exhaust) and fans with small water motor, for the same. This requires no spur-gearing to get up speed, but will work with a small quantity of water, and a fall of 12 or 15 ft; and may be erected at small cost.

To conclude this part I do not pretend to have invented anything new, but it may be there are some adaptations or ideas brought together, any or all of which are capable of improvement to an indefinite extent.

WM. CAMERON.

TEA WITHERING &C.

I have now to make a few remarks on tea withering, and the curing of more delicate products than cinchona bark. In regard to bark there is a wide margin to go upon in the matter of temperature—it may be dried slowly just, so as to prevent mouldiness, or it may be dried at a temperature approaching that of boiling water, as the alkaloids do not decompose till far above that point. Tea withering—a sort of partial drying—requires far greater care. I may note that what I have to state might have come with a better grace and more weight from an experienced tea maker, which I am not, though drifting quickly into that industry. I may also state that it is on the advice of several of our best tea makers that I have ventured to take up this subject; and as it is only with some of the tea-making apparatus that I am to deal, it does not necessarily follow that I can make tea good or bad. From all the information gathered during years, from the best authorities on tea-making, it is clear that the whole of the after processes depend on the first, or "withering." This appears clear enough when we consider that the withering puts the leaf into a condition suitable or unsuitable for the process of rolling, bruising or breaking up, whereby the fermentation will be effected.

Tea makers all agree that in the wet districts at certain times great loss is sustained by the waste of time, and deterioration of the tea by the "withering" failing, from the excessive dampness of the air. Some say that over their furnaces, in wet weather, the process goes on all right, but the limited space at command renders this of little value. Others say heat is bad for the leaf. It is held by some that light is an essential in tea withering. When such differences of opinion exist, it becomes impossible to reconcile them: the fact is there is likely some truth in all these conflicting ideas. The result aimed at is the same, and the difference lies in the ideas of the means by which it is brought about. Light is likely a great help to withering, as the leaves go on breathing in the way of plant-life, after they have been severed from the parent plant; *thus* facility for parting with water is continued, even if the contents of the leaf-cells are not gradually being altered, even chemically. So let those who wish it have light in their withering-houses; but in the sort of weather requiring artificial aid the light will be rather weak for an appreciable good effect.

In view of the withering being yet well and correctly done by artificial means, I have put the question to tea-makers, as to what kind of weather the best teas are made in. The replies have been invariably the finest weather, dry and equable, settled, etc.

Now in designing anything to take the place of natural the safest way is to imitate the laws of nature, or indeed we are but using them all the time, though storing forces, and directing them in unusual lines, may at first sight falsely appear to be something more. Now for tea withering we have to imitate a dry day, not too hot, or some undesirable change may come in your tea. I have now to describe as briefly as possible furnaces suitable for drying air, for withering tea, or drying cocoa, cardamoms, or other vegetable products; the same in principle but quite different in construction to the cinchona bark drier.

A furnace for ordinary fuel is required, with brick flues or metal pipes, or boiler and hotwater pipes, zigzagging in a large outer casing. The flues or pipes are to be surrounded with moisture-absorbing materials, such as brick-bats, coral stones, lumps of charcoal, &c., any substances which have the property of quickly absorbing moisture from the air. By suitable openings below in the furnace casing the air can be admitted and discharged heated above. But, say, it is not heated air that we want: it is dried air. Well, to get it we must heat up the furnace till the moisture is driven off through an opening to the outer air; then shut all openings till the mass of the materials have cooled down by simple radiation of the heat. This may be greatly assisted by thin metal pipes laid through and through the mass. Now after cooling down, if air be drawn through these absorbent substances it will part with its humidity till the balance is restored and this dried air we purpose to use for tea withering, or other work of the kind. It may be used at the necessary degree of humidity and temperature, which experience may determine. I trust I have made myself understood. Now to keep up a supply of this dried air, a second or twin furnace is required, so that while one is in operation the other is cooling down, to be used in succession. The larger these furnace casings and the mass of the absorbents, the more economical will they be, within certain limits. This is little draw-back, as the materials are inexpensive. The rough plan which I have here may assist my description a little.

The drying-house may be built of any suitable materials, wood, stone, or brick, or glass and iron: but the outer shell must be made as airtight as possible when at work, the only openings being those for the admission and discharge of the drying air.

For saving of labour and to prevent injury to the more delicate products by too much handling, or bruising by being rolled about, the following plan is suggested, and forms an essential feature in the general plan of this drying apparatus, viz., to fill and discharge the drying-house by travelling webs, instead of using trays, shelves, or tats filled and emptied by hand.

The construction may be as follows:—Suitable frame work of wood or iron to be erected, filling the house entirely, save necessary passages, which can be temporarily shut, when drying is going on.

This framework is to carry rollers, pulleys, gearing, &c. for the moving of endless or reversible webs of cloth or other material of open texture, to support the seeds or leaf to be dried. These webs may be of any workable length and breadth.

The webs at the feeding end are to be mounted—on rollers—moving for 2 or 3 feet in slots, so, if the rollers are all pushed inwards, except the lowest, the projection formed by it is the feeding bench for the web. When charged the next is pulled out to the extremity of the slot in the frame, filled, and so on till the house is charged. When withering or curing is accomplished, the webs can be then moved in the same direction, when the contents will be discharged at the other end, into a suitable receiver for conveyance to other machinery if required. The distance apart of the webs can be regulated by the bulk of the stuff to be dried, leaving free passage for the air. At 6 in. apart, a room 8 ft. in height would give a superficial drying area, equal to 16 floors. So the saving of space is secured, fuel and labour being also economized. I have consulted a gentleman who had the benefit of a scientific training in engineering, in his youth, and he assures me it will be easy to design suitable gearing, to move the webs for the drying-house, as may be required, and with this remark I may conclude.

W. CAMERON.

HAPUTALE RAINFALL.

A correspondent dating from "Below the Pass: elevation 3,400 feet above sea-level," sends us the figures for rainfall during the past year, as follows:—

Rainfall during 1883:—

	Greatest fall during each month.	Inches.	No. of days.
January...	·43 on 16th	2·29	16
February..	2·73 on 4th	8·35	10
March ...	1·73 on 6th	6·88	11
April ...	3·70 on 26th	17·66	16
May ...	6·42 on 8th	9·11	13
June ...	1·05 on 1st	1.62	5
July ...	2·10 on 12th	5·62	9
August ...	3in. on 7th 4·65 on 14th	11·04	16
September	·95 on 14th	3·50	9
October...	2·20 on 1_th	14·13	19
November	2·85 on 3rd	21·97	30
December	1·82 on 13th	8·65	17
	Total...	110·83	175

The total rainfall is almost exactly equal to the average of the group around Abbotsford on the Dimbula or south-west monsoon side of the dividing range, but there is this grand difference that, while rainfall equal to an average of 36 inches is almost incessantly falling in June and July in Dimbula, those two months on the eastern side of the range are bathed in sunshine, the fall for June 1883 having been only 1·62 inch in 6 days and for July (during which an exceptional rain-storm of 2·10 inches occurred) was 5·62 on 9 days. It is in Oct. and Nov., the north-east monsoon months, that Haputale gets its 36 inches The rainfall is ample in distribution as well as quantity for tea, but pruning time and chief flushing time will probably differ as the coffee harvests do in the western and eastern mountain districts. Our correspondent writes:—

"Although Uva has long been the favoured district for coffee, with such rainfall, do you think, Mr. Editor, there is any reason to doubt that the cultivation of tea will pay? A few have gone in for it on a small scale, but by the time we have the railway to the Pass this cultivation will have largely increased and the tonnage of tea down to Colombo be no inconsiderable item in the railway accounts."

We have no doubt of it: Haputale and Uva generally will yet be scenes of a large and profitable tea production, and to help forward this enterprize as well as to aid in reviving coffee the promised railway extension is urgently required. It is not tea alone, but cinchona, cacao, cardamoms, rubber and other products, as yet undeveloped, for which Uva is fitted by its rich free soil and specially genial climate.

Another correspondent sends us a detailed statement of the rainfall at the Pass (about 1 200 feet higher up) for the past three years, and, curiously enough, the results are far below those obtained so much lower down. Local circumstances, especially the features of mountain ranges on which vapour clouds strike and are compelled to deposit their moisture, have much to do with amount of rainfall absolutely and in exceptional rainstorms. The figures for the Pass are:—

1881	79·71	inches.
1882	68·23	,,
1883	90·08	,,
Average of 3 years ...	79·34	,,

a quantity amply sufficient for tea culture, as reference to the climate of Assam, Cachar and Sylhet will show. The distribution of rain is far better in Ceylon than in the Indian districts. In the three years the rain in January varied from 2·24 to 6·94 inches, the average being 4·20. In February the variation was from 3·49 to 8·39 and the average 5·28. In March the range was 1·97 to 5 05 and the average 3·30. In April the variation was 8·04 to 10·30, average 9·19. May ranged from 6·07 to 12 77 and the resulting average is 8·43. June, the driest month varied from 1·04 to 2·47, average 1·70. In July the range was from so low as 0·84 (in 1881) to 3·36 last year, the average thus being 2·14. In August the rain begins to increase and we get from 2 08 to 5·99 with an average of 4·36. September differs but little from August, 2·96 to 6 68 and an average of 4·35. We now come to the north-east monsoon months, and we get for October 7·66 to 14·78 with an average of 11·21. Then comes November with 8·31 to 16·49 and an average of 13·05. Finally, December varies from 7·27 to 18 03, the average being 11·80. Looking at the record for 1883, the alternations of rainy and rainless weather are most marked. January 17 days gave more or less rain, so low a quantity as 1 cent being recorded. February had only 9 rainy days and March 7. April was distinguished by 13, May 16, June only 7 and July 10. In August rain was recorded on 13 days, and September 9. This number was doubled in October, while in November, the very rainest month of all, there were 7 rainless days. In December the rainy days were 13. It will thus be seen that for growing and flushing the climate is good and for tea making most favourable. Oh for the railway to the Pass, to create and then carry the large tea traffic of Uva!

MESSRS. JOHN GREIG & CO.'S TEA MACHINERY.

We have received a letter from Messrs. John Greig & Co., of Edinburgh, regarding their comprehensive series of machines, which not only roll and dry tea, but wither the leaf, and also cut it into squares and triangles so as to prevent so large a proportion of dust as is usually the case. Tea planters generally, although many of them believe in the beneficial effect in wet weather, of gentle, diffused artificial heat for withering purposes, do not favour the idea of withering entirely by fire heat. Most of them object also to the cutting of tea leaves, because the resulting tea would be classed and sold as "broken tea." But we believe the head of the firm of Messrs. John Greig & Co. had experience as a tea planter, and it will be useful to our readers at this juncture to hear what the inventors and manufacturers of tea machinery, which certainly has the merit of great comparative cheapness, have to advance in favour of the principles and performances of their inventions. Messrs. John Greig & Co., writing from Edinburgh on Dec. 13th, state:—

"You have our most grateful thanks for your article in your issue of the 15th October last. We thank you very much for the intelligent and kindly interest you take in any new inventions calculated to further the development of the industrial resources of your beautiful island into the interior of which our Mr. Greig travelled in 1858, when he had an interview with the late Mr. Ferguson.

"Your article is a very fair critisism on the *Scotsman*'s report at the exhibition (public) held here with the various machines in operation.

"There were four reporters from several newspapers but the *Scotsman*'s reporter came late, after all the explanations had been ended, when Mr. Greig was engaged on the trials of the machines. Consequently through the attention he had to devote to the planters and others present he got only hurried explanations, and besides he was a gentleman who had not the slightest knowledge of the simplest mechanism, so that he made a complete bungle. The report is very far from correct: he has mixed up one thing with another, and to Mr. Greig as an experienced tea planter and engineering the thing is simply ludicrous.

"In order to correct false impressions, by last mail we forwarded by B. P. a correct report from the *Grocer* by a reporter who has taken evidently in former years an interest in mechanics. Also we sent you our latest circular and if we mistake not, working drawings of the new stoves (the multum in uno), also the cyclone withering machine.

"The stove is the same in effect as the sirocco, but much cheaper and has the advantage, each section having different degrees of heat for rapidly drying wet tea, gradually lessening heat as the tea becomes drier, thus reducing risk of burning or scorching to a minimum and making use of the whole of the heat from the fuel on the tea before the smoke and heated gases enter the chimney.

"The leaf-cutting machine, in which we know you have taken an intelligent interest for some time past is intended for several purposes, for cutting up into squares and triangular pieces, the large succulent leaf of the Assam and hybrid leaf particularly at the first of the flushing season when the leaf has grown rapidly and is soft enough to roll up into tea. This saves an enormous amount of broken tea and dust compared to the present barbarous method of after the long screws of dry crisp leaf are ready for sorting to make it the proper lengths for the market, bruise it by the hand over a sieve having meshes of a size 4 or 5 to the inch. 2nd purpose.—When the leaf is ½ or ¾ finished with a rolling the red and coarser leaf remains flat, then use a large bamboo riddle having meshes of about ½ in square and, for convenience for quickly filling and emptying, should be hung by one string tied to one edge attached to roof. All the finer leaf which is partially rolled falls on mat on floor and the flat and coarse leaf left on upper side is chucked to one side; the partially rolled leaf is put through cutting machine and all the particles longer than ½ inch will be cut—this is then finished in the rolling. Here the bag rolling machine which we have adopted comes in preference to a cup and saucer machine with all due deference to Kinmond and Jackson, because neither will roll up the leaf properly unless there is a certain quantity in the hole between upper and lower tables, but with a bag any quantity large or small, as is required by separating by riddling, will roll up quickly and well. It is becoming known that by rotary bag rolling machine (not Nelson's Mangle) prejudice is being overcome, the tea is screwed or harder rolled up than by any other none bag machine. Then the course leaf thrown to one side is either cut up in cutting machine and rolled into broken black, or broken up in machine without cutting.

"It will thus be seen with 2nd purpose all the broken tea and dust is saved with the finer tea, as it all passes down of its self into its various classes without the hand being required to break it through first sieve, and also all the labor is saved in picking out red and coarse flat leaf from the bulk or unsorted tea.

"3rd purpose. At the first of the season there is a good deal of watery sap in the leaf, and by the hitherto system the pekoe bud and other two or three leaves are plucked all on one stalk; these are all rolled together by the hard rolling to roll up the otheir leaves the pekoe nib becomes *quite black*, is not seen for about two months of the first of the season amongst the pekoe tea. Now as the pekoe nib is already rolled up beautifully by nature no rolling is required for them except very, very lightly in order to express a little of its juice to cause them to take on the fermentation or rather oxidation, for it is really not fermentation.

"In order to enhance the value in the broker's eye for such pekoe, after the leaf is withered it is all before rolling put through the cutting-machine, the nibs are thus cut loose from the other leaf, some are cut through the middle, some the full length, but that does not matter, as broken pekoe, if of a pure pekoe flavor uncontaminated with the juice of the coarser leaf will command as good a price as long pekoe or nearly so.

"This cut leaf is then riddled in the same manner as by 2nd purpose by meshes of about ⅛ of an inch. This will let through the nibs and the stalks only, the pressure of the stalks do not matter, as they are again mixed with the pekoe and pekoe souchong. These nibs and stalks are put into the bag of the Greig Link and Lever Rolling Machine which is so constructed that the nicest pressure can be felt by the hand on the lever, giving only as much as causes the bag to revolve on the fluted barrel. One minute's rolling is enough. These nibs when treated in that manner will, when fired, or dried turn white flowery pekoe which is then mixed with the black pekoe or souchong when it is sorted, thus very much enhancing the value of the same.

"We find many planters particularly managers of companies very apathetic regarding the sawing by the use of the cutting-machine. In connexion with riddling there is prejudice as they no doubt suppose it gives them extra trouble, but the machine will make its way, and particularly by any kindly and impartial assistance you may give us.

"Regarding the sifting-machine the red leaf on top sieve is thrown out and picked by hand like any other machine."

The report from the *Grocer* to which allusion is made was quoted into the letter on tea machinery by Mr. A. M. Ferguson, junior, which has appeared in the *Tropical Agriculturist*, and we notice in the copy enclosed in the letter we have given above, there is a correction of "five minutes" into "three to five minutes" as the time in which green leaves treated in the "cyclone withering and drying machine" are found to have "that kid-glove feeling which indicated that the withering process is completed." We cannot render Messrs. Greig & Co. better or more impartial assistance than we have done in allowing them so fully to state the case in favour of their machinery, but final judgment will, we suppose, largely depend on the results of the trial which has taken or will take place at the Calcutta Exhibition. If, as has been stated, some of Messrs. Greig & Co.'s machines are at work in Ceylon, we shall be very glad to hear accounts of their performances.

JOTTINGS FROM NETHERLANDS INDIA.

Our readers will see, from the following very interesting communication from a special correspondent, that the Java coffee crop is likely to be large, that cinchona culture is progressing in Java, but that some of the Java tea is of such poor quality that it sells at 25 cents of a florin (about the same as the cents of a rupee) per lb.:—

From all accounts 1883 crop as regards coffee will be a bumper one, weather having been most propitious, specially for the first blossom. On 31st October last, the N. I. Government found reason to raise the year's estimate made a month previously by 12,000 piculs, so that this stood at above date at 1,083,240 piculs, while I should not be surprised if the crop were eventually to exceed 1,100,000 piculs. As you are aware, this represents native plantation coffee, and this yield is likely to be kept up, as, in lieu of the old played-out coffee districts, Government authorities have taken care to have fresh ground planted out, under the old feudal system which still exists in the shape of "forced labour" *vice* "taxes." The Preanger districts will, I think, however, prove an exception to this rule, as, strange to say, coffee estates do not reach an old age there, while their crops cannot compare with those more to the Eastward, proving that the soil is not so rich as in more favored parts of the Island. Hence, in the Preanger, Government are not so much turning their attention to coffee as to cinchona. While Government has not been dormant, private enterprize has of late been exceptionally active, and judging from the large area of land already opened up and still in course of opening up along the slopes of the "[illegible]" and Kawi Mountains in the Pasaruan and Probolingo residencies, [illegible] shall, at no great [illegible] be able to make up for the deficiency [illegible] so-called West India preparation or [illegible] Ceylon. I may here note that with regard to the generally accepted notion that no Englishman or rather foreigner can obtain and hold Government waste or forest land in Netherlands India, I have H. M.'s Consul at Batavia, Mr. A. P. Cameron's authority for saying that such is far from being the case. On the contrary, any foreigner residing in Java and elsewhere in Netherlands India, may apply for and obtain, under the same rules and regulations applicable to the Dutch themselves, Government waste lands. Be this as it may, I know, at all events, that foreigners can purchase and become possessors of such Government contracts running for 75 years from their original holders.

The size of most of these contracts is 500 bouws—one bouw = $1\frac{3}{4}$ acre—and quit rent varies from \$6 to \$20 per bouw per annum, payable on the sixth year from time of purchase, the average amount being at \$9 per bouw. The purchase sum for such contract varies naturally with circumstances, but if the site and soil be good, \$50 per bouw, or say, roughly speaking, £7 per acre is not considered out of the way, and this is by far the pleasanter and more practicable way of acquiring land for coffee or cinchona, as delays in the instance of ones applying to Government for waste land, are endless and very vexatious. I would always advise my friends therefore to adopt the former plan, specially, as oftentimes a great bargain is to be picked up.

With regard to cinchona, I can only say that its cultivation is extending steadily, planters sticking to best sorts of Ledgers. I know how provoking it must be to those less fortunate to hear of others being lucky enough to possess Ledgers and such high class cinchonas, but it now lies within their reach to be as well off, for the Netherlands India Government now hold periodical sales—one takes place at Bandong today—at which Ledger seed from the original parent-tree imported into Java in 1866 is put up in parcels of 20 grammes,—$28\frac{1}{2}$ grammes going to an oz. avoirdupois—at an upset price of \$2·50 per gramme, while seed from typical Ledgers (seedlings of above original Ledgers) can be had at an upset price of \$1 per gramme in packets of 50 grammes. For *succirubra* seed, Government has put an upset figure of 20 cents per gramme and for some *officinalis* 5 cents per gramme. The banks and also planters' agents would, doubtless, readily undertake to secure seed for their constituents, through their Batavia correspondents at above sales, while I would beg of your readers to dismiss all fears regarding quality of the seed, based on past experience of Java investments; for what the Government sells will be fresh and good, *that* may be relied on.

The tea planters in Java are up in arms against the proposed ministerial fiscal changes, inasmuch as it regards the import duty in Holland on tea, which it is intended to raise from \$25 to \$40 per 100 kilogrammes, equivalent to a rise from, say, $2\frac{1}{4}$d to $3\frac{1}{2}$d per lb.; and a very strong memorial, by way of protest, has been sent in by the said planters to the home Government. They adduce that in 1868, and again in 1876 when a similar rise in duties was mooted but abandoned, the average price of Java tea in Holland was $77\frac{1}{2}$ and $62\frac{1}{2}$ cents per $\frac{1}{2}$ kilo (1 and 1-10th lb.) respectively, whereas at present it is only 40 cents; hence the rise now would be proportionately much greater. Again Java tea is for the greater part of such poor quality that there are estates who cannot obtain a higher average price for their crops than 20 cents the kilo (2·2 lb.), thus they would be paying a cent per cent 'duty.' I think I mentioned in my last that the Java planters are gradually but surely replacing their China tea shrubs with Assam hybrid. G. P. T.

VINES IN POTS.

There are probably few products of the vegetable kingdom which command our interest more than the vine. In addition to its utility to a great number of our race, the many references to it in the fine poetic language of the Old Testament and the beautiful illustrations in the New, its lovely foliage, the sweet though short-lived fragrance of its blossom, its grasping tendril, and the tender grape, all combine to charm our youthful fancies and grows with us as we grow in years, and it seems to have had the same effect in long bygone ages. We know that from the time of the botanist king of Israel, the artist and architect have drawn upon it to beautify and embellish their work. This raises the question, why is the vine so little cultivated in Ceylon, at least in the southern half of it? The natural reply is, the vine is a deciduous plant and requires the rest of a winter which we have not got. This is true: vineyards, though simple to cultivate could never be brought to any degree approaching perfection here. My object in writing is to draw attention to their culture on a very small scale, within the reach of anyone. This can be done in pots, vases, buckets or tubs, what we might call portable culture; and in hopes that someone may be induced to try it, I would offer a few outline details.

A cutting with two joints—one to send out roots, the other branches—is your first requirement. Next take a large flower-pot, or wooden bucket with some holes in the bottom for drainage. Put some pieces of brick or small stones over the holes and throw in two or three handfuls of charcoal, to preserve the open drainage. This done, fill up the pot with rich free soil, in which there should be a good proportion of decayed vegetable matter and sand. Next put in your cutting and press the soil firmly down to prevent its retaining too much water which loose soil always does. You have only now to place it in a safe and suitable place, give it some water and watch for its growth. The first year it will only grow shoots, and these should be pinched off when they get to be over 3 feet or so, otherwise they will grow long, spindly and weak. When they have had a fair length of growing season and begin to show the autumn tinge, they want rest. The soil should be allowed to dry gradually till quite dry—this is bringing winter upon them. They will soon ripen and drop their leaves, which is the signal for cutting down or pruning. This is simple enough. You cut all the season's growth away, leaving only a spur with two or three buds of each shoot, to produce the wood of next year and upon which the fruit has to grow.

Thus the culture of one year is over, and you have only got a bare stick of 8 or 9 inches high with some spurs on the top stick in a bucket, which you need take no further notice of for a few months. The perfection to which they bring vine culture in Australia proves how suitable a substitute the terrible drought of the hot season there is for the cold dead winter of Europe. The writer has seen clusters of grapes weighing each 8 and 9 lb. grown on the banks of the Yarrayarra. We in Ceylon have no such long draught, neither do we require it for the stump we left in a pot: we can keep it as long dry as we like.

Now, for the second year, let us give our stump a little larger pot or bucket with some fresh rich soil, place it in a favourable spot and give it water, or let it have rain, which is best. It will soon send out fresh shoots and charm you with its growth and beauty. The shoots should be stopped as before and staked to prevent their being broken or twisted. This year you should have some bunches of grapes, to assist the growth of which the plant should get some liquid manure. The vine delights in good living.

I would be glad if these few imperfect hints would lead anyone to try the pot or tub culture of the vine. It would be especially interesting for ladies. What finer ornament for a family anniversary on the centre of the table than a vine in fruit? I have seen ful in a 10-inch flower-pot with seven beautiful bunches of grapes on it. What could adorn the tables of the Colombo Agricultural Show room better than an exhibition of vines in tubs? It is to be hoped some public-spirited person will offer a prize for the best specimen. They can be grown to any size or trained to any shape. The system mentioned above is the field system, but you can train them in the fan, the spiral, the baloon or any shape, or up the lattice-work of your verandah or arch over your garden-walks, and best of all you can eat the fruit thereof. M.

[We saw just such grape culture in perfection in Inverness, but that was in a conservatory. Our correspondent evidently refers to verandah culture, but we should think that, upcountry, grapes could be grown well under glass.—ED.]

FISH-CURING: AN ANCIENT TRADE.

(Communicated.)

For a long time before the Tamils of the North were subdued by Parakrama Bahu VI, and Jaffna reduced to the position of a conquered country, Hindu Kings reigned in Jaffna holding their Court at Nallur, near where the Church Mission House now stands, and the tall steeple of St. James's rears its head. Adjoining the Mission premises, there is a large garden of coconut, palmyra and other fruit trees, and a large artificial tank or reservoir of water, supposed to be the bathing place of the royal family. Here and there, sunk deep in the ground, may be seen the ruins and remains of ancient buildings; but no excavator has dug deep enough or cared to unravel the history of the past or the departed glory of Jaffna.

The chronicles of this period having been either lost or destroyed, or none having ever existed, the history of the period is solely derived from tradition and preserved in the names of places.

During the reign of one of the Hindu Kings two chieftains, named Chéntán and Kusmán, carried on a large and flourishing trade in fish-curing along the sea coast, stretching from Mylitty to Mathakal. The villages along this coast consisted then, as they do now, of people who live by fishing and other sea-faring trades. The two chieftains were brothers, who by an amicable arrangement amongst themselves, took each his share of the coast to carry on his trade without interfering with the other.

The head-quarters of each are even now known by their respective names, Chéntán-kulam and Kusmán-turai, places where even now the fishing craft of the coast use to lie on their oars, holding communications with the people of the villages.

In process of time, the fish-curing trade assumed such stupendous proportions, as to tempt the cupidity of the neighbouring village-chiefs. Chéntán and Kusmán held the entire fishing population of the coast in their pay, and they could have weilded their power to the terror, if not to the total extermination of the inland chiefs; but they were nevertheless peaceful, peace-loving and loyal, and for the sake of peace they did not grudge occasionally to satisfy the cravings of the needy chiefs in the shape of layerses. But this tended only to more and more tempt the avarice of the insatiate chiefs. Their cry, like that of the daughters of the horseleach, was ever and anon in the same strain, "Give! Give!"

The fisher-chieftains found it high time to resist further demands and accordingly some of the messengers sent by the village chiefs to obtain presents from them, were insulted and sent back to relate to their liege lords the story of their disgrace.

The village chiefs were not slow to perceive their situation, nor slack to concert measures for carrying out their own ends. A council of war was convened at once, and consultation held, as to how to dispose of the refractory, contumacious fisher headmen, some were for open war, others proposed arson as the only means of destroying the factories and fish-stores, and one proposed to disclose a secret, a certain jungle berry, to poison all the fish along the coast. But one more acute than the rest could rely on nothing so sure and effectual, as accusing the leaders of the fishing population to the king as persons having political designs on the kingdom. To denounce the trade as a nuisance, to declare it an open violation of the Saivite religion, and to urge that the village people could hardly live by reason of the stifling stench from salt-fish godowns, were all proposals made and declined. It was unanimously resolved, therefore, to charge Chéntán and Kusmán with treasonable designs.

This was accordingly done. But the poor king found himself in a fix. He was already in bad odour with the king of Kandy. He knew that Portuguese vessels were hovering about the coast. Whatever he might have done at any other time, just then, he was hardly prepared to offend so large and so powerful a body as the fishing population. He proposed to Chéntán and Kusmán to leave the country. They readily agreed, and with some of their followers, settled in Batticaloa—the progenitors of the large fishing population of the eastern province—what was Jaffna's loss was Batticaloa's agin.

TEA BLENDING.

TO THE EDITOR OF THE "AMERICAN GROCER."

We would like you to tell us the best formula for mixing tea—to use some of the India teas. We have lost the papers that had the mixtures in some time ago. We want to use at least four kinds of tea, and oblige, W. A. MORGAN & Co.

In reply to our correspondent's inquiry, it is impossible to lay down any hard or fast lines for blending teas. What would suit one neighbourhood or district would be unsuited for another. The art of blending tea is as much the ability of discerning the wants and requirements of the consumer as anything else. Our correspondent desires to use four teas. Here he is evidently mistaking the art of blending altogether. It is not the quantity, but the kind and quality which produces a desirable mixture. Before any reliable directions could be given, it would be absolutely necessary to know exactly what character of teas our correspondent has in stock; also the taste of the neighbourhood. All we can do under the circumstances is merely to give the experience of others. If an agricultural population, it has been found to answer to blend one part India tea, one part basktd-fired Japan and the balance Amoy Oolong, in order to produce a medium-priced tea of good, sustaining liquor. In this mixture it is best to use a broken India tea, as you get considerably more body at the same price than if you used whole leaf. In mining districts we should think that a mixture of Japan, Moyune and India tea would meet with approval; say one-half Japan and a fourth each of Moyune Young Hyson and India tea. In districts where Formosa Oolong is sold extensively, India tea can be used to great advantage. Procure a Cacha district India tea and a very fine flavored Formosa. Buy the Formosa entirely for flavor, and blend them in equal qualities; they blend excellently. To mix a good English breakfast, first of all secure a very choice Moning Congou, a very fine flavored Chingwo Kaisow, a choice broken-leaf India Pekoe and the finest India Pekoe, care being taken that the India tea will sustain its briskness on the addition of cream. This is necessary, because a few India teas lose their briskness directly there is an addition of milk or cream. Blend the above in four equal parts. It is always best, where practical, to blend the tea some time before you use it, afterwards placing it in an air-tight iron bin so that the flavors will become more assimulated.

[Our readers will notice that in America the value of Indian teas, especially broken teas, for blending with China and Japan teas is fully recognized. The next step will be to recognize the merits of the Indian and Ceylon produce as pure teas, to be used unmixed.—ED.]

THE NEW CHEMICAL PROCESS FOR SUGAR EXTRACTION.

In the opinion of the patentees more has been said about the practical difficulties in the way of working the Ekman-Espeut-Fry process than the facts of the case really warrant, we mean especially with reference to the necessity for employing lead-lined converters. It must be borne in mind that the two processes of treating the cane for sugar and the megasse for paper stock are conducted under very different conditions, and we are told that though a lead-lined vessel is absolutely essential for the latter because bi-sulphite of magnesia and 90 lb. pressure of steam are used, it is not so in the former, where only a mono-sulphite and 15 to 20 lb. of pressure are the conditions to be provided for, and that, in fact, copper will answer this purpose admirably, whilst to counterbalance its greater first cost, there is its greater durability. It is satisfactory to know that, at any rate there need be no practical difficulty about constructing converters out of copper at a cost not by any means prohibitory which will serve for the treatment of the sliced canes in the first or extraction process; and, as regards the conversion of megasse, which it will be admitted is one of the most important features of the process, there is no reason to suppose that it will defy the skill of our engineers. On the contrary, Messrs. Pontifex and Wood, of the Farringdon Works, who have long occupied a leading place amongst makers of sugar machinery and plant, claim to have already solved the problem with a steam-jacketed converter constructed in concentric rings, and with the lead lining attached to the iron plates in a peculiar way, allowing of its being easily and cheaply renewed in any part where a fault may be discovered. The advantages of such an arrangement are obvious, and there is another not less so, viz., that, being built in rings, which are bolted together when the converter is set up for use, there is no single piece even of the largest size converter which weighs more than between two and three tons, whereas the whole vessel will not weigh less than from sixteen to eighteen tons, and our readers will readily appreciate what it means to be handling such a mass as this latter, whereas in pieces it could easily be disposed of. Nor must it be supposed that this is in any sense experimental work with Messrs. Pontifex and Wood, as they have for many years been constructing lead-lined cylinders for the conversion of starch into sugar, and these have answered admirably, but then they are not steam-jacketed.—*Planters' Gazette.*

NEGRO PROPRIETORS IN JAMAICA.

The current number of the *Jamaica Handbook*, to which we briefly called attention in our last, contains valuable information upon the trade and production of the Island, from which it is evident not merely that European enterprise is extending in various new directions, such as cinchona, cocoa, &c., whilst the exports of sugar and rum last year were larger than for nearly forty years previously, but that the economical condition of the negroes forming the bulk of the population has also greatly improved. The total exports for the past financial year amount in value to over a million and half sterling, being an increase of more than £370,000, (we give round figures throughout) on the previous year, and of £205,000 on the average of the five years preceding. On the other hand, the imports have decreased by £70,000, and as this decrease was mainly due to the largely-increased production of ground provisions and other necessaries grown by the native population, it must really be counted as so much gain on the whole to the people—in other words, to the negroes themselves, who form the practical working body of the colony. If they have paid so much the less to outsiders for food, it is because they have raised so much the more themselves for consumption. When we come to examine the details of the figures, the results are still more striking. The industries peculiarly affected by the free black on his own account show a great general increase. True, last year was a bad one, owing to drought, for the coffee crop, the principal stand-by of the industrious hill negroes; and the exports fell to 66,000 cwt., valued at £133,000 as against 87,000 cwt. (£231,000) in the preceding year, and 96,000 cwt. (£249,000) in 1879. This is a serious loss, but the fact that in spite of it the total of exports was more than maintained is a very promising one for the future of the colony. At present the industries are becoming more varied, and a loss in one direction may be more than counterbalanced by a gain in another. The most noticeable of all the features in the report is the immense and steady increase in the small negro's business *par excellence*, the fruit trade with America. In 1867 this consisted of a few bunches of bananas and barrels of oranges, valued at £725: last year the export of oranges alone had risen to 35 millions, and the value of the trade was £124,000. For a small country like Jamaica, with only half a million of inhabitants, this is a very large sum indeed; but what makes it all the more important is the fact that the fruit is almost entirely grown by the small negro peasant proprietor, and that the money thus goes directly into the hands of the people. The total number of holdings of land in the island is fifty-two thousand, of which nearly ten thousand are less than one acre, and twenty-six thousand are between one and three acres; and the proportion of these small holdings under cultivation is far and away greater than the large estates, a vast part of which still remains in wild land. All these facts go to confirm the belief, already held by most of those who know the West Indian negro personally, that the small proprietors are steadily, though slowly, progressing in habits of industry, thrift, and civilisation.—*Planters' Gazette.*

PANAMA.

An interesting report on Panama has been issued by the Foreign Office in their last volume of trade reports. The acting Consul at Colon writes:—"Panama has increased in population since the establishment of the Interoceanic Canal Company. There are now in Panama and its immediate suburbs over 20,000 inhabitants according to last year's census. There is a village just being finished outside the town called Pueblo Nuevo, where a mixed population of West Indians and Colombians reside. Along the line of the canal there are about 6,000 British subjects, and at Colon there are fully 4,000 to 5,000. Panama, with the villages on the line and Colon, musters a population of 56,000 souls, of whom half are of British nationality. The climate of Panama during the dry season (December to April) enjoys a steady and equal temperature of 27 to 29 centigrade. During the wet season (April to November) the heat is very oppressive, owing to the great dampness of the atmosphere and the want of breezes. Light southerly winds prevail during the wet months, and strong northerly trade winds during the dry. A singular coincidence to be remarked at Panama is that the winds during the dry season fall and rise with the tide. This phenomenon also takes place with the wet season, when, at low tide, there is scarcely a breath of air. The showers generally fall at this moment, preceded by heavy storms of thunder and lightning. The air is charged with electricity, and heavy rain clouds hang over the Isthmus, which melt in heavy showers as soon as the electricity is discharged in the form of fork and sheet lightning. Within my recollection I have seen buildings struck by lightining; the towers of the cathedral were struck last year, and several large masses of stone were detached by the stroke. Notwithstanding the frequency of these accidents from lighting, there is not a single lightning conductor in the whole town. The railway wharf received a discharge in October last, which tore up and splintered several planks. Three people were killed on the Savanna. The Isthmus is covered with thick vegetation; the wonderful verdure grows pell-mell; the variety and luxuriance are marvellous. Great trees overshadow an interminable and impenetrable jungle of lesser growth, made up of an endless number of nameless plants and vines, all pushing, struggling, clambering towards the light. The flora is perfectly gorgeous and bewildering in beauty and variety. The solar rays cannot penetrate such layers of thick foliage, and the soil always remains saturated. There is no mutton in the country; the little that can be procured is obtained from the south steamers at Panama and Colon from the Royal mail by special favour. It is supposed to be a great luxury to have a leg of mutton, and friends are generally invited to come and partake when it is the luck of some resident to possess the article. Very often goat flesh is passed off for lamb, but connoisseurs detect the difference immediately. Fish is plentiful; the word Panama in Indian means 'plenty of fish.' There are fish of every kind; lobsters and shrimps abound, and undoubtedly plenty of oysters. The Atlantic species are sperior, the flesh of the Pacific kind not being so firm, and getting tainted very soon. The Isthmus for 50 years was not visited by any phenomenon such as earthquakes, &c.; very slight oscillations were felt, but nearly imperceptible to a great many. Lately we have had a succession. The first that took place after this long silence was on the 7th of September last year, at 3-20 a.m. The city was roused by a severe oscillation from north to south, accompanied by a rumbling noise. The façade of the cathedral was destroyed, the columns and balconies of the Parliament House were thrown down, and several public and private edifices were rent. Since then we have had a series, varying in intensity, from three to five per month, and the extraordinary coincidence exists that they are regular and more severe at the new moon."—London *Times*.

PLOWS AND FANNING MILLS FOR INDIA.

Of the superiority of our agricultural tools and instruments there are no two opinions. The world has acknowledged them as the best of the kind in the market. Why then is not our foreign trade therein larger? Simply because there are only a few countries advanced enough in agriculture to be able to use advanced machinery in the cultivation of the soil. As an illustration of this portion of our argument, our Consul-General at Calcutta says:—

"The Indian 'ryots' (agriculturists) cultivate 200,000,000 acres of land and plow the same from two to five times every year, with no better implement than an iron-pointed wooden stick, which does not turn over the soil, but only stirs and shakes it to the depth of 3 to 4 inches. The enormous quantity of small grain annually produced on these 200,000,000 acres is cleaned and separated for food and for the market by the same system of hand-winnowing which was in use among the Israelites of old, and which, for the European grain trade at least, is now deemed inefficient."

Under these circumstances it would be worse than useless to ship our agricultural implements to India, and yet by simply modifying some of them to suit Indian requirements—and the same modification will apply to many other countries—there is an opening in that empire for a very large trade in certain agricultural machinery, notably plows and fanning mills. Our Consul-General, in calling the attention of our manufacturers hereto, gives the following advice:—

"The small American garden plow, which turns a furrow of 8 or 9 inches, and is so light that a ten years' old boy can carry it on his shoulder and a good sized pony can work it in the field, is, in my judgment, the very plow to introduce into India where an immense market awaits the successful manufacturer. It would, however, have to be made somewhat different from the home model; the beam should be very light and long (much like a common wagon tongue), with a slight incline upwards, so that the end could be fastened with a clevis to the yoke of a pair of bullocks of the size of common two-year old American country steers (the cattle here are yoked so far apart that there is room close to their hind feet for the working of the plow); the handle or handles should stand nearly upright in order that the plowman may walk so near his cattle that he can readily catch hold of their tails, because the Indian bullock-driver will insist on regulating the motion of his cattle by jerking and twisting their tails near the root with his hands. In all other respects it should be just like our light garden plow with a high polish, so as to scour easy in the wet, heavy soil, but otherwise the finish might be plain and cheap, so that the plow would come within the means of the poor tenantry who compose the agriculturists of India.

"The fanning mill should be made with special reference to cleaning and separating wheat for the European market, and should be small, light and cheap. It is very seldom that one ryot has more than 50 or 60 bushels of wheat to clean, and time is of no special object to him; the mill therefore need not be made to do much work in a day, but rather to do it well. A little village community would probably become joint owners of one such mill, but there are 450,000 agricultural villages in India, and in many instances the 'zemindar' (land proprietor) would buy it and let it out on hire to his tenants. Many attempts have been made to introduce these implements from Europe, but so far the samples have proved too heavy and expensive. There is a universally acknowledged want for both of them, and arrangements can easily be made for their trial at the Government experimental farms."—*American Exporter*.

PASTORAL AND AGRICULTURAL PROSPECTS IN TASMANIA.

Tasmania, in its climate, and to a considerable extent in its soil, is well adapted for agriculture. By far the largest area of land devoted to cereals and root crops is in the northern half of the island. Along the north coast, from Ringarooma to Circular Head, the country is dotted with homesteads Tourists from other colonies flit from Launceston to Campbelltown and thence to Hobart, and imagine that they have seen Tasmania. Such persons, however, get a very erroneous idea of the aspect and resources of the country. The visitor should take the Western line of rail from Launceston to its terminus at Deloraine. He will pass through some rich and productive land, such as that near Evandale, with its surface rising and falling like huge ocean waves; Bishopsbourne, where the wattle blooms in rare perfection and the gorse hedges flame between the wheatfields; Westbury, Exton, and Deloraine, with picturesque homes, substantial buildings, and every sign of comfort, and even of wealth. From Deloraine to Latrobe the road is rough. It is here that the Mersey and Deloraine line (which Parliament has decided to complete) is to run. A few miles out of Deloraine we come to the "Black Forest," a forest no longer, and then Dunorlan, all splendid land. Latrobe is the centre of a rising district. From Kentishbury, Barrington, Railton, the Nook, Northdown, and elsewhere, the farmers cart their produce and drive their cattle to that place. The road thence lies along the north-west coast. At Kentishbury several sturdy Scotch families are located. The best lands in this part of Tasmania were originally, with few exceptions, very heavily timbered, and in some instances covered with impenetrable scrubs. The eucalypti are from 20 ft. to 30 ft. in circumference at the butt. I have seen a family lodged in a fallen tree, which served them not only for a dwelling, but for the storage of their produce. There are also in these scrubs the myrtle, the sassafras, the musk with its odorous leaves, and huge tree ferns flourishing in the leafy gloom. This land, however, is too good to be suffered to remain idle, and much of it is cleared. The best soil is volcanic in its origin, and the prevailing volcanic rock is basalt in the North, and in the South dolorite, a variety of greenstone. The farmer does not generally undertake the herculean task of clearing his land at the first. He rings the larger trees and burns off the rest. These trees that are left stand dead, gaunt, and bare in the midst of the wheat and potatoes, every storm bringing down some of the branches. There is a fine reach of country from Port Sorell to Emu Bay, which generally goes by the name of the North-west Coast. Rivers, navigable for a short distance, such as the Mersey, the Forth, and the Leven, afford the means of transport for produce and commodious harbours. The land grows excellent wheat, oats, barley, hay, and potatoes. Cattle are fattened for the various towns on the coast and for the Launceston market. The number of acres under wheat in Tasmania was 46,221 this year, and 51,757 last year. The difference is accounted for by the activity in mining and the scarcity of labour. The total number of bushels produced this year has been 946,889, against 977,365 last year. The average yield is 20·27 bushels per acre, against 18·88 last year, showing an improvement. The price has ranged from 4s. 6d. to 6s. per bushel. The total produce of barley was 89 739 bushels The acreage devoted to oats was 28,849. The average yield of rye was 16·51 bushels. Linseed produced 885·66 lb. per acre. The average price was 2½d. per lb. In root crops there is an increase of 1,004 acres. The total produce of potatoes was 37,526 tons, of turnips 23,272 tons, of carrots 1 281 tons, of mangolds 17,250 tons, of onions 226 tons. The number of acres of hay was 38,043; the average price was from 65s. to 105s. per ton.

The settlements that I have referred to—especially those of the north-west coast—are comparatively recent, but there are others that are much older (quiet towns) that were in existence long before Queensland was settled, and when the blacks corroboreed on the banks of the Yarra where Melbourne now stands. Longford is one of these places. It is twelve miles from Launceston, and is the centre of a wealthy agricultural and pastoral district. The soil is lighter than that of the coast, but, when manured with guano or bonedust, it yields excellent crops. From Longford, farms that have long been cleared and are let at a good rent extend for many miles. There is a splendid expanse of agricultural land to be seen from the road to Cressy, about three miles from Longford—fields of wheat and oats, interspersed with small tracts of forest, where the sheep find shelter; farmhouses, with their outbuildings and haystacks, away to the base of the western tiers. The late Henry Reed, Esq., owned a great extent of farm land and was said to be a good landlord. His property has been divided among his children. I mention him because, more than any other man, he has left traces of his character and energy in the northern part of Tasmania.

As we move towards the Midland districts and the South we find the pastoral interests flourishing. The neighbourhood of Perth, however, which is only ten miles from Launceston, is the home of the Messrs. Gibson, father and son, who are most successful in breeding merino sheep. Mr. Kermode, of Mona Vale, and the Messrs. Parramore, all residing within a short distance of Ross, are well known in Queensland as successful breeders of stud sheep that bring fancy prices.—*Queenslander.*

REMARKS ON BALATA AND OTHER PSEUDO-GUTTAS.

BY JAMES COLLINS.

The great value of gutta-percha, the fear of the supplies, in time, not equalling the demand, has led to the recommending of various substances as substitutes, or as supplementary, to the present supplies of gutta-percha. The following notes may be taken as a short *resumé* of the subject, and indications are given as to the way in which these substances may possibly be utilised. For convenience, these various substances are grouped geographically:—

I.—AMERICAN SOURCES OF SUPPLY.

Natural Order, *Sapotaceæ.*

Balata Gum* (*Mimusops Balata*, Gærtner,) known also as paardenvleesch (horseflesh), bullet tree, boerowé, bolletrie, &c., is found in Demerara, Berbice, British Guiana, Antilles, Jamaica, and Surinam.

Professor Bleekrod was one of the first writers on the subject, his communication being addressed to the Society of Arts, in 1857,† and the tree described and named by him as *Sapota Mulleri*. In 1860, Mr. Walker‡ communicated samples, &c., received by him from Dr. Van Helst, of Berbice; and, in 1864, Sir William Holmes§ also drew the Society's attention to the same subject.

The tree is a large one, with a trunk of about 6 feet in diameter, and furnishes a wood much liked for building purposes. The Dutch name, "paardenvleesch," is given on account of the wood being of the colour of horseflesh. The bark is thick and rough, and the fruit is of the size of a coffee-berry, sweet like a plum, and with a hard white kernel, which yields a bitter oil. The leaves are glossy, oval, and acuminated. The milk is drunk by the natives and when diluted with water is used as a substitute for cows' milk. The tree grows in groups, and in alluvial soil.

The "Balata" gum is of a character somewhat between caoutchouc and gutta-percha, combining in some degree the elasticity of the one with the ductility of the other, freely softening and becoming plastic, and easily moulded if plunged in hot water. What small parcels were sent to this country met with a ready sale, and were remarkably pure and free from adulteration. But, unfortunately, through the difficulty of collection, the undertaking being dangerous and unhealthy, the supply of this excellent article has fallen off.

The Balata is collected by making incisions in the bark, about 7 feet from the ground, and a ring of clay placed round the tree to catch the milk as it exudes. The yield is said to be in profusion, especially at the time of the full moon, and the operation can be repeated every two months in the rainy season. It takes six hours to bring about coalescence by simple atmospheric influence, but very quickly by boiling in water. A large tree is said to yield as much as 45 lb. of "dry gum."¶

II.—INDIAN SOURCES OF SUPPLY.

Natural Order, *Sapotaceæ.*

Panchontee, or Indian gutta tree (*Dichopsis elliptica*), is

* The term "gum" is here used in its colloquial, not in its scientific sense.

† *Journal of the Society of Arts*. London, Oct. 8. 1857.

‡ *Ib.* Aug. 24, 1860.

§ *Ib.* Mar. 4, 1864.

¶ *Trinidad Chronicle*, Sept. 2nd, 1873.

the *Bassia elliptica** of Dalzell, and the *Isonandra acuminata* of Cleghorn†, and is found distributed through the Wynaad, Coorg, Travancore, Anamally, and Neilgherry Hills, Sholah Forest, Cochin, and the Sircars. According to General Cullen, it "appears to be common in all the forest tracts at all within the influences of the south-west rains."

This tree, which is now placed in the same genus as the true Malayan gutta-percha, is a large one, attaining a height of from 80 to 100 feet. The gum is obtained by tapping, a pound and a-half being obtained from one tree, by five or six incisions, a large tree yielding from 20 to 40 lb. of sap. Many experiments have been tried with the raw milk, and General Cullen and Dr. Cleghorn used every exertion to bring the substance prominently forward. The simply dried milk was found wanting in several essential qualities for telegraphic purposes, but has been recommended as a sub-aqueous cement or glue. When dissolved in ordinary gutta-percha solvents, it, after the evaporation of the solvent, remains some time soft and viscid, and partaking somewhat of the characteristics of bird lime. When cold it is hard and brittle.

Natural Order, *Euphorbiaceæ*.

Cattimandoo (*Euphorbia Cattimandoo*, W. Elliot), is found in Vizagapatam, and was first brought to notice by the Hon. W. Elliot, who was awarded a prize medal by the jurors of the 1851 Exhibition. This spiny euphorb grows to the size of a shrub or small tree, and the milk flows out freely when a branch is cut. The natives use the milk as a cement to fasten knives in handles, &c. Under the influence of heat it becomes soft and viscid, becoming very brittle on drying.

The Milk Hedge, Indian Tree Spurge, or Tirucalli (*Euphorbia tirucalli*, Linn), common in the Coromandel, Malabar, Bengal, &c., is a succulent unarmed plant attaining a height of about 20 feet. Its inspissated juice is used for various, chiefly medicinal, purposes in India, but has a very acrid character, rendering its collection a very dangerous operation to the eyes.

Natural Order, *Apocynaceæ*.

Alstonia, or Pala Gum (*Alstonia scholaris*, R. Br.).—This tree is found distributed through Travancore, Coromandel, Assam, and in Ceylon. It attains a height of fifty feet, and its wood and bark are much valued in India for their medicinal qualities. To Mr. Ondaatje is due the credit of recommending Pala gum as a substitute for gutta-percha.‡ It readily softens in water, and retains, when cold, good impressions of any objects. Good specimens, properly prepared are, however, much wanted.

Natural Order, *Asclepiadaceæ*.

Mudar Gum (*Calotropis gigantea*, R. Br.).—This shrub is found distributed throughout the Peninsula and Southern Provinces of India, in waste places, and grows to a height of 6 to 10 feet. Ten average trees are said to yield about one pound of gutta-like substance, which is plastic in hot water, and in other ways behaves like gutta-percha. *Calotropis procera* is said to furnish a like product.

III.—CEYLON SOURCES OF SUPPLY.

Natural Order, *Sapotaceæ*.

Ceylon has many species of *Dichopsis*, *Isonandra*, and other closely allied genera, which are likely to yield a gutta-like substance. The late Dr. Thwaites, the talented director of the Government gardens at Peradeniya, informed me that the natives did not collect any gutta, and one sample sent to the late Sir W. J. Hooker was unfavourably reported on. In some parts of Ceylon, the climate is similar, if not identical, with the Malayan Archipelago, the home of the true gutta-percha.§

IV.—AFRICAN SOURCES OF SUPPLY.

At the Cape of Good Hope there are many species of euphorbias which yield a substance very similar to cattimandoo, but like the *Euphorbia tirucalli*, Linn., the juice is so acrid as to give intense pain and irritation to any part of the body with which it may come into contact, especially the nostrils. The Rev. J. C. Brown, whilst botanist to the Cape Government, paid much attention to the subject, and the juice has been recommended as an anti-fouling dressing for ships' bottoms.

Mr. Barter, whilst on the Niger expedition, collected a specimen from a species of *Chrysophyllum*, which was said to resemble gutta-percha. Tropical Africa should undoubtedly yield some such substance.

With regard to these various substances, it may be said that Balata gum has an assured value of its own, and efforts should be made by cultivation or acclimatisation to utilise this valuable substance. With regard to the others, the consideration of some of the aspects of the gutta-percha question may throw some light on the subject.

The utilisable products existing in plants is a most important question in phyto-chemistry. As to their use and characteristics whilst in the plant we know little, and that little is almost entirely inferred from the characteristics of the products after they are extracted from the plant. Thus, indigo does not exist as indigo (as we know it) in the plant itself, but is the result of fermentation after the juice is extracted from the plant. Sugar-cane juice too, furnishes us with an illustration as to how quickly products change after taken from the plant. The juice whilst in the cut cane even does not change, but as soon as it is expressed it speedily ferments, and uncrystallisable sugar is the result—a result which is retarded at least by the addition of lime. Thus with these and many other substances, exposure to atmospheric influences, induces change, and a new set of chemical combinations are inaugurated. Some products, such as alkaloids, acids, resinous matters, &c., are not used, so far as is known, in the economy of the plant, and are accordingly removed from young and active portions of the plant to store cells or reservoirs; whilst others, such as gums, starches, &c., undergo many changes, are changed from starch to gum and to sugar, and are freely used up in the sustentation and growth of the plant. In cinchonas it has been proved by analysis that those growing in hot valleys have a greater development of bark and a lesser elaboration of alkaloidal contents, whilst in the mountains the reverse is the case. This may arise from the alkaloid, or its primal constituents, being used up in the elaboration of tissue, or its larger formation being at the expense of tissue, or it may be from simple translocation, that is, a process of removing products from the active part of a plant to store cells or reservoirs.

With regard to gutta-percha, these facts have a very important significance, and are worthy of all attention, bearing as they do also on pseudo-guttas. Gutta-percha, as it flows from the tree, is a viscid fluid, acquiring milkiness and concreteness on exposure to the atmosphere, and unless arrested, the change results in two resins, *albine* and *fluavile*. Thus, according to M. Payen, the analysis of commercial gutta-percha gives—

	Per cent.
(*a*) Pure gutta (an hydrocarbon, milk-white in colour and fusible)...	75 to 82
(*b*) Resins soluble in boiling alcohol, and consisting of two parts:—	
(1) Crystalline or albine, a white crystallisable resin, crystallising out of the alcohol as it cools	16 to 14
(2) Fluavile, a yellow amorphous resin, falling in a powder on the cooling of the hot alcohol in which it is soluble	6 to 14

It is thus apparent that the change of pure gutta into a resinous-like mass takes place naturally, if means are not taken to stop it. This resinification I have often witnessed. If two bottles of equally pure and identical gutta be taken, and the one bottle hermetically sealed, and the other left exposed to the atmosphere, the first will retain its goodness, and the other will become resinified, and as brittle as shellac. Again, from experiments extending over years, both at home and in the East, I have found "getah muntah," or raw or "uncooked" gutta, soon become a resinous mass, being, in fact, in character like so much kowrie gum or cutch.

This change, I have proved experimentally, can be lessened, retarded, or altogether obviated, by thoroughly well boiling the product immediately after collection.

There is also another fact to bear in mind, with regard to this proneness to chemical activity in gutta-percha. In cutting through the bark to arrive at the laticiferous, or milk-bearing vessels, many other vessels and cells become

* Kew Misc., iii., p. 76 (1851).

† Report on Pauchontee, Madras, 1858.

‡ *Journal of the Society of Arts*, London, vol. xii., p. 30, Feb., 1861.

§ *Vide* Thwaites' "Flora Zeylanica" (preface).

ruptured, containing tannic, gallic, and other proximate principles, and the presence of these no doubt initiate and accelerate oxidation. In opening bottles of milky juices, a turbidity and effervescence is often noticed, owing to the formation of a brownish liquid, the colour of which is probably due to the presence of gallic acid, and gallic acid has been found to exist naturally in parenchymal cells and milk-ducts. In blocks of gutta-percha which have not been properly prepared, these foreign substances induce the presence of a brown, fermented, and putrid liquid, which decomposes the internal mass. Now, most of these foreign substances are soluble in water, and in these process of boiling the gutta would be eliminated.

These considerations seem to prove that some, at least, of these pseudo-guttas are worthy of, and indeed require, fresh trials before their utility can be certified, or otherwise.

To those who have the opportunity, I would recommend that samples should be collected in the manner I have already pointed out in the *Journal* of this Society.*

These samples and results, if submitted to competent authorities, would enable the question of these substances being utilisable as substitutes, or rather as supplementary sources of supply, to be set at rest.—*Journal of the Society of Arts.*

MICA.

Large quantities of mica are being discovered in many parts of the country, much of it unfitted for the purpose for which it is chiefly used. Nature very seldom creates a supply without making somewhere a demand that shall utilize and develop the treasured resources. It is, therefore, evident that some new uses will sometime in the near future be discovered for this mineral, made up of so many valuable elements.

Two new uses for mica have recently been patented. One is a compound of ground mica, flour and cement, which are mixed, pressed into shape, and baked for jourpal boxes. The other is for use as a mixer in starch gloss, and oily compositions, the mica being reduced to an impalpable powder. Chemistry reveals the fact that mica is composed of silica, alumina and potash. Silica is one of the hardest substances in nature, represented in its purest form as rock crystal.

Alumina is also an exceedingly hard substance in its impure form known as emery or corundum, so extensively used in polishing operations; and in its best estate, it is shown in the ruby and the sapphire.

Potash, the other principal ingredient of mica, is well-known in the arts, the supply being chiefly from the ashes of vegetable life, which has been absorbed from the supply furnished by the granite rocks. It will be seen that science will yet find a wide field in which mica will be used extensively.—*Mining Review.*

JAVA COFFEE-GROWING.

TO THE EDITOR OF THE "QUEENSLANDER."

Sir,—In your issue of the 7th, in the article on coffee planting in Java, I notice an error which requires correction. The writer, in describing the West Indian curing process, states as follows:—"The coffee is allowed to remain in the reservoir from thirty to thirty-six hours, to allow of fermentation setting in. This process is necessary for the purpose of removing the inner silver skin, and if well carried out the object is perfectly achieved; but, with careless fermentation, the silver skin adheres to the berry, and cannot afterwards be removed." I will try in a few words to show that the curing of the coffee in the cisterns is not for the above-stated reason.

When ripe, the coffee is red, and is called cherry; we talk of so many baskets of cherry. The cherry is passed through the pulper (your diagram shows what we style the old rattle-trap), and the pulp, or skin, is pulled off, leaving the parchment bean all covered with saccharine matter, so much so that it is impossible to grasp a handful of it and retain it all. It is to remove this thas fermentation is allowed. After fermentation the coffee it washed; it then presents the appearance of a bean covered with a strong white skin, or husk, called parchment. This is exposed for several days to a strong sun, and when dry enough is packed off, say to Colombo; here it is again dried for two to three days, and then husked by being put into a circular trough, over which roll four or two enormous wheels, weighing generally a ton each. These remove the husk without injuring the bean, and now the bean presents a changed appearance; it is closely fitted with a thin skin of silver called the silverskin. This is winnowed off, and the coffee packed off for sale. Should the coffee be allowed to ferment too long it will give the husk a black appearance in place of the snowy white one it should have, and, although this does not injure the inner contents, the brokers, &c., will depreciate its value.
—I am, sir, &c. Old Planter.

VEGETABLE TALLOW FROM SINGAPORE.

BY W. T. THISELTON DYER, C. M. G., M. A., F. L. S.

The very interesting note on the above substance, by Mr. Holmes, in a late number of the *Pharmaceutical Journal* (November 24, 1883, p. 401), requires a word of comment. We have not, as far as I know, received a specimen of the vegetable tallow known as "Minjak Tankawang." But Madame de Vries de Vries, who was lately on a visit to England, brought to Kew, on behalf of Professor Van Eeden, of Haarlem, a specimen of a plant of which he informed Sir Joseph Hooker, in a letter (November 11, 1883), the "Indian name is Minjak Tankawang, and it yields a fat." I have little doubt, therefore, that this is the plant which yields the vegetable tallow about which Mr. Holmes has written. Madame de Vries de Vries added that Professor Van Eeden "had shown his plant to Mons. Pierre, from Charenton, author of a Flore forestière de Cochinchine, whom perhaps you know. Mons. Pierre thought it likely the plant is no *Hopea*, but belongs to the *Sapotaceæ.*

This opinion is certainly correct. The plant is no *Hopea*, but, undoubtedly, *Sapotaceous.* The curious point, however, is that my colleague, Professor Oliver, informs me that he is unable to refer it to any known genus of the order. For the present, then, till more complete material is obtained, it must remain undescribed. Madame de Vries de Vries adds in a susequent letter that "the plant .... came from Bandjermassing, Isle of Borneo."

The name, Minjak Tankawang, has been applied to many *Dipterocarpeæ*, especially Hopeas, and W. H. de Vriese published in 1861, at Leyden, a folio tract under this name, containing a number of descriptions of new species. It is *à priori* unlikely, however, that any species of *Dipterocarpeæ* would yield a vegetable tallow from the seeds, because the members of the family are characterized by the presence of oleo-resins in the tissues and not of fatty bodies. On the other hand, the seeds of *Sapotaceæ* are rich in the latter class of substances, *e.g.*, argan oil from *Argania Sideroxylon*, mee oil from *Bassia longifolia*, shea butter from *Butyrospermum Parkii.*

I suspect that Mr. Holmes's specimens will prove identical with a substance which has long been known and which in the Kew Museum is referred doubtfully to a species of *Bassia.* We possess specimens of "Tankawang oil" and the decorticated seeds which yield it, which came to us from the India Museum. They are labelled "Borneo, *Bassia* sp." We also have an old Kew specimen labelled "Concrete oil from a species of *Bassia*; Sakarran; Sir James Brooke," which is probably the same thing.

We may fairly, I think, hope that now the origin of this interesting substance has attracted the attention of Mr. Holmes and Professor Van Eeden, the doubts attending it will be cleared up. As a contribution to this end I have written this brief note.—*Pharmaceutical Journal.*

RICE PLANTING IN THE STRAITS SETTLEMENTS.

Consul Studer, of Singapore, says that the chief agricultural implement used by planters in the Straits Settlements is the hoe, termed in the Malay language "chankoli," and the system of planting by Europeans and natives is a very primitive one, namely, a number of coolies furnished

* *Vide* "Africa," &c. Letter by James Collins, *Journal of the Society of Arts,* April 25th, 1879, p. 467. See also "Report on the Caoutchouc of Commerce," to Her Majesty's Secretary of State for India, p. 46, iv., 1872.

with as many hoes. The hoes are all of the same shape, about six inches wide and eight or nine inches in length, and are nearly all made by Chinese blacksmiths, and purchased at the rate of about one shilling each. With these common hoes, the coolies do all the planting, dig ditches, make excavations, and fill the baskets that serve in lieu of wheelbarrows for removing earth, *débris*, or stones. They carry two baskets at a time, suspended from either end of pliable stick or bar, carried across their shoulders. An effort has been made to induce the coolies to use wheelbarrows, but hitherto without success. For the removal, however, of objects too heavy for one or two men to carry any great distance, they use two-wheeled hand carts, which are large unwieldly vehicles, and on which they pull and push very heavy loads. The rice-planting natives, when planting lowland rice, have an article resembling a plough, made of very hard wood, and drawn by buffaloes. It consists of a beam, into which a sharpened broad stick of wood is inserted, the beam having simple arrangements at either end for guiding and drawing the implement. With this, after the rice field is covered and watered, they stir and loosen the mud, then women come with bundles of rice settings, grown in seed-beds near their houses, and, armed with a sharp stick, plant a few settings to a hill, the hills being about one foot apart each way. When the crop is ripe, they do not use scythes, but with a very small sickle they cut it about two-thirds the length of the stalk up from the ground, and carry it to a shed under cover. The Chinese and Siamese, instead of threshing it, tread it with buffaloes on hard clay ground. This process separates the unhulled rice, called "paddy," from the stacks. To remove the hulls from the rice, and polish the kernels, the paddy is taken to mills or hand-machines, the latter being clumsy, hard to work, and very primitive in their construction. The Malays, not having buffaloes, separate the paddy from the stalks by hand, and, as a rule, they plant no more than they need for their own use. For the cultivation of upland rice the natives use the common hoe, breaking the soil as deeply as possible, and they transplant their settings when the rainy season commences. This species of rice is not so yielding, the kernels being smaller than is found in marsh paddy. The hill rice is of excellent quality, but only sufficient for home consumption is planted. Consul Studer says, that there appears to be a rooted objection on the part of the planters to use ploughs, as they incline to the belief that it would be impossible to break up with them land which was covered with stumps and lubricate masses of large and small roots, and that they would be useless in "lallang fields," "lallang," in Malay, meaning a species of long and very tough grass, growing very thickly and luxuriantly, used chiefly for thatching roofs. Tracts of "lallang"; are met with in many provinces, and each tract indicates an abandoned rice field, or a gambier or pepper plantation. Soon after cultivated land has been abandoned, "lalling" grass, especially on heavy clay soil, will spring up, and so thickly that seeds blown from trees in the jungle, or carried by birds, will find no chance to take root.—*Journal of the Society of Arts.*

INDIAN WHEAT.

If well cleaned, properly packed and carefully stowed in the exporting vessels is likely to take first rank amongst cereals. Witness the following extract from a report by Messrs. MacDougall Bros. of London, at the instance of the Secretary of State for India:—We pronounce them to be exceedingly useful wheats, in fact, hardly equalled for what is deficient and wanting in the English markets by any other wheats. Their chief characteristics are just those in which the wheats grown in our variable climate are most deficient. Their great dryness and soundness render them invaluable for admixture with English wheats that are in any degree out of condition through moisture, and the great proportions of the wheats harvested here have been in that condition for some years past, a condition that must prevail in all other than that of wheats harvested and stored during fine favourable weather; and this the English farmer knows, greatly to his cost, is a state of climate that is by a long way the exception rather than the rule. Added to their dryness, the thinness of the skins of these wheats, and consequent greatness of the yield of flour, must always place them in the front rank as a "miller's" wheat, whenever they are handled with reasonable intelligence and skill.

Such unprecedented yields of flour, as shewn by these wheats, ranging (by ordinary grinding) from 77·46 to 80·52 per cent against English 65·2 and American spring 72·2, speaks volumes in their favour, and their value is still further increased by another of merit of almost equal importance, viz., a larger percentage of bread may be obtained than from any other of the flours included in this review.

That, for the best of these Indian wheats (the fine soft white), on the day they were valued on Mark Lane market, a price was offered as high as that for American winters, New Zealand or English (see list of values in synopsis), proves that the great value of the Indian wheats is becoming recognised here, a knowledge that will ere long extend to all our markets. The other lots of Indian (Nos. 2, 3, and 4) were lower in value to the extent of 4*s.* to 5*s.* per quarter, as might almost have been expected from the difference in colour and other characteristics; still, as these latter wheats become better known here, this difference in price will be somewhat lessened. Their beany flavour is not a serious obstacle, as fair average deliveries, when well cleaned and properly dealt with, can be employed in the proportion of 25 per cent to 50 per cent along with home-grown or other wheats, such as Americans, possessing a fine sweet, milky, or nutty flavour.

Glancing at all the facts here elaborated, it is evident that these wheats afford a larger margin of profit both to the miller and baker than to any other.

We venture to record a conviction we have long held, strongly emphasised by the results of these experimental workings, of the measureless importance of the great resources of the Indian Empire being developed to the utmost in producing wheat for this country. Farmers here are finding that to live they must produce beef and mutton rather than grain, hence the greater need of resources of supply under our own control.

It is evident such a conviction is common to the members of your Honourable Council, as testified by their unceasing efforts in this direction. And we desire heartily to congratulate them upon the important fruits arising from their labours. The character and general excellence of the Indian wheats are improving with the deliveries of each successive season. The Indian wheats now specially under review were delivered to us in excellent condition (see details, with freedom from dirt (except Lot No. 3), barley, gram, and other impurities, also with a freedom from weevil, rarely equalled by Indian wheats, except the prime parcels of the past season, and there is no doubt an outlet in this country and the European continent for unlimited quantities at prices that shall prove remunerative to all parties concerned, either in their growth, transportation, or conversion into flour and bread.

TEA AND ITS SUBSTITUTES.

(*Continued from page* 169.)

RHAMNACEÆ.

11 *Sageretia theezans*, Brongn. (Sacaretia, or Tia of Chinese).—A thorny shrub 6 to 8 feet high, with smooth shining, green, egg-shaped leaves, somewhat resembling those of the common Tea. The fruit is dark brown, globose and succulent, about the size of a Pea; has a sweet taste, and is eaten largely where it grows, and the leaves are used as a substitute for Tea by the poorer classes in China. It grows in China and Japan, and according to Brandis's, *Forest Flora* extends into India, being "common in places on the eastern flank of the Suliman range at between 2,000 and 8,000 feet; in the Salt range, and in the North-west Himalaya between 3,000 and 8,000 feet from the Thebam to the Sarda."

12. *Paullinia Sorbilis*, Mart. (Guarana).—A woody plant, described as of a climbing habit, with an angular smooth stem, and alternate pinnate leaves on long stalks. It bears an ovoid or pyriform fruit about the size of Grape, and contains usually a solitary seed (rarely two or three). These seeds have been described as having the appearance of "Horse Chestnuts in miniature." The plant is a native of Brazil, where the seeds are used in the preparation of

a beverage, as well as in medicine. The name Guarana is derived from a native tribe, Guarinis. The following is the mode of preparing the seeds:—After being dried, and the aril removed, they are powdered; water is then added, and the mass kneaded into a kind of dough, which is rolled into cylindrical masses 5 to 8 inches long, or spherical lumps, and finally dried in the sun or by fire-smoke. When so treated they become very hard, and of a darkish brown colour, and can be kept or carried about for a long time. It has an astringent bitter taste, and a smell somewhat like chocolate. Its medicinal properties are regarded as tonic, febrifugal, nutritive, and slightly narcotic. It acts as a restorative and nervous stimulant similar to that of ordinary tea and coffee. In Brazil it it extensively used in the preparation of a refreshing and nutritious drink made by putting a tea-spoonful of the prepared Guarana in a glass of sweetoed water. It has been introduced into this country, and recommended in diarrhœa, neuralgia, nervous headache, &c.

LEGUMINOSÆ.

13. *Psoralea glandulosa*, L. (Jesuits' Tea, or Calen).—A dwarf shrub with trifoliate leaves, native of Chili, where an infusion of the leaves is drunk as a tea—more, perhaps, for its medicinal value than as a refreshing beverage, having vermifuge and stomachic properties. The plant has a smell like Rue.

14. *Cyclopia genistoides*, Vent. (Bush Tea, or Honigthee).—A glabrous shrub with ultimate sessile trifoliate leaves, and bluntly mucronate linear leaflets, which are used at the Cape, where the plant grows, as a substitute for tea. The aroma is said to strongly resemble that of Chinese tea, and the taste to be sweetish astringent. It is valued at the Cape as a restorative, and a decoction or infusion is often given to promote expectoration in chronic catarrh, or even in consumption. The leaves of C. Vogelii, Harv., are said to be used for a similar purpose.

15. *Borbonia parviflora*, Lamk. (Stekelthee).—A glabrous shrub with compressed angular winged branches, and alternate, cordate, many-nerved, mucronate leaves. The plant is common at the Cape on the Lion's Head and Table Mountains, and a decoction is used as a medicinal tea in asthma, and as a diuretic.

16. *Astragalus Bœticus*, L.—A procumbent plant, native of Spain, Barbary, Sicily, and the Levant, the seeds of which, when roated and ground, are used in Hungary more as a substitute for coffee than tea.

ROSACEÆ.

17. *Cliffortia ilicifolia*, L. (Doornthee).—A South African shrub common in the district of Uitenhage, where the sharp-pointed and spiny leaves are used as tea, and as an emollient and expectorant in coughs.

18. *Prunus spinosa*, L. (Sloe, or Blackthorn).—This is introduced because the leaves were at one time extensively used for adulterating Chinese Tea, and it is said that they form the best substitute known.

SAXIFRAGEÆ.

19. *Hydrangea Thunbergia*, Sieb. (Amatsji, or Tea of Heaven).—A Japanese shrub found on the mountains of Aiva and Sonaki, where the leaves, which are oblong and serrate, are, when dried, used by the natives as tea, under the name referred to above, and by the Chinese as "Di-sido-san." It is sometimes known as "Sweet Tea" by the Japanese, who assert that there is a variety of the same plant with bitter leaves, which they call "Kakassoo."

MYRTACEÆ.

20. *Leptospermum scoparium*, Forst. (New Zealand Tea tree).—A shrub 4 to 6 feet high, native of New Zealand and Australia. The leaves were used by the seamen of Captain Cook's expedition as a substitute for tea. The flavour is an agreeable bitter, and when fresh they have a pleasant smell, which is partially lost in drying. A strong infusion has been found emetic in a similar way to green tea. "They were also used with Spruce leaves in equal quantities to correct their astringency in brewing beer from them, and they rendered the beer exceedingly palatable."

ONAGRACEÆ.

21. *Epilobium angustifolium*, L. (Twan Tea).—The leaves of this well-known plant are used in Finland for making tea. When so prepared they have quite the appearance and smell of black tea.

COMPOSITÆ.

22. *Solidago odora*, Ait. (Blue Mountain Tea).—A plant 2 or 3 feet high, with a slender erect pubescent stem, and linear lanceolate leaves, entire, acute, rough at the margins, and covered with pellucid dots. It is found in woods and fields more or less abundantly in all parts of the United States. The leaves have an agreeable, warm, aromatic taste, and a fragrant smell. They are not only valued in America for their medicinal properties, but a large trade is done with them under the name of Blue Mountain Tea. Quantities of this so-called tea are said to be brought into Chicago. The following account has been given of it:—"This tea is gathered in large quantities on the Blue Mountains, and the mountains to the north of that range. The tea matures in the latter part of September, and is gathered until late in October. It is then cured and put up into packages, selling on the mountains at from 20 cents to 30 cents per pound, but retailing in villages and towns at 1 dol. per pound. The tea has a very pleasant amomatic flavour, and is held by many persons in great esteem."

20. *Helichrysum nudiflorum*, Less. (Kaffir Tea).—A common herbaceous plant of South Africa, with amplexicaul, ovate lanceolate, radical leaves, and narrow, lanceolate, sharp-pointed cauline ones. The plant is demulcent, and an infusion made from it is given in phthisis, catarrh, and pulmonary complaints generally. An infusion of the leaves forms the tea. An allied species, H. serpyllifolium, Less., furnishes Hottentots' tea. The plant, like the last species, is demulcent and emollient. The leaves have an agreeable smell, and for the purposes of tea-making are highly esteemed by the people. The Duinen-thee—so named from the plant being abundant on the Cape Downs—is yielded by H. imbricatum, Less.

24. *Eupatorium triplinerve*, Vahl. (E. Ayapana, Vent.).—A slender, glabrous, erect, perennial herb, native of the Amazon Valley, has been introduced into India, Mauritius, and other parts of the world. It has had a reputation on account of its medicinal value in fevers, cholera &c.; its general use, however, is as a gentle tonic. The leaves, when dried, have a smell somewhat resembling hay, and have been used as tea in Bourbon.—*Gardeners' Chronicle.*

A STANDARD WORK.

Our Netherland Indies have hitherto taken little share in this movement, but this will improve. Burton says of it "this weed—the *madar*—so common in the East, may one day become for the West an important article of commerce." And it is sincerely to be wished that our India may take the hint and share in the renewed activity; she possesses the material itself in great abundance. Besides being worked up by European industry, to mix up with finer textures, this fibre is also used in N. Africa, Arabia, &c., like the *kapok* with us, for stuffing mattrasses and bedding. It is also employed now as a material for paper, and as such, answers pretty well. The natives apply the *milky juice* to bad ulcers, and contrive to use the fine, silky fibre, so difficult to spin, as rope yarn.

The other useful genera and species, among others the *indigo*, *nila* (*Marsdenia tinctoria*; II. 491) have all passed into regular cultivation; the *wali kambing Sarcolobus Spanoghei*: II. 502), however, not yet; much in demand for hunting and fishing, for instance to catch tigers.

Convolvulaceæ (II, 582).—Among these several genera, as the *Oebi* (Batatas) which, however, are also largely cultivated everywhere, furnish the *kankoeng* (*Ipomoea reptans*; II. 601) etc., tubers, roots, stalks, leaves, which gathered together from the woods or marshes, are articles of daily occurrence at the pasars.

Solaneæ (II. 633).—With the *Solaneæ* it is the same; their products, *Sol. melongena* (II. 653) with several varieties and little diverging sorts, as *terong*, *capsicos* (II. 657) etc. are much cultivated, yet much is also gleaned from the wilderness; even more than of the preceding group, in request also for the European table. It is unnecessary to treat here of the potato or the tobacco, neither of them indigenous, but imported, but we must mention the *thorn-apple*, *ketjoebscon* (*Datura* spec. div.; I. 656), used pharmaceutically by the natives as anodyne against worms, eruptions, etc. (formerly also by thieves in warongs to stupify their victims) this is now seldom heard of any more

Verbenaceae (II. 857).—Abounding in good and available woods, also some medicinal plants.

At the head stands of course the Javanese *Djati, Tectona grandis* (II. 900), a sort, covered, according to local influences, especially the quality of the soil—with fine, coarse, lime-crystals, soft or hard fibre; *horn-djati* (*djati soengae*), *oil-djati* (*djati lenga* or *minjak*), *lime-djati* (*djati kapoer*) etc.*

Then the *Vitex*, of which the *Vitex leucoxylon, pubescens* and *punctata* (II. 863, 864). *Kajoe arak* furnish excellent wood for household use, and charcoal, *taban* and *gofassa* for the building of houses and ships and appurtenances, as masts, sloops, oars, etc.; the *lagoendi, Vit. trifoliata* (II. 295), a medicine used also by Europeans, especially for infantine diseases, and a few others.

Lastly the *Avicennias* (II. 911), among which the *Kajaoe, api* p, for fine charcoal, and *mangi* p *poetih* for smaller objects.

Cordiaceae (II. 913).—Also good kinds of wood as the *Kendal* of Java *Cordia bantamensis* (II. 917), and *salamoeli* of the Moluccas and N. Celebes, the *pramasada* of Java (*Cordia subcordata*, II. 914), not abundant, but one of the best woods that India possesses for furniture, in larger dimensions for house-posts and waterworks, etc. In Sumatra partly supplanted by the smaller *noenang* (C. *subdentata*, Miq., e. g. Sumatra, 244).

Labiatae (II. 934).—Sundry spicy productions and medicinal, such as the *Ocimum basilicum, gratissimum* and *sanctum, daoen selassi* (II. 937) also of some repute among Europeans, and the not unsavoury *Javan potato, kenting djawa* or *koemili* (*Lolsne taberosus* (II. 953).

Sapotaceae (II. 1,033).—One of the most remarkable families of plants of the whole Archipelago, less for their woods, none of which are of any great importance than for their flowers, edible fruits and seeds, oils, and especially for their milky juices. Foremost stands of course the *getah-pertja, Isonandra gutta* (II. 1,038) the *getah taban* (sometimes but wrongly called *getoh toeban*) as 1st sort; then the *getah-pertja* proper of E. Sumatra, on Borneo's west coast *njato doerian* as 2nd sort, and from the same region, but more southerly, the *getah girek* as 3rd sort. Among the natives the *Eajak name njato*, the Sumatran *balam*; the appellation *getah-pertja, Sumatran gum-resin*, was introduced by commerce in order to have a distinct name for Europeans, but it is, as we said before, vague. Inferior sorts come from the east coast of Borneo and perhaps the west coast of Celebes, by Mangkasar also to Singapore, the centre of the trade in this article; the *getah-pertja* of the east coast of Celebes begins also to become more known. (Tijds. v. N. 1877, p. 120, 1883, p. 75.)

The oil of the fruit of the *Isonandra gutta*, now almost extinct by the wanton destruction of the trees, was formerly much used and was in some measure an article of commerce.

A substitute for the *getah-pertja*, still furnished as such, but which is deserving of attention on its own merits, is the *balam tandoek* of Sumatra, from the *Ceratophorus Leerii* (II. 1,043), also as *Sapotacea*. Attempts to extract from the *Sawoe manila*, the *sapotille* (*Achras sapota*; II. 1,035), a substitute for *getah-pertja*, failed; probably only temporarily, for the elements are present. The fruit is one of the most savoury of India.

The Javan *Cacosmanthus macrophyllus* (II. 1,040) furnishes a remarkable product, the *karet-moending*, somewhat like Indiarubber, but more approaching the *getah-pertja*, and which has likewise found its way into the market.

The *Mimusops Elengi* (II. 1,042) gives the favourite odoriferous *tandjong*-flowers, so assiduously collected; another, *Mim. kauki* (II. 1,042) the beautiful wood *kajoe sawoe*, so much used for household furniture.

The *Sideroxylon nitidum* (II. 1,037 gives the Javanese *ironwood, Kajoe bessi*†), hard, durable, and used for house building and partly for ship building. In West Java the tree is called *njaloe*.

* Vide Class 20, lett. D. *Forest-culture*, where the Djati is amply treated.

† The appellation "*ironwood*," applied to some other sorts, has become rather vague, and is besides very little used by the natives, who have a special name for every sort.

Ebenaceae (II. 1,043).—The *Ebenaceae*, like their next in kin, the *Sapotaceae*, have not yet been sufficiently examined; they furnish, like the latter, all kinds of products to the native trade; this family has, however, sorts of woods which we know only by name; also some edible fruits.

Besides the black ebony, *Kajoe arang, Maba ebenus* (II. 1,051), obtained in considerable quantities from North Celebes and the Western Moluccas, and sent especially via Manilla to China, a light and a dark-brown figured sort, occurs *najoe ipil*, which is highly valued.*

Akin to this is in Java the *Kajoe merak, peacock-tree* (*Leucoxylon buxifolium*; II. 1,050), giving a wood, which young is very bad, but old excellent. Further there deserve to be mentioned the Javan *kleedong*, a good wood, *Diospyros* spec? (II. 1,044) *melanoxylon* (?), fruit edible and much preserved, and *bidara goenoeng* spec (?), *Diosp. heterophylla* (?).

Gnetoceae (II. 1,066).—Among the *Gymnosperms* the *Gnetaceae* come first in consideration in our review, especially the *ganemo* (Moluc.) *Koelan* (Mangk.) *garintoel* (Jav.) *tangkil* (Sound), *manindjoe* (Mal.), the *Gnetum gnemon* (II. 1,067), with a fibre used largely in Java and Sumatra, but less in the E. part of our Archipelago, which is used for nets and then tanned with *r. efoe*, obtained from a not well-defined *Sponia* (*timorensis, amboinensis* 12. 124 (?) very nearly allied to the Javanese *anggring Sponia velutina*); an excellent tan, as yet overlooked by our European commerce and industry. Other *Gnetum* sorts yield good fibre and edible fruits besides.

Abietinae (II. 1,068.—One of the best sorts of *damar*-resin, the *damar poetih, white damar*, much exported from the Moluccas, via Mangkara and Singapore to England, lately also to Netherland, comes from the *Dammara alba* (II. 1,070). The native trade provides the Javan Cottondyeries, etc., with them the damar cannot be dispensed with in "batikking."

Podocarpeoe (II. 1,070).—To this family we owe the heavy *kibima* of West Java (*Podocarpus Latifolia*, II. 1,071), used for building purposes in posts and planks, the *ki-merak* likewise sought for posts, etc., from the same regions (*Pod. spec. div.*), the fine *Kajoe poetri, princess-wood* (*Podoc. cupressina*; II. 1,071), also much in demand; it furnishes Japan also with some of the finest woods.

Palmae III 1).—We can hardly consider the productions of the very extensive group of *Palms*, so various in nature that *Miquel* classes them in a sub-division of his Flora, as *wine sago, farinaceons, fruit-bearing, wood* and *rattan palms* (he might have added *fibre*-palms, *e.g., Liristona*,) any longer as forest-productions; though the *aren-palms*, in some places, in accordance with ancient tradition, not planted (this is left to the care of *loewaks—Paradoxuras trivirgotus* and other birds—that delight in their fruits, and disseminate the kernels in and with their excrements), but found everywhere; the *rotan* still collected in the forests, and some others. Their products are, besides, pretty generally known, and therefore an enumeration of a few of the principal productions will suffice here.

At the head stands, of course, the *cocos-palm* (*klapper*, from *kalapa, krambil*), the *cocos nucifera* (III. 64), indispensable in domestic use, and the oil of which, abounding in stearine, is furnished in great quantities to the European marts. Then, an important article of commerce, *the sago* of several *metroxylon*-sorts (III. 139), *kirai*, etc.; further of the *areng-palm* (*Arenga saccharifera*; III. 35), *gebang* (*Corypha umbraculifera*; III. 49), *Soewankoeng Caryota maxima*; III. 39), etc. The general name of the gluten furnished by them is *sagoe*, or in Javanese *pati*, but some species received sperate names; so the *sago* of the *areng*-palm is called in Java "Ongkok."

Of the *Arecas* we must distinguish the *Areca-Catechu* (III. 8), from which a matter is extracted rich in tannic acid, and brought into commerce: one of the inferior

* Not to be confounded with the *Ipil-wood* of the Philippines designated there as *Eperna falcata* (?). The wood is very durable, dark-brown, equal, and not variegated like Menado and Batjan *ipil*. In the Moluccas occurs the *Adenanthera falcata*, the *Kajoe Salowako*, a wood of which shields are made. Whether the definition is correct remains here undecided. The Surinam *bijlhout* was reliably defined as *Eperna falcata*.

species of *gambir catechu*, or *terra japonica*. Whole ships' load of the fruit, also of the shelled nut, are annually exported to China, a good deal to Bengal, both for sirichewing, and for the dyeing of cotton. The above-mentioned *klapa*, *areng-palm* and *gebang*, besides the *lontar* or *siwallang* (*Borassus flabelliformis*; III. 45), yields the *klapper* or *Java-sugar*, formerly so much in request by the European trade, and still much used in European and Indian households.

The juice obtained by tapping from the cut stalks of the drupes, from which these sugars are boiled, is drunk also as *toewak*, *sagoweer*, etc., either fresh or fermented, sometimes infused with *kajoe timor* or other *strychnaceae*, and in the Moluccas, especially in Ambon, where the abuse of this intoxicating and enervating beverage is greatest, is brought daily to all the passars in large bamboo tubes (*lodongs*).

After further fermentation this *toewak* or *sagoe weer*, produces the yeast, *ragi*, which is used everywhere for bread, pastry, etc. Where this is not procurable, *legen* is used, which is obtained in the same manner from the *cocos-palm* (*klapper-tree*).

The wood of the *Caryotas*, *Arecas*, *Lividonias* (III. 57); sometimes the *Licuala*, *wiroe* (III. 54), is used to make all kinds of smaller objects of daily use in house building, and even in hydraulic works, for posts, etc. The leaves for thatching, for all kinds of domestic utensils, baskets, etc. Finally, the fibre of a good many sorts finds a ready application.

The *rotan*, *pandjalim* from the *Calamus*, *spec. div.* (III. 103), may still be called a complete forest-production. Neither are the Palembang *rotan*, for pike-staves and walking-sticks, nor thin cane of Bandjarmassin, used for binding, chairs, etc., and matting, nor the *rope-rotan* of Java, nor the twisted *anchor-cables* of the Moluccas, productions of culture. They are an article of active commerce and export both to European and Indian commerce, all the various sorts being much in request.

In the matter of gum-resin, the *Daemonorops Draco* (III 95), also denominated *Calamus Draco*, furnishes one of the best species of *dragon's blood*. Rumph's description (in Amb. Kruydt-boek; V. p. 114, tab. 58) of the *rotang*, *djernang*, *Palamyncus draco* is, also for what he mentions about the manner of preparing the *dragon's blood*, *sanguis draconis*, still amply worth attention. Inferior sorts of *dragon's blood* are obtained from the *gebang*, *poetjoek*, etc. (*Coryphra umbraculifera*; III. 49) and the *wiroe* (*Licuala spectabilis* and *spinosa*; III. 52).—Vide, however, *Pterocarpus indicus*.

Pandaneae (III. 152)—The Pandaneae, so nearly related to the Palms, give as the most important product for commerce, fibre for mats; *tikar*, *klasa*, *glarun*, etc., of all kinds of sorts, some of them very fine, such as the *tikars* of the *Pand. samak* or *ketjil* (III. 165), which are plaited of the leaf-fibre. The young shoots of the *Pand. odoratissimus* (III. 156), shred present at all passars, much sought for in the interior, in great request on account of their odour, must also be mentioned here.

Polypodiaceae.—Of these, though many of the genera are now and then used by some local governments for house building, the only sort to be noted as of any value in commerce, is *penawar-djambee*, of a couple of *Cibotium* famous as a steptic.

Aroideae (III. 188), *Cyperaceae* (III. 250), *Gramineae* (III. 354), etc., have all partly fallen into regular culture, or need not be mentioned here. What the *Musaceae* (III. 586), *Bromeliaceae* (III. 584), etc. yield in useful product, is now obtained by regular cultivation, though they still occur besides and in good quantities in a wild state. The same is the case with the *Agaveae* (III. 583), originally not even indigenous, and therefore called by the natives *transmarine ananas sabrang*, at present wildly spread in a wild state. The *mendong* and other *Carex-species* (III. 346) are here and there worked up into small objects, and furnish fine plaitwork; *bamboo* (III. 415) is still fetched in great quantities from the woods, but quite identical with the regularly cultivated sorts. So we may here terminate this review, though rather reluctantly; the subject is in many details of far-stretching importance, but the limits we had set, to give a review of the "*Forest-productions*" did not even allow the mere mention of many productions.

An enumeration, for each branch, of all the materials for house and ship building, hydraulic works or household utensils, trade and industry, proved as good as impossible within our limited space, with the great changes going on in the use of local resources; while besides many materials are made subservient in many localities to all the details of social and domestic subsistence. So there remained only to offer a slight, and as much as possible a connected sketch of those materials, which are collected within the limits of "*Forest-productions*," to meet the requirements of social existence in those regions, and of trade and industry.

May the object—*the illustration of the productions exhibited*—be attained, and this contribution, however slight and superficial, serve as a stimulus to strive after a better knowledge of a number of the productions of our Archipelago, which, more largely known, would find more application, and thus contribute to the advantage of social existence, and the improvement and welfare both of our own country and of her beautiful possessions.

West India.—West India, save a few little collected *gum-resins*, furnishes no *Forest-productions* properly so-called, and even the eminently good sorts of wood of the interior remain restricted to local use, and unregarded by commerce. The earlier attempts of our Government and of others to reduce it to a regular branch of trade remained unaccountably abortive. Mr. H. A. Van der Speck Obreen, Engineer-in-Chief of the Navy, gave a general description of the "Timbers of European Guyana"; the "Tijds. voor Staath. en Statistiek," VI. p. 495, has an article on "The Wealth of the Surinam Forests in Cabinet-makers' woods"; in which among the rest, the *locust*, *green and yellow-heart*, *bébé*, *bolletrie*, *axe-wood*, *cedar*, *wane*, *kopie*, *krapa*, *peter-wood* and *sage-wood* are treated. The "Ned. Tijds. v. Nijverheid, 1877," give some informations concerning these; some other articles of Jhr. Van. Sijpesteijn, Focke and others treated this subject; we must refer the reader to them, not to depart too far from our limits.

The general impression concerning these woods was far from being unanimously favourable, the cause of many doubtful results was the *want of proper preparation*, a consequence of more general want of resources, especially of labour, and in this respect the prospects are still rather unfavourable. When once the means are discovered of providing for this, then our Guyana possesses an abundant store for us in her Sylvan flora. The recently published "Enumeration of the Surinam Plants and Cultivated Herbs, Trees and Woods,"* of Mr. Westerouen Van Meeteren, just returned from Surinam, gave us again an ample view of the field still to be explored, and pointed out what remains still to be done. This treatise is deposited at the exhibition. VAN MUSSCHENBROEK.

[Without intending it we have been guilty of an oversight in mentioning the work, by understating the pages of the voluminous work. The volume consists of 830 pages.—ED.]—*India Mercurry*.

VEGETABLE WOOL OR SILK-COTTON.

BY JAMES COLLINS.

In the *Journal* for September 28, 1883, p. 972, there is a note, taken from the *Moniteur des fils et tissus*, respecting a description of "Vegetable wool" from Java, exhibited at the Amsterdam Exhibition, under the name of *Kapoc*.

Kapoc, or kapok, as it is more usually rendered, is a Malayan word, signifying cotton or a cotton-like substance, *i.e.*, silk-cotton; real silk being known as *sutra*. *Kapas* is also used in Malay for cotton or silk-cotton, the same vernacular name obtaining in Bengalee and other dialects; but in this latter case the term is restricted to true cotton plants (*Gossypium spp*). Kapok silk-cotton is furnished by the *Eriodendron anfractuosum* DC., the *Bombax pentandrum* of Linnæas. The plant has been placed in various natural orders, some giving it a place in Bombaceæ, others in Sterculiaceæ, or in Malvaceæ. The tree is from 50 to 60 feet in height, the trunk being prickly at the base, and the branches growing out horizontally. There are five to eight leaflets, lanceolate in shape, and either entire in

* This enumeration included some later, formerly unnoticed data, and contains on the whole 1,000 names among which in 630 numbers, about 600 sorts.

their margins or serrated towards the apex. The capsule, or fruit, is five-celled and five-valved; the cells contain many seeds, covered with silky [illegible] hairs, which form the kapok or vegetable [illegible] of the tree, when mixed with spices, is used [illegible] complaints, and the seeds [illegible] tree is of rapid growth, and is [illegible] appearance. It is found in India, the Indian Archipelago, and in Africa, and other countries. In the East generally, Kapok is used for stuffing pillows, &c., and for tinder, but it has been found that the smoothness of the fibre prevents cohesion or "felting," so unless rendering it unimportant for spinning purposes. In Africa the tree is looked on with veneration, and is termed the "God-tree," in some districts it being looked upon as a sacrilege to cut the tree down. Still the trunk is used for making canoes, and although the wood is soft and liable to the attacks of insects, if soaked in lime-water it becomes much more durable. The silk-cotton, either alone or mixed with cotton, is largely utilised in Africa. The young leaves are used as food, and form not a bad substitute for "Ocro" (*Hibiscus esculentus*).

Another tree yielding silk-cotton in India is the *Cochlospermum gossypium*, DC., the *Bombax gossypinum* of Linnæus; a member of the tea order (Ternstrœmiaceæ). It is a tree attaining a height of 50 ft., and the soft silky hairs surrounding the seeds are used for stuffing purposes. The tree has large conspicuous yellow flowers, and is not uncommon in Southern India, Travancore, and Coromandel. The *Calotropis gigantea*, or Mudah tree (Nat. Ord. Asclepiadaceæ), also yields a like substance.

In America, both north and south, various so-called "milk-weeds," as *Asclepias verticillata*, and other plants, such as species of *Bombax*, &c., yield silk-cottons, whilst the *Asclepias syriaca* obtained the attention of European agriculturists as early as 1755, and paper has been made from the cortical fibres of this plant. The young shoots of the plant too are said to equal asparagus in flavour.

These are only a few of the plants yielding silk-cotton, which might be mentioned. Silk-cotton has made its appearance in the markets from time to time, and in 1851, the jurors of the Great Exhibition recommended this substance for stuffing purposes, and in mixed fabrics, and notices respecting it have occasionally appeared in this *Journal*. For the lining of quilts, quilted petticoats, &c., silk-cotton seems to answer admirably, but its want of cohesion, or non-felting qualities, renders it of no use for spinning purposes, except as a mixture to impart a silky gloss to the fabric so mixed. The price is low, it is light in weight, elastic and soft, and is said to resist the attacks of insects.—*Journal of the Society of Arts.*

IS THE RHODODENDRON POISONOUS?—I observe that Dr. Lindley (*System of Botany*) says that Rhododendron ponticum is "venomous," and it is often stated that honey made from its flowers is poisonous. I should be very glad to know whether these assertions rest on good ground. Mr. Webber writes to the *Agricultural Gazette* (Nov. 19, 1883) that he has recently lost several sheep in consequence (as he believes) of their having eaten the leaves of Rhododendron. He does not state whether the remains of Rhododendron leaves were found in the stomachs. I observed here a few days ago that some lambs had been eating leaves of Rhododendrons, either ponticum, or hybrids of ponticum. The quantity eaten was not very large, but no bad result has followed. The leaves are, I believe, bitter, and as a general rule both sheep and cattle let them alone; but it is a question of some importance whether they are or are not poisonous, as it becomes a question whether it is prudent to plant them in open pastures, and also whether bees should be kept in places where the shrub exists in abundance. [illegible] that Xenophon's soldiers, [illegible] Persia, suffered [illegible] from the flowers of the [illegible] uncertain what shrub [illegible] Dr. Lindley says [illegible] not as—or more—[illegible] The flower of this shrub is [illegible] tree than is that of the Azalea, and it is said to be extremely poisonous.—ALEX. [illegible]—*Gardeners' Chronicle.*

SOME experiments in manufacturing potash have been made by Dr. Warth at the Dehra Dun Forest School, and 250 maunds of undried sal wood yielded 3 seers of potash. —[illegible]

VANILLA, SUGAR, &c., IN TAHITI.—The cultivation of Vanilla [illegible] carried on at the present time to [illegible] the yield amounting to between 2,000 lb. an[illegible] annually. In the matter of sugar, however, the three or four small plantations at present worked are said to be insufficient to meet even the demands for home consumption. Oranges, Limes, Coconut and other fruits [illegible] with little or no care or culture.—*Gardeners' Chronicle.*

"THE TROPICAL AGRICULTURIST."—We have before us the [illegible] volume of this publication, compiled by Messrs. A. M. & J. Ferguson of Colombo. It is a veritable mint of information for planters of coffee, tea, sugar, cinchona, [illegible], and other tropical products. The difficulty, as in all similar cases, will be for the practical man to discriminate from all this mass what is really of practical use to him. There are no better means than that this journal affords of collecting and contrasting the experience of different men under the same or different circumstances. —[illegible] *Chronicle.*

TEAK WOOD.—I understand, says a writer in the *Garden*, that some of our enterprising hot-house builders are introducing this wood into horticultural buildings, and it is expected it will supersede pine to a considerable extent. It is light, strong, and durable, and not difficult to work. Teak baskets for orchids are now common, and gardeners know how much more lasting they are than those of hazel and other common woods. Lightness and elegance of structure are important considerations in hot-houses in more ways than one, and in this respect teak has the decided advantage, for it enables the builder to dispense with heavy rafters and beams, and is not much less durable than iron, to which it is preferable in other respects.—*Timber Trades Journal.*

HOW TREES SEARCH FOR WATER.—Mr. Daniell Swett, of Bay Farm Island, has sent us a curious root formation of the eucalyptus. It was found in the bottom of his well, about 16 feet below the surface. The tree to which the roots belonged stands 50 feet from the well. Two shoots pierced through the brick wall of the well, and sending out millions of fibres, formed a dense mat that completely covered the bottom of the well. Most of these fibres are no larger than a thread, and are so woven and intertwisted as to form a mat, as impenetrable and strong as though regularly woven in a loom. The mat when first taken out of the well was watersoaked and covered with mud, and nearly all a man could lift. Now it is dry, and almost as soft to touch as wool, and weighs only a few ounces. This is a good illustration of how the eucalyptus absorbs moisture, its roots going so far as to find water, pushing themselves through a brick wall, and then developing enormously after the water is reached. Mr. Swett thinks one of the causes of the drying up of wells is the insatiable thirst of these vegetable monsters.—*Alameda Argus.*

THE CORK OAK IN NEW ZEALAND.—In a paper read before the Auckland Institute, Mr Justice Gillies gives the following particulars —In 1855 the late Dr. Sinclair planted a young Cork Oak received from Kew. It is now 40 feet high, 14 feet in bole, with a crown of about 40 feet in diameter. The trunk at 3 feet from the ground is now 5 feet 9 inches in girth after stripping. For several years it has produced acorns, from which the present occupant of the grounds, Mr. John Hay, has raised a number of young oaks, and distributed them liberally through New Zealand. In 1877, I stripped the tree for the first time, and got a large quantity of virgin cork, [illegible] the first stripping being of no commercial value. In February last, I again stripped it, [illegible] the bark found the product to be 70 lb [illegible] cork fit for pint corks, and [illegible] It will thus be seen that [illegible] twenty to twenty-seven years old [illegible] then every five years [illegible] 10 [illegible] weight of marketable cork. [illegible] in quality with each stripping. On [illegible] New Zealand product with imported bark, [illegible] that the annual growth of the bark in Auckland is equal to that of the imported.—*Gardeners' Chronicle.*

BREAK-UP OF THE QUININE MANUFACTURERS' SYNDICATE AND THE PROSPECTS OF THE CINCHONA MARKET.

We must wait in order to be able to appreciate the full effects of what, from our special telegram, appears to be the dissolution of the Quinine Manufacturers' Syndicate by the action of the Howards in reducing the price of their quinine to 6s 3d per ounce. If the other manufacturers follow suit, 1884 may probably see the great fever medicine down to 5s an ounce, with enormous benefit to suffering humanity, and ultimately, we trust, with corresponding benefit to the at present unfortunate planter. The lowering of the price of an article of world-wide use has always the effect of largely increasing consumption, and subsequently the use of the article is continued, even if prices go up considerably. But even if prices are to remain permanently at one-half those which have for many years prevailed, that state of things will be better for the planters' interests than the deadlock which recently existed. The manufacture of the febrifuge will be so largely increased to meet increased consumption, that there will be a steady market, instead of a fluctuating demand with periods of depression when produce must be sold at unremunerative prices. As far as Ceylon is concerned, there can be no doubt that supplies of bark will for several years to come, be on a greatly re[illegible] scale. Twig bark and shavings from imma ure trees will cease to go forward, in view of the bitter experience of the past, in which prices did not pay freight, not to speak of the large numbers of trees uprooted or coppiced, that those which survive will be years before they yield marketable bark again. Discouragement has already done its work, and on many estates we have no doubt cinchonas have been removed [illegible] to make room for the new favourite, tea, or to give old King Coffee a better chance, for that revival of which many see signs of promise. Meantime, we should like to see the question of gradual reduction of alkaloids, instead of the increase which some reported, set at rest by a series of well-conducted and trustworthy experiments. In Java the progress in Ledgerianas has been ever onward. No doubt all in Ceylon who possess suitable soil and climate would do well to devote their attention to this the finest kind, with its thick bark, rich in alkaloid; but people can only cultivate what will grow, and there is a great deal of room for druggists' bark. There seems room to hope for an improvement in the demand for cinchona bark, and there certainly is much room for improvement; much room also for the use of the febrifuge where it is not now used. If we could get correct information we should probably find that not a tenth of the supply which ought to accompany the French troops to the marshes of Tonquin is on board the French transports. For the French army at home, we know the supply is scanty, while in Russia, where marsh fever is specially prevalent, we believe no quinine or allied febrifuge is supplied to the troops. The prices given for quinine and the risks run to obtain supplies of this medicine during the Civil War in America proved how essential it is for the southern portions of the United States. In truth only a fraction of the human family is as yet able to use what would be of benefit to all, and would save millions of lives annually. There is, therefore, we submit, a good prospect before those who have successful cinchona plantations of a fair market for their produce, especially the better qualities.

TEA CULTIVATION IN ASSAM.

(From the *Englishman.*)

From the report on the state of tea culture in Assam for the year 1882, we see that there were 1,017 gardens in existence during that period. Of these 743 are situated in the Assam valley, and 274 in the Surma valley. The area under cultivation during the year was 178,851 acres, divided between mature and immature plants, in the proportion of 156,707 acres and 22,144 acres respectively. The land taken up by the planters during 1882, but not yet planted out, was 6[illegible]4,511 acres, so that the total area actually held by them was 783,362 acres, or an increase of 76,713 acres over that of 1881. Within the last five years, the area under tea, together with the total area taken up and held as tea grants, have increased greatly. In 1878 the figures stood at 587,[illegible] acres, while in the year under report, we find it to have increased to 783,362 acres, thus giving an increase of 195,[illegible] acres in five years. The yield of tea in the year under notice amounted to 45,472,941 lb., of which 17,383,136 lb. were manufactured in the Surma valley, and 28,089,805 lb. in the Assam valley. The increase over the out-turn of the preceding year amounts to 7,901,630 lb., or an increase of 20 per cent. Some part of this increase, it is said, is to be accounted for by the fact that better information has been obtained this year, but undoubtedly a great portion of the increase shown is a real increase given by a larger acreage of mature plant, and helped by a more favourable year. The average yield per acre of mature plants has been 290 lb., as compared with 282 in the previous year. Of the tea districts, K[illegible] heads the list with an out-turn of 12,721,327 lb., and S[illegible] comes next with 11,347,337 lb. The other districts come in the following order:—Lakhimpur, 8,125,257 lb.; Sylhet, [illegible] lb.; Darrang, 4,556,198 lb.; Naugong, [illegible] lb.; Kamrup, [illegible]51,[illegible] lb.; and Goalpara, 66,[illegible] lb. The following figures illustrate the growth of tea production in Assam during the last five years, and will, perhaps, be of interest to our readers:—

	1878.	1879.	1880.	1881.	1882.
Assam	lb.	lb.	lb.	lb.	lb.
Valley	[illegible]	19,650,524	21,493,639	23,725,026	28,089,805
Surma Valley	[illegible]	11,735,812	12,519,944	13,848,285	17,483,136
Total	[illegible]	[illegible]	34,013,583	37,571,311	45,472,941
Average per acre of mature plants	2[illegible]0	278	282	282	290

In Goalpara the average cost of cultivation is believed to be R15 to R50 per acre, and the cost of manufacture of a lb. of tea 2½ annas. In Kamrup the cost of cultivation ranges from R50 to R100, and the cost of manufacture from 5 to 9 annas per lb. In Naugong the cost of cultivation is estimated at R70 per acre, and the cost of manufacture, including carriage to Calcutta, at 7 annas per lb. In Lakhimpur the cost of cultivation is returned from R1·4 to R240 per acre, and the cost of manufacture from 5 to 8 annas per lb. In Ka[illegible], the cost of cultivation is between R100 and 120 per acre, while in Silhet, R59-11-0 is given as the average cost of cultivation, and 5 annas as the cost of manufacture per lb. For the other districts no estimate is given.

Of the fifty six tea companies holding estates in Assam and registered in India, two show no paid-up capital, while the remaining fifty-four represent a paid-up capital of R1,71,18,6[illegible]7, and of these the following details are given: Eleven have struck their balance-sheets of profit and loss only up to the 31st December, 1881, forty-one have struck their balance-sheets up to the 31st December, 1882, and two concerns, with a capital of R5,17,639, have struck no balance-sheet of profit and loss. Of the forty-one companies which show balance-sheets of profit and loss in 1882, twenty-four companies show profits amounting to R4,40,254, and seventeen companies show losses amounting altogether to R2,46,088. The net earnings upon the capital employed during the year 1882, by the forty-one companies which have struck balance-sheets for the year, were, therefore, R1,94,166, or only 1·5 per cent. on their total capital of R1,27,84,443; the twenty-four companies which made a profit obtained a return of 5·8 per cent. on a capital of R75,95,903; while the seventeen losing concerns lost at the rate of 4·7 per cent. on their capital of R51,91,540. [Unless, therefore, the increased consumption of Indian tea leads to better prices, or unless cost of production can be largely reduced, it is clear that many Indian "concerns" must be soon closed up.—ED.]

A COFFEE GRADING MACHINE.—A new machine for grading coffee has just been produced in America. A blast of air is made to strike a sheet of falling coffee, so that stones and heavy impurities fall into one pipe, the large berries into another pipe, the small ones into a third, and the broken berries, husks and shells into a fourth. —*South of India Observer.*

LANTANA FIBRE.—Says the Wynaad correspondent of the *Madras Times*:—I have often wondered why an enterprising company has never been raised to do something lucrative with Lantana. It stretches away by the mile over some districts. The stems are of a tough, fibrous consistency, and would, I should imagine, be well adapted for many purposes. At present it is merely regarded as the grave of by-gone glories and the renovator of worn-out land.

AUSTRALIAN FRUIT IN INDIA.—A test shipment of Australian fresh fruit, consisting of oranges and lemons, is now in the market. This fruit was put on board the P. and O. Co.'s. Steamer at Sydney, and notwithstanding a fortnight's delay at Colombo, arrives at Calcutta in excellent condition. The result is so encouraging that an attempt will be made with peaches and apricots which are now in season in Australia, and can be supplied in unlimited quantity.—*C. and M. Gazette.*

AGRICULTURE IN BURMA.—In agricultural matters the progress made is not very great, but fairly satisfactory from all the data placed at our disposal. We need not refer to the cultivation of rice which, being easy and understood by the people, requires no fostering care to procure a yearly increase. The people like their own old fashioned mode of cultivation and will none of the—to them—new fangled ploughs and reaping machines. The form of agriculture which requires the encouragement of Government is that which from the laziness of the people rather than from the unsuitability of the soil or climate, is foreign to the country. We are glad to find that coffee planting is making rapid advances at Tavoy and in the Karen Hills. There is nothing, so far as we can see, to prevent coffee thriving on the plains in and about Rangoon. Mr. Fowle has about 100 plants of the Liberian species, about a year-and-a-half old, which could not be excelled. Mr. Aldis' farm in Maulmain, conducted on thoroughly scientific principles, should, in a short time, show most satisfactory results. Mr. Lucas, who is now devoting his attention to the growth of the mulberry with a view to the production of silk, a few years ago used to turn out from his land splendid silky jute. We notice that the Government have experimented in Arakan by planting 623 acres with the pepper vine. Mr Fowle's plantation at the Lakes, where he has produced this year 10,000 Havana tobacco plants, besides ground-nuts, beans and sessamum shows plainly enough what can be done with care and enterprize. Mr. Martini's little *brochure* on maize also points out another channel into which agricultural enterprise might be profitably directed on a large scale: but the question of cheap labour is the point on which the success of everything turns. Tea, cinchona, sugar, potatoes, and all sorts of peas and vegetables, could be grown successfully enough but for the cooly question; for all that has been done to increase immigration by subsidizing steamer Companies has not helped in the least to lower the rates for labour.—*Rangoon Gazette.*

WHAT KILLS FRUIT TREES.—Deep planting is one error—to plant a tree rather shallower than it formerly stood is really the right way, while many plant a tree a they would a post. Roots are of two kinds—the young and tender rootlets, composed entirely of cells, the feeders of the trees, always found near the surface getting air and moisture, and roots of over one year old, which serve only as supporters of the tree and conductors of its food. Hence the injury that ensues when the delicate rootlets are so deeply buried in the earth. Placing fresh or green manure in contact with the young roots is another great error. The place to put manure is on the surface, where the elements disintegrate, dissolve and carry it downward. Numerous forms of fungi are generated and reproduced by the application of such manures directly to the roots, and they immediately attack the tree. It is very well to enrich the soil at transplanting the tree, but the manure, if it be in contact with or very near the roots, should be thoroughly decomposed.—*Ploughman.*

INSECTICIDES.—The three most important and valuable materials now in common use as insecticides in the United States are—(1), arsenical compounds; (2), emulsions of petroleum; (3), Pyrethrum. 1. *Arsenical Compounds:* Paris green and London purple may be used in suspension in water in the proportion of from half a pound to 1 lb. of the powder to 40 gal. of water. When mixed with flour or other diluent the proportion should be one part of the poison to twenty-five or more of the diluent. 2. *Petroleum Emulsions:* A satisfactory emulsion may be made in the following proportions:—Kerosine, 1 quart; condensed milk, 12 fluid oz.; diluted with water, 36 oz. This is emulsified by violent churning, and before use it may be diluted with water from twelve to twenty times. Equal parts of kerosine and condensed milk may also be thoroughly mixed or churned together, and then diluted *ad libitum* with water. 3. *Pyrethrum:* Pyrethrum can be applied, (1), as dry powder; (2), as a fume; (3), as an alcoholic extract, diluted; (4), by simply stirring the powder in water; (5), as a tea or decoction. As a powder it may be mixed with from ten to twenty times its bulk of wood-ashes or flour, but before use should remain for twenty-four hours with the diluent in an air-tight vessel.—RILEY, *in "Encyclopædia Americana."—Gardeners' Chronicle.*

DEAD WOOD ON TREES.—The editor of this magazine, stated in these columns some years ago that a dead branch on a tree makes almost as great a strain on the main plant for moisture as does a living one, and many of the practical directions in this magazine have been based on this fact. Some good people, not satisfied with the authority called Prof. Bessey's attention to the statement, who thus replies in the New York *Tribune:*—"I have been asked whether the statement lately going the rounds of the American papers that 'a dead branch on a tree makes almost as great a strain on the main plant for moisture as does a living one' is accurate or not. The statement is coupled with another referring to its practical application in tree culture, the conclusion being that every dead branch 'should be at once cut away.' Briefly it might be answered that the first statement is true in the main, and that, without any doubt at all, the conclusion is a wise one, and ought to be followed in practice. To explain this matter will take considerably more space, and in order to understand it we must go to vegetable physiology and inquire into the nature of the evaporation of water from plants. It was long supposed to be a physiological process, and was considered to be entirely different from ordinary physical evaporation. As long as this view was held the process was called transpiration, to distinguish it from the physical process. The breathing pores, the stomata, which occur in the epidermis of all leaves in great numbers, were supposed to be organs of transpiration, which was considered to be one of the most important functions of the leaf."—*Gardeners' Monthly.*

ARE THE EARLIEST TEA CROPS FROM ESTATES ALWAYS THE BEST?

We ask, in view of what Sir James Caird said at the meeting of the Lebong Tea Company:—

I am happy to be able to say further that better prices have been realised from the early shipments of the Company's crop this year. The markets of late have not been so favourable, as those interested in this question must be aware; but we have reason to hope that the average result will show an improvement on last year. Some tea from the Barnesbeg estate has realised a high price, and a leading firm of brokers—not those employed by the Company—have drawn attention in one of their circulars to the fine quality of the Darjeeling teas from some of this Company's estates. Mr. Christison will be, no doubt, prepared to tell you that the quality of the Barnesbeg tea results from the fact that it is a comparatively new cultivation. Most of us who know anything of tea cultivation have found that it is in its earlier stages of cultivation that land if it is good, yields the best results.

Mr. LAW observed that the first duty devolving on the meeting was, he thought, to thank the directors for having called the present meeting so as to give the shareholders an opportunity of making Mr. Christison's acquaintance. (Hear, hear.) He was very glad to meet their general manager, and to see him looking so well. (The Chairman: He has been twenty years in our service, and does not seem the worse for it.) Now, there was one question he should like to ask. The teas that had come very much into favour lately had been the Darjeeling and Ceylon teas. The latter, in particular, had commanded this year very much better prices than the Assam teas. What he wished to know was whether the same seed and plant were used in the Ceylon as in the Darjeeling district? He quite confirmed what had been said about the high quality of the Barnesbeg teas. They had had during the past season as fine Darjeeling teas as had ever come to hand, and also tea of a very fine quality from Ceylon, but not much fine tea from Assam, so that the Barnesbeg teas had quite stood away. The current was now running in that direction, and undoubtedly these would be the teas in demand for the next few years. In former times Indian teas were used only to the extent of one-tenth in the combination with China teas, whereas now any one who knew his trade would use half-and-half. In conclusion, the speaker remarked he had heard with pleasure that the Board had engaged a gentleman possessed of mechanical knowledge because he understood that machinery was each year more largely used in the preparation of teas, and it was, therefore, very desirable the Company should have some one on the spot capable of repairing machinery if it got out of order (Hear, hear.)

Mr. CHRISTISON, replying to the foregoing remarks, stated that he had an opportunity of visiting Ceylon on his homeward voyage. He had stayed in the island ten days, and had inspected several tea-gardens. It is worthy of note that one of the oldest gardens he had visited had been planted with seeds from the estates of the Lebong Tea Comp ny, while the plants in the newest gardens closely resembled those under cultivation at Barnesbeg, which were a sort of hybrid Assam. Therefore it might be said that the variety of plant seen in Ceylon was similar to that in Darjeeling. With regard to the high quality of the Ceylon teas, referred to by one of the speakers, this was explained by the plants being young, the freshness of the soil, and the small quantity made. For these reasons he did not think they need apprehend any great competition from Ceylon, particularly in view of the fact that the tea-producing capabilities of the island were limited.

Mr. LAURIE suggested that when the Ceylon planters began to make tea in larger quantities they would not be able to turn out so good a quality.

Mr. CHRISTISON coincided in this view, and added that the growers were sanguine of replanting the old coffee estates with tea plants, but he did not share that anticipation, and contended that the supply from the island must always be limited.

Mr. WILSON asked what were the prospects as to the extermination of the red spider.

Mr. CHRISTISON answered that he hoped they had got over the worst of that difficulty. The plant was steadily regaining its vigour, and he was very sanguine now that the result of the working during the next six years would be more satisfactory than had been the case in the last six years. At the same time, it was to be borne in mind that the plants recovered slower than he had expected, and that they must expect to be troubled every year more or less with the red spider.

After a remark by Mr. TYE regarding the character of the cultivation carried on the Company's estates.

Mr. CHRISTISON observed that the red spider disease had been largely brought about by the excessive degree to which high cultivation had been practised during the last few years. This order of things had been since reversed, and their chief object now was careful cultivation. The present was an expensive system of cultivation, but it was the one that paid best in the end. The experience he had had, and the study he had made of the potato disease—similar in many respects to that of the red spider—led him to believe that the best cure lay in improving the general healthiness of the plant. (Hear, hear.) He might add that various remedies had been tried, such as lime-water, tobacco-juice and sulphur, but with no very satisfactory results. Nevertheless it was his intention to attempt one other cure on his return—namely, the application carefully carried out of paraffin-oil judiciously diluted with water so as to prevent any injury accruing to the plants.

The CHAIRMAN said that Mr. Christison's reference to the similarity between the spider and the potato disease reminded him that some years ago, the late Dr. Darwin had instituted a series of experiments, with which he had been good enough to associate him (the speaker), with a view to trying whether the potatoplant could not be so invigorated as to enable it to resist the disease. There could be no doubt, speaking from the latest experience on the subject, that in this suggestion the best cure was to be found for this terrible disease.

Mr. LAW felt no hesitation in repeating before Mr. Christison's face what he had already said behind his back, and in moving that the best thanks of the shareholders, together with an expression of confidence in his management of the Comp. uy's affairs in India, be accorded to the general manager.

Mr. TYE seconded the proposition, which, on being put, was carried unanimously.

Mr. CHRISTISON briefly acknowledged the compliment.

Mr. LAW had pleasure in moving a vote of thanks to the directors for their courtesy and consideration in affording the shareholders an opportunity of meeting Mr. Christison prior to his return to India.

Mr. TEMPLE LAYTON seconded the resolution, and in doing so asked, as a partner in the firm of brokers who sold the Company's teas, to be allowed to endorse the statement of one of the speakers as to the particular favour in which this Company's teas were held by the public generally. Now the season why Indian tea had gained public favour so rapidly and considerably—a fact testified to by the returns of the past month, which showed an increase of 800,000 lb. in Indian tea, and a falling of 500,000 lb. in China tea—simply lay in the fact that consumers found that they got a better article from Inida than China. All this pointed to the necessity of maintaining the quality of their tea, otherwise the time might come when the Ceylon people would cut them out of the market as India had done China.

All the above is very interesting to us in Ceylon. We suspect there is more room for the expansion of the tea enterprize here than Mr. Christison imagines. But we are utterly at sea as to what this gentleman meant as excessive "high cultivation" encouraging red spider, while the object now is careful cultivation. The red spider in not a fungus like the potato rot and leaf-disease, but as insect, as are all the tea blights of which we have read.

TEA BOXES.

(To the Editor of the *Indian Agriculturist.*)

Sir,—Will you allow me a little space in your columns to give publication to the result of an experiment tried by me on wood used in the manufacture of tea boxes. My attention was first drawn to the subject by an articlo in the *Indian Agriculturist*, dated 1st of March 1883, from which I learned that some pieces of a tea box which had corroded the lead lining, and destroyed the tea, had been sent to India by Professor Dyer of Kew to be identified. As this is a question of great importance to all interested in tea, I determined to try an experiment with the different kinds of wood used by manufacturers in Silchar, and obtained from each workshop two small boards of each kind, one seasoned and the other green. Between these boards I placed a piece of tea lead, tied them together and put them in an almirah. After two weeks they were opened and examined, with the result that the green board of the wild mango (*Mangifera Sylvatica*) had corroded the lead, the surface exposed to it presenting exactly the appearance described by Professor Dyer—*i. e.*, it was covered by a white coating of carbonate of lead. When held to the light, it presented the appearance of having been perforated with a pin. The surface in contact with the seasoned wood was untouched. From this, it seems pretty evident that the green mango wood contains chemical properties injurious to tea lead, which are either dissipated or otherwise rendered harmless by the process of seasoning. The other kinds of wood had no effect on the lead. H. J. Young.

Asst. Conservr. of Forests, Cachar Division.

Silchar, October 4th 1883.

REPORT FROM A LOWCOUNTRY ESTATE NEAR HENARATGODA.

22nd Jan. 1884.

From the 24th Nov. to the 11th Dec. the weather was dry, thence to 24th it was showery, and on the latter day we had a terrible thunder shower that lasted only 30 minutes, but in that time did immense injury. Since then, we have only had two slight showers. The wind has been blowing a stiff breeze, rising at times, to the dignity of a gale, and at times blows as stiffly and steadily by night as by day.

The fungus is *in statu quo*; but, as no coffee tree on the place is free from it, we may expect it to play its usual game, when a change of weather favours its propagation.

I have gathered a part of the crop, and will go over the field again in a few days, but on the trees that have been rendered bare by the fungus, ripening does not proceed satisfactorily—the berries colour to a certain point, and remain so for weeks.

Everything seemed to enjoy the dry weather and grow with greater vigor for the first fortnight, but its continuance checked the spurt, and now some things are setting up a flag of distress.

The surviving cacao in the old field has suffered a good deal from the wind, and the coffee has been stripped of all badly affected leaves, indeed many trees are under bare poles. The tea and cardamom nurseries require daily watering, and our wells begin to fail. The Ceylon tea seed has given a larger proportion of plants than the Indian, but they do not appear to me to be so strong at the same age. All the very small seeds have failed to germinate, and most of those of hemispherical shape; many seeds have germinated in the ground, but neither send a radicle down nor a stem up.

In some parts of the field the tea is making great strides, but on other parts it is still hanging back; when the dry weather set in there was a general start, but that has been checked the more advanced plants however still hold their own. One plant left in the nursery; has attained the height of four feet eight inches, but it is a single stem, without a branch;* I prefer those that are from two to two and a half feet, with from forty to fifty branches.

The nutmegs continue to thrive, but only a small proportion of the cloves have survived. If the bearing of the pepper should be such as the vigorous growth of the plants indicate it will become an important item in balance sheet by-and-by. The few vanilla plants have been getting so well that I will be able to add to the extent when the rains come, something like four to one. I am carefully watching the 600 highcaste, arecanuts, along the roads, and I think unless the drought continues an unusual length of time they are pretty safe I have enough cardamom plants in the nursery for the field I propose planting with them. The cotton trees grow with such rapidity, that I think each will be sufficiently advanced by May to support a pepper plant. I have ascertained that the price offered for this kind of cotton, by a Colombo firm, is R8 per cwt. including the seed, and only rejecting the outer husk; and each tree is at three years old good for twenty pounds. I would like to know what the Australian price is.

I have said little about Ceara rubber lately, but I have not ceased to study, in search of the means of obtaining the largest measure of the secretion, with the least labour and least injury to the trees. If the system that has grown out of a twelvemonth of persistent experiment fails in practice, I will leave the problem to some stronger brain. The system I have formed has not yet been put in practice, as the principal tool has only lately taken form in my mind, and I have to get it made, but as soon as it has been tried I will report progress. It is very evident that unless 1 lb of rubber can be collected at or under fifty cents, we have only introduced another weed into the country. Meantime, I may say that half the trees grown from seed are good for nothing; and as soon as their character is ascertained I would root them out and replace them with slips from a good jat, if it is ultimately found that the cultivation is worth carrying on, which is still somewhat doubtful. It has become clear, that planting 10×10 feet is a mistake: the proper distance is 20×20 feet, or 108 to the acre; and unless each tree yields 1 lb per annum, at a cost of fifty cents, the plant ought to be exterminated, as soon as possible. I have no trees that will yield one pound of rubber, coax and tickle them how you may. From a perpendicular gash six feet long, the milk ceases to flow in less than five minutes, and the result when dry is a mere scale, five hundred to the pound. Whether the yield improves with the age of the tree, I am unable to say, but it is probable that it does so.

26th.—Drought still.

* Is our correspondent certain? Branchless Liberian coffee trees are common, but branchless tea plant we never saw.—Ed.]

THE "CHALLENGE" TEA-ROLLER.

Sir,—My attention has been drawn to a paragraph which appeared in your paper after the trial of the "Challenge" tea-roller, which took place here.

I deny that leaf was "found to have been thrown on the floor and left wet and thick. The leaf was spread over shelves and floor in the usual manner, with care; it was *not* thick.

From a perusal of the letter above referred to one would come to the conclusion that *all* the leaf was brought in wet, *all* the leaf was thrown on the floor, and *all* the leaf was "unworkable." This is not the fact. The morning leaf *alone* was wet with dew, and *some* of the leaves, in spite of hand tossing, had been laying stuck together 2 or 3 thick.

It will be seen that only 2 rolls were put back into the machine for a second turn. These contained the under-withered leaf.

I cannot conceive what caused the writer of the above-mentioned letter to make such a grave misstatement. Either he took his information at second-hand from incompetent sources, or he wilfully distorted facts, hoping thereby to benefit the "Challenge," and without regard to the feelings or interest of others. In the former case, he is to be pitied; in the latter avoided. H. L. S. Ingles.

Mariawattie, Gampola, 22nd Jan., 1884.

[The above was sent to the local "Times," and Mr. Thompson, who wrote the letter complained of, has apologized,—after a fashion.—Ed.]

A Ceylon planter of experience states that tea plants raised from cuttings, run to seed, and that the liquor made is not so strong as from leaf taken from plants raised from seed. He adds that the leaf will tend to deteriorate the teas by mixing. We can hardly accept these statements as correct. The Hill planters have more experience of tea than those in Ceylon and ought to have to say something on the subject. Propagation by cuttings as far as we have heard here is unobjectionable in every way.—*South of India Observer.*

Correspondence.

To the Editor of the Ceylon Observer.

WANTED TO KNOW.

Munzerabad, 18th Dec. 1883.

Dear Sir,—Would the correspondent from Upper Maskeliya, who writes from thence in *Tropical Agriculturist*, page 442, answer the following questions :—(1), Name of estate where a cooly could only "pick five trees per diem"; (2) year when it occurred, as "brave and halcyon days" is a trifle vague; (3), number of trees per acre on particular estate; (4), how many berries there is in a bushel. A rough estimate will be sufficient. I have been told by Ceylon planters that coolies will pick a bushel with ease by midday, so that, we may safely say that *the* cooly picks two bushels "from five trees per diem." I shall be much obliged for answers to same, so that the usual picking off an acre in the "brave and halcyon days" may be known. Let us hope that the cardamom poochie will not inflict much damage. A poochie eats a small percentage in this district, and, no doubt, your correspondent "Aberdonensis" will kindly forward information regarding *Hoolka* "cardamoms." Should any of your correspondents send cardamoms to London in boxes, let them beware of partially-seasoned wood.—Yours faithfully,

LOONIE.

PAPER-MAKING FIBRES.

Warwick Lane, Paternoster Row, London, 19th Dec. 1883.

Sir,—Can any of your readers inform me if Ceylon produces a fibre in sufficient abundance to become a marketable commodity for paper makers?

The requirements are that the fibre must not require more chemicals to separate it from its envelope of silver and woody matter than is required for Esparto. Secondly, that the supply must be constant, and in sufficient quantities. Thirdly, the price on the Thames or the Tyne must not exceed that of Esparto, say £8 10s per ton for very clean fibre to £6 for inferior.

Bamboo is on its trial, but it is expected that the quantity of chemicals required to convert it into pulp or "half stuff" fit for the paper makers, will be found too large and costly, to admit of its economical employment.—Your obedient servant,

J. VERNON WHITAKER.

[Bamboo being excluded, we believe we can answer at once on behalf of our readers and say that no fibres from Ceylon can be placed on the Thames or the Tyne at even twice the prices named.—Ed. C. O.]

CEYLON GAMBOGE.

Lunugala, 3rd Jan. 1884.

Dear Sir,—Kindly let me know through the medium of your columns, whether the gamboge I herewith send you is of any value, and if there is any local market for it in Colombo; also the easiest and cheapest way of extracting the gamboge, and how to prepare it.—Yours truly,

A. G. C.

Note by W. F.

Your correspondent should have told you the name of the tree he procured the gamboge from, or sent a specimen of the tree for identification. His specimen dissolves only partly in water, and, instead of a deep yellow, a pale milky one is the result.

The specimen is, therefore, not likely to be from the only plant in Ceylon which produces a gamboge of any value.

Of the genus *Garcinia*, with which that of *Xanthochymus* has been incorporated by Sir Joseph Hooker, we name the following plants indigenous to or growing in Ceylon, all of which produce a yellow gum-resin rom incisions in the bark or unripe fruits:—

1. *Garcinia mangostana*, Linn., the famous mangosteen fruit, a native of the Indian Archipelago, but now common in Ceylon, especially at Kalutara. The gum from this plant is of no value.

2. *G. cambogia*, Desrouss. This is the common goraka, with ribbed fruits of various forms, sizes, colors, and degrees of sweetness, some of them nearly equal to the mangosteens. The gum from this tree, though described by Mr. W. P. Ferdinands in one of your issues and in the *T. A.* as the gamboge of commerce, is worthless as a pigment, because it does not dissolve in water, but will in turpentine, and then forms a yellow varnish, which might be used for brass or copper vessels.

3. *G. echinocarpa*, Thwaites. The madol-gaha of the Sinhalese,—and hence Madul-sima—from the fruit of which an oil is extracted by the Sinhalese and is used in lamps, but it is thick and not good. A common forest tree from the Western Province across the island to Madulsima.

4. *G. morella*, Desrouss. This is the gokatu or kana-goraka of the Sinhalese, and the only tree in Ceylon which produces a gamboge which can be used as a pigment and in medicine, and was sent from Ceylon in former times as real gamboge; but the tree from which the real gamboge is procured is a native of Siam, and, though supposed to be the same as *G. morella*, it has now been separated by Sir J. Hooker, and called *G. Hanburii* in honor of the late Daniel Hanbury, who published a figure and description of it. For an exhaustive account of this plant, and a summary of information on the subject of the gamboge-producing plants of India and Ceylon and the modes of collecting the gamboge, see the article No. 33 in *Medicinal Plants*, by Bentley and Trimen, vol. 1, copied into your *Tropical Agriculturist* for 1882-83, pp. 530-1.

The gamboge is procured from incisions made in the bark of the tree, and is collected after it has dried to some consistence on the bark.

5. *G. terpnophylla*, Thwaites. This tree produces a hard and heavy timber, and is known as the kekatiya of the Sinhalese, but produces gum of no value as gamboge. It is a common small tree from the Western Province to the central parts of the island.

6. *G. xanthochymus*, Hooker, fil. formerly *Xanthochymus pictorius*, Rox., and *X. tinctorius*, D. C. This is a small pyramidal handsome tree with a dense mass of long dark green leaves quite common as a cultivated plant near Colombo and elsewhere in the island, and known as the rata (foreign) goraka. Its yellow fruits are eaten when ripe and make a fairly good tart. Though the specific names of Rox. and D. C. would indicate that its gum was used as a pigment, Rox. said of it that it yielded a large quantity of indifferent gamboge.

7. *G. spicata*, Hooker, fil. This is a common plant in the Northern and North-Western Provinces, and is a very abundant small tree or large shrub in the peninsula of Jaffna and well-known there under the Tamil name kokoti, and which the late Dr. Gardner pronounced to be the real gamboge tree, but this is of course a mistake. This plant was described as *X. ovalifolius* Rox. and *X. spicatus*, W., and A. Towards Chilaw it is found as a considerable sized tree. There are several small ornamental trees of this plant growing in the Circular Walk from seeds sent to the late Dr. Elliott by the late Mr. Dyke, Government Agent of the Northern Province, about 30 years ago. These plants appear to be quite diœcious. This plant is the ela-gokatu of the Sinhalese, and Thwaites says that the tenacious gummy matter which exudes from the trunk is of no value.

W. F.

RUBBER CULTIVATION IN BANTAM.

Tjiekandie Oedick, 7th January 1884.

DEAR SIR,—To commence at the commencement I beg to wish you all a happy new year and the "Old Rag" and *T. A.* many years of prosperity to come.

The saying is "Nothing succeeds like success." Success has not been our fate in Bantam during the last years with regard to indigenous crops. But *rubbers* make an exception in our case, and their success is so certain that we are going the "whole hog" in that line. I have now about 30,000 *Ficus elastica* and 5,000 Ceará a part of which we are going to tap during the next dry season. We have just received two bushels of Ceará seed from Ceylon, which will be planted out this year. We then expect to have a *respectable* plantation which will be yearly increased up to a *million* or more trees. I like the Ceará the best for various reasons. They are easily propagated from seed grown rapidly in any soil and at any height. They can be closely planted, and seem to harmonize with all other trees. I have Ceará and Liberia growing shoulder to shoulder and both doing well. The Ceará makes a capital shade tree for coffee, and I am now planting *pepper* to run up the trees. My letter will prove to be like a Dutchman's or lady's—the substance or point at the tail-end or in the *postscriptum.* The fact is I have an "*axe to grind,*" and, as you are known to be blessed with the necessary snap and go-aheadativeness, I knock, at your door. Please favour me with your candid opinion regarding the best method of tapping and preparing rubber. My *partner* is *a sanguine Aberdonian,* and I am a *Yankee*: thus for your countryman's sake I hope you will do the thing. It may not be uninteresting to your go-ahead Ceylonese to know how I plant my rubbers. The *principal* work is done with an 8 h. p. *steam plough* (Fowler) which turns over about four acres a day 14 inches deep, taking out the *alang-alang* grass by the roots: you call it Illeck [iluk.—ED. C. O.] I think; it is the horror of all planters here. We then proceed to plant *Ficus elastica* 20 feet. Between the *F. e.* (in the row) we plant Liberia coffee *at stake (*with seed) and down the middles Ceará rubber 10 feet apart. I plant *all my coffee at stake now*! My plan is little and good. A tree raised where it is planted is worth a dozen sickly plants out of the nursery transplanted by natives who have no interest in anything as long as they get their pay at the end of the month.

More anon from yours very faithfully,

H. E. KIMBALL.

[Our correspondent will see from correspondence in the *T. A.* that improved methods of tapping have been adopted, but that the whole question of the profitable extraction of the gum is still under debate.—ED.]

VARIETIES OF FRUIT ON THE SAME TREE.

10th January 1884.

Dear Sir,—In your issue of the 8th instant, Mr. Holloway asks for information as to the cause of one of his cacao trees bearing three varieties of fruit. This peculiar phenomenon, though unusual, is by no means so rare as might be supposed, being an effect of fertilization by pollen from a different variety, and is a remarkable instance of the prepotency of strange pollen on the germ, even to the modification of the embryonic attributes. The most frequent instances of its occurrence are witnessed in the apple, where two varieties planted close together bear fruit resembling each other, principally upon their adjoining branches. Several cases have been noted where portions only of the fruits have presented the appearance of those borne by the variety whence the male element was derived, and a very remarkable instance of this was produced by fertilizing the flower of an orange with the pollen taken from a lemon, and the fruit resulting from their union in this case had one segment of the peel in which all the characteristics of the lemon were produced, colour, flavour, &c. On Mr. Holloway's cacao tree No. 1 is the natural fruit; in No. 2 the direct action of the pollen from the Trinidad tree has so far predominated over the female element as to also affect the ovarium, and the characteristics of the two fruits, or rather capsules, have become fused equally; whilst in No. 3 it has gained so complete an ascendency that the attributes of the male element alone are exhibited. These two variations should produce very superior plants, and Mr. Holloway should preserve their identity very carefully so that he can subsequently ascertain their respective inherited qualities with no chance of error. What is popularly termed throwing back amongst animals is analogous to this phenomenon, but of course flowers cannot 'throw back' since they can only be fertilized once.—Yours faithfully, SWADDY.

ANOTHER TRIAL OF SUGAR CULTIVATION IN CEYLON?

Rock Hill Estate, Badulla, January 11th, 1884.

DEAR SIR,—Having recently met with some sugar planters from Queensland and Fiji, and from what I saw of the sugar industry during my residence in India, I am inclined to believe that it would grow and pay well, if cultivated in the lowcountry. The ryots of India pay five rupees per acre for irrigation, and you may rely on it, that they would not, or rather could not afford to do this; unless they realised handsome returns for their time and labour.

I know sugar was tried here some years ago, and it proved a failure, except in the case of Baddegama. I consider the want of experience coupled with the possibility of their having planted an inferior jât in bad soil caused this. The fact of two or three men ing failed is no reason that the cultivation should be looked upon as a foregone conclusion. Take even certain coffee districts which have long since been abandoned, did the fact of their having proved failures defer others from planting the fragrant bean in other parts of the island?

Sir Arthur Gordon has been Governor of two countries where the sugar industry was paramount, we might look to him for assistance in the way of giving grants of land should any planters take up the cultivation of this valuable product. GUNNER.

TEAK SEEDS.

Kew Gardens, Slave Island, Colombo, 12th Jan. 1884.

DEAR SIR,—Can any of your correspondents say how teak seeds can be made to germinate? I have tried to do so by adopting various methods and failed.—Yours faithfully, M. S. J. AKBAR.

MODIFIED LEAF DISEASE AND HOPE FOUNDED THEREON.

Kandy, 15th January 1884.

DEAR SIR,—I enclose a couple of coffee leaves picked at random. You will observe that the fungus has turned brown and dried up without advancing beyond the pin-spot stage. May we not hope that there is something in the atmosphere inimical to the proper fructification of *H mileia?* Who knows! perhaps Sir Arthur Gordon's advent is to inaugurate an era of prosperity for poor Ceylon! HOPEFUL.

DISCOLOURED TEA LEAVES.

Kandy, 17th Jan. 1884.

DEAR MR. EDITOR.—Can you tell me what is the matter with the enclosed tea leaves?—they are off plants about 10 months old; and also can you tell me if black bug does harm to tea?—Yours faithfully,

TEA.

[The leaves are of a coppery colour and look as if withered. Many years ago, we sent similar leaves to the late Director-General Thwaites, who said the affection was of no consequence. We have not seen black bug on tea so as to harm it.—ED.]

THOMPSON'S TEA-ROLLER.

Colombo, 21st January 1884.

DEAR SIR,—I regret advantage should have been taken to misread my letter to the Ceylon "Times" describing trial of 15th inst. For instance (if my recollection serves me right) no such words as "well fermented" or well-fired were used, or even suggested; the appearance only of the teas is spoken of, the names of well-known and respected witnesses being given who also as stated had their attention drawn to the state of the leaf. I cannot see that the public care to know how or why the leaf was as it was; * and even if they did, one cannot always command the space nor do they care to trespass on the courtesy of an editor, to go into uninteresting details to explain the difficulties caused by the end wall of tea-house being down to get a firing machine erected, the extra work and general confusion caused by the same and by the sudden and complete change in the system of manufacture just being inaugurated, added to this the disorganizing effect of a pay day. † I feel that any practical man will quite understand this, and I address them only. To others I would remark "nothing succeeds like success," and since the Mariawatte machine has been working daily most satisfactorily, that it is sold and other orders are in hand I think is sufficient reply to carping critics. ‡

I also take this opportunity to answer one of your correspondents' suggesting reduction in prices. I would say in the first place that the actual cost of the machine is much greater evidently than your correspondent thinks, and the value of such machinery is not based on its cost of construction, but on the money it brings to the purchaser by economical production or production of a better article or both. This machine does both, and I invite comparisons with any other method or machine and have yet to learn that any will for a moment compare with the "Challenge," although the present prices are lower than other recognized machines. This machine will, if kept in full daily work, more than pay itself in two months. § Since it clears about £2 per day, it comes to this: the purchaser gets 50 per cent per month during his manufacturing season. If anyone can suggest a better investment for a tea planter, the writer would be pleased to hear of it. Some are appreciating this transparent fact by availing themselves of the present prices as they are much more likely to rise than fall. ‖—I am, dear sir, yours very faithfully,

ANDREW THOMPSON.

* The public, having been appealed to, had certainly a right to know the whole circumstances of the case.—ED.

† All this we are glad to see, for the sake of the superintendent of Mariawatte.—ED.

‡ It is *not* a sufficient reply to those who regard "80 to 90 per cent of pekoe" as a violation of veracity.—ED.

§ "Pay itself in two months!" *Credat!*—ED.

‖ Most decidedly they ought to rise in price, *if* they produce 80 to 90 per cent of pekoe and pay themselves in two months.—ED.

MR. W. CAMERON ON THE ANTIQUITY OF THE CLERIHEW PRINCIPLE.

Ythanside, Dimbula, 22nd Jan. 1884.

DEAR SIR,—Although, in my remarks on the use of heated air moved by fans, etc., for drying purposes, I used the name "Clerihew" as being best known here, yet the invention is old, and likely belongs to the learned and eminent Dr. Andrew Ure. It was in use for ventilation in public buildings in London forty years ago nearly.—Yours faithfully,

WM. CAMERON.

THE KOLA-NUT TREE IN CEYLON.

23rd January 1884.

DEAR SIR,—By this post I am sending you a fruit of the kola-nut tree, as I promised some time ago. The parent tree was imported by Mr. Wall, in September 1879; and the fruit that I am sending you is one of a bunch of five, which are the first that have ripened. The tree, which is planted on the poorest of iron-stone gravel, at an elevation of 900 ft., is 15 ft. high by 8 ft. across, and as the leaves are fairly tough (not unlike those of the better kinds of mango, which, indeed, it slightly resembles in growth), I should say that Mr. Prestoe's description of it in the current No. of the *T. A.* is correct, that "it flourishes in comparatively poor soil and in exposed situations." In fact, for hardiness I should place it midway between the cacao and the Ceará rubber. Like the former it produces a large amount of abortive blossom. The pods vary much in size and number of seeds, the one I am sending you being one of the best. When ripe, the pod splits open slightly and falls to the ground. You will find the seeds have a pleasant smell, and, if the tree is not already established in Colombo, you may think it worth while to plant them.—Yours faithfully, ARTHUR G. ROBSON.

[We are much indebted to Mr. Robson for his interesting letter. The pod resembles that of the cacao, but is green in colour and with rough excrescences on the surface. The seeds look like very large jak-fruit seeds (we had no idea the seeds would be so large) with shining yellow skin. The odour is very much that of over ripe apples. The open pod display six big seeds (three opposite three).—ED.]

MR. THOMPSON'S "CHALLENGE" ROLLER.

The Sanatorium, January 24th, 1884.

DEAR SIR,—With reference to a "leader" in your issue of 22nd instant, in which you state that you *do not believe* that 80 or 90 per cent of pekoe has or can be made by means of the "Challenge" roller, I beg to state that this is quite possible, but does not depend so much on the roller as on "fine plucking" and on what sieve is used in the sorting.

From some rather fine plucked leaf and using a medium meshed sieve I turned out between 85 and 90 per cent of BROKEN PEKOE, valued at 2s 6d per lb., a short time ago.—Yours faithfully, K.

[By discriminative picking and seiving of course, it is possible to get *all* pekoe. But that is not ordinary tea manufacture.—ED.]

MESSRS. JOHN GREIG & Co.'s TEA MACHINERY.

Colombo, 24th Jan. 1884.

DEAR SIR,—In response to your invitation for accounts of the working of Messrs. Greig & Co.'s tea machines in Ceylon, we have the pleasure to give you the following extract from a letter addressed to us by Mr. George Kyd, of Fairlie, Dolosbage:—

"I have to say that I found the Greig Rolling

Machine, we had on Kellie estate, to do its work very well indeed. It makes a good, even roll, giving the leaf a good twist, and does not break the leaf so much as some other machines in use. The quantity of work I could get out of the machine was about 200 lb. of withered leaf per hour. *I have no hesitation in recommending the machine for the quality of the work that it does.*"

We have in stock several of Messrs. Greig & Co.'s machines for hand, steam or water-power, and shall be happy to give full particulars of same on application.—Yours faithfully, W. H. DAVIES & Co.

MR. W. CAMERON'S CINCHONA AND TEA DRYING APPARATUS.

Dear Sir,—I have been glancing over Cameron's plans of a "bark drier," and his remarks thereupon. It seems to me that he is out in his views on one or two particulars; and, as the subject is of importance to planters at present, I need no apology, I think, in showing where I believe he is mistaken.

1st.—Regarding the comparative merits of iron and brick as a heater, he says something about iron giving out heat by radiation, and brick by conduction. I think he is wrong in that: I would say it is the other way. However, the chief point regarding their respective merits is, that the conductivity of iron compared to brick clay is about 30 to 1. Consequently a flue of clay, to extract from the fire the same amount of heat as an iron flue, would have to present a surface 30 times as large. For economy of space, therefore, iron is preferable.

2nd.—It is hardly correct to say that the limit of heat extracted from the fire is merely "*that sufficient be left to take the smoke up the chimney.*" In a long flue, for example, near the fire it is being heated up to, say, 600°, that is, the flue takes out the heat at 600°; a little further from the fire, it takes it out at 400, then at 300, 200, 100 and so on. Now if you want to use heat (say heated air) at 400, all that is taken out at a lower temperature than 400 will not raise the temperature of your heated air, but lower it. Therefore, the limit of the amount of heat you extract from a fire, is the temperature you wish to use the heat at. If you wish 400, it is 400 or a little over 400, as you must allow for waste in transfer. All below 400 must be disposed of up the chimney. For quick reception, and quick giving out of heat, at high temperatures, metal has the advantage. Copper is about three times as good as iron, so copper is used in the flue tubes of boilers.

3rd.—Mr. Cameron seems hardly to have understood the "Clerihew," and so has failed to see one very important particular in which it has an advantage over his method.

When hot air comes in contact with moisture, the water is evaporated, taking from the hot air its heat to effect the evaporation; consequently the air gets cooler, and with its moisture tends to *descend*. In Cameron's drier, this result may be expected. The hot air finds its way up through among the bark, what of it is effectual in drying bark gets heavier by the process and tends to go down again, to get reheated before it ascends. But although it may be reheated, it is not so good for drying as fresh unmoistured air. Also any portion of the originally heated air that escapes without moisture rises and passes off uselessly. By reversing the process, and sending the dry air in above the bark and drawing the *heavy moist air* that has done its work out below, only used air is removed, and *all* the dry air has to do its work. If he would reverse his process in accordance with this, he would find his drying not by half so expensive.

For want of observing this, he has failed to comprehend the principle of the "Clerihew." The fan in the "Clerihew" is not to *help* the air-pressure resulting from the heated air, but to *overcome* it. In the "Clerihew," the air, after being heated, ascends by a flue to the upper story, being raised by the greater pressure of the external air, of course. To *overcome* this pressure and draw the heated air down, the fan is used, having its place below the floor, or if there be more than one floor below the floors, of the air-tight room. Thus drawn down through the coffee, tea, bark, or whatever is a-drying, all the good of the heated air is taken out of it. I do not quite understand his system of shelves *movable* and otherwise. I observe he states what is very true, "that the air will go through where it can get easiest. Therefore any *hole* would allow air to pass, and so go to waste. A large hole would let all the air pass, so that, it seems to me, the movable trays would be a mistake, as when removed, all the rest of them would be useless till the movable one was restored to action. Even any inequality in the thickness of the coffee, &c., spread over the floor is a disadvantage, as the greater quantity of heated air would pass through the thin-spread, where there was least required. Such are a few points that seemed to me to be defects in Mr. Cameron's plans. I send them to you, that the judges may take them for what they are worth.—Yours truly,

J. B.

[We find that it will be impossible for us to reproduce the plans.—Ed.]

SUGAR CULTIVATION IN CEYLON.

Kandy, 26th Jan. 1884.

Dear Sir,—I have lately noticed a letter in your paper relating to the cultivation of sugar in Ceylon. Some years ago I had occasion to investigate the circumstances under which sugar has been successfully cultivated in Australia.

With a view to reopening the subject of its cultivation in Ceylon, I may state, that I then heard from a good authority, an Australian sugar planter himself, that with improved machinery, methods of manufacture, and good variety of cane, a repetition of the failure of sugar-planting in Ceylon would be impossible. As far as I can remember I have the authority of your valuable paper for stating that the canes grew *most luxuriantly* in the Dumbara valley when first planted, and the failure was only owing to the imperfect apparatus and method of manufacture of those days, which have since been so far improved that with modern machinery for boiling, etc., and a good variety of cane, the manufacture might be, and in fact is, rendered easy.

If sugar can be made at Baddegama—"and very good sugar it is" it can be made elsewhere in Ceylon.

As I have mentioned above, the canes grew most luxuriantly formerly in Dumbara, and a very large yield was expected; but when the juice was put into the boilers it was boiled and boiled and boiled, with no result. This on the face of it shows an imperfect method of manufacture, for it is admitted that there was abundance of juice in the canes, and has since been remedied at Baddegama, which was at first equally a failure.

Now, as to the land fit for sugar cultivation in Ceylon, much might be said. I myself know of thousands of acres between Badulla and Kandy, with a fair rainfall, rich soil, and facilities for transport by road and river to Kandy or Trincomalee, level enough to enable ploughing, etc., to be carried out, and only awaiting the introduction of capital and energy to become a scene of activity and prosperity, instead of the dense feverish and deserted wilderness it is at present. If capitalists who are now seeking in Borneo, New Guinea, Fiji and the wilds of Australia for sugar land could only be induced to undertake the cultivation in Ceylon, an era of untold prosperity both for *natives* and Europeans would be at hand. The villagers would each be growing his cane-patch for the central mills from stools supplied by the companies, or by an enterprizing Government, or would find remunerative employment on the adjacent estates. Roads, tramways, or even railways would permeate the sugar districts, and *fever*, poverty and starvation would cease to haunt a great extent of the lowcountry of Ceylon. For Queensland, Borneo and Fiji, where there are not half the facilities for obtaining a constant supply of cheap and efficient labour, and where the soil and climate are no better suited for the cultivation than in many parts of Ceylon. Sugar is rapidly extending, vast mills costing fabulous sums have been put up, tramways laid down on the estates, steamers employed for the carriage of the produce and vast fortunes are rapidly being accumulated by the fortunate proprietors.

Now, Mr. Editor, seeing it is proved that at Baddegama sugar, and first-rate sugar, is now made, although at first equally a failure with the Dumbara estates, why not employ a small space in your valuable paper in drawing the attention of wealthy Australian capitalists, such as those who founded the Colonial Sugar Company, etc., to the great facilities for this cultivation in Ceylon? Here they will find labour cheap, and abundant vast tracts of land ready for the plough, and, let us hope, under Sir Arthur Gordon, an energetic and enterprizing Government to back them up and assist them with grants of land on easy terms, and enable them to make a start in opening up the wildernesses of Ceylon and benefitting the proverty and fever-stricken natives.—I enclose my card and remain yours, VEDDA.

LIEUTENANT COLONEL EDWARD MONEY, whose previous works on Indian tea have for some years been accepted as an authority in this country, has just published another small pamphlet on the same subject which he heads, "The Tea Controversy (a momentous Indian Question)—Indian versus Chinese Teas. Which are adulterated, which are better?" The pamphlet is chiefly intended for the purchasers of Indian teas in England. As might be imagined, the author is strongly in favour of Indian tea, though he somewhat lessens the value of his opinion when he admits, as he candidly does, that "regarding China Tea, I claim no more than a general knowledge but it is the knowledge of one whose attention during a quarter of a century has been given to all that appertains to tea. I have, further, during all that time, watched closely the race between China and India in its varying aspects, and thus known intimately the conditions of the time gone by, when Indian Tea was unknown except to a few, and those that exist today, when the Indian imports from nearly one-third of the consumption in Great Britain." Still Colonel Money argues out the question of superiority fairly enough. He shows that the indigenous tea of India is superior in many respects to that of China, but that it may be improved in hardihood by "a dash of the Chinese plant in it." He gives the following reasons for this superiority, which he boldly challenges any one to deny. Indian teas are, he says.—1. "Grown on large estates, the cultivation and manufacture being superintended by educated and skilled Englishmen. 2. Manufactured in a clean way by machinery, as opposed to hand manufacture, which is the reverse of cleanly. 3. Unadulterated. 4. Stronger, thus going further, and in consequence more economical. On this point I have shown that a superior class of plant, and a hotter and therefore more suitable climate, necessarily give this superior strength and body to the Teas. In conclusion, I say, *if* Indian Tea is the better and the more economical, why not discard the woeful mixtures offered on all sides and at least give it one fair trial to satisfy yourself? Believe me if you drink Indian Tea for one week, you will, I know, endorse all I have said in its favour, and drink no other ever after."—*Englishman*, Jan. 11th.

CEYLON GAMBOGE.—We have been furnished with the following extract, evidently taken from the *Public Ledger* :—

"GAMBOGE.—Of 23 boxes 15 boxes sold, good pipe partly run £15 17s 6d, ditto run and slightly damp £15 5s, fair and course mixed £13 17s 6d to £14, ordinary coarse £11 15s, lump and pipe £11, pickings £11. 1 box Virgin from Ceylon sold, tears at £14 5s."

The prices are per cwt, so that the Ceylon "virgin" gamboge sold in London for over 2s 6d per lb. The merchant who shipped the consignment tells us, he is prepared to pay R1 per lb. for all that is brought him in the form of "tears," that is clean and free from pieces of bark. The tree is indigenous and plentiful, and the proper mode of obtaining the gum is to make an incision in the bark and let the yellow liquid run into a section of bamboo and there dessicate. From articles which have previously appeared in our paper it will be seen that the true gamboge tree is *Garcinia Hanburii*.

BECHE-DE-MER.—In my report for 1881 I suggested the imposition of some royalty on the beche-de-mer trade. The discovery that these marine slugs subsist largely on living coral which is known to exist extensively around the coast of Ceylon in shallow water sufficiently explains the fact of the abundance of these animals in the Gulf of Mannar. An examination of the export Customs returns would show whether trepang is shipped from Ceylon to Singapore in sufficient quantity to render worthy of consideration the question of the imposition of an export duty on the article. The prices realized by the sale of trepang at Singapore are, according to quality, as follows :—

	Dollars per picul.		Dollars per picul.
Trepang, Blah. (cut open) ...	35	Trepang, Buangkulet No. 3 ...	12
" Hitam bulat	30	" Balat passier	12
" Pandan ...	35	" Lebin kulet limao ...	12
" Gamat tikam	50	" Jepoon ...	20
" Buangkulet, No. 1, large	30	" Karang ...	16
" " No. 2,	20	" Kachang goreng	8

Calculating the dollar at the nominal value of two rupees, and the picul at 133⅓ lb, the Singapore prices range, therefore, from R13 to nearly R60 per hundredweight. Still higher prices are realized in China.—*Mr. Haughton's Report on Mannar for* 1882.

GROUND NUTS AT TRINCOMALEE.—A correspondent writes on 24th Jan. :—I find an inquiry from 'an upcountry planter far from encyclopædias, &c.,' what ground-nuts are? This vegetable is successfully grown here at Kinniyaq on the west, and Nilāvelli on the north of this district; and as it was only recently exhibited to His Excellency the Governor at the Horticultural Show, it strikes me at once to answer the query. 'It is Arachis in botany—kind of earth pulse belonging to the pea tribe—botanically related to the bean tribe—grows only in sandy soil in climate at least as hot as of the south of France, being iintroduced there from Spain—said to be a native of America, Brazil, Africa and warmer parts of Asia. It is sometimes called underground kidney beans, earth-nuts, American earth-nuts and Mandubi. Yields from 80 to 100 fold—seeds or pulse are eaten boiled or roasted. It contains oil equal to olive or almond oil for lamps or table, and is said to be much used in the manufacture of soap and chocolate. The roots have qualities of liquorice and the herbage is good for cattle food.' Two different species are cultivated in this district and only enough for local consumption—value I seer at 6 cents.

CINCHONA CULTIVATION BY THE INDIAN GOVERNMENT.

TO THE EDITOR OF THE "MADRAS MAIL."

Sir,—In your issue of the 31st ult. the writer of the article on cinchona points out that Government have made a mistake in cultivating the inferior varieties of that plant, and advocates the total abandonment of such plantations as those at Darjeeling, and the opening out of fresh land for the growth of some of the more valuable and true quinine-producing varieties. If the writer had thought for one moment what the effect of such conduct on the part of Government would have on private enterprise, I do not think he would have given such advice. Government, some years ago, seeing that private enterprise was incapable of thoroughly testing the experiment of growing cinchona in this country, undertook to try it, and went to great expense in doing so. Having, however, shown that cinchona can be profitably grown in this country, I think they should leave the rest in the hands of private individuals. I do not go so far as to assert that their present plantations should immediately be abandoned; it would hardly be fair to expect this; but I do think there should be no extension whatever, and that the existing plantations should be gradually year by year rooted up. Within the last few years hundreds of acres in various parts of the country have been opened out for the cultivation of this valuable plant, and extensions take place every year. Would it then be a proper step on the part of Government to enter into competition with their planters? Now-a-days when so much is written and talked about developing the resources of the country by private enterprise, surely it is not the part of Government to hinder such, as they most assuredly will do if they continue to compete with the planters. Having established the cultivation and seeing that private individuals are perfectly prepared to carry on and extend it, Government should gradually retire from the field. Let them rather now try and perfect the experiments for producing locally a cheap and efficient febrifuge; this done, I feel that any quantity of the valuable bark will be forthcoming. And, moreover, Government, by exempting all lands planted with cinchona from taxation until the fifth year, instead of the third, would only be doing justice to planters. The principle of taxation of coffee is all that is asked for; if coffee is exempted until it comes into bearing, why should not cinchona have the same grace extended to it.—Pet.

NEW FIELDS FOR PLANTING ENTERPRISE.

The staples of planting enterprise on the Nilgiris are represented by coffee, cinchona and tea, and planters are generally content to stand or fall by these. This resolute adherence to specialties was all very well when coffee held the premier position in the market of all Indian products; when the borer and other pests were unknown, and when fluctuating seasons were of rare occurrence. Under the altered state of affairs, however, when borers of sorts, grubs, red spider, &c., demonstrate the ills to which the above products are heir, it is high time that the planters turned their attention to other sources of wealth, and embarked in the cultivation of products as yet untried on a large scale in this part of the world, but which have proved a lucrative source of income to investors in America and Australia, in localities where the climatic influences, soils, &c., are precisely similar to our own. When coffee became in a measure discredited, and proved rather a broken reed to lean upon, to those who staked their capital exclusively on its cultivation, in the confident expectation of amassing wealth, a steady development of cinchona planting took place, and plantations sprang up as if by magic. "No borer, leaf rot, or disease here," said the sanguine quinine-bark men; but, alas for their prognostications, the defects of coffee suddenly developed themselves even more numerously in cinchona, and already the halcyon days of the cultivation appear numbered. The bark when first taken off the tree yields medicinal alkaloids in great quantity, but each additional harvesting of bark, whether by the shaving or stripping process, shows a steady deterioration in quality, and the only point now in dispute is whether bark deteriorates most under the former or latter system. That it does deteriorate under both methods is incontrovertible, and planters must face the fact that, after a few strippings or shavings, a cinchona tree, which is comparatively the most expensive plant in the world to bring to maturity, is valueless to them. This, of course, to use a slang, but trite, phrase, "takes the gilt off the gingerbread," and renders the lucrativeness of chinchona planting a matter of doubtful certainty. The above arguments apply, though in a different way, to tea. Under these circumstances, it is matter for surprise that planters do not turn their attention to other enterprises which have proved lucrative elsewhere under similar conditions of soil and climate as we are possessed of in the Nilgiris. The tobacco plant thrives here in a wild state in the most luxuriant manner, and the natural inference is that it would amply repay cultivation. The arrowroot tuber, too, is quite at home in our soil, and it has been proved that it gives a return of R400 net profit per acre of cultivation; and the sago palm is another indigenous product, the cultivation of which could be turned to profitable account. Though it is generally believed that the sugar-cane cannot be grown with profit on the Nilgiris, the opinion appears to have been formed on the results of very partial experiments. In some places, at about four thousand feet elevation, we have seen the cane growing luxuriantly; but it is entirely deficient in saccharine. In other localities the success of the cultivation belies the above result. For instance, at Neddivuttum, which has an elevation of about five thousand feet, some Chinamen have succeeded in growing the cane almost to perfection. Its quality may be gathered from the demand for it among the natives going backwards and forwards in the Wynaad. Some of the cane growing in this neighbourhood is of a dark red colour, and the juice is quite as rich in saccharine matter as the lowcountry cane. In Coimbatore, with defective crushing appliances, and with expensive irrigation water, the cultivation yields natives a return of over cent per cent, and yet the cultivation is restricted. European energy and mechanical appliances for extracting juice ought to make the cultivation of sugar-cane quite as profitable as coffee proved in its most palmy days. We may also indicate the lucrativeness of the rubber cultivation. The three best species of rubbers, *viz, Ceara, Castilloa elastica,* and *Hevea* all thrive on the *slopes* of our mountains.—*Madras Mail.*

Substitute for Coffee.—A writer in the *Bulletin of the Tuscan Horiticultural Society* recommends the fruits of Galium pisiferum of Boissier as a substitute for coffee. The plant is a native of Palestine, and is readily cultivated.—*Gardeners' Chronicle.*

The Orange Trade—usual at this season of the year when this fruit, of perennial bearing, may be had in greatest plenty and perfection—is very brisk with the United States, particularly New York. The Yankees, who always swore by the Havana Orange, seem to have discovered that its congener of Jamaica is equal if not superior to it. It is certainly larger and has a thicker skin which, erroneously believed to be a mark of coarseness and inferiority, seems to have been discovered to be what it really is, a protection and preservative of the Jamaica fruit. Hence the increasing demand for it.—*People's Banner.*

NOTES ON CHOCOLATE.

Some interesting notes on Theobroma cacao, the botanic source of chocolate. by the distinguished French chemist, M. Boussingault, appear in a recent number of the *Comptes-Rendus* of the Academy of Science. M. Boussingault observes that although the cacao is now very common in the hotter parts of America, at the time of the Spanish conquest it appears to have been only cultivated in Mexico, Guatemala, and Nicaragua. In the time of Montezuma, the Spaniards carried it to the Canaries, to the coast of Venezuela, and to the West Indies. It needs a deep, rich, moist soil; nothing suits it better than newly cleared forest. All the plantations existing present local analogies; they are all in well-sheltered spots on the banks of streams. and not very far from the sea coast. When an eligible site is found, if there be not enough shade, it is provided by planting bananas and other quick-growing essences. In Guayaquil, cacao plants are raised direct from seed; in Venezuela they are reared in nursery-beds, and afterwards set out. The seed germinates in eight or ten days. In their second year, when the plants average three feet in height, they begin to form heads. As a rule, when the temperature is favourable they blossom in the thirtieth month. The best temperature is 27° to 28° Cent. (80° to 82° Fahr.). Few plants with flowers so small produce such large fruit. A bud measured by M. Boussingault, when on the point of opening, was only one-tenth of an inch across. The flowers appear in clusters all down the branches, and even low down on the stem, and along the ligneous roots which straggle over the surface of the ground.

Cacao is husked by moderate heat, and the exterior portion of the fruit rendered friable by "vannage." Like coffee-berries, the fruit acquires in roasting an aroma due to the presence of an aromatic principle in infinitesimal quantity. The cacao fruit, husked, lightly roasted and the seeds separated, is the basis of chocolate. French preparations of chocolate usually contain 55 to 59 per cent of sugar; Italian chocolates 40 to 53 per cent. Pure chocolate should contain nothing but cacao and sugar. Probably any excess of the latter deteriorates the peculiar properties of the former. M. Boussingault found that for long journeys in that part of America, a special mixture of 80 per cent of cacao with 20 per cent of sugar formed a very welcome and valuable addition to the usual traveller's rations of air-dried meat, maize biscuit, and cassava cakes.

Cacao is a vegetable compound of fat, sugar, starch, and certain bone-forming phosphates, which give it a considerable similarity of composition to milk, whilst it contains, what milk does not, a certain amount of theobromine and a delicate aromatic principle.—*Australian Trades Review.*

THE PREPARATION AND USE OF RHEEA FIBRE.

BY DR. FORBES WATSON.

What is Rheea? This is a specimen of rheea of one length. This is another specimen of rheea of a different length, and here is a specimen of rheea in the dry, semi-succulent state. When green and fresh, these specimens are of course different to what they appear now, and they have characteristics which I shall notice farther on. Unfortunately, I am not in a position, at this season of the year, to present you with more than this solitary green specimen, for the illustration of one or two points which I should like to lay before you before proceeding with my subject, which, instead of being in the form of a written paper, will consist of remarks which I shall endeavour to make as clear as I can. You will observe, on breaking this sample of green rheea, I succeed in getting off a certain quantity of green fibre, tearing it down in this manner. I wish to refer, in the first place, to the composition of the component parts of this bark. The outside portion consists of a film to which a very distinguished chemist has applied the term cutose. Below that there is a bark which contains the green colouring matter of the plant, that is called vasculose, and next to that comes the fibre itself. That fibre, and the bark attached to it, is united to the stem by another principle, which is called pectose. Now, the problem of getting the bark separated from the fibre constitutes the great difficulty which has hitherto impeded the use of this fibre. In China they succeed in removing the bark and other matters, to a certain extent, by means of scraping. They scrape off the whole of the bark substance as far as possible, and they produce it in the condition of what is called China grass, of which this is a sample. You will observe from the appearance of the plant itself, that it has nothing of the character of a true grass, and belongs to the exogenous class of plants. Now, up to the present time, the whole of this fibre, as it has appeared in the market, has been prepared by hand. There has been a certain quantity prepared in the dry state by applications which I will afterwards refer to, but so far, in China, the whole of the China grass which has been introduced into the market has been prepared by hand, with the result that the cost of the fibre has never yet been reduced to an extent to make it pay, and you never can have the fibre at a less cost than from £49 to £50 per ton. It is this which has impeded the introduction of the rheea fibre and so-called "China grass," and their extended use in this country. During the last twenty or twenty-five years many attempts have been made to manufacture this, and as far back as the year 1860, when I had the honour of reading a paper in this room upon the plants of India, I showed then a number of most interesting samples, sixty in number, which had been prepared in Bradford from this fibre. At that time, and subsequent to that, a large amount of capital had been expended upon the manufacture of the China grass, and the various fibres; and a great deal of money has been lost within my own knowledge. I should say I could add up £150,000 of capital which have been sunk in this fibre since that time, all arising from the difficulty of getting it sufficiently cheap. The moment you excited a demand for the fibre, the price rose; it has even gone up as high as £85 a ton; and this killed the trade. What we have to do tonight is to see whether there are any elements which would lead us to suppose that we can now get it cheaper—that is really the object of my story tonight. The Government of India has for a great number of years—going back to the days of the East India Company, which took a warm interest in this matter, I may say for the last eighty years, at least—devoted very considerable attention to the question of the introduction of this fibre. The East India Company directed attention to it by importing regularly, year by year, considerable quantities. About five tons, if I remember rightly, was annually sent to this market to afford an opportunity of trying it. It was considered, after a time, that we had a sufficient knowledge of the fibre and its properties to warrant the authorities in discontinuing the importation. However, in 1869, Lord Mayo, who took an active interest in all agricultural matters in India, offered a prize of £5,000 for a machine which would extract this fibre from the green rheea; and our Chairman superintended those experiments, which were afterwards carried out in 1870 with this object, and his report, I must say, is a model of what a report should be on such a subject. The result of these trials were negative, in the sense that only one machine presented itself for trial, and after examining the whole of the evidence about it, General (then Colonel) Hyde reported that it was not sufficiently good as regarded both the quality and the outturn. It did not fulfil the conditions which the Government indicated should be fulfilled, and only a small prize, £1,500, was awarded to the machine. After that the matter was referred to the India-office, and various attempts were made, with which I had somewhat to do, to see what could be done in order to have a test of machines in this country; and at one time I was in hopes that we might obtain a sufficient quantity of green material to have a practical trial here on the spot, and that we should have at least one opportunity of testing the fibre in its green condition. Those hopes were not fulfilled. A certain gentleman kindly promised to let me have the whole of his crop of fibre, which he expected to cover something like twenty-five acres; but his imagination had been such, that on my sending to a district not far from Marseilles, and making arrangements with the railway companies to have the whole of the crop conveyed *grande vitesse*, there was only about two or three acres planted with rheea, and the crop was very inferior, not to say "scrubby," throughout; consequently, I only got $1\frac{1}{2}$ tons instead of 25 tons; therefore, that attempt failed. A good many experiments were made to see whether it would be possible to extract the fibre from the stalks in their dry state, and these experiments showed that it was quite possible to prepare satisfactorily the fibre, which was worth about £15 a ton less than China grass, but was still sufficiently good to give hopes that, if you got the rheea dried, it might be a matter of consideration whether something might not be done. The Government of India, however, saw the difficulty of extracting the fibre from the dry stems; inasmuch as you cannot get them dried except during certain seasons in India; it would require artificial means to dry the stems properly, which would be much too expensive a plan. Hence the method of preparing the fibre from dry stems had to be given up, and the Government of India, after a certain time, resolved to re-offer this prize, and two or three years ago another competition took place, but with the same result as at the first one. No machine at this second competition was considered worthy of a prize on that occasion, and I believe that no portion of one was awarded. The samples which were sent for examination to this country were examined by my colleague, Mr. Collyer, and other brokers, and declared to be very far inferior from what it should be if it were to be comparable in quality with China grass. That represented the position of matters up to very recently. About two months ago I was asked to go to Paris for the purpose of examining a process by which one could succeed in stripping the stems very readily, subjecting them to chemical treatment afterwards. I had a double object, in addition to finding out and seeing what could be done by this process—it was a *dernier ressort* if we could not get a machine to do the work, and said, "Let us get the next best thing;" and, accordingly, I went to Paris for the purpose of examining this process, and I will describe the results which I saw, which were very interesting. The method is a conjoint one, and is known as the "Favier-Frémy" process. It consists, in the first place, in facilitating the removal of the bark, with all its adherent fibre, by the action of steam. Immediately after it is cut, it is not difficult to remove the bark, and almost all the fibre attached to it, leaving a very little fibre behind. If the plant is allowed to lie a certain time after cutting, a few hours will make a great difference, the quantity of fibre left on is largely increased. I find it goes up in this way to nearly as much as 15 per cent in stems which were several days old before they were peeled. When cut fresh, you get off, by the hand, nearly the whole of the fibre—it peels off—there is a little fine fibre remaining, but very little; this, however, must be done immediately the plant is gathered. The process of steaming—putting the stems into a box with a false bottom, and letting steam in below, so facilitates the separation of the bark, that you get everything, and this dark rough fibre is the result of the steaming upon some of the rheea stems, grown in Hampshire, which I took from this country to Paris with me for experiment. I may mention that I found the rheea which I got here was very much longer and better grown in some respects than that which I got in Paris. That process facilitates the getting off of the bark, but having got this off, the question is what to do with it. Now, M. Frémy, the distinguished French chemist, and his able assistant, M. Urbain, made a number of experiments, with a view of determining the best way of getting rid of all this black bark—I will call it black bark; I am not using scientific language—and they came to the conclusion that it was necessary to employ a high-pressure boiler, in addition to a solution of caustic soda, for that purpose; and, in testing this process, I found the pressure was very considerable indeed, the temperature in the boiler, as I ascertained by experiment, being 295 degrees of Fahrenheit; and at the end of the operation, which extended over four hours' time, the fibre was taken out of the boiler, still in a black condition. But the theory was that the high pressure had aided the caustic soda in dissolving the whole of the gums, including the bark, which is the difficult thing to get rid of. Now this bark and fibre, as removed from the boiler, was then placed in a solution of hydrochloric acid, and almost at the moment it touches the acid, that which looked a black, dark mass, speedily clears, and you see the beautiful fibre making its appearance. I felt that this settled the question of getting the fibre in a very nice condition. When I came to examine it more minutely, however, I found this alteration was one of appearance only; the bark to a large extent was simply in a changed condition, not dissolved by the alkali; it still remained there, and continued to do so throughout the greater portion of the subsequent operations. I can only now give you some of the general features of the case, but shall be happy to enter more minutely into the matter at any time at Mr. Collyer's office, No. 141, Fenchurch-street. I found that this process did produce a certain effect upon the material. This sample is a dried sample of the fibre as it leaves the Frémy boiler, and it contains a very considerable proportion of gum undissolved; it contains very nearly as much as China grass, which is prepared in the other way. It is true it is looser, and more easily dissolved out, but there it is. Here is a sample of fibre from the acid solution, which is the same as that which was afterwards in this state placed in a chlorine solution of some strength, and I find this loses a very considerable percentage of its weight. However, the point I am coming to is this; after leaving Paris I made experiments to see whether it was necessary to have this high-pressure boiler at all. It is anything but a simple operation; when you come to operate upon many tons of material it is difficult to manage, and a high-pressure boiler always means expense. Thus came the question, was it necessary? and I was desirous to find out (whilst I was very pleased with the Favier portion of the process, as it got the fibre off the stems very readily), since no machine was available, whether a future, so to speak, might not be opened up by adopting this process. I was anxious to get rid of the high-pressure boiler, and my experiments —made in my own laboratory—show clearly enough that it is not necessary. I have here samples (I have them in a fresh condition) which are in a sticky-looking mass. They have been simply boiled in the Frémy solution, and I find all my bark here is just as readily removed as that from the boiler. It is, perhaps, a little more adherent together, but in after operations that can be got rid of as readily as possible. Therefore I had to come to the conclusion that the high-pressure boiler was not required—that we could get all these results without it—and that would be one great gain. That is a very important consideration. This represents the position, so far, of the matter when I returned from carrying out these experiments in Paris.

I now come to what happened next. Fortunately, I had asked the nobleman who, year after year in times past, had allowed me to have, for the use of my department all the rheea stems which grew in his garden, and he has been good enough to allow a certain proportion of the stems to be left standing for experiment on my return, and I had thus the materials for carrying out some experiments, the results of which will appear at the end of my paper. I had heard, when recently in India, of Messrs. Death and Ellwood's machine, the invention of Mr. H. C. Smith, as a very ingenious machine, which had been successfully used for extracting the fibre from leaves of the Agave plant, similar to those now before you. For instance, here is a specimen of the sort of leaf with which that machine would deal. Here is another kind, and here are several other leaves to which I shall have occasion to refer presently. I knew it had dealt with these successfully, but I had no idea that it would do for rheea. In fact, I had come to the conclusion (though I never put it in writing, by-the-bye) that we should never get a machine that would do for the rheea. I could not conceive of any machine which we could apply without crushing rollers in some way or other. I saw no difficulty in getting a machine which would extract the fibre, but the point was to get one which would do this, and leave it in a good condition as regards quality. When asked to test this machine, I did so very willingly, and my test was this: I had in stock at the time a considerable quantity of rheea stalks nearly five feet long, and some of very much shorter lengths. That is to say, I had rheea stalks as thick as my thumb, and nearly five feet long, and others smaller than my little finger. With these I tested the machine, and was surprised for the moment to find that the large and small sticks were operated upon with equal readiness. Here is an actual portion of the fibre prepared on that occasion, from these very stems. The secret of the success of this machine lies in this, that one-half of it is, so to speak, water. Now, I will explain what I mean by this, as it seems a somewhat out-of-the-way remark. Imagine this tumbler that I hold in my hand to be the cylinder of the machine, 18 inches in diameter. It is provided with what are called beaters, that is to say, a certain number of projecting ribs, and it revolves in front of a feeding table at a great rate. It is worked at 600 revolutions a minute. This operation goes on in front of the feeding table, as it is called, and this constitutes the whole machine, as regards the mechanical portion, with the exception of the water. Below, and at an angle of about 45°, a strong flattened jet of water passes, and I will tell you what the effect of that is. The cylinder, remember, is rapidly revolving; you feed in at the side here, the beaters catch and break up the sticks into very small pieces, and the jet of water, coming from below, meets the fibre, and keeps it up against the beaters, so that it is really beaten in a stream of water. The result of this is, you not only get the fibre cleared of a large portion of its gum, but you have next to no waste, and what little there is, is excellent for many purposes—it can be made use of, as most other waste products can. Thus is explained the secret of the success of the invention, and how it solves the problem of a machine for cleaning rheea.

I may mention, with regard to this rheea which I experimented upon, that it was three days old. In order to obtain the full success, the rheea cannot be too freshly cut. I should say that it ought to be operated upon within six hours, and that it should be kept in the shade until operated upon. I took some stems, which looked to me perfectly fresh, but when I broke them I found that the colouring matters and the gums had sunk into the fibre, which, if it had been quite fresh, you would have been able, after scraping, to blow through, but you could no longer do so, thus showing the necessity of having the stalks quite fresh to operate upon. I again made a series of experiments to try this machine in preparing other fibres, and I have here tonight a large number of specimens. For instance, there was one very interesting series of experiments which I made with the Moorva (*Sanseviera zeylanica*). This plant grows as a weed in Madras and other parts of India. In fact, it is such a nuisance that the people sometimes do not know what to do with it, but this machine tells us what to do with it. The sample which I hold in my hand was prepared upon the occasion to which I have alluded. Here is a sample which is prepared on the commercial scale in India by this machine, and, I may say, with regard to that particular fibre, that it has been proved that it will compete fairly with Manilla hemp, which occupies a very important place in this market. Here is a sample of cord made from it, and you can all see how beautiful and white it is. This cord is made by one of the principal makers in the kingdom, and his report is that it is 7·4 stronger than Manilla, and over 4 per cent lighter. This machine has been the means, already, of bringing this new and important fibre to notice, and it operates upon the plant which produces it with great facility. Then I had some large aloe leaves, some of the leaves being as thick as my arm. Here is a specimen of New Zealand flax which was prepared by the machine. I am indebted to Mr. Christie for this sample, which, I believe, has come from Africa. The surprising thing is the ease with which the machine operates upon all sizes of leaves and stalks, taking them all, little and large indiscriminately, without any special adjustment or setting whatever; this fact, therefore, shows that the character of the action was a very simple and effective one. With regard to the question of setting, I may just mention that the beaters were adjusted at a quarter of an inch away from the table, so that it was clear the New Zealand flax which I have just shown you was not struck by them. All these stalks and the others received rapid blows from the beaters, but this could not have got any, because the leaf is not one-tenth of an inch thick; therefore, the total action arose from the beating of the water, the leaves being held up by the current, and the beaters coming round and round, worked the whole of the refuse out of it, and produced the fibre which I have shown you. In short, this machine is what I venture to call a universal fibre cleaner. It cleans every fibre, and it will extract the fibre from every plant into which nature has put one.

There is one other question, namely, will it extract the fibre from jute? I reason in this way. Jute is a plant very succulent in its nature, and something like China grass. The stem is about the same thickness, and in many other respects it is the same, so that I think the inference I draw is a fair one, and that this machine will clean jute, and thus be the means of introducing a superior class o this important fibre into the market. Jute is now prepared by a retting process. If done, as one gentleman whom I see here has prepared it, in a running stream, you get rid of the rotting or retting, and obtain the fibre in the best possible condition; but if it is prepared in a stagnant pool, with lumps of mud to keep it down, it becomes partially decomposed, and you will necessarily get weak fibre. Jute prepared by this machine—as I said before, is likely to supply a new class of jute, one taking a high place in the market. In the same way the machine will settle one or two other moot points. It will afford, I believe, the means of cleaning another fibre which has attracted a great deal of attention, namely, *madar*, or *Calotropis gigantea*, which grows as a weed all over India. The juices of this plant are more difficult to deal with than even those of the rheea, being of a gutta-percha character; and if, as anticipated, it is found possible to clean it by this machine, it may be the means of introducing another new fibre to commerce.

Let us now look at the character of the machine. It is a very simple machine; I have described it to you, and there are photographs of it here, and arrangements can be made for those who are really practically interested in it, seeing the machine at work. It is easily worked. The power it requires is small; one horse-power being sufficient. Of course the question of the supply of water is an important one. Now, there are two ways of doing this, the first being from a height. In a hilly country you can have a tank some sixty feet up, which will give you the pressure required, which is only thirty pounds; or you may use the pump which is attached to each pair of machines to give the necessary pressure. The pump is specially adapted for working the machine, and is not liable to get out of order, not being a valve pump; and it will be found, I believe, to be admirably adapted for the purpose. The quantity of water required for working the machine amounts to about 400 gallons an hour. That is a good deal, perhaps, but you can use the same water three or four times over, if you let the refuse sink away from it, and draw it back by means of a hose, so that 1,000 gallons a day will represent the quantity of water necessary to work with. With regard to the question of water, there is this to be borne in mind—that it is very desirable that the water should be secured and turned to account for helping the plants to grow; that is to say, it should be used for irrigation, for it contains a great deal of the nutriment of the plants. We all know that if you wish to grow crop after crop of any plant, it is necessary to restore the constituents in the form of artificial manure, where in this case, if the water is put upon the land, the soil will repossess itself of what has been taken out of it. In the same way the broken up stalks should be collected and used for manure or fuel. I may say this, that with regard to the question of the number of crops that you expect of China grass or rheea fibre, some people will tell you that there will be as many as four or five, and I have met enthusiasts who spoke of six or seven. No plant can be grown on the same soil, time after time, unless great care is taken to restore the elements to the soil which have been taken out, and that is the case particularly with regard to rheea. In China they manure and till the ground very carefully.

Now, one word more about the machine, with regard to the important question of outturn. The experiments which have been made here are very interesting as regards the quality of the fibre, but they are no guide as to the quantity of outturn, and, therefore, I have to depend for this upon the evidence which has been laid before me, and which has led me to the conclusion that a pair of machines will turn out from 140 to 250 pounds of clean fibre in a day, according to the assiduity and skill with which the machines are worked. If a man dawdles over his work, he will not turn out so much as the man who goes to work with a will. There are other elements which should be considered. The other day a complaint was received from a gentleman to the effect that the machine worked capitally, but he could only get forty pounds out of it in a day's working. The next mail brought a letter to say that he had been thinking of making a suggestion with regard to the working of the machine—namely that they should take off the roots from the plants, because he found that the earth which was attached to them rather interfered with the working of the machine! This gentleman had been putting in roots and all, and then complained that the outturn was not so good as might be expected.

Returning to rheea, what are its prospects *now*? I have indicated that, for the last 25 years or more, the great search has been for some machine to clean it. That machine we have now got, or, at least, I believe so. I think the facts which I have mentioned point clearly in this direction. I started by pointing out that it was not possible to sell China grass in this country under £49 to £50 a ton, that is to say, the cost of preparing it by hand prevented its being sold at a cheaper rate. To clean one ton of China grass, it would take upwards of a thousand Chinamen one day, that is to say, each pair of hands can clean only from one to two pounds. In experiments which were carried out by Mr. Thompson and Mr. Mylne at Baheea, they found that only a few ounces could be cleaned by one person—nothing, in fact, at all approaching the two pounds which the Chinaman cleans, which is a considerable quantity, and the result of great practice. If, however, we get a machine which will do it, as I believe we now have, it will reduce the price very considerably.

With regard to the cost of working, I will mention to you what appears to me to be a fair estimate, after making every allowance, including the cost of labour, the carriage and cutting of the material, the cost connected with the engine, and of fuel, &c., and this estimate shows that it is possible to clean fibre with it at a cost of from about £7 to £1 a ton calculated on 100 lb. of fibre for the working day per machine. Suppose it is only 50 lb., which is dependent, as I said before, on the assiduity with which the machine is worked, it will only come to probably between £10 and £12. Such being the case: the result will be that China grass may be introduced at a much cheaper price than hitherto. What that price will be I cannot say, but I think it will be possible to sell at £30 to £35 a ton—possibly less; still it will always be an expensive cultivation. I am satisfied that those who think they are going to grow this plant at a very cheap rate, are mistaken. Great care must be taken in its cultivation, but in any case it will still always command a good price. The demand for it is likely to be very large, and it will, in consequence, continue to fetch a good price; those who grow it need, I believe, have no fear upon that point.

As to the yield per acre of rheea, there are no fresh facts since I went into the question for my report in the year 1875. I am aware that there are some notable facts which have been founded upon experiments made in Algiers. Estimates have been made, showing that you could get forty tons per acre, but I think these will require to be verified before we can accept them. Any way, I do not see that we can conclude at the present—I hope I shall be mistaken—that each crop will yield more than 250 lb. per acre. You may, however, obtain three crops, or even four in the year, which would bring it to 1,000 lb. per acre.

The question of cutting and storing of the plant are practical questions which will have to be considered hereafter. One of my objects, in the experiments which I carried out in Paris, was to determine, as far as I could, the height to which the plants should be grown in order to give the largest yield of fibre. Some people say that the plant should be grown to the height of 6 feet; some say they should not be more than 3 feet; but the results of my experiments, as you will find from the table at the end of my paper, point to the fact that 3½ to 4 feet is about the right height to grow them. If the length is not more than 2 feet, the fibre is very fine, but the chances are you get more waste, and not such a good percentage of fibre. In the long stems the fibre is not so fine as in the medium ones; in short, the medium stems from 3 ft to 4 ft. are about the right length to cut. This has an important bearing upon the question of the number of crops which can be obtained. It is clear that if you allow the plant to grow 6 or 8 feet high, you cannot expect to get as many crops as when only 4 feet. Moreover, there is this characteristic; all these stalks which you see here are from the same plant, that is to say, the shoots have come from the same root. Having determined the proper length, the stems should be gathered accordingly, only those being cut which have attained the right height; in this way a continuous crop may possibly be secured.

We find that with China grass there is a great variety in quality. Here is a sample of short China grass, and here are others which are much longer. These variations in quality gives rise to the complaints which are frequently made. If you grow it, however, a certain standard length, it will be likely to produce it of a definite quality, and that is what is wanted for commercial purposes.

With regard to the comparison of the machine-prepared rheea fibre and ordinary China grass—here is a sample of the former, and those who have an opportunity of examining it will find the fibres are separate, and nearly fit for spinning. There is a very small amount of gum in these fibres, and if you take the China grass in your fingers, you will find that it is very stiff, owing to the large quantity of gum that is left in it. In the machine this gum is washed out; but by merely scraping, you leave it in. The amount of gummy matter in the machine-prepared sample is about 19 per cent, as compared with from 25 to 35 per cent in China grass. I feel satisfied that in this sample, had the stems been operated upon when freshly cut, the proportion of gum would have been consideraoly less. If it is 19 per cent in this, I should say that if it had been cut fresh it would have gone down to 15 per cent or even less; but these are points upon which I hope to make experiments in India, where I shall have an opportunity of doing so on a larger scale.

Now, what is rheea good for? It is difficult to say what it is *not* good for. It is the strongest fibre in nature. According to the experiments made by Dr. Forbes Royle, it is two and a-half times as strong as the best Russian hemp. Compare it with flax. Many years ago, one of the largest flax spinners in the kingdom spent a considerable sum, £20,000 I believe, in trying to use China grass in the place of flax, but the experiment was given up, owing to the hairy character of the yarns produced. It is, however, quite possible to prepare rheea in a way which would enable it to be spun on flax machines; and we find tablecloths and beautiful fabrics of this material equal to anything that could be produced from flax. It is also an admirable substitute for wool, especially for mohair and other lustre wools. On the table are illustrations of what it is good for, and many of these specimens show what can be done with it in that respect. From what I hear, there is likely to be a run upon lustre wool shortly, as it appears likely dead surface wools will go out of fashion, and lustres come into vogue again, thus leading to an increased demand for rheea. Then, as to silk. Rheea is prepared in various ways, so as to leave the gloss upon it, giving it all the appearance of silk, and it is certainly far superior even for mixing with silk than jute. Many of the ladies present know that the silk dresses which they buy now are very inferior as compared with what they used to be some years ago, the difference arising from their being adulterated with jute. No doubt the ladies would like to see the persons who mix jute with silk locked up for life, and most men will agree that the scoundrel who dares to put jute into sailcloth deserves to be hanged, for that might often mean death on a lee shore.

I do not know that I have much more to say upon this subject. My story has been rather a long one, but I have done my best to give you some idea of the present position of the matter, and how it is likely to be altered by the existence of this machine, the result of the genius and intelligence of Mr. H. C. Smith. It is interesting just to think of how he came to invent it. What first suggested it to his mind was noticing the great aloes, the stems of which grow up to 30 or 40 ft. Mr. Smith observed during the monsoon in the Mauritius that where the inner leaves were dashed against these great stems, they were broken up, the result being that the pith got washed away, and the fibres were left hanging. This suggested, to his mind, the idea of a machine in which a rush of water would play the same part, and he was fortunate enough to find in Messrs. Death and Elwood a firm possessing the largest experience in the manufacture of fibre-cleaning machines for a similar object in South America and elsewhere. The result of this combination has been the production of the present simplo and highly effective machine.

With regard to the exhibition of the machine previously referred to, it will not be possible to show it at work upon fresh rheea, but there is a supply af Agave and other leaves which will show its action upon them,

Observations:

* Containing Bark = 16·85.

† " " = 17·71.

‡ The bark could not be separated with sufficient accuracy for the determination of its percentage *per se*.

§ This sample was apparently not quite so fresh as the others.

‖ Calculated upon Nos. 1, 2, and 4 only.

and there is some rheea now on its way from Algiers, which may come in time for a trial on Tuesday next, although it will be far from fresh. The various samples now exhibited will be on view at Mr. Collyer's rooms, 141, Fenchurch-street, and I shall be happy to give any special information which it may be in my power to afford.

In conclusion, it is my duty to express my thanks to Messrs. Garnock, Bibby & Co.; A. Donisthorpe & Nephew; J. Glazebrook & Co.; J. Grathvohl; George Hall & Co.; Richard Harris & Sons; Herbert E. Hounsell, Limited; Charles Rhodes; F. Wilkinson; and very specially to Mr. W. Whitaker, for the interesting series of specimens exhibited on this occasion; as also to Mr. Howson and to Mr. Lascelles Scott—to the former for assistance in connection with the trials of the machine, and to the latter for assistance in the investigation, a small portion of the results from which only appear in the Tables, pages 573-574.

Amongst the specimens exhibited in illustration of the foregoing paper were rheea and China grass in various stages of preparation, from the stalk to the finest bleached fibre, also many fabrics, including lace and other curtains, shawls, hosiery, handkerchiefs, muslins, sailcloth, &c., made entirely from rheea; also some ropes and twine spun from "Moorva," fibre produced by Messrs. Stains & Co., from the plants growing wild on their Madras Government concession in the Coimbatore district.

DISCUSSION.

Mr. Wm. Haworth said he could confirm what Dr. Forbes Watson had said with regard to rheea and all other such fibres of India, that the stem should be acted upon, if possible, immediately after it was cut from the ground. It was as easy to separate the fibre in that state as it was difficult to do so afterwards. In 1842, he grew rheea, just for a sample; he cut it, and placed it immediately in a running stream of hot water from a condensing engine, and by this means the bulk of the fibre was very easily separated by hand. All the gummy matter appeared to be separated, and a more beautiful sample he never saw. The moment the stem was taken from the water, and just held at the tip, you could draw the whole circumference of the bark and fibre away from one end of the plant to the other; then, drawing it through your hands again, you could separate the bark, and all that was required was to wash the fibre in hot water. He held that if this machine could be placed on a plantation where the plant could be cut immediately it was ready, especially if hot water were used with it, it would accomplish all that could be done by hand, and would give a very satisfactory result. Rheea would make the warps of the finest cotton goods, and the wefts could be made of Sea Island or other fine cotton. He had seen it used in Lyons for the warp of piece goods, and very beautiful goods they were. It could be used for the very finest materials up to the coarsest. He had seen plants growing near Calcutta from seven feet to ten feet in height; and the time to cut them was just when they were beginning to flower. Next after it would come the mudar, the only trial of which yet made had been from plants growing wild, spreading out into a number of branches, and forming seed pods, like flax; but if this were sown more closely, it would grow much taller, nearly all stem, and would make even a more beautiful plant than rheea, though not so strong. He was quite sure there was a great future for all these Indian fibres, if they were looked after and treated in the way now described.

Mr. Martin Wood remarked that the large prize offered for the machine for cleaning rheea fibre was the first special effort made by Lord Mayo towards developing the special industries of India. His own impression was that Mr. Greig's machine scarcely had fair play. The time announced was 1st April, but the trial did not come on until the end of August. He believed Lord Northbrook, who witnessed the experiments, considered the machine a decided success. It turned out something like 150 lb. per day, which came within the condition of costing less that £50 a ton. That, however, was now an old story. He was anxious to see the machine described succeed, because it seemed just what many had been wishing to have introduced for the purpose of developing the fibres of India. Dr. Watson was, do doubt, enamoured of the rheea plant, but for his own part, there were many reasons which made him take more interest in what he might call the Cinderella fibres—the aloes, the mudar, and others. However important and interesting these results were with regard to the rheea, it was a hundred times more important that these commoner fibres should be utilised. If this machine could be worked with 1 horse-power, it could perhaps be worked by hand, and if so, it was one of the most invaluable inventions India could have, for the great difficulty there was to get motive power. The cultivation of rheea was limited, because he believed it would not grow in the plains, but only at an elevation of some 2,000 feet, or in the hilly districts at any rate; and it would involve the outlay of considerable capital. These common fibres, however, cost nothing, they were within the reach of the mass of the people, and if they could be utilised by the aid of our wonderful mechanical appliances, they would be a most important adjunct to the food crops and coarse agriculture of the country.

Mr. Kahlert said his firm had had a sample of rheea grown in Sumatra, on the plains, near the northern coast.

Mr. W. Haworth said his experiments in growing rheea were made on plains near Calcutta, than which you could not find any place much lower. He had found it growing wild on the slopes of the Himalayas, at Darjeeling.

Dr. Forbes Watson said the best sample he had seen was grown in Egypt.

Mr. Liggins would suggest that a drawing should be published, so that they might see the nature of the plant, and also information given as to how far apart the plants would grow best. Within his recollection the sugar-cane was planted 3 feet apart, but it was discovered in Barbadoes that they grew much better 5 feet apart, and he believed, that on some of the most fertile lands they were planted from 7 to 8 feet apart. If a larger production of cane was produced in this simple way, at the same time decreasing the cost of planting, the same result might be produced in the case of this plant. He should also like to know whether it required a swampy soil, and whether it would stand the heat of the tropics without frequent rains. The esparto grass in the West Indies would not grow except on swampy soil, and possibly this would be the same. Between thirty and forty years ago he was much interested in trying to get perfected in England similar machines to that now described, but it was found that nothing could be done without an amount of water in connection with the rollers, which rendered it impossible to work at a profit. The aloe, which grew in great profusion in the West Indies, was not utilised because of the difficulty of separating the gummy matters for the want of a sufficient supply of water. He and his friends found that they could not get English manufacturers to alter their machinery to use a new material. About the same time, he imported a considerable quantity of a very beautiful substance called silk cotton, but no manufacturer in England or France would take the trouble to look at it. So it was, some years ago, with esparto; the difficulty always was, with a new material, to get manufacturers to alter machinery. He was much pleased with the specimens of cordage shown, and could speak from experience as to the importance of reducing both the weight and size of ropes used for rigging.

Mr. C. F. Cross said Dr. Watson had spoken of the jute industry in connection with this machine, but he thought its application would revolutionise the present trade. He had pointed out, from an examination of the fibre, that the whole of the jute imported into the country represented degraded fibre, and he had satisfied himself, by chemical examination of the nature of a large number of bales of jute, that there was sometimes a considerable developed degradation of fibre in the centre, especially when it was packed with the least dampness, involving the passage of the constituents of the fibres into soluble matters, and consequently great depreciation in value. He inferred that not only were the portions to be examined degraded, but probably the whole bulk. He was far from wishing to say anything in depreciation of this new machine, but he should like to ask whether some of the lesser practical questions might not be lost sight of in view of the great theoretical triumph accomplished. He though these might out-weigh, in the case of the Cinderella fibres which had been referred to, the advantages. In the first place, it would be very difficult to organise the jute industry into any concerted action for the adoption of a machine of this kind, the qualification being in the hands of a large number of small producers, each of whom worked his own fibre. Then, of course, the cost of production had been put from £7 to £10 a ton, and when they remembered that jute was retailed at about £18, it seemed to him the margin left was somewhat narrow. Dr. Watson called the machine a universal fibre cleaner, and it might prove to be so; but chemists still believed that there was a certain future for chemical manipulation in the case of fibres which it was impossible to treat mechanically. When you had simple bast, as in the case of rheea jute, the handling of the fibres was easy, but where you had the bast built up into internal stems, such as wood—where you had fibre to deal with like straw, where the bast elements were solidified into curiously complex substances—there was a great future for chemistry, and this remarkable machine, would have to run a considerable race until the functions of the two were properly adjusted on a chemical basis. He was interested in certain new processes, which had been worked at a considerable cost for the chemical treatment of fibres. With regard to rheea and other fibres which had been treated by this machine, he thought they were apt, in the face of new results, to over-estimate a little the value of the fibre. It must be remembered that affinity of rheea for colouring matters was very weak, and, therefore, he thought its substitution for silk was perhaps more than they could expect, or for other things where the property in taking a fast colour was desirable. In the Favier and Frémy process there was a conjunction of chemical and mechanical treatment, but this machine of Mr. Smith's did not seem to be worked in connection with any chemical treatment; very likely under previous chemical manipulation of a large number of these complex structures, the isolation of the fibres would be more easily accomplished, and the fibre produced would be of considerably higher order than would be produced by the machine alone. Lastly, he would ask if the inventors had any hopes of being able to apply it to the flax industry, which was a very important one, particularly in Ireland, where such a machine was greatly needed. for he did not think there was any product which came into the market in such varying quality as flax.

Mr. T. Christy remarked, with regard to the price of rheea fibre coming down, it might not be known to many present that since it had come into the market, experiments had been made for turning it into a material closely resembling leather. Comparing the two, he might say that the value of leather bands was about 5s. a lb., and that of rheea fibre 1s. a lb. at the utmost. These bands had been tested, and a 3-inch rheea fibre band was found to do the work of a 9-inch leather band. That being so, there was not much fear of rheea going down. One other important fact, not mentioned by Dr. Watson or by Mr. Cross, was this, that if the fibre were wetted, it was most difficult afterwards to preform many of the chemical operations upon it. Mr. Ekman had had most excellent results in his process by treating the rheea after it had been worked in Mr. Smith's macbine. That was a very great feature in this new process, and might be the means of enabling a dyer to bring up the colour of the fibre, which, at present, had been found very difficult.

Mr. Collyer said Dr. Forbes Watson had asked him to reply to the various points raised, as he, unfortunately, was not able to hear them. It was very evident that Mr. Martin Wood had but a very partial knowledge of the rheea plant and of its mode of cultivation. His own impression was that it grew more favourably in rich alluvial soil than on the hills; certainly, he had himself had samples both from high and low levels, and he thought that the lower ground plants were the best; at any rate, there was not much difference. As Dr. Watson had said, the finest he had seen was grown in Egypt. With regard to Mr. Liggins' questions, no doubt superior cultivation would give a better result than merely trusting to wild plants. It stood to reason that with rheea, like all other plants, cultivation improved the fibre, and a great result would be obtained, and probably a more economic result, if it were carefully attended to. With regard to close or open planting, he did not know that there were any facts yet ascertained, but his impression was, taken from analogy, that growing rheea for the sake of the fibre, it would be better to grow it rather closely together, because if it were grown far apart, you would get a wide bushy plant, which meant a great number of breaks in the fibre; the straighter you could have the stem, and the fewer leaves upon it, the better. He could hardly speak as to the nature of the soil, but he thought a rich alluvial soil was best. As to esparto growing in swamps, it struck him as being new, for he always thought it grew on stony, mountainous soil.

Mr. Routledge said the esparto grown in Jamaica was declared by authorities not to be really true esparto.

Ma. Collyer said with regard to the quantity of water required for the machine, he was told by the engineer that it required less than the quantity now used for washing the fibre when prepared by other processes. As to silk cotton, that hardly came within the range of the paper, but he might say the Dutch were far in advance of us, as he had noticed it in the Amsterdam Exhibition, and in Holland it could be sold for 8d. per pound, whereas in England you could not get 2d. The quality of it was better however. As to the rope, the makers told him the breaking strain was 7,705 pounds, which was something greater than a similar rope of best Manilla hemp. The smaller cord, which was made for fishing lines and net purposes, stood a strain of 80 pounds, and broke at 81, which gives 7·4 greater strength than the best quillot Manilla, and, at the same time, was 4·72 per cent lighter, which was 12 per cent in favour of the yarn made of this fibre. He could not say the cost, but if it weighed 5 per cent less, and was 7 per cent stronger, he should argue the cost would be much less than if made of Manilla.

Mr. Liggins asked if it was liable to rot.

Mr. Collyer said he could not answer that question, because until this machine appeared on the field none of this fibre ever came to England in commercial quantities, though he had known it in samples for twenty-five years; it was, practically, the creation of the machine. He had sent samples to various people, and none gave an unfavourable opinion: the worst was that it was at least equal to Manilla. It was a new fibre brought into the market for the first time, and was the first attempt of the natives to use the machine, so that it had not yet been practically tried. He agreed with Mr. Cross that jute was a degraded fibre, and one of the greatest merits claimed for this machine was that it would stop that degradation; that it would give all the fibre nature put into the plant in the purest and strongest condition, for this reason, that the action of the water was peculiar, and different to any other process. When the skin of the plant was broken, all the acids contained in it at once set up a deleterious action, and commenced to injure the plant, but the advantage of this machine was that the deleterious matter and strong acids, which tended to weaken and discolour the fibre, were at once swept away before they could act upon the fibre. Incidental to that was the fact that it did away with the necessity of retting. Wherever this machine went, retting would become a thing of the past. It would have the same effect on flax, if they took the flax young enough. He firmly believed it would do away with retting altogether as regards flax, hemp, and every other fibre, including jute. They had to deal with 800,000 tons of jute a-year, 50,000 or 60,000 tons of Manilla hemp, and a great many thousand tons of other fibres, which showed what an enormous product of fibre there was throughout the world. He personally claimed for the machine that it was the best for every fibre, always excepting bristle fibres. As to chemistry, it seemed to him the great advantage of this machine was that they did not want a chemist at all. According to their belief, rheea was not bast at all; jute was bast. As to the affinity of rheea for colouring matters, he had lately made a tour amongst the principal manufacturers of Europe, and they all told him of the difficulties that did exist in dyeing it; fast colours had been, by recent improvements, effectually obtained. His information was that, at £30 a ton, there was no limit, practically, to the quantity which could be sold; at £40, it would go slowly; at £50, with the present price of wool, it was barred. One man said to him, "If you bring it down to £35, you will sell a lot; if you bring it down to £30, nobody knows the quantity we can use." In addition to all the present outlets, there were many new things constantly coming under notice, such as Mr. Christy had referred to. A new one sprang up only the other day, and he believed that in a short time felted carpets would be made of wood instead of wool. Of course, for a time the increased supply of fibre may have an inconvenient effect on the market, but the fittest would survive, and if any had to give way, it struck him it would be the old-fashioned people, not those who had the best fibre, at the lowest price.

Mr. W. Haworth said jute was not so much bast as rheea, but neither was really bast. Bast was always taken from the interior of the bark of a forest tree. Jute was called "a lie," but how was it so much came into consumption? He remembered the first 35 bales shipped from Calcutta as a sample by the East India Company, and when it came home there was great difficulty in disposing of it, but now the consumption, in Great Britain, was about 2,200,000 bales of 400 lb. each, and the whole quantity required to be produced in India was upwards of six million bales. If, therefore, it was an inferior article, there was nothing yet which would take its place, unless it was rheea. He believed the younger persons in the room would see a larger quantity of that come into use even than jute.

The Chairman, in proposing a vote of thanks to Dr. Forbes Watson, said he would say a few woods drawn from his experience in India, where he had superintended the experiments instituted by the Government. With regard to this fibre, the rheea plant for these trials was cultivated in the Botanic Gardens at Serampore, which was practically on the plains; and Mr. Sandys also cultivated the plant at Baugulpore, which was in the delta of the Ganges. The Government also cultivated it in the Botanic Gardens at Calcutta, in order to enable machinists to obtain a supply to use in their endeavours to design a machine for preparing it. In Assam it grew wild, and with regard to its rotting, he might say it was used there for fishing lines, and he did not think any fibre which was liable to rot would be used for such a purpose. He had a fishing line from Assam which had been ten years in his possession. No doubt this plant required careful attention, and as far as he could ascertain from what was done in the Botanic Gardens, Serampore, the maximum amount of crops would be three in the year. But there was another question which had not been touched upon; it was a very quick growing plant, and in that part of India grew best in the rains, and in Calcutta during the hot stagnant atmosphere of the rainy season. For fourteen days he carried on the experiments, and he had found the crop was very different at the end of that time from what it was at the commencement, showing a considerable growth in the stems. It was quite certain that, to secure an excellence in fibre, the stems should be cut at a certain point, and therefore considerable care must be exercised in regulating the growth to enable the crops to be cut in proper succession. All this was a question for the future, because little attention had as yet been paid to the cultivation of the plant. There were two factories in India where the rheea was prepared, one began by Colonel Thelwall in the Deyrah Dhoon, the other in the Dhoons of Kangra. In these, some attempts to prepare the rheea by machinery was made, but the work was done mostly by hand, the method employed being to scrape the fibre after it had been stripped from the stalk on a table with a sensitive machine, namely, the hand and the knife. This machine of Mr. Smith's appeared to provide a substitute for the hand in the film of water which held the rheea up to the scraper, and it would probably be better prepared by that means, because the way in which it was held up was better; all previous attempts had been to scrape the fibre. Mr. Greig asserted that he adjusted the rollers of his machine so that the fibre was scraped between two knives, but as the fibre was only about 1-1000th nch, it was obviously impossible to adjust two rollers to travel with that nicety. The result was that the machine did not scrape the fibre, and it was found that as the supply of water was increased, the condition of the fibres turned out improved. This was entirely confirmed by what Mr. Haworth said; he pointed out that they put the fibre into a stream of running water, which softened the gum and carried it away. This gum was of a remarkable character.* One Saturday in September, Mr. Greig had broken up in his machine a large quantity of fibre, there being a close murky atmosphere. The fibre was placed in a shed. and remained there until Monday morning, and on the Monday morning the mass, as high as that table, was like a lare mass of isinglass glued up together with the fibre in it, nothing could be done with it, and it had to be thrown away. That showed the absolute necessity of attacking the stem the instant it was cut, with a running stream of water to carry the gum whilst it was in its natural state. It was then easily attacked, but let it wait or dry in any way, then the difficulty commenced and increased. The colour of the fibre also darkened in proportion with the delay in removing the juice. Mr. Greig's machine consisted of two rollers with scrapers, but there was another machine from America which was not tried, which broke the stems in a somewhat similar manner to this machine of Mr. Smith's, only there was no water employed, and hence it failed. The excellency of this machine was in its simplicity and in the application of water. The jet of water held up the mass of stems to the beaters; the instant the beater scraped off the bark, and all that adhered to keep the mass together, the fibres got separated, and they were so fine that they fell through, and into the film of water, leaving only the agglomerated portion to be worked upon by the beaters. thus the fibres are cleaned all round, while in the hand process they are only cleaned on upper and lower surfaces. That was a kind of self-adjusting sensitive cushion, and on its results the machine depended.

The vote of thanks having been carried unanimously, the proceedings terminated.—*Journal of the Society of Arts.*

MAURITIUS: THE SUGAR INDUSTRY.

To give an idea of the importance of the sugar industry in Mauritius, we append a passage of an article which appeared the other day in the *Planters' Gazette*:—"According to the latest authorities the cultivation of sugar-cane in Mauritius occupies approximately 117,048 acres of land, out of a total area of 432,680, and secures employment to 61,613 labourers, all of Indian extraction, out of an Indian population of 246,821 individuals. The sugar-houses amount to 170, but lately they were more numerous. The decrease of their number is due to this circumstance, that many owners on the brink of ruin have wisely deemed it expedient to incorporate themselves into Joint Stock Societies as much as possible, and fused their establishments into central ones under the general name of 'Sugar Estates Companies.' These have proved to work very satisfactorily. Out of the great quantities of raw sugar manufactured in this island, the majority has been sold for exportation, which has entertained an extensive commercial business abroad. The following figures show, in round numbers, the annual average quantity exported, by decennial periods. from 1812. It will be seen that the increase was progressive and steady, except for the last ten years, in which the quantity was a little below that of the preceding decade; a fact due, no doubt, to the disastrous effects of hurricanes which are rmited in these regions:—In 1812-21, 3,348 tons; 1822-31, 20,485 tons; 1832-41, 32,246 tons; 1842-51, 49,799 tons; 1852-61, 108,974 tons; 1862-71, 113,792 tons; 1872-81, 111,840 tons. The annual average value yielded by the sugar exported during the last ten years amounted to R28,933,492. I have no data by which to determine with accuracy the consumption of sugar in Mauritius, but I think it may be fairly fixed on an average at about 17 kilos per head per annum, which estimate will appear very liberal when contrasted with the consumption of sugar in France, which stands as follows:—From 1812 to 1816 it was of 500 grammes only, and has gradually increased and reached in 1869 the sum of 8 kilos. But in Great Britain it is reported to have been much more considerable, namely, from 8 kilos in 1840 it would have raised to 24 kilos in 1870, and to 26 kilos in 1875."—*Adelaide Observer.*

* When the experiments with Mr. Greig's machine were concluded, all the rollers, &c., were found to be thickly covered with a very hard varnish, so hard, that it could only be taken off by a chipping chisel. It had the appearance of lac. The analysis of this dry juice gave as follows:—"The juice contains 62 per cent, by weight, of oxalate of lime; and, besides this, some alumina, oxide of iron, and other mineral matters which dissolve in hydrochloric acid, the residue, insoluble in dilute hydrochloric acid, consists of colouring and resinous matter, and forms 2·5 per cent by weight of the dry juice."—H. H.

NARDOSTACHYS JATAMANSI, THE SPIKENARD OF THE ANCIENTS.

When, some fifty years ago, Dr. Forbes Royle was Superintendent of the Botanical Gardens at Saharanpur the hillmen of Garhwal were wont to bring down the roots of Nardostachys for sale in the bazars at the foot of the hills. On one occasion Dr. Royle obtained several pounds of the freshly dug root from Nagul, a village situated at the foot of the Himalayas about five miles N. E. of Dehra. These roots were planted partly at Saharanpur, partly at Mussoorie, and one of the former which vegetated during the cold weather is figured on Plate 54 of Dr. Royle's well-known Illustrations of the Botany of the Himalayan Mountains. Another figure on the same Plate is that of a natural plant from the hills, and is an excellent representation of the plant as it is found in its real habitat.

Nardostachys Jatamansi, DC., which belongs to the natural order of Valerianeæ, grows in the alpine Himalaya at elevations above 11,000 feet, Vedarkanta, Shalma, and Gossainthan being among the localities mentioned by Royle. On the high ridge separating the Jumna valley from that of the Ganges, it is quite common, and has been found by the writer far above the limit of forest vegetation, between 12,000 and 13,000 feet. It is also common throughout Tihri-Garhwal at suitable elevations.

In Dr. Royle's time we are told that "the roots of *Jatamansi*, no doubt the Spikenard of the ancients, were brought down in large quantities from the Himalayas to the plains, whence they are distributed over every part of India, being highly esteemed as a perfume, and for their uses in medicine." Now-a-days this export has almost ceased, at any rate from Tihri-Garhwal. I was given to understand that the Rajah of that State had imposed a tax on the article, and that it no longer paid for the trouble of digging it up and carrying it many days' march to the bazars and entrepôts along the base of the hills. At the present day the root is chiefly brought to Najibabad in Bijnor, but even there the annual imports do not exceed twenty maunds. From Najibabad it finds its way to Delhi, Saharanpur, and other places in the north of India. The retail price in Saharanpur and Dehra is about 10 to 12 annas per seer.

This plant is interesting as being of immense antiquity, and the eminent orientalist, Sir William Jones, has satisfactorily proved that the *Nardos* of the Greeks, the *Spikenard* of Holy Writ, the *Jatamansi* of Sanskrit, the *Sumbul* of Persian writers on Materia Medica, and the *Balchur* of Indian bazars, are one and the same plant.

It has been objected that the fragrance of the Jatamansi is not such as to warrant the probability of its having been highly esteemed by the ancients, but Dr. Royle justly replies that "it is both incorrect and unphilosophical to infer the tastes of another time and country from those of the age and place we live in. In the instance before us, however disagreeable it may be to some, there is no doubt that the Jatamansi is highly esteemed in the present day throughout the East, both as a perfume and a stimulant medicine. Indeed, from the number of complaints enumerated in Persian authors, for which it is said to be a cure, this root may lay claim to the title of a true *panpharmacon*; and with respect to the fragrance, I consider that of the true Jatamansi to be far from disagreeable."

The root, when thoroughly dry, has in my opinion a distinctly pleasant, though rather strong, scent, and I shall be glad to receive any information regarding its value with the European perfumers, and whether it is employed by them in the preparation of any of the numerous perfumes which they offer to the public. It has before now been procured in a chemist's shop in London, and no doubt it is well known to the trade, though there is probably not much export.—A. S.—*Indian Forester.*

SUPPOSED TEA.

TO THE EDITOR OF THE "AMERICAN GROCER."

I herewith mall you two samples home-grown tea, so called. No. I, about five years old, grown and cured in Louisiana, and No. 2, now green, grown in Texas. Please give your opinion as to their genuineness and value in your next issue.—Yours truly,

E. C. CRAWFORD.

No. 1. This sample was in such a bad condition that it was impossible to determine anything about it. Commercially it is valueless. No. 2 is not tea at all.

CURE FOR BATS.

TO THE EDITOR OF THE "MADRAS MAIL."

SIR,—Advise "Tectum" to hang to the ceiling (or any place) infested with bats a few branches of any thorny bush. The thorns injure the bats' wings, and they leave to inhabit some other locality. Take off all leaves from branches. V. S.

SIR,—With reference to a letter signed "Tectum" in your issue of the 21st instant, I would suggest sulphur fumigation to your correspondent to get rid of his bats. Care should be taken to turn out any other animal that may be in the room, and remove all ornaments, more especially gilded or metallic ones, and then put two tablespoonsful of sulphur in an earthern chatty, and throw in it some live charcoal. Should the roof be lofty, a tripod of bamboos might be formed and the chatty containing the sulphur be placed on its apex some distance above the floor. The doors and windows of the room should be closed except one, should your correspondent be disposed to let the bats escape alive; otherwise they will all be killed by the sulphurous smoke, and it may be necessary to search the roof to remove the dead bats to prevent their becoming a nuisance. The advantage of fumigation is not only to destroy bats, but also to remove the strong musty smell that always exists where bats congregate. After this has been done, your correspondent should take equal parts of carbolic acid and lamp oil, mix them well together, and paint the rafters, couples and joists of the room where the bats congregate. Should the painting not be feasible, woollen rags steeped in the oil should be stuck among the rafters, or fastened to them with a tack or two; the bats will immedidately forsake the locality and not give further trouble. Kerosine oil may be substituted for the carbolic acid. JOHN SHORTT.

THE CENTRALIZATION OF TEA FACTORIES: THE MOST CERTAIN METHOD OF INSURGING THE CHEAPEST PRODUCTION AND HIGHEST QUALITIES OF TEA.

Instead of each estate having its own factory, there should be a factory between each group of estates. The best machinery, the best tea-maker, the advantages of combination and the undoubted command that large breaks have upon the market would all result from the organization of such a scheme.

It may be said; it has already been tried and failed; but it must be remembered that anything of this kind which has hitherto been tried has been undertaken too far from the estate whereon the tea is grown. Tea must be *fully packed* before leaving the house wherein it is made.

The great principle of good work is a division of labour, and I cannot think otherwise than that this is very applicable to tea. We should have the tea planter and the tea-maker, and those who can have the best planter and the best maker will succeed the best; and they will certainly be as a rule the tea-growers who can form the largest combination.

Of late years the improvement in the manufacture of tea has made large strides, and all, save withering, can now be performed by machinery; yet with all this I have not yet heard of a thoroughly well-arranged tea-house in *any* part of the world. That is a complete building of itself, which, from beginning to end, is not full of additions, which might have been provided for in the original building. Tea has to be rolled, fermented, fired, sorted and packed, and these works are still mostly done by unscientific means, or, if not so, the continuity of the processes is confused and involved. Some places have better organized factories than others; the best are, however, very backward from what they should be. The wasted heat from the driers usually escapes without in any way further aiding withering, which it could easily be made to accomplish.

Several adjoining estates in a workable area might easily combine for the purpose of one good efficient tea factory, instead of four or five small, unsatisfactory and incomplete tea houses. For the former, the inducements would be higher, the appliances more complete. A man said to me a short time ago: "The worst of tea is that it will require constant and unwearied care, the requirements may change, so will then the process of manufacture: as others improve, as they certainly will, so will our manufacture have to, and we shall be quite at the mercy of our manager." It will differ from happy-go-lucky coffee, for the tea will not manufacture itself as coffee may be said to have done. This unity of action is not so much on account of cheapness of manufacture, rather uniformity and certainty of quality; which no small factory can maintain, and it can never be accomplished without a thoroughly organized application of machinery. Those who use rolling machines already observe a far greater uniformity in their teas, and this must be the case, and will improve more and more as machinery is used and perfected. I know that in anything it is difficult to induce Ceylon men to unite. It is only in view of so much to be gained that I suggest it, and to declare our impossibility to accomplish here what succeeds so well elsewhere is not only to admit an inferiority, but to prefer going on without either effort or desire for improvement.

There are many ways in which this combined system could be made to work, but none I think better than—firstly, that the manufactory, building, land and machinery be the joint property of the interested, estates; secondly, that a separate account be kept of the factory, which would of itself have to show a profit by a charge made upon the making; thirdly, that owners have the option of sending their own tea home in bulk or separately. The management. of course, would be at the disposal of the proprietors.

A system based upon some such plan as this might be made to answer, if planters determinedly seek their own interests. W. F. L.

[NOTE BY ED.—The idea shadowed forth in the above letter is in every respect an excellent one, but like all such schemes, would meet with much prejudice from planters, who are rather naturally jealous of their own produce, and who think that their own particular estate produces a better sample than their neighbours, while they would not like it to be mixed with that of others. Were the leaf of each estate, in such a central factory as "W. F. L." here indicates, kept distinct, one of the many advantages of the scheme would be lost, though of course it could be done, and we think should be done, in spite of any loss in simplicity of working. That the erection of a large well-regulated tea-house in the centre of a group of estates would not only be more likely to be the means of more even breaks of tea being turned out, but would probably lessen the cost of manufacture per lb. considerably, we firmly believe. This system would be peculiarly of advantage to closely adjoining estates, and those of small acreage, which otherwise would have to incur the cost of separate tea-houses, and all its paraphernalia, besides having to pay another European for the supervision of the tea house which would make the cost of superintendence very heavy on a small acreage. All this would be obviated by the scheme proposed above, as the manager of a garden, even of large acreage, whose tea was made at a central factory, could concentrate his attention on the *cultivation* of the plant, and the more legitimate work of the planter proper, without even the aid of an assistant. This subdivision of labor would, as it always does, induce economy as well as efficiency—the two great elements in skilful manufacture.]—Local "Times."

TOBACCO CULTURE IN VIRGINIA.

BY C. N. BERKELEY, AMELIA CO., V. A.

The "Old Virginia Leaf" has probably seen its best days. Whatever were the means by which the staple attained its great reputation, the planters have not troubled themselves to sustain it. Formerly, the facility of raising tobacco through the double advantage of rich soil and cheap labor, with the profit of ready sale, induced all who could to plant as large a surface of the crop as was possible. Complaints, however, as to quality began to be heard sometimes before the war, but were unheeded, and now, while the demand continues steady, the increased cost of producing the weed, and the decline in prices, have borne heavily on the farmers, and their favorite crop is fast losing its place as a paying product.

To secure a crop of tobacco, two things must be assured: a full plant-bed, and a full planting. The bed is a spot in the woods, with a southern exposure, cleared off to the required number of square yards, which varies from 500 to 2,000. Great care is necessary in the preparation, the first part of which is the burning. This is done to kill all grass-roots, and seeds of weeds, that they many not grow with the plants. Parallel rows of poles (skids) are laid, four feet apart, extending the length of the bed; across these is built a good sized ridge of wood, reaching from side to side, then fired along its whole extent. After burning until the coals and ashes have covered the ground underneath, the fuel is pulled over upon a fresh strip of ground, the process being repeated until the bed is burned all over. A powerful breaking-plow is used to tear up the plot, followed by grubbing hoes and rakes, kept going until the charred, stumpy area is turned into a nice soft bed of uniform fineness. It is necessary to put strong manure on the bed to make good plants. The seed is then sown, mixed with dry ashes, at the rate of a gill to the 100 yards, and put in by a brush, a small-tooth rake, or by stamping. Plenty of brush must be put on the bed to protect the young plants from late frosts. Having manured his land, the farmer makes lists (throwing three furrows in one), and cuts them into hills. The best planting time is from the middle of May to July; after this, the cut-worm and heat destroy all replanting. After a rain, the plants are drawn from the bed, and dropped by one person for two others, who make a hole in the hill, insert the root, and press the earth close. The working of the crop is the same as with corn. When the tobacco is high enough to have ten leaves, after pruning, the bud is taken out, to prevent seeding, and the plant grows broader and heavier, but no taller. With the second week in August comes the fly which fastens its white eggs upon the underside of the leaf, from which the worms hatch by hundreds. Unceasing attention for three or four weeks is imperative, to keep down worms and suckers, or they will destroy the crop. Cutting is begun about the middle of September. The plants are split from the top to within six inches of the root, severed, and turned bottom up to "fall," after which they are collected in piles of about a dozen each, and hung by the splits on sticks riven for the purpose. Some farmers cure tobacco on scaffolds in the field, but the rule is to house and fire at once. When the stems are dry enough to crack, the curing is done, and some damp day is chosen, when the tobacco is "in order," to "strike" and "bulk" it. Stripping is done during winter.—*American Agriculturist.*

NOTES ON SOME NEW ECONOMIC PRODUCTS RECENTLY RECEIVED AT THE ROYAL GARDENS, KEW.

BY W. T. THISELTON DYER, M.A., C.M.G., F.R.S., F.L.S., ASSISTANT DIRECTOR.

A copy of this paper, extracted from the Linnean Society's Journal, has been sent to us by Mr. Thiselton Dyer. It coantains a notice of West-African Indigo; Inhambane Copal; Ogea Gum; Bhaib (Pollinia eriopoda, Hance), which the late Major-General Munro, C. B., promptly identified the plant with *Spodiopogon angustifolius* (Trin. in Act. Petrop. vi, ii. p. 300; Spec. Gram. t. 336). It may be convenient to reproduce here what is stated in the Kew Report, for 1878 (p. 45):—"*Eriophorum comosum.*—This plant is well known in North-western India, where, under the name of *bhabar ghas*, it is largely used as a material for ropes. It was submitted by Dr. King to Mr. Routledge, who writes to us:—'A small quantity of bleach brings it up to a good colour. The ultimate fibre is very fine and delicate, rather more so than Esparto, and of about the same strength; the yield, however, is 42 per cent., somewhat less. I think I may venture to say it will make a quality of paper equal to Esparto.'" Wax from Rhus vernicifera, Dec; Myrica-wax from Jamaica; Various species of *Myrica* yield a wax in different parts of the world. The berries are simply boiled, and the wax rising to the surface is skimmed off and moulded into cakes. Mixed with tallow, the wax of *Myrica cordifolia*, L., is used at the Cape in candle-making. *M. cerifera*, L., yields asimilar product in N. America, and a variety of species are utilized in a similar way in Central America. The Kew Museum possesses a candle of *Myrica*-wax from the "W. Indies," presented by Professor Ansted, and a moulded block of what is probably a similar material from St. Domingo. For the first authentic sample from these islands we are, however, indebted to D. Morris, Esq., F.L.S., Director of Public Gardens and Plantations, Jamaica. The following particulars respecting it were contained in a letter dated March 15, 1883:—"I am sending in a separate parcel a small specimen of wax prepared by Mr. Hart from one of our native trees, which may be of sufficient interest to have a place in your Museum. It has been prepared from the seeds of *Myrica microcarpa*, Benth., an amentaceous plant, growing abundantly on the hills of Jamaica at elevations of about 5,000 feet. The seeds were simply boiled with water for about half an hour, and then allowed to cool, the wax forming (when cool) a cake on the surface of the water. This was melted again in an earthen vessel to allow the dross to settle to the bottom, after which the wax becomes clean and clear." As the tree is very abundant in Jamaica, and is of no use except for fire-wood, it would be a very desirable thing if any commercial use could be found for the wax, as it can be prepared in such an exceedingly simple manner. Trapa verbanensis, De Notaris; Ngai Camphor.—The specimen sent by Mr. Frater is not white, but greenish grey, which may be due to defective purification. I can, however, scarcely doubt that it is identical with Ngai camphor, of which a specimen previously existed in the Kew Museum; this Hanbury attributes to *Blumea balsamifera*, DC. It is interesting to notice that, according to Kurz ('Forest Flora of British Burma,' vol. ii. pp. 82, 83), *Blumea balsamifera* is abundant in our Indian possessions. He describes it as "an evergreen shrub, sometimes growing out into a small tree." He further remarks:—"A most common and troublesome weed, freely springing up in deserted toungyas and savannahs, along river-sides, &c. all over Burmah, up to 3,000 feet elevation . . . . . Yields camphor equal to the Chinese one."

DRAINAGE.

It shews how rarely drainage is practised on Indian Tea Plantations, that an article in the *Tea Gazette* should commence thus:—

Draining is an operation, the less a plantation requires the better. As has been justly remarked, the tea industry must not be handicapped by expensive expedients being necessary to the full developement of the plants. *Draining*, or the reclaiming of land from too moist a condition, is necessarily a tedious and expensive work, requiring no small amount of engineering knowledge and capital. And that the results amply repay the capital and skill applied to the carrying out of such reclamation in densely populated countries, where money is abundant and arable land scarce, cannot be doubted. But that tea should not be grown, and will certainly not *pay* under such circumstances, is equally certain.

However, it sometimes unhappily happens, that a portion of a garden has been planted on marshly land, or in a situation exposed to inundations, either from neighbouring streams or excess of rain water. In such a case, rather than abandon the plot, or allow the plants on it to sicken and die off, it may perhaps be better to attempt some simple expedients to correct the initial blunder.

The conclusion of the article runs thus:—

It should never be forgotten, that *stagnant water is one of the deadliest enemies of the tea plant.* Its presence is invariably indicated by the yellow, stunted, debilitated appearance of the bushes and the abnormal abundance of seeds on their branches.

There is only one alternative to *draining* a plot of tea, and that is *abandoning it*, for it will never give a remunerative yield—even if it does not die out.

The more an earth weighs, the greater is its power of retaining heat. The darker its color, and the smaller its power of retaining water, the more quickly and strongly will it be heated by the sun's rays.

The greater the power of containing water, the more has it in general the power also of absorbing moisture when in a dry, and oxygen when in a damp, state from the atmosphere.

When endued with a high degree of consistency, it is slow to become dry.

The greater the power of containing water, and the greater the consistency of a soil, the colder and wetter, of course, will that soil be, as well as the stiffer to work, either in a wet or dry state. Coldness in retentive soils is caused chiefly by the removal of the water of drainage by evaporation. That the evaporation of water produces cold is well known:—it cools wine; in hot climates it produces ice.

Humid soils are little benefited by summer heats, because water, in a *quiescent state*, is one of the worst conductors of heat with which we are acquainted. Water warmed at the surface transmits little or no heat. The small warmed portion expands, becomes lighter than that below, and consequently retains its position upon the surface, and transmits on heat underneath. When water is *heated from below*, the portion first subjected to the heat, rises to the surface, and every portion is successively subjected to the heat, and rises, and each having lost some of the heat at the surface, is in turn displaced. Constant motion is kept up, and a constant approximation to an equal temperature in the whole body.

Drainage elevates the temperature of the soil, because, by removing the water of drainage, it prevents that constant evaporation by which the surface heat is lowered.

But it also acts in another way; many experiments have shown that in retentive soils, the temperature two or three feet below the surface of the water-table is, at no period of the year, higher that 46° to 40° in agricultural Britain. Drains placed two or three feet below the water-table, draw out water of the temperature of 48°. Every particle of water which they withdrew at this temperature is replaced by an equal bulk of air at a higher, and frequently at a much higher, temperature. *The warmth of the air is carried down into the earth.* The temperature of the soil, to the depth to which the water is removed, is in course of constant assimilation to the temperature of the air at the surface.

Lavergne, in his "Rural Economy," says:—"Take this flower-pot:—what is the meaning of this small hole in the bottom? to renew the water. And why renew the water? because it gives life or death: life, when it is made only to pass through the bed of the earth, for it leaves with the soil its productive principles, and renders soluble the natritive properties destined to nourish the plant. Death, on the other hand, when it remains in the pot, for it soon becomes putrid, and rots the roots, and also prevents new and nutritive water from penetrating." *The theory of drainage* is exactly described in this figure. —*Indian Tea Gazette.*

GREEN MANURING.

When land is continuously cropped without restoration of the constituents of plants it becomes annually less fertile, through the diminution of the substances which enter into the composition of plants—those which exist in forms suitable for absorption by the roots being gradually exhausted; and although a much larger quantity of the same materials exist in the soil, they occur (says MacIvor) "in insoluble and unassimilable conditions, in the form of undecomposed fragments of various rocks, mica, felspar and others, and only become useful as nutriment for plants when natural agencies at work in the soil have rendered them soluble and therefore available." In order, therefore, to afford time for these agencies to act to such an extent as to reduce the insoluble into soluble substances that can be appropriated by plants, a year's cropping is intermitted, and the ground is rested under what is termed a fallow, being frequently stirred, the better to expose the particles of soil to the action of meteoric and chemical influences, whereby it is to some extent recuperated and its productive powers restored. The air furnishes ammonia and nitric acid, the two principal sources of nitrogen, one of the priccipal constitnents of a fertile soil. It must not be supposed, however, that fallowing is a substitute for manure, for the mineral constituents required by plants are not at all increased, but only a portion of them rendered soluble, and therefore the more completely that object is gained the sooner will the land be deprived of them, and its approach to barrenness accelerated. It thus becomes a question with the farmer what is the best method to pursue under the circumstance of a gradually lessening yield from his land; whether to go on obtaining only a crop every second year, or perhaps two crops in three years, or whether to lay out a larger portion of capital on the land, in the form of manure, so that he may obtain a crop every year. With many farmers the question will be simply a matter of calculation, for over a large portion of the colony manure of any kind cannot be obtained unless a considerable expense is incurred. But there is another mode of procedure in the cultivation of green crops to plough into the land, which it is in the power of nearly every one to carry out, and although it does not add to the mineral constituents of the soil, nor prevent ultimate impoverishment, it is greatly more efficient in the work of changing the insoluble constituents of plants into a condition to be appropriated as plant food.

The nitrogen that is added to the soil during the time it lies fallow is liable to be washed out by heavy rains, drainage water almost invariably carrying off more or less, so that much of what has been gained through chemical action during the season may be washed away and lost should a heavy rain occur before the next crop has had time to appropriate it. This danger of loss is entirely obviated by the cultivation of a green crop, which seizes upon the nitrogen as fast as it is formed and retains it for the use of the succeeding crop, in the form of organic compounds, and when the crop is ploughed into the ground, where it rapidly undergoes decomposition, the nitrogen is again liberated and ready for the succeeding crop, while the remainder is changed into humus, one of the most valuable constituents of soils, exercising a beneficial influence on both the chemical and physical condition of the soil; for though not in itself of any practical importance as plant food, it serves (says MacIvor) "by dissolving in rain water, to promote the liberation from insoluble combinations of the valuable constituents present in the soil. But according to the same authority these are not the only beneficial chemical results brought about by green manuring; "the plants in decomposing set free the mineral or ash constituents they drew from the soil in forms of combination more readily available to the succeeding crop than these were in the state in which they naturally existed in the soil. In addition to thus preparing the mineral constituents already present, green manuring with deep-rooting plants actually replenishes the surface soil in these substances: food hitherto unavailable to the grain or other crops is drawn up from the subsoil by the deeply penetrating roots of the lupin or clover and brought within reach of the succeeding crops."

Recurring to the presence of humus in the soil, and its value as a retainer of nitrogen which exists in the soil chiefly in the form of humus. by tillage and bare fallow the humus is oxydised, and the soil loses a portion of its store of nitrogen. Continuous corn cropping with artificial manures tends in the same direction. On the other hand laying down in grass, the ploughing in of green crops, or the application of farmyard manure increases the proportion of humus in the soil; and although humus may not have the power of combining with the nitrogen of the atmosphere, it is undoubtedly capable of absorbing ammonia, of which the air always contains a small amount, and is thus, apparently, one condition of maintaining fertility.

It has been proved that the soluble nitrates are formed most rapidly in the soil in the end of summer and beginning of autumn, and if a green crop is on the land at the time these nitrates are taken up by the plants and rendered insoluble by entering into other compounds in the substance of the plant, whereas the grain crops, which come off early, finish their growth before the time for the most rapid formation of nitrates has arrived, and, as previously remarked, there is danger that a considerable portion of these nitrates may be washed away by heavy rains, which do occasionally fall during the autumn months, before the new crops' are in a condition to absorb them.

Shading the soil is another function of green crops which is by many, both culturists and scientists, considered to be highly beneficial to the land. Indeed its value has been so long and so commonly recognised as to have passed into the proverb that "Snow is the poor man's manure." "Science and experiment have shown," says Professor Knapp, of Iowa, "that what is so beneficial in winter is even more advantageous in summer, and that few things can be more harmful than to denude the soil and allow it thus to remain for a length of time."

The cultivation of green crops is nature's plan of enriching the soil; we know that the face of the earth has not been always covered with soil capable of producing either the grass of the field or the trees of the forest, but that the gradual increase in the number of plants and the fertility of the soil were co-existent, one being the consequence of the other, and the complete shading of the soil has always been a concomitant of progress, while wherever the soil remains, or has been made bare, there barrenness prevails.

Green crops are further beneficial, inasmuch as they are of great assistance in clearing the land of weeds, which may be in part smothered by the plants and the remains destroyed when the crop is ploughed under, without the necessity for the frequent ploughing and scarifying necessary to clear a foul fallow.

The choice of the kind of plant to grow for green manuring must depend upon a variety of circumstances, such as the nature of the soil, the climate and others, but chiefly on the cost of seed, which, if not very low, might cause a loss instead of a profit. Clover, peas and other leguminous plants are highly recommended for the purpose, and where the soil is of a calcareous nature, they are effective both by supplying a large amount of vegetable matter, and by their deep rooting, especially red clover, bringing up from the subsoil the mineral constituents which the roots of wheat or other grain cannot reach, and depositing them near the surface for the benefit of future crops. The lupin, which belongs to the same natural order, has proved to be an excellent preparation for the grain crop wherever it has received a fair trial; it is capable of suppressing all kinds of weeds, including sorrell; it, however, cannot yet be obtained in the colony, but it is one of those plants of which farmers might provide themselves with the seed. Rape and White Mustard are perhaps the most commonly grown for the purpose; they do well on all soils in tolerable condition, but, if the soil is poor, it is advantageous to further their growth by means of artificial manure. Oats and rye are also suitable for the purpose. If the former are sown with the first autumn rains, they may be fit for ploughing down soon after midwinter, and may be succeeded by a crop of rye, which will be ready in time to admit of being followed by rape, mustard, or some similar crop, or even by a crop of potatoes. Green crops should be ploughed in just as the flower begins to open, with the exception of grain, which is ready as soon as it has attained a sufficient length. It is a common and frequently a profitable practice, to consume a portion of the crop with sheep or other stock, and to carry out the practice successfully, the crop should be assisted with a portion of artificial manure; which will benefit both the stock and the succeeding grain crop.—*Leader.*

FLIES AND BUGS.

SUGAR CULTIVATION IN CEYLON.

The writer who signs himself "Vedda" (page 566) having sent a copy of his letter to another journal, in which it has been published, it is only the importance of the subject which induces us to notice the letter and its contents. In the south of the island, along the banks of the Gintara and Matara rivers; in the Mahaoya Valley, near Negombo, in the Western Province; and in the Dumbara Valley and at Peradeniya in the Central Province, sugar cultivation has been tried on a large scale, capital and experience having been applied to the enterprize; but, except in the case of the isolated and not extensive plantation at Baddegama, the sugar grown on which finds a local market, all the experiments ended in failure. Mr. George Wall took part in some of those experiments, and in lately writing on the subject he did not seem to favour the idea of fresh trials. It is true that the sugarcane, which is believed to be indigenous to Ceylon, grows luxuriantly in many parts of the island, and that pieces of sugarcane form a favourite article of food with the natives. It is also true that many superior varieties of the cane have been recently introduced to sugar-growing countries from the Pacifi islands and other places, and that progress in the manufacturing processes has been equivalent to a revolution. But the question is can difficulties founded on paucity of lime and phosphates in the soil and the presence of excessive moisture in the atmosphere, be overcome? The question is not the absolute quantity of juice in the cane, but the density of that juice. We were present at trials in the Burdekin district of Queensland where the juice expressed from "Rose Bamboo" and other canes gave percentages up to 11. We doubt if any cane in Ceylon would show more than 7 or 8 by Beaumé's instrument. But that is a matter of experiment, and the quality of the soil in the drier regions of Ceylon can be proved by analyses. It might pay here as in Mauritius to use bones and guano in sugar culture, but perhaps Mr. Wall can tell us whether such fertilizers were not used in the experiments of forty years ago. We by no means desire to discourage fresh experiments. Our alluvials cannot compare with those of Java and Northern Queensland in natural richness; but we are not liable to the frosts and droughts of Australia, and we are more favourably situated in regard to labour and means of communication than even the sugar planters of Surabaya. The revival of the sugar cultivation here was, naturally, a favourite idea with Sir James Longden, and perhaps Sir Arthur Gordon may determine to put the matter to the test of experiment. But we should like to see experiments as to the density of juice and its readiness to crystallize, and also analyses of soil and estimates of the probable cost of liberal applications of lime, superphosphate and guano to enable such soil to bear crops of cane equal to 30 tons per acre and producing two tons of clean sugar. Experiments of this nature are quite within the scope of the functions of Government. If they were carefully conducted and the results made public, private enterprize would have the necessary evidence on which to act.

The letter from the Director of Public Instruction, which we insert below, is a valuable contribution to the materials necessary for forming a decision on the question of the probable success of sugar cultivation in Ceylon, and after the instructive history of the tea enterprise, long deemed a failure in consequence of the defective experience of the Brothers Worms with China tea and China tea makers, we hold our mind open to all the facts which can be adduced in favour of a further trial of sugar. Be it noted, however, that the Baddegama sugar lands are mainly old rice fields, and that citronella oil, used chiefly to perfume toilet soaps, is an article not in extensive demand and the market for which could be readily swamped were Mr. Curtis' system to be extensively followed. There are other products, however, besides lemongrass, the growth of which could be alternated with sugarcane. For instance, gram or maize, but, as both these would take more potash, lime and phosphates out of the soil than the grass, manure would have to be used. Or, if a considerable area of land were available, portions could be left fallow in succession, after bearing a crop of canes and a crop of "ratoons." But guano, or other similar manures, would certainly be needed at a very early stage of the enterprize, however conducted. In Mauritius and Demerara, we believe, returns of cane and sugar have increased just in proportion to the extent to which fertilizing substances were applied. Even rich lava soils give out after a time, if cropped without the application of manures, and we have neither decomposed lava nor anything resembling it. The late Mr. Bowman, gave us an account of an experiment conducted by Mr. Wray at Penang, which suggested to us the idea that some of our river delta and backwater mangrove swamps might be redeemed by means of drainage and bunds for sugar cultivation. Mr. Wray's swamp was full of shells, which was deemed a most important advantage, but we have never heard the subsequent history of the experiment.

We regret to say that we cannot answer from personal experience or observation Mr. Green's query as to artificial manures in "the forties," but we scarcely think that men like the late Baron Delmar and the late Lord Elphinstone would have abandoned the enterprize without a full trial of fertilizers and their effects. But this is just the question on which Mr. Wall, from his direct connection with the previous attempts to grow sugarcane on a large scale, can speak with authority, and we trust he will give the public the benefit of his knowledge and state his views as to the possible success of experiments tried in the light of all the experience acquired and the vast improvements made in regard to canes cultivated and in the machinery and processes of manufacture.

SUGAR CULTIVATION IN CEYLON: ROTATION OF CROPS.

31st January 1884.

Sir,—I have read with interest the letter signed by "Vedda" and your article on "Sugar Cultivation in Ceylon" in your issue of last night.

May I point out one matter not dwelt upon?

In the course of a tour on official work, I spent an hour or more on Baddegama estate last week, and Mr. Curtis, the manager (an old West Indian planter), attributed the success of Baddegama and the failure of other sugar estates to the fact that they planted up sugar only, and it soon exhausted the soil and failed, while at Baddegama they plant in "rotation" sugarcane and citronella, one part of the estate being under one and another under the other, in turn.

Apart from profiting by the good old-fashioned system of "rotation of crops," which is so seldom remembered in this country, the citronella grass, after the oil has been boiled out, forms a most valuable manure for the soil of the estate; it is first placed under the cattle and makes excellent "farm-yard manure."

Mr. Curtis made no secret of this, and told me that I was at liberty to make any use I pleased of the information which he gave me.

You, sir, will know whether the charge brought by Mr. Curtis against the old sugar failures is correct or not. But at any rate the rotation of sugar-cane and citronella at Baddegama is a matter of public interest, and———*it pays.*—Yours faithfully,

H. W. GREEN,

Director of Public Instruction.

CINCHONA BARK AND QUININE.

From the Annus Pharmaceuticus in 1883 of the *Pharmaceutical Journal and Transactions*, the editor, Dr. Paul, sends us the following interesting extracts:—" The article which has probably occupied the pen most has once more been cinchona bark, one fact becoming more and more apparent that although cinchona cultivation is still increasing in different parts of the world, especially in Ceylon and Jamaica, considerable uncertainty exists as to the exact species that are being grown. It is evident that until this confusion is cleared up the commercial cultivation of the plants can only be carried on by rule of thumb, and the assistance the chemist would be capable of rendering to the cultivator will be minimised through the shortcomings of the botanist. Nevertheless some interesting facts have been placed on record, and one or two of these point to the probability that when the botanist has done his work, he will only have made it still more evident that the cultivator must always look to the chemist to help him to decide under what conditions of growth any species or variety of "Cinchona" may be made to produce the most favourable yield of alkaloid. In the first place Dr. Trimen has reported some experience with what were believed to be succirubra plants all raised from one kind of seed, which seems to show that elevation has a great influence on the development of alkaloids, nearly twice as much alkaloid being found in the bark grown at a height of 5,500 feet as in the bark grown at 1,500 feet, whilst the alkaloid in the former case was mainly levorotatory (quinine and cinchonidine) and in the latter case principally dextrorotatory (cinchonine and quinidine). Analyses made by the late Mr. J. E. Howard of barks from different elevations in Jamaica and in Ceylon appeared to confirm this inference, and it is worth mentioning that in all the cases the bark grown at the lower elevation, though considered to have the best appearance, was poorest in alkaloid. Mr. D. Howard has recorded the observation that whilst in renewed bark produced on trees after stripping according to Mr. McIvor's plan in which alternate strips are removed down to the cambium, the proportion of quinine is higher than in the original bark, the reverse is the case in renewed bark produced after the "shaving" process, in which the bark is usually removed uniformly and superficially, the tendency being then to develop cinchonidine at the expense of quinine. * He also states, as evidence of the field there is for skill in the selection of cinchonas for cultivation, that he has met with original "red bark" yielding 4 or 5 per cent of quinine, whilst calisaya bark from individual trees, grown in Ceylon under apparently similar conditions, varied from 3 to 9 per cent in the yield of quinine. Such a result is perplexing; nevertheless, the general results seem to show that, other things being equal, the plants yielding the most valuable barks grow in the richest soil, which is quite in accord with what might be expected and also with the experience of Mr. Broughton, published a dozen years ago. A similar lesson as to the relative effect of the depth to which the bark is removed appears to be taught by some analyses, made by Mr. J. Hodgkin, of different pieces of Ceylon succirubra quill bark taken from the same consignment, some being natural, some renewed, and some partially natural and partially renewed on the same piece. In the renewed portion of the natural-renewed quill, where the shaving removed would necessarily be decreasingly thin, the quantity of quinine was less than in the entirely natural quills, while the cinchonidine was more than double. The entirely renewed bark showed an increase of quinine equal to 75 per cent, which more than outstripped the increase in cinchonidine. The cinchonine did not show much variation, but there appeared a considerable diminution of alkaloid in the natural bark in juxtaposition to the renewed bark. Similar results have been obtained before, though Mr. Hodgkin has been the first to make them known. Of course the value of any inferences drawn from these results would be dependent upon the extent to which the different pieces analysed were comparable one with another. Dr. Hesse has added two more to the already long list of cinchona alkaloids,—concusconine and concusconidine,—and he has endorsed the claim of the substance isolated from cuprea bark almost simultaneously by three sets of observers to be considered a new alkaloid. He, as well as others, has failed to obtain the crystalline compound of quinine and quinidine which was rather too hastily assumed to have been mistaken for a new alkaloid, but Messrs. Wood and Barrett have now published definite instructions for the preparation of this compound, as well as compounds of quinine and quinidine and quinine and cinchonidine with benzene, the difference in form of crystallization of which they state may be used as a delicate test for an admixture of cinchonidine with quinine sulphate.

* We cannot accept this question as at all settled. —ED.

Whilst on the subject of cinchona bark, it may be mentioned that Dr. Paul, having been struck by the fact that a sample of professedly B. P. liquid extract of cinchona contained only a very small amount of quinine, was induced to examine several other samples collected from different sources and found that they all agreed in containing but a very small proportion of quinine, varying from mere traces up to 2 grains per fluid ounce. As the liquid extract, if it fully represented the alkaloidal contents of an official bark, would contain about 35 grains to the fluid ounce, Dr. Paul made further experiments to ascertain whether an explanation was to be found in the official process being insufficient for the complete exhaustion, in which he used a sample of ordinary "flat calisaya," as now met with, and a sample of Indian bark, both of known composition. Upon analysing the liquid extracts made according to the B. P. process and the residual marks, it was found that only about one-seventh part of the alkaloids in the original barks had passed into the preparations. These results were communicated to the Pharmaceutical Society at an Evening Meeting and gave rise to an animated discussion, Professor Redwood maintaining that the official conditions as to the choice of a bark had not been complied with, and that, therefore, the experiments could not be used as criteria in estimating the value of the official process. A remark made by Dr. Paul to the effect that he could not confirm a statement by Mr. Ekin as to the tincture being a good preparation led that gentleman to request Messrs. Hogg and Braithwaite to make some independent experiments, the result of which went to demonstrate the correctness of Dr. Paul's statement, that after the preparation of a tincture of cinchona by the official process as much alkaloid remains in the bark as the spirit has taken out. Connected with this discussion a bye-controversy was started in respect to the well-known preparation of the late Mr. Battley, which, however, revealed little beyond the fact that that gentleman knew better how to keep a secret than was commonly supposed.

Considerable progress was made during the year in working out the chemical and pharmaceutical history of nux-vomica and its preparations, in a series of investigations conducted by Messrs. Dunstan and Short. The first step was to contrive a process for the analysis of the drug, which consisted in exhausting the powdered seeds in an ingeniously contrived apparatus with a mixture of chloroform and alcohol, removing the alkaloids from this mixture as acid sulphates by shaking with dilute sulphuric acid, and then after decomposing with ammonia taking up the liberated alkaloids again with chloroform. When this process was applied to specimens of seeds authenticated as from Bombay, Cochin and Madras, it was found that their richness in alkaloid corresponded with the order in which they are named, ranging in one series from 3·46 per cent. in Bombay to 2·74 in Madras seeds. This variation, which had previously been suspected, having been established, it followed naturally as a corollary that it should be reproduced in the preparations, as indeed appeared in a paper sent by the same authors to the Conference meeting, giving the results of analyses of a dozen commercial specimens of tincture of nux-vomica. In this paper, the authors, availing themselves of the insolubility of strychnine ferrocyanide in dilute sulphuric acid as a means of separating that alkaloid from brucine, were able to show that not only did the proportion of total alkaloid vary, but that there was also a variability in the relative proportions of the strychnine and brucine present. In the results obtained, however, there were signs of another cause of variability in tinctures of nux-vomica, besides the quality of the seeds, which induced the authors to experiment as to the effect of using alcohol of different strengths, and they came to the conclusion, laid before an Evening Meeting last month, that the best results were obtainable in using a mixture of 100 volumes of rectified spirit with 25 of water as a menstruum. Practically the same results were arrived at by Mr. Conroy, who having called attention to the probability after the reading of the first paper, had been working independently on the subject. The use of sodium chloride to assist in the preparation of tincture of nux-vomica seeds had been recommended by Mr. Rother on chemical grounds; but Messrs. Dunstan and Short came to the conclusion that though the exhaustion of the seeds is facilitated by it, which they attribute to a physical and solvent action, the ultimate practical gain is doubtful. In a report upon twelve specimens of extract of nux-vomica the same authors showed that, as was to be expected, the range of variability in total alkaloid and in the relative proportion of strychnine and brucine was quite as great in that preparation, a fact that effectually disposes of the suggestion that the extract might be used as a basis for preparing a uniform tincture.

The bark of *Hymenodictyon excelsum*, which is used in India as a tonic bitter, has been investigated by Mr. Naylor, with the result of disproving the presence of æsculin, which had been alleged, and the isolation of an alkaloid free from oxygen, to which the bitterness appears to be mainly due, which he has represented by the formula $C_{24}H_{40}N_3$ and named "hymenodictyonine," and a peculiar neutral principle. Cusparia bark has yielded to Messrs. Körner and Böhringer three hitherto unknown alkaloids, two of which they have named "cusparine" and "galeipine." Mr. Gerard has succeeded in obtaining "gelsemine," the characteristic alkaloid of the root of *Gelsemium sempervirens*, in a crystalline form, and as the result of analysis has attributed to it the formula $C_{12}H_{14}NO_2$. Dr. Hay has reported the isolation from *Canabis indica* of a new alkaloid, which from its physiological properties he has called "tetanocannabin." Theobromine has been found to accompany caffeine in the kola nut by M. Shlagdenhauffen, the compliment being returned, according to Herr Schmidt, by caffeine accompanying theobromine in the cacao nib, where, Dr. Galippe says, it always has copper for a neighbour.

COLONEL MONEY ON CEYLON TEA.

Colonel Money in his recently published pamphlet on "Indian *versus* Chinese Teas" writes as follows :—

Under the term "Indian," I include Ceylon teas. The plantations in that island are distant, as the crow flies about 350 miles from the tea gardens on the Neilgherry or Blue Mountains in Southern India. These latter are separated from the tea cultivation in Bengal by 1,500 miles, and from that in the North-West of India by about the same distance. Thus, as the tea grown in these last three localities, though so far separated, are all, and truly, named Indian teas, we may well admit Ceylon (which is so close to the Neilgherry gardens) into the list. It is well also to do this because the tea plant in Ceylon was introduced from India, and thus the characteristics of the Indian shrub, as also the made teas, are more or less alike. The object of this little pamphlet being confined to the question "Indian *versus* Chinese Teas," I cannot here dilate separately on Ceylon teas.* What I say as regards Indian teas applies generally to them ; but this much I may add, that if the quality of Ceylon teas keeps up to the high standard they have maintained last year and this (the cultivation is quite in its infancy), India will have cause to be proud if Ceylon teas *are* classed together with the teas of Madras, Bengal, Central India, and of the North-West Provinces, under the general term Indian teas. In fact, the term Indian teas is a very wide one. It includes, as we have seen, the products of localities more than 1,000 miles apart; localities, too, which differ greatly in their climatic conditions. There is, however, another and a still more important difference between some Indian teas than any caused by figures of latitude, I shall allude to elevation. Some teas are grown in the plains, some in the hills; that is to say, some at three or four hundred feet only above sea level, some at eight thousand feet or one-and-a-half miles, and at all intermediate heights. These teas differ greatly: the lower teas are the stronger, the elevated the more delicate flavoured.* Besides the point mentioned, soil and rainfall are also differing causes, and I might add others, but enough to prove what I have said—viz., that the term "Indian teas" is a very wide one.† Though differing so much, there is still a family likeness in all Indian teas, and in that similitude they are opposed to Chinese. There is more body, or strength, in the Indian tea of any grade than in a similar one from China ; in other words, the former will go further. This is due to two causes—firstly, that the Indian tea plant is *not* the same as its China brother; secondly, that the Indian climate is the hotter and more forcing of the two.

In a note, Colonel Money states that in the Assam forests he saw indigenous tea trees twenty feet high. In the remains of a nursery put down on Abbotsford estate, Ceylon, in December 1874, with first-class hybrid seed from the Assam Company, a tree was measured more than a year ago, which had attained a height of 27 feet.

*Ceylon, as a tea-producing country, is discussed in the fourth edition of "Tea Cultivation and Manufacture," pages 183 and 290.

* A choice is thus given. Those who like strong and economical teas, with a marked flavour (economical because they go so far), will find all they want in the teas grown at low elevations ; while, if delicacy of flavour is the chief point sought, the teas of the Himalayan Mountain regions, the Neilgherry or Blue Mountain teas, and those from the high lands in Ceylon will be found perfect in that respect.

† For full details of all the tea-producing districts in India, see "Tea Cultivation and Manufacture."

THE SUGAR INDUSTRY IN PENANG.—New machinery of the latest invention has just arrived per S. S. *Glenelg* for the Batu Kawan and Prye Estates. This is the result of the visit of Hon'ble J. M. Vermont to the West Indies. We may now expect that our sugar manufacture will be on an equal footing with the best refineries in Europe. Mr. Edmund Brown has just returned from Java where he visited the large sugar fabrics to better qualify himself for the manufacture of sugar. He speaks highly of the reception he met there from the planters.—*Penang Times.*

TEA IN FIJI.—Some time ago, special attention was directed to the capabilities of Fiji, and particularly of the island of Taviuni, for the cultivation of the tea plant. On this subject a correspondent now writes :—"With this I send a memo. received three days ago. It speaks for itself, and I need only add that the samples referred to were grown and cured on Selia Lailai, Taviuni. The gentleman to whom I forwarded them writes : 'I have just received through Mr. Scoular, a merchant in Dunedin, the opinion of one of the best London tea tasters, a Mr. Nelson, who has been in the business for some thirty years, and which I have much pleasure in forwarding to you. From it you will see that there is a good future for Fiji as a tea growing country, if the industry is persevered in." The memo. runs :—"We have tasted the Fiji teas and consider them good promising teas with capital liquor, and if well cultivated ought to take well. If they could be brought forward a little more decided in flavour, the broken flowery pekoe would be good value at 2s to 2s. 1d., D.P.; pekoe, 1s. 8d. D.P. ; souchong congou, 1s. 3d. D.P." If this favorable report should induce a more extensive cultivation of the product, the colony may before long be in a position to congratulate itself upon the addition of another important item to its list of exports.—*Fiji Times.* [But how can cultivation be there extended, when is not sufficient labour for existing cultivation.—ED.]

ANALYSIS OF SOME SAMPLES OF NATURAL AND RENEWED SUCCIRUBRA BARK FROM THE SAME QUILLS.

BY JOHN HODGKIN, F.I.C., F.C.S.

A parcel in a recent consignment of Ceylon succirubra consisted of quills of natural and renewed bark in juxtaposition; these quills were about a foot long, the upper half being renewed bark (No. 3), whilst the lower portion was natural (No. 2). As in the same consignment there were parcels of bark entirely natural (No. 1), and also bark entirely renewed (No. 4), an opportunity offered itself for testing whether the renewed and natural barks in direct contact with one another afforded intermediate results to those obtained from the unmixed barks.

The quantity experimented upon in each case was identical, and the percentage of moisture contained in the various barks was noted, in order that the analyses might be brought to one level for greater ease in comparison. The results, therefore, have all been calculated to Moens' standard hydration, viz., 13·5 per cent. The natural bark was carefully separated from the renewed bark by means of a pair of scissors. This was easily done, since the quills were thin and the bark somewhat flexible, owing to the high percentage of moisture contained therein.

No.	Description of Bark.	Percentage of moisture in the bark.	Quinine sulphate.	Cinchonidine sulphate.	Quinine.	Cinchonidine	Cinchonine.	Quinidine.	Amorphous alkaloid.	Total alkaloid
1	Natural Quills...	13·33	1·352	0·948	1·014	0·711	0·661	Trace	1·222	3·608
2 3	Natural portion from Natural Renewed Quills	14·61	0·622	0·911	0·467	0·706	0·819	,,	0·888	2·910
4	Renewed portion from the same Quills	15·96	1·471	2·076	1·050	1·557	0·817	0·051	0·810	4·285
	Renewed Quills	13·81	2·311	2·379	1·711	1·781	0·717	Trace	0·871	6·116

It is worthy of note that the hydration differed considerably in the natural and renewed portions in the same quill. The renewed portion contained more water, probably owing to the soft spongy renewal, which had evidently been accomplished by shaving and not stripping.

The result are rather surprising, but it must be carefully borne in mind that trees grown apparently under precisely similar conditions, from the same seed, and in addition, presenting the same physical appearance, will, on analysis, turn out widely different as regards their chemical composition.

If it should be the case that the natural bark (No. 2) has suffered in the renewal, it will probably be found to be owing to some temporary injury to the tree caused by the shaving process, as in McIvor's experiments no such deterioration was found. As regards No. 3, of course, the reason for such a small increase in alkaloid is due to the fact that this bark consisted of those portions of the quill where the shaving ended, and, consequently, only a very thin layer of original bark had been removed.

Where a thicker layer, as in No. 4, had been removed, the increase in alkaloids was well marked. No. 3 was the only one that gave an appreciable quantity of quinidine, the others only giving a faint trace.—*Pharmaceutical Journal.*

FURTHER NOTES ON VEGETABLE TALLOW FROM SINGAPORE.

BY E. M. HOLMES, F. L. S.,

Curator of the Museum of the Pharmaceutical Society.

I have perused Mr. W. T. Thiselton Dyer's comments (*Pharm. Journ.*, Dec. 15, p. 462) on my previous paper on this subject (*Pharm. Journ.*, Nov. 26, p. 401) with much interest, and have to thank him for drawing my attention to the existence of a fat obtained from a Sapotaceous plant at Bandjermassing, and to the admirable treatise on Minjak Tangkwang by Dr. W. H. de Vriese.

I cannot, however, agree with Mr. Dyer that the Sapotaceous plant he mentions as coming from Bandjermassing is the source either of the fat or seeds sent to me by Mr. Jamie from Singapore, and mentioned on p. 371. These seeds and fat came from Pontianak and Sarawak, not from Bandjermassing.

Mr. Dyer has expressed the hope that his doubts attending the origin of this interesting substance will be cleared up by myself and Professor Van Eeden. I have much pleasure, therefore, in giving such information as I possess, and will take up, *seriatim*, the various points raised by Mr. Dyer (p. 462).

I. With regard to the Sapotaceous plant sent to the Kew Herbarium by Madame de Vries de Vries, Dr. W. H. de Vriese expressly states, in the tract alluded to by Mr. Dyer, that several different fats pass under the name of "Minjak Tangkawang," and enumerates some of them, as shown in the following quotation, from p. 9:—

"The fat, Minjak Tangkawang, is also known at Singapore under the name of Vegetable Tallow. But under this name different kinds of fats occur in Borneo, Java and Japan. Thus there is—

"1st. The vegetable tallow of the fruit of an *Isonandra* (Gutta Percha tree) prepared in the eastern part of Borneo.

"2nd. The fact of *Cylicodaphne sebifera* (*Litsæa sebifera*), a kind of Lauraceous plant. This is obtained from one of the largest and most lofty trees of the westerly part of Java, and is brought over to the middle and east of Java. Near the Court-house at Salatiga a large tree stands, the seeds of which furnish 500-600 candles annually, sufficient for the lighting of the house. This is the *Minjak Tangkallah.*

"3rd. The fat of *Stillingia sebifera*, the tallow or wax tree of Japan.

"4th. The fat of the berries of *Rhus succedanea* of Japan.

"5th. The fat of different *Sapotaceæ*, from species of *Cacosmanthus* in Java.

"All these and many more are classed under the name of vegetable tallow, affording another instance of the enourmous confusion in names and articles in commerce."

To the above list he adds six species of *Hopea* which he calls tallow trees, and which I shall allude to hereafter.

The Sapotaceous plant mentioned by Mr. Dyer is, therefore, judging from the above remarks by Dr. W. H. de Vriese, only one out of several used for the purpose. Whether it be identical with the No. I. *Isonandra* of Dr. de Vries's list or no, I have no evidence to show; but the plant in the Kew Herbarium received from Madame de Vries de Vries, and alluded to by Mr. Dyer, also comes from the eastern side of the island, Bandjermassing being in the south-east of Borneo. This plant, I learn from Professor Van Eeden, is now determined by M. Pierre to belong to a new genus of *Sapotaceæ*, thus confirming Professor Oliver's opinion. Dr. Pierre has named it *Diploknema sebifera*, and the description and figures will, Professor Van Eeden believes, shortly be published in the *Archives Néerlandaises des Sciences Exactes et Naturelles*, issued by the Haarlem Society of Sciences, a copy of which Professor Van Eeden has kindly promised to forward to me as soon as published.

It is evident, therefore, that Mr. Dyer's Sapotaceous plant is only one of the numerous sources of Minjak Tangkawang, but there is no proof that it yields the particular kind described by me.

II. The next point raised by Mr. Dyer is the following:—He remarks (p. 462) "It is *à priori* unlikely, however, that any species of *Dipterocarpeæ* would yield a vegetable tallow from the seeds, because the members of the family are characterized by the presence of oleo-resins in the tissues and not of fatty bodies." This is given as a reason why the vegetable tallow I have mentioned cannot be derived from a Dipterocarpous plant.

In confirmation of my opinion that the seeds sent me by Mr. Jamie *are* those of a Dipterocarpous plant, and that fixed oil *is* obtained from Dipterocarpous seeds, I may say,—

a. That previous to publishing any account of the fat, I had shown the seeds sent with it to Professor Oliver, who at once referred them to the *Dipterocarpeæ* and now agrees with me that they probably belong to the genus *Shorea*, as limited by Bentham. This genus is said by Bentham to be scarcely distinct from *Hopea*, the former having as a chief distinguishing character three or more of the lobes of the calyx enlarged unequally when in fruit, and the latter only two enlarged.

b. That in the No. 1 Museum, at Kew, there are specimens of the fats of the seeds of two Dipterocarpous plants, viz., the fat of *Vateria indica*, well known to yield resin in the bark, and the vegetable tallow from Singapore. In another part of the Museum, among unnamed products, there are some of the larger Dipterocarpous seeds, identical with those sent me by Mr. Jamie (probably *Hopea macrophylla*, de Vriese). There is also a specimen of the fruit of *Lophira alata (Dipterocarpeæ)* labelled "Seeds from which an oil called Meni is obtained."

c. In Dr. W. H. de Vriese's tract, six species of tallow trees which are said by him to yield the vegetable tallow, Minjak Tangkawang, are described. These are *Hopea macrophylla*, *H. splendida*, *H. Balangeran*, *H. aspera*, *H. lanceolata* and *H. Seminis*.

In the copy of this tract in the magnificent botanical library at Kew, some of these species have been identified doubtfully, in what I am informed is Mr. Dyer's handwriting, two of them as a species of *Shorea* and one as a species of *Vateria*. The only explanation that seems possible is, either that Mr. Dyer had not read the text, which is in Dutch, and had referred only to the Latin description of the species, or that he doubted the statements of Dr. W. H. de Vriese and of other authorities whom Dr. de Vriese quotes, that the vegetable tallow was obtained from any Dipterocarpous plants.

d. Mr. F. W. Burbidge, the author of a most interesting book on Borneo, has kindly furnished me with the following information concerning the preparation of oil or fat from Dipterocarpous seeds:—

"The only place I saw the manufacture of oil from Dipterocarpus seeds was in a little village situated on the Lawas River, between Labuan Island and Brunei. The seeds are placed in a leather bag or folded mat, which is enclosed in a tough palm sheath folded into a V-shape, so as to form a spout for the oil to drain into the receptacle placed to receive it. This sheath is placed obliquely in the press, so that an 'oil shed' is formed, towards the side on which the receiver or cooking pot is placed. The oil press or *Tendasun* consists of a stout plank placed on two upright supports, fixed also into another stout plank at the base. In an opening in the horizontal planks are two vertical boards placed obliquely, between which the bag of seeds is placed, the pressure being applied by wedges forcibly driven in behind the vertical boards.

"The Dipterocarpous seeds (at least three species are used) are collected and thrown into heaps, and are then allowed to 'massuck' as the Malays say, or 'blet' as we should say in English, before they are pressed. The pure oil is used in cooking and the refuse is used in the making of candles or rather rude torches. The process here described is used by the Kadyans, a clean and healthy Mahommedan tribe of Borneans, who live on the Lawas and Merapok rivers, and to whom animal fat is an abomination."

Mr. Burbidge gives a sketch of the fruits, which are evidently Dipterocarpous, and apparently have more than three enlarged calyx lobes; they correspond well as regards size with the smaller Dipterocarpous seeds I have received from Mr. Jamie.

e. Professor Bernardin, of Melle-lez-Gand, in reply to my inquiry if he could give any information as to the botanical source of Minjak Tangkawang, says, "I think the tallow comes from *Hopea macrophylla*, *vide* Wiesner, *Rohstoffe*, p. 197." He sends me a portion of a seed said to yield it, which corresponds exactly with the larger variety sent be by Mr. Jamie.

I hope the above statements from competent authorities may be sufficient to show that I am justified in saying that the particular kind of Singapore vegetable tallow sent me by Mr. Jamie is derived from Dipterocarpous seeds, which may be referred to the genus *Hopea* by most writers on the subject, although by some botanists they may be considered to belong to other genera of *Dipterocarpeæ*, and that it is *not à priori* unlikely that any species of *Dipterocarpeæ* would yield a vegetable tallow from the seeds.

I may add here, that I can see nothing improbable in the occurrence of fixed oil in the seed of a plant which yields a resin or oleo-resin in the bark, etc.. The *Dipterocarpeæ* is not the only family in which this occurs. *Canarium commune* (*Burseraceæ*) yields a semi-solid oil from the seed and an oleo-resin from the bark. *Garcinia pictoria* (*Guttiferæ*) also yields a fat (solid in this country) from the seed and a gum-resin from the bark. The chemistry of plant life is so little known at present that we are scarcely in a position to say under what circumstances or by what means resins, fat and caoutchouc are formed in plants, or that all of them might not be formed in the same plant, either by vegetable ferments or by strictly chemical processes.

III. The last point raised by Mr. Dyer is the identity of the vegetable tallow presented to the Museum by Mr. Jamie with two or three specimens in the Kew Museum.

I have seen the specimens in the Kew Museum, and, through the kindness of the Curator, Mr. J. R. Jackson, have been permitted to examine them.

I find that one of the specimens in the form of a cylinder is identical with Mr. Jamie's Dipterocarpous tallow, although labelled "*Bassia* sp."? Another specimen labelled, as Mr. Dyer remarks, "*Bassia* sp.", is of quite a different character. It has a rancid odour, is in crumbling irregular pieces, and resembles in appearance and consistence the fats of *Bassia* generally, and it is quite possible that it may be derived from the Bornean Sapotaceous plant recently named by Dr. Pierre. The third specimen labelled "Concrete oil, from a species of *Bassia; Sakarran;* Sir James Brooke," is totally different from the other two. It is enclosed in a bamboo joint, and consists of an almost pulverulent micaceous mass, with a strong and fragrant odour, between that of sassafras and nutmeg. The crystalline scales of which it consists closely resemble in appearance those of myristic acid. The fat appears to have soaked through the bamboo and has formed an efflorescence of micaceous crystals outside it. I should judge from the above characters that the fat is obtained from the seeds of some Lauraceous plant, possibly from the *Cylicodaphne sebifera* mentioned by Dr. W. H. de Vriese.

To recapitulate: The vegetable tallow and seeds presented to the Museum of the Pharmaceutical Society by Mr. R. Jamie are certainly of Dipterocarpous origin, and are, in all probability, the produce of trees which have been placed by Dr. W. H. de Vriese in the genus *Hopea*, but which may possibly belong to allied genera, according to the views held by different botanists, but they are undoubtedly *not* of Sapotaceous origin.

The Sapotaceous plant sent to Kew by Madame de Vries de Vries, named by Dr. Pierre, is most probably the source of one of the kinds of vegetable tallow of Borneo and possibly of the second specimen in the Kew Museum, but not of that presented by Mr. Jamie to the Museum of the Pharmaceutical Society. Lastly, the aromatic tallow, No. 3 of the Kew Museum, from Borneo, is most likely the produce of *Cylicodaphne sebifera*, although, in consequence of the absence of an authentic specimen for comparison, it is difficult to satisfactorily determine its identity. This last-named product seems, however, worthy of attention as an aromatic fat and of chemical examination with respect to the fatty acids and volatile oil it contains.—*Pharmaceutical Journal.*

PROGRESS OF PLANT KNOWLEDGE.—How the knowledge of plants has progressed of late years may be illustrated by that curious family Orchideæ. Linnæus could count all his genera on his fingers; now Bentham and Hooker in their recent work describe 334.—*Independent.*

TEA AT HIGH AND LOW ELEVATIONS IN CEYLON.

We insert below letters of a most satisfactory character as to the success of the leading "new product" at a very low elevation and a high altitude in Ceylon. On "Citrus" (near Galle) some of the plants must be growing only a few feet above sea level, for the highest point on the estate is only 200 feet above that level. The tea grown and prepared on this place, which Mr. Ziegan has sent us, is excellent, so that there is vast room for extension in the "lowcountry" of Ceylon. If on such low places the soil is lighter and the climate more forcing, leading to earlier exhaustion, facilities for the application of fertilizers will be easy in proportion, and there will be the great advantage of contiguity to port of shipment.

The quality of the tea grown on the high estate in Dimbula is shown by its average price of 1/4½ including broken tea and dust. And now we have most favourable information regarding what was a matter of doubt at one time, the yield at very high altitudes The superintendent of Abbotsford gives the detailed figures for a year's pluckings, showing an average of over 400 per acre, in the first year after proper pruning was resorted to, and he is sanguine of an increase on this quantity during the year on which he has entered with very satisfactory results. The average rainfall at Abbotsford may very safely be taken at 110 inches, of which fully one-third falls in the two months of June and July, the rest being fairly distributed over the year: the comparatively dry and genial season extending from December to April inclusive, August and September are medium months, while October and November are wet and misty, but with nothing like the rainfall of June and July. There is no lack of moisture, and the soil has proved itself an excellent tea soil. Col. Money would ask about the temperature with a shake of his head, when told of the altitude. But latitude (only 7° from the equator) atones for latitude, and that the temperature favours the luxuriant growth of tea is shown by the results. The cold is sometimes keen at night and in the early mornings, but it can be very hot indeed on cloudless days. No sufficient observations for temperature have been taken at Abbotsford. But we can in judge this way. At Langdale, close by; 4,600 feet altitude, careful observations by the late Mr. Heelis resulted in a mean temperature of 65·96°, mean a maximum of 73·5° and a maximum of 89°. The lowest temperature observed was 45·5° and the mean minimum was 58·3°. In every month of the year the temperature had reached 79°, up to 89° as a maximum. Let us take the mean temperature at 66°. The mean temperature of Nuwara Eliya, 1,600 feet higher up, is over 57°, but, as the grassy plain, from evaporation and radiation, is considerably colder than the forest land above, we may certainly add 2° to get the mean temperature of forest land, which Abbotsford is. The fall in 1,600 feet, therefore, is from 66° down to 59°, or 5°. This would give a fall of 1° for every 320 feet, and as the height at which the tea referred to is grown is 5,600 to 5,800 feet, the mean temperature may be taken at somewhat under 63°, giving a climate excellent for human health and very good for tea, Col. Money to the contrary notwithstanding. Abbotsford ranges from 4,650 to 6,075 feet elevation, and if coffee does not revive (there has been considerable improvement this year), we have no doubt the whole expanse of 549 acres will soon be covered with tea.—We give the above information as an encouragement to the many of our brother-planters who have land at similar elevations in a similar climate. There is plenty of wind occasionally in Dimbula, but is is not an eddying, tearing wind, and tea seems not to be affected to any great extent by it. The case is different, we believe, in some other districts, and that circumstance will have to be taken into account. But, after allowing for poor or worn out soil and injurious winds, there are vast tracts, in the high and the lowcountry of the western, southern and central portions of Ceylon, eminently fitted for successful tea culture.

TEA AT LESS THAN 200 FEET ABOVE SEA LEVEL.

Colombo, 28th Jan. 1884.

Dear Sir,—With the exception of tea grown on "Downside" estate in the Morawak Korale district, and which appears to have turned out so successfully, I find no mention made in your paper of tea being manufactured in any other place in the lowcountry, and conclude therefrom that up till now very little has been done to cultivate that product in the southern district, although the land there seems peculiarly adapted for the cultivation of a first-class tea, when prices such as 3s 6d to 5s for broken pekoe and 2s 4·5d for pekoe are quoted in Mincing Lane for Morawak Korale tea. I have now the pleasure of forwarding you some samples of tea grown on "Citrus" estate near Galle, highest elevation about 200 feet, and which is perhaps one of the lowest places where tea is grown in this island, this being entirely a hand made tea and manufactured under great disadvantages, I think the result is fairly satisfactory, so much so that when some time ago I was dubious about the result and hesitating as to planting out more, I am now convinced of its proving a success.

I may mention that on a small acreage where tea and Liberian coffee are planted in alternate rows, both seem to thrive better than where planted separately; more so, however, is this the case with the latter. The trees in this patch look exceedingly well, and I trust the crop will be proportionately good.—I am dear sir, yours faithfully, W. ZIEGAN,

P. S.—The two samples of broken pekoe and pekoe are quite new, but the packet I send you is some months old and can be used at once. I trust you will like it.

W. Z.

YIELD OF 400 LB. OF TEA PER ACRE AT 5,600 TO 5,800 FEET ALTITUDE IN DIMBULA.

Upper Abbotsford, Lindula, 1st Feb. 1884.

Dear Sir,—As all reliable statistics regarding tea are especially valuable to Ceylon planters just now, I know you will not hesitate to publish the accompanying statement of the results of a piece of tea, which, as you will see, is under 5 acres. It has not specially been cared for, and is one of the most exposed parts of the estate. From 11 months' picking off 110 acres I find that I have made 1 lb. of tea for every 3·96 lb. of green leaf. At this average the bungalow field would show 409 lb. per acre for the full 5 acres, which it is not; but, counting the full acreage and the full quarter for leaf, it is now placed beyond doubt that the highest tea estate in Dimbula has given over 400 lb. per acre. I may, say, too that through ignorance this field was abominably picked to begin with, or fully 500 lb. could have been got. At the end of this month I hope to give you similar statistics respecting our whole 110 acres, which, through the same bad picking, will, I think, be slightly under the 400 lb.; but, with the experience I now have, I have very little doubt that I shall this time next year, if spared, be able to point to 500 or 600 lb. the acre. And yet poor Cameron was accused of exaggerating!—I am, yours faithfully,

A. M. FERGUSON, JUNR.

FORESTRY IN CEYLON.

(From the *Engineer*, Dec 28th, 1883.)

One of the most valuable contributions to our knowledge of the important subject of forestry is the report, recently made public by the proprietors of the *Tropical Agriculturist* of Ceylon, by Mr. F. D'A. Vincent of the Indian Forests Department on the forests of that island. Called in by the Colonial Government to inspect the condition of the vast forests which exist in Ceylon, this officer's report makes it evident that his advice has not been sought one whit too soon to check the almost certain destruction of what yet remains of valuable forest reserve. The need for urgent measures may be estimated by the fact that in the hill country of the island all that now remains of this is not above 100,000 acres, while in the low country, which is estimated to have an uncultivated area of 9 000,000 acres, only about one-third to one-half can be said to now consist of forest. The remainder became mostly low scrubby jungle, the only growth which the now impoverished soil can produce, and fully demonstrates how this impoverishment has been brought about. For centuries it has been the custom of the natives to roughly fell a few acres of forest, burning off the logs, and on the fresh soil so obtained to cultivate one or two crops of grain, and then to abandon the land and seek fresh ground. The result has been that more than one-half of the valuable forests have been destroyed; for over areas so treated by this "chena" cultivation, as it is termed, there springs up only a thorny and almost valueless jungle. This absolutely prevents the growth of really fine timber, the seedlings of which may take root in such spots, as it chokes the young saplings, denying them both the light and air necessary to that growth. Spasmodic efforts appear to have been made to check this practice; but centuries of usage, and therefore of almost prescribed right, have rendered it most difficult hitherto to do so. As for the so called Forest Department of Ceylon, whish was inagurated about ten years back or so, there seems every reason to fear that it has been productive of little good. The few officers appointed to it were wholly untrained in forestry, and, with the best will in the world, they have been able to accomplish but little. Indeed Mr. Vincent points out that the rivalry between the officers of the several provinces to make their charges return revenue has resulted most injuriously, while their efforts to nurseries of valuable trees have been so ill-directed that the results up to the present have been almost *nil.*

The forests of Ceylon abound in most valuable woods. Its ebony is famed in China, and has almost the entire monopoly of that market. Satinwood furnishes the most durable of woods, while pali and halmalilla are also most useful. But years of the destructive process we have referred to have thinned off such trees to an alarming extent, until even the supply of satin sleepers for the local railways is seriously threatened. Between 30,000 and 45,000 of these are now required annually, and as railway extension in the island becomes more developed, a much larger number will certainly be used up. A satinwood sleeper Mr. Vincent states to outlast two to three of creosoted pine; but he writes, "To cut 30,000 satinwood sleepers—requiring 6,000 trees annually—from the forest, would at present mean the speedy extermination of the tree, although when the forests are so large 6,000 stems a year of our principal timber is no exorbitant demand." The ebony supply also is daily becoming shorter. It has been the custom for the Government officials to issue licences to fell a certain number of ebony trees, and in their search after those suitable the fellers have tapped hundreds of immature trees to ascertain if they contain the valuable black-hearting, and those so treated have rapidly decayed, denuding the forest of this tree to a far greater extent than the commercial demand for the wood would have caused. It is evident that if so wasteful a course be longer permitted, the time is not far distant when all hope of the forests being remunerative to the Government will cease.

As to the mountain zone, independently of the necessity of reserves of trees to protect the sources of mountain streams and for general climatic influences, they serve in Ceylon another most important function, that of wind screens. To those who have not visited Ceylon, it is difficult to realise what the force of the wind is in the hill country, isolated as that portion of the island is in the centre of vast surrounding plains stretching on all sides to the seaboard. It is no uncommon thing for carts heavily laden with produce to be wind bound for days at particular spots or to hear of those rash enough to attempt to pass such spots being blown over the precipice—bullocks and all. Then, again, one of the chief obstacles to cultivation in the hills is this same enemy the wind, which often blasts in a single night the hopes of the planter whose lands have not been wisely chosen in a sheltered spot. To guard against such disasters

Mr. Vincent deems it absolutely necessary that wooded belts should be kept in certain positions, and it will be necessary by the slow process of planting to make up for the destruction which has been permitted in many localities. That gentleman does not spare the system under which the forests have been treated in the past. He denounces as wasteful and extravagant in the extreme, and reveals a laxity on the part of many of those charged with their management which is scarcely creditable. In several of the Government Kachcheries the accounts of timber sales and licences have been so ill-kept that all Mr. Vincent's attempts to obtain correct data proved unsuccessful. The selection of timber for felling has further been left to subordinate and unpaid native headmen, with the result of complicity between them and the licencees, leading to such over-supply and shipment that Messrs. Churchill and Sim reported recently the London market for satin wood "to be completely glutted with wood for the past six months, and we now hold a large stock, for which we cannot obtain £6 per ton—of 50 cubic feet—whereas twelve to fifteen months ago we were selling at £20." Mr. Vincent remarks as to this: "Satinwood is, therefore, 25 per cent cheaper in the London docks than in the Ceylon Government sale depots."

The second portion of the paper under reference deals with the measures necessary to establish a better condition of affairs. Primarily stringent legislation is insisted upon, which, while recognising well-established existing rights, shall effectually stay robbery and destruction in the future. Mr. Vincent would not have *all* Crown forest treated alike. There should be "reserves" and "particular reserves," certain privileges being accorded to the public as regards the first which should not be available in the latter, in which the systematic measures for the encouraging reproduction will be carried on. For the forest r holds that to attempt the fullest supervision over the whole area of forest in Ceylon would be impracticable. The attention of the officers of the department would mainly be directed to these "particular reserves," their upkeep and development; while the Government Agents would be empowered by the new legislation proposed to check waste in the ordinary Crown reserves. We have thus briefly dealt with the leading features of Mr. Vincent's valuable report. The preservation of forests in our colonies means economy in public works, the development of which means progress. The subject treated of is, therefore—and quite independently of its importance as affecting climate—one of great interest to the large body of engineers scattered throughout our widespread Colonial Empire; and to them we should strongly recommend the careful study of Mr. Vincent's most elaborate paper, which is accompanied by a map of Ceylon showing the disposition of the forest areas treated of in it.

THE CARDAMOM HILLS OF TRAVANCORE.

I spent several days with A. at Odumenshola, and joined him in his various visits to the neighbouring Tavalum and gardens, as well as on his rounds road making, and I had many opportunities of watching the work of collection and curing the cardamoms. Our ride to a large Tavalum was very interesting as we passed through miles of cardamom forest through which bridle paths had been cut. The Tavalum we visited was some distance beyond the forest, and was a busy scene, as a large amount of cardamoms were being dried on the natural barbacues of rock, and women and children were busy stripping the capsules off the scapes that had just been brought in. From here we rode over a pretty undulating grass country to Callapara where A. had a large permanent camp for warehousing the cardamoms from the neighbouring forests. * * *

THE CULTIVATION OF CARDAMOMS.

I fear I have digressed a great deal from the subject of cardamoms, and must return to my notes. From what I could learn there are two varieties of cardamom in the Travancore forests. One crop comes to maturity about October, and the other in January. The varieties appeared to be caused by difference of rainfall and soil; the former growing in a misty wet climate, and poorer soil than the other, which grows in a comparatively dry climate, and fine rich soil. My small experience was confined to the latter variety. Land having been selected, the Superintendent has to be applied to for leave to open the garden. Nothing is charged in the way of assessment till the garden comes into bearing, when a rate of ten per cent. on the crop is charged for land tax. Only certain forests will grow cardamoms, and the presence of a few wild plants is a safe indication of the suitability of the soil. They will not grow in bamboo or reed jungle, nor will they thrive under munga-murrum, mella-murrum, or dammer trees. The best aspect is a northern one and a steep incline is better avoided. The finest gardens, I noticed were on easy undulating land, and in such situations I was informed they lasted for years. The opening and preliminary work is very simple. Operations begin in April by the cutting down of all undergrowth to 6 or 8 inches in diameter; and here and there large trees of rapid growth are cut down. No burning is done as in coffee clearings, and the felled branches and undergrowth are allowed to rot. In the following October the young cardamoms begin to sprout. Where they are too crowded, it is necessary to thin them out and transplant them into the open spaces, and where the plants have sparely sprouted, it is also usual to sow the ground with seed. The seed should be sown before the monsoon. The growers prefer stocking their gardens with spontaneously grown plants, which they say last longer and come late, bearing earlier than those grown from seed. For two years nothing further is done. In the third the clearing should be weeded, and the small sprinkling of crop gathered. In the fourth year a thorough weeding ought to be done, and the decayed stocks and leaves heaped up between the clump of cardamoms. The garden is now in full bearing, and will require regular attention. The weeding should be done in November, and the crop comes immediately to maturity with the letting in of light and air. Cardamoms require light showery weather in March and April, when the flowering scapes are ready to blossom. In rich soil the scapes will run out to 3 and 4 feet in length, but shorter growths give better results in the way of crop. The failure of showery weather immediately after the blossom will ruin the prospects of the crop, and though the scapes will sometimes throw out a second blossom, the result is generally a poor one. The fluctuations of crop are therefore great, and as hail storms often occur about the blossoming time, the risk and uncertainty of crop is much increased. Cardamoms begin to ripen in November, but it is often late in January before the growers will pick the crop, and a great deal is destroyed by snakes, rats and vermin of every description. Judging from what I saw in the garden, of capsule shells, probably one-third is lost in this way. Chetties from the neighbouring villages in the Madura District, are the principal growers and they usually began the cardamom harvest when about half the remaining capsules on the scapes are ripe.

The scapes with the cardamoms on are removed to the small collecting stations, and cured by a process of drying in the sun and exposure to the dew. The morning after the collector the capsules are carefully removed from the scapes, and dried on the rocks. The fleshy shell soon loses its green or brown colour under the three or four days drying, and is then fit to be removed to the weighing stations. Cardamoms lose two-thirds, three-quarters, or even four-fifths of their measure by drying; the exposure to dew is supposed to give a bleached look to the sample. Some cardamoms I noticed had a green tinge which no amount of drying could remove, and was supposed to be caused by the nature of the soil they came from. Could the crop be gathered in, as it ripened, there is no doubt a much better sample could be secured, but I was informed that it would not pay the growers to do this, as the Travancore Government made no distinction in the price for bad or good qualities, and the result was the loss of much of the ripe fruit and the character of the rest being damaged by indiscriminate packing of mature and unripe capsules together. A second curing and winnowing is given at the weighing stations, and there is a further drying and winnowing on the coast when the cardamoms are ready for the buyer. On the coast the best descriptions will realize as much as R4 per lb. (Dutch) but the grower only receives a third of this, and when all deductions from this third are made for watchmen, land tax and other pretty charges, the amount really paid is nearer one fourth than one-third. From notes taken of the cost of cultivation, I was doubtful whether the growers could make anything by the transaction, but the fact of their continuing to cultivate is proof that they do make something. A. considered it paid the growers if they secured two good crops to three bad ones; but he admitted that it was very difficult in bad seasons to get the owners to take in their crops, and he dad often to do so at the Government's expense. At one time the produce had been as high as 3,000 cwt. but had subsequently dwindled down at a tenth of that quantity. Since A.'s incumbency more land has been opened up and abandoned gardens brought into cultivation, and he had lately a crop of 1,500 cwt. A more liberal policy on the part of the Travancore authorities would soon double the cultivation. Nearly all the cardamom growers are British subjects, owing no doubt to the fact that the forests, as far as the Pereyaur had once been under British jurisdiction. About the second decade of this century, this tract was transferred to the Travancore Government, and the cultivators who were British subjects continued their occupation under the new rule. Roughly estimated about 20,000 acres were under cultivation, and from what I could learn there was forest-land enough available for extending the cultivation five fold. The yield an acre in even favourable time does not exceed 20 to 25 lb of cardamoms.

In addition to cardamoms the Travancore Government collect ivory, wax, galinuts and other hill products, and obtain some revenue from teak and blackwood, and also from cattle grazing fees. Altogether the average nett revenue comes to about 2 lakhs of rupees. No land is granted for otherwise than cardamom cultivation—a wise policy on the part of the Travancore Government, as without losing their forests they obtain a safe though fluctuating revenue. Still there is a good deal of land suitable for grain cultivation which is not allowed to be cultivated though ready with a light tickling of the surface to yield fine crops. The wandering hill tribes in return for Sircar service are alone allowed to grow any grain, and they are restricted to old nursery clearings.

Though the cardamom hills are unoccupied at present by any resident population, there was a time when they must have been inhabited, as ruins of forts, rude carvings, and inscriptions plentifully testify, but there are no traditions of the old inhabitants, and the present hill tribes, according to their own account, are but comparatively recent settlers. The present Hill men are of either Tamil or Malayalam origin, and seems to have settled on the hills in the last three hundred years. They are fine men in physique though living in feverish places and according to census returns are on the increase. The Railway has made the country accessible, as twenty-four hours from Railway Station of Ammanackenoor would land the sportsmen at some of the finest shikar ground in Southern India.—*Madras Mail.*

CINCHONA PROSPECTS.

Although the present prices of bark are discouraging to those who have capital invested in cinchona on the hills of Southern India, it seems that brighter days are dawning and that prospects for the future are very fair indeed. We take the following extract from a late number of the *Planters' Gazette* (Dec. 1st. 1883.)

"In several instances Ceylon bark valued at 6d per unit of quinine sold for 7d. On the whole the opinion in the trade is that the market is not likely to go lower for bark of fair quality if planters desist from sending enormous quantities of almost worthless twigs, and the South American imports diminish as they have done lately. There need not be much fear about the latter. if,—as we have been assured—a large portion of such bark is now in stock, and with not more than 9d to 1s per lb., actually cost 1s 6d per lb. for carriage from the interior where it was collected, to the shipping port. Whatever may be the precise figures it is quite certain that American bark sold at present prices leaves a heavy loss, and therefore shipments are not likely to be maintained."

Probably not. It would take merchants of super-sanguine disposition to continue shipping bark which had cost them eighteen pence a pound for mere carriage to a market where the produce was unlikely to result in anything bun loss of 25 to 50 per cent on their cash outlay: planters o the hill ranges of Southern India may therefore look for a steadily improving market until prices will overtop the minimum of 1s 6d. We are informed that the harvesting in these districts on an average costs about one anna per pound of dry bark, and that carriage, shipping and home charges, bring it up to about four pence per pound by the time it is placed on the home market. A margin of a shilling a pound clear profit is quite enough to make the planting of cinchona a desirable investment to those who can afford to wait, and it seems likely that this margin will be considerably exceeded. In the elaborate minute of H. E. the Governor on the administration of the Madras Presidency in 1883, appears the following paragraph.

Dr. Trimen the Director of the celebrated gardens at Peradeniya in Ceylon, was deputed, at the request of this Government (thanks to the kindness of Sir James Longden, G. C. M. G., the then Governor of the island and its dependencies) to visit the cinchona plantations on the Nilgiris in company with Mr. Lawson and Dr. Bidie. The outcome was most satisfactory to us, and will, we trust, make these great plantations be worked more and more, not with a mere view to profit, but for the more important object of helping cinchona-growing in Southern India, to ever better and better results. There are problems connected with this industry which are still unsettled, and, if we do not undertake to solve them, it is difficult to see who in this Province can afford to do so. Cinchona can be grown in many parts of the tropics; but that country will probably ultimately derive most benefits from growing it which takes most pains to arrive at the best methods, by the joint labours of the botanist, the chemist, and the horticulturist. For the purpose of the Government, too much cinchona cannot be grown. For the purposes of the planter, too much may be easily grown, and the latest sales are not specially encouraging to those who expect rapidly to make fortunes under the auspices of the Countess of Chinchona.

Our contemporary the *Madras Mail* makes some very pertinent remarks on this subject, and appears to think that the fact of the manufacture of quinine being in the hands of a very few capitalists who in fact form a small "ring," is at the bottom of the present low prices of bark. The *Mail* adds: "We believe the time is not far distant when other manufactories will be started. This is what we urgently require in India. At present there is the anomaly of a large demand for quinine, which can with difficulty be satisfied, and only at exorbitantly high prices, and at the same time there are thousands of bales of bark which the brokers of Mincing Lane are unable to sell. In the interests of mankind it is desirable that this anomaly should be done away with. The millions of the lower classes who suffer from fever and other diseases which yield to quinine, demand that the price of the medicine should not be beyond their means. What is now wanted, especially in Madras, which will probably be one of the largest cinchona countries in the world, is a central manufactory where the bark can be worked up without reference to the European 'ring.'"

We would go farther than this. Sulphate of quinine is doubtless a very beautiful preparation of the drug and likely to hold its own among the wealthier classes and with the physicians who prescribe for them: but it i probably not by any means the most economical form of using the bark-and it is to a really cheap form that we must look for benefit to the millions. In Owen's cinchona manual (1881) occurs the following passage.

"As to red bark, it has been pointed out to us by Dr. Trimen that the bark is in itself a valuable drug, largely prescribed, and that Professor Flückiger has suggested its being fixed on as the official form of cinchona bark in the new German Pharmacopeia. We all know well its value as a source of Quinetum, of a febrifuge which can be cheaply made and sold, and which ought to create an almost unlimited demand."

Now if "Quinetum" can be *cheaply made* from red bark there is no question as to its being sold readily enough, considering that the fever stricken population of the four quarters of the globe are crying for a specific at a price not beyond the reach of the million. The Government Febrifuge manufactured at Calcutta, can be issued, it seems, to Government hospitals and the like, at a cost of 8 8 per pound, and is magnanimously offered to the millions at the slightly enhanced price of R20 per pound plus postage, or say a profit of 150 per cent with the additional advantage in most parts of India of the would-be purchaser having to wait so long before he can get it that he will probably be either cured or dead before the remedy can reach him. And in these days when anomalies are called in question does it not seem anomalous that in the very midst of a quinine producing district, the fever stricken population should have to be supplied with the manufactured article from England or at nearest from Calcutta?

Further; twigs and small branch, though they do not pay to send home, are manifestly of *some* value, inasmuch as they will fetch from 1d to 4d per lb. in London. Why should not these be worked up on the spot into a febrifuge? or even into some form which by diminishing the bulk to a tenth—a twentieth—or a fortieth—would allow the product to be sent home for chemical manipulation, at a moderate cost for freight and home charges—instead of being mere waste on the estate? Chemists to the front! Invent a process, and help the millions and the planters too.—*South of India Observer*, Jan. 19th.

TEA—ITS ACCESSORIES.

In our last number we commenced this subject, and we must confess we do not plunge into its labyrinths without serious misgivings, whichever way we look, we see shoals ahead. In our daily contemporary we see India-rubber cited as one of the crops which might become a useful accessory to tea on old worn-out teelahs, but we noted with interest what a "Tea-planter" wrote on the subject, and we can thoroughly endorse what he says, which summed up, amounts to this, that if the Rubber Tree is planted in Assam or Cachar between the leaves of Tea on abandoned teelahs, the result would not justify the expense. In Darjeeling we believe those accessories, as we may call them, are grown with partial immunity to the plant, but in Cachar and Assam nature seems to revolt against them, and does not see the force of allowing the crops to grow together. We are aware that it is being tried on some portions of abandoned gardens, but as yet the experiments is too young to say whether it will develop into a success, although one thing has so far been practically evolved, namely, that as soon as the Rubber Tree comes to any size, farewell must be said to the leaf from the tea bushes, as this is simply devoured by the blight insect as well as being a prey to fungi of different kinds. We ourselves have seen plants of the Ficus Elastica growing on the old abandoned teelahs of one or two companies, but from what we could learn on the subject, the growth was about one year in arrear of what it should be. Our knowledge on the subject of the treatment of the Ficus Elastica is most primitive, and we think that Government ought to make a move in the matter to assist these experiments. In Assam proper we believe Government farm one or two Rubber Mehali, but not successfully, and last cold weather we were informed that Government intended to send Dr. Geo. Watts into the Naga and Lushai country to endeavour to find out the best treatment for the trees, as well as to ascertain the best mode of tapping the trees, the best age at which to tap them, &c., but we believe they afterwards abandoned the idea, or at any rate we have never been able to find out if anything came of it. There can be no doubt that something of the kind is worthy of the attention of all concerned in tea. In Darjeeling the Cinchona plant seems to supply the necessary want, but the blight pest makes it an almost impossible task to suggest an accessory in Assam or Cachar. In Java we have seen Vanilla attempted, but we cannot say with success, as even then the blight seems to luxuriate in the shade provided by the trees upon which the Vanilla are trained. We have an idea that arrowroot might be tried with success, as the shade thrown out would not be sufficient to tempt the blight insect, and being an annual crop, as well as a root crop, the cultivation given would 'no doubt' improve the worn teelahs without wasting much. We have heard, with what truth we cannot vouch, that some arrowroot was grown in Cachar and sent to England, and pronounced to be in every way a superior article to that exported from the Straits and other places; and no doubt with proper appliances it could be improved. So far as we heard the means used to bring the article into a marketable shape were of the most primitive sort. The tops cut off as is done in the Straits and put into the ground form an excellent manure, and portions of the pulp, &c., are used for fattening cattle, pigs, &c., and would no doubt be in demand amongst the coolies at, although a small, yet a remunerative rate. This is however far from solving the real difficulty, and what we want is a plant that will be a source of revenue to the garden and a terror to the blight. That there must be some plant peculiarly obnoxious to the mosquito blight, we feel assured, and we wonder that Mr. Wood-Mason did not, when on his scientific tour, find it out. Whether it would be remunerative we cannot of course say. [The above is from the *Indigo and Tea Planters' Gazette*, and is not over-encouraging to Assam planters. Looking at the belief in Ceylon that shaded coffee bushes are free from fungus, it is curious that shade should aggravate blight in Assam. The value of rubber cultivation has yet to be proved, while a small addition to arrowroot and vanilla would swamp the market.—ED.]

TEA-SIFTING BY MACHINERY.

(From the *British Trade Journal*, Jan. 1st.)

We will now briefly describe the sorting, sieving, or classifying of the dry tea for the market. It is very essential that the leaf receive as little handling as possible after it has been dessicated. For a long time a strong prejudice existed among the planters against the use of woven-mesh wire sieves, it being contended that not only was the tea broken by coming in contact with the small sharp wires, but that the "bloom" was rubbed off and the market value thereby deteriorated. To obviate this, small country-made cane sieves were used, the weaving of the sieves being so arranged that the glossy smooth side of the cane should be on the top side. Thus, when a quantity of tea was placed in the sieve to be treated the smooth side of the cane did not injure it. Enterprizing planters had some doubt of this theory, and the result was that mesh wire sieves had a fair trial and gained the day. It stands to reason that, as there are twice the number of holes or meshes in a wire sieve that there are in a cane one, the tea had twice the chance to get through. Thus, much less motion was required, and, consequently, much less bloom was rubbed off.

The ordinary mode of hand-sieving is to place two tea-chests on the floor 5 or 6 feet apart; to stretch over these two bamboos, on the ends of which sit coolies with their faces towards each other, and a hand-sieve before them resting on the bamboos. This they pull backwards and forwards, and jerk or knock it on the bamboo till the tea is sorted as they desire.

About the year 1873 a sieving-machine was constructed by Mr. William Jackson, which consisted of long oblong trays, one size of mesh following another in a longitudinal direction. These sieves were placed on a long plane incline, and had a short reciprocating motion given to them. They were suspended by wooden springs or hangers to a suitable framework, and the unassorted tea passed from the higher end to the lower, each class dropping through the sieves into suitable receptacles as it passed along. This machine did fairly good work, but it fell into disuse, to some extent, owing to its bulky and cumbersome nature.

The next in the field was Mr. Ansell, who practically worked on the same line as Mr. Jackson; but he superimposed his sieves in a zigzag direction over each other, and having secured them firmly to each other by brackets, he carried the whole on suitable wood or steel springs attached to a framework made of wood. The sieves also received a rapid reciprocating motion, and the tea, instead of passing along an incline plane of sieves dropped from the lower end of the one on to the higher end of the other, the assortments being carried off by suitable trays and spouts fixed under each sieve. This machine is well spoken of, but like the one previously described, it has, we are informed, the disadvantage of requiring much room, and we believe the whole of the tea to be sorted has to be carried to a height of about 12 feet before it can be placed in the feeding-hopper.

Another sifting-machine has recently come into the market. It is by Mr. W. Jackson, and we hear it described as the cleanest and neatest working sorter the planter has received. The sieves are superimposed, but are placed all on the same incline; that is to say, the inclination of all the sieves is in one direction, so that they can be placed very close to each other, and the height of the machine so reduced that it can be fed from the floor of the tea-house. Another peculiarity in the construction of this machine which must commend itself to tea-growers is the entire absence of any framework beyond that which actually constitutes the frames of the sieves. The power required to work the machine is merely nominal, and we have only to say that Messrs. Marshall, Sons & Co., of Gainsborough, are the manufacturers, to give those interested confidence in its construction. It is styled the "Eureka," and can be seen at Messrs. Marshall's stand in the Calcutta exhibition.

IRON TEA FACTORIES.

The question of factories for tea gardens, of a durable character and at a moderate cost, is one of so much importance to tea planters in India, that no apology is necessary for directing attention to an iron structure exhibited in the International Exhibition by Messrs. A. & I. Main & Co., of Glasgow and London, whose agents are Messrs. Duncan Brothers & Co., Calcutta. The particular structure to which we refer is especially adapted for use upon tea gardens, and is termed a "Tea Factory." The complete factory consists of three spans, and a withering loft, the centre span being 30 feet to 40 feet wide, and usually about 16 feet high to the eaves, and of course it will be understood that the building can be made any required length. Along each side of this main span is a "wing" or side building, each about 15 feet wide, and the three roofs are carried by four rows of malleable iron columns of a section combining great strength with lightness. To form the withering loft, a fifth range of similar columns is run up the centre of the main span, standing about 10 feet high, which carries cross joists also of iron, and upon these are laid the timber joists to which the flooring is nailed in the usual manner. The great merit of this arrangement is its simplicity, and the fact that all the essential parts of the building are of iron and consequently permanent. The flooring and its joists can be got at for renewal with perfect ease, and none of the permanent parts of the building are affected. The columns also are worthy of notice. They are of malleable iron—not cast—and are thus light for transit, especially inland transit—and being prepared for fixing into concrete foundations, are easily handled and erected. The roofing is strongly made with iron principals and ties, and the method adopted by Messrs. Main & Co., for securing the galvanized sheets to the iron framing of the roof, is one of extreme simplicity and strength, and enables the roof to withstand the most severe Nor'Wester without the "wind ties" usually adopted in less strongly constructed iron roofing. Provision is made for light and ventilation, and the whole building possesses an appearance of great neatness and thorough adaptability to its puropse. The prices we learn are very moderate, and from the figures given to us, we would say that such an iron building must compare favourably in cost with brick and timber work, and we are not surprised to learn that Messrs. Main & Co.'s iron factories are being generally adopted upon Indian tea gardens.

In the same exhibit there is a light and simple form of a portable steel railway and wagon, especially adapted for tea gardens, and we would expect that Messrs. Main & Co.'s patented system, from its cheapness, simplicity and completeness, will form a most valuable adjunct in the economical working of a tea garden.—*Indigo and Tea Planters' Gazette.*

NOTES ON SUNGHIE UJONG.

After about six hours journey in the cart, Rantow is reached, a little village with a police station to the right and the Coffee estate of Messrs. Lister, Hill and Raithbone to the left. These gentlemen own about 130 acres of ground planted with Liberian coffee and cocoa. The coffee trees are from two to three yeas old, and look healthy and in full bearing, no doubt in better condition generally than those in the estates at Johore and Singapore. About two hundred piculs of the coffee and cocoa berries have been sent to Singapore and a large quantity is lying in bags in the store huts ready to be shipped. Then pepper plants thrive luxuriantly. The soil of Sunghie Ujong has been pronounced very good and it is surprising that many more planters have not directed their steps thither instead of going to such an out of the way places as North Borneo. They have only to go to the place and see for themselves to be convinced, and the Resident, an amiable and courteous gentleman, has always been found ready to render every assistance to travellers and planters in prospecting the country.—*Straits Intelligence*, January 16th.

ADULTERATED TEA.

Examiner Davies, after consultation with the appraiser, with the largest tea importers and with Professor Batchellor and Dr. Davis, the chemists at the Government laboratory, recently agreed upon a standard for determining the percentage of impurity which shall be hereafter deemed sufficient to exclude all colored teas, whether from China or Japan, and especially to be applied to tea dust. According to this standard, 8 per cent of foreign substances will be permitted, but where a cargo of tea is found to exceed that proportion the examiners will refuse to pass it.

This new rule was put in force yesterday, when Examiner Davies rejected as entirely unfit for consumption 600 packages of Japan dust ex steamships Pembrokeshire, Mosser and City of Tokio. The Government is determined to put an end, through Mr. Davies, to the importation of all classes of adulterated tea which is above the standard laid down by their examiner, and the sooner importers realize the fact the better for their pockets.—*American Grocer.*

SUGAR CULTURE IN BRAZIL—AND IN CEYLON?

In placing the following translation before our readers, we would attract attention to the fact that a density varying from 8° to 10° Beaumé is calculated on in regard to the juice of the sugarcanes grown in Brazil. Who will try experiments with the juice of Ceylon-grown canes? * Could the industry be resuscitated here, sugar culture much more than that of tea would give occupation to small farmers in growing produce for central factories, for canes would not suffer from handling, transport, delay and possible putrefaction as tea leaves might. It will be seen that the Company, of which "Senhor Scott-Blacklaw" is Manager, have contracted to pay 14s per ton for cane. But this, no doubt, means on delivery at the mill. In the Mackay District in Queensland, the usual payment to growers of cane is 10s per ton, *on the field*, the purchaser cutting and carting away the canes. The average yield being about 30 tons per acre, this means a gross revenue of £15 per acre, of which we should think that one-half is clear profit: say £7 10s per acre, which for 50 acres in cane would mean £375 net income, and for 100 acres £750. As we remarked the other day, enormous changes and advances have been made in the manufacture of sugar within the past third of a century, and it is possible that now sugar could be grown and made to pay in Ceylon. An account of the general experience of the Baddegama estates and mills would be valuable.

(Translation from *Jor. do Commercio*, 30th Nov. 1883.)

Mr. Scott-Blacklaw, the representative of the "Rio de Janeiro Central Sugar Factories Company," has just submitted for the approval of Government the plans, estimates and designs of appliances, as well as a description of the processes for manufacturing sugar, and the contracts entered into with the farmers for the supply of cane to the central factories which the said Company has to establish in their municipalities, both of which are in the province of Rio de Janeiro.

In the first of these townships, the Company has got contracts made for furnishing annually 21,250 metrical tons (1.000 kilos per ton) for the price of seven milreis per ton (equal to 14s English), calculating that the saccharine density be 8° Beaumé as a minimum; in the second 16·090 tons is contracted for at the same price.

The factory at Araruama will have the necessary capacity for grinding 240 tons of cane every 24 hours; and if the juice has a density of 10° Beaumé, this at $12\frac{1}{2}$ tons of cane to the ton of sugar will be 20 tons of sugar per day.† The factory at Mangaratiba will grind 160 tons of cane per day, and with cane juice at the same density will produce 13 tons of sugar per day.

The representative of the Company, Senhor Scott-Blacklaw, expects that by August the factory at Araruama will be in active operation, and that at Mangaratiba by December next year (1884).

The appliances, we are assured, are of the most perfect kind, and are ordered from the Scottish engineering firm of *Dale Brothers, Kirkaldy, Scotland.*

The Agricultural Railways will have a gauge of 82 *centimetres* ($32\frac{1}{4}$ English inches), and the Company expects that it will be able to run two trains per week between *Iguaba-grande* and *St. Vincente de Paul* for the transport of passengers and goods. These will run regularly in connection with the local service of steamers in the Araruama lake.

We are informed that in Mangaratiba, the weakest of these two townships in the supply of cane, there are extensive waste lands well adapted for the cultivation of this *graminea*, and that private owners have large tracts uncultivated and disappropriated. This point appears to us well worthy of being enquired into. If there exist zones of Government land in Mangaratiba, the sale of these after dividing them out in lots will be profitable to the State, and time ought not to be lost in establishing both European and national colonies on these lands, whether they (the lands) belong to the State or to private individuals. Without entering into the question of the mistakes made in some instances in managing colonization, here is a case that will soon pay its original cost. If it were possible to locate a few hundreds of these families before or as soon as the sugar factory commences operations, they would supply to the enterprize what it requires, and the produce would find at once a market.

One of the founders of the large factory at Quissaman (in the Province of Rio de Janeiro) announces the fact that around the factory, as a natural consequence of the division of labour (the factory taking the cane from the farmer as soon as he deposits it by the side of the Agricultural Railway), there had sprung up an agriculture quite suited to the small farmer. If we require official testimony to this grateful fact, it would not be possible to desire one more enthusiastic and valuable than that of our late Minister of Agriculture, Buarque de Mecede.

The territorial conditions favouring the expansion of agriculture in the hands of small farmers in the district of Mangaratiba, it will be quite inexcusable if the colonial system is there left undeveloped, since the setting up of a central factory there will be the means of the products of the soil being profitably utilized.

In this case nothing else requires to be done but to mark off the land available for colonists, reserving what may be required for public uses, and show us the establishment of a colony in a few months, the land being sold in lots. The expenditure on such work will reproduce itself in a very short time, for the colonists will soon see themselves in a position to pay back what may have been advanced them, the production of the district will be increased, not only will there be created a tributable material for the State, but the latter will be recompensed for the risk it may have run in guaranteeing interest to such enterprizes. The State will run no responsibility, and the factory will have soon to increase its capacity.

We need not say anything on spontaneous immigration. We think that an immigration entirely abandoned to itself, without any true course, without any north, without any aid that can serve for its guide and protection, is not suited for a country situated like ours, and we do not know of a similar system in any other country under the same conditions. To direct a current of men, we must do as we would with a current of water, we must hew out a channel.

* Mr. Curtis' letter reached us after the above was written.—Ed.

† A return of one ton of sugar from fifteen of cane is the usual average in Queensland.—Ed.

COFFEE AND CHICORY.

An interesting lecture has been recently delivered on "Coffee and Tea," by Dr. G. V. Poore, Vice-Chairman of the Council of the Parkes' Museum.

The dietetic value of coffee, in the opinion of this authority, is of a high order, and particulars are furnished with regard to the preparation of this delightful beverage which may be of service to some of our readers. The making of coffee requires a little care, and certain rules must not be neglected if the real virtues of the aromatic berry are to be perfectly utilized. These are briefly stated as follows by Dr. Poore :—

1. Be sure that the coffee is good in quality, fresh roasted and fresh ground.

2. Use sufficient coffee. I have made some experiments on this point, and I have come to the conclusion, that one ounce of coffee to a pint of water makes poor coffee, one-and-a-half ounce of coffee to a pint of water makes fairly good coffee, two ounces of coffee to a pint of water makes excellent coffee.

3. As to the form of coffee pot, I have nothing to say. The varieties of coffee machines are very numerous, and many of them are useless encumbrances. At the best they cannot be regarded as absolutely necessary. The Brazilians insist that coffee pots should on no account be made of metal, but that porcelain or earthenware is alone permissible. I have been in the habit of late of having my coffee made in a common jug provided with a strainer, and I believe there is nothing better.

4. Warm the jug, put the coffee into it, boil the water and pour the boiling water on the coffee, and the thing is done.

5. Coffee must not be boiled, or at most it must be allowed just to " come to the boil " as cook says. If violent ebullition takes place the aroma of the coffee is dissipated and the beverage is spoiled.

Due attention being given to these simple requirements, and premising, of course, that the coffee is not adulterated and of good quality, we can promise as the result a " cup of coffee " of such exquisite aroma as is unhappily strange to the experience of most people in England, where the proper mode of preparing coffee for the table is certainly not popularly understood. We are pleased to assist in ameliorating this unfortunate state of things by making a further quotation from Dr. Poore's lecture :—

The most economical way of making coffee is to put the coffee into a jug and pour cold water upon it. This should be done some hours before the coffee is wanted, overnight for instance, if the coffee be required for breakfast. The light particles of coffee will imbibe the water and fall to the bottom of the jug in course of time. When the coffee is to be used, stand the jug in a saucepan of water or a bain-marie (*i.e.*, in a water-bath as a chemist would say), and place the outer vessel over the fire till the water contained in it boils. The coffee in this way is gently brought to the boiling point without violent ebullition, and we get the maximum extract without any loss of aroma.

There is, however, a preliminary to all this which we must not omit to mention, as it is of cardinal importance. The coffee berries should be roasted as shortly as possible before being ground for infusion; the coffee drinker ought to have his coffee roasted and ground at home, or make arrangements to secure a like result. This is not a difficult matter, for it is quiet easy to roast coffee in "a small frying pan or a pipkin, or any suitable vessel," and it can be pulverized without the help of a mill, but care should be taken not to pulverize it too finely, as this injures the taste and flavour. And this should be especially noted that raw coffee does not deteriorate, but actually improves by being kept in a dry place. The older the raw coffee, the better it is, and therefore the thrifty housekeeper need not hesitate to buy it in quantity—a bag at a time, if he finds it convenient, but he must, we need hardly point out, be certain that the raw coffee so bought by him is of really good quality.

We perceive that Dr. Poore denounces every adulteration of coffee, and that he very justly qualifies a admixture of chicory as an adulteration. He states as follows :—

But I hear somebody say, "Chicory is not an adulteration, for Mr. Gladstone says so ;" and it is quite true that in his Budget Speech for 1882, the following words fell from the lips of that eminent statesman: "At present every description of admixture with coffee is permitted, and we have long proceeded on the principle that the admixture of chicory with coffee was not an adulteration, that it was an admixture rooted in the habits of many countries, and that people would not drink coffee without it. But of late a practice has grown up of producing all kinds of substitutes under the name of coffee, and that, I cannot but think, must in some degree account for the strange and singular state of the figures that I have laid before the committee. We shall not attempt to interfere with the admixture of chicory with coffee, but, we propose that it should not be allowed to introduce other miscellaneous admixtures with coffee."

Accordingly, by Act of Parliament, chicory was as it were called to the Upper house, and coffee and chicory in the eyes of Mr. Gladstone and the Right Hon. Joseph Chamberlain are now convertible terms, so that a new word seems necessary for the brown powders which are sold in the shops as breakfast beverages. As for coffee adulterants, other than chicory, they are now obliged to be sold in packets bearing the precise labels. They have been raised to tho dignity of patent medicines, and always wear a government badge in public.

Now chicory was called to the Upper House on August 14th, 1882, and on the following day a minute was issued by the Board of Customs for the instruction of their officers, in which the following clause occurs —"As dandelion root is very cognate to, and not easily distinguishable from that of chicory, the officers will not on their own responsibility attempt to distinguish these roots, but will regard them all as chicory."

So we must imitate our friend the grocer and take off our hats to the dandelion, as he takes rank alongside of the old aristocrat coffee and that parvenu chicory. It is very difficult to see what has been the object of the Government in these regulations. My own belief is that from every point of view, moral, financial, and dietetic, they are a mistake.

It will be seen from the figures given below that the United Kingdom at present stands lowest as regards its consumption of coffee per head of population :—

Holland consumes	21·00	Germany consumes	5·00
Denmark ,,	13·82	France ,,	2·73
Belgium ,,	13·48	Austria ,,	2·13
Norway ,,	9·80	Greece ,,	1·42
United States	7·61	Italy ,,	1·00
Switzerland ,,	7·03	United Kingdom	0·94

—*South American Journal.*

TEA DRINKING.

The medical papers do not sympathize with the Dean of Bangor in his recent denunciation of tea drinking.

The *British Medical Journal* says that if tea be pure, and free from poisonous "facings," the daily drinking of an infusion of it, in anything like moderate quantity, is free from all risk, either immediate or remote. It declares that an infusion of tea—good tea, of course, is presupposed—is a harmless restorative and stimulant, which has taken a high and lasting place amongst human comforts. Properly used, it refreshes after fatigue, enlivens the dull, and cheers the depressed, while it aids digestion, promotes the removal of an effete material, and has some protective virtue against extremes of heat and cold.

The *Lancet* :—To say that over much tea-drinking acts as a dangerous revolutionary force amongst us is scarcely on all-fours with the acknowledged high physical and mental standard of men of our own times. If we were to follow his argument to its logical end, we should not be surprised to find that the use—or abuse—of the popular beverage through so many years had by its debasing and destructive tendencies, in virtue of the process of natural selection, caused the tea-drinkers to go to the wall, or set each man against his fellow, and brought Macaulay's New Zealander to contemplate the ruins of St. Paul's, or Campbell's last man to bewail the infatuation of his sacrificed ancestors To fix the ills and misfortunes of race and individual upon one or other besetting fault, such as excessive tea-drinking, is as unreasonable as to ascribe the brain disease of a madman to his insane acts. We would not for a moment be held to countenance the abuse of what in moderation is undoubtedly a tranquillizer of the temper, and a pleasant and harmless stimulant. Times enough we have directed attention to the injurious practice of taking strong tea to excess, and especially upon an empty stomach, and to the harmfulness of ingredients such as artificial colouring matter, employed for sordid gain. But there is a medium in all things, even in those where the worst is not very bad or the best very good. Hardworked minds and fatigued bodies are often the better for some gentle stimulant that rouses into gentle activity the nerves which minister to animal life and comfort. Tea has its uses and abuses, like most other things; but we are inclined to think that the latter are an insignificant set-off to the former.

TEA DOCK CHARGES.

There has for a long time past been great discontent in the tea trade as to the dock charges, the method of sampling, and the way in which the teas are delivered. This feeling has culminated this week in a meeting of the trade, at which thirty-five of the leading firms were represented, and at which great unanimity of feeling prevailed. The committee of the Wholesale Tea Dealers' Association have, for some time past, endeavoured to cope with the evils complained of in detail by taking up the questions with any new warehouses that may be started; but this policy has hitherto had little effect, and to many appears an undesirable way of approaching the question. The bold and general movement pointed at in the second part of the resolution submitted to the meeting, appears to be what is required. Even five of the larger houses, firmly united, have conquered far greater obstacles than those involved in obtaining a complete reform in the dock and wharf charges of London; and with the unanimity of feeling shown at a meeting of no less than thirty-five firms, there ought to be no difficulty about obtaining juster treatment from the docks and wharves. It seems most unfair that the tea dealers should pay heavily increased charges, in order that the wharfingers and dock companies may pay increasing secret discounts, which have risen up to 50 per cent to the tea importers. The practice in itself is highly undesirable, as is clearly shown by the secrecy with which it is conducted, and it is certainly impossible to see what good purpose it serves. With reference to the question of tea delivery and warehousing, there is no doubt that no reform will be really effectual which does not entirely alter the warrant, weight-note, and deposit system, with all its antiqated absurdities and formalities; but if the tea dealers are not prepared for so complete a change, a material reduction in the dock charges is, no doubt, an alteration which all can work for.

A meeting of the tea trade was held at the Commercial Sale Rooms, Mincing Lane, on the 14th December, Mr. Hillhouse (of the firm of R. Hillhouse & Sons) in the chair. That gentleman having explained the cause of the gathering, Mr. Francis Peek (of the firm of Francis Peek, Winch & Co.) made remarks to the following effect:—

You will remember that some time ago the Wholesale Tea Dealers' Association appointed a Committee to act in their behalf in all matters affecting the interests of the trade, especially in regard to the opening of new bonded tea warehouses, the multiplication of which involved a serious increase in both trouble and expense to to the trade. The Committee, acting under this authority have prevented the addition of one warehouse which they consider unsuitable, and have enforced a reduction from the excessive charges for sampling, etc., on two other warehouses which have changed hands. A warehouse has recently been opened under fresh ownership, and the proprietors decline to give that abatement in charges which has been agreed to by the two to which I have just alluded. Under these circumstances it was thought desirable to call a meeting of the trade, in order to ascertain, by an expression of their opinion, whether or not they are still of the same mind as when they first gave the Committee authority to act in their behalf. This is the first question that you, gentlemen, will have to decide. But in additon to this, the members of the Committee also desire to obtain from you the power to act in your behalf, and not in your behalf, only, but in behalf of the entire wholesale and retail trade of the country, in an endeavour to obtain an alteration in the charges and the regulations affecting the purchase and delivery of tea, which are at present considered—and rightly considered—a great grievance. First, let us take the question of sampling. I do not think I speak too strongly when I denounce the present system of sampling the most clumsy, the most annoying, and the most dishonest that could well be contrived. You all know how it is carried out. A purchaser is supposed to have an unlimited supply of all kinds of tea in his possession and, on receiving a sampling order from a broker, to send equal value to what he is about to draw, to be substituted in the package from which the sample is taken. Practically, of course, and necessarily, the purchaser has nothing of the kind, and simply sends what he has. Let me give one instance of the result. The firm which I represent purchased twenty half-chests of fine Indian tea, costing 3s. 2d. per lb. A customer in the country wrote up, complaining that in one half-chest of this parcel which had been sent him there were 5 lb. of common tea. I accordingly had the remainder of the parcel examined, and found that altogether there were 24 lb. of tea worth about 1s per lb. In other words, the purchaser of twenty half-chests would lose about £2 12s. I would ask you, is this an honest system? Is it not rather a disgrace to the trade? Must it not be altered? The export trade in tea of the country, as no doubt you are aware, has considerably fallen off. May not the cause be found in the fact that anywhere but in England they do not understand why, when they purchase a chest of tea, they should find two or three pounds of inferior quality inserted in it. The warehouse-keepers have been applied to, to remedy the evil. They are very willing to do anything, but——and this "but" stands, and will stand, in the way, until you force them into compliance. The next grievance is the condition in which packages are delivered. Often the tea is simply running through them. Abroad they have a term for teas coming from England. You may occasionally see teas offered "*In English Order*," which means simply in a disreputable condition. It is useless to appeal to the warehouse-keepers on this point. They say they cannot afford to employ more men. I now come to the question of charges: I should think ours is the only trade in the world in which the owners of property cannot inspect that property without paying 6d per package for doing so. He cannot sample his own property without paying 6d for obtaining the sample. He cannot have a card nailed with a tin-tack on a package without paying 1d for the operation. These charges, you will remember, were not very long ago raised to their present amount on the plea that the cost of labour had increased; but, strangely enough, within a very short time, we heard that the merchants were receiving an extra 15 per cent discount on the charges on teas which they placed in the hands of the warehouse-keepers. And this is really the key to the whole position. The warehouse-keepers pay no regard to the wishes of the dealers, they charge them exorbitant rates, they treat their complaints with indifference, simply because they believe they are powerless; and it is for you, gentlemen, to say whether you are content to remain in this position. But I have not yet quite done with the iniquitous conduct of the warehouse-keepers; they absolutely refuse to give proof that they deliver the same quantity of tea as is entrusted to them, and have the assurance to insist that if you require such proof you must pay at the rate of 2d per package for it. Once more, and I have done, so far as this part of the subject is concerned; they charge different rates to different rates to people. For instance, as an importer, I hold a parcel of tea on which I am paying a farthing per week per half-chest for rent; as a dealer. I hold another parcel upon which the same warehouse-keeper is charging, in respect of the same sized packages, a half-penny per week. Now, gentlemen, for the remedy. The werehouse-keepers complain that they are making no money. This is not astonishing, for there is an old adage that unfair dealing never yet did prosper. But one thing is certain: they will make no change unless we compel them. I believe we can do so, and what I ask you is in passing this resolution unanimously, to give your representatives, the Committee power to act in your behalf, and as they will be acting not only in the behalf of the wholesale trade, but also in that of all your customers I would deprecate any selfish isolation on the part of any house of respectability. At a meeting which took place between the representatives of the new warehouse and a portion of your Committee, some words were spoken by one of the leading brokers of the trade, who represented the warehouse, which seemed to me most unjust. Referring to some statement that had been made to the effect that the wholesale tea dealers were but loosely held together, he turned round upon us of the Committee, and said: "Oh, you cannot hold together. Just let a tea be offered at ½d under its value, and you will all fall to pieces." Now, gentlemen, I call that a gross libel. In plain English, it means that though there may be honour among thieves, there is none among the wholesale tea dealers, and that for a paltry advantage they would go back from their word. My experience at any rate, has been to the contrary. It has been my lot to be engaged in two struggles for the interests of the trade, the first when the double brokerage was abolished, the second when importers were compelled by the revised conditions of sale to deliver tea sold within a reasonable time. The same statement was then made and it was falsified by the result. The trade held honorably together, and the battle was gained. And it will be so in this case. All that is required is that we shall know our own minds, that we shall be careful to demand only what is just and fair to all parties, and then that we shall be determined to obtain it. The system under which tea is dealt with by the bonded warehouses is clumsy, injurious to the trade, dishonest to the buyer, and exortionate to dealers both in London and throughout the country. Let all who feel disposed to fight the battle signify their determination by signing the resolution, and I do not believe that anyone will then be dishonourable enough to go back from it. If any such firm should exist, at any rate it will be known as one which justifies the contemptuous epithet which, as I have said, was employed by one of the leading brokers.

Mr. Francis Peek then moved the following resolution:—

"That this meeting confirms the following resolution of the 23rd February, 1876:—'That no addition be made to the present list of bonded warehouses without the approval of the Committee of the London Wholesale Tea Trade Association.' And also requests the Committee to take steps to relieve the trade from the present unfair charges and unsatisfactory regulations as to carding, sampling, and delivery of goods, at present enforced by the bonded warehouse-keepers."

The resolution was seconded by Mr. Burbidge, (of the firm of Burbidge, Pritchard and Bartleet), who fully confirmed the views of the previous speaker.

Mr. Oglesby (of the firm of J. & J. Batten & Co,), raised the point, whether the limitation of the number of bonded warehouses would not tend to create a monopoly.

Mr. Leckie (of the firm of Joseph Tetley & Sons) preferred not to be bound by the action of the Committee.

The resolution was then put to the meeting and unanimously carried; and the public proceedings terminated. —*Produce Markets' Review.*

MINERALS IN BURMA.—From the last Administration Report we learn that 115 tons of coal were extracted during the past official year from the mine in the Okpho township of the Henzada district. There are 28 tin mines and 1 lead mine in the Mergui district, but no information is given of their annual produce. In the Karen hills sub-division of the Toungoo district two mines, producing lead, silver and plumbago, are worked by Messrs. Darwood and Walker. These have only been lately opened, and the outturn, so far, is said to be about fifty tons. No information regarding the galena extracted from Mr. Law's mine at Teetawlay in the Salween district is given in the Report. The stream near Shoaygyeen, where the sand used to be occasionally washed for gold, is said not to be worked now.—*Rangoon Gazette.*

OIL AND OIL CAKE FROM TEA SEED are thus noticed in the *Indian Agriculturist*:—Some ten or or twelve years back, experiments were made in expressing oil from surplus tea-seed, but beyond arriving at the fact that a certain quantity could be extracted, and that it possessed considerable lubricating qualities, the matter was allowed to drop, chiefly we imagine, because the demand for seed, for its more direct purpose, of propagating the plant, rendered its cost, for experimental purposes, prohibitive. Now, however, that China seed is a drug in the market, and there are numerous gardens planted with that variety temporarily or finally abandoned, the subject might with advantage be revived, and, perhaps, these tracts, in which large sums of money have been sunk, may yet be made to yield some revenue, however small. The cake might also prove of value. No harm could be done, and but slight expense would be incurred, if a sample of both cake and oil were sent to London, where their commercial value could be ascertained.

INDINA AGRICULTURE.—The *Indian Agriculturist* writes:—The report of the Saidapet Farm for the last year, will be found elsewhere in our columns, and possesses very great interest. Mr. Robertson tells us that the interest now taken in agricultural education is widely extending. In Ceylon they are forming a School of Agriculture. In Bombay, they are developing the Agricultural branch of the College of Science; and he tells us that other provinces will shortly follow the lead given in Madras. Its University proposes to encourage the study of agriculture by making the subject one of those selected for the examination for the Science degree, and it is hoped that ere long agriculture will be placed on the same footing as medicine and engineering, and that a special Agricultural degree will be established. If there was one thing more than another that alarmed Sir J. Caird, during his investigations into the agriculture of this country, it was the great disproportion between the producing powers of the soil and the increase of the people. His suggested remedy was that every acre of land under cultivation, should be made to yield more, rather than to trust to an increased area of producing land. Even were this available, we must look for intensive, rather than extensive, farming. It is therefore to be hoped that by placing at the service of the students, all the aids that science can afford, and by bringing to their knowledge the results of practical experience in this and other countries, something may be done towards bringing about this result, as it will be through the agency of the students of our colleges that any widely-extended improvement in native husbandry will be effected.

Correspondence.

To the Editor of the Ceylon Observer.

THE ANOTTA OR ARNOTTO.

DEAR SIR,—Can you inform me whether the *Anotta*, which is described in Webster's Dictionary as "an elegant colouring substance, obtained from the pulp of the seed vessel of the Bixa Orellana," is procurable in Ceylon? Is the Bixa Orellana a Ceylon plant? and what are its Sinhalese and Tamil names?—Yours, &c., SLAVE ISLAND.

[Full details regarding this plant have been over and over given. It is common in gardens, and its apple-like blossoms and red pods give it value as an ornamental plant. The chief value of "the elegant colouring substance" is to dye butter and cheese.—ED.]

THE MODEL DUKE ESTATE.

British Burma, 4th Jan. 1884.

DEAR SIR,—You will be surprized when I tell you that I have had the Chief Commissioner and his lady here. I was so proud when I saw the greatest lady of all the land of British Burma mounted on her smart little Burma pony, dressed in her modest form, with her wideawake hat and plain band round it, a pattern to womankind.

She walked round my small new clearing and admired my little planties, and came upstairs along with the Chief and party and admired my neat little bungalow. Such a nice lady one seldom meets in one's lifetime.

The Chief* is a most observing man, and one who goes and sees for himself: in fact, the right man in the right place; if I do not get my own way here, it will not be his fault.

I had Coffee Arabica, Coffee Liberica, and hybrid tea, and also indigenous tea. I found hear also rubber, nan last if not least, "Yerba Mate" to show them.

I have found "Yerba Mate" here, and have secured a few plants already. The Chief was much taken with the ', Mate"; and it will thrive here, and I trust to put another luxury on the table before many years, if spread.

I shall enclose to you a few leaves of "Yerba Mate" foryour "botanist." Kindly ask Wm. Ferguson, Esq., to report upon it.†

The Chief was here at work every day, inspected all Government offices, schools, jails, roads, wharfs, and went from here to Natzudong and from thence to Mergui. He is an early riser, up at 4 a m. and out at 5 a.m. He took the wind out of a few of his subs and walked them round—the very man for a thorough Governor.

I have bought 100,000 plants that will be ready for this season, coffee of kinds, tea, cacao, and rubber, and I am getting 2 cwt. of coffee from Mr. Pelly, Tongoo, for seed, and 4 maunds of tea seed from Kaugra Valley.

I expect to hear from Ceylon about cacao from a good old friend, but you are all so busy planting tea. I hope to see Ceylon turn the corner yet. You have got the men that will do it, good men and true, still in Ceylon. An Assam planter that had been in planting since 1865, who had visited Ceylon lately, said to me: "Ceylon men will outstrip India yet." I said, "How 's that?" Says he. "They have got the energy that 's lacking in India, and a better climate for health, lots of labour, and a splendid transport."

The roads are now being pushed on here, and much need for them, only gravel roads. We want old Macadam badly in this fertile wilderness.

I see the laird expects 10 cwt. per acre. He has got lots of pluck in him still, and I trust you may all get bumpers and better times. Aberdeen Gordon they said would not turn over his *leaves*, but I will bet you a new hat he will turn over *heathen Muniandi*, if need be.—Yours faithfully,

JAMES D. WATSON.

* Mr. Crosthwaite, acting for Mr. Bernard.—ED.

† Mr. W. Ferguson reports that the leaves sent are *not* those of an ilex, but of quite a different plant.—ED.

ASSAM TEA SEED AND LOCAL SEED.

19th January 1884.

DEAR SIR,—I note a discussion in your papers about tea seed as to which is best, "Assam seed or local seed." If you have a climate in which the tea plant does not grow naturally, I should then recommend local seed as being acclimatized; but, failing this reason, if I was putting out a garden for myself to stick to, I would give the preference to Assam seed direct from Assam, and a very fine even Assam hybrid I obtain from Tiphook tea garden. This jât your readers may have to go a long way before they can beat it.

The seed is large and heavy, 16,000 to 19,000 only going to the maund; it is well-packed on the garden, and germination starts in the boxes as a rule.

I believe that this seed could be delivered in Colombo within a fortnight of its leaving the garden, which would give the Ceylon planter a very long pull in that he would receive it in good condition, and be able to look after it.

I have known the Tiphook jât to be sown as high as 5,000 feet, where the temperature in winter borders upon a heavy frost for India.—Yours faithfully,

DARJEELINGITE.

P. S.—I believe in obtaining tea seed from Assam, as the plants, as a rule, are stronger from seed grown in Assam and there is a great deal in bringing your seed from a distance. Here, in India, most orders are booked for seed between the months of April and June, as after then the best tea seed of good jâts is not to be had.

MR. HOLLOWAY'S CACAO TREES.

Maria, 29th Jan. 1884.

DEAR SIR,—I am much obliged to "Swaddy" for the information contained in his letter of 10th inst. in reply to mine in your issue of 8th inst.

The two Trinidad cacaos I have are two distinct kinds:—(1) one a long fruit, pointed at each end (male, I think); (2) one an egg-shaped fruit (female. I think)—planted 20 feet apart near the bungalow,

I have this day cut six ripe fruits of each variety from the tree that bears three varieties, with the following result:—

No. 1 (the natural fruit) contained from 16 to 25 seeds each pod, weighing:—wet seed from 2½ to 4½ oz., shell 12 to 18 oz.

No. 2 and 3 (green to yellow or red) contained from 40 to 46 seeds each pod, weighing:—wet seed 6 to 8 oz., shell 9 to 12 oz.

I have also cut four pods from each of the Trinidad, result:—

No. 1 contained from 36 to 42 seeds each pod, weighing:—wet seed from 5 to 7 oz., shell 12 to 15 oz.

No. 2 contained from 40 to 46 seeds each pod, weighing:—wet seed from 6 to 8 oz., shell 12 to 18 oz.

I have also weighed cured seed ready for the market, 46 seeds weighing 2¼ oz.—new and old same. I have since found several more trees bearing, in addition to the natural fruit, some fruit of the green to red or yellow kind, the weight of seed and shell the same as on the variegated tree.

Whereas this shows a large gain to the fruit (seed) and less nourishment required for the shell, as it is much less in weight, I am now carefully collecting and planting all seed of the new variety as advised by "Swaddy," and trust the trees from this seed will show as good result as the parent trees.

7 pods for 1 to cured seed, or say 800 pods for 1 cwt.—Yours faithfully, J. HOLLOWAY.

P.S.—Can my bees have carried the pollen from the Trinidad to the other trees ?

MR. WM. CAMERON'S CINCHONA DRIER.

Ythanside, Dimbula, 31st Jan. 1884.

DEAR SIR,—In the *Observer* of 28th instant, I find a letter criticizing my "Bark Drier," and, as the subject is important to planters, I offer a few remarks in reply.

It is not advisable for me to go into argument about drying or heating—the subject is rather abstruse—and better spend the time in reading some of the many works on Natural Philosophy—now so easily procured—where, under the respective headings, information on the subjects of air, heat, light, &c. may be found in reliable form.

I would not have taken notice of "J. B." 's letter, but for the fact that most of his observations *are in themselves true*, and therefore, when misapplied, all the more calculated to mislead. He has quite failed to understand the principles of action embodied in my "Drier." This I am not surprized at, as my description of it was brief, and the plant are too rude to give a complete explanation, nor was such my aim. Enough, if I helped to set others to think on the subject. Now to reply.

1st. "J. B." rightly notes the respective heat-conducting powers of iron and clay—to be as 30 to 1. Quite so: I know there is a great difference. It would follow that my heating surface must be 30 times as large as one with the metal. Granted. The whole area of my drying-house floor gives out heated air, as against a concentrated blast of hot air in the "Clerihew."

I did not "say something about 'iron' giving out heat by radiation and 'brick' by conduction." For my plan of equalizing the distribution of heat, brick, in part, is preferable to iron, to give gradual diffusion.

2nd. With my "Drier," *it is correct* to say that the heat *lost* is just what is required for the draught of the flues. All the rest is abstracted, by the air carried along and over the flues, in its passage into the drying-house. The temperature of the discharge at the chimney may be the same as that of the drying-house, while in the "Clerihew" it would be the same as that of the last row of pipes heated. In other words: by my design the loss of the fire heat is at *drying-house* temperature, by the "Clerihew"; the loss of heat is at *furnace* temperature. "J. B." is quite right about limits of heat; if 400° is required, you must lose the rest, as in raising steam or (at higher degrees,) melting metals. But what has this got to do with the "Drier"? In it, the heat in the furnace may be 400°, and is so, but by diffusion in the air drains, it may be economized for use at 90°.

3rd. I don't think I have failed to understand the "Clerihew," but in my plan for using heated air I had to make a difference. "Clerihew" gives a portion of the heat at a high temperature, while I try to secure the whole nearly at a moderate temperature. In my "Drier" the air is removed before it can get cold and heavy; and there is no more for it to fall and rise again re-heated I am not quite sure of "J. B." 's meaning about the "heavy moist air" descending in the "Clerihew": air holds most moisture *not* certainly when cold. If it has become so cold as to be removed with greatest facility by being drawn *down below* as "J. B." recommends, it is not then at an economic drying degree. I prefer to draw the heated air up and along—while it is doing the "duty" available—due to the difference of temperature between admission and discharge. Heat is lost in this operation as in all others, when an exchange of forces takes place.

The trays "moveable" or otherwise which "J. B." does not quite understand, are always in position when the drying is going on, and only moved for filling or emptying; in fact, they are but parts of the floors of the "Drier."

I trust a few essential points of difference have now been indicated between the "Clerihew" and the "Drier." What the result may be, time will show, but what I contend are *improvements*, "J. B." thinks *defects* arising from my ignorance of the principles of the "Clerihew," an apparatus long fallen into desuetude from causes which I have roughly and incidentally noted above.—I am, yours faithfully,

WM. CAMERON.

P.S.—The above remarks do not apply to the design for tea withering, etc. W. C.

GIANT TEA BUSHES.

Upper Abbotsford, Lindula, 6th Feb. 1884.

DEAR SIR,—As there is an idea that we have only *one* giant tea tree instead of hundreds, I give the dimensions of some I measured last week:—

Seed Bearers.

Diameter.

ft.	in.		ft.	in.
15	8	by	13	9
20	4	,,	18	8
21	0	,,	19	7
15	8	,,	15	7
16	0	,,	11	9
19	0	,,	18	0
19	6	,,	18	6
13	10	,,	13	0

height 22 feet; circumference of stem 22 inches.

Plucking Bushes.

Diameter.

ft.	in.		ft.	in.
	8	by	3	7
7	2	,,	6	0
9	9	,,	8	6
8	0	,,	8	1
7	6	,,	7	3
9	3	,,	9	0
9	10	,,	8	0
10	5	,,	7	3
10	5	,,	9	6
12	4	,,	10	3
7	9	,,	7	0

The big tree is now 25 ft. 8 in. in diameter, or 77 feet in circumference.—Yours truly.

A. M. FERGUSON, JR.

GLASS-HOUSES FOR TEA FACTORIES are thus noticed in the *Indian Agriculturist* :—Glass roofing material for factories and outhouses is coming into such general use in many parts of England, where it is found to answer admirably, that the feasibility of its more general introduction into this country is worth attention. Excepting in and around the Presidency towns, most of our factories consist of wretched, dingy, ill-lighted sheds, with thatched roofs, in which it is difficult to conceive how manufacture can be properly carried on. There were lately on exhibition at the Islington Agricultural Hall glass roofs put together without putty, so perfectly water-tight, that business was carried on, while a stream of water to show their intactness, was kept running over them all day long. Roofs such as these are well fitted for the sorting and rolling houses on our tea plantations, having the recommendation of lightness, cleanliness, uninflammability, and being perfectly water-tight. Blinds would keep the glare and heat out, while the glass could be protected, from hail, by wire gratings. Sorting could go on in the tea-house without the women crowding round the doors as now, owing to insufficient light; while the manager would be better able to determine whether his rolled leaf had acquired the requisite degree of *color*. Glass houses, moreover, are exceedingly portable, and at a proper height from the ground would attract the heat less than iron.

THE COOLIE QUESTION IN QUEENSLAND.

The MacIlwraith Government in Queensland having been defeated on the question of land grant railways, a general election was about to take place in the which the question of cooly labour will be a burning one. Mr. Hume Black, who represented the Sugar planting interest of Mackay District, wrote thus to reassure the white working men :—I pledge myself to see that all coolies shall, at the termination of their agreements, be compelled to return to India, or re-engage for tropical or semi-tropical Agriculture. That any person employing them otherwise shall be punished by fine at the rate of ten shillings per day for every day they are so employed. That all expenses connected with their introduction, Depot, Hospital, and Gaol expenses, and return passages be paid by those employing them. That any Captain landing coolies in Queensland or any of the adjacent islands instead of returning them to India be liable to a fine of from £100 to £500. I shall also see that any further regulations are made that may be necessary to confine coolies strictly to those occupations for which only they should be allowed to be introduced, namely, Tropical and Semi-Tropical Agriculture.—*Mackay Standard.*

BLUE GUMS AND RED.

TO THE EDITOR OF THE "AUSTRALASIAN."

SIR,—As many folk are disappointed in growing blue gums, in consequence of their dying when a few years old, for the benefit of such I give my experience of about 30 years, about which time since I planted a lot of blue gums, some of which are standing now, but a number of them died off when about 12 ft. high. I planted again in the same places with a like result. I then tried the red gum (land poor, with yellow clay close to the surface), and they have grown very well, and are now 30 ft. high, healthy, and of good shape. I plant a few every year, and my plan has been to go to places where they grow naturally on the margin of the creeks and dig out a plant with a sod of earth, and after fencing a panel square, dig about 3 ft. square and place the sod in centre, and they grow in either wet or dry places; but not in loose sand (where blue gums will do well). I fancy the Geelong and Skipton plains would grow red better than blue, and as now is a good time to plant, perhaps you will insert this. The blue gums now growing with me are in better soil and sand. The red will also grow well in good soil, but not in sand.—I am, &c.,

J. H. J.

[Blue gums have been extensively sown as breakwinds on some of the large estates in the western districts of Victoria. The practice has been to plough very shallow—not more than 4 in. deep; then harrow and sow seed at the rate of two and a half ounces per acre, and finish by rolling. The trees have generally grown well.—ED.]—*Australasian.*

THE NORTHERN TERRITORY.

QUARTERLY REPORT.

The following report by the Acting Government Resident of the Northern Territory was laid before the Assembly:—

Government Resident's Office, Palmerston,

SIR—I have the honour to forward the following quarterly report on the state of affairs in the Northern Territory, and am glad to say that both pastoral and mineral pursuits are making steady progress. Agriculture, although as yet only in its infancy, is also beginning to show that good crops can be grown here in suitable localities. As it may be of benefit to the country and of interest to the general public to have the fullest information as to how our several industries are progressing, I have, with the assistance of several managers, obtained the following information :—

AGRICULTURE.

I regret to have to report the complete abandonment of Owston's sugar plantation on the Daly River. This is very much to be regretted, as many of the difficulties incident to the commencement of any new industry had been overcome, and I am informed by those who visited the site recently that the cane was growing most luxuriantly in the nursery, which contained twenty acres. One of the drawbacks to the Daly River is its difficult navigation, and probably this had something to do in influencing the shareholders to withdraw, but this is a difficulty that could be overcome by the use of small steamers of light draught. The land selected for this plantation I am sure is capable of growing good crops. Work has also been stopped on Mr. Sergison's Adelaide river plantation. Mr. Biddles, the new manager for the Delissaville plantations, has been very energetic since his arrival in examining the country on the Douglas Peninsula, and has, I understand, succeeded in finding some land on which he hopes to grow good crops of cane. That cane of good quality can be grown in the Territory is beyond doubt. At the small plantation of Messrs. Cloppenberg & Erikson on the Douglas Peninsula, and at any of the numerous gardens worked by Chinese in the neighbourhood of Palmerston, cane of excellent quality may be seen; but then it must be remembered that these are only small patches, and the occupiers are too wise to try and force a growth on any other land than that which is suitable. Had care been taken in the first instance to select land suitable to the growth of sugar-cane, that industry would have been now in a very different position to that which it at present occupies. Cane of good quality has been successfully grown on the McKinlay River on the gold-fields—of course, only a small quantity—a sample of which I forward with the other exhibits. I am glad to say that Mr. Poett's cinchona and coffee plantation is making steady progress. It is now between ten and eleven months since that gentleman commenced operations, and commenced by planting coffee both of the Arabian and Liberirn varieties; also cinchona, indiarubber, tobacco, and cotton. With regard to coffee, the success so far has been beyond anything that Mr. Poett anticipated, and it must be remembered that he is no mean judge, having been occupied for nearly a quarter of a century in Ceylon as a coffee-planter. There are half a milion young coffee-plants of excellent growth, and presenting a highly satisfactory appearance. Mr. Poett says nothing in or out of Ceylon could be more encouraging or more suggestive of the future success of coffee cultivation in the tropical portion of Australia than the present appearance of this nursery; he challenges inspection and courts enquiry. It is also a matter for congratulation and encouragement that the greatest enemy the coffee-planter has ever had to contend with, viz., the *Hemileia vastatrix*, has not put in an appearance. The nursery also contains several thousand plants of the cinchona succirubra, which, notwithstanding that their treatment had in a great measure to be left to unpractised hands, the result is considered to be on a par with that of a successful nursery in Ceylon. Some of these plants are sixteen months old, having been planted by Mr. Mackinnon previous to active operations being commenced on the plantation, and are now over four feet high. Mr. Poett is of opinion that cotton and indiarubber may be safely added to the list of vegetable products that will grow successfully in the Northern Territory when labour at a sufficiently cheap rate can be obtained. He strongly advocates the adoption of Malabar labour for plantation work, and has kindly furnished me with particulars of their cost in Ceylon as against the cost of Chinese labour here at the present time, the cost of Malabar labour in Ceylon being for the month £19 15s. 11d., as against £99 18s. 4d. for an equivalent of Chinese labour in the Territory. No doubt, until cheaper labour in introduced, such a great difference in the price of labour will be a bar to some of these industries. I am happy to say that there are large areas of land equal, if not superior, to that which Mr. Poett is operating upon, but being much farther inland are not sought after at present. They will, however, when a railway is made to Pine Creek, come within easy reach. Then these lands would, with good management, give a handsome return for capital, and afford occupation to a large number of labourers. It is a fact well known in agricultural history that moderate success in coffee-planting returns a good percentage upon the outlay, and that those who are thoroughly successful reap profits calculated to satisfy the expectations of the most sanguine. On the block of land on the Adelaide River, 5,000 acres, originally granted to Mr. Sergison, and subsequently transferred to Messrs. Fisher & Lyons, cultivation has been commenced. In September last year cane-cuttings were planted, and during the wet season twenty-three acres of maize were grown. Both cane and maize grew well until towards the end of January, when, unfortunately, the crop was eaten off by large numbers of rats, and within a fortnight of the time the maize was fit to gather they took everything before them, and the labour of thirteen men employed during the previous six months was lost. Ploughing is now being proceeded with on this plantation, and efforts will be made to get 200 acres under cultivation by the end of the year; and I sincerely hope they will be crowned with greater success than they were rewarded with last year. There is one other obstacle to successful cultivation here, and until the fact is boldly looked in the face and combated with, I do not think the best results will be arrived at. I refer to the long dry season. As a rule, very little rain falls for seven months in the year, but I believe that this drawback can be successfully overcome by artificial irrigation, and in many places at no very great cost. At the time I commenced occupying my present position the previous quarter was drawing to a close, and I am not aware whether Mr. Price furnished any of the following information; I therefore give the following list of exports and imports for the last six months:—Exports.—Gold, 12,398 oz., £43,448; tin, 7 tons 8 cwt., £370; sugar, 4 cwt., £2; sundries, £259; total, £44,079. Imports.—Total value for last six months to date, £54,739. Customs.—Revenue for last six months, £9,248 19s. 4d. Passengers.—Inwards, 539; outwards, 208. Leaving a balance of 331 in favour of immigration.—G. R. McMINN, Acting Government Resident.—*Adelaide Observer.*

THE CREOSOTE PLANT AND AMERICAN LAC.—In certain portions of the south-west in the United States is a shrub which grows abundantly, and particularly on the borders of the Colorado Desert, where it is so luxuriant that it acts as a barrier to the drifting sand. This is the Creosote plant (*Larræa Mexicana*), and is a sure sign of a barren soil, for it flourishes where nothing else will, and although it gives the scenery a beautiful verdant appearance, it has such a strong repulsive odour of creosote, that no animal will touch it. Even for fuel it is almost useless, as it can scarcely be made to burn. The odour is due to a resinous matter, of the value of which the Pimos Indians have long been aware, as they collect and form it into balls, which they kick before them as they journey from one point to the other of the trail. This exudation has been shown by Mr. Stillman, of California, to be identical with the gum-lac of India, and he believes that the lac is secreted by the insect found in it, and that it is not, as usually supposed, the result of an exudation of the plant caused by the punctures of the insect. The Entomologist of the Bureau of Agriculture does not consider that the insect itself is the same as the *Carteria lacca*, the incrustations of lac on the creosote plant not being so thick as that produced by *C. lacca*; but as it presents a similar system of large and complicated excreting organs, he has named it *C. larræ.*—*Public Opinion.*

A NEW TEA PEST.—A correspondent of an Indian contemporary, writing from Lower Assam at the end of July, thus describes a new pest and his method of dealing with it:—"About the end of May numerous caterpillars, about an inch long and of a dullish brown color, were noticed; but they did not at first attack the tea plants. However, they shortly began to do so, eating the bark of the one and two-year old shoots and causing the plants to die back; in some cases nearly to the ground level. Small low *jat* plants suffered most. At first only a patch separated from the rest of the garden by a road was attacked, but later they spread over the rest of the garden. I have only just finally got rid of the caterpillars. I had millions gathered and destroyed, and in this operation I found that lying down pieces of mango, which attracted large numbers of caterpillars, was of some assistance. In gathering the insects it was necessary to use a small piece of bamboo as a pair of tongs, as the caterpillars induced an itching sensation if touched with the skin. This pest has hitherto been unknown in Lower Assam, as far a I can ascertain."—*Planters' Gazette.*

TEA CULTURE IN THE UNITED STATES.—Many experiments have recently been made in the cultivation of the tea plant in the United States, and generally with excellent results. In California the plant has been cultivated with considerable success. The difficulties which the tea-planter has to overcome are not insurmountable, and the United States *Economist* considers that it is an industry which might very profitably be carried on in the South. It requires but a small outlay of capital and a small quantity of land. In the tea districts of Japan there are but few agriculturists who devote themselves exclusively to tea culture; the growth is generally confined to nooks and corners which cannot be very easily used in any other branch of agriculture. The indications both in the older systems of culture in Oriental lands and in the experiments in America, go to prove that the business may be profitably pursued as a supplement to other agricultural enterprises. Each farmer may raise enough for his domestic consumption, for 10 or 12 trees will furnish enough tea to meet the wants of a family of eight persons. As to the question of the United States competing with China and Japan in the markets of the world that is problematic. There has not yet been witnessed enough of the tea production to judge of its ultimate results as an industry. Besides this, the price of labour, the high tariff duties, and the cost of transportation are all to be taken into consideration in estimating the efficiency of a tea industry as a separate branch of agriculture; but the labour to cultivate a few tea plants would only absorb the odds and ends of a farmer's time, which might otherwise go waste, and the feasibility of this has been proved. In different portions of the United States the healthy and promising growth of plants has been secured, so that more may be heard of the culture in the future.—London *Times.* [We do not doubt that tea can be grown in the United States, but the high price of labour will prevent any large attention to the product. It will be better for the farmers of the Union to grow wheat, maize and cotton, and buy tea grown in Asia.—ED.]

BREAKFAST BEVERAGES.

Each of our commoner breakfast beverages, namely tea, coffee, and cocoa, present sundry relative advantages and disadvantages, which have been well established by scientific experiments and general experience, and which are qualities that sometimes assume a special importance in certain conditions of health, habit, occupation, climate, and disease. Warm infusion of tea has been proved to have a marked stimulant and restorative action on the brain and nervous system, and this effect is not followed by any secondary depression. It further increases the action of the skin, and raises the number of the pulse, while it has a little effect upon urination, excepting simply as a watery diuretic. It tends to lessen the action of the bowels. Dr. Parkes found that tea is most useful as an article of diet for soldiers. The hot infusion is a patent protective against extremes both heat and cold: and Sir Ranald Martin proved it to be particularly valuable in great fatigue, especially in hot climates. Coffee, like tea, when used as an article of diet, especially affects the nervous system. It is a brain-and-nerve stimulant; in very large dose it produces tremors. It increases the action of the skin, and it appears to have a special power in augmenting the urinary water. It increases both the force and frequency of the pulse. Unlike tea, it tends to increase the action of the bowels. Coffee has been proved to be an important article in a soldier's dietary, as a stimulant and restorative. Like tea, it acts as a nerve-excitant, without producing subsequent depression. It is serviceable against excessive variations of cold and heat, and its efficacy in these respects has been established in antartic expeditions as well as in India and other hot climates. Dr. Parkes pointed out that coffee has a special recommendation in its protective influence against malaria. While admitting that the evidence on this point was not strong, he held it to be sufficient to authorise the large use of coffee in malarious districts. Coffee should be used as an infusion. If coffee be boiled, its delicate aroma is dissipated. The theobromin of cocoa is, chemically, identical with the thein of tea, and the caffein of coffee. While tea and cocoa are comparatively valueless as true foods, cocao, by reason of the large quantity of fatty and albumiuoid substances it contains, is very nourishing, and is of high dietetic value as a tissue-forming food. Compared with tea and coffee, it is a food rather than a stimulant, being akin to milk in its composition and place in the diet-scale. It is useful to sustain the weakly, and to support the strong in great exertion, as a readily assimilable and general form of nourishment—*British Medical Journal.*

LIBERIAN COFFEE AND CACAO.

(*Report from the Kurunegala District, Ceylon.*)

It is very interesting and satisfactory to notice how new products are gradually occupying their allotted positions in the lowcountry. In the Kurunegala district, in most places, Liberian coffee appears to have been a success, possibly not quite up to expectations; but then take a retrospective view of what these expectations were, and it will be seen that such prospects were not, as a rule, realized in the palmiest days of coffee cultivation. Suffice it to say, that it pays and that the past season has been done in which leaf-disease has not acted so prominent a part as previously, which makes the Liberian coffee planter more hopeful than he was. The average crop of Liberian Coffee on full bearing trees cannot, throughout the district, have been less than 5 cwt. the acre, which, at R37 is R185, leaving a profit of R100. This must be considerably over the average of profits of most cultivated products. Were it not for the bugbear leaf-disease, I conclude there are many who would prefer Liberian coffee to cocoa in this district, as it is certainly a hardier and less fastidious plant, growing almost as well upon ridges as in ravines, which cocoa will not do; nor will it fully thrive, except in sheltered hollows and valleys.

Cocoa upon many places is now bearing its first appreciable crop, and has assumed full possession of the land —a sea of green with pendant crimson and orange pods, beneath a chequered shade of jack and other trees. No cultivation has a grander appearance, and I should think none is more valuable. With care and attention it has the name of being not only a long liver, but a tree which for a life-time repays its owner a very high return for money invested. It is, however, not the most certain of cultivations. I doubt if it can be profitably grown over a fourth of the area upon which it has been planted. There are spots upon cocoa estates where it would seem every enemy of the plant congregates; as though one having assailed the unfortunate plant, others must perforce follow suit, and, if possible, by their joint efforts exterminate it utterly. Close at hand are other cocoa estates without a visible enemy upon them. This to my mind rather goes to prove that so-called enemies of plants, like wolves and other creatures in the animal world, prefer what they attack to be already the victim of misfortune. With the wolf this is to be understood, but with caterpillars, beetles, aphidea and sap-suckers generally, it is more difficult to discover their object. The only one which occurs to me is the tendency to decomposition in the sap; the first change of which would possibly be the conversion of its starchy ingredients into sugar, and most of these small pests have a great partiality of anything sweet.—"Local" Times.

CULTIVATION OF THE ORANGE TREE IN SPAIN.

The United States Consular Agent, at Gras, writting on the propagation and cultivation of the orange tree in Spain, says that it does not thrive in the open air, except above 43° latitude, and then only in sheltered spots. When the average temperature reaches from 15° to 16° Réaumur, the apparent vegetation of the orange tree commences, which, as a rule, takes place in the month of March. The blossoming requires a mean temperature of 18°, the first flowers appearing in April, and frequently continuing throughout the whole of May. The blossoms are found on the secondary branches, but principally on the tertiary ones, or, in general, those formed during the previous year; but this is not an invariable rule. The soils in which the orange tree thrives well are of very distinct compositions, as there are as many orangeries in Spain on sandy as on clayey soils. Great attention is generally paid by the cultivators not only to the surface but also to the subsoil, as there are frequently parts where the soil is loose and of good quality on the surface, but very compact and bad beneath, or *vice versa.* Orange trees may be propagated either from seed or from cuttings; the former system perpetuates the species and creates new descriptions, afterwards improved by cultivation. The second method, either from shoots, cuttings, or grafting, continues the race, and, at the same time accelerates the fruitage, which is always later with the trees produced by the first-named system; but, in exchange, the trees raised from seed are more robust, and live to a much greater age. In cultivating plants from the seed, attention must be paid to the soil, in order that it may be of good quality, and free from creeping herbs or seed, and it must be in a good situation so as to receive the sun in all parts, besides which it must have an abundance of water for irrigation. All seeds are sown in flat plots, and if delicate, the soil is lightly manured, and at the same time excavated and loosened, so as to give the plant greater freedom for growing. The plots, when prepared, are opened out in parallel rows of about four inches deep, and about one foot apart from each other. To obtain the quantity of seed required for sowing, when the proper time arrives, the general method is to divide the orange with a knife, taking care not to cut it so deeply as to touch the seeds, or to in any way injure them. Theso are then picked out, and placed in the shade to dry, after which they are preserved either in paper packets or earthenware pots in a dry place. When the seed is once obtained, and not required for use for a certain time, it is placed in layers of sand, to prevent it becoming too dry or opening. When the time has arrived for the seed to be sown, the soil is carefully prepared, being well watered and dug up. If the earth is compact and formed of hard lumps, these are broken up and smoked, and made up in *hormigueros*, which are heaps of dry vegetable refuse, covered over with earth, having a small opening near the ground, in which is introduced a wisp of straw. On setting fire to the straw, the whole mass gradually consumes itself, forming a small heap of vegetable ashes and earth. These ashes are equally distributed over the surface of the soil, and this is immediately afterwards manured. The ground has to be divided in long and narrow plots, having small irrigating canals between each, which must be sufficiently deep so as not to allow the water to reach the superficies of the rows. The seed is soaked in water for two days, and afterwards thickly sown. The young plants are from four to six weeks before appearing above the surface, and, as soon as they have acquired a certain development, which occurs at the end of a year, the plantation is commenced. This generally takes place from the middle of February to the beginning of March, according to the condition of the plants. The trees are planted in the plantation at a distance of from forty to fifty centimetres apart, and on transplanting the young trees a series of light beds are made. The trees are planted in regular files, but on the opposite side of the beds to that where they are irrigated, thus preventing the wrter from reaching the young shoots. The top soil is frequently loosened with a weeding hook, and thus the beds gradually get lower, until they become level with the surrounding earth, at the time when the plants have taken firm root, and are flourishing. The plantation is irrigated once in every three weeks in ordinary weather, but oftener when it is very dry. At the expiration of a year in the plantation, the young plants are sufficiently advanced for grafting, this being one of the most important means for the propagation of the orange tree. The system of grafting generally adopted is that of the grafting of a bud. These buds are selected from those of the previous year, and of the June shooting; and according to the size of the parent stem, one, two, or even four are placed, for should the parent stem be thick, and have only one bud grafted on it, the excess of sap would suffocate it. On placing the buds, the parent stem is probed, and they are applied to the most salient parts which the stems may present, as it is considered that it is here where the greatest quantity of sap is found, and it is done, when possible, in the part facing the north. The grafts are tied with esparto grass, and allowed to remain in this state for twenty-one days; if at the end of this time the bud continues green, the grafting is correct, in which case the shoot is cut off about four inches above, and it at once moves if it has dried. Sometimes it commences moving before the grafting has thoroughly taken place, in which case it is immediately cut. Great care is taken in transplanting the roots; they are dug out with a large spade, with a quantity of earth adhering to them, and this earth is surrounded with rotten or dried leaves, and tied round with cords. When the orange trees are taken to the spot for planting, the bottom of the holes is first lined with the earth which has adhered to the roots, until it is estimated that on planting the young tree it will be, after irrigating the soil, at about the same depth as when in the nursery, and as soon as the tree is placed in position, the virgin earth remaining round the sides of the hole is thrown in. Before closing up the hole, about twenty quarts of water is thrown in, if there is a probability of irrigating within a few days; if not, a small quantity of water is added. The orange may be submitted to two systems of cultivation, planting the trees at a considerable distance from each other, or planting them close to one another. The latter system is the most costly, but is productive of better results. In the first year of transplanting, ridges are formed at the sides of the rows of orange trees, at about the distance of about seventy centimetres from the trees, and in the month of April the trees are manured, at the distance of about fifty centimetres from the trunk, and a trench dug round it, in which the manure is placed and covered over. In February of the second year, about two or three pounds of manure are placed at the edge of the ridges, and manure is again deposited in April round each tree. In the third year the young roots have reached as far as the ridges, and the trees commence bearing fruit. The ridges are now broken down, the whole surface irrigated, and *hormigueros* are made. At the distance of about a yard from the trunk of each tree, small holes are dug, and two or three pounds of guano deposited in each, after which they are covered up. In the fourth year the fruit is plucked, and the pruning of the trees is commenced, this operation being generally effected between February and May, and repeated every year. All dry branches are cut off, as are also all ricketty shoots, and the crooked branches which cross one another, and as soon as the pruning is completed the working of the soil is commenced. Consular Agent Loewenstein says that the orange cultivator must be always on the watch, both as regards the weather and the condition of the soil, the utmost care and vigilance being required to ensure the successful cultivation of the tree, and the production of a good supply of fruit.—*Journal of the Society of Arts.*

SUGAR CULTIVATION IN THE ARGENTINE REPUBLIC.

The enormous development of the sugar industry in the northern provinces of the Argentine Republic, and the field which it offers for the advantageous employment of English capital, is worth the attention of your readers. There can be no question that sugar-growing is the department of agriculture here which has the greatest future before it. At present, the Republic does not produce more than half enough to meet the home consumption, and it is obvious that there is ample scope for the further extension of the industry, if only to meet our own requirements, to say nothing about an export trade. Capitalists in this country are powerless to cope satisfactorily with the problem, owing to the fact that they are scattered all over the country. On the other hand, foreign capitalists, whose efforts could be advantageously concentrated would find the industry a paying one. The lands most suited for sugar cultivation are in the provinces of Tucuman and Santiago del Estero, in the interior. They are both, however, connected with Buenos Ayres by a good service of trains, and by this means the despatch of produce to the capital and the introduction of sugar-machinery is rendered comparatively easy.

OFFICIAL ENCOURAGEMENT.

It must be admitted that former Governments have, in spite of political and other troubles, done all in their power to stimulate the industry, and for this purpose have not hesitated to draw on their scantily-supplied exchequer. In 1877, for instance, a law was passed providing that members of the Sugar Planters' Society should be exonerated for fifteen years from the payment of all municipal taxes then established or to come in force subsequently. Actuated by the same spirit, the Argentine Government has not only reduced the railway rates, but has declared that all machinery and implements destined for use in the cultivation and manufacture of sugar shall be introduced absolutely free of duty. There is a cosmopolitan society in Santiago composed of English, French, and German agriculturists, who work side-by-side with natives, Dutchmen, and others. The members of this body have, in the course of a few years, raised themselves to positions of comfort and competency, and now receive that mead of respect and honour which the Argentines are ever ready to bestow on natives and foreigners alike who successfully breast the hill of life by hard and honest toil.

FACTS AND FIGURES.

That this letter may be of practical utility, I will give the cost of sowing and cultivating a sugar-cane *cuadra*, or plot, 150 yards square, for the first year, and the probable crop. These figures are exact, and can be verified by any of the diplomatic agents of the British Government:—

Cost of Sowing and Cultivating Sugar-cane Plot 150 *Square Yards.*

Seeds	$105
Labour	120
Keep of labourer	100
Cost of land	30
Drainage of plot	100
Cost and keep of 7 head of cattle	120
Cost of ploughs	55
Cartage of crop to factory ...	70
	700

Crop of a Plot 150 *Yards Square.*

7,000 arrobas of cane (about 78 tons) at $0·07 per arroba	$490

These figures prove beyond doubt a clear return of 66 per cent of the capital invested for the first year. In the following years the results would be far greater, as the main outlay has already been made. Mr. St. Germes, who may be called the parent of the industry in Santiago, is clearing 15 per cent on capital invested in an estate which was offered to an English syndicate for 80,000*l.* last year. A return like this is not thought very much of here, where the ordinary bank rate is from 10 to 12 per cent. English capitalists seem unaware of the political status of countries like this. They are chary of an investment which cannot fail to produce certain and guaranteed results in fields that are full of wealth, yet will often advance millions to some petty State which is beyond hope of solvency. In conclusion I may add that considerable rivalry exists between the planters in several sugar-growing provinces, and in the so-called contests that have been held, subject to the decision of competent arbitrators, the palm has alternated from one to another. Santiago del Estero, however, is at present the holder of the coveted distinction.—*Cor., British Journal.*

MANURES—PRACTICE WITH SCIENCE.

The fifteenth volume of the ninth edition of that stupendous work, the *Encyclopædia Britannica*, has recently been issued by the Messrs. Black, and amongst many articles of the most varied interest there is one specially attractive to agricultural readers, namely, Dr. Voelcker's article on "Manure." He defines the principal constituents of manure to be nitrogen, in the form of ammonia, nitrates, and nitrogenous organic matters: organic matters not containing nitrogen (humus); phosphoric acid, potash, soda, lime, magnesia, silica, sulphuric acid, and chlorine, by far the most important being the nitrogen, phosphoric acid, and potash.

With regard to nitrogen, Boussingault long ago proved that plants do not possess the power of taking up by their leaves and of assimilating the free nitrogen of the atmosphere. A fractional percentage of the atmospheric nitrogen undergoes conversion into nitric acid and ammonia, which become dissolved by rain or dew, and so find their way to the soil, thus adding to the store of soil nitrogen, but in altogether too insufficient a quantity to meet the requirements of remunerative crops. At Rothamsted the amount of nitrogen annually deposited is 7·21 lb. per acre, of which 6·46 lb. are in the form of ammonia, and 0·75 in the form of nitric acid. But it has been proved that the loss of nitrogen in the form of nitrates in the drainage water from cultivated soils is much greater than the total amount supplied to the land in rain and dew. The experiments on the continuous growth of barley at Rothamsted from 1852 to 1875 afford direct evidence of the insufficiency, not only of the atmospheric supply of nitrogen, but likewise of that present in the soil in the form of nitrogenous organic matter.

The deep and moderately stiff soil at Rothamsted contains the mineral elements of plant food in abundance, so that it was possible to grow corn crops for over twenty-five years without any manure. But the crops in the second half were less than those in the first half of this period, and full crops were never obtained. While the application of mineral manures alone produced only a slight increase in the case of wheat, and not much better results with barley, nitrogenous manures, on the other hand, applied either as ammonia salts or nitrate of soda, produced a strikingly large increase. While good crops of wheat and barley can be grown by the annual addition of 14 tons of farmyard manure per acre, the best results are proved to follow the use of a mixture of mineral and nitrogenous manures.

The quantity of nitrogen carried of in the Rothamsted crops was determined with these results:—Over a period of thirty-two years (to 1875) wheat yielded an average of 20·7 lb. of nitrogen per acre per annum without any manure, but the annual yield has decreased from an average of over 25 lb. in the first eight to less than 16 lb. in the last twelve years, and since 1875 it has been still less; over a period of twenty-four years barley, when unmanured, yielded an average of 18·3 lb. nitrogen per acre per annum, but with a decline from 22 lb. in the first twelve to 14·6 lb. in the last twelve years. Similar experiments on oats, roots, pulses, and grass crops all show the steady decline in produce when grown continuously without nitrogenous manures, and thus prove that the soil, and not the atmosphere, is the chief source of nitrogen in plants. Great as was the effect produced by the nitrogenous manures, however, it was found that two-thirds of the nitrogen supplied was unrecovered in the increase of crops when the ammonia salts were sown on wheat in autumn. But when nitrate of soda, which is always applied in spring, was used, the quantity of nitrogen unrecovered was not much more than half that supplied. What becomes of the one-half or two-thirds of the nitrogen which is not recovered in the increase of the crops? Analyses of the drainage water from soils supply the answer to this question. Figures are given showing how great may be the loss of nitrogen by drainage when ammonia salts or nitrates are liberally applied to the land in autumn, or even when applied in spring if there be much heavy rain; also that a quantity of nitrogen, occurring as nitrates in drainage water is increased correspondingly with the amount of ammonia or nitrate put on the land. Besides the nitrogen removed in the crop and that lost in drainage, a small proportion is found to be retained in the soil itself, but the amount depends on the nature of the manure; ammonia salts and nitrates yield but very small residues, and exert little or no effect beyond the first year, while bones, cake, and such manures leave large residues of nitrogen in the soil, which tell markedly on subsequent crops. Phosphoric acid and potash pass but little into the drainage water, but are retained almost entirely in the land, while the less important mineral matters, lime, magnesia, soda, chlorine, sulphuric acid, and soluble silica pass in large quantities into the drainage water. Dr. Voelcker makes the following inferences:—First, that much more nitrogenous material must be applied to the land than would be needed to produce a given increase in the crop, supposing all the nitrogen to be recoverable; and secondly, that nitrogenous organic matters when applied to the land undergo decomposition, and are gradually resolved into ammonia compounds, which, after being retained a short time by the soil, are finally oxydised into nitrates, in which form they are most available and beneficial to plants, but are not absorbed by the soil, and are readily washed out by rain.

Phosphoric acid is next in value to nitrogen, partly because of its natural scarcity in cultivated soils, and partly because it is required alike by corn and forage crops in larger quantities than lime, magnesia, and other minerals which are more abundant. Phosphate of lime is more or less assimilable by plants according to the more or less porous condition of the phosphatic manuring materials. Hence the object of treating mineral phosphates with sulphuric acid, and converting the insoluble tribasic phosphate of lime into a soluble superphosphate. For this manufacture alone, England imports over half a million tons of phosphatic minerals per annum.

As to the action in the soil, Dr. Voelcker remarks:—"The acid or soluble phosphate of lime in superphosphate, when applied to the soil is first dissolved by the rain and equally distributed in a portion of the soil, in which it must be precipitated and rendered insoluble before it can be assimilated by the plant." It is this intimate distribution and subsequent precipitation in a most finely divided state that would seem to cause the beneficial effects of superphosphate, and its superiority over undissolved phosphates. It supplies at once phosphoric acid, lime, and sulphuric acid to the soil, and is much used in conjunction with nitrogenous materials. Superphosphates are manufactured of various strengths, the percentage of tribasic phosphate of lime, rendered soluble by acid, being taken as the basis of valuation.

Potash forms an important constituent of all crops, particularly root crops. Sandy soils, as a rule, are poor in potash, while clay soils usually contain sufficient. Autumn cultivation, subsoiling, and similar means of facilitating the free access to the air gradually liberate the potash from the insoluble silicates in which it occurs in clays, and then set it at the disposal of plants. Potash occurs in farmyard manure, urine, all excrements in oil-cakes, and largely in wood ashes. On most soils, in good agricultural condition, the addition of potash manure gives little or no effect, but on poor, sandy soils or worn-out pastures, potash salts, used with superphosphate, dissolved bones, and guano, produce most beneficial results.

The following remarks on the application of manures are very valuable—"Farmyard manure in order to be most beneficial, should be applied as quickly as possible after it is made, the best time being autumn or early winter. Nitrate of soda should be applied as a top dressing early in spring; its effects will be seen in the first season only. Ammonia salts, guano, dung, &c., are best applied to heavy land in autumn or winter, either before the seed is sown or after the plant is fairly above ground, but in the case of light land early in spring. The effect of bones in the various forms of dissolved bones, bone dust, raw bones, &c., will last two or more seasons, according to the quantities used and their respective solubility. Lastly, the presence of lime is essential to the economical use of manures." —*Mark Lane Express.*

THE INDIAN TOBACCO MANUFACTURE.

India supplies herself with cheroots as well as with tea, but no one will venture to say that her cheroots are at all equal to her tea, though the latter is just as much a manufactured article as the former, and much more difficult to produce in approved merchantable form. The tea industry is much more recent in this country than the cheroot industry, and we would naturally expect to be able to get better cheroots than tea. But the fact is otherwise. And strangely enough, while the price of teas of every quality is being lowered, the price of cheroots is steadily increasing. Again, while the quality of all teas is improving, the quality of all cheroots is, if not degenerating, certainly not improving. The only conclusion we can come to from these facts is, that the tea industry is in the hands of a more intelligent class than the cheroot industry. The cheroot manufacturer seems to understand how to fix the price of his produce on the political economy law of supply and demand, but he fails to appreciate the pecuniary advantages to be derived from an improved quality of production. In this respect he appears to be in the last degree conservative, and to take for the rule of his life the motto, "As it was in the beginning, is now, and ever shall be;" and so the quality of the Indian cheroots of 1883 is no better than those of 1833. While Manilla competed with India in cheroots of the higher qualities, it was not to be expected that the manufacture of cheroots in this country would improve very much, if at all. Up to the middle of the present century, and for ten or fifteen years thereafter, Manilla supplied the Indian market to a considerable extent with cheroots of the higher qualities, and Southern India, of which Trichinopoly was the chief manufacturing town, was content to supply the cheaper and lower quality of article. The price of the best quality of the Manilla manufacture was about six times greater than that of the Trichinopoly manufacture. This being the case, it seemed hopeless to expect any part of Southern India, Lower Bengal, or even Trichinopoly itself to make an attempt to compete with Manilla. It was said that the best quality of Indian tobacco was far inferior to the medium quality of the best Manilla tobacco, and that the best quality of Manilla tobacco could not be grown in India at all. Under this view of the industry we can well understand why no efforts were made to improve the best qualities of Indian tobacco. But for the last fifteen or twenty years the Manilla cheroot supply has been lost to India, and the quality of the present importations from that country are probably inferior to that of the best Indian cheroots. Practically, the Manilla supply has gone, and the Indian cheroot manufacturer has virtually a monopoly of the trade in this country. But, as we have said, he has done nothing to improve the manufacture, while he has advanced the price of his produce at least 100 per cent. At first sight, this condition of a rapidly-growing and a well-paying industry appears difficult to understand. It seems either that the whole class of cheroot manufacturers in this country are incapable of discerning their own pecuniary interests, or that it is impossible to improve the quality of the Indian tobacco or quality of the cheroot offered for sale in the Indian Markets. When we consider the variety of climate and the various qualities of the soil in this country, there appears to be no good reason why the best qualities of tobacco at least cannot be improved. The qualities of tea, coffee, cotton, and wheat have been vastly improved, and tobacco, we think, is capable of some, if not of equal, improvement. Tea growing and manufacture have been studied in China by Indian planters; why should not tobacco planters and cheroot manufacturers go and study the growth of tobacco and the manufacture of cheroots in Manilla? The result would pay, we feel assured. Whatever may be the difficulties in the way of improving the quality of the cheroots supplied by India to her own markets, if there are any real difficulties at all, the fact stands out clearly and lamentably that the Indian cheroot manufacture is not a thriving, but probably a declining, industry—certainly for the higher qualities. It may be said that the manufacturer is quite satisfied so long as he can sell the whole of his produce at a paying rate, and that he has no inducement to improve the manufacture. This view is both commercially unsound and dangerous, and is calculated to raise competition once more from without, or to make the consumer seek tobacco of other qualities, such as are used in the cigarette and the pipe.

Apart from the question of improving the present quality of Indian tobacco, there is sufficient cause of complaint in regard to Indian cheroots as now manufactured. The chief object which the manufacturer seeks to accomplish is apparently to produce quantity, especially in the high-priced cheroots. Thus we find ourselves provided with cheroots of inconvenient length and thickness, dimensions such as smokers do not want. The dimensions are wrought out by the unpardonable sin of packing the interior of the cheroot with tobacco stalks. This packing with stalks should be made a felony at the least, and be punishable under the Penal Code. The smoker does not want the stalks in his cheroot; nay, he totally objects to them, inasmuch as they destroy the flavour of the tobacco and cause many a cheroot, which might otherwise be smoked, to be thrown away unconsumed. If stuffing cheroots with tobacco stalks is little less than a swindle, what shall be said for the other vexatious proceeding of the manufacturer, viz., that of mixing tobaccos of various qualities in one cheroot, and cheroots made of different qualities of tobacco in the same box? This diversity of produce is a sore evil. The purchaser is first deluded in the purchase of his cheroots, and afterwards disappointed when using them. It is the wide experience of the users of Indian cheroots that the qualities even of the best and most highly-priced cheroots are seldom or never similar. Various qualities are to be found even in small boxes of 100 and in bundles of 25, while it is difficult to procure the same quality of tobacco twice over when similar boxes are purchased from the same dealer. How often is the smoker constrained to throw away about half a box of cheroots because of the difference in the quality of the tobacco. This waste doubles the price of the cheroot to the consumer. Years go on, and these villainous practices of packing cheroots with tocacco stalks, of mixing tobaccos of different qualities in single cheroots, of packing cheroots manufactured of different qualities of tobacco in the same box, and supplying cheroots of different qualities of tobacco under the same name and brand, continue with unabating regularity, causing the user to believe that the manufacturer does not distress himself in the least about the claims of conscience. The user of the Indian cheroot, who pays R25 per 1,000 for his purchase, really expends R50 per 1,000 in the article, because of the variety in the cheroots he buys. It was never so with the higher brands of Manilla cheroots, for all were equal in quality, and none were thrown away unconsumed. For many years some of the long established Bombay European firms imported the higher-priced cheroots from Manilla for their friends. The quality was always good, and the price fair. Subsequently John Treacher engaged in the business, and the supply was always reliable and satisfactory. The price for No. 1 cheroots ranged from R80 to R100 per 1000, which may be considered high in comparison to the price of "trichys" and other similar manufactures, but the Manillas were always of equal quality, and practically the purchaser of 1,000 obtained that number of usable cheroots. The manufacturers supplied what the mark on the box declared the contents to be, and the purchaser was never disappointed. Now that there is no hope of a supply of the quality of cheroots from Manilla, the Indian manufacturer should wake up to his own interest, and improve his produce in the way we have indicated. The public have borne the existing imposition long and patiently enough; it is now time we should have a little reform. Bombay has a large number of cheroot dealers; many of these dealers seem to be able to secure a living by dealing in cheroots alone. Surely, some of these dealers can influence the manufacturer sufficiently to put a stop to the unreasonable practices which check the growth of what ought to be a great Indian manufacturer. Let the Indian chroot manufacture be brought up to the im proving level of the tea manufacture, and the public will be satisfied. It is sad to see a thriving industry degenerating in the days of its prosperity, at the risk of commercial suicide.—*Bombay Gazette.*

THROUGH THE INDIAN TEA DISTRICTS.

(BY A CEYLON PLANTER.)

DARJILING, Nov. 13, 1883.

I paid a visit to the botanical garden here, which seemed a very useless institution; its only interest to me was the fact that it had been almost eaten out by the cockchafer grub. Although the garden is only about 10 acres in extent, millions of chafers and grubs had been destroyed. It is three years since the pest appeared, and the Curator said they were, he thought, on the wane. The damage done exceeds anything I have seen in Ceylon, thousands of shrubs and plants having been killed outright. Some fields of tea adjoining the garden showed no signs of suffering, but I was told that in a newly-planted clearing a large percentage of deaths had been attributed to grub. At the Mungpoo Cinchona Plantations, too, the chafer swarms, but Mr. Gammie informed me that grub had never done any damage to the cinchona; perhaps it would have been different had there not been an ample food supply of other vegetable growth. My visit to the Government Cinchona Plantations was a particularly enjoyable and interesting one, thanks to Mr. Gammie's hospitality and instruction. Instead of finding the establishment in danger of ceasing to exist in another 3 or 4 years, I found it steadily increasing in value and importance. Mr. Gammie estimates that they will have eight years' supply of succirubra bark at the rate of 400,000 lb. per annum; and then the Ledgeriana and Robusta clearings, which are the varieties now planted, will come in. In all about 2,500 acres are in cultivation, but this is scattered over treble that acreage of land. The harvesting is nearly all done by uprooting, a suitable system where there is sufficient fresh land to admit of the acreage being kept up by cheap annual extensions. On the Rungbee plantation I saw some 16-year-old succirubras, and, although we still have individual trees in Ceylon better than on Rungbee, we have no patches to equal some of the slopes there. On Mungpoo there is a 60-acre field of robusta hybrids, 4 years old, which promises well. Mr. Gammie has classed them into nine sorts—all of these types we have in Ceylon—and finds that there is a correlation between the botanical features and the analytical value of the different types. The best, No. 7, which is a difficult one to give a recognisable description of, is something like a very broad-leafed officinalis, and gives 6·12 per cent sulphate of quinine. The ledgerianas are of course the "pucka" article, just the same as our Ceylon ones. They are 16 years old, and decidedly "scraggy" in appearance, without any low branches. Although they blossomed freely, they have this year set very little of their blossom, and, as a consequence, the supply of seed will be extremely limited. As we have Dr. King's authority for saying that these trees are the same as those in Java, I think we may safely limit the existence of Mr. Howard's "ledgeriana" to his own writings. Mr. Gammie was good enough to show and explain to me the whole of his process of alkaloid extraction, and even crystallized some sulphate of quinine from Officinalis bark in order that I might thoroughly understand the process. Mr. Gammie's quinine is equal in appearance, and no doubt in quality, to the best European make. The regular manufacture of quinine is to be commenced shortly. There is a well-grown 7-year-old specimen of *ficus elasticus* in front of Mungpoo bungalow. The milk flowed freely from punctures, and Mr. Gammie expressed his opinion that for many situations this might be the best rubber to cultivate. It would probably grow in Ceylon at higher elevations than any of the American rubbers, for the one at Mungpoo is growing at 3,800 feet, I think. Mr. Gammie was good enough to promise me some seed later on.

WESTERN DOOARS, Nov. 17, 1883.

The Darjiling hill estates, as most of your readers know, are planted on slopes which are very much steeper than the average of our Ceylon cultivated hillsides. Owing to its depth, I would consider the soil, on the whole, rather better than ours, although wanting in any surface mould. Nearly all the land on which tea is now planted had been previously cropped by natives, and no signs of trees or stumps remain. The estates are greatly broken up by ravines, waste patches and landslips, which, added to the weeds and grass-grown roads, are to the Ceylon eye more suggestive of abandonment than cultivation. After seeing fields of tea from 20 to nearly 30 years of age, which, without a particle of manure, look vigorous and give good yields, one is greatly struck with the apparent *permanency* of the cultivation, and the Darjiling planters would scoff at the idea of danger from old age. Most of the tea factories are very substantial, expensive buildings, similar in style to the coffee stores built in days of yore on Delta and other Pussellawa estates. Machinery is invariably used for rolling, but I was surprised to see that nearly all the firing was done on chulas, even in factories where driers had been put up, the reason for this being that during the heavy pluckings, the weather is generally so wet and cold that the heat from chulas is necessary to heat the factory and effect the withering. I noticed that, on the hill estates, leaf is only weighed in once a day, but on the plain estates, twice. Having met Mr. Kimmond, of machine celebrity, I have heard the *pros.* and *cons.* of most machines well discussed, and I have seen almost every roller yet invented. The one which interested me most was Thompson's "Challenge," it being different in principle to any of the others, with the very great advantage that the smaller sizes can be worked by hand. The machine consists of a drum, horizontally laid with two cones revolving at slow speed, apex to apex, in opposite directions inside the drum. The large open feeding hopper on the upper side of the drum enables the leaf to be seen during the rolling, and gives free passage to air, so that the leaf never heats. One of these machines which I saw at work on Rungneet estate had given great satisfaction. The quality of the tea had improved and the saving in labour was very considerable. With that machine, four men had rolled off 18 maunds of leaf in the day, but I think six or eight coolies would be necessary were such a quantity taken in regularly every day. Another planter, who also used hand-power, spoke very favourably of the machine, but, on the estate from which I write, one of the large forms of the same machine driven by steam-power does not do well, as I saw this morning when it was in use. There is no reason why it should not do equally well with steam or water-power as it does with hand, if the machine is well made; but hitherto the machines have been made in Calcutta, and the workmanship is not what it should be. I believe arrangements are being made to have the machines constructed in England, and such machines would be of great use in Ceylon, where we have so many small gardens. They would be to the large rollers what Walker's discs were to the pulpers. The price of the smallest is rather high, viz., R700. It takes one maund of leaf, and rolls it in a little over half-an-hour.

This estate is one of the largest in the Dooars, and has a large factory, with 4 rollers, 4 drying machines, 2 sifters and 2 equalizers, all driven by a powerful engine. Regarding machine-sifters, I find that free access to the tea during sifting is a *sine qua non.* The hand must get in to throw back the leaf, break knots, and break through the leaf which sticks in and clogs the mesh. I have seen several estate-made ones, which, although they take up room, do the work quite satisfactorily at the rate of 30 or 40 maunds of tea per day with four men employed. The soil here in the Dooars is good, of great depth, the land being originally very heavy grass land, which seems nearly as good as forest land. The "lay" of this estate is much like that of Mariawatte, and good driving roads run in all directions over it. An elephant is kept to plough and harrow new clearings and to cross the rivers in the wet season. The rivers are a source of great inconvenience. The largest one, the Teesta, is a broad heavy stream, fed from the snows, which it would be almost impossible to bridge. Other drawbacks to the Dooars are fever and droughts. One drought of six months' duration occurred some years ago, and in ordinary seasons there are really only seven plucking months, during which, however, the growth is very strong, quite as much as in Ceylon during a similar period. My visit to the tea districts has caused me to modify, amongst others, my opinion as to the suitability of various climates for tea cultivation. I would no longer consider a two or three months' drought much disadvantage, and, other conditions being suitable, I can see no reason why the climate of Uva should not prove well suited for tea, and, with a shorter plucking season, give a sufficient yield. Ambeganuwa may grow very good tea, but I think it would grow better if the rainfall was less and the drought more pronounced. The tea made in dry weather is undoubtedly better than that made in wet, and I heard from a traveller, who had just come from Japan, that he saw an acre of tea there covered in with a large awning to keep off rain and dew, in order that some fine, flavoury, fancy tea might be gathered. I would now be much more hopeful of tea cultivation being successful in the Kalupahani Valley than I was. The land there is not steeper than many of the Darjiling estates, and the wind, except on the very bleak, exposed portions, is not, I think, much worse than that experienced on some of the Darjiling estates, where factories and bungalows often have their iron roofs lifted. One planter told me that trees were often blown over, and at times the gusts were so strong that it was almost impossible to walk against them. Hail, too, sometimes does great injury coming down in large flat pieces, and in balls as large as a marble. I heard of iron roofing having been penetrated at one place last year. I quote the rainfall at Sington estate, near Darjiling, on some of the upper fields of which snow lay last year.

Sington Rainfall.

Cheap labor is *the* advantage, and a very great one it is, that Darjiling has in tea cultivation—the average pay there for men and women being only 19 cents per day, as compared to 29 cents in Ceylon. This does not include the question of head-money; our kanganies' pay being equalled by what is paid there to sirdars and chuprassies. On other important points, the comparison is generally favorable to Ceylon. Most of our estates, certainly those in the young districts, are better off in the way of charcoal and timber than any of the Darjiling hill estates. There are no logs or stumps on the estates there, and such a thing as reserve forest is almost unknown. Most of the charcoal is carried up from the Teesta valley, 6 or 8 miles off, and costs on some estates as much as R1·25 per maund. Chests which hold 90 to 100 lb. cost about R1·40, exclusive of lead and soldering. The cost of transport to Calcutta of course varies with the distance from the railway, but, on an average, costs more than twice what it would from our young districts to Colombo. Tea-lead is cheaper in Calcutta than in Colombo. I was offered it at R14 per cwt. Agency charges are also less, being 50 cents per chest.

On the important question of jât, I tried to get all possible information, and I found the general opinion, with which I agree, to be that for *quality* in a flavory drinking tea nothing was better than the China plant. I have before me the account sales of 269 chests of the Darjiling Company's teas recently sold at an average of R1·20 per lb., while 15 chests of broken pekoe fetched as much as 3s. 10½d. These teas were all from China bushes. On the question of *quantity*, one or two planters expressed it as their opinion that, at a high elevation in Darjiling, the China plant gave just as much as the hybrid, but for low or medium elevations, of course the palm was given by all to a good Assam hybrid plant. It seems to me that in Ceylon we will have two classes of tea, viz., the strong low-grown mixing tea and the milder, but more flavory, hill-grown, drinking tea. For the former, plants of the indigenous, or very high-class hybrid Assam will be of the utmost importance, but, for hill plantations, I would prefer the strong, vigorous, rather dark-leaved hybrid to the very large light-leaved type, which so often displays a thin spare habit of growth, when planted at high elevations. Regarding seed, I would only prefer Indian seed of good jât to Ceylon seed of similar jât on the score of a fresh stock. I saw neither more nor less care taken in the collection of seed in India than I have seen and practised it in Ceylon—perhaps, in India, they have the seed lying longer in the capsule than we do.

I was introduced to various blights, red-spider, mosquito blight, green fly, &c., and I fancy that mosquito blight is the one we have most cause to fear. I also saw and heard about an insect which for a time at least did great and even fatal damage in the Kalutara district, but I forget, if indeed I ever knew, its name. It is that small grub which covers itself with a barky envelope and hangs like a small icicle from the stem and twigs. Picking off and destroying the insect is the only remedy.

As the subject was exercising our minds so much when when I left Ceylon, I made a point of getting an illustration in pruning from every planter I met. I found heavy pruners, light pruners, and pruners who sought safety in the happy medium. "Cutting down" the plant, as it comes to a bearing age, at, say, 2½ or 3 years, is a recognized method of shaping the tree, and, viewed in that light, there seemed to be nothing in the late Mr. Cameron's heavy cutting, contrary to proper cultivation, *but*, if to be repeated year after year, the general opinion was that the bushes would soon be worked out. In Darjiling proper, the annual growth is far less than in Ceylon, but, in portions of the Terai and Dooars, the growth is much the same as it is with us. In Darjiling, about 2 inches of the new wood, *i. e.*, wood formed since the previous pruning, is left, and in the other districts about 4 inches, and in all cases the thin, non-flushing whips are cleaned out. Of cource, in time the trees get too high, and require a modified cutting down again. The old idea that a tea bush should be table-shaped is exploded, and no one thinks of trying for a clean stem. A bush shaped more like a bowl or a cup would be the ideal. Trees of good jât rebel against being cut straight across, and, long before the plucking season is over, they begin to "tower" in the centre; to counteract which "saucer" pruning is adopted. I would be inclined to top back (though of course, not to pluck) plants of good jât at an early age, and so induce several stems, more in the cinnamon-bush style. I think further experience is required before deciding what system of pruning is best adapted for Ceylon, and it is unlikely that any one system would suit our varied conditions of climate. I see no reason why we should prune the whole of our estates at one time, when our climate gives us the very great advantage of being able to pluck all the year round. If our crop can be spread over 11 months, we can work much more economically as regards the extent of factory machinery required, than is possible in India, where the great bulk of crop comes in in 6 months. Concerning manufacture, I found that, except as regards the use of machinery and the manipulation of great quantities, there was little to be added to what I first learned at Loolecondura, 10 years ago. Amongst rolling machines, Jackson's "Excelsior" is the favorite, amongst dryers Kinmond's takes first place, and Ansell's sifter is to be preferred to Jackson's, which from the great amount of travelling done by the tea, is likely to "grey" the coarser grades I doubt if that machine (Jackson's) could ever turn out sharp black looking teas as those sent to the Exhibition from Galboode and some other estates. An equalizer saves so little labor that, unless enormous quantities have to be dealt with, I would prefer to break the tea through an ordinary sieve. Ansell's machine is one of the simplest and cheapest. I did not find the idea that machine-dried teas were superior to stove-dried ones received by everyone, or even by a majority. I noticed in the last London sale lists many of the very top prices, particularly the Darjiling Cinchona Association's were reached by estates where all the teas are dried on "chulas." On the score of quality, all that the machine-dryer can claim is that it is much easier to keep up and dry all the teas day after day at the same temperature, and so with very large quantities ensure a uniformity which is perhaps unobtainable when the "chula" is used. I saw Mr. Kinmond's latest improved machine at the Exhibition, and that gentleman, who intends visiting Ceylon shortly, was good enough to explain all its advantages, and when I remarked on the disadvantage of all his machines, viz., their very high price, he informed me that a discount of 5 per cent on one machine, or 10 per cent on two machines, could be granted.

I went to India a doubter; I return a believer. Ceylon has many advantages, the chief being our climate, giving us 9 or 10 months of plucking season. And here, be it remarked that our prolonged flushing season renders the liability to great loss from blights and insect plagues much less than in India. In a country where there are only six months to pluck in, the attack of a blight, which causes a cessation of flushing for three months, occasions much more loss than a similar attack in a country that has almost continued growth. Our coolies do more work, I think, than the Indian ones, and, generally, our estates are much more economically worked, so that, quite apart from any increased yield, I think our teas can be produced at as low a cost as those of India. I mean as far as estate expenditure goes. Most of the Indian gardens being worked by Companies, the expenditure between the estate and the market is naturally much greater than it would be in the case of an individual proprietor, who has no Secretary or Director to pay; and the wonder is how many of the Companies pay any dividends at all, when they are burdened further with such large capitals, some standing at over £100 per acre.

The question of how our average yield will compare with that of India is a very difficult one to settle satisfactorily. We cannot look upon the Galbodde, Mariawattie, and other large yields as any help towards determining what the average of some years over all our land will be. Tea will not grow to pay everywhere, and some land has been planted in Ceylon that can never bring anything but disappointment to the proprietor and discredit to the enterprise. Various blights, too, will, in ordinary course, make their appearance and have their effect on the outturn. We will certainly see a higher average yield than Darjiling, perhaps from 300 to 350 lb. per acre, and if we can get Darjiling prices with that quantity our future is secure. Depth of soil is necessary to permanency, and I fear that some of our lowcountry estates will be short-lived, unless manuring can be cheaply carried out. No manuring is done in India at all, nor could it be done nearly so cheaply as in Ceylon. I attach less importance than I did to the vicinity of charcoal and timber, though it is very desirable to have the command of them. The command of water-power, such as most of our estates have, is a great advantage, and goes far towards making small estates, *i.e.*, under 300 acres, offer acre for acre as good a profit as large ones. On the point of size I can see nothing to justify in Ceylon the idea that tea would not pay on anything except a large scale. Of course, there is always some saving in certain items when great quantities are dealt with, but the difference in average profit between large and small tea estates will not be greater than it was in the case of large and small coffee estates. In Ceylon, as a rule, I would prefer a hill estate to a lowcountry one, unless the soil of the latter was particularly good. I do not, however, think that the difference in altitude makes a Darjiling estate at 5,000 feet equal to a Ceylon one at 7,000 feet. The difference is much less due, I suppose, to our insular position on the one hand and the proximity to the great plains of India on the other. Our climate at 5,000 feet is just as raw and bleak as it is in Darjiling at the same elevation, but we never experience the dry cold which checks all vegetation both there and in the plains for four, or sometimes five months. I think nearly all our opened land in the young districts will grow tea well, and almost any new land in the old districts will be equally good. There is no use planting tea on really bad land—much better abandon such at once. I do not mean this remark to apply to the poor ridges and patches which make themselves visible on all estates, and which for the sake of the surrounding good land must be kept up; these occur also on the Indian estates. Those who reserve their best land for coffee or other products, and only plant tea in the poorer portions of their estates, must not expect to reach the yield of the best Indian estates, where the best land has been given over to tea. On the other hand, the slightly decreased yield of tea which the presence of cinchonas, cocoas, or other products in moderation occasions, will be more than made up by the return from those plants.

We have been so accustomed to depression and disappointment in Ceylon, that it is difficult to believe that prosperity will ever again attend our efforts; but I feel sure that in tea we have a product which, although it will never give the maximum profits of coffee, will give us steady returns, and again raise us to the first position in tropical agriculture; *but* it must have justice shown it, and be carefully planted on suitable land.—T. N. Christie in local "Times."

INDIA CROP AND WEATHER REPORT.

For the Week ending the 29th January 1884.

General Remarks.—There has been slight rain in Madras, Sindh, the Punjab, and in one of the native states of Rajputana during the week. Harvesting continues in Madras, Mysore, and Coorg; in four districts of Madras the yield is reported below average, and in two districts up to the average; in Coorg coffee has yielded a good crop, but the outturn of paddy has been under the average. Standing crops promise well throughout the Presidency, except in part of the Bellary and Chingleput districts where they have been injured. In Bombay the rabi prospects are generally good, but some damage has, from various causes, been done to the crop in parts of seven districts. Cotton-picking is still going on in the Berars, and the prospects of the rabi there and in Hyderabad are favourable. In Central India and Rajputana the rabi crops continue to do well, except in Sutna and Ulwar where rain is needed. The rain which fell during the week in the Punjab was confined to the districts in the north and west, and the crops in the districts to the south-east of the province are much in want of rain. In the North-Western Provinces and Oudh the weather has been cloudy, but no rain has fallen, and it is urgently required for crops on unirrigated lands. In some districts of the North-Western Provinces the rabi crops are in ear.

In the Central Provinces the crops are thriving and prospects are excellent.

No rain has fallen in Bengal, and the crops on unirrigated lands in Behar and Chota Nagpore are reported to be suffering much from want of rain; in other parts of the province they are fair. Oil-seeds and pulses are being harvested, and sugarcane is being pressed with an average yield. In Assam the prospects of the winter crops continue good, and harvesting has begun in some places. The rice harvest is over in British Burma, and the prices of paddy are favourable.

Small pox continues generally prevalent, and cholera is severe in the Tanjore district of the Madras Presidency; there is some cholera also in Hyderabad, Bengal, and Burma in a sporadic form. Prices are stationary, but high inBengal.

Madras.—General prospects good.

British Burma.—Twenty-five fatal cases of small-pox in Rangoon; some cholera in Tharrawaddy and Thongwa; slight cattle-disease in Prome, Thongwa, and Thayetmyo, otherwise public health and health of cattle good: harvest practically over.

Assam (Gauhati.)—Weather getting warm; harvesting of sali crops nearly finished; public health fair.

Bonedust.—The great value and productiveness of bonedust as a manure was exemplified by the various exhibts made by Mr. E. Thorne, of Bulimba, at the late summer show. Aided by this fertiliser, he has made the indifferent forest soil of Carina rival the better soils elsewhere in the production of immense kohl rabi, swede turnips, ironbark pumpkins, cabbages, and custard marrows, for each of which he succeeded in winning first prize—several of which were not included in our prize-list published at the time of the show. Five kohl rabi (turnip-rooted cabbages) weighed ½ cwt., and some fresh imphee fully 8 ft. long was shown, grown by the aid of Booth's bonedust. There is nothing equal to facts in settling doubts and difficulties, and it gives us great pleasure to draw our farming friends' attention to this fertiliser, for we have for many years contended that for general use its cannot be surpassed. It is not so prompt in its action a when prepared with sulphuric acid and made into superphosphate of lime, but it is much more lasting, its effects being plainly seen on crops after several years. It has always been our conviction that bonedust was a more valuable and legitimate fertiliser than guano, and in one respect it has invariably shown its superiority over that highly stimulating manure by steadily increasing the fertility of the land to which it has been applied. A dressing of from 3 cwt. to 5 cwt. per acre is a liberal one, and all cultivators may safely calculate upon a very remunerative return in the form of crops for its use.—*Queenslander.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, January 17th, 1884.)

IMPORTED FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White ...	Slightly softish to good hard bright ...	£7 a £8 10s

TEA AND OTHER MACHINERY AT THE CALCUTTA EXHIBITION.

Our readers will be int rested in the contents of a letter from Calcutta to a firm in Colombo, regarding Jackson's t a machinery and other articles manufactured by Messrs Marshall, Sons & Co. of Gainsborough and 79, Farringdon Road, London. Writing on February 6th, the correspondence states:—

All the awards out are for our circular saws, which have got the first-class certificate and gold medal; Excelsior tea-roller, first-class certificate and gold medal; thrashing machine, first-class certificate and gold medal; Eureka tea sorter, second-class certificate and bronze medal; and grinding mill, second-class award and bronze medal.

Our competitors in rolling machines stand as follows:—
Kinmond, second-class with bronze medal.
Lyle ,, ,, ,,
Greig ,, ,, ,,

In sifting machinery, Ansell has the first-class certificate and silver medal; Eureka second, and Greig no award.

In drying machinery, Kinmond two gold medals; one of these is for a coke-dryer, which has not been used in any of the tea districts.

With regard to the "Eureka" sorter being second on the list, unfortunately none of the jury happened to know it, but one of them works three of Ansell's machines: hence the results.

We do not mind Ansell getting the medal so long as we have got the business, the Eureka is a universal favorite with all who use, and who have seen it work.

Its only fault lies in being two small for those immense concerns we have in India, but it is to be made three feet wide to contend with this, and by another year we hope to do a large business in sifters.

Mr. Thompson as you are aware did not exhibit the "Challenge" in Calcutta.

CHILLIES.

Somebody told me that the birdseye chilly had become one of our exports, and that a good price was being offered. Having hundreds of plants growing as weeds, I stopped the children from gathering them on their own account; but though the crops are very large, neither on nor under the bushes do I ever find any ripe fruit. A pound of green fruit can often be picked from a single bush, but what goes with the ripe I cannot take upon me to say. All kinds of feathered creatures are said to be fond of them, but I never see them at it, though I have watched for them.

It is only a step from the small chilly to the big one. About two months ago, I planted in a small enclosure, close to the bungalow, twenty plants of a variety that grows to four inches in length. I secured the seed from a chance-sown plant that supplied my household for six months, and grew to three feet high and three feet wide. The young plants are now from a foot to eighteen inches, with from six to ten fruits. As they continue in full bearing for nearly a year I cannot put the crop per plant at less than 1 pound of dry fruit, and as 4,840 plants go to an acre; the crop of an acre would be 64 cwt. 3 qr. 8 lb., which at 50s per cwt. would give £162. A great deal too good to be true, but sufficiently encouraging for an experiment on a larger scale than twenty plants. The bazaar price of the common green chilly is 6 cents per 100, and the size of this variety is about one to five inches.—*Cor.*

COCONUT CULTURE.

Though coconuts have grown in Ceylon from before the dawn of history, it is only within living memory they have been planted in large tracts, for the purpose of external trade. It is said that the coast line, to the south of Colombo, was planted under the auspices of the Dutch Government, but till within fifty years the tree had hardly penetrated the country beyond the coast line. Perhaps the first tract of 100 acres, or upwards, was planted by a Dutch gentleman, about the beginning of the present century, on the banks of the Kalugauga, a mile above the town of Kalutara, but as a coconut estate it stood alone for nearly forty years.

The true start of coconut planting took place after the sale of the Government cinnamon jungles, when the bulk of the Kadirana lands went into the possession of English capitalists, several of whom planted considerable portions of their properties with this tree, much to the satisfaction of those who possess them now and do them justice: to those who take all, and give nothing, they are not so liberal in their bounty. Soon after the Kaderane estates had been formed, Europeans purchased large tracts of land in the Northern and Eastern Provinces, and there coconut planting was initiated on a large scale and at a heavy cost. The original proprietors lost largely by the enterprize, many of them were ruined, and others disgusted. The estates were sold at what they would fetch, when ten, twelve, and fifteen years old, and the purchasers made their fortunes.

It was only about thirty years ago that the natives began to turn their attention to coconut planting, and found it highly suitable to their habits and mode of thinking. The plant could survive through more neglect, than any other; by giving the land over to goyas, and securing the land share of their crops, they not only got the heaviest part of the work done for nothing, but recouped themselves in the cost of the land and all other expenses. Here, however, vast numbers of the native proprietors stopped, till in 1860 anyone passing through the Western Province must have been struck with the numerous tracts of jungle, amid which a few coconut plants here and there showed a few sickly leaves. Gradually, many of those neglected fields came into the hands of more wealthy or more energetic proprietors, and the work of renovation is still in progress. The old-school native proprietor still clings to his old views of getting a coconut estate without spending anything in creating it, but a new generation has come on the stage, with minds opened by education for the reception of logical deductions, men that can put themselves into harmony with at least the more prominent facts of nature, and now there are native proprietors who keep their properties in the best condition, so far as leaving the whole benefit of the land to the cultivated plant; one thing they still lack, but that, too, will come to them under pressure of facts. Coconut cultivation has, like that of cinnamon, fallen almost entirely into native hands. The European wants quicker returns, the native can wait; he is among his own people, and his sole living is not dependent on his coconut land. In native hands, the cost is small for the upkeep of a coconut property, and the native hope of returns is not placed high; no one ever thinks of selling his bearing property, and the only estates that come into the market are the property of prodigals who have wasted their substance, or traders who have come to grief. Then he who has a coconut field has an income that may fluctuate with the seasons and the markets, but is never a total blank.—*Cor.*

[Our correspondent ought to know, but our impression has been that kurakkan and sweet potatoes are always largely grown by natives amongst young coconut-palms.—ED.]

WOOD FOR TEA BOXES.

(From the *Indian Tea Gazette.*)

In my last I drew attention to Roghu, or Kodom, formerly "Nauclea Kadamba," as one of our best box timbers, also to Sotiana, Chutni, or "Alstonia scholaris," and Pati honda, which is "Cinnamomum obtusifolium." I omitted to notice that the last is called obtusifolium perhaps in consequence of the way in which the points of the leaves are damaged.

I have frequently searched the foliage of a felled tree for an entire leaf, and generally failed to get even one perfect,—all seem eaten by some insect. It would be interesting to know if this peculiarity is local, or common.

Poma—"Cedrela toona," or the Tun tree, before noted in No. for June 16th, is an excellent box-wood; it is both light and strong, though not very tough; unfortunately it is not a very common tree, and if used for boxes, the supply would likely run short. It is easily propagated, and grows rapidly, so that it is a good one to have in reserves. It is apt to split in felling, unless care is taken. Ponia boxes weigh about from 20 to 25 lb., and this is not the same wood that comes to us as "Cedar" from Burma: the latter is heavier, harder, and less attacked by white ants. S. E. P.

TIMBERS FOR BOXES.

(From the *Indian Tea Gazette.*)

One of the lightest woods we have is Simol (Bombyx) or cotton tree, and I have known whole chests made of it weigh only 12 lb. though the wood was ½ an inch thick. Boxes are often made of it that are sent home, and if cut, say 5 inches thick, it might be fairly safe if well put together. It is however liable to split if it receives hard knocks.

One of the best woods for boxes is Roghu, formerly Nauclea kadamba or Kodom, "Anthocephalus kadamba,"—called Kodom in Bengali, and Halamba in Sinhalese. When seasoned it is fairly light, strong, and tough. In Assam it generally has a tolerably straight, clean stem 30 to 40 feet long, which is continued up through the head or crown, the latter composed of a mass of *radial* branches.

As a rule the head of foliage is domed, and the lower branches have a tendency to droop and hang down all around. Roghu is one of the very few trees that generally carries its stem, of central axis, right through the crown to the very summit; and when young it is very symmetrical.

Externally the bark is dark brown or grey, and fissured by cracks longitudinally; inside it is a brown or dark dim color. When young, the bark is particularly clean and smooth, and of a pale grey green.

There is no heart, and the wood is yellowish white, soft and even in texture, easily cut, whether green or seasoned. The leaves are stiff, large and entire, pointed, and with short footstalk; on old trees they are from 8 to 10″ long × 5 or 6″ wide. Much larger on young trees, and I have measured one 31″ long × 20″ wide, on a one-year old plant 10 ft. high.

The flowers are small and clustered in a ball, 2″ diameter, that ripens about October.

Roghu has several peculiarities worth recording; the growth is remarkably rapid for the first 6 or 8 years, becomes slower on to 20, and then is very slow. During the first 2 or 3 years it grows some 10 feet per annum in height, while the girth in same period is often an inch per month. I have cut 10″ planks for boxes out of Roghus only 8 years old, and am now felling a good many that are 16 years old, and at six feet up, measure (an average of 5) to 5′ 5″ girth, while at 30 feet up they measure 3′ 8″ in girth. Up to 8 or 10 years old it grows so rapidly as to be worth planting, but after 15 or 20 years, is so slow that it is most profitable to fell when about 12 years old.

Another peculiar feature of this tree is the difficulty of propagating it from seed, while at the same time it springs up in millions naturally on new clearances. I once estimated that I weeded out 450,000 Roghu seedlings on 25 acres of clearance. Taken altogether this tree is one of our best for Tea boxes, both on account of its natural qualities as a wood, and as a tree; and the pity seems that it is not more extensively grown by Planters and Government, especially as it takes such a short time to reach useful size. It is on this latter account I place it first *on the list of Box* timbers.

[Is this the tree which grows so plentifully on land cleared of forest and then abandoned?—ED.]

TEA FROM FIJI.

A further examination of the tea brought from Fiji by the Hon. Jas. E. Mason, grown upon his estate on the island of Taviuni (the Alpha tea and coffee estate), was made by Messrs. Gilmore, Younghusband, and Co., of Custom-house-street. Mr. Mason at one time intended to remain here until the next trip of the "Penguin," but has decided to return to Fiji, being satisfied that there will be no difficulty in finding a market in New Zealand for the grand flavoured and full-bodied teas that may be produced in Fiji. Mr. Younghusband, in liquoring the samples brought by Mr. Mason, compared them with teas of high-class quality from India and China, and reports as follows upon the two samples:—

"Pekoe Souchong.—Leaf large, with some tips. Requires earlier plucking and more careful sorting. Liquor malty, fairly pungent, and flavoury."

"Orange Pekoe.—Leaf small, black, full of tips. Liquor—rich dark liquor. We are unable to report more fully on this, the samples having been damaged by sea water.

"This tea resembles the Indian hill tea in character, and only requires a few improvements in the manufacture to rank well as a tea for drinking alone."

This is a very favourable report, so far as it goes, and taken in connection with the previous reports Mr. Mason has received from other places, it shows a general agreement that Fiji is likely to be a fine tea-growing country. From the Orient Tea Company, Melbourne, Mr. Mason has recently received the following report on a sample of tea sent to that city:—"Leaf—poor, and not properly sorted out. Fermentation and manipulation rather irregular. Liquor—very good; infused leaf bright and equal to finest China congous; thoroughly pure and without a single bad or decayed leaf. Liquor strong, pungent, and well flavoured, being similar to many Indian growths. The liquor itself being so good, we do not see why Fijian tea should not, with improvement in manufacture, rank with the best-grown teas in the world.

In 1882 Mr. Mason sent a sample of the two kinds to Melbourne for chemical analysis by Mr. Frederic Dunn, analyst, Industrial and Technological Museum Laboratory, who reports as follows. Upon analysis they gave:—

	Pekoe Souchong.	Pekoe.
Percentage of moisture ...	8·85 ...	9·00
Percentage of mineral ash ...	4·40 ...	4·36
Percentage of extract (total)...	48·28 ...	45·80
Percentage of soluble salts ...	3·00 ...	2·98
Percentage of theine ...	1·60 ...	1·78

The percentage of mineral ash and soluble salts found in these teas closely resemble the amount obtained from the Ceylon Exhibition teas. Taking into consideration that the above samples are the result of an experimental trial, the results are highly satisfactory, and the analysis speaks well for Fijian teas.

Tea and sugar will in the near future form important articles of export from Fiji.—*Sydney Mail.* [*If* the labour difficulty can be solved.—ED.]

GREIG'S TEA-CUTTING MACHINE.

As everything connected with tea is interesting at present, we reprint Messrs. Greig & Co.'s method to be adopted in working the Greig patent green leaf tea-cutting machine.

In order to get the best possible results from the use of the machine, adopt a system of sifting or riddling. The riddles of various size meshes are easily made entirely of Bamboo, by a cooly. They should be about ½ feet in diameter, and hung from one edge by a string from roof, so that one man can, by letting one edge drop on floor, kick in the leaf to be riddled, and when separated can tilt and throw over to one side the large leaf from its upper surface, in that manner the work is very quickly and well done. There are three or four uses for the machine, first,—for cutting the large soft succulent leaf *that will roll up*, which occurs in Assam in the first of the season; they are plucked separate from the upper leafs, but put into same basket, these are afterwards riddled out by a mesh about 1-inch "square" after withering, these are cut by machine, rolled and fired separately, and mixed with Souchong.

Second Method—*To save red leaf-picking*, the whole of the plucked leaf is rolled only half or three quarters from being finished, when it will be seen the older leaf remains nearly flat, this three quarter rolled leaf is sifted by a mesh of about ½-inch square letting down the finer rolled leaf, and the flat old leaf thrown to one side to be cut by machine, then to be rolled or crushed into broken black. These leaves being cut, the second rolling extracts the juice, and blackens what would have been otherwise red leaf. a higher price is the result, and *expense of red leaf picking saved*, the finer leaf which falls through on floor, should be cut by machine or not, as thought necessary, but it be should rolled again to finish it thoroughly; in this tea red leaf is entirely absent.

Third Method.—At the first of the season, the Pekoe nibs do not show in the tea, owing to there being so much juice in the leaf. The hard rolling required blackens the nibs when rolled together, and takes on the coarse juice of the older leaf.

Put the whole of the pluckings through machine; this will cut off the nibs, some through the middle (broken Pekoe), some the full length—this before being rolled is sifted by a one-eighth of an inch mesh, which will let down the nibs and stalks, and keep back the flat cut leaf. These nibs are gathered and put into bag of rolling Machine, and rolled very, very lightly, just sufficient te sweat through the juice to cause it to ferment; when fired these nibs will turn out to be very fine pure uncontaminated flowery Pekoe (white), with the finest Pekoe flavour, and would command by itself a fancy price; but it is mixed, stalks and all, with the sorted black Pekoe. The tea broker, seeing these white nibs, would give a much higher price than he would if no nibs were to be seen, as would otherwise be the case.

Fourth Method.—The rougher method (for small gardens) to cut up all the tea. Roll, dry, sift none, fan out the red leaf, and send it all to the market, thus saving broken tea and dust.

By using the Machine for one or other of these purposes above described, and by judgment and discrimination in using meshes of a size suitable for the kind of tea being manufactured, whether Assam (indigenous), Hybrid, or China, it will be found most valuable by considerably increasing the revenue from the whole season's tea.

In connection with the above system, a Bag Rolling Machine, such as the Greig Link and Lever, or a Lyle's, or improved Haworth Machine, is best adapted to roll up the various large or small quantities of separate leaf.

In reference to the above system of manufacturing tea, Colonel Money, in his Prize Essay, at page 121, says:—"There is plenty of room yet for inventors. The machine, as before observed, most to be desired is one to separate the small Pekoe leaves from the others, ere the rolling of the leaf is commenced. If such a machine existed, it would much increase the value of all Indian teas; and if the Agricultural and Horticultural Society are inclined to offer a prize for any machine, is should be this." Also at page 115 he says: "That such a machine is possible I am certain, and the inventor would confer a boon on the tea interest far beyond the inventor of any other machine, for all the other processes can be done by hand without much expense; this cannot."

W. Haworth, Esq., an eminent and well-known authority on tea, writes to us, "That for the last dozen years he has been advocating this system of cutting the leaf before the subsequent manipulation, and is glad to know such a machine has been invented."

PROPAGATING PLANTS FROM LEAVES.

It is quite a common thing for nurserymen to propagate plants from single leaves of some species of plants, and the operation is not a very difficult one. When a nurseryman has got hold of a specially good strain of Gloxinia, for instance, he may take a leaf or two off the plant and cut several nicks through the midrib, then planting the petiole or stem of the leaf to its full length and firmly in the mellow soil, the leaf lying flat upon the surface, and the pot or pan in which the leaves are planted is covered with a bell-glass in the stovehouse. After a short time a number of bulbilles form at the places where the midrib is cut through, these send forth roots, and then a number of plants are produced to reward the industry of the propagator. There is one plant in particular which derives its name from the peculiarity that it can be propagated in numbers from a single leaf —the Bryophyllus, from bryo to sprout or grow, and phyllon a leaf. This, however, is not so interesting a plant as Lilies and Gloxinias are. There are many other plants that will be reproduced from the little bud that is developed in the axil, or at the bottom of the stem, where the leaf and branch are joined, but this is really bud propagation. The plants that can best be multiplied from leaves are such as produce bulblets upon the leaves and at the junction of the petiole and main stem or branches. The best kind of soil for this kind of work is a mixture of equal parts of leaf-mould, peat, and silver sand. The bottom leaves of such plants are sometimes too far advanced, and those at the top are not sufficiently mature, therefore the middle leaves are most likely to give the most satisfactory results. When it is seen that the broken parts of the midrib have callused and rooted, the glass may be lifted for a few minutes each day in order to inure the tender plants to fresh air. Of course the glass is put over to keep a moist, warm, still, atmosphere about the leaf, which would otherwise wither and die. As the plant advances, the exposure is increased, until the bell-glass can be permanently tilted and finally removed. The so-called "leaves" of Epiphyllums and varieties of Cacti (really branches) can be cut up and will strike, or the stems of tree ferns, Dracænas, and very many other plants can be cut into slices and planted, when each slice will become a plant, but this is very different from propagation from leaves. We have often taken a single leaf, with a bud attached to the stem, from a Fuchsia, and planting it with the point of the bud "peeping" through the soil, have been rewarded with a nice little plant in a short time. With leaf propagation quiet a different series of events take place. There is no bud to begin with, but bulbs are developed upon the wounded midrib, then roots proceed from the bulbs, and then the leaves follow. Leaf propagation is a very interesting operation, and those who possess the requisite accommodation may with profit to their minds perform experiments upon such plants as they think can be propagated by this means.—*Adelaide Observer.*

COFFEE AND TEA.

The lecture delivered by Dr. G. V. Poore, at the Parkes Museum of Hygiene, three weeks ago, on Coffee and Tea, has been published by H. K. Lewis, in pamphlet form, and we have been favoured with a copy. The lecture commenced by discussing at some length the dietetic value of both, and with this view entered fully into analyses of the chemical constituents of each, and their effect upon the human system, coming to the conclusion that they possessed comparatively little value as food, but were most useful as stimulants. As to the relative dietetic value of a cup of coffee and a cup of tea, Dr. Poore quoted some German analyses, which he thought might be regarded as fairly accurate, and then went on to say:—"It follows from these analyses that, supposing all the dissolved matter to be available for the needs of the body, the dietetic value of a cup of coffee is more than twice that of a cup of tea and if we assume that the stimulating power is due to the contained alkaloid, then *qua stimulant* the cup of coffee has more than three times the value of the cup of tea. Further, Binz observes in the third edition of his 'Elements of Therapeutics' that 'the alkaloid which tea contains appears to be less easily absorbed than that of coffee owing to the very large quantity of tannic acid present.' The tannic acid in tea is doubtless one of the causes why it is as a drink so attractive. It is slightly astringent and clean in the mouth and does not 'cloy the palate,' an expression for which I can find no scientific equivalent. Tannic acid is also one of the dangers and drawbacks of tea. It is largely present in the common teas used by the poor. Now the rich man who wishes to avoid an excess of tannic acid in the 'cup that cheers' does not allow the water to stand on the tea for more than five, or at most eight minutes, and the resulting beverage is aromatic, not too astringent and wholeosme. The poor man or poor woman allows the tea to simmer on the hob for indefinite periods with the result that a highly astringent and unwholesome beverage is obtained. There can be no doubt that the habit of drinking excessive quantities of strong astringent tea is a not uncommon cause of that atonic dyspepsia, which seems to be the rule, rather than the exception, among poor women of the class of sempstresses. Coffee then has a slight value as a nutriment, and a very high value as a stimulant; when mixed with boiling milk in the form of café au lait it forms the ideal of breakfast foods for body-workers and brain-workers, and a very small quantity of black coffee taken after a full meal serves to stimulate the stomach to the necessary digestive effort, and to ward off that sleepiness which is often the attendant of satiety. That it is advisable to eat something whenever coffee is taken seems to be an idea as old as the habit of coffee-drinking itself, and Dufour, a French writer of 1672, says that there was a proverb among Orientals to the effect that, 'If one had nothing else to eat before drinking coffee, it was advisable to swallow a waistcoat button or else go without the coffee altogether.'"

The first portion of the lecture treated of tea and coffee together, but the latter and longer portion was devoted to coffee alone, Dr. Poore explaining that he thought there was great need of instruction with regard to it in this country. After a brief sketch of the history of coffee, and its introduction from the East into this country, he proceeded to deal with the different descriptions of coffee in detail. A Mincing Lane friend had supplied him with 16 typical samples, which he classified according to colour as follows:—

Price per cwt.		
160s	"Fine brown Java"	Li't brown, uniform
40s	"West Coast of Africa" ...	Light brown, irregular in colour.
70s	"Liberian (Ceylon)" ..	Brown with faintest suspicion of green
1[illegible]0s	"Fine long berry Mocha" ...	Brown with faint tinge of green
100s	"Ordinary Mocha"	Greenish brown
52s	"Manilla"	Dark greeny brown
54s	"Good ordinary Santos" ...	Dark greeny brown
60s	"Good ordinary Java" ...	Brown, with more green
56s	"Good ordinary Guatemala"	Brown, with more green
130s	"Mysore"	Greenish
93s	"Neilgherry"	Greenish
70s	"Good La Guayra"	Greenish
92s	"Fine Ceylon" (lighter in colour)	More distinctly green
78s	"Medium Plantation (Ceylon)"	More distinctly green
70s	"Costa Rica"	More distinctly green
52s	"Good average Rio"	Brownish, greenish, blackish

Arranged according to size, the following is their order, and the price of each is also given:—

	No. of seeds in a unit measure holding 50 grams of water (about 2½ oz.)	
Fine brown Java ...	187 ...	160s per cwt.
Fine Mysore ...	198 ...	130s "
Fine Neilgherry ...	203 ...	93s "
Costa Rica ...	203 ...	70s "
Good ordinary Guatemala...	207 ...	56s "
Good La Guayra ...	210 ...	70s "
Good average Santos ...	213 ...	54s "
*Fine long berry Mocha ...	217 ...	130s "
Good ordinary Java ...	223 ...	60s "
Fine Ceylon Plantation ...	225 ...	92s "
*Good average Rio ...	236 ...	52s "
Medium Plantation (Ceylon)	238 ...	78s "
*Manilla ...	218 ...	52s "
*Ordinary Mocha ...	270 ...	100s "
*West African ...	313 ...	40s "

Those sorts which are marked with an asterisk are irregular in size and colour, and have the appearance of being carelessly prepared; and the reason why Rio, Manilla, and West African fetch the least money seems obvious enough.

"Cultivation, climate, mode of preparation, and age, are all factors which help in determining value. There are the same differences in coffees that there are in other kinds of fruit, between the wild crab apple, for instance, and the Newton pippins; and by the art of cultivation, the coffees of Java, the East Indies and Ceylon, and some of those from Central and South America, have become more than rivals for Mocha. If you will look at the coffees from Rio and the West Coast of Africa, and compare them with those from Mysore and the Neilgherrys, you will appreciate the value of careful preparation and thorough cleaning."

Dr. Poore warmly advocated the more general use of coffee, and recommended that it always should be made strong, and from a good quality of bean. He had a good deal to say in regard to the roasting and prepartion of coffee, and in conclusion he devoted considerable space to the question of adulteration, arguing that the decline in the consumption of coffee in England was due mainly to the development of adulteration under Government patronage. Our space will not, however, permit us to follow him into this branch of his subject occasion on the present occasion, but we shall probably recur to it in another issue.—*Planters' Gazette.*

THE importance of seasoning timber otherwise than by the ordinary process of time is admitted by all who are called upon to use unseasoned wood under urgent circumstances. To dealers and those who can afford the necessary appliances the application of steam will commend itself. The prinoiple is the following: A large percentage of sap in all woods consists of water. This water heated to boiling point expands sixteen hundred and fifty times. It follows that if wood be heated to 212° the boiling point of water the capillary cells can contain only one sixteen hundred and fiftieth as much water as at ordinary temperature, the expanded water escaping as steam. The proportion of moisture left in the wood is after steaming less than that demanded by its ordinary hyroscopic condition. The steaming should be gradually done so that the sap may be dissipated without rupturing the cells by its expansive force when being converted into steam. The steam should be generated in a suitable boiler and allowed to escape at a pressure of two or three pounds.—*South of India Observer.*

QUININE.—The sophistication of quinine sulphate with a cinchonine salt, which occurred some time ago in Paris, has occasioned the issue by the French War Department of an official test for the purity of the samples of quinine sulphate that may be submitted to that department, and the test is an exemplification of the truism that a little knowledge is a dangerous thing. Among the nine tests that are given it is required that the sample shall be white, homogeneous and crystalline; and that when calcined it shall not leave a residue exceeding 25 centigrams per 100 grams (that is, 0·25 per cent). It should not contain any quinidine, salicin or other foreign matters; its aqueous solution should be prefectly clear and alkaline to test-paper; moreover, it should consist of quinine, 76·25; sulphuric acid, 9·12; water driven off at 100°, 12·00; water combined at 100°, 2·33. Finally the quantity of cinchonine admitted by tolerance should not exceed "two-hundredths." Apart from the other singularities in these requirements, no mention is made of cinchonidine, the alkaloid commonly occurring in samples of commercial quinine sulphate, and it is difficult to understand the reason of fixing the limit of water at 12 per cent.—*Pharmaceutical Journal.*

MESSRS. COOPER, COOPER & Co., the well known London Tea Merchants, seem to understand their business, and the uses of advertising. We read in a home paper that not long ago they sent out pamphlets about their teas, upon which 15 tons of paper were expended, and the postage of which cost upwards of £800. This was exclusive of their advertising mediums in the London districts. Messrs. Cooper, Cooper & Co. buy and sell a large quantity of Indian Tea, a taste for which is certainly spreading in England. It cannot fail to do so, if only old fashioned housekeepers in the old country can be brought to understand that from two to three minutes is ample time for infusion in the tea pot. From ten to twenty minutes may be all very well for the decoction of herbs, and dyes, and dirtinesses, known as China Tea; but so long a steeping of course utterly ruins the flavour of the real article and renders it acrid, bitter and bilious. And then the British public is apt to blame, not its own stupidity and the tradition of the elders, but "that dratted Indian Tea" or "the very peculiar taste, my dear" this Assam, or Darjeeling tea, has.—*Indigo and Tea Planters' Gazette.*

FIBRES.

SIR,—A correspondent in one of your issues a short time back (signing his letter "X.") desired to know the percentage of fibre that might be obtained from the leaves of the pine-apple plant.

As I have at various times conducted experiments on plants in Ceylon yielding fibres, I found the out-turn from aloe and pine-apple to be about 75 per cent; the latter requiring to be gently handled owing to the delicate nature of its fibre.

I shall be happy to render "X." any further information he may require on this subject on his communicating with me direct, either by personal interview or by letter.

The following are extracts from one of the reports of fibres I sent to England:—

Aloe.—No. 1 sample worth £31 per ton.
,, 2 ,, ,, £29 ,,

Pine Apple.—The pine-apple fibre is very pretty, and, if it could be got in quantity to sell here (in London) at £35 per ton, it would soon make a market for itself at a much higher price; but spinners will not alter their machinery for working it unless quantity could be guaranteed.—X. ZETO.—Local "Times."

JAPAN CAMPHOR.

The American Consul at Nagasaki, in his report to the Washington Government on the trade, &c., of the country for last year, gives the following interesting information on Japan camphor:—

The manufacture of camphor is an important industry on the island of Kiu Shiu (Kew Shew.)

From the port of Nagasaki there were exported in the year 1882, 15,186·18 piculs, valued at 227,792 dollars. A picul is 133⅓ pounds. From other ports of the island not yet open to foreign trade, a large quantity was shipped by native merchants in native vessels to Shanghai in China, and Hongkong, whence it finds its way to India and England; little or none of it is exported to the United States. The camphor tree grows abundantly all over this portion of Japan. It is found alike on high elevations and in the valleys and lowlands. It is a hardy, vigorous long-lived tree, and flourishes in all situations. Many of these trees attain an enormous size. There are a number in the vicinity of Nagasaki which measure ten and twelve feet in diameter. The ancient temple of Osuwa at Nagasaki is situated in a magnificent grove of many hundred grand old camphor trees, which are of great age and size, and are still beautiful and vigorous. I am told that there are trees in other places in Kiu Shiu measuring as much as twenty feet in diameter. The body or trunk of the tree usually runs up twenty and thirty feet without limbs, then branches out in all directions, forming a well proportioned, beautiful tree, evergreen and very ornamental. The leaf is small, elliptical in shape, slightly serrated, and of a vivid dark-green colour all the year round, except for a week or two in the early spring, when the young leaves are of a delicate tender green. The seed or berry grows in clusters and resembles black currants in size and appearance. The wood is used for many purposes, its fine grain rendering it especially valuable for cabinet work, while it is used also for ship building. The roots make excellent knees for ships.

I have sent many seeds of the camphor tree to the United States, in the hope of adding to our own arboriculture. In the manufacture of camphor the tree is necessarily destroyed, but, by a stringent law of the land, another is planted in its stead. The simple method of manufacture employed by the natives is as follows:—The tree is felled to the earth and cut into small pieces, or, more properly speaking, into chips. A large metal pot is partly filled with water, and placed over a slow fire. A wooden tub is fitted to the top of the pot, and the chips of camphor wood are placed in this. The bottom of the tub is perforated, so as to permit the steam to pass up among the chips. A steam-tight cover is fitted on the tub. From this tub a bamboo pipe leads to another tub, through which the inclosed steam, the generated camphor, and oil flow. This second tub is connected in like manner with a third. The third tub is divided into two compartments, one above the other, the dividing floor being perforated with small holes, to allow the water and oil to pass to the lower compartment. The upper compartment is supplied with a layer of straw, which catches and holds the camphor in crystal in deposit as it passes to the cooling process. The camphor is then separated from the straw, packed in wooden tubs of 133⅓ pounds each, and is ready for market. After each boiling the water runs off through a faucet leaving the oil, which is used by the natives for illuminating and other purposes.—*Indigo and Tea Planters' Gazette.*

COFFEE-PLANTING IN THE BAMBOO DISTRICT OF COORG.

Of all our British possessions, Ceylon long ranked first as the great coffee-producing colony. It has now lost all claim to this distinction. About ten years ago there was a great and sudden rise in the price of coffee, which caused an unusual flow of money into the island. Land fetched a hundred per cent over its real value, and an unhealthy spirit of speculation was engendered. In due course the usual reaction set in. Prices fell; and as leaf disease and abnormal seasons came on apace, all planters whose business had not been conducted on a strictly commercial basis were speedily brought to ruin.

The province of Coorg is little known outside the Presidency. It was favoured with no influx of money beyond the legitimate proceeds of its trade, and there was thus no field opened for speculators. Grown, as it is, under the grateful shade of fig, jack, and other forest trees, the Coorg coffee enjoys a comparative immunity from leaf disease and other pests. The seasons have generally been productive of a good or fair average crop; in short, the prosperity in Coorg is attributable to the absence of leaf disease, abnormal seasons, and over-speculation, while the ruin in Ceylon has been in proportion to the intensity of these conditions.

The object of this paper is to point out that Coorg offers a good field for a certain number of young men possessed of enterprise, good health, and a small capital. There is still a limited quantity of "waste land" available, and there are always a few estates partially or wholly opened out offered for sale. The present should be a particularly opportune moment for acquiring land, as it is probable that thirty estates and upwards, the property of the chief proprietor of the district, will shortly be offered for sale in one block or individually.

Coorg is situated in the western Ghats. Tellicherry, on the west coast, is sixty miles distant, and Mysore, the railway terminus for the east coast, is the same distance from the heart of the planting district. It is expected that a railway through Coorg will soon connect Mysore with the west coast, when a great impetus will be given to planting operations. The climate is healthy and pleasant, and not subject to great extremes of heat and cold. The general elevation is 3,000 to 4,000 feet. Good sport can be had, both with gun and rod. Almost every wild thing, from an elephant to a snipe, may be shot, and there are miles of good mahseer runs on the Cauvery, Barapolly, and other rivers. There may be about two hundred European residents, most of whom are connected with the planting interest.

Looking at the enterprize from a purely commercial point of view, the writer will be careful to avoid everything like false colouring, and to present, as far as he can, a correct and truthful picture. Nearly the whole of what is known as the "bamboo district" is suitable for coffee. The soil, too, is nearly all rich, though not equally so. Some parts have advantages over others in point of climate. This last is very important—perhaps the chief point to be considered.

The intending settler would do well to look about him and gather the best information before investing his money. Better still, he should seek employment under some able manager for, say, a couple of years, when he will have learned the language, and fairly mastered the details of his business. This arrangement need not prevent his acquiring land meanwhile, or purchasing an estate if a favourable opportunity offers itself. In the latter case the work had better be entrusted to a manager while the purchaser is gaining his experience on another estate.

Now, with regard to the amount of capital required. Crown land is plentiful enough, though not readily obtained, the Government having adopted a rather strict policy of conservancy. A great deal of land is in the hands of natives, and this can be purchased at from £3 to £8 an acre, according to the situation and quality of the land. Crown forest, when put up to auction, generally brings a little more than these figures. Coffee plantations in full bearing are to be purchased at from £40 to £60 an acre. To bring a plantation into full bearing, allowing for price of land and interest on money, will cost from £30 to £40 an acre. The average size of a plantation is 150 acres, and to bring that into bearing, without borrowing, would require a capital of £5,000. With half the capital it can be done in this way. Say the land costs £1,200, and the first year's expenditure is £1,200. If the planting is a success, sufficient money can be raised to carry on for another year and a half, when the first crop will be gathered. The rate of interest will be from 8 to 10 per cent. Again, a property in bearing, say 150 acres, may be bought for £7,500, a third of which only need be paid down, and the balance, £5,000, in instalments running over three or four years. In this latter case the interest would probably be 7 per cent. If it can be avoided, it is clearly the best way not to borrow.

It next comes to be considered how the investment will pay. A choice estate in the bamboo district of Coorg could certainly not be bought for less than £60 an acre. It is cheaper in the end, however, to buy such an estate, with a suitable climate and rich soil to work on, than to take one without these advantages for half the price. Suppose an estate of 150 acres is bought for £9,000. If properly cultivated it will continue to yield, on an average, 6 cwt. per acre. The yearly crop will thus be 45 tons, which will net, say, £75 a ton, or £3,375. The upkeep of such a plantation at the outside would be £2,000. This would give a profit of £1,375, or 15 per cent per annum, on a capital outlay of £9,000. These calculations are based on practical knowledge, and sufficient margin is allowed for unpropitious seasons and other contingencies. Many of the best properties give an average yield of 7 cwt. per acre, and under skilful management the working expenses will not be more than £10 to £12 per acre, or say, £1,650. The price of coffee, too, is fixed at a low rate, and the writer's last season's crop of 85 tons brought an average net price of £81 per ton. Under favourable circumstances, then, it will be seen that some 30 per cent on the outlay may be obtained.

Following a business that gives such good returns, it will naturally be asked why all planters have not made their fortunes. The question is answered thus. In no single instance has a planter started operations with sufficient capital, and so his enterprize is clogged with debt. Again, all the companies and large proprietors opened land in unsuitable districts, and profits from good estates were swallowed up in carrying on unprofitable plantations. Furthermore, it is only within the last eight or ten years that a proper system of cultivation was understood, far less carried out. At one time the "borer" swept over the country like a scourge, and it looked as if all coffee property would have to be abandoned. At this juncture, on one or two plantations, shade began to be grown, and a superior style of cultivation to be introduced. The effect of these new methods fell on the bewildered and well-nigh despairing planters like a revelation. Gradually the improved system came to be adopted on all properties, and with the most successful results.

Prior to this new era, estates had fallen to a low ebb, through debt and neglect. Several years of skilful management were required to recover lost ground, and it is only now that properties are getting freed of their incumbrances, and the fortunate owners beginning to enjoy the fruits of their labours.

I have said nothing of the cultivation of cinchona, which has been making rapid progress during the last four years. It does not appear to flourish in the more eastern and drier parts of the province; it requires moderately steep land and free open soil, and thrives best of all on the Ghat land, which is not so well adapted for coffee. Cinchona is being interspersed with the coffee, for the double purpose of affording shade and yielding a valuable bark, which in a few years will greatly add to the revenue of the planter.—J. C.—*Field.*

ESSENCE OF PURE COFFEE.—We hope that at last a genuine "essence of coffee" has been produced, for from an advertisement in the *Pharmaceutical Journal* we notice that Messrs. Ridgway & Co., tea and coffee merchants, of London, have, in conjunction with Messrs. Allen & Hanburys, the well-known chemists, produced a preparation which they call *café vierge.* We read :—

This Essence is extracted at Allen & Hanburys' laboratory by a new and very perfect process, by means of which the delicate flavour and aroma of the Coffee are retained without any of the coarseness and acridity which are so often perceptible in the ordinary brewing of the ground berries. It is exquisitely soft and delicate in flavour, and will be found quite unique, no essence at all comparable in quality and strength having heretofore been offered to the public. By its use *all waste is avoided*, as it is only necessary to prepare the exact quantity required, a single cup being as easily made as a larger quantity. It may be made *entirely with milk*, and, thus prepared, is more nourishing than the usual household coffee, which must of necessity contain a considerable proportion of water. A very pleasant and invigorating beverage is made by adding one or two teaspoonfuls of the *Café Vierge* to a bottle of Seltzer or Soda water, or a glass of cold milk (with sugar to taste); and used in this way the Essence will be found of great convenience to tourists, travellers, and sportsmen, more especially as, being very highly concentrated it occupies little bulk. The Essence will also be found extremely useful for flavouring ices, creams, cakes, &c.

We give the proprietors this gratis advertisement on account of the important bearing the subject has for Ceylon coffee planters. In the advertisement under notice the letters of the words of "*café vierge*" represent coffee beans, placed in various positions, those placed sideways, however, being more like acorn cups than coffee beans.

THROUGH THE TEA DISTRICTS OF NORTHERN INDIA.

(TO THE EDITOR "INDIAN TEA GAZETTE.")

DEAR SIR,—A "specimen sheet" of the *Tropical Agriculturist* of 1st September was sent to me a short time ago from Colombo. In it I observed a letter as above, headed from a Coffee Planter, signed T. C. Owen, dated from Tezpur, who evidently came up to our valley with the intention of picking holes in our system of Tea cultivation and manufacture, from a prejudiced Ceylon point of view.

In Ceylon we all know that the Island is traversed and intersected by fine roads, also boasts a rail-road, by which cooly labour can be conveyed with ease to the remotest parts. All the old coffee factories have, or can, be easily converted into tea factories, or built at half the cost we are compelled to pry for pucka work in Assam.

CONTRACTORS.—There are plenty in Ceylon to bring our cheap labor from the main-land, who weed by contract, and keep all the gardens and paths nice and clean for managers to walk or ride, or to inspect their work with the greatest of ease.

Perhaps he is not aware that flat gardens and Teelah gardens must be treated quite differently towards the close of the season. A flat garden should be kept clear of jungle, until the last flush has been gathered: a Teelah garden, to induce the bushes to flush well into November, should not be scraped or cultivated after the month of September. I have seen it tried, and the manager boast of his (Teelah) garden being clean all over October—the consequence was, the neighbouring garden that was allowed to remain as it was in September gave leaf into December, whilst the clean garden's manager had to close its packing house. This shows that Mr. Owen cannot be so well posted up as he wished the readers of the *Tropical Agriculturist* to believe.

We could also drain our lands and Teelahs had we the same cheap and abundant labor at our command as the Ceylon men possess. After sweltering for eight months in isolated gardens, we certainly do enjoy a few days' recreation at X'mas time. But we make up for it by attending to our building, hoeing, and cooly-seeking, for the new year—all such worries being unknown to Mr. Owen or the planters of Ceylon.

No allowances are made by Mr. Owen for many drawbacks we suffer under here in Assam, as regards the want of labour during the rains. We are only too glad to get our land hoed or scraped in place or hand weeded *à la* Ceylon, and should a cooly in his ignorance hoe away a small portion of the by-paths amongst the tea, we cannot complain or cut his pay, or off he goes, should he be a local cooly.

Put Mr. Owen, or any other Ceylon man newly commencing tea in Assam, to undergo all the worry and vexations of collecting labor, and *then keeping it about him* for one season only—coupled with bullying letters from agents, he would have criticised us more leniently, and not drawn such comparisons.

Because *one of our number*, whose garden lies close to Gauhati, allows his dogs to bark about in the green leaf and tea houses, and greasy babies to roll in the tea also, it does not follow that we all allow these dirty tricks to be played in our tea and packing houses. I can name scores of Assam packing houses that are as cleanly kept as any could possibly be kept in Ceylon, and where no man dare attempt to stamp down tea into a chest without first placing a clean cloth over it, and scores of planters in the valley who are still quite capable of teaching Mr. Owen a thing or two, simply because they have spent many of the best years of their lives amidst its swamps and lonely jungles, finding out by weary years of toil that knowledge which Mr. Owen vainly imagines he has learned by a pleasure trip up the Bramapootra.—RICHARD G. EADES.

A NEW INDUSTRY FOR PENANG.

It is a pleasing task indeed when one is able to call attention to the starting of a new enterprise, and still more so, when its prospects are almost assured since the material produced by this fresh departure in Penang is becoming daily more and more a necessity all over the world. We refer to the Coir trade. So far back as 1881, the late Hon'ble Forbes Brown proposed going in for the coir manufacture; and articles were written in this paper pointing out the enourmous waste of useful material in the shape of coconut husk, which then, and up to a late date, was only either used for fuel or allowed to rot on the ground under the trees. Mr. Vermont, who went home in 1872, made enquiries as to the requisite machinery to work this stuff up, on behalf of Mr. Brown, and returned with full information, but unfortunately, owing to the other important matters, such as the opening of Prye Estate, etc., which engrossed the whole attention of Messrs. Brown and Vermont for the time being, the matter was left in abeyance, and finally the former's death put a stop to all further action summarily. After the lapse of eleven years, the largest representatives of cultivation in this Settlement have come to the front again, and they may well be congratulated on having resolved to carry out the idea which Mr. Forbes Brown intended to have done nearly half a generation ago.

In concluding this prelude to the account of the opening ceremony of the "Ayer Etam Coir Works," we will only add that the psoprietors have extraordinary advantages. Their works are in the midst of a fertile coconut country, and what adds more than anything to the value of them is the fact that they possess a very large water-supply, which can work a turbine capable of giving motion to the extent of 50 horse power if necessary. At present the machinery is only worked up to the extent of 8 horse power, but as the Company intend extending their works, they are, as stated above, in position to command the required force to drive machinery to the extent of 12 times their present requirements. The produce of the manufactory has been very highly reported on in the English markets, and we are confident that the speculation undertaken by the Company will return goldon harvests.

The works were publicly opened Mrs. McNair on last Saturday morning (19th Jan.) at 7·30 a. m., in the presence of a large gathering of the inhabitants of Penang.—*Penang Gazette.*

A TOBACCO PARASITE

is thus noticed in a letter from W. Wilson, Esq., Director of Revenue Settlement and Agriculture, Madras, dated Madras, 3rd October 1883.

I have the honor to forward, for your information, a note on "Bodu" (*Phelipæa Indica*), a vegetable parasite, which last season committed great ravages on the tobacco crop of the Godávari delta, and shall be obliged by your informing me whether tobacco in your district is found to suffer from the same or any other vegetable parasite, and, if so, how the evil is combated and to what use the parasite is put if removed from the tobacco plant.

(*Enclosure.*)

NOTE ON "BODU" *Phelipæa Indica.*

1. Early in June of the current year, I received from Messrs. Arbuthnot & Co., of Madras, a letter, dated 11th May 1883, forwarding a communication from Messrs. Hall, Wilson & Co., their correspondents at Cocanada, regarding a vegetable parasite known in Telegu as "Bodu," which had last season attacked the tobacco crop on the Godávari lunkas, causing great damage and loss to growers.

2. *Its Description.*—The "Bodu" is described as a yellow-stemmed succulent asparagus-like shoot growing perpendicularly from the root stock of the tobacco plant, sometimes singly, sometimes in clusters of 5 or 6 together: its height is from 6 to 9 inches, and it has a tiny bell-shaped flower of a yellow, pink, or pale blue colour.

3. A specimen of the parasite preserved in methylated spirit accompanied Messrs. Arbuthnot's letter, and was at once forwarded to Professor Lawson for identification and the suggestion of such remedies as might occur to him.

4. Messrs. Hall, Wilson & Co.'s letter clearly pointed

to soil-exhaustion and consequent decrease in plant vigour-and in the letters addressed from this office to Professor Lawson, the Collector of the Godávari, and Messrs. Arbuthnot & Co., it was suggested that in a dressing of salt, petre and common salt might perhaps be found at once the most suitable manure for the soil and the cure for the disease.

5. In his reply, dated 11th June 1883, Professor Lawson said that the proposed remedy would probably decrease the pernicious effects of the parasite by increasing the vegetative activity of the tobacco, but would not destroy the pest.

6. Besides writing to Professor Lawson, I addressed also the Collector of the Godávari asking for any information it was in his power to give me on the subject, and I took advantage of the recent deputation of Mr. Benson, Assistant Superintendent of the Government Farm, on a tour of agricultural inspection in the Kistna and Godávari deltas, to direct his special attention among other things to this. The season of his tour was not the best that might have been got for the investigation, as there was no tobacco on the ground then, but it was thought that Mr. Benson would be able notwithstanding to acquire a good deal of useful information on the subject. The result has not disappointed the expectation; Mr. Benson was fortunate enough to find "Bodu" *in situ*, and has submitted an interesting report on the whole question of tobacco culture in the Godávari, the "Bodu" pest and its possible remedy.

7. The result of the various inquiries made is briefly as follows:—

The parasite has been identified by Professor Lawson as the *Phelipæa Indica*, natural order *Orobanchaceæ*, and from Mr. Benson's inquiries it appears to show first about a month after the seedlings are transplanted from the nurseries to the fields, and about a week after the first and in general only weeding the land gets. At first sight, therefore, the stirring of the soil in weeding would seem to be the stimulating cause of its growth, but Mr. Benson further states that it appears also on fields that have not been hoed at all.

From the report of Messrs. Hall, Wilson & Co., it was thought that the "Bodu" was confined to the Godávari lunkas and attacked only plants of the natural order *Solanaceæ*, the only plants that were observed to suffer from it being the tobacco and the brinjal.

Further inquiries, however, showed that it attacks the tobacco of the upland villages, and that its attacks are not confined to the *Solanaceæ*, the Sub-Collector of the Godávari reporting that it also attacks turmeric (natural order *Zingiberaceæ*), but apparently without injuring it.

8. *The Cause of the Pest.*—Various opinions have been expressed as to the cause of "Bodu." Messrs. Hall, Wilson & Co.'s letter pointed, as already remarked, to soil-exhaustion. The ryots appear everywhere to ascribe it to this and to excessive moisture; their testimony is to the effect that it always increases on land not frequently silted by the river freshes. Mr. Benson does not think that this can be admitted to be the real cause, as it is found indifferently on all kinds of soil, the best and the worst. This argument is not conclusive however, as the parasite might have appeared first on exhausted soils and spread thence to the better ones. There can be no doubt that the evil has extended with the extension of tobacco, which the parasite seems chiefly to affect, and that its attacks are now more persistent owing to the accumulation of its seeds in the soil. It appears to be somewhat capricious in its attacks, some fields and plants being entirely free from it, though in the immediate neighbourhood of others that may be suffering severely from it.

9. *Its Effects on the Tobacco.*—Opinions differ, too, as to its effects on the plants it attacks. Some say that the tobacco dies if it is not removed; others that the removal of the parasite involves the death of the tobacco; and others, again, that the parasite may weaken the tobacco, but cannot, except in the case of a weakly plant, kill it. The general opinion is that it does no material injury to strong healthy plants on good soil, but injures greatly, even to killing, weakly plants on poor soil.

10. *Its Uses.*—In the Punjab, the kindred *Phelipæa Calotropidis* is used for cattle fodder, and there seems to be no doubt that in this province also it might be used for the same purpose. Notwithstanding the assertion of the ryots of some parts of the Godávari that cattle will not touch it, there seems every reason for believing the contrary testimony that though they may be averse from it at first, they in time become greedily fond of it, and when fed on it yield more and better milk then when otherwise foddered.

11. *The Remedy.*—The "Bodu" propagates itself by seeding. One obvious remedy for the disease is, therefore, as suggested by Professor Lawson, the persistent removal of the parasite as soon as it appears above ground and before it seeds. This requires, of course, a general and continuous co-operative movement on the part of growers not only in the deltas but in the uplands, and this, it is to be feared, is hardly to be expected. If removed from the tobacco—and it can be removed by the most gentle pull, breaking clean off at the junction with the root stock—after it has seeded and merely thrown down, as it appears generally to be, besides the plants on which it grew, the worms that had their abode in its flowers attack and eat up the tobacco, and its seed remains to propagate a fresh crop in the next season. When removed from the plant, it should be removed from the field and given to cattle, which undoubtedly feed on it and like it. The most obvious remedy was, in Messrs. Hall, Wilson & Co.'s opinion, liberal manuring, but this it was, they thought, hopeless to expect the ryots to adopt so long as they get the Godávari silt. They suggested, however, that the ryots might be induced to manure their seed-beds heavily so as to ensure a strong and healthy seedling to begin with, but from Mr. Benson's report it would appear that the tobacco nurseries are now very highly manured. All authorities consulted concur in recommending the liberal use of manure as a means of at least minimizing the evils of an attack of "Bodu," but Mr. Benson does not seem to think that this would be requireed except in the case of the high lands which the Godávari freshes do not cover. Another remedy is interculture and change of crop; but as the "Bodu" does not, as was at first thought, confine its attacks to plants of one natural order only, it might be found that mere change of crop would not starve the parasite out.

PRESERVED GINGER.—The following is an account of the process as given by an American eyewitness:—"The ginger root, a large white variety, is first dug and the outer skin scraped off. This is chiefly done in the country surrounding Canton, where it is raised. It is then shipped down to the city in boats, carefully washed, and thrown into large kettles, where it is boiled for about twenty-four hours. It is then taken out and thrown into salt water, and allowed to remain there about twenty-four hours more. After this it is taken out, the rough edges trimmed off with a knife, and thrown upon tables, which are surrounded with operators, holding in each hand a kind of three-pronged fork, with which they prick the root until it is thoroughly punctured through and through. It is then washed in fresh water and dried in the sun for a time, afer which it is again placed in large kettles, containing abtut an equal weight of sugar, and boiled for about twove hours; it is then taken from the kettles and put into lelge earthen jars. The syrup is poured over it, and it is alloared to remain therein for several days—sometimes weeks—wwen it is boiled up again for a short time, and is then rehdy for packing. It is put up in jars and half-jars, such asaall dealers are familiar with, and packed in cases containi ug six jars or twelve half-jars. In all the various manipulatio ns the Chinese are particularly dexterous. The process of putting the network of rattan over the jars, by which they are carried and handled, a workman would seize a piece of rattan, twist it into two rings just big enough to go over the top and bottom, and with another slender strip would weave a network between these two rings so quickly that one could hardly believe that it had been accomplished by an individual, and not by some marvellous machine. The pasting of the papers over the tops of the jars is also a curious piece of work. One end of a long strip of paper is first stuck to the edge of the jar, and the strip is then twisted over and over, each time receiving a little dab of paste, until the jar is hermetically sealed, and all thist is done with such exceeding quickness and dexterity tha you can hardly follow the motions of the operator's hands

THE CULTIVATION OF TREES OF THE INDIA-RUBBER SPECIES.

A letter was received from Mr. J. A. Robinson, and read as follows, at a meeting of the Royal Agricultural Society of British Guiana:—

Mount Street House, Wrexham, North Wales.

To the Secretary of the Royal Agricultural and Commercial Society of British Guiana.

SIR,—Some time ago I ventured to trouble you respecting a prospect for cultivating trees of the Indiarubber species—the chief feature—a most valuable one being the *propagation* of these from adult stems—thus very materially hastening the period of yielding.

The method is very simple, when known it is successful, and it is *known only* to myself and another. For reasons given in my former letter, we are desirous if possible of carrying out the prospect in British Guiana. My former letter on the subject may not have come to your hands, and I now beg to ask the favour of a reply from you as to whether it is likely either your Society, or any one member of it, would take an interest in the undertaking? We ourselves *know* the practicability of the business, and the great prospects it would afford is in the future, if properly started, and are ready to throw ourselves into it to the extent of our means, relying entirely upon *results*, of which we are confident.

We do not wish to lose another season—we wish to establish the business in a British Colony as a matter of preference, and as we are unacquainted personally with anyone in the Colony, may I beg the great favour of a reply, with, possibly—if you do not care to enter into the matter in behalf of the Society—a list of names of the members, as we should like to communicate with one or more of them on the subject. They will, we presume, be probably well acquainted with the trees and their produce, and it is only such gentlemen we would wish to broach our scheme to.

Apologising for the trouble we have given. I am, Sir, yours faithfully, J. A. ROBINSON.

The acting Secretary said he had made enquiries at Mr. Campbell's house respecting the letter referred to by Mr. Robinson, but there was nothing known of it. He supposed it must have been mislaid. He had written to this gentleman, stating that his letter would come before a meeting to be held this month (the present one), and that the matter would then be considered. He had also forwarded to him a copy of Mr. Jenman's communication on Indiarubber trees of this colony, and a list of the names of the Directors of the Society, in case he wished to communicate with any of those gentlemen. The Chairman suggested that a copy of Mr. Robinson's letter be referred to Mr. Jenman, which was agreed to.

THE DWARF PALM AS A PAPER MATERIAL.

BY JAMES COLLINS.

In a recent number of the *Journal* (August 17th, 1883), there is a short note on the above plant, and the following is a slight account of it:—

The Dwarf Palm, *Chamærops humilis*, of Linnæus, has a great interest in geographical botany, as it marks the northern limit in Europe of the natural orders of palms, being found growing wild as far north as Nice, in 43° 44' north latitude. In the countries bordering on the Mediterranean Sea, it is very plentiful. In South Grenada it grows up to an elevation of 2,000 feet above the level of the sea, covering large tracts and preventing cultivation; also in Southern Europe generally, Western Asia, and Northern Africa, covering waste and uncultivated ground like our furze *(Ulex Europæus*, Linn.), does in this country. In Algiers it is a perfect weed, looked upon even as a scourge, its deep and tough roots giving great trouble to agriculturists; but then "a weed is but an unutilised plant, or a plant in the wrong place."

This palm is naturally of a dwarf habit, of three to four feet high, with long creeping roots, from which spring numerous suckers, forming dense tufts. If these suckers be removed, the plant attains a height of from 20 to 30 feet. The leaves are fan-shaped, rigid, and furnished with prickles.

The palm is not without its uses. The Arabs use the fibres found at the base of the leaves, mixed with camel's hair in the fabrication of their tent covers, which are lasting and impervious to rain. The leaves are also used largely in Southern Europe for the making of hats, brooms, baskets, cordage, sails, and also for thatching purposes. In France, as far back as 1854, the dressed fibres were used as a substitute for horsehair, being firm and elastic, and also in the manufacture of carpets, sailcloth, thread, and paper, and known as African or vegetable hair. When freed from resin and properly dressed, although not so long in staple, the fibre has been spoken off as much representing flax. Of other species of *Chamærops*, there are about a dozen cultivated in European gardens. *C. Fortuni*, a native of northern China, grows to a height of from twelve to twenty feet, and its leaves are used in the making hats, and in the manufacture of a kind of coat well suited for wet weather. *C. Richiana*, very common in Afghanistan, furnishes material for hats, fans, brushes, sieves, sandals, pouches, ropes, &c. Its seeds are used as bullets, or for rosaries, and its young leaves or "cabbage," form an article of food.

The dwarf palm, therefore, seems to fulfil all the conditions necessary for becoming a staple article of commerce. It is plentiful, easily obtained, easily cultivated, if necessary, and if sent over in a semi-prepared or half-stuff condition, the question of freight would not interfere with its utilisation by paper manufacturers.—*Journal of the Society of Arts.*

HARVESTING CINCHONA BARK.

There seems to be a pretty general fear that coppicing may be such a severe shock to the tree that a large percentage may die and fail to throw out suckers, but I think this is very much exaggerated. The shaving process, it is well known, causes a small percentage to die after each shaving, but I very much doubt whether coppicing, *if properly carried out*, is half as fatal to a number of trees as the more fashionable process. There is no comparison between the cheapness of the two methods of harvesting, that is, if the shaved trees are carefully covered with mana grass or paper afterwards, for that operation itself costs quite as much if not more than actual harvesting. Many a tree has been killed by careless shaving, which, no matter how complete the superintendence, or how effective the instrument in the hand of the coolies, is impossible to guard against; whereas coppicing gives a large amount of bark at a very low rate per lb., and from the experience I have of this process, with very little risk of any great number of trees being killed by it. I know of an estate where about 450 *succirubra* trees, 7 years old, were all cut down within a week of one another, as soon as the gang of coolies could get round to them, and but 3 per cent failed to again make a start and now bid fair to be as large trees at 6 years old as the first stems were at 7. Those that failed to live—fifteen in number—were one and all of them trees *that at the time of coppicing had no sucker growing*. What should be done is this: at least 18 months, if not more, before it is decided to coppice, one or two suckers should be allowed to grow right at the collar of the tree, and great care should be taken that in no case those that do make a start should be taken off by weeders, till one or two really healthy suckers are started. With care, by the time it was decided to coppice the trees, a very large percentage of them would have large healthy suckers growing, some only small and a few none at all. Any deaths that occur after coppicing, I feel sure, would be amongst these latter, for it must be a very violent shock to the tree to have its trunk severed and be deprived of *all* its leaves. The trees that have suckers on the other hand are not deprived of all their leaves, and the shock to them is much less. They (the suckers) grow very much quicker than plants, and the failures need not be greater than five per cent I feel sure. The trees that I have shaved more than once, often have a much larger percentage of deaths. Canker attacks them, and being weakened they more easily succumb. It is almost impossible to keep an accurate account of the number of trees shaved and the number that afterwards die, and, again, how many of these deaths can be attributed to constant shaving or canker induced thereby. But I can certify that the deaths from coppicing, if carefully done, and suckers allowed to grow previously, are very small indeed. I am aware how difficult it is for some to abstain from shaving, but if any can I feel sure he will not repent of his forbearance.—G. B.—Local "Times."

VEGETABLE PRODUCTS OF JAVA.

The British Consul, reporting on the trade and commerce of Java for the year 1882, says that in many parts of this island, especially to the eastward, tobacco, which in former years was a fruitful source of wealth both to Europeans and natives, has become almost a thing of the past, and even in eastern and southern Java, where several planters have persevered in the cultivation, the results are such as to warrant but little hope of the industry being continued.

Under the head of tea it is said that planters have paid increasing attention to the improvement of their gardens, and with few exceptions have quickly adopted all improvements in machinery proved to be successful in British India and elsewhere. The yield of Java gardens (nearly entirely confined to the westward portion of the island) is rapidly increasing, and every care is being taken to introduce the best description of plants, the preference being still given to the Assam hybrids. Exports to England and Holland have been nearly equal during the past year, the low price of British Indian tea in the London market having caused shippers to direct a large portion of the late production to Holland.

Arrack appears to be an important production of Batavia. It is stated that from the coast distilleries at Cheribon, Samarong, and Sourabaya, a fair proportion was exported to Europe.

Private exports of cinchona, although considerably larger during 1882 than in the preceding year, only amounted to 181,354 Amsterdam pounds, but as numerous cinchona gardens, commenced some five or six years ago, must shortly begin to yield, this article may soon be expected to take a prominent position in the list of exports from Java. Various concessions of land in the high districts of East Java have lately been granted for the cultivation of cinchona, and working capital has been readily forthcoming, showing general confidence in the future of this culture.

Under the head of "Government Cinchona Plantation" the following statement is made:—The Government cinchona crop is steadily increasing year by year as the plantations are enlarged. The year's crop (1882) to December 31 amounted to 230,000 Amsterdam pounds, as against 165,000 Amsterdam pounds in 1881, and 100,000 Amsterdam pounds in 1880; but this figure does not represent the whole crop, the remainder of which will be gathered during the commencement of 1883. The 1881 crop netted in Holland 218,441 fl. 75c., or about 1 fl. 32c. per Amsterdam pound.

Experiments were made during the year with a view to ascertaining what percentage of alkaloid was contained in the bark of the young Ledgeriana trees grown from the seed of the parent tree, from which it would appear that bark of four years old when in good condition contains from 9 to 11·75 per cent quinine, or fully more than the older parent trees.

The number of trees in the Government nurseries and plantations at the end of 1881 and 1882 stood as follows:—

Young trees in the Nurseries.

	1882.	1881.
C. Ledgeriana	820,700	515,000
C. succirubra	198,300	199,300
C. officinalis	186,800	22,300
	1,205,800	736,600

Trees in the Plantation.

	1882.	1881.
C. Ledgeriana	604,900	620,680
C. Calisaya and Hasskarliana...	445,500	520,000
C. succirubra and caloptera ...	474,500	596,000
C. officinalis	475,500	458,100
C. lancifolia	9,000	12,100
	2,099,400	2,207,480
Total number of trees	3,305,200	2,944,080

Black Pepper.—The "Lampong" crop of 1882, which constitutes the bulk, if not the whole, of the so-called Batavia Pepper, was during the year unusually large, being estimated at about 53,000 piculs, as against an average of 23,000 to 25,000 piculs for the last two years. The crop commences to arrive at Batavia during August, and the final sendings would be received until well into March of the present year.—*Planters' Gazette.*

TAVOY, BRITISH BURMA.

SIR,—Noticing a short paragraph on planting in Tavoy in one of the home papers, and thinking that some description of the resources of the country, its people, customs, &c., may not be uninteresting to your readers, we take this opportunity of sending a few notes thereon. About the end of last year, we left Rangoon in the mail steamer, and, after a run of forty-four hours, arrived at the mouth of the Tavoy river. As we steamed slowly up, the view obtained of the country was really glorious. The eye wandered over miles of paddy fields, the hills, clothed in all the glory of tropical verdure, forming a pleasing background. The edges of the river were lined with a species of palm tree, with a leaf very like that of the coconut, which is used for covering houses. The leaf, when mature, is made into a kind of tat by the women, and forms a good water-tight roof, which is indispensable in a country like this. After a thirty miles run, we anchored off the Custom-house, at a village named Thayets Choung, and were transferred, bag and baggage, to a steam launch, and, after steaming some five hours, arrived at our destination, Tavoy. As the journey was one of business rather than pleasure, we hastened our departure to the coffee lands, it being our intention to occupy one of the 320-acre blocks, now being advertised, on very favourable terms, by Government, for the cultivation of tea, coffee, cardamoms, cinchona, rubber, cocoa—and, in fact, all tropical products. The first two days' journey was mostly through paddy fields and low-lying country, our traps being carried the first eighteen miles by bullock carts, and the balance of the way by elephants. The latter, like their masters, object to hard work, and to carry more than an average 400 lb. The third day's journey of twelve miles brought us to the banks of a large river, which we think will eventually be our outlet, as it is only seventeen miles from the planting districts, and navigable for all ordinary river craft.

The hills are well suited for all tropical cultivations, running north and south, rising to an elevation of 4000 feet; and intending planters will indeed be hard to please if they cannot select land to satisfy them from amongst the many square miles of virgin forest. The view we obtained from the summit of one of the trigonometrical survey stations Nat-Ya-Doung (pronounced Ny-a-dong, and meaning in the vernacular Fairy Water Hill), surpasses all description, and well repays one for toiling up. On the one hand is seen a stretch of park-like country bounded by the sea, and on the other countless miles of virgin forests, interspersed with rivers and streams. Being obliged to return to Tavoy to complete our arrangements, we determined to change our route, and sent a man on ahead to engage a boat at Min dat, a village on the banks of the river we have mentioned. Next morning we re-embarked, and, after narrowly escaping being run down by a junk, reached Tavoy—dirty, tired, and hungry. Here we astonished the natives by making a frantic rush to the Chinaman's, the emporium of the place, and discussed our late adventures over sundry bottles of beer, tinned meats, bread, &c.

Another month saw us hard at work on our land, and we are now busily engaged making nurseries, so as to commence planting operations next season. The fine weather, with occasional showers, gauging 25 in. to 30 in., lasts from November to April; and during the remaining or wet season we shall have, we conclude, from what we have already registered, about 220 inches of rain. The fine weather is the cold season, the nights and mornings being extremely chilly, and the heat during the day excessive. Of the indigenous fruits, the durian is the most highly prized. The natives eat it ravenously, and Europeans who have acquired a taste for it like it immensely. Mangoes, pines, oranges, &c., are abundant when in season. Orchids of many beautiful kinds are common. The staple food is rice and, amongst the many objectionable mixtures they make, is one called nappy, composed of rotten prawns, fish, and shrimps, all mashed up together, and it smells, if possible, worse than the durian. Elk, red-deer, pea and jungle fowl, &c., are very plentiful, elephants, tigers, &c., being found higher up. The only hill tribes we have to deal with are the Karens. They are very similar to the Burmans, but of better physique and more primitive. We would call the attention of ladies at home who advocate divided skirts to jackets *à la* Karen. They are easily made. A sack, the dirtier the better, decorated with pieces of coloured rag, should have three holes cut in it, one for the head and two for the arms. The loins are covered, from the waist downwards, with a "loongy." This is made of two yards of variegated cloth, with the ends sewn together, and forms a cool and comfortable dress, and is worn by Europeans in place of pijamas. The women, when working, discard their jackets, tying the loongy over their breasts. —PIONEERS.—*Field*.

THE PHYLLOXERA.—A very interesting communication was lately read before the French Académie des Sciences concerning the immunity from phylloxera of all vines planted in sandy regions. The writers, Professors of Agriculture at the École d'Agriculture of Montpellier, point out that at Aigues-Mortes and in the neighbouring sandy tracts the vineyards have remained perfectly free from the pestilence, and that in other places offering similar conditions—Mirabel in the Drome, for instance—recently planted vines are forming a source of wealth to the community.—*Planters Gazette.* [Then the application of sand might kill the insects?—ED.]

ARTIFICIAL COFFEE.—At the present low price of coffee it would hardly seem the best time to bring out a new substitute, but a M. Sormani, of Pavia, in the *Ann. di Chim. appl. Farm. et Med.*, announces that he has discovered quite a new and serious adulteration of coffee, which is being practised by the manufacture of artificial berries. These berries are composed of the meal of beans and acorns, with chicory and some quartz powder to bring the mixture to the requisite specific gravity. A dough is made of these ingredients, which is cut by a special machine into the shape of coffee berries, and after drying has exactly their colour. Sormani says he has found as much as 50 per cent of these artificial berries mixed with the genuine. On roasting, they take just the same colour as the genuine, but they are discovered by soaking in water, when the false berries soon fall to pieces. Paper coffee beans are now in large demand in America. They are made out of vegetable pulp, coloured brown, put into a mould, dried, and the odour given by shaking them up with ground coffee, after which they are mixed with real beans.—*Planters' Gazette*.

THE CAUSE OF DEW.—If dew fell it would fall for the same reason that rain falls; but dew does not fall. It is simply a deposit of moisture always contained in the air to a greater or less degree, and which, when there is enough of it, will always form on any cold body exposed to the moist air, in precisely the same way that a cold bottle or stone, taken from a cold cellar and suddenly exposed in the shade to the moist, warm summer air, will become wet. This is not sweating nor does this moisture come out of the bottle or stone as many people believe, but from the air. It is for the same reason that moisture will condense against the window-panes when the air is cold outside and moist inside, the moisture slowly freezing while its deposits form crystal-ice which we so often admire in winter. When the weather is cool enough the moisture will even freeze plants and grass, and then we call it hoar frost; if it does not freeze it is simply dew. The only point left to be explained is why does the ground become so cool during the night, so much cooler than the air above, as to cause the latter to deposit its moisture. This was for many years a vexed problem till Wells first suggested the radiation of obscure heat, which takes place from the surface of the earth through the clear atmosphere into the space above, and so causes the surface to become much cooler than the air itself. He demonstrated this by means of thermometers placed at different heights, and also by the fact that dew is only deposited on cloudless nights. When there are clouds they reflect the heat or prevent it from escaping. The surface of the earth thus being kept from cooling, no dew is deposited.—*Farmers' Review*.

ENTERPRISE IN PERAK.

The Slim clearings have been selected as investments, with regard to soil, transport and general position. They have been holed throughout with 18 inch × 18 inch holes, most is drained and the first portion well-roaded. They commence at 300 feet elevation above sea-level, running to 1,100 feet Immediately behind the last point the hills rise to 4,000 feet, distance one-and-a-half miles Sixty acres (the lower portion) are planted with Liberian coffee: the second portion, fifty acres, is to be planted with Liberian coffee, pepper, nutmegs and a small patch of Arabian coffee. The rainfall for four years averages 99·9 inches, and the extreme fall for one month has been 17·61 inches, October, 1882, the break of the East monsoon. Transport is very cheap, by river, in boats of about three tons size. Roads are being opened up through the districts, and a large planting concession of land is on the point of being worked in Ceylon interests. In the towns and inland centres of population labour is plentiful, but far up-country it is the only difficulty. When the free immigration of Tamil coolies is finally settled, matters will go more smoothly. Permission is given by the home Government for their free entry, but an old Ordinance remains to be repealed by the Indian Government.

As to the tin-mining, that is indeed a speculation, and it has yet to be proved whether or not Europeans can profitably work tin with China labour in what is, to all interests and purposes, a China colony. The Chinese themselves make money, and at present have the chief number of the mines in their own hands. A little tin is worked by Malays in a very feeble manner. On the whole, the climate is good, the shade temperature at foot of the hills ranges from 64 to 90° Far. the latter not often felt. Game is plentiful and tigers are common; but little sport can be got on account of the jungle prevailing everywhere. The snipe-shooting is very good indeed, where the country is in the least open, near the river banks, and I have seen patches of chena at mid-day crowded with them, these patches are near the paddy-fields.—Perak, October 28th.—Cor. Local "Times."

TEA, COFFEE AND CINCHONA ON THE KAREN HILLS.

The *British Burma Gazette* contains an interesting report from Mr. J. Petely on the cultivation of Tea, Coffee and Cinchona on the Karen Hills, North-east of Toungoo, carried up to so late a date as the 12th of September last. Regarding tea we are told that "this produce has not been increased Considerable loss accurred since 1881 amongst the shrubs set out, owing to destruction by moles, crickets, and other causes, as shown in former reports, amongst both tea and coffee; vacancies have been filled up, and the total quantity of shrubs at this date are about 25,000. About half are yielding flushes, and the manufacture of good tea continues as heretofore on a small scale. The whole of them will probably yield next season."

The report of September 1881 on coffee "showed 3,447 bearing trees, 1,620 nearly bearing, and seedlings 29,638. These latter are coming on well, about one-third bearing maiden crop; in fact all up to two years' growth, with a sprinkling more or less. About this number has been kept up by filling in vacancies where the young plants have been killed by crickets. As the bulk of them are past the stage of liability to destruction from crickets now, a considerable increase of crop may be looked forward to for next season (December 1884). The yield of coffee in 1882-83 was 4,200 lb. It should have been more, but for loss from the attacks on the ripening crop by birds, civet cats, and other destructive animals. Sample of season 1881-82, sent to the London market, has been pronounced really good berry and of fair market value.

On cinchona the report tells us "about 1,500 trees (Succirubra) have been coppiced, and 500 uprooted of five to seven years' growth, the bark prepared and sent to the London market, 5,300 lb., dried and well packed. The 'quill' and large branch realized from 8½d. to 1s. 6d. per pound, a low figure, but good average and fair rates in the present glutted and very low state of the home market, competing favourably with other red bark. Small 'branch' and 'twig' gave dead loss, fetching only 1d. per pound as against 4d. for similar kinds sent last year. When the market was favourable and demand greater, a small lot of 300 lb. having been sent then as a trial shipment, 'branch' fetched 1s. 5*d*. to 1s. 8*d*. and 'twig' 4*d*. On the whole it appears that cinchona can be grown profitably on these hills, and with proper care in harvesting the bark in future, rejecting the unpayable small branch and twig, it is calculated to prove a fair investment. With this in view all available young plants and shoots have been set out this year, considerably increasing this produce. The coppiced stumps are mostly throwing out shoots freely, a pair only of which are kept on each stump for the future tree. The quantity now under cultivation is about 30,000 trees, plants and shoots. The products of the plantation all continue free from disease, and the climate is favourable to growth, especially mild during the rainy months. The thermometer is from 66° to 72° during the 24 hours, the extremes of heat and cold during the day and night being at one time very great, as at Toungoo and the plains. The young plants of cinchona, especially *Calisaya*, are coming on well."—*Englishman*.

QUEENSLAND.

After spending some months there and devoting my time to seeing the country, I will give you my opinion of its capabilities and prospects. The want of a suitable labour-supply cannot but militate against its success for some time, if not for ever. In no case can the labour-supply ever be so regular or so cheap as it is in Ceylon. The working man, who is beyond a doubt "boss" of the position, has a strong objection to the Indian labourer. Indian labour is an unknown quantity to him; he knows but little or nothing of it, and does not want to; he has an instinctive dread of it and contents himself with the dogged reply, to any attempt at conversion, "no black labour for me." I don't think there is any doubt that the present South Sea Island labour traffic will be suppressed. The labourers are undoubtedly happy and well-treated in Queensland, but I question if, in the first instance, they are fairly come by. So, as far as labour is concerned, the immediate future prospects of tropical agriculture in Queensland will receive a severe check. That coffee, tea, cinchona, and cocoa will grow in Queensland, I am quite satisfied. At Brisbane and Mackay, coffee is growing well and bearing, considering the severity of the winter in those places. The former is 600 miles south of the tropics and the latter only just in the tropics. My advice to any one desirous of trying coffee and cinchona in Queensland would be to go straight to Cairns and take up land 16 miles inland along the line of roads; there he will find soil rich enough for anything, and a suitable climate. For cocoa, one must go further north, above Cooktown, though I take it, the blacks are still troublesome there, and the climate somewhat unsuitable to the health of the European. I have heard Queensland spoken of by Ceylon men as a parched-up country. This may apply to the interior, but certainly not to the east coast, for there the rains are frequent and sufficient. I take it tea would do best on Hinchinbrook Island, where there is moisture, heat and soil. There is not, however, much opening for Ceylon men as planters in Queensland, even though the industry does go ahead. The colonial fancies himself too much, does not think he has anything to learn, and is quite prepared to leave the country and teach the Ceylon man *everything*, even planting itself. A Ceylon man might, however, do worse than settle in Mackay and make a beginning by taking up a homestead selection of 160 acres at 2s 6d an acre, payable over 10 years. On this he could build his home, do a little farming sufficient to supply most of his home requirements, run a few cattle and horses, and plant as much coffee as he could see his way to work, which, at 1s 6d. to 2s per lb., would repay a considerable outlay. I should have done this myself, as I intended to return to Queensland from this and settle there; but circumstances decided for me, and I am a settler here. Here, as in Queensland, one must be able and willing to turn their hands to anything, and it would surprize you what one can do when he tries. If his head is rightly screwed on, his muscles in order, and his heart of the right kind and in the right place, it is surprizing what a very presentable house a man can turn out for himself, buying his timber, planed and cut to lengths, as he can. One must take off his own boots here, and more; but then it is no effort to do anything in such a climate.—Cor. Local "Times."

RUBBER HARVESTING EXPERIMENTS.

It is contended that a cooly will be able to tap in the method proposed by Mr. Wall 300 trees in a day—that is practically 1 acre—so that if it is gone over daily for 240 days in the year, it will cost R84, at 35 cents a day for collecting alone. To this must be added—rolling in a ball, drying weeding, and sundry other expenses, which would certainly bring the cost per acre up to R120. If each tree gave half a pound per annum, 150 lb. would be the result for an acre of 300 trees; and were only R1·50 obtained for the rubber, as much as R225 would be the gross income, less R120 for upkeep, leaving R105 as profit. But very much more than R1·50 per lb. should be obtained, and doubtless will be, as the ball rubber and that of Mr. Gilliatt has been valued at R2 per lb. By the use of improved methods, which will inevitably suggest themselves as we proceed with the cultivation, not only may the cost of harvesting, which at present is high, be very sensibly reduced, but the quality of the rubber obtained be very much enhanced by the adoption either of some such simple process as "W." alludes to, whereby he obtains the clean looking balls of rubber, or by the use of some cheap spirit such as that used by Mr. Gilliatt.

There is a great deal of enquiry amongst planters at home with reference to Rhea, and I have heard several express an intention of trying it, provided they can obtain a supply of plants or seeds; but the question is—where can either be procured? I have had a long talk with Dr. Forbes Watson this week, but he naturally does not wish to forestall the lecture he was to deliver on the 12th January to the Society of Arts. Nevertheless, I have obtained from him one or two items of interest. He tells me that, though all efforts to procure fertile seed from Rhea in India have hitherto failed, it has undoubtedly been obtained both in China and Algeria, and Dr. Watson thinks it just possible that, with proper care, good seed might be gathered from the wild Rhea recently discovered in the Wynaad, though it is impossible to speak with certainty on this point, as the reason for sterility in other parts is rather obscure, some attributing it to the immaturity of the plants or seeds, and others to the absence of a peculiar insect by which in China the work of impregnation is accomplished. But, even without seed, the plant is very easily propagated, as the stems, if notched and laid in the earth will very speedily throw out rootlets, and then the roots spread very rapidly. Dr. Watson does not believe that anything like 40 tons of stems per acre per annum will be grown in Ceylon or India, as they say has been the case in Algeria. He points out that any plant that is asked to give three or four crops a year of great bulk must either be grown in exceptionally rich soil, or that is rendered so by manuring and high cultivation. It is a common mistake, he thinks, to suppose that Rhea will do well in poor soil. It will grow doubtless, but cannot be expected to bear anything like the weight named. He estimates 250 lb. of clean fibre per acre per crop, and the number of crops must depend upon circumstances. I am glad to hear that M. Vetittart has pronounced a very favourable opinion of the Wynaad Rhea, to the effect that under cultivation it would probably give a fibre equal to the best China Grass.

I have been favored with the following estimates for the creation and upkeep of a Rhea estate prepared by a Wynaad planter of long experience and high reputation, and therefore to be trusted; they will doubtless interest Ceylon planters, but they have reached me too late for any comment:—

ESTIMATE OF COST OF PREPARING GROUND AND PLANTING ONE ACRE RHEA PLANTS IN SOUTHERN INDIA.

Clearing land of undergrowth and small trees, digging oversoil, and removing jungle roots, burning roots and brushwood and surface draining ...	R25	0	0
Roads and watercourses for irrigation ...	15	0	0
Lining and planting 16,000 plants ...	15	0	0
2 Weedings	5	0	0
Native superintendence	12	8	0
Contingencies 10 ℔ cent	7	8	0
	R80	0	0
16,000 Rhea plants or roots—R5 ℔ 1,000...	80	0	0
Supposing buildings available, per acre ...	R160	0	0

It may be advisable for this permanent cultivation to terrace the slopes of the hills to save wash and facilitate irrigation, which would cost R25 per acre more.

ESTIMATE OF COST OF UPKEEP OF ONE ACRE RHEA PLANTS.

Rent of land and Government land-tax ...	R4	0	0
4 Weedings at R2·8 ...	10	0	0
4 Waterings at R3 ...	6	0	0
Manuring—R24 per acre ...	24	0	0
Native superintendence for 25 acres ..	12	8	0
Contingencies 10 ℔ cent ...	5	8	0
	R62	0	0

Sale of separated roots and cuttings will cover charge of amortization of original planting cost.

ESTIMATE OF CROP EXPENSES PER CUTTING OF 250 lb. FIBRE, OR 500 lb. RIBBONS.

Cutting and trimming off leaves ...	R3	0	0
Carriage to boiler or machines, @ R13·8 per ton per mile of distance ...	1	8	0
Cost of drying or baling ...	0	12	0
Or R47·4 ℔ ton of fibre ℔ 250 lb. ...	R5	4	0

R30 ℔ ton cost of carriage to coast for shipment.
Ribbons R45 ℔ ton approximate cost of steaming treatment.
Fibre R160 ℔ ton approximate cost of treatment by machine.
Ribbons worth from £15 to 20 ℔ ton.
Fibre worth from £45 to £50 ℔ ton.
—Cor. Local "Times."

THE DUKE MODEL ESTATE, TAVOY.

(*From Mr. James D. Watson, The Duke Model Estate, Tavoy, to the Director of Agriculture, British Burma, dated the 6th October 1883*)

I have now much pleasure in forwarding to you a report of the surroundings of Tavoy. I have already inspected over 20 miles down the Mergui road and from the point opposite the anchorage of the British Indian steamers where the S. S. *Aragyee* now lies at anchor, near to the Thayetc aung post office. I started off from the dâk bungalow at Thayetchaung and went up and over the "Pawdu Hill," the highest point there, and over the other hill adjoining. I was much pleased by the appearance and formation of the soil; it will compare with any in Ceylon, which has none so good at the same elevation. Like all tropical countries, it varies from good to bad to a certain degree, but in even the poorest soil in Tavoy we can grow tea, I am now certain, to perfection: in this fine moist forcing climate there is not the slightest doubt about this. Coffee we can also grow in the more favourable spots in a tract of land with good drainage. The coffee here planted by natives is no criterion, as they do not cultivate and they always plant it in flat land. This is altogether against the nature of the coffee plant, and we will improve upon this considerably. The natives only want to be shown how this can be attained. I have seen coffee near Tavoy 15 *years old* in a Burmese garden, and it will compare with any of the same variety in Ceylon. The trees were loaded with crop, bending down the branches to mother earth. We will succeed in coffee also; this is my honest opinion.

Cocoa.—In the flatter land we can grow cocoa. The soil in the flat lands is equal to that of the best cocoa lands I have seen, and I have been on the best cocoa estate now in Ceylon, namely, Palla Kellie. What will be most favourable to this most valuable plant here is this—we have no *winds*. Wind is cocoa's enemy, and I am certain we will grow this plant here to perfection. Ceylon cocoa now brings 100s. in the London market per *cwt.* I have myself ordered 2 *cwt.* of cocoa seed from Ceylon from Palla Kellie estate.

Cardamoms.—Cardamoms can also be grown with great profit; they are indigenous to the Tavoy district. On my way down to Thayetchaung, about 11 miles from here, Mr. Wallace, an officer in the Public Works Department, took me into the jungle and showed me cardamoms growing and bearing splendidly in a wild state,—large bunches of fruits nearly ripe. I will send you a book on this cultivation that will interest you.

Liberian Coffee.—Coffee, Liberia, we can grow. I am also certain to cope with any in other parts of the world. When down at Mergui I had the pleasure of seeing this valuable plant growing to perfection and now bearing crop,—a fair maiden crop. This plant we can grow at sea-level and in all flat lands. In this district it can be grown on the hills as well and up to 2,000 feet elevation with profit. I got a few plants from Captain Butler and I did not lose one. Although but small plants they are growing splendidly, also hybrid tea and coffee, Arabian: all doing well.

Cinchona.—I fancy that *Arakan* will be better suited for this valuable product. My fear is that in the Tavoy district we have too much rain. But I am going to give cinchona a fair trial. I have made a present of seeds to James Petley, Toungoo, and also Captain Schwalky and Theobald and Dixon, Natyadaung, also Captain Butler, Mergui, and yourself for Arakan, and directly I know people willing to take the trouble to give this plant a trial, I will give them seed and also instructions how to cultivate the same. I think we will succeed here with *C. succirubra* and *Ledgeriana*, and I am about to give them a fair trial.

Land.—Land fit for the cultivation of the different products can be had near to the now existing roads within from 6 to 8 miles, and I shall now suggest to you that the road to go into the interior ought to commence from Thayetchaung. There is a range of hills that runs almost east and west: the road ought to enter from the base of the Pawdu Hill. This you will see, I know, yourself directly it is pointed out to you: this will lead into virgin jungle on both sides and reach the hill known by the name of the "Cow's Hump." Planters would then have no excuse to complain. As "many men, many minds," so with planters; those that choose high elevation, there it is up to 4,000 *feet* and first-rate virgin soil: the distance cannot be more than 20 miles from there to this large, magnificent "Cow's Hump" hill, and this takes planters away from the sea.

Natyadaung is not fit for the different products that a planter has to give a written guarantee to your Government for. In my humble opinion it is *too near* the *influence* of the *sea air*, but the flat land can be turned to account there also for different other products that I shall refer you to hereafter if wished.

If you start from Thayetchaung and go right into the interior you have such a splendid field before you and a *road or rail* running direct for the wharfage and near to where large ships can safely lay at anchor. The great secret is not to make mistakes in starting a new enterprize. This has cost me a good deal of thought and hard tramping in wet and sun, and I have not put my hand to paper until I gave this important subject due consideration and balanced one side with the other.

This takes planters away from villages and it opens up the country grandly at little expense to the Government, and this will be a great boon for the planter: he can get his supplies of rice close at hand. A rice-mill can be put up here at little expense as timber is near, and a new town built: it will soon grow, merchants will follow the planters in due course, and difficulties will disappear if the right sort of hardworking men are put in power here, who will not throw difficulties in the planter's way but put aside all humbug and be fair between man and man.

Labour.—I find no difficulty about labour, but I find what the Chief Commissioner said to me to be correct, that is, that the maistries cheat and do much to discourage our labour. They are given contracts from Government, and instead of being looked after by the immediate supervision of the Divisional Officer, as is done in Ceylon, they are left here to, and in the power of, the contractor, who takes advantage of them in every possible way. We want to know our workmen and look after them ourselves; not to loll about in the morning, but be up by 5 A.M. and look after our different duties in the *field* until 10 A.M.; give them then a couple of hours at midday and see that they finish their different tasks by 5-30 P.M., and have every man on *our own "check-roll*," then one knows them and one knows their ways. The Burmese are a nice docile people, willing servants, and cheerful workmen, and we must study their ways and treat them just like children; and we will teach them yet that there is a sweetness in honest labour, and also teach them how to cultivate their hilly ground and improve the flavour of their different fruits. Directly they see the advantage of this they will do it with profit to themselves and advantage to your revenue.

I have also inspected the lands from Tavoy right into the heart of the jungle for 16 miles, and find that we can get land 9 miles from here well adapted for the cultivation of the different products I have now mentioned and an elevation from 1,500 up to 2,000 feet.

This morning I got up early and went to the end of the *Siam road* as far as the road is made passable, and I could see at a glance that there is a grand opening in this direction; nothing but hill and dale for miles and miles; soil free subsoil; just the country for all our products, and a splendid climate. I have never been in better health though out daily in sun and rain, and I find I can do just as good a day's work here as in Ceylon.

I fear this long letter will weary you, as it is of greater length than I intended, and if you choose you can publish it to the *world*, as what I have written are plain facts, and you can also put my name. I have already written to the *Ceylon Observer*, Colombo, and expressed my ideas of your grand country, and also expressed my thanks to yourself and the Chief Commissioner for the very kind way in which you received me.

TEA IN THE KANGRA VALLEY.

It is remarkable that whilst Tea is so universally used in England the public should know so little about it, and be, therefore, such indifferent judges as to what they should look for as the signs of a good article. There is a mistaken notion still abroad that "flowery Pekoe" is made of the white, camellia-like blossom from the bush, and that several species are cultivated to produce the various qualities of Teas. Many of your readers may feel an interest in learning something concerning the Kangra Valley Tea district and the method of cultivation, picking, and making of the Tea grown there. The exhausted leaves from their teapots will then guide them in their future purchases; when they have learned that in carefully-made and honestly-packed Tea there are no sticks or other incongruous matter, but simply the leaf of the cured, dried Tea which has opened and expanded in the water to something like its pristine state. All the kinds of Tea, which are described as Pekoe, Orange Pekoe, Pekoe Souchong, &c., are picked at the same moment, from the same stem, from the same bush. The barely developed little leaf, covered with a delicate down, which is just unfolding on the top of the spray, is to produce the finest Tea; the first perfect, but still tender leaves, the next; and the broader ones, lower down, the Bohea, or coarse Tea. These leaves are all manufactured together into Tea, as we shall see presently; and the best Tea to drink is, perhaps, the liquor derived from the mass as it stands. But the different sized leaves are all laboriously sorted by hand, after manufacture, before they are exported to the English market, to meet the requirements of the trade and in accordance with the China mode. These carefully sorted leaves have to be mixed again to make a Tea for actual use, such, for example, as Pekoe Souchong which is, perhaps, the best mixture; and some of the finest Tea goes to make coarse China Teas drinkable and fit for the market. The coarse Teas from the Kangra Valley are sold in India and are not exported to England, where we get the mass of our Tea concentrated, as it were, by this removal of all leaves of scanty strength and flavour.

THE KANGRA TEA PLANTATIONS.—These lie along the slopes of the North-West Himalayas, nestling at the feet of grand mountains of from 10,000 to 19,000 feet high, and comprising, between the Ravee and the Sutlej, 8,000 square miles of country. The district of Kangra proper, leaving out the sub division of Kulu, and the highly picturesque native states of Mundi, Sooket, and Chumba, extends from the Beas, where the natural watershed divides it from the Hooshiarpore district, to the boundary of the Mundi State, near Byjnath, on the one side, and to Noorpore on the other. It is in this lovely valley that most of the European Tea-planters have settled, and made around them comfortable homes and homesteads, which remind the sun-scorched visitor from the plains of India of far-off English farms. At the upper part of the valley, and lying opposite to a huge gorge in the mountains, from which the planters obtain their daily supply of ice in the summer, lies Palumpore, the head-quarter station of the Tea district, with its Government offices, rest-house, dispensary, planters' club, and beautiful little church. Palumpore, which is 4,000 feet above the sea-level, enjoys an excellent climate for eight or nine months in the year; during the other months the heat and rains are somewhat disagreeable, although admirably adapted to the growth of Tea. The beautiful little station is situated on a series of genely sloping knolls of green turf, thickly studded with Cheel trees (*Pinus longifolia*), and has the universal Kangra background of mighty mountains. The place is greatly indebted to the exertions of Sir Douglas Forsyth, who did a great deal for it and its immediate neighbourhood whilst he was the Commissioner of the district. His attempt to establish an annual fair at Palumpore, to induce traders from Yarkand and other distant provinces of Central Asia, to open up trade with British India, is a matter of history; and the causes of its failure are written in the records of the diplomatic offices of England and Russia. When land has been selected and purchased (no easy task in a district where, by a mistake in the settlement, a great portion of the waste, or uncultivated lands suitable to Tea were given to the natives, and where the bargains have for the most part to be made with the wily intriguing Hindoo), and whilst it is being cleared of jungle and prepared for a Tea garden, the seed for the future plantations must be sown. The original seed which was used in the district was introduced by Dr. Jameson, the official Government pioneer of Tea cultivation, who selected Hotta, Bawarnab, and Negreta as gardens, and sowed that seed which he had brought from the Debrah Doon, and which became so reproductive in the soil of the Kangra Valley that it now supplies the planters of its native Doon, and many of the younger Tea districts. H. H. the Maharajah of Cashmere has of late been a large purchaser of seed, for, not content with energetically pushing on the growth of vines and hops, his Highness seems bent at the same time on producing something with which his people may cheer themselves and escape inebriation. The seed is carefully removed from all Tea bushes in the garden during October and November by boys, girls, and women. A large yield of seed is an indication of something wrong in cultivation, or season, or soil. The planter's object is to grow as much new, vigorous leaf as possible, and cultivation suited to leaf production is not productive of an abundance of seed or fruit; and, therefore, all that advertising dealers and brokers tell the public about flower and seed is simple nonsense to those who understand the business, and have ever seen Tea grown and made. The ripe seed, which is picked in the autumn, has not shed its outer husk, and is sown entire as it comes from the bush in neatly-made nursery drills a foot apart and 4 inches deep, a shaded spot being selected for the seed bed, that it may be protected from the cold of winter and the parching heat of the full summer's sun. As the necessary decay of the seed takes place in germination, the outer husk decays and feeds the young plant. Although this care is necessary in raising seedlings in the comparatively temperate climate of Kangra, the hot steaming climate of Assam, where Tea is indigenous, produces all vegetation in such luxuriance that the seed has but to be dibbled into the land which it is permanently to occupy like a row of beans.

CULTIVATION.—The periodical rains commence in the Kangra district on or about June 15, and, if they be not too heavy, the seedlings may be transplanted to their places in the garden at the beginning of July. For this planting out, arrangements will have been made during the winter months. In rich soils, where the growth of the bushes will be quick and luxuriant, the seedlings are put in at greater distance from each other than in poorer soils, where the bushes will be longer in approaching each other. According to soil, these pits, $2\frac{1}{2}$ ft. deep by $1\frac{1}{2}$ ft. wide, are dug in rows varying from 5 ft. by 5 ft. in good soil, to 3 ft. by 4 ft. in poor soil, and into each of these pits from ten to twelve seedlings are planted. The coolies who put them in are drilled by a jemadar, or head-man; who takes his place and orders from the planter himself; and so well is the work done in this way that the plants are rarely an inch out of the direct line, or of the proper depth in the soil. Under the magic wand of English energy, what was but now virgin soil of the forest or the village common, or the arable land of the natives, is a young Tea plantation, and yet ready to be plucked, but growing wondrously fast, needing to be carefully terraced to keep the soil up, if it be on a slope, and to be sometimes irrigated in hot, dry weather. In three years the plants in good soil begin to be profitable, and need no further waterings, although they are not in full bearing for, perhaps, seven or eight years. During their minority each plant requires cultivation, constant hoeing, fairly liberal manuring, and judicious pruning. In November the winter cultivation of the mature bushes begins. Divisions of men—the strongest and possibly the least intelligent—are told off to hoe the garden throughout 1 ft. deep; and this hoeing work should go on all the year round with variations at different seasons of the depth of hoeing.

PRUNING.—Simultaneously with the hoeing, so that all that is cut off the bushes may go back and be buried in the soil, the pruning commences. As pruning is one of the most important works on a plantation, so is it one on which there is the greatest difference of opinion. A great many experiments have been made in the art, and probably planters have not yet learned all the science of the subject. Ten years ago an indiscriminate slashing off of the top of the bush and cutting three or four large holes into the body of the plant, to let in light and air, was the style of pruning most in vogue, chiefly on account of its fancied economy. By this method of pruning numberless shoots no doubt sprung up in the spring, but from the very fact of their being so numerous, the bush was choked up as to all after-growth, and became a mass of unproductive crows'-feet. Thorn pruning was next tried, and it may answer admirably in a cold climate, but certainly it is not the proper method for shrubs in high temperature, such as Tea requires, for they need protection from the sun and from electric and winter hail, without which the wood branches and the sap dries. Coppicing, as a last remedy for old woody plants, was then tried; but the remedy is a most severe one; the plant loses much strength by the inevitable bleeding which takes place, and consequently the new shoots it makes are weak and feeble. A new method of pruning which has been introduced into the valley is at present the approved one. The old, white, gnarled wood, and all the "whip-cord," is cut off entirely an inch or two below the surface of the soil in such a way as shall cause the bush to bleed as little as possible. Then all the long, straggling shoots are cut back, no matter how good their material may be; and lastly, all the shoots are cut back close to the finest and growing from the axilla of the leaf, which is left to act as shelter. Bushes of about 4 ft. in height are the most convenient for boys and girls to pick from, and some of the finest bushes in the Kangra Valley gardens are of this height, and 6 or 7 ft. in diameter. Pruning operations are going on from November to the end of the first week in March. Boys in India are almost always sharper and more active and willing than men. Strong, picked men cut out the thick, tough wood from beneath the s il, and the lighter purning is done by the boys. The best pruner cannot average more than twenty full-grown bushes in a day.—*Indian Agriculturist.*

TOBACCO OF COMMERCE.

(*Paper read before the Chemists' Assistants' Association, by C. E. Palmer.*)

My reason for selecting the words "Tobacco of Commerce" as the title of my paper is that there are altogether more than forty species of tobacco, but only about ten of them are to any extent used.

BOTANICAL ORIGIN OF THE PLANT.

All tobacco is derived from the genus Nicotiana. The nicotiana is a genus of the N. O. Atropacea, consisting of sticky-leaved herbaceous plants, natives of tropical America and Eastern Asia. The genus derives its name from Jean Nicot, a Portuguese, who introduced the tobacco-plant into France in 1560. *Nicotiana Tabacum* furnishes more than half the tobacco used in this country. The specific name is derived, according to Humboldt, from the Haytian word for the pipe in which the herb is smoked. *N. Tabacum* is a handsome plant attaining a height of 3 to 6 feet, with large oblong lance-shaped leaves, some of which are attached to the stem for some distance before they are given off (decurrent). These leaves are covered with minute hairs, on the summit of which a gland is situated, which secretes the viscid fluid that invests the surface of the plant.

The flowers are in panicles on the end of the stem; the corolla is more than an inch in length, funn - shaped, with a distended throat, and of a pretty rose or pink hue; this species is largely cultivated in South America, Virginia, China, Holland, and various parts of Germany and France.

The cultivation of tobacco is illegal in this country, except on a very small scale in a botanical garden, and has been prohibited by law since 1660.

N. rustica is the next important species, and is grown in the East Indies, Manila, and in other quarters of the globe. It is a smaller plant than *N. Tabacum*, has stalked ovate leaves, and a *greenish* corolla, with a cylindrical tube; it grows more quickly, ripens earlier, its leaves dry more easily, and may with some care be made to retain its green colour, which is quite impossible with those of *N. Tabacum.*

N. repanda is a native of Havana, its leaves clasp the stem, and the corolla is *white*, with a slender tube. This species is used in the manufacture of some of the most highly-esteemed cigars.

N. latissma is employed in the manufacture of Orinoco tobacco, but none is to be obtained now.

N. quadrivalvis and *N. multivalvis* have, as their names imply, four-valved or several-valved capsules; these species are chiefly used in the manufacture of cigars.

HISTORY OF TOBACCO AND SMOKING.

It is stated by Von Martius that the practice of smoking tobacco has been widely diffused from time immemorial among the natives of South America as well as among the inhabitants of the Mississippi as far North as the plant can be cultivated. Europeans first became acquainted with tobacco in 1492, when Columbus and his followers landed in Cuba, and they introduced it into Europe for its medicinal properties. The custom of inhaling the smoke was learned from the Indians, and by the end of the sixteenth century had become generally known throughout Spain and Portugal, whence it passed into the rest of Europe and into Turkey, Egypt, and India, notwithstanding that it was opposed by the severest enactments both of Christian and Mahommedan Governments.

The first tolerably-exact description of the tobacco plant is that given by Gonzalo Fernandez de Oviedo, Governor of St. Domingo, in his "Historia general de las Indias," printed at Seville in 1535. In this work the plant is said to be smoked through a branched tube of the shade of the letter Y, which the natives called "Tobacco."

It was not until the middle of this century that growing tobacco was seen in Europe, first at Lisbon, whence the French Ambassador, Jean Nicot, sent seeds to France (in 1560) as those of a valuable medicinal plant, which was even then diffused throughout Portugal. Monardes, writing in 1571, speaks of tobacco as brought from Spain a few years previously, and valued for its beauty and for its medicioal virtues.

The practice of smoking tobacco did not gain much ground among the nations of the North until Sir Walter Raleigh and his companions introduced it into England in 1586. At first it met with the most violent opposition. Kings prohibited it; Popes fulminated Bulls against it; and Sultans sentenced smokers to the most cruel kinds of death. Persecution, however, only helped to spread it, and at present smoking may be said to be universally practised by both civilised and uncivilised man.

COLLECTION AND PREPARATION FOR THE MARKET.

There are two ways in which the leaves are collected, viz., that in which the plant is cut off near the root, and that in which it is only stripped on its leaves.

1st. The tobacco harvest begins in August, when the plants are regarded as ripe. At this period the stems are cut off from the plants just above their roots, and then hung up in the drying-houses, where they are exposed to a considerable degree of heat, and during the process of curing, as it is termed, they become moist, or in other words are said to sweat. They are then further dried and stripped of the leaves, and the latter are then tied up in bundles called "hands," and packed for exportation. Leaves from South America are sent over in stout hides of cattle, which are there too abundant to be costly. Tobacco from North America and the West Indies comes in boxes, timber being there very plentiful; the Asiatics use strong coarse cloth of hemp or flax.

2nd. The plant is stripped of its leaves, which undergo a "sweating" process for four days by being placed in large heaps. They are then hung up in airy sheds to dry, again placed in heaps, and sweated for one or two weeks, and, while slightly moist, tied up in bundles called "hands," and put into barrels for exportation.

PRINCIPAL VARIETIES OF TOBACCO.

Returns, Virginia, Dutch, German, Kentucky, Bird's-eye, Irish roll, Cake tobaccos—From *N. tabacum*; from 6 to 7 per cent of nicotine.

Turkish - - From *N. rustica.*
Orinoco - - From *N. latissma.* Not to be obtained now.
Latakia - - From *N. rustica.*

N. repanda, cigars
N. quadrivalvis, cigars } From 2 to 3 per cent of nicotine.
N. multivalvis, cigars

Professor Thiselton Dyer has just proved that the Latakia tobacco which has hitherto been always supposed to be derived from *N. rustica* is prepared from the flowering pannicles, and even the capsules of *N. tabacum*, and that its peculiar flavour is due to being smoked for some months in the smoke of the wood of *Pinus Halepensis.*

M. Vidal, of Manilla, says that *N. Repanda* is not to be found in Cuba either wild or cultivated. All the Manilla plant is quite the same, having, indeed, been brought from Cuba.

MANUFACTURE.

The tobacco leaves having arrived in the bonded warehouses of this country, every hogshead or bale is opened, that the importer may be satisfied as to its quality; the net weight is taken for the calculations of the custom duty before removal, the waste, which is sometimes large, being consigned, together with the sweepings of the warehouses to the Queen's pipe, a furnace appropriated to the destruction of all contraband tobacco.

During the fermentation which takes place in the curing, nicotine and nicotianine are secreted from the juices of the leaf, and during the further fermentation in the manufacture of dried tobacco these properties are often dissipated, and carbonate of ammonia produced. The manufacturer's first business is to separate the leaves. In order to do this without breakage it is necessary to moisten the "hands" of tobacco; for, although it is said to be impossible (doubtful) to reduce the moisture below 10 per cent, yet even a much larger proportion is required to render the leaf pliable. The process of damping completed, the leaves are spread out singly, the central rib (which contains albuminous matters which would not be agreeable to the smoker) is removed by hand, and the right and left halves are smoothed and laid in a separate pile. The largest and stoutest leaves are selected for cutting and spinning; the most perfect in form are reserved for the wrappers and outside folds of cigars; broken or defective leaves are used as "fillers," or insides, of cigars. This work of stripping and sorting is generally done by girls and women, and, simple as the operation seems, it requires for its proper performance a degree of dexterity attained only by long practice. In removing the mid rib it is difficult to avoid tearing the leaf, which seriously deteriorates its value. The less torn the leaf used for cutting the longer and finer will be the fibre of the shag.

Tobacco-cutting is the process by which the fermented leaf is prepared for the pipe and the cigarette. "Shag" is the generic name of all the varieties which have passed through the cutting machine except *Cut Cavendish* or other cake tobacco, so cut to save the smoker the trouble of using his own knife.

Bird's-eye differs from the other kinds of shag only so far as it retains a greater proportion of the mid-rib of the leaf. As the leaf passes under the blade of the machine it is cut transversely, and the horizontal section of the mid rib, which is of a woody tissue and lighter in colour than the softer parts of the leaf, give the distinctive name of this variety.

There have been many mechanical contrivances for cutting tobacco, several of which may be found at work in English factories, but it will be necessary to describe only one. I select the combined pressing and cutting machine of Mr. Robert Legge, of London, because it is in much more general use than any other, and possesses the peculiarities which have been most approved of in the rest. It is now employed in about fifty London houses, all the Bristol factories, and other large towns in the country, in the Government manufactories of France and Portugal, and in many large establishments in Germany, Russia, and America.

This machine, receiving the bulk of the leaf in a trough or feeding-box, draws it inwards between rollers, which subject it to sufficient pressure to make the mass firm for cutting.

The lower roller is of large diameter and made of wood, so as to form a cylindrical chopping-block, on which the knife descends. The upper rollers are small and made of metal. They press the tobacco onwards from the feeding-box to the knife, and are so fitted as to yield according to the thickness of the feed. The rollers revolve in unison with the strokes of the knife, which determine the fineness of the shreds into which the leaf is cut. One of the largest of these, driven by two-horse power, will make 300 cuts per minute, and turn out 200 lb. of fine shag, or 400 lb. of the description called French cut, in a single hour. The cut tobacco, when removed from the machine, is placed on trays (usually of copper) heated by gas-flames, and these tossed about and shaken by hand until it is sufficiently lightened to be fit for smoking. The chief difficulty to be overcome in all attempts to expedite tobacco-cutting is the clogging of the machinery by the mucilaginous juices of the leaf, and the strict Excise regulations, intended to prevent adulteration, forbid the admixture of any substance that might reduce the obstacle.

ROLL, OR TWIST.

This is a preparation of tobacco which is made by first spinning the leaf into the form of a rope. There are several varieties, some coarse and thick, like pig-tail or Limerick twist, others thinner and of finer grain, called "ladies' twist," or, because of its lighter colour, "brown twist."

CAKE CAVENDISH.

This was until recently a forbidden manufacture in this country, its importation being legalised only as lately as 1863; and so long as the Excise laws exclude sweetening matter from the preparation of tobacco, it is not likely to become general. Under a special Act of Parliament the Richmond Cavendish Company is permitted to produce sweetened cake tobacco, but, as all its operations are carried on in bond, the manufacture is limited. Where, as in the Richmond Company's works at Liverpool, the sweet ingredients are added there is no essential difference between the foreign-made and the British-made article. This sweetened Cavendish is made from the best Virginian leaf cured in the ordinary way, with the addition of treacle, sugar, liquorice, and other flavourings, and pressed into cakes of various sizes. Unsweetened Cavendish is produced in various factories under the same regulations as other kinds. In this case the tobacco is quite equal to foreign Cavendish for all smoking purposes, but chewers prefer the sweet taste of that prepared with sugar. The process of manufacture is exceedingly simple, but to meet the mechanical difficulties attendant upon expelling air and moisture from the leaf, and forcing the fibrous particles into a more or less homogeneous mass, hydraulic and other contrivances have been brought into play. Cake tobacco is made from ordinary shag, which is wetted and made into a mass, then pressed into moulds to ensure uniformity of weight until the parts adhere firmly together; girls next enfold it firmly in wrappers of perfect leaves; the cakes are then passed through a series of moulds, each smaller than its predecessor, increasing pressure being employed by hydraulic-power until each cake is turned out dry and hard, ready for the ornamental wrapper which finally receives it.

By this time the juices of the mass have been evenly distributed throughout the whole, giving it the rich, dark colour which smokers prefer.

Those kinds of Cavendish which are lighter in colour are prepared in precisely the same way, but in a dryer state.

CIGARS.

In giving some account of the manufacture of cigars I may be allowed to point out the fallacy which lies at the root of the popular preference for the cigars of Havana. It will be granted that some Cuban tobacco is the best tobacco, and, of course, when worked by the best manufacturers, makes the best cigars; but it cannot be said that the cigar-makers of Cuba are more skilful than those of Great Britain, or that they have a monopoly of the best tobacco. It is a known fact that only a very small quantity is imported from Cuba in any shape, and it is notorious that much of that which is exported from Cuba is not grown there. Cargoes of leaf are shipped from America and from

Europe, manufactured into cigars there, and sent back as Havana cigars to the countries where the leaf was grown.

The Cuban manufacturers are allowed to use what sauces they like; to this is to be attributed the superior colour or gloss, and the delightful fragrance which characterise Havana cigars when first brought over here. In skill the British cigar-maker can match the world.

The cigar-maker when at work is seated at a bench of table, and his tools are a sharp knife, a gum bottle and brush, and a flat square piece of wood called a cutting-board. He spreads on the cutting-beard a perfect half-leaf of tobacco, trims it with his knife into the shape most convenient for the wrapper, or envelope, of a cigar; he then takes in his right hand a bunch of less perfect leaf, or "filler," and rolls it into a long oval form with his fingers, then encloses it tightly in the wrapper, rolling the cigar under his left hand till the taper end is formed, gums the leaf firmly at the tip, and cuts the blurred end square with the knife to complete the operation.

Expert workers are able to gauge the requisite quantity of leaf for each cigar so accurately that the weight given out for 1 lb. of medium size is seldom found to exceed or fall short of the required hundred, strict uniformity of appearance being preserved.

Many machines have been devised for performing this work, but none altogether supersede hand labour. The cigars when made are examined and sorted according to the shade of colour of the wrapper. "Full-flavoured," "medium," and "mild" may thus come out of the same batch of material, the distinction lying in the greater or less pungency of the outer leaf. Having been sorted, the cigars are tied in bundles of fifty with slips of ribbon, placed in cedar boxes, labelled, closed up, and sent to the drying room, where they remain until sufficiently seasoned for smoking. The time required for drying varies from a few days to several months.

SNUFF,

when pure, is merely ground tobacco scented with otto of roses, oil of geranium, oil of bergamot, Tonquin bean, and oil of pimento. It is largely adulterated with starch, rice, oxide of iron, powdered logwood, mahogany; black, white, and cayenne pepper. Refuse roots, such as rhubarb and gentian, and senna, oak, and ash leaves are frequently used to adulterate snuff. Pearl ashes and ammonia are sometimes added to give pungency to snuff.

COMMERCE.

Of all the varied products of the earth tobacco is the substance most universally used by mankind.

The weight imported into Great Britain and Ireland with the knowledge of the Customs authorities in the years 1880, 1881, and 1882 is given below:—

	1880.	1881.	1882.
Unmanufactured ... lb	59,548,877	47,385,480	35,890,472
Value	£1,756,742	£1,390,800	£1,174,969
Manufactured and snuff lb	3,694,994	3,070,432	4,070,816
Value	£1,144,159	£1,231,802	£1,388,220

Retained for Home Consumption.

	1880.	1881.	1882.
	lb.	lb.	lb.
Unmanufactured	48,261,775	48,481,049	49,055,938
Manufactured and snuff ...	1,309,436	1,339,444	1,450,198

In England we consume about 1 lb. 8½ oz. per head of the population. In British Burma, where men, women, and children smoke, the consumption is 7 lb. per head, as compared with 1 lb. per head in India. The revenue derived from tobacco and snuff constitutes one-tenth of the entire revenue of this country. Revenue for the year 1881-82 from all sources, 85,822,281*l*. Of this amount tobacco and snuff yielded 8,838,176*l*.

ADULTERATION.

Notwithstanding the stringent laws of the Legislature the adulteration of tobacco is very common.

The enormous duties added by the State to the cost of tobacco are a strong temptation to the use of cheaper materials when they can be easily disguised, or with difficulty detected. When what is called cheap shag can be brought at 2*s*. 8*d*. per lb. in the market, it is evident that it cannot be all tobacco which has paid the duty of 3*s*. 6*d*. per lb., especially as a sound tobacco from which good shag can be made can scarcely be got for less than 5*d*. or 7*d*. per lb. Water is most largely used for adulteration. All the adulterations employed, however, are not so harmless as water; others use liquorice, gum, logwood, calomel, and salts of iron, stramonium, coltsfoot, beech, &c. These are best detected by the microscope. The use of otto of roses, orris root, oils of neroli and bergamot, Tonquin beans, &c., to perfume cigars is illegal.—*Chemist and Druggist.*

IMPORT OF JUTE INTO GERMANY.—According to the *Central-Blatt für Textil Industrie*, six full cargoes of jute were discharged at Bremen during the first nine months of 1883. Four of these were imported from Calcutta by one large German manufacturing establishment. The total quantity of jute thus received was about 60,000 bales, worth £175,000. —*Journal of the Society of Arts.*

HOW TO MAKE COWS GIVE MILK.—A writer in the *Southern Farmer* says that his cow gives all the milk that is wanted in a family of eight, and that from it, after taking all that is required for other purposes, 260 pounds of butter were made this year. This is in part his treatment of the cow: "If you desire to get a large yield of rich milk give your cows every day water slightly warmed and slightly salted, in which bran has been stirred at the rate of one quart to two gallons of water. You will find, if you have not tried this daily practice, that your cow will give twenty-five per cent more milk immediately under the effects of it, and she will become attached to the diet as to refuse to drink clear water unless very thirsty. But this mess she will drink almost any time and ask for more. The amount of this drink necessary is an ordinary water pail at a time, morning, noon, and night."

A TALIPOT PALM FLOWERING IN ITS TWENTIETH YEAR is thus noticed in the Proceedings of the Madras Agri Horticultural Society:—Read letter from W. S. Whiteside, Esq., dated 7th October 1883, stating with reference to the account of the Talipot palm in the Proceedings of the Society of 25th March 1882,* that in January 1862, when he was Under-Secretary to Government, he occupied the house in Teynampett, where Mr. Arundel now resides, and planted in the garden two Talipot palms, one of which has disappeared, while the other is now a thriving young tree; and that when put in the ground they were small plants with only two or three leaves. Recorded with many thanks for the information. The tree which has disappeared, was the tree referred to as bearing fruit in 1881, "in a compound by the side of the Mount Road," and was probably only 20 years from the seed, instead of about thirty years as supposed, a fact which renders its precocious fruiting the more surprising. It is also remarkable that the twin tree is still growing vigorously without signs of flowering.

Correspondence.

To the Editor of the Ceylon Observer.

CEYLON SEED NUTMEGS.

8th January 1884.

DEAR SIR,—In the interest of planters in general and *Indian* ones in particular, I write to warn them against purchasing Ceylon seed nutmegs for trial as a new product

I recently purchased a considerable number, which I was assured were quite fresh, for trial on my estate.

On writing to a friend, a planter of long standing, mentioning what I had done, he in reply said:—"It is to be hoped that you have purchased nutmeg plants, and NOT seed, as sometime ago a friend and I were induced to purchase a large number of so-called fresh nutmegs from Ceylon; they were put down very carefully in a nursery according to directions received, but not a single nutmeg germinated. Some little time after, we purchased another batch from what we were told was a reliable source, with however the same result. They were all BOILED evidently before being exported."

My experience being precisely the same, I think that planters thinking of speculating in seed nutmegs for trial should follow *Punch*'s advice to those about to marry. Don't!!—Yours faithfully,

ANTI-HUMBUG.

I enclose my card.

[Our own experience is that nutmeg seeds are very difficult of germination, and of course the difficulty is increased by export and delay. The idea of the nutmegs having been boiled is simply idiotic.—ED.]

CARDAMOM POOCHIES.

Munzerabad, 21st Jan. 1884.

DEAR SIR,—A friend of mine, a Mr. Gilden, found certain insects *inside green* cardamoms, and we were puzzled to know why they should have been formed in unripe capsules; so we referred the matter to a scientific authority in the person of a planter near this, well-known to you, whose name is at the foot of the following letter. I send this on to you for the information of your readers.

Would you enquire if the Sinhalese have any objection to cutting bamboo in moonlight?

AB RDONENSIS.

I have recently examined some unripe cardamoms, which had suffered from the depredations of a minute insect, and having noticed that frequent inquiries have been made relative to it in the *Ceylon Observer*, I venture to make the following remarks:—

The insect is a very small beetle (order *Coleoptera*) of a dark, brown or black colour, and is in my humble opinion identical with the Canarese "cootay" which attacks numerous jungle woods, etc., after felling. Among these I may mention:—

Watties (basket reeds).
Ooprantee (*Hernandia peltata*).
Benday (*Eriocarpus aimmoanus*).

"All such insects undergo a complete metamorphosis. They issue from the egg in the shape of a grub, which in many species is very destructive to plants and wood. In time they assume a pupa form; others emerge as perfect beetles." (Maunder.)

In the case of the cardamom, I think the fact that I have found the insect in the larva and perfect state inside the capsule suggests the probability that the female punctures the outer skin and lays its eggs therein, and the grubs feed on the immature contents of the cardamom and having passed the pupa state emerge as perfect beetles by the small round hole.

The natural enemies of these are birds, toads and lizard (Lacertinidæ).

Warm spots are most favourable to insect development. The natives of Mysore take the precaution to cut watties and bamboos when there is no moonlight. It might be found possible to bestow some care in this direction when clearing wattie ravines. GRA. ANDERSON.

[Our entomological referee states:—"I do not recognize the beetle described by Mr. Anderson. A year or more ago, you sent me some cardamom pods that had been penetrated, and seeds eaten by a wire-worm. Mr. Anderson does not say why the natives of Mysore take the precaution to cut watties and bamboos when there is no moonlight. Until we know this, we cannot tell whether there is any good in it, or a mere superstition." The closing remarks were in reply to our suggestion that not cutting bamboos on moonlight nights was a mere superstition. On a clear moonlight night, it is cool because of the radiation of heat, but we cannot see how that can affect bamboos or insects.—ED.]

SUGAR CULTIVATION IN CEYLON AND ELSEWHERE.

Baddegama, 7th Feb. 1884.

DEAR SIR,—With reference to Mr. H. W. Green's letter in your issue of Jan. 31st, *in re* rotation of crops on this estate, I did not mean to convey, in my conversation with that gentleman, the impression that I attributed the failure of other sugar estates in this island entirely to non-rotation of crops. I do not know their history sufficiently well to allow of my giving so decided an opinion.

With the exception of "Shandon" estate on the Gintota river, I should be more inclined to attribute the failures to climate and insufficiency of rainfall (which I do not think should average less than 90 inches per annum). Wray, on page 48 of his "Practical Sugar Planter," says:—"The climate most congenial to the sugar-cane plant is of a warm and moist character with moderate intervals of hot dry weather attempered by refreshing sea-breezes. It has always been found to grow most luxuriantly on islands and along sea-coasts of mainland, which leads us to conclude that the saline particles borne on the sea-breeze exercise a powerful effect on the growth of the plant. The influence of the sea-breeze, however, is exerted in many ways; as by imparting moisture to the soil even in the hottest weather and driest season, by supplying to it the major portion of the saline matter borne inland, and by affording to the leaves of the cane matter for assimilation, add to which the abundant dew, which it decidedly affects."

With regard to the density of cane-juice in this island, you are quite correct in putting it at 7° to 8° Beaumé. I have occasionally registered it 9° here.

The quantity of sugar contained in cane-juice, in volume and weight (as calculated by Dr. Icery of Mauritius, see the *Sugar-cane* for Sept. 1869), the degrees of density being according to Beaumé at 77° Fahrenheit as follows:—

Degrees Beaumé.	Crystalizable sugar per gallon of juice.	Weight per cent of crystalizable sugar in juice.
7°	1·05	9·9
8°	1·31	12·3
9°	1·59	14·9
10°	1·88	17·4
11	2·17	20·0

Rich clay soils, mixed with sand (siliceous) and decayed vegetable matter and soils formed by decomposition of granite are about the most suitable for the sugar-cane.

The following analysis of a virgin clay soil of Demerara (analysed by Dr. Phipson, see the *Sugar-cane* for Dec. 1879), and which may be taken as a type of Demerara clay soils generally, may interest you and your readers.

Water	...24·18		...97·32
Organic matter	... 7·87	Phosphoric acid	... 0·10
Silicate of Ammonia and Silica	...64·42	Sulphuric acid	... 0·08
Lime	... 0·44	Chlorine	... 0·05
Magnesia	... 0·29	Oxide of iron, Alumina etc. (soluble in HCl)	2·45
Potash and Soda	... 0·12		
	97·32		100·00

—I am, yours faithfully, S. E. B. CURTIS.

[It is curious that Mr. Curtis should have attributed previous failure to deficiency of rainfall, while we thought too great humidity was the real cause, in preventing crystallization.—ED.]

IRON AND BRICK AS CONDUCTORS AND DIFFUSERS OF HEAT.

DEAR SIR,—Before replying to Mr. Cameron's remarks in defence of his "drier," it seems to me a special tribute is due to his philosophic spirit. It is not often one sees such a calm and philosophic defence of a great scheme ; also he is to be commended for having put the matter into a debateable form.

The chief points on which Mr. Cameron differs from the "Clerihew" plan are in the use of brick rather than iron ; and drawing, with his fan, the air *up*, instead of *down*.

The use of brick, instead of metal, for the *transmission* of heat is contrary to all custom. The problem is to transfer the heat from the fire, smoke, etc., through some medium that will keep in the smoke and only *transmit* the heat to the air outside of it.

Now, in practical works of all sorts, brick is used because of its low diathermous quality to *retain* heat. To prevent heat passing from their boilers to the air outside, engineers cover them with brick. The baker uses brick for his oven, because it returns the heat *inside*, and does not let it out. Smelters of iron use brick for their furnaces ; and while the heat inside is far above the melting point of iron, the outside may be touched with the hand.

Mr. Cameron very properly puts the case as to be tested by the temperature at which the fire-heat leaves the heating flue for the chimney.

He says : "By my design the loss of the fire-heat is at drying-house temperature." Is it so ? or anything like it ? Suppose the *outside* of the brick of his flue at the exit to the chimney be at drying-house temperature, say 90°, what will the *inside temperature* be. The experiment can easily be made, and, I think, I may safely say that, when the outside of the brick (that is, the side furthest from the heat) is 90°, the inside will be far up in the hundreds. For not only is brick's diathermous quality, when compared with iron, as 1 to 30, but the brick is 3 or 4 inches compared to a half-inch of iron, which increases the advantage of iron from 30 to 1 to 6×30 or 180 to 1, supposing the figures correct.

The next point is "up or down." If Mr. Cameron will make the experiment of kindling a fire on the floor of a large room, he will note that soon a *current* is established of heated air, smoke, &c., upwards. When the smoke reaches the roof, it gets cooled, by contact with the roof and in other ways, and begins gradually to spread out, filling the room from the roof downwards. But it is not the heated air from the fire that is kept lowest. The current of smoke from the fire goes continuously through the heavier smoke to the roof, and occupies the space next to it. If a hole be opened in the roof, there will be established a *current* from the fire to it, through among the heavier smoke, the hotter and lighter going first, and the heavier last. Now, what is wanted is to remove the cold air that has done its work in drying, and an experiment on smoke will show that that can be done most effectually by driving away the coldest from below.

Or, if Mr. Cameron tests his plan with a thermometer, he will find that there is a *current of the hot air from the hottest part of his flue taking the easiest course to the fan*, and the rest of his drying-room is filled with comparatively cold and saturated air, as the "wet and dry bulb" thermometer or other hygrometer would show.

Hoping I have not trespassed on your space more than the value of the question at issue deserves, I remain, yours truly, J. B.

[The discussion is most interesting and valuable, and has an immediate bearing on a question which has been raised regarding economy of fuel in producing heat in tea-driers. One of Jackson's in use on Abbotsford does its work well, but the consumption of wood fuel is equal to 4 lb. for 1 lb. of dried tea, while it is claimed for other driers that 1 lb. of fuel will suffice for each pound of tea. We gather that the remedy in the case of the Jackson lies in a judicious use of brick, so as to concentrate the heat where it is specially wanted?—ED.]

MR. GRAHAM ANDERSON ON FUNGOID DISEASES AND ARTIFICIAL MANURES.

Mysore, 24th January, 1884.

DEAR SIR,—In a recent issue of your invaluable *Tropical Agriculturist* you published a letter recommending superphosphate as a remedy for "rust" in sugarcane, and in your note you inquire if anyone has noticed a similar beneficial effect on coffee suffering from leaf-disease.

Many months ago, I had the pleasure to hand you a memorandum of my humble conclusions in regard to the effect of certain manurial preparations containing phosphates and alkalis, and, in my letters dated 10th March and 26th June 1881, I ventured to point out the widely different results obtained by the use of chlorides, nitrates and sulphates. Subsequently, you were also kind enough to publish another letter of mine relative to the benefits derivable from the careful selection and change of seed.

These papers were supplementary to an essay which I had written on fungoid disease, in which I advanced a theory, founded on observations made on coffee for several years past, that the presence of food congenial to the life and requirements of the parasite occurs during a peculiar transitory state of the starchy and sugary constituents of the cell-sap arising in all probability from a deficiency of alkalis and phosphates in an *available* condition in the soil.

This essay was submitted by the Government of Madras for opinion and report to the Conservator of Forests and the Superintendent of the Government Central Museum.

I need scarcely say that the view expressed by the Conservator of Forests on my humble suggestions did not tend to stimulate me to proceed with my investigations, but I was specially grateful for the encouragement extended to me by the valued remarks made by Surgeon-Major Bidie, C. S. I.

After having read the Forest Conservator's report and compared it with the result of the Governmen

Cryptogamist's investigations, I confess I had not the courage to write any more on the subject, as I well knew that botanically speaking Mr. Marshall Ward's conclusions were absolutely perfect.

During last season, having still the courage to believe that fungoid pests can only attack plants during a period (which may be either limited or prolonged according to inmate peculiarity of constitution or to concomitant circumstances) during which, from some cause or other, some vital function is held in abeyance, I adopted measures for placing 2,400 plants under experimental observation and applied to them twelve different artificial mixtures in conjunction with cattle manure.

Although I am not yet prepared to generalize on the results obtained, still I personally feel confident that my very humble experiment has demonstrated one fact with certainty; and that fact is that each of the various chemical mixtures has produced a distinctly separate effect.

A feeling of profound diffidence is only natural when one remembers that each square mile of country may have and generally does have separate and special requirements, and that measures which are simply carried out because they had succeeded so well in one locality are very apt to prove disappointing in another or even to induce unexpected complications which will take much time and money to remove.

The preparations used by me were as follows:—

- Bonedust.
- Mineral phosphate.
- Oilcake and refuse.
- Lime.
- Sulphate of potash.
- Do of magnesia.
- Do of ammonia.
- Do of lime (gypsum) and (acidulous).
- Nitrate of potash.
- Chloride of ammonia.
- Kainit.

Some of the mixtures from want of skill on my part were evidently too stimulating; some tended to make the trees run too much to crop, others to foliage; but I am at least thankful to say that my venture was so far a success as to enable me to state without hesitation that the experimental block cropped far heavier than any other portion of the 500 acres under my management.

After pruning and next blossom, I hope to be able to judge better than I can at present, but I venture to express an opinion that kainit, containing as it does a large quantity of chloride, requires considerably more skill to use to advantage against leaf disease than some other forms of potash.

The addition of gypsum appears to facilitate matters, and as kainit is so cheap, I consider it is well worth the trouble to make another set of experiments in order to gain reliable information as to how it can be utilized with success in conjunction with some of the economical descriptions of nitrogenous manure which are locally available.

I feel disposed to hazard the opinion that where potash has not given satisfactory results it may possibly have been owing to the form in which it was applied or to the amount and availability of the nitrogen which accompanied or succeeded its application.

We essentially require a slowly acting preparation, if we apply manure early, but we must as carefully guard against a check as against a stimulant.

I have only very recently had the good fortune to obtain a copy of M. Ville's delightful work on artificial manures, and, while most respectfully recommending it to the attention of my brother planters, I beg to be permitted to again endeavour to show cause why that most delicate of all operations, the investigation of the nutrition of leaf-cells, should be regarded as an essential part of any attempt to unravel the mysteries connected with the appearance of fungoid pests on cultivated plants. M. Ville clearly confirms the statement that phosphates are indispensable to sugarcane and gives an account of a most interesting experiment conducted by M. de Jabrun at Guadaloupe as follows:—

		tons.	cwts.
Normal manure	...	23	0
Manure without Lime	...	20	0
Do do Potash	...	14	0
Do do Phosphate	...	6	0
Do do Nitrogen	...	22	8
With no manure	...	1	4

Professor Schrottky, has already announced his opinion that superphosphates, nitrates and chlorides appeared to increase the tendency to leaf-disease, whereas phosphates, sulphates, &c., had an opposite effect.

Now this conclusion was arrived at by experiments most carefully conducted, not by applying these substances to the *soil*, but by a process of inoculation or introduction through the cambium cells.

M. Ville's researches in regard to the requirements of beet-root would however lead one to conclude that everything depends on having a well-balanced mixture, and this is precisely also the experience which I have gained from my humble little experiments.

In applying a chemical manure, the difficulty appears to be to find out how far we may trust the soil to come to the rescue. If we trust to the soil to supply alkalis we may very probably discover that we have trusted in vain, and, hence, where superphosphate has been applied by itself or in conjunction with cattle-manure to a soil deficient in alkalis or too rich in iron, its effects have been most disappointing, whereas a simple mixture of bone-dust and cattle manure always maintains a well-earned reputation as the safest and best of all applications to coffee.

Now, we are told that phosphate is the dominant constituent of sugarcane and we have also learnt that its application (under fitting conditions) has had an appreciable effect in checking an attack of "rust"; I fail therefore to lose confidence in the efficacy of judicious constitutional treatment in tending to lessen the liability of coffee to attacks of *Hemileia vastatrix*.

Potash is the dominant constituent of coffee, and I still venture to maintain my long-cherished opinion that leaf-disease is only a temporary embarrassment which can be overcome by the following means:—

1. The application of slowly acting phospho-nitrogenous manures in conjunction with alkaline preparations early in the season.
2. Rapidly acting chemical manures in the form of light-dressings during the monsoon and composed of such substances as an analysis of the soil and due appreciation of the effects of climate and culture shall indicate as desirable or necessary.
3. Due regard to the importance of maintaining the soil in good mechanical condition.
4. Increased attention to the matter of change and selection of seed with a view to obtaining increased root-developing power.

I avail myself of the opportunity to append some valuable extracts from M. Ville's delightful book and from other authorities in the hope, now that topical applications have had a fair trial, someone far better able than I can ever expect to be may be induced to make a few more experiments in regard to the likes and dislikes in health and debility of the plant, which for the last 21 years has afforded me a most comfortable livelihood, and the cultivation of which I still have every reason to regard as constituting one of the safest of all investments for capital, but which, nevertheless, has special requirements which, under the varying influences of soil, climate and culture, take time and experience to arrange for.

I sincerely hope that the investigation of the causes of fungoid visitations generally may soon enter upon a new phase and venture to predict that if the physiological purposes for which lime, phosphates and alkalis are required in plant-life are carefully determined, it will be found quite as possible to prevent certain soluble transition products in the leaf-cells being preyed on by microscopic parasites as to render the starchy gloss on Manchester piece-goods proof against an attack of mildew.

GRAHAM ANDERSON.

[The extracts to which Mr. Anderson alludes are given below. When M. Ville's book appeared, we reviewed it fully and made copious extracts. Subsequently Lawes disputed his theory that farmyard manure could be entirely dispensed with.—ED.]

(*Extracts.*)

MANURES.

Effect Consequent on a Want of the Dominant Constituent.

"Who does not remember the terrible effects produced in Ireland by the potato disease at the time of its first outbreak? I shall say nothing of the explanations that have been given of these formidable scourges. Whether the parasites are the cause or the effect of the evil, whether they owe their origin to microscopic germs floating in the atmosphere, or result from the evolution of cells of certain tissues which become independent of the relatively superior organism of which they form a part, and live henceforth a life of their own; whatever be the explanation that is generally accepted, one certain fact, inflexible in its manifestations, governs all, viz., that the absence, or, at any rate, the scarcity of the soil of certain elements indispensable to the life of plants, multiply if they do not absolutely give rise to those diseases of which we have just been speaking. For six years, these phenomena at Vincennes have not changed. Wherever the soil does not receive potash, or where it gets no manure, the plants are poor and stunted with withered and dry black leaves, and that too in the month of June, when the other plantings are still in a state of luxuriant growth."

"Vines are subject to similar effects, and although my experience is less extended in this direction, it enables me to be equally positive. Where potash is lacking, the leaves do not attain their full development; in the month of July they become red and spotted with black, after which they become dry and are easily reduced to powder under the pressure of the fingers."—VILLE.

"Besides this, the lack of potash in the soil is coincident with the appearance of potato disease, whence we may draw a second conclusion that when plants are deprived of their dominant mineral constituent, and consequently of one of the most essential constituents of their existence, they become the prey of inferior organisms such as microscopic fungi, aphides, &c. We have here a startling and unexpected explanation of the cause of one of the most terrible plagues with which the farmer has to fight, namely, plant diseases. For many years the same phenomena have been reproduced at Vincennes with invariable regularity. Until the end of May, besides the very marked differences in the size of the plants in the different plots, nothing striking seems to indicate the great change which is on the point of taking place. The change first manifests itself about the middle of the month of June, and invariably begins with the plot which had received manure in which the potash has been suppressed, as well as in that which has received no manure at all. The plants in the plots which have been dressed with normal manure are luxuriantly green, but those in the plot which has received no potash, and in that which has received no manure at all, a number of copper-coloured spots begin to make their appearance and shortly afterwards begin to spread very rapidly, gradually extending themselves over the whole of the foliage and drying up the plant as if a burning wind had passed over it."

"Until lately, I always thought that the leguminosæ and the potato were the plants which showed a special preference for potash, but the vine distances them in this respect in a most surprising manner. In the case of the potato the suppression of potash manifests itself by a diminution of the crop; with the vine, however, little or no fruit makes its appearance, and we virtually get no crop at all. The vine itself barely sends forth two or three feeble shoots, and the few shrivelled leaves are hardly as large as a crown piece, whilst those of the plants which have been dressed with normal manure are as large as a man's hand. In the plot without potash the leaves first turn red and then black, drying up and shrivelling like those of the potatoes which have received the same treatment."—VILLE.

Special Manures and Necessity for having a Well-Balanced Mixture.

"On one plant in particular, viz., beetroot, I have varied my experiments *ad infinitum*, in the endeavour to increase its saccharine richness, and have three times out of five, obtained richer roots with potassic chloride associated with ammonic sulphate than with potassic nitrate. These first experiments justify my hope of one day seeing specific functional manures practically applied. We will now pass from the general classification of manures and their reciprocal relations to the study of the rules to be observed in selecting the formulæ best suited to each kind of plant. These rules are necessarily a repetition of those which I have already laid before you, namely, to know the dominant constituent of a plant, the proportion it is necessary to employ, and the proper proportion of the subordinate constituents."—VILLE.

Necessity for Careful Selection and Change of Seed.

"All the different species are susceptible of certain changes which are capable of becoming hereditary. Races and varieties have no other origin. Unimportant in a botanical point of view, these deviations often become of great importance in agriculture, because, under the same conditions of soil and manure, one variety often produces twice as much as another.

"For three years I grew parallel patches of wheat, one being English red wheat, the soil and the manure were the same in both cases. The English wheat throve wonderfully, whilst the other, notwithstanding the great care taken with it, turned out badly.

"During the autumn it always showed a marked advantage over the English soil, but in the spring, although some late frosts occurred, it was attacked by rust, whilst the English corn being less advanced took no harm whatever." —VILLE.

(SEED CORN.)

(*Extracted from the "Field," 13th October 1883.*)

The selection of seed most suitable for climate and soil is a subject of grave importance to the English farmer, inasmuch as the success or failure of our crops depends in a large measure on our judgment in this matter. We are mostly aware of the influence of selection, and our faith in the value of pedigree corn in transmitting its properties in some measure to its offspring influences our choice of seed; but it is not generally known that the climate in which our seed corn is produced may have a material influence on its value. A highly interesting report on this subject is appended to the catalogue of Swedish seeds exhibited at the Amsterdam Exhibition by L. J. Wahlstedt, the Swedish Commissioner, from which we shall briefly quote. The essay, originally in Swedish, has been translated into French by J. H. Kramer. After describing the topography, climate, and soils of his country, the commissioner goes on to state that for a long time it has been known as a fact, that various plants grew best when the seed came from more northerly latitudes. This question has recently received careful consideration by scientific men. During more than thirty years Professor Schubler, of Christiania, has given us his researches, not only as regards cereals and common vegetables, but also as to a number of plants cultivated in many parts of Norway, up to the extreme north of the country. The results of his researches may be summed up as follows:—

1. When a plant is gradually transported from south to north, or grown at a greater altitude above the sea, which is the same thing, it becomes after some years acclimatised,

odd reaches maturity in a shorter time than was formerly the case, although the mean temperature of its new home may be sensibly lower than that of its original locality. If, after some time, the seed of such plant is taken back to its old climate, it ripens for some years at an earlier period than before its transportation to a more northerly situation.

2. Nearly all plants growing in elevated situations possess more smell and colour than the same plants cultivated at lower latitudes.

3. The seeds of most plants increase to a certain point both in size and weight, according as they are transported towards the north—on condition, however, that this transport is not all at once, nor carried beyond a point at which the plants can attain perfect development during the short summer of these regions. In again acclimatising to the south, *i.e.*, to their original locality, the grains assume at the end of some years their original dimensions.

4. Seeds grown in a northern locality have a thinner skin, germinate more rapidly and evenly, and produce more vigorous plants than such as are natives of more temperate climates.

These conclusions of Professor Schübler have been confirmed by the researches of such authorities as Petermann of Gembloux, Nobbe of Tharand, &c. The former states, in his "Researches on the Seeds Produced in High Latitudes," that seeds of clovers, firs, and pines grown in Sweden in latitudes from 55° 20′ to 60° 40′ are distinguished from those of more temperate regions by their germinating power, seen not only in the percentage of growth but also in rapidity of growth, by their purity, and by greater weight.

As regards red clover and Alsike clover, the important fact has been proved that Swedish seed was exempt from dodder, and this not so much on account of care in cultivation, as from the absence of this pest in the northern regions. The high germinating power on one hand, and absolute increased weight on the other, of northern seed, explain the precocity and quality which, according to Schübler and other experimenters, it possesses when transported from the north towards the south, and when compared there with native grain. As a further evidence of these facts, Professor Nobbe states that the result of trials on red clover in divers parts of Europe proved that seed from Upsala, in Sweden, gave the best results as to size of grains, the second place being gained by seed from Aas, in Norway.

As regards the germinating power of Swedish seed, M. Nobbe's experience confirms that of Professor Petermann, viz., a much greater force than that of either German, Belgian, or French seed. This quality was not confined to clover seeds only—of which, for example, German seed had a mean germinating power of from 60 to 70 per cent, whilst Swedish seed frequently reached 90 per cent—but was equally true of cereals and root crops, which possessed a mean germinating power ranging from 90 to 100 per cent. In his experiments with Swedish seed of cereals, different varieties of clover, turnips, &c., more than 90 per cent germinated in a period of three days. Besides this, the root growth of Swedish seed is equally remarkable. By actual experiment it was found that, whilst 100 grains of German barley had developed 188 primary roots in three days, an equal number of Swedish grains yielded 333 roots in the same period; in the matter of length the difference being also noticeable—namely, 1,192 millimètres of root in the German seed, against 2,662 millimètres in the Swedish seed. Also, as regards the proportion of bran to total grain, many comparative experiments had all been favourable to Swedish grain. Those, for example, of Professor Haberlandt, on fourteen samples of oats, showed that seed from Christiansand in Norway had the least percentage of bran. Professor Nobbe's experiments on the same point were equally satisfactory. As confirmation of what had been advanced, the author gives the result of experiments on germinating power of Swedish seed at the station at Christiansand during the four years that it has been in work. A great number of these occurred in 1881, when the harvest was unequal, and under very unfavourable conditions of temperature.

	Samples.	Mean of Germinating Powder.
Wheat	36	95 per cent.
Rye	99	93·07 ,,
Barley	138	94·93 ,,
Oats	126	95·00 ,,
Peas	44	99·02 ,,

The investigations at the same station as to the proportion of bran to flour in nineteen different samples of oats from the Province of Christianstad, grown in 1881, gave a mean weight of 25·82 per cent, with a maximum of 28·85 per cent, and a minimum of 23·85 per cent., Considering that the weight of skin often equals half that of the whole grain, it will be evident that these results are very satisfactory, and establish the high quality of Swedish grain in this important particular.

After proving that these superior properties are enjoyed more or less by all kinds of seeds grown in Sweden and similarly situated countries, Mr. Wahlstedt proceeds to consider to what circumstances these qualities are attributable. One of the most important appears to be the greater duration of daylight during the northern summer, it being a fact that in the most northern parts of Sweden there is practically no night for sixty days in June and July. The short nights of summer result in a more equal temperature throughout the day, as after sunset there is not time for either air or soil to become sensibly cold before dawn. A third important condition is probably the equal moisture during the period of growth, which arises on the one hand from the gentle warm rain which falls at this period, and on the other from the abundant atmospheric humidity which prevails. Natural richness of soil, and latterly the addition of suitable manures, are conditions that must not be overlooked, as well as the great care exercised by Swedish farmers as to clean cultivation and careful selection of seed.

The next point considered by Mr Wahlstedt is what advantage those who farm in lower latitudes may obtain by using, from time to time, seed grown in more northern climates. Already the value of clovers, grasses, turnips, and the different kinds of culinary vegetables from such a source is established over a large part of Europe, and in England especially. The case is quite different as regards the common cereals, which have only quite recently been introduced, experimentally, into the temperate climates of Europe. The most characteristic properties of cereals of northern growth are recalled—viz.: (1) size and uniformity; (2) high germinating power; (3) great purity, and almost entire absence of weed seeds; (4) quick development and rapid ripening. As regards the size of the grain, it is well known that the embryos of seeds of the same sort possess similar weight, whether the seeds are large or small. As regards the large seed, their dimension and augmentation depend on the better development of the reserve of nutriment which exists in the seed; and the more there is of such nourishment, the greater the supply of food for the young plant during the earlier stages of its growth, and the more rapid its development. Experience, confirmed by numerous experiments, has shown that the plant which has obtained a good start usually finishes well. Thus, he goes on, the use of northern seed is accompanied by the following advantages: Germination is more perfect and regular; the young plants are more uniform and strong, especially as regards root growth; above all, they are more capable of resisting unfavourable influences, whether these arise from bad weather, absence of sun, or are caused by insects or vegetable parasites. At a more advanced stage, the plants are more bulky and grow with greater vigour, for the reason that root growth is more developed. Finally, the same plants yield better both of grain and straw, and come to maturity more rapidly. The extra cost of northern seed is thus amply repaid. Mr. Wahlstedt concludes his valuable report by describing the measures taken by large proprietors, and by the leading agricultural institutions, to promote and encourage more careful attention to the growth of seeds of various kinds in districts specially for such production. Numerous stations have been established, and in nearly every province societies have been founded with the object of encouraging good cultivation and careful selection. And farther publicity has been given to this important subject, by exhibitions during the last three years, at Christianstad in 1880, at Boras in 1881, and at Sundsvall in 1882; and this year a similar exhibition has been held at Kalmar. In order to prove by experiment the value of seeds from Sweden for Central Europe, a Mr L. O. Smith, a Stockholm merchant, has placed at the disposition of the Royal Academy of Agriculture a considerable sum, in order that grain and other seeds may be sent to different countries, and carefully tried against the native seeds of each district. The results are anxiously looked for. Lastly, figures are adduced from official statistics to prove that the area of cultivated land is rapidly increasing, and that, if experience confirms these views as to the value of Swedish cereals, production will be found equal to the demand. It would be very desirable that our national society should investigate this question, and institute experiments at Woburn or elsewhere, in order to determine whether the introduction of seed corn from the northern parts of Sweden would be beneficial.

Necessity for Physiological Study.

"Nobbe has recently shown that if food-materials otherwise complete but possessing no potassium are supplied to plants (as buck wheat) they behave as if they were absorbing only pure water."—SACHS.

"The combinations of food-materials must be subject within the tissues to progressive changes of position in addition to and in consequence of their chemical transformations."

"The nutrition of all plants hitherto examined for this purpose is impossible or abnormal if any of these elements are wanting."

"The constant occurrence of compounds of phosphoric acid in company with albuminoids as well as of potassium salts in organs containing starch and sugar points towards definite relations which they may possess to those chemical processes that immediately precede the processes of construction of plants."—SACHS.

"They do not assimilate and show no increase in weight, because no starch can be formed in the grains of chlorophyll without the assistance of potassium." (Nobbe.)—SACHS.

"Lime is partly of use as a medium for conveying sulphuric and phosphoric acids in the absorption of plant-food, and partly for its power of fixing the oxalic acid which is poisonous to the plant."—SACHS.

Necessity for Chemical Manures.

"The modern system of scientific agriculture has for its foundation the artificial production of plants by the help of simple chemical compounds in defiance of all the traditions which the old system has handed down to us. From the day on which the modern system was first practically adopted, chemists, far from forbidding the use of farmyard manure, have simply advised farmers to abstain from using manures which are too strong for their particular purpose, but to rectify and complete the imperfect composition of farmyard manure by the addition of chemical compounds, which is a very different matter. Finally, we cannot pass over in silence the new means that the association of chemical manures with farmyard manure gives to the agriculturist. Let us suppose a sowing of colza and of wheat well manured; the winter has been rigorous, the spring late, and the plants have suffered. With farmyard manure only you could do nothing, and the yield would be bad. It is not possible to spread on the land more farmyard manure during the month of March, besides, if it could be done, its action will be radically *nil*. The farmer is thus condemned to remain an impassive spectator to an inevitable mistake. But if, on the contrary, chemical manure be added, all will be changed; 176 lb. of ammonic sulphate per acre will suffice to give a sudden impulse to the colza and the wheat, and the result is certain."—VILLE.

Necessity for Experiments.

DIFFERENT MANURES IN POTATO CULTURE.

An article in *The Field* last year, relating the results of an important series of experiments on the use of various manures in the cultivation of potatoes, conducted in 1881 at the Munster Agricultural and Dairy School, near Cork, attracted a good deal of interest throughout England. During the past year a similar series of experiments were conducted at the Albert Model Farm, Glasnevin, near Dublin, and the results obtained ought to be made widely known. The experiments were carried out under the superintendence of Dr. C. A. Cameron, Dublin, well known as an able and experienced agricultural chemist.

The manures tested were kainit, nitrate of sodium, sulphate of ammonia, and mineral superphosphate, and they were tried singly and in various combinations. The results obtained will be most clearly shown by the following table, in which the plots are arranged in order of the highest marketable yield:—

Manure.	Cwt. per acre.	Cost per acre.	Marketable potatoes.	Small potatoes.	Diseased potatoes.	Total per acre.
		£ s. d.	T. C. Q.	T. C. Q.	T. C. Q.	T. C. Q.
Nitrate of sodium ...... Mineral superphosphate	2 4	2 8 0	2 11 0	1 7 2	0 6 2	[illegible]
Kainit	6	0 14 6	2 6 2	2 0 0½	0 [illegible] 2	[illegible]
Kainit ... ... Nitrate of sodium Sulphate of ammonia Mineral superphosphate	2 1 1 2	1 11 6	1 19 0	1 12 0	0 2 2	3 11 0
Kainit ... ... Mineral superphosphate	4 4	1 7 0	1 19 0	1 14 0	0 8 2	4 1 2
Superphosphate ...	8	1 12 0	1 5 2	1 19 0	0 1 0	2 10 2½
Sulphate of ammonia Superphosphate ...	2 4	3 0 0	0 19 2	2 2 2	0 5 2	3 7 0
Sulphate of ammonia	3	3 6 0	0 8 2	1 18 0		2 6 2
Kainit ... ... Nitrate of sodium Superphosphate ...	3 1 3	1 16 3	0 8 0	2 11 0	—	2 19 0
Kainit ... ... Sulphate of ammonia Superphosphate ...	3 1 3	2 2 3	0 8 0	2 3 0	0 0 1	2 11 1
Nitrate of sodium...	3	2 8 0	0 6 2	2 0 2	0 0 1	2 9 1
No manure ...	–	—	1 3 2	1 9 2	0 4 2	2 17 2

This table is calculated to teach important lessons. The most striking feature in the Irish potato experiments in 1881 was the remarkable results brought out by the use of kainit. This year again kainit stands pre-eminent. It produced by itself the highest gross yield, and that, too, at by far the lowest cost. Kainit, applied at a cost of only 14s. 6d. per acre, gave a yield higher in gross weight, and only 4½ cwt. less in marketable tubers, than a mixture of nitrate of soda and superphosphate, costing £1 13s. 6d. per acre. The marketable potatoes from kainit thus cost barely 4d. per cwt. for manure, while those from nitrate of soda and superphosphate cost nearly 1s. per cwt.—an advantage to the kainit of more than 13s. per ton. Kainit in use with other manures also did well, generally adding to the yield. It will be seen that a mixture of kainit and superphosphate, costing £1 7s. per acre, gave a much higher yield than a dressing of superphosphate alone, costing £1 12s. per acre.

The table indicates that superphosphate as a single manure ranks next to kainit, and there is no doubt that, judiciously applied, it forms a very useful manure for potatoes. In conjunction with nitrate of soda, superphosphate gave the highest yield of marketable tubers, but with sulphate of ammonia it did badly.

Next to the pre-eminence given to kainit, perhaps the most important feature brought out is the very poor results realised by the nitrogenous manures, nitrate of soda and sulphate of ammonia. By themselves it will be seen that they gave very small yields—indeed, much below the plot that received no manure at all—in potatoes of a marketable quality. When given along with inorganic manures they did no better, having evidently, to some extent, neutralised the good influence of these.

Dr. Cameron analysed the sound potatoes from each plot, and the percentage of dry matter varied somewhat. The plot dressed with nitrate of soda and superphosphate stands highest, with 28·60, and the others follow in this order:—The plot dressed with kainit, nitrate of sodium, sulphate of ammonia, and superphosphate, 28·12; the plot dressed with sulphate of ammonia alone, 28·12; that with kainit, sulphate of ammonia, and superphosphate, 27·50; that with superphosphate alone, 27·04; that with nitrate of soda alone, 27·00; that with kainit and superphosphate, 27·00; no manure, 26·90; sulphate of ammonia and superphosphate, 26·10; kainit alone, 25·80; and kainit, nitrate of soda, and superphosphate, 24·30.

The column showing the quantity of diseased tubers does not bring out very startling results. It is curious to note that the nitrogenous manures produced little or no disease, while kainit shows about 7 per cent of disease —a circumstance contrary to previous experience.

"By unveiling the sources of plant production, science has done her work; it is now for the State in conjunction with the farmer to do theirs."—VILLE.

"Notwithstanding all that has been said against experimental fields, it is now clearly proved that their testimony is the only one that can be relied on; the only practical method of fixing with certainty the composition of the soil with respect to the requirements of agriculture."—VILLE.

PLANTING IN TAVOY, BURMAH.

An interesting letter from Mr. James D. Watson, of the Duke Model estate, Tavoy, to the Director of Agriculture, is published in the Supplement to the last *British Burma Gazette*, for general information. Mr. Watson takes a most cheerful view of the capabilities of the Tavoy hills. In the flatter land he thinks the soil is equal to that of the best Cocoa lands in Ceylon, and he has seen the Pallakelle estate in Ceylon, which is the best in the island, and produces Cocoa which fetches 100 shillings per *cwt.* in the London market. Cardamoms are indigenous in the Tavoy district, and Mr. Watson saw them growing and bearing splendidly in the jungle about 11 miles from Thayetchoung. Liberian coffee will, he thinks, grow to perfection, as a few small plants obtained from Captain Butler were "growing splendidly." Cinchona, Mr. Watson thinks, will do better in a less rainy climate, but he intends giving it a fair trial. Mr. Watson's *couleur de rose* views of the labour question will, we trust, be borne out by subsequent experience. He thinks the Burmese "a nice, docile people, willing servants and cheerful workmen," which was hardly the estimate formed of them by the late Mr. O'Riley and some other planters in this province. We hope, however, that when the Tavoy planters teach them to cultivate their waste lands and show them the profit and advantages to be derived from doing so, they will be tempted to put aside their proverbially lazy habits and imitate the industry and activity of their women-kind. It is satisfactory to learn that, although out daily in sun and rain, Mr. Watson has never been in better health than whilst prospecting in the Tavoy district, and he finds he can do as good a day's work there as in Ceylon.—*Rangoon Gazette.*

TIMBER TRADE OF CHILI.

Timber, according to the *North-Western Lumberman* (Chicago), is somewhat abundant in all the provinces south of Santiago. There are said to be over one hundred kinds of indigenous trees, of which not more than thirteen ever shed their leaves, and these are mainly utilised in ship-building and house carpentering. There are a few ornamental woods but such trees are scarce. The Araucauian pine grows on the mountains south from the Biobio, the trees looking from a distance like gigantic umbrellas. The Chilian cedar is regarded as the most important tree. The most abundant timber is the Lombardy poplar, and silver-leaf poplar or aspen. The Jesuits began planting these trees two to three centuries ago for fencing purposes, and miles of poplars in line are found following the courses of ditches, or marking out areas. When sufficiently large, these great hedgerows are attacked with the axe, the trees being cut down so as to leave the stumps about 8 feet high. The Lombardy variety is principally used for making brake-blocks, and the aspen makes good timber.

Facilities for receiving and getting out lumber have always been meagre and miserable. There is no harbour at Valparaiso, and the vessels arriving are obliged to lie at anchor within easy reach of the shore, while the cargo is unloaded by swarthy and muscular natives who station themselves at intervals of about two rods out in the surf, on a line reaching from boat to beach. They pass the lumber from one to another along the queer line of transporation. The natives go on a jog trot through the shallow surf, and often keep up the action all day with little cessation.

Up to a recent period there has been no means of manufacturing the domestic timber. It was simly formed by hand, and made up into boards of certain dimensions, which were regarded as standard, but never figured in feet, being sold by the piece. In some of the less progressive sections, boards have passed as a medium of exchange. To the lumber that is received into Chili from foreign ports, the Government applies the metric system of measurement, on which its duty collections are based. In additien to lumber, considerable wood is cut in the tan-bark business. Red-wood is being raised in the coast region 1,000 miles from Valparaiso. The timber country is generally mountainous, while the rivers abound with bars. In addition to the woods that have mentioned, there is a fine variety which resembles beech, while another has a fine grain, and there is a third variety of a reddish colour which polishes nearly as finely as cedar.

Latterly, however, several portable saw-mills have been brought to Chili from the manufactories of the United States, and other improved means are being employed, while the imports of lumber are increasing. Very little manufacturing of goods from wood has been carried on, but enterprises in this direction are contemplated, and, in fact, in course of establishment. Furniture and similar articles have been imported somewhat extensively, but the duties have been made very heavy on such goods, and are reckoned by the weight instead of the exact value in each case. The inhabitants have found importing to be a very expensive business, and it is proposed to build factories for the manufacture of boxes, the importation of which has been heavy, sash, doors and blinds, furniture, &c. Men of capital are now engaged in investigating the details in connection with such enterprises.

From fifty to seventy-five vessels are engaged in trade between Valparaiso, which is the most important west shore port except San Francisco, and other points. Lumber and common freight are combined.

The wages of peons are from 40 to 50 cents per day, two pieces of bread and one meal of beans being conceded in addition. General unskilled labour commands 1·25 dols. per day among the natives, and artisans obtain 2·50 dols. per day and find themselves. Intelligent foreigners can get from 3 to 6 dols. per day. In the case of the surf-packmen, they obtain large pay, sometimes making as high as 10 dols. per day.—*Journal of the Society of Arts.*

MACHINE AND HAND MANUFACTURE OF TEA.

SIR,—I send an estimate of what I consider the saving between tea made by machinery and hand, viz., 3·70 c. in favor of machinery. I have based my calculations on an estate giving 50,000 lb. of tea, and the working of a Jackson's Universal and a Sirocco. I do not consider these machines capable of manufacturing tea on an estate giving a larger yield than this, as the greater proportion of tea on estates comes in during 4 or 5 months of a year. The roller is capable of doing 400 lb. of manufactured tea in 10 hours, and the Sirroco 360 lb., so that I have only taken an average of 300 lb. per day, on account of machines requiring nearly the same number of people to work them, when only making 150 lb., as when making a larger quantity. The cost of the machinery I have put down as near as possible what my machinery here cost me. My charcoal and firewood I have to carry some distances to the factory, which makes it a little more expensive than on some estates.

GRAHAM HOGG.

RICE CULTIVATION IN SUMATRA AND JAVA.

(*From a Tour in the Lampongs, S. Sumatra, by H. O. Forbes.*)

In Java, in the cultivation of their rice fields, the natives pursue, except in very mountainous parts, the system of irrigation, by which, in a most wonderful manner, they cover broad tracts of country, not only where it is level, but even where the land lies in considerable slopes, as so well described by Mr. Wallace in his "Malay Archipelago." In the southern part of Sumatra, however, though rivers abound, and there is much level land, the natives do not seem, till very recently, to have been acquainted with this manner of cultivating rice, but have always taken their crops from forest land, which produces a far less return of grain, and of a quality much inferior to sawah, or wet-field grown paddy. Here, however, they had just begun to try the plan; and during our sojourn a West Java man, brought over expressly for the purpose, was engaged in laying out for the villagers their first sawahs, and instructing them in the art of irrigation.

Sawah cultivation is a great saving of labour, as the same land can be used year after year without the application of manure, the land renewing its strength from the decomposition of the straw which is left on it after the crop is cut—for the natives reap only the grain—and from the rest of several months between the seasons, during which, moreover, the buffaloes have the unrestricted privilege of roving over it. On the other hand, the ladangs, or dry fields, can be used for not longer than two or three seasons. To make his ladang the native goes after the virgin forest, leaving his old fields to produce new forest, second-growth forest, if the "alang-alang" grass does not get the upper hand. The virgin woods contain the really interesting and valuable vegetation of the country. The trees of the virgin forest are, to a great extent, the lineal descendants of the vegetation that has always existed on the island since it came into its present condition at least. Perhaps indeed some of the aged giants may have actually witnessed the young days of the present geological cycle, how many thousand years ago we may only conjecture. By virgin forest, I mean such as has never been interfered with, while second-growth forest is that which follows the clearing of large tracts, either by natural means, such as fires, or by the woodcutter's axe. In the virgin forest, death and decay are just as rapid as anywhere else. Individual trees are constantly falling out of the ranks, but their place is taken by younger members either of the same or of neighbouring species; but, just as happens at home on a smaller scale, when this ancient forest is devastated to any great extent, such as a few acres, the trees that arise belong to a different lineage, the new wood is in a great bulk of different species, which also, strange to say, were but rarely to be found in the old forest. Whence they come it is not very easy to say. The original forest is rapidly disappearing; each year sees immense tracts felled for rice fields, more than is actually necessary, and also much wanton destruction by wilful fires. Trees of the rarest and finest timber are hewed, half burned, and then left to rot; amid their prostrate trunks a couple of harvests are reaped, then the ground is deserted, and soon fills up with the fast-growing and worthless woods, or falls a prey to the ineradicable alang-alang grass already mentioned. Our children's children will search in vain in their travels for these old forests of which they have read in the books of their grandfathers; and to make the acquaintance of the trees themselves, they will have to content themselves with what they can glean from the treasured specimens in various herbaria, which will then be the only remains of the extinct vegetable races. In every clearing, here and there, trees, from their gigantic size, have escaped the axe, and been allowed to stand unmolested. One cannot resist a feeling of pity for the solitude of these towering monarchs, whose grandeur, concealed as they stood amid the multitude of their peers, can now be seen in all its stateliness. They look the very picture of strength and immobility; yet, though they have withstood, in the company of their fellows, the storm and sun of centuries, they survive their solitude but a very few seasons, getting feebler and feebler year by year, one great limb after another dying and dropping off, till all life ceases, when some lightning flesh or sudden blast measures the noble tree's length on the ground. To obtain specimens of the ancient arboreal race was one of the principal objects of my journey, a task slow and difficult of accomplishment, for but few trees can be felled in one day, and good eyes are required to tell at a height of 150 ft. or 200 ft. if there be fruit or flower to be got in return for the labour and time spent in felling the trees.—*Field.*

GRAFTING IN A NEW ASPECT.

A gradual revolution of opinion is in progress on the subject of grafting fruit trees, and it almost looks as if we should shortly have to unlearn a good deal on the subject. The theory of grafting has hitherto been very simple. Physiologists say that the object of grafting is to promote vigour and fertility; hence weak-growing apples are grafted on the hardier and more vigorous wild crab, peaches on the plum, and so on. Another reason for grafting apples and pears is that neither are readily propagated by cuttings; otherwise probably trees propagated in that way would succeed as well as grafted ones, if not better. Nurserymen and raisers of fruit trees graft as a matter of course, and because it is the readiest way, without concerning themselves about the advantages or disadvantages of the system, and the crab stock is invariably used for apples of large size, and the wild pear and other hardy kinds as a stock for the pear. There can be no doubt about the hardy nature of these stocks, if that be of much advantage to a fruit so hardy in itself as the apple or pear; but in other respects neither of these stocks can improve the quality of the fruit of the graft, as they only produce inferior fruit themselves. Lately, the subject of raising apple or pear trees from cuttings or layers has received more attention, but there is a want of experience on that point. It is worth while to mention these matters, in order to disabuse people's minds of the idea that the crab stock possesses some mysterious virtue and is indispensable, which is not the case. The use of the quince stock for the pear, and the paradise for the apple, is far more intelligible; and the influence of these stocks on the scion and its fruit is clearly discernible. In fact, the object of using these stocks is quite the opposite of that for which the natural crab or pear stock is employed; and the use of the one really implies the condemnation of the other, for we graft the same varieties on the two stocks side by side, in the one case to make the tree grow strongly, and in the other in order to restrain its vigour—and the object in both cases is to induce fertility. This fact is not sufficiently realised amongst us, but its significance is evident. The French are more consistent than we are in this matter, for they prefer the quince and paradise for trees of moderate size where grown in gardens.

These remarks are, however, only by the way, and lead us on to what we have called the "new aspect" of grafting. Hitherto it has been taken for granted, and without any reason, that the stock, whether used because of its hardiness or vigour or permanently influenced the subject grafted upon it, even when not allowed to produce any growth of its own; hence, in grafting apples, plums, vines, roses, and other plants, the rule has been to employ the root of the stock only, with sometimes a portion of the stem, as in the case of standard trees and roses, &c. For some time, however, the fact has been gradually forcing itself on the minds of gardeners, that by this method the value of the stock is greatly impaired, if not lost in numerous instances. It is found that by grafting a weak variety on another and stronger variety, a more vigorous growth is the result at first, but that in the end, and sometimes very soon after, the graft becomes just as weak as if it had been on its own roots. The reason of this is plain on reflection. A strong root produces a strong top growth, and while the strong top remains and extends the root extends reciprocally in the same ratio. When, however, we cut the top off and substitute by grafting another and weaker top in its place, the root is for the time paralysed, and never afterwards does more than respond to the weaker growth grafted on it. This is very easily demonstrated in the case of the vine, numerous examples of which the writer has seen. I more than suspect, too, that the reason why the quince and paradise roots require so much pruning in this country is, that while they do restrain the luxuriance of the strong-growing subjects grafted on them, they are at the same time acted upon reciprocally, and made to grow stronger than they would do if they bore their own natural and less vigorous branches. A correspondent, in writing on dwarf stocks for apples years ago, said they should "furnish a dwarf and fertile growth without any rootpruning whatever;" and this is what was expected of them in culture, and what theorists said would happen, but it is found that such trees require regular root-pruning under some circumstances. On the other hand, it may be well believed that the crab and pear stocks are enfeebled by having weak varieties worked upon them in the reverse way.

The general conclusions I draw from observations are, that the root of a stock alone, when a more vigorous growth in the scion is desired, is of very little use; that the way to get the benefit of the union is to allow a portion at least of the foliage of the stock to grow as well as the scion; and that it would be advantageous, and certainly not injurious, to graft weak varieties with stronger ones at both ends, which may be considered a species of double grafting, but not in the sense in which that term is used generally, which means grafting one variety on the top of another, and only allowing the last to grow. Lastly, I believe that none of the dwarfing stocks, like the quince or paradise for example, will maintain trees in a permanent state of fertility at least, till the trees acquire age and have overgrown the stock, but must be root-pruned only in a less degree than the crab stock, especially the quince, which produces stronger pear trees than the paradise does apples. This is my experience here in our cool soil and climate. All our quince stocks have been pruned over and over again, and their roots are always found to be just in proportion to the vigour of the alien top they bore.—J. S. W.—*Field*.

GUTTA-PERCHA.

BY JAMES COLLINS.

The earliest notice concerning gutta-percha I have come across, is contained in John Tradescant's catalogue of his "Rarities preserved at South Lambeth."* In this is mentioned "plyable mazer wood, being warmed in water, will work to any form." It is also by no means impossible that some of the historical "mazer cups" may have been made from this material,† the mottled appearance of gutta-percha answering to the descriptions given, and its lightness, strength, and non-liability to fracture, would render it a good substitute for the true maple. "Mazer-wood tree" is also one of the vernacular names of the gutta-percha tree.

To Dr. William Montgomerie, a surgeon in the East India Company's services, belongs the honor of first bringing this substance before the commercial world. He first noticed it in Singapore in 1822, and experimented on it; and in 1842, whilst again in Singapore, he recommended it to the Medical Board of Calcutta as a substance useful in the making of surgical splints. He also sent samples to London to the Society of Arts, who warmly took up the subject, and, in 1844, awarded Dr. Montgomerie their gold medal. In 1843, Dr. (afterwards Sir) José d'Almeida sent a sample to the Royal Asiatic Society, and some persons have confounded these two circumstances. Dr. d'Almeida, it should be remembered, sent gutta-percha as a curiosity, whilst Dr. Montgomerie, long before this date, experimented on the substance, and recommended it as likely to prove of great utility in the arts and manufactures.

In 1847, Sir W. J. Hooker* named the plant *Isonandra gutta*, from specimens supplied by Mr. Lobb, who was at that time collecting plants for the Messrs. Veitch, the eminent nurserymen; and Mr. Motley, whilst in Borneo, added materially to our information. Dr. de Vriese, on the part of the Dutch Government, did good work in this direction, he giving descriptions of eighteen plants yielding this substance.†

Gutta-percha, as it appears in commerce, is of a reddish or yellowish hue, nearly as hard as wood, and of a porous structure. When cast or rolled, it assumes a fibrous structure, and acquires a tenacity in a determinate direction. At a temperature of 32° to 77° Fahr., it has as much tenacity as thick leather, but not at all elastic, and less flexible. In water, towards 120° Fahr., it softens and becomes doughy, although still tough; at 145° to 150° it becomes soft and pliant, assuming the elasticity of caoutchouc, becoming again hard and rigid on cooling. It is highly inflammable, burning with a bright flame, and its electrical properties are well known.

Gutta-percha, like many other milky juices, is found stored up in an irregular network of tubes (*Cinenchyma*, or lactiferous tissue), in the middle layer of the bark; the outer layer, largely developed in the cork oak, is known as the corky layer, or *epiphleum*, and the inner, largely developed in fibre-plants, is known as liber-layer, or *endophleum*. Thus the bark has to be cut into to free the milky juice.

Gutta-percha trees are confined to the natural order Sapotaceæ, an order yielding succulent fruits, such as the sapodilla plum (*Achras sapota*), vegetable butters as from the seeds of various species of *Bassia*, whilst from species of *Dichopsis* (*Isonandra*), and other genera, we have the peculiar gum-resin, or hydrocarbon, known as gutta-percha. A short description of the better known tree will be sufficient for the present purpose.

Dichopsis gutta (*Isonandra gutta*) is known under various names, such as gutta-percha, gutta taban (the more correct), gutta durian, gutta niato, and many others. The word gutta, gutab, gatta, gittàh, as it is variously spelt, signifies in Malay, gum or juice. The second name is the name of the tree producing this gum, the same tree having a different name in different localities. The tree is found in the Malay Peninsula, Sumatra, Borneo, and throughout the Malayan Archipelago generally. It grows to a height of 60 to 80 feet, with a diameter of 2 to 5 feet. The leaves are inversely egg-shaped and entire, pale green on the upper side, and covered beneath with a reddish-brown shining down. The flowers are arranged in clusters of three or four in the axils of the leaves. The fruit is a small oval berry. The gutta, as it flows from the tree, is of a greyish colour, at times somewhat roseate in hue, possibly arising from the colour of the bark. There is also an oblong leaved variety of this species. Of other kinds mention may be made of the following:—

Dichopsis macrophylla, the Ngiato putih or white gutta-percha of Borneo, the gutta of which, according to Motley, is of a second-rate quality.

Dichopsis Motleyana, yielding a very low kind, known as gutta kotian (Motley).

Payena dasyphylla, yielding a second-rate quality, known as gutta benton, in Borneo (Motley).

Payena Leeri, yielding gutta balem-tandock, &c., in Sumatra and Java.

Besides these there are species of *Chrysophyllum*, *Sider-*

† Dr. Vriese, Plantæ Batavæ Orientalis Lug. Bat. 1856; De Handel in Getah-Pertja, 1856.

oxylon, *Bassia*, and *Mimusops*, also said to yield gutta-percha.

The names of varieties of gutta-percha are exceedingly numerous, and many are no doubt synonymous, and a bare mention of a few of these will suffice. In all, the words gutta-percha may be used as a prefix to these names.

Waringen.—Borneo. Well spoken of.

Nettu.—Borneo. Said to be of a second quality.

Ploot.—Borneo. A third quality.

This is a Dyak term, and seems to be applied to varieties all alike.

Papua.—Borneo. Fourth class.

Rana.—Borneo. Very low quality.

Katella, Jankar and Kladi guttas are only used for adulterating better qualities.

Daging.—In the Malay Peninsula, gutta daging is well known, the term daging meaning "flesh," the gutta having a very gristly character. It is much like Balata, and is a capital gutta.

Muntah.—Under the name gutta muntah, or white Borneo, this kind made its appearance in the English market some years ago. Muntah means "raw," and is applied to all guttas which have not been cooked or prepared. Hence the term is applied to the lowest as well as the best varieties. If not speedily used up, it loses all its value by becoming resinified.

In the Brow and Boolongan districts, on the east coast of Borneo, Capt. Lingard informed me that there are three kinds of gutta-percha recognised by the natives.

(1.) Kalapeich, or Lota lanyut, or "tough gutta," is the first and best quality. It is known in the English market as Lingard's "Nima" brand.

(2.) Kalapeich, or Lota mooka, or "spongy gutta," yields about 10 per cent less gutta, and the tree is more difficult to cut down.

(3.) Kalapeich, or Lota kapur, yields about 20 per cent less than No. 1, and in the wet season even 30 per cent less.*—*Journal of the Society of Arts.*

(*To be continued.*)

TILLAGE AND MANURE.

It is unfortunate for young farmers that the text books of botany devote but little space to those branches of their subject which involve the life-history of plants. This should be altered. A science which merely christens plants, and is only rich in names and classifications, cannot be of much service to agriculture. There are, no doubt, several volumes from which young farmers may derive valuable practical information on plants and soils. They may learn something of the root-development of plants, and the depth at which they feed, from the experiments at Rothamsted; and "Plant Life," by Dr. Masters, is a little book most ably written, and quite within their reach. But the question of the depth of tillage is almost invariably treated in scientific works and agricultural writings from a general rather than a practical point of view. It has become a habit with many writers to recommend deep cultivation as a matter of course, when in point of fact it is purely a question of expediency. "A soil of double depth," they inform us, "must be of double worth," and this is a proposition one need not dispute; but at the same time it will be readily understood that such a method of treating a practical subject cannot commend itself to the rent-paying farmer. He would naturally reply, "Even if it be true that double depth means double worth, the fact cannot greatly concern the occupier of land, who can hardly care to increase its absolute value, but only its usefulness to himself."

Mr. Mechi, with all his merits as an agricultural agitator, sometimes brought discredit on his writings by approaching practical subjects from a theoretic standpoint. He used to advocate the ploughing up of pastures and the doubling of the depths of furrows as matters of patriotic duty, and, at a time when the price of corn compelled the country to increase its pasturage, he still harped on the old string and lamented the infatuation. "Is it come to this?" he wrote when the London Farmers' Club recommended the conversion of unprofitable arable land to permanent pasture; and he might just as well have exclaimed of the 5 in. or 6 in. furrows at Rothamsted—and Sir J. Lawes never exceeds 6 in.—"Is it come to this?"

A young farmer seeking information as to the depth of tillage best adapted for his particular soil, finds too frequently that theoretic writers recommend deep tillage as sound in principle apart from any other consideration. The fertility of the soil, they say, is proportioned to the depth and quantity of the substance to which the roots of plants have access, and they give this as a reason for increasing the depth of the staple under all circumstances. On the contrary, young farmers and others seeking information on this subject ought to be warned of the propriety of proceeding experimentally. As a matter of fact, it rarely happens that the crops are increased by deeper tillage without the use, at the same time, of larger quantities of manure; and on this point there is undoubtedly a great deal of misunderstanding in the public mind. Certain politicians might be named who constantly advocate small holdings, and the reclamation of our waste lands by means of the spade, without being aware that manure is quite as necessary as tillage, and that the difficulty of obtaining it is a bar to small plots under ordinary circumstances. Mr. Jesse Collings, for example, seems to be ignorant that plants, like people, live by food, and that tillage is not a substitute for manure. Mr. Joseph Arch has evidently been misled in regard to the effects of tillage. At a recent meeting of the Trades Union Congress introduced, as he has done on previous occasions, the subject of the waste lands, and repeated one of those transparent fallacies which the text books of our schools should prevent any person from entertaining. It is time that the humblest class of school boys were taught enough of soils and of plants to be able to refute the economic errors of such politicians as Mr. Arch and Mr. Collings. Every schoolboy should know that a virgin soil may contain the remains of many crops that have grown and decayed on the spot, and that mere tillage, without manure, may suffice for such soils during several years; but he should know too that virgin soils are by no means all alike. Woe betide the man who settles on an American "pine barren" or an English heath! And he should also know that the arable land of an old country does not usually contain much unexhausted fertility in the remains of former crops, and will not produce the four or five crops of a single rotation without liberal applications of manure to most of them.

The example of gardeners has been urged upon farmers; but on this point it may be said briefly that the great crops of the market gardeners of Barking and the neighbouring district are solely due to the large quantities of manure obtained from the London stables. They plough generally to a depth of six or seven inches. The method of cultivating flower gardens need not be noticed here, the object being the attainment of beautiful specimens of the horticultural art, irrespective of the cost. The truth is, that practical farmers must regard the subject of deep tillage solely from a practical point of view, and, so far from being guided by general principles, they should consider each particular case in detail on its merits. It does not concern them that the roots of plants are sometimes found at a great depth, or that the subsoil might in most cases be decidedly enriched by manuring it. "Look," says the enthusiast, "at the miserable pale subsoil immediately below your six or seven inches of cultivated land! Why don't you manure it as gardeners do?" Perhaps the best reply to the teachers of such doctrine is, "Have you tried the plan you recommend, and what was the result from a money point of view?" In the tillage of the soil about one hundred tons per acre are moved for every inch of depth, and, making allowance for the weight of the bearing, the cost of cultivation increases in a higher ratio than the depth; and its effect on the increased yield of crops should increase in like manner, or the operation cannot be profitable.

Baron Liebig has explained that plants assimilate food in proportion to the extent of root surface, and as the mineral food is fixed in the soil and has to be fetched, so to speak, it can only be available when the roots come into actual contact with it. A plant possessing double the root development of another plant will grow in a soil which, so far as the plant with only one half the root surface is concerned, is exhausted. It will do so because it possesses double the chance of meeting with food. It

* See also some remarks on Malayan varieties by the late Mr. Murton, "Journal of the Society of Arts," Oct. 11, 1878.

is no doubt a desirable piece of information that the quantity of food which plants obtain from one and the same soil is in proportion to the root surface, but any enthusiastic farmer who makes this a reason for increasing the root surface by tempting the roots downwards will quit his platform as a practical man. It is his duty to his annual balance sheet that he should set the cost of deep farming against the increased crop. He should also ascertain whether the root surface cannot be doubled and the crop increased by more economical methods than that which has just been noticed. He should inquire the circumstances of mechanical texture which rule the depth to which plants feed. We know that roots will follow air and water almost to any depth, and that they will spread and feed to a depth of several feet in a well aerated subsoil. They find food there, and the price of the food is the cost of tillage which renders it accessible; but if the same amount of food were supplied at the surface, would not the result in the increase of the crop be greater and the cost less? A simpler question is, does it pay to plough more than 6 in. deep in ordinary soils? Most farmers have answered this question as it has always been answered at Rothamsted in the practice of Sir John Lawes, whose usual depth of ploughing on his home farm is from 5 in. to 6 in.

A capital letter from an American agriculturist was published ten years since, rebuking Mr. Mechi for advocating deep ploughing under all circumstances. A number of traders, who amused themselves by farming, belonged at that time to the New York City Farmers' Club, and the practice of deep ploughing having been recommended by Mr. Horace Greeley—the Mechi of the United States—the club united in persuading the farmers to adopt it. Many of them did so, but when it came to a question of dollars and cents the practice was abandoned. It was found that on virgin soils, in some cases, deep work increased the corn crop, the subsoil being of fertility; while in the majority of cases the poor stuff below did not improve the crops. According to this shrewd American, the "remedy" for agriculture was manure. The exhaustion of the soil had already made some progress even in the case of rich virgin land deeply ploughed, and the only remedy was manure. Sir John Lawes has been consulted by Cousin Jonathan on this same subject of exhaustion, and his suggested remedy has been the application of manure. "It is evident," said the author of that very sensible letter of ten years ago, "that if our mining and manufacturing interests increase as rapidly as they have done in the past, the time will soon be here when we shall not be able to feed any more than our own population." He adds, "If the farmers of England and we of the Eastern States were indiscriminately to practice Mr. Mechi's plan of deep ploughing, we should be in a worse boat than ever."

Whatever may be thought of the writer's argument that the effects of deep as well as shallow work would wear out, it is an undoubted fact that the increase of manure has become the question of the day, both in England and America. If fertilisers were cheaper, we could even cultivate the wastes at a profit; we shall never do so by means of mere tillage, whether by plough or shade.—H. E. —*Field.*

GLUCOSE, OR GRAPE SUGAR.—Regarding the manufacture of glucose, or grape-sugar, which has occupied so much attention of late in America, it is stated in a recent report that, owing to the unwillingness of manufacturers to impart information, it is difficult to obtain trustworthy statistics in regard to the aggregate quantity produced. Latterly, however, prices of refined sugar have fallen so low in America, that its adulteration with the corn product has ceased to be as profitable as heretofore. The cultivation of sorghum, and the production of sugar therefrom, is still in an experimental stage. The maple sugar industry continues to be of considerable importance in some of the Eastern and a few of the Western States, but there appear to be no reliable data on which to found an estimate of the quantity produced. The State of Vermont is perhaps the largest producer, the quantity now manufactured being estimated at 15,000 tons, the other States producing altogether about 5,000 tons.—*Gardeners' Chronicle.*

SOME AFRICAN KOLAS.

IN THEIR BOTANICAL, CHEMICAL AND THERAPEUTICAL ASPECTS.*

BY E. HECKEL AND F. SCHLAGDENHAUFFEN.

Among the vegetable products of the African soil, there is perhaps none more interesting and valuable than those which under the various names of "kola," "gourou," "ombéné," "nangoué," and "kokkorokou," are used as articles of consumption throughout tropical and equatorial Africa, as equivalent to tea, coffee, maté and cocoa. Used under the form of seeds, probably from time immemorial, by the native tribes, these products are of varying botanic origin, and their history has been up to the present time imperfectly known; but the authors have been able to avail themselves of the observations of some recent travellers to clear up some obscure points.

The products which are included by the authors under the name "kola" (the various synonyms quoted being special to particular countries) consist of seeds, yielded by two families of plants and differing very much in appearance. The kind most widely distributed, the "true kola," which by some of the natives is called the "female kola," comes from the Sterculiaceæ; another variety, called by the author "false kola," is known among the negroes as simply "kola," or "male kola." Before the authors' researches only the "true" or "female" kola was known, and it had been ascertained to be yielded by the *Sterculia acuminata*, P. de Beauv. (*Cola acuminata*, R. Br.) To this Messrs. Heckel and Schlagdenhauffen are able now to add information concerning the "male" kola, hitherto unknown, and to give reasons for believing that various other species of *Sterculia*, besides *S. acuminata*, yield kola seeds.

Dealing first with "female" kola, the authors describe at length *Sterculia acuminata* from specimens, the description agreeing with Oliver's description of var. *a* (Fl. Trop. Af., i., 220). According to the best information, the tree—which is from 30 to 60 feet high, and in general aspect resembles the chestnut—grows wild upon the western coast of Africa comprised between Sierra Leone and the Congo or Lower Guinea, reaching into the interior about five or six hundred miles, where it appears to follow the limits of the palm. Upon the eastern coast in appears to be unknown in places where it has not been introduced by the English. Dr. Schweinfurth, speaking of the country of the Nyams-Nyams, near lake Nyanza, says that among the imposing forms of vegetation a *Sterculia* of the kola kind predominates and is called locally "kokkorokou." In the country of the Momboutous (24° E. long., 3° N. lat.), too, upon asking for kola he was supplied with the fruit in its rose-coloured envelope; but the only information he could obtain there concerning it was that the nuts were found in the country in the wild state and were called "nangoué" by the natives, who chewed slices of it whilst smoking. Karsten, in his 'Flore de Colombie,' describes the plant as growing wild in the moist hot woods near the southern coast of Venezuela, but the authors believe it was probably introduced there about the same time as it was introduced into Martinique, and that it was sown by African negroes, who brought it into those countries in the same manner as they are known to have introduced *S. cordifolia* for the sake of its delicious fruit. It has also been introduced successfully by the English into the East Indies, the Seychelles, Ceylon, Demerara, Dominica, Mauritius, Sydney and Zanzibar, and by the French recently at Guadeloupe, Cayenne, Cochin China and the Gaboon. In all these stations the kola tree flourishes best in moist lands at the sea-level, or a little above. At Sierra Leone some fine trees are found at an elevation of 200 or 300 metres, but not higher than that.

The kola tree commences to yield a crop about its fourth or fifth year, but it is not until about its tenth year that it is in full bearing. A single tree will then yield an average of 120 lb. of seed annually. The flowering is nearly continuous after the tree reaches maturity, so that a large tree bears flowers and fruit at the same time. There are two collections; the June flowering yielding the fruit in October and November and that of November and December in May and June. When the fruit is ripe it takes a brown-

* Abstract of a lengthy memoir read before the Union Scientifique des Pharmaciens de France (*Journ. Pharm. et de Chimie*, [5], vii., p. 553; viii., 81, 177.)

ish yellow colour. In this condition dehiscence of the capsule commences along the ventral suture, exposing red and white seeds in the same shell. It is at this period that they are gathered. It has been stated that there exist two varieties of kola, one yielding exclusively red seeds and the other white; but the authors have been repeatedly assured that this is not the case, and that one and the same capsule may contain fifteen seeds varying considerably in size, white and red together, without the white being considered less ripe than the red. The carpels are from 6 to 9 centimetres long and 3 to 5 thick and the spongy pericarp is about 2 or 3 millimetres thick. As many as five or six ripe carpels may result from a single flower, and these may each contain from five to fifteen seeds; but sometimes carpels are met with containing only a single seed. The seeds removed from their envelope weigh, according to their development, from 5 to 25 or 28 grains. The epiderm is the principal site of the colouring matter, and beneath it the cotyledonary tissue consists of a mass of cells gorged with large starch granules comparable to potato starch. It is in these that the alkaloids caffeine and theobromine are found in the free state.

The collection is conducted with great care and is made by women. The seeds are removed from the husk and freed from the episperm. In order to maintain their value among the negroes, it is necessary to keep them in a fit state and in good condition. They are, therefore, carefully picked over, all damaged and worm-eaten seeds being removed, and the sound seeds are then placed in large baskets, made of bark and lined with "bal" leaves (*Sterculia acuminata*, Car., or *S. heterophylla*, Beauv.?); the seeds are heaped up and then covered over with more "bal" leaves which, by their thickness, resistance and dimensions, contribute not a little to the preservation of the seeds by keeping them from contact with dry air. Packed in this manner the seeds can be transported considerable distances, remaining free from mould for about a month, during which time it is not necessary to submit them to any treatment in order to preserve them fresh beyond keeping the "bal" leaves moist. But if it be desired to keep them beyond that time the operations of picking and re-packing have to be repeated about every thirty days; the seeds being washed in fresh water and fresh "bal" leaves placed in the baskets. The baskets usually contain about 3 cwt. of seeds. It is in this condition that "kola" is sent into Gambia and Goree, where the principal dealings in the seeds are carried on. In Gambia they are sold in the fresh state to merchants travelling with caravans into the interior, who dry them in the sun and reduce them to a fine powder, which is used, mixed with milk and honey, by the tribes of the interior to make a very agreeable, stimulating and nourishing beverage. It most frequently arrives at Sokota and Kouka in the Soudan and Timbuctoo, where large sales of the seeds are made, in the fresh condition; from the Soudan markets it is carried by caravans to Tripoli, and from Timbuctoo into Morocco. As might be expected the value of the kola increases as it makes its way into the interior of Africa, and the authors state that some of the tribes furthest removed from the sea pay for the dry powder with an equal weight of gold dust. Kola plays an important part in the social life of many of the African tribes, and the authors mention some of the occasions upon which it is used in terms almost identical with those in a paper read at an evening meeting of the Pharmaceutical Society eighteen years ago (*Pharm. Journ.*, [2, vi, 450). An interchange of white kola between two chiefs is indicative of friendship and peace, whilst the sending of red kola is an act of defiance. An offer of marriage is accompanied by a present of white kola for the mother of the lady; the return of white kola is equivalent to acceptance of the suit, whilst red means rejection. The absence of a supply of kola from among the marriage presents would endanger the whole arrangement. All the oaths are administered in the presence of kola seeds; the negro stretches out his hand over them whilst he swears and eats them afterwards.

Fresh kola is used as a masticatory, as is also the dried powder, by the tribes in the interior. When fresh the taste of the seeds is first sweet, then astringent and finally bitter. When the seeds become dry the bitterness diminishes, giving place to a sweeter flavour; but upon steeping them in water for a couple of days the original bitterness is nearly restored. Preference is given for mastification to seeds containing only two cotyledonary segments, it being asserted that they are less rough than those with four to six segments: but the authors did not find anything in their chemical examination to explain this preference. The practice of kola mastication, which is always accompanied by the swallowing of the saliva, does not injuriously affect the teeth, as is the case with the betel nut, but tends to render the gums firm and exercises a tonic influence on the digestive organs. The seeds are reputed to clarify and render healthy the most foul waters, and to render tainted meat edible, and when chewed, either fresh or as a dry powder, and the saliva swallowed, to be a sure preventive against dysentery. They are also said, like *Erythroxylon Coca*, to possess the physiological property of enabling persons eating them to undergo prolonged exertion without fatigue, which is probably to be attributed to the caffeine they contain. Further it is said that kola exercises a favourable influence upon the liver, and that white people, living in those regions, who chew a small quantity before meals escape constitutional changes due to affections of that organ. They are also believed by the negros to have aphrodisiac properties. With respect to the assertion that the pulp or powder of the seeds thrown into foul water has the property of cleaning it, an experiment made by the authors would appear to show that any action in this direction would be due to the formation of a kind of mucilage, which would act mechanically like the white of egg.

It has been pointed out that the name "kola" is applied in Africa indifferently to several Sterculaceous seeds other than those of the two varieties of *Coca acuminata*, although these are the most valued in the native markets. It is probable that the African plants capable of yielding seeds resembling the true kola are *Cola Duparquetiana*, Baill., *C. ficifolia*, Mast., *C. heterophylla*, Mast., *C. cordifolia*, Cax., and perhaps *Sterculia tomentosa*, Hend. But the authors think it doubtful whether these seeds contain caffeine, otherwise they would be as much sought after as the true kola.

In order to determine chemically the composition of kola seeds, the authors made a large number of experiments; the details fill many pages in the original paper. The dry seeds were first operated upon, and the process which appeared to give the best results was to exhaust the dried powder successively with chloroform and alcohol. The chloroform percolate was a yellowish liquid; this was evaporated to dryness, and the residue treated with water, which separated a fatty substance with an odour recalling that of cacao butter and entirely saponifiable by caustic potash. The yellow liquid upon concentration after filtration, deposited silky needles of caffeine, but when the solution was rapidly evaporated and the residue treated with water, ether or chloroform it no longer completely dissolved without using a considerable quantity and boiling, and upon such a solution cooling a small quantity of a compound crystallized out in microscopic prisms and octahedra which proved to be theobromine. The substances separated by chloroform from the dry nuts, were—caffeine, 2·348 per cent; theobromine, 0·023 per cent; tannin, 0·027 per cent; fat, 0·583 per cent.

The kola powder was then dried and exhausted with alcohol. A mahogany coloured extract was obtained, which when treated with boiling water dissolved entirely, but the solution on cooling deposited a large quantity of colouring matter. The aqueous solution was precipitated with triplumbic acetate, the precipitate decomposed with sulphuretted hydrogen, and a liquid obtained, free from bitterness, containing a considerable quantity of a tannin giving an intense green colour with persalts of iron, and a soluble colouring matter that formed lakes in contact with metallic solutions; the residue of the aqueous solution, after removal of excess of lead, was found to contain only glucose and a small quantity of fixed salts. The colouring matter deposited upon the cooling of the boiling water used in dissolving the alcoholic extract differed in its nature from the soluble colouring matter. It appeared to be an oxidation product from the tannin and presented considerable analogy to cinchona red; in order to distinguish it, therefore, the authors have named it "kola red."

The composition of the alcoholic extract from the dr nuts (5·826 per cent) was found to be—tannin, 1·591 per cent; kola red, 1·290 per cent; glucose, 2·875 per cent; fixed salts, 0·070 per cent.

The entire composition of the kola nut is compared by the authors with that of tea, coffee and cacao as follows:—

	Cacao (Mitscherlich).	Coffee (Payen).	Tea Green (Peligot).	Tea Black (Peligot).	Kola (Authors).

These results, it is pointed out, differ somewhat from those obtained by Attfield (*Pharm. Journ.*, [2], vi., 457), especially in the recognition of the presence of a second alkaloid and of tannin. The proportion of caffeine is higher than that observed in any coffee or, except in rare instances, in tea, and exceeds that of theobromine in cacao. The alkaloid exists in kola, as in tea, uncombined, but in coffee, according to Payen, it is present as chlorogenate of potassium and caffeine. It is worth mentioning that the authors report the presence of a considerable proportion of caffeine and some theobromine in the pericarp, but the material at their disposal was too scanty for an exhaustive investigation in this direction. The leaves, wood and bark were also examined for alkaloid, but gave negative results. As in the case of coffee, kola undergoes a considerable loss of caffeine (three-fourths) during roasting, while the quantity of essential oil present is augmented.

Some experiments have been made with this kind of kola in the treatment of the atonic diarrhœa to which Europeans are frequently liable in tropical countries. The results have been fairly satisfactory, and through the efforts of M. Heckel the medicine has been supplied to some French colonial stations for a systematic trial. The preparations used are an aqueous extract, an alcoholic extract and a wine. The alcoholic extract is made by exhausting fresh kola with five parts of 60° alcohol and the wine by macerating the same proportions of kola in a sweet white wine during a fortnight. Neither of these preparations, however, completely exhaust the kola, at last as far as the caffeine is concerned. The preparation of an aqueous extract presents considerable difficulty in consequence of the quantity of starch, which forms an manageable magma.

Concerning the "male kola" or "kola bitter," as before stated, nothing definite was known, and as recently as the year 1882 it was referred erroneously to a species of *Sterculia*. In the 'Flora of Tropical Africa,' Oliver says:—"The kola bitter of Fernando Po is the product of trees belonging to the Guttiferæ." The authors were led by this remark to attempt to obtain from various parts of the eastern coast specimens of the plant yielding "kola bitter," and although the flowers did not reach them they received specimens of the branches, leaves and fruits, together with a sufficient quantity of seeds to allow of a complete analysis being made. All the specimens received from various places corresponded in their characters, and showed that the kola bitter is the produce of a single Guttiferous species and not of several. From the material at their disposal the authors refer it to a new species, *Garcinia Kola*, Heckel. The plant is described as a tree of variable aspect, 10 to 20 feet in height, bearing towards the base of the branches large opposite leaves (12 in. long by 7 in. broad), with short petioles, whilst at the extremity of the branches the leaves are much smaller (5 in. by 2 in.). The leaves are oval, slightly dilated at the base, mucronate at the apex, without stipules, full green on the upper surface and greyish underneath. The fruit is a berry the size of an apple, with a rugose epiderm covered entirely with rough hairs. It presents three or four divisions, each containing a large oval cuneiform seed, rounded on the external and angular on the internal face; the seeds are covered with an abundant soorish yellowish pulp, constituting a true arillus. The fruit has at the base the persistent calyx still adherent to the peduncle, and sometimes the persistent corolla, and at the apex the persistent stigma. The plant is reported to occur all along the eastern coast of Africa and of Senegal, intermixed with the *Sterculia acuminata*, flourishing under the same conditions, but less widely distributed. In its known characters the plant would appear to be closely allied with *Garcinia Morella*, which, however, is essentially an Asiatic species. The seeds present one convex and two plane surfaces, the former being towards the circumference of the fruit. They are covered by an apricot-yellow episperm, below which is a large yellowish-white macropodous embryo, devoid of cotyledons, and with numerous depressions on its surface. The tissue is denser and closer than that of true kola and crackles under the teeth; it consists of a compact mass of very homogeneous cellular tissue, interspersed here and there with laticiferous vessels of varying size containing resin, the cells constituting which are filled with starch granules larger than those occurring in true kola.

Upon chewing these seeds a strongly bitter, astringent and yet aromatic taste is perceptible, which is quite different from that of true kola, and approaches in its aromatic flavour that of green coffee; it is this aromatic flavour that is esteemed by the negroes. It is worthy of remark that although the use of these seeds does not produce any notable stimulant effects or ward off fatigue, they are as much sought after and fetch nearly as high a price on the eastern coast as the true kola. In the interior, however, they are unknown. The authors are of opinion that these seeds owe their properties to the resin they contain, which is slightly stimulant. By the negroes they are thought to exercise an aphrodisiac action, which the authors consider doubtful, and as a masticatory, they are said to be a valuable remedy for colds.

An examination of fresh male kola nuts for caffeine gave negative results, the chloroform, ether and alcoholic percolates being all free from alkaloid. Besides colouring matter, tannin and glucose, two resins were separated. One of these was brown, hygrometric and soluble in ether and melted at the temperature of the water-bath; the other was yellowish white, soluble in ether, alcohol, acetone and acetic acid, insoluble in carbon bisulphide or petroleum spirit, and had a high melting point.

A large proportion of the paper is devoted to a study of the constitution of caffeine and several of its derivatives, in reference to the identification of the alkaloidal substances obtained by the authors from the female kola. —*Pharmaceutical Journal.*

Saccharate of Coffee.—O. Paresi, in an Italian medical journal, describes a new method of concentrating and administering the useful constituents of coffee, viz: roasted coffee, best, one part, refined sugar two parts with warm water sufficient for the purpose. The coffee is exhausted, and in a convenient displacement apparatus, of all its soluble constituents, by means of the warm water; the clear brown percolate is mixed with the sugar, and invaporated at temperature not exceeding 122 deg. Fahr., in a suitable apparatus, for low dryness; and finally reduced to powder, and kept in well closed vessels. The product is a brownish powder, of a coffee odour, a sweet and slightly bitter, but very agreeable taste, and very soluble in cold water. Dissolved in boiling water, it yields a very fine cup of coffee; on being made into a paste with tragacanth, it may be formed into tablets or troches, these being a very convenient shape for use.—*Planters' Gazette.*

GARDEN SCREENS.—A capital screen may be made as follows:—Fix a good post the required height at each end of the space to be shut out, then from their tops strain a strong galvanised wire, also, perhaps, another halfway down if a rapid covering or a high screen is wanted. Now plant Virginian Creeper at the bottom, 12 ft. apart, and train it up to the top. It will sometimes run along the wires of its own accord, but if not, a very little trouble will cause it to do so; then it will hang down delightfully, swinging to and fro in the wind, and getting thicker and thicker every year. If in a conspicuous position, plant alternately with the Virginian Creeper, Clematis Jackmanni or lanuginosa. These, running widly through the mass of Virginian Creeper, with their lovely flowers peeping out here and there, will soon form a sight worth looking at.—*Australasian.*

THE ORANGE IN NEW SOUTH WALES.—What apple culture is in England, that of the orange is in New South Wales; the Parramatta district, near Sydney, being to Australia what Kent, with its countless luxuriant orchards, is to the United Kingdom. The scenery of the Parramatta River is not unlike that of the Thames above Richmond, only more romantic and beautiful, especially during spring-time, when the wonderful profusion of wild flowers imparts an additional charm to the picture. Even the masses of rock, which in many places rise boldly from the edges of the stream, are decked with bright-coloured clusters of Australian natives flowers of the most lovely and varied description. The trees also claim a large share of admiration, not only from the lover of the beautiful in nature, but also from the utilitarian; for they include the orange, with its bright green foliage and dainty white flowers or rich golden fruit, both often being seen on the tree at one and the same time. The orange is not only a picturesque adjunct to the garden, but also more than repays the trouble and cost of cultivation. From a tree, appropriately known as the "poor man's profit," there was gathered this year an orange weighing 30 ounces, and measuring 16½ inches in diamerer. Of course this was exceptional, but rich and luscious oranges are as plentiful in the Parramatta district as blackberries in an English country lane during autumn-time.—*Public Opinion.*

HENEGUEN OR SISAL HEMP.—In a recently issued Government report on the trade and commerce of Mexico, the following appears:—"Heneguen, known in England as Sisal, or Sisal Hemp, and so called from the name of a port whence large shipments of it used to be made, is the product of a plant of the Agave family, and is grown almost exclusively in the peninsula of Yucatan. Its uses for the manufacture of cords and ropes were known to the ancient inhabitants of Mexico, but it is only within comparatively recent times that its value has been recognised in other countries, and it has come to be an important item of export. It is said that cables of Heneguen are superior to those made of Hemp, in that they retain their flexibility unaltered by cold or wet; but in spite of this and of the great and growing demand for it, especially in the United States, the price is always considerably below that of a similar class of Manilla. Ixtle is the fibre of another species of Agave, which flourishes principally in the United States of Tamaulipas, San Luis de Potosi, and Vera Cruz, and is of somewhat finer texture than the Heneguen. Up to quite recently no apparatus has been found that will satisfactorily separate the fibre from the pulp, and it is probably due to this that the price of it is so much higher than that of Heneguen, which can be treated by machinery." To show the enormous development of these industries in the past fifteen years, it is stated that "the United States, which takes on an average 80 per cent of the gross amount of fibre produced in Mexico, imported in 1867, under the head of Hemp and Jute, 975 tons of these materials, whereas in 1881 the imports under the same head amounted to 17,454 tons." The writer of this report had made some confusion in the trade names of the fibres, as well as in their botanical classification, referring them to the genus Aloe. The Sisal Hemp of commerce is furnished by Agave Ixtil, Karwinski, var. Sisalana, Engel., and the plant is called "Sosquil" in Mexico, and "Cabulla" in Central America. To extract this fibre the fleshy leaves are scraped with a long wooden implement, having three sharp edges; by this process, it is said, all the Sisal Hemp brought to market, as well as the infinitely larger quantity used by the natives themselves is slowly and laboriously extracted, the produce being only from 5 lb. to 6 lb. per day. The report refers the Sisal Hemp to plants belonging to the Aloe family, instead of which, as is well known to our readers, the species of the genus Agave belonging to the Amaryllidaceæ.—*Gardeners' Chronicle.*

A NEW DRUG called extract of guachamaca, by M. Schipper, is said by him to resemble curare, without possessing any of its dangers. The general symptoms produced by the injection of about 15 grains of the dry extract into the skin of a man were at first a light and then a deeper sleep, which lasted from two and a half to three hours, as well as a slight muscular spasm. The breathing and circulation were not affected.—New York *Hour.*

PLANTS SUITABLE FOR PERMANENT CULTIVATION IN DRAWING ROOMS.—A correspondent suggests that "a selection from the following list will make pretty and permanent groups: —Aralia Sieboldi (two variegated forms), A. quinquefolia, A. q. gracilis, A. heteromorpha, Dianella tasmanica, Aspidistra lurida and A. l. variegata, Dracæna Australis and D. a congesta, Rhodea Japonica and the variegated varieties, Griselinia lucida, Lomatias of different sorts, Asplenium bulbiferum, various Scolopendriums, Farfugium grande, Ligularia Kæmpferi, Pittosporum tenuifolium and eugenioides, Yucca Whippler, Y. albospica and angustifolia; Choisya ternata is also a most distinct and accommodating shrub. I have seen various bamboos tried for indoor decoration, but always with unsatisfactory results. Both forms of Aspidistra prefer a shady situation, as, of course, will the few ferns mentioned. If these are kept well supplied with water at the root, the atmosphere will always be moist enough. Occasional spongings of the foliage is of importance, as also is a good shower-bath outside, either with tepid water from a watering-pot or a warm shower of rain." Another correspondent writes:—"Room plants may consist of Arum lily (Calla), Aucuba, Aspidistra lurida, New Zealand holly fern, and red and green Dracænas. A walnut put into a pot of rich earth as soon as ripe makes a very handsome and uncommon pot plant the next summer, and has a delightful perfume. A Spanish chesnut, too, is useful planted in the same way. All these plants are kept in good foliage by occasionally sponging the leaves with tepid water, and if allowed to get too dry they are recovered by plunging the pot over its rim in water for an hour or so. This drives out the air and lets in the water."—*Australasian.*

HAND AND MACHINE MANUFACTURE.—Mr. T. C. Owen writes us regarding the estimate Mr. Graham Hogg was good enough to furnish us with the other day of the saving to be effected by the employment of machinery in tea manufacture as follows:—"Mr. Hogg's estimate is very interesting and well drawn up, but his allowance for depreciation of machinery is too high, I think. We have water-wheels, for instance, 20 years old and more on many estates and as good as new. He also omits all reference to the innumerable savings by employment of a lessened labour force, and to the saving on initial cost of factory buildings owing to the less space required for machinery. Then there are sifting, breaking, and equalizing machines to be allowed for, and surely fuel, which in the future will be an important matter, is made more of when burnt as wood than when a large portion of its combustible parts are *wasted* in turning it into charcoal."—The allowance made by Mr. Hogg for wear and tear of machinery, we stated at the time to be in our opinion rather high, unless it was intended to include initial cost, which no one as yet seems to have made allowance for. Though 7 per cent as the amount of wear and tear of water-wheel masonry, water course, &c., appears high, yet we doubt whether the repairs which have been undertaken in most stores from time to time, do not aggregate this on the gross amount expended. There are water-wheels and water-wheels, some requiring with the masonry, constant overhauling, and others little if any, but it is always best to be on the safe side. Again, we do not think that any allowance should be made for the saving effected in the initial cost of factory buildings owing to the lessened space required for machinery, as such an allowance would be very difficult if not impossible to approximate, but the same cannot be said of Mr. Owen's other objections. Allowance should certainly be made for the loss of fuel which occurs when charcoal is used for hand manufacture, but this, as well as the small saving obtained by the employment of a lessened labor force, is difficult to estimate, though it is well to note their existence as tending to show that Mr. Hogg's estimate is an eminently safe one.—Local "Times."

PRODUCTS OF THE UNITED STATES OF COLOMBIA.

The following interesting letter from Consul Anibal Gonzalez, of the United States of Colombia, at Philadelphia, contains many points that will be of interest to many of our readers. The letter was prompted by an article upon the cultivation of tea in that country, which appears in a recent issue of this journal.

PHILADELPHIA, January 12th, 1884.

Editor American Grocer and Dry Goods Chronicle:

On my arrival from New York yesterday, I found your most esteemed of January the 4th, and also a copy of your most valuable paper.

Allow me to state that tea planting in my country (United States of Colombia) is not a new or imported idea. Tea is also primitive in my country, and even before the Spanish domination there. tea was found in several regions of the country; but, unfortunately, our War of Independence, and afterwards, the civil struggles, did not allow my countrymen to cultivate the thousands of natural, rich products of the soil.

But now we have entered into a new era, and we want to be a little known by the United States of America.

They have in this country mostly a wrong idea of South America, and generally they have no idea at all. It is not understood that we are only a very short distance from the shores of Colombia. The distance to the districts where they have tea plantations can very easily be done in less than 20 days, all by water; two days by land.

We know very well that we must not export tea of inferior kind, as we want to gain credit for our exports, this being the base of prosperity and success.

We export superior coffee, called here La Guaira, Maracaibo, Savanilla, &c. We export Quina bark on a large scale, and we get in Europe the best prices. For instance, the quina known by the mark "Z" of La Compania de Colombia, is sold sometimes before arriving into the port.

We have all the climates of the world, and no change of seasons. In a district of 70 miles, you find sugar-cane plantations, coffee plantations, tobacco plantations; and corn, wheat, potatoes, &c., at a distance from the first-named of only 15 miles.

I thank you very much indeed for your article and information.

I have the honor to be, very respectfully,

ANIBAL GONZALEZ.

THE CULTIVATION OF TOBACCO IN SUMATRA.

The growth of the fragrant weed in the Dutch East Indies is conducted on a large scale by Companies formed for the purpose, many of which hold very large properties and give employment to great numbers of laborers, those most preferred being the Chinese. It is claimed for the tobacco produced that it especially adapted for use as wrappers for cigars, the leaf being very light, and burning readily with a white ash. This prevents the cigar from burning down the centre, whilst the flavour is so pure that it does not interfere with the finest fillings. The produce is shipped to the Amsterdam and Rotterdam markets, where it is sold in large lots by private contract, it having been found that the system of selling by public auction is neither in the interest of the importer or of the trade generally. It is not an unusual occurrence for tobacco worth £400,000 to be sold in one day. The trade, which may be said to have begun in 1865, has developed rapidly. In that year the produce prepared for the European market was but little over 30,000 lb., whereas in 1882 it had reached the enormous figure of 17,000,000 lb., and had been steadily increasing. Considering how easily tobacco can be grown in British India, and what scope there is for the development of the industry, we are glad to be able to place before our readers some account of the system pursued in Sumatra by one of the leading Companies engaged in the enterprise.

The Deli Maatschappij was established in 1870, and now owns eleven estates in the island, and is interested in various others. On each of these estates there is a staff of one manager and or five other European assistants, and about 550 permanent laborers, besides a variable number employed in clearing jungle, etc. The Company maintains two hospitals for its laborers, with a European doctor and apothecary, and a native staff to each. Forest land is usually selected for the crop, and the soil should be a loam, and if possible of volcanic origin. Proximity to the sea is undesirable, as the presence of too much salt in the air and soil causes the leaves to burn badly. Only one crop of tobacco is taken from the land, and it is then cropped with paddy for one year. and then left fallow for about ten years, during which the jungle is encouraged to grow up. Consequently a large area of land is required to each estate, and as only portions of the land are annually cropped, only temporary buildings are erected, they being used for two years only, and then a move is made. The land is laid out with much regularity with a system of parallel roads, and in fields extending about 300 yards on either side, those on one side being used one year, and those on the other in the next. The fields are about one acre in extent, and each is in the charge of a Chinese cooly, who practically cultivates it on contract, being paid prices varying from R3 to R21 for every 1,000 plants he delivers to the drying sheds according to the quality. But plants worth less than R7 a thousand are rarely taken, as they would not repay the cost of preparation. A cooly plants about 10,000 plants, and receives on an average about R14-8 a thousand. Besides this he cuts a number of rattans, and makes during the eight or nine months' work in the fields in all about R180 to R190, besides earning more for any work he does in the drying sheds. The cooly does everything required on the land, from burning the jungle to cutting the plant when ripe, and hanging it in the drying sheds. The crop is raised during the dry season, and takes two or three months to mature after transplanting from the nurseries. It is harvested during the months of June, July, and August. In the drying sheds the leaves are dried for three or four weeks, and are then stripped, tied in bundles, and piled in heaps in order to cause fermentation. Great care is taken in this last process, the piles being turned as soon as the heat becomes great, until the colour of the leaf gets fixed. When this is effected the leaves are sorted according to their length, and undergo a final process of fermentation. They are also carefully sorted according to their colour, and resolved into about fifty or sixty sorts packed separately for export in mats with hydraulic pressure. The sorting requires great experience, care, and attention, and the cooly when working at it earns about R14-8 a month.

In climate and in soil, Sumatra appears to be favored for this crop much beyond what we are in India, but there can be no doubt, from the evidence we have in the Dindigul and Godavery tobacco now produced, that with an equal amount of care and supervision, both in the curing and in the assortment of the leaf, the local industry might be very greatly developed. It is only necessary that our Indian tobaccos shall be better cured and carefully sorted so that they may be true to brands, for a great trade, we believe, to spring up in the article with other parts of the world. This is a direction in which private enterprise has never yet been steadily maintained in Southern India.—*Madras Mail.*

PRACTICAL RESULTS IN DRYING COCOA: MESSRS. WM. CAMERON AND J. B.'s SUGGESTIONS.

SIR,—I have read with much interest the articles upon *drying* which have appeared in the local papers—both Mr. Cameron's and J. B.'s. Since I have been a cocoa and tea planter, it has been my object to attain some practical knowledge upon this subject, and, with all due respect to Mr. Cameron, I find all my experiments fail absolutely. or are unnecessarily expensive, so far as I have the principles as laid down by Mr. Clerihew. In a previous letter of Mr. Cameron's, he tells us that Clerihew's system was known at home 40 years ago—possibly it did not occur that it must be nearly 40 years ago since the first Clerihew store was erected in Ceylon.

It is not my intention to enter into theories or general principles of drying as laid down in formulas, but to plainly relate the result of my experience, which quite accords with the principles laid down by "J. B." But more than this, they prove that Clerihew understood a system of drying far and beyond the conceptions of ourselves, if I may judge from my own ideas and from the ideas of those I have consulted.

Of all substances to dry, nothing comes up, for sheer difficulty, to cocoa. Place it wet in a close room at a temperature of 160°, and the cocoa will mildew (I now believe from the steam it will produce) in about five hours. Draw or exhaust the air upwards, and the result will be the same. Exhaust from the bottom, at the rate of a fresh atmosphere, every two minutes, and you will, with a temperature of 110°, safely dry your cocoa.

I have come to the conclusion that the chief aim in drying is to distribute the dry air as much as possible, and on no account to allow it to escape until it has, to its utmost, done its work; and, as far as I can see, this can only be accomplished effectually by the rapidity with which it is wafted away by the fan. The moisture must be evolved, not only from the material, but from the chamber.

All attempts to dry cocoa by allowing the heated air to rise vertically through it have failed. First, economically, as the heat is so much wasted; and second, its effect is not as even as if the heated air were drawn through it and exhausted from beneath. Furthermore, the results of drying from heated air rising through the cocoa have not been satisfactory. The cocoa has been overdone on the lower side and unsufficiently dried upon the upper, resulting in a very inferior sample.

The great principle cocoa planters have discovered in drying cocoa is that all cocoa-Clerihews should be worked with the strongest fan power, but the lowest possible temperature. The heat may injure the produce, the draught can do it no harm. Personally, I am contented with the chamber being from 110° to 120° *Far.*; but the fans must exhaust the room every two minutes.

Instead of thinking that Clerihew's system is falling into disuse, I may say that I have listened to others and carried out their views, but always without success, and it is only by means of Clerihew-pipes, Clerihew-fans, and the Clerihew-store that I have been able to make head-way against cocoa curing.

At first I should have written as Mr. Cameron does, for I did more: I acted as he suggests, and have been a loser thereby. These experiments have cost me time and money, while had I been contented with the old recognized system, I should now be a richer man.

A summary of the Clerihew-system as I understand it is—1st, an exposure of the produce to the heated air; 2nd, the heated air to be retained with the produce for a sufficient time to take up its greatest quantity of moisture; 3rd, this being accomplished the vitiated air should be removed as quickly as possible. Now, it will, I think appear clear that there is a loss in the heat being *drawn upwards*, when it might escape too quickly, which is not the case when it is drawn down.

In a Clerihew-store, comparatively drawing up heated air with the same force as drawing it down, the result will not be equal to 50 per cent in practical drying, and if persisted in the heat must be double in quantity and firewood in proportion to produce the same drying effect, and such heat would result in scorching the lower side of the substance dried. With the same heat as in Clerihew's system as would dry cocoa, when the heated air is drawn up, the cocoa mildews.

I think Mr. Vollar, of Pallekelle, will bear me out in all I say as regards drying cocoa.

Upon drying tea I cannot think differently than that a principle of drying adopted to one can be economically applied to the other; so I should prefer "Kinmond's" dryer to the "Sirocco," as I know the principle of the former is more like Clerihew's system—indeed I see little difference.

The information I now give is entirely practical, after much personal research, and I may say some manual labour.—W. F. L.—Local "Times."

Watermelon Syrup.—It is claimed that a syrup can be made from the watermelon finer than that from sorghum or even the West Indian sugarcane. What is needed is a method of crystallising the syrup.—New York *Hour.*

THE EUCALYPTUS IN SOUTHERN EUROPE.

Not greatly inferior in importance to the introduction of the Cinchona into India and certain of our colonies has been the diffusion of various species of Eucalyptus throughout our Colonies and in the South of Europe. In this island the species are too tender to be anything more than curiosities, though E. Gunnii survives the unfavourable conditions of a Kew winter, and E. coccifera has formed a good-sized tree at Powderham Castle, Devonshire, and has even flowered (see vol. xiii, p. 395). But it is to our colonies that the cultivation of these trees is a matter of importance, and it may, therefore, be not inappropriate to call the attention of our readers to a valuable memoir on the species of Eucalyptus introduced into the Mediterranean region, recently published by M. Naudin in the *Annales des Sciences Naturelles.* We have frequently had occasion to allude to the splendid monograph in course of publication by Baron von Mueller which must serve as the standard of scientific information on these trees for years to come. M. Naudin's object is more restricted; he confines himself to the species introduced into Europe, and he studies them from a cultivator's point of view, not from dried specimens or trees in one stage of growth only, but from the germination to the ripening of the fruit. The rich collections of the Villa Thuret and other gardens along the Riviera have afforded him the means of doing this. We have then in the treatise before us one of those botano-horticultural memoirs which are of such special value to cultivators.

One of the first points noticed is the variation in the form of the leaf in the same plant, which is so marked a feature in the species best known in this country, E. globulus. M. Naudin points out how the seedling plants of various species differ one from another in this particular. If the trees are pollarded, shoots are produced from near the base of the trunk, bearing leaves similar to those of the juvenile plant, and leaves of this form are often produced without any injury to the tree having taken place. This partial reversion to a previous condition is no bar to the production of blossom, as flowers and fruit are produced on these juvenile looking shoots as well as on those of the adult branches. We have, then, in the Eucalypti the same condition th[illegible] occurs in so many Conifers, Thuias, Junipers, &c., a[illegible] to which we owe many of the Retinosporas of our [illegible]ardens. In the latter class of plants the disposition of the breathing pores, and the production of the leaves on branches of different character of growth, point to a difference of function, which is not hinted at by M. Naudin in the case of the Eucalypts, although he suggests the possibility of the diversity in form having been due to cross or hybrid fertilisation.

M. Naudin passes in review the "characters" that have been proposed to distinguish the species, such as the form and nervation of the leaf, the size and habit of the tree, some being small, others furnishing trees which exceed the famous Sequoias of California in height. The characters afforded by the bark of the full-grown trees, such as are recognised by the foresters, and which have been adopted by Baron von Mueller are also noted; but for his purposes M. Naudin prefers characters taken from the inflorescence, flowers, and fruit. Singularly enough it is not yet ascertained whether fertilisation takes place before or after the fall of the little cap which at first covers over the stamens and styles. If before, then cross-fertilisation would not occur as a rule. M. Naudin, however, suspects that the fertilisation takes place after the fall of the cap, and that much of the variation met with is due to crossed impregnation. This would certainly seem the most probable view, though against it we have to set the opinion of Baron von Mueller, whose experience is so large that no one would be disposed to question it unless he felt very secure of his facts. So far as the Riviera is concerned, and the few species there grown, the question as to the self or cross-fertilisation surely could speedily be settled, even if it were more difficult to prove actual hybridity.

As to propagation, M. Naudin recommends seeds in preference to cuttings, there being no difficulty in raising the seed in seed-pans under glass in a warm greenhouse or propagating pit. As the seeds are very small the should be covered with only the slightest possible coverin of earth. It is not so easy, however, to rear the seedlings during the two or three months of their existence, except in the case of those which have been grown in the open air. If they have to be pricked out from the seed-pad the risk of injury is great. This pricking out is best done early, when the plants have only three or four leaves. They should be placed in small pots, in a compost of vegetable mould, sand, and loam, in equal proportions, and should be placed in a shaded position till they have established themselves, when they must be exposed gradually to sun and air. Injurious watering is the greatest danger likely to befall them. M. Naudin points out that they are naturally plants of a very dry climate, with abundance of clear light. As they grow on the plants should be shifted into larger pots with a larger proportion of loam *terre franche*, and with good drainage: the pots can be protected in winter if necessary, and planted out in the open the next year (M. Naudin is writing in the Mediterranean regions).

The site where the Eucalypts are to be planted should be chosen beforehand, for they admit to rival near them and by their rapid growth make large demands on the soil, which should therefore be deep, though there are some dwarf-growing "scrub" species which do well on a shallow rocky soil.

When it is desired to make a plantation, the trees should be planted in lines at equal distances, at first thickly, each tree having a space of 4 square metres—that is to say, there should be 2,500 trees per hectare (a hectare is rather more than 2 acres). After three or four years clearances should be made by removing alternate lines of the trees, first lengthwise and after an interval in the opposite direction, so as to leave space between the trees as they grow. Pruning should scarcely be required unless in the case of misshapen trees. At the end of ten years the number of trees per hectare should be by the means above detailed reduced to 400—500.

Felling may commence after about twenty years, according to circumstances, the trees having by that time acquired a height of 20—25 metres, and a girth at 1 metre about the soil of 2·50—3 metres.

The profit to be obtained, of course, will vary according to local circumstances, but under ordinary conditions a very satisfactory result may be counted on.

For the most part the Eucalypts are trees of warm temperate regions, where the winter is mild, the spring rainy, the summer hot and dry. Very few of them are found in the tropics. Some of the Tasmanian species, such as amygdalina, coccifera, or some from the Australian alps—E. Gunnii, coriacea, polyanthema—may succeed near the sea in Western Europe. Some species are limited in distribution by soil characters, some being found on sandstone, some on basalt, granite, or limestone. Incidentally M. Naudin speaks of the value of the flowers as food for bees.

The culture of the Eucalyptus in Southern Europe only dates from the last quarter of a century, but the trees are now to be counted by hundreds of thousands. Without pledging himself to any opinion as to any special vritue in Eucalypts, such as has been claimed for them, M. Naudin points out how valuable trees are as sanitary agents, and especially in countries like some parts of Italy, Algiers, and Turkey, where the indiscriminate felling of the forests has rendered the country a desert. What a melancholy spectacle for the traveller in these countries, formerly flourishing and deeply populated, to see them now barren, reduced to their rocky skeletons, or with their plains alternately scorched by the sun, or transformed into pestilential swamps. The remedy is now known, and it is not beyond the power of a civilised Government to effect it in time by means of replanting, and a proper system of forest conservancy. The condition of Algeria, which M. Naudin has studied for himself, leads him to advocate replanting there on the largest possible scale, in spite of the inevitable cost and difficulty of the proceeding. Various Oaks, Abies Pinsapo, Pinus halepensis, Pistacia atlantica, &c., form the natural timber of the country, but these have been recklessly destroyed, and meanwhile timber and firewood are urgently needed by the growing population. M. Naudin shows how the Eucalyptus globulus will supply in the same period of time at least four times as much timber as an Oak.

With these remarks, with which all who have considered the subject must in substance concur, M. Naudin prefaces his detailed description of the thirty-one species which he has been enabled to study from the seedling to the fruiting stage. Descriptions of these are given in Latin, as being serviceable all over the world; and, as we have said, the primary distinctions are based upon the inflorescence, the flower being solitary, or cymose, umbellate, or panicled. Afterwards come characters founded upon the number of flowers in each inflorescence, the distribution of the stamens, the form of the calyx-lid (operculum), &c.

M. Naudin has had many other species under observation, but only includes those which he has been enabled to study from the seedling stage to maturity. We may add that there is a collection of several species represented, of course by small specimens only, in the Temperate-house at Kew.—*Gardeners' Chronicle.*

GUTTA-PERCHA.

BY JAMES COLLINS.

(*Continued from p.* 635.)

The trees yielding gutta-percha are very restricted in their geographical distribution. Gutzlaff defines the limits as 6° N. and S. L. and 100° to 120° E. L., but I am inclined to think this area much too wide. In this I am supported by Captain Lingard, who has traded largely in gutta-percha, and collected it on the spot. He gives the limits 4° N. and 3° S., still further restricting the finer varieties to 4° 5′ N. and 1° S., with a temperature whose outside limits is 66° to 90° Fahr., and a very moist atmosphere. The lower kinds, of course, grow outside of these circumscribed limits, and are found near the sea coast on low but not swampy ground, whilst the best varieties grow inland on hill slopes and in groves, surrounded by other forest trees, at an elevation said to be from 100 to 600 feet above the sea. Gutta-percha trees are indigenous to Singapore, although only two or three are now to be seen as curiosities. In that island the mean total rainfall for five years ending 1873 was:—1869, 90·63 in.; 1870, 123·24; 1871, 109·45; 1872, 75·30; and in 1873, 85·60 inches. This rainfall is variable at different periods, and the year may be divided into three periods of four months each:—

1st. From January to April, during which the rainfall is very variable and uncertain.

2nd. From May to August, which may be termed the dry season, and is the period, as a rule, in which the rainfall is least.

3rd. From September to December, which may be called the wet season, and during which, as a rule, the rainfall is greatest.

As to temperature for the same period:—The highest was in 1869, 92°; 1870, 93°; 1871, 91° 5′; 1872, 92°; 1873, 92° 5′. The lowest was in 1869, 69°; 1870, 69°; 1871, 69°; 1872, 67°; 1873, 68° 5′.

It appears, therefore, that gutta-percha trees thrive best where they have a light loamy soil, at the foot or slopes of hills, surrounded by primitive jungle, and with a moist temperature not rising above 95° or sinking below 66° Fahr.

The collection of gutta-percha generally takes place directly after the rainy season is over, as in the dry season the gutta does not flow so readily; during the rainy season much gutta is washed away as it flows out, and the collectors are more liable to ague and jungle fever. Often the natives go in companies, receiving advances in money, clothes, food, and tools to be afterwards deducted, although it is not uncommon that through the non-success, death, or knavery of the collectors, the trader loses both principal and interest. Natives, too, collect gutta in their own vicinities, and barter it at trading stations.

The yield of a well-grown tree of the first or best variety is from 2 to 3-lb. of gutta-percha, whilst full grown trees of from 100 to 140 feet high have been known to yield as much as 50 to 60-lb. of gutta. The average yield of different varieties, differs materially, sometimes as much as 30 per cent. Gutta-percha, too, often loses 35 per cent of its weight in drying during the first six months after collection.

The method of extracting gutta-percha is much the same among the Malays, Chinese, and Dyaks. The trees are cut down just above the buttresses by means of "billiongs."

a chisel-like axe, a "parang," or long knife with a sword-blade, 12 to 14 inches long, or an axe perfectly wedge-shaped. The last is used by Chinese, the two former by Malays; they are all of the native manufacture. As soon as the tree is felled, the greatest haste is made to lop off all the branches, otherwise the gutta-percha ascends to the leaves and is thus lost. Narrow strips of bark, 1 inch broad, and six inehes apart, are next cut out around the tree, except the part of the trunk buried in the ground, the contained gutta of which, about 25 per cent, is lost. The bark is then beaten with mallets, and the gutta flows slowly, changing from a yellowish white to a reddish tinge, and rapidly concreting. Bamboos, pieces of bark, &c., receive the juice as it flows. This "raw" or gutta-muntah, is collected together and pressed into a ball or slab, a hole being made in it for facility of carriage. It often reaches our market in this raw state. For the preparation of good gutta, these balls are boiled in a shallow iron pan, called a "quali," kneaded into balls or fanciful shapes, and then the result is ready for exportation. This boiling is most important if the good qualities of the gutta are to be preserved.

There is a further process which the gutta-percha has often to undergo at the port of shipment, that of "reboiling." This consists of classifying and assorting the numerous parcels, of all sizes, shapes, colours, and qualities, into certain classes. These parcels are often adulterated to an alarming extent. The Chinese are great adepts at this classification, and the custom is to mix together small parcels of different varieties, so as to produce a "standard sample." This is done by slicing the gutta, boiling in large shallow iron pans, and constantly stirring. Sometimes the juice of the lime fruit or cocoa-nut oil is added during the boiling, the former to hasten coalescence, and the latter to give a better appearance to the product. When sufficiently boiled, the gutta is taken out of the pans, pressed into large moulds, and packed for shipment.

At various periods during the last 15 years, the subject of gutta-percha and its supply for commercial purposes has engaged my attention, and a brief *résumé* of the results of these inquiries may not prove out of place. In these remarks I may have to repeat a little of what I have stated with regard to pseudo-guttas, but this I do for sake of completeness.

As will be seen, there are numerous varieties of gutta-percha, and these differ most materially in character and value. These varieties are often mixed by natives, and great harm is done thereby to a good gutta. But the greatest harm in this direction is done by the Chinese and others, at the port of shipment, by the process of "reboiling." Pracels of different varieties, particularly if of low or inferior quality, are mixed together, and a certain quantity of best gutta added to give "tone" to the parcel, and allow of its passing muster. Sometimes this "tone" only consists of a skin of good gutta over a core of bad. Now, some of these "low varieties" have no right to be classed as "gutta-percha," unless, indeed, we extend or "expand" the significance of the term so as to include such substances as kowrie gum, gambier, and cutch. This indiscriminate mixing, to a manufacture, is a serious matter, and I believe that, in some cases, where a "fault" occurs in a cable, it arises from the fraudulent admixture in the gutta of some such resinous substance and its subsequent crystallising out. It must be borne in mind that a small percentage of such an admixture may render a cable utterly useless at a most critical moment. That such a reprehensible practice of admixture does take place, I have had personal opportunities of observing. There are many varieties of gutta-percha which are valuable, but the mixing of these different varieties should be left to the manufacturer at home, as he alone can best judge of the mixture or blending most adapted for the purpose he has in contemplation.

That there is a necessity for boiling gutta-percha before sending it home seems to me conclusive, and if not properly performed by the natives it should be done by the merchants before shipment, and for the following reasons:—

Pure gutta-percha, as it flows from the tree, is a viscid fluid, acquiring milkiness and concreteness on exposure to the atmosphere. By the absorption of oxygen it splits up in time into two resins, known as *albine* and *fluavile*. This proneness to resinification in gutta-percha I have often noticed and experimented upon, and that by boiling the gutta-percha as soon as possible after collection this is arrested, I have proved both at home and abroad. Thus if a piece of "raw," or gutta-muntah, be taken, and the half be well boiled and pressed, it will retain its good qualities, whereas the other will become a resinous mass. Thus, through the gutta not being thoroughly well boiled at first, what would otherwise be of good quality becomes deteriorated in quality, or absolutely useless.*

In preparing gutta, therefore, for market, all large blocks should be cut open, well boiled, and pressed in the form of small thin slabs. This should also be done with gutta-muntah, and thus not only will freight be saved, but gross adulteration and depreciation of value by chemical changes will be reduced to a minimum.

In my paper at the Society of Arts, on "India-rubber," and my report on the same subject to the Secretary of State for India, I gave the opinion that it was not necessary to cut trees down to obtain the Indiarubber, and that trees, after allowing a certain period of rest, could again be "tapped." This, where carried out as I indicated, has not only proved practicable, but also a great saving, and a much more economical method of working a forest.

The native evidence against "tapping" gutta-percha trees is nearly overwhelming. They insist on the necessity of cutting down the trees. This may arise from indolence, a wish at one operation to obtain the greatest possible quantity without a thought to future supply, or from the want of sufficient aggregation of the trees within a resonable distance, to obtain a sufficient quantity of gutta to repay collection. Gutta-percha does not flow so readily as Caoutchouc does, and also more rapidly concretes. The yield in the rainy season is nearly double that of the dry season, due possibly to two reasons, first, that nature has not yet been called upon to use up the gutta-percha for the elaboration of new tissues, or, second, the greater amount of moisture causing greater fluidity in the gutta-percha milk. The Dutch Government tried to induce the natives to practice "tapping," but without success, and "boring," as is practised with the sugar maple, met with a like result. The question can only be set at rest in a well regulated plantation.

The many and various purposes to which gutta-percha is now applied are legion, rendering an enormous and regular supply absolutely necessary. For our commercial supplies of any staple article, we cannot long depend on the spontaneous products of the forest; a statement that, to an economic botanist, has the full force of an axiom. These products are collected in a most reckless and destructive manner, and then only when other and better, or, at least, easier means of livelihood fail. The requirements of civilisation and space for agricultural pursuits, jungle fires, &c., are great destructive agents to the existence of forests. Often have I seen a spot which had cost nature centuries to fill with her wondrous handiwork, turned by recklessness into a veritable charnel house.

As to the number of gutta-percha trees which have been destroyed, Dr. Oxley calculated that to supply the 6,918 piculs (1 picul equal 133⅓ lb.) exported from Singapore, from the first January, 1845 to 1847, 69,180 trees were sacrificed; and, according to the *Sarawak Gazette*, 3,000,000 trees were required to supply the 90,000 piculs exported from this district during 1854 to 1874. These are only two instances, the first, showing the trade in its infancy; and the second, that of a limited and comparatively small producing locality. In fact, the gutta-percha tree has only been saved from utter annihilation because trees under the age of 12 years do not repay the trouble of cutting down. Still, it is clear that the growth of young trees of the best varieties has not kept pace with the destruction, but are becoming much scarcer, so that recourse now, more than ever, has to be had to the products of very inferior varieties.

At the present time there is a great difficulty in obtaining sufficient supplies of the best varieties, especially for telegraphic purposes.

Cultivation and acclimatisation is our only resource, and the Government of the Straits Settlements have a splendid opportunity for carrying this matter out. We have now a great amount of power and influence in the Malayan Peninsula, and could easily introduce a form of Forest Conservancy. By letting or "farming" out these forests for collecting gutta and other forest products, the working expenses of conservancy would be secured, the native rajahs

* *Vide* "Remarks on Balata and other Pseudo-Guttas," Jour. Soc. Arts, Nov. 23, 1883, pages 15 and 16.

paid a small royalty, and possibly an addition made to the colonial revenue. A clause to be stringently enforced should be inserted in all such contracts, namely, that for every tree cut down, two or three should be planted in the place thereof.

The Indian Government, acting on the advice of the late Mr. Howard, F.R.S., Mr. Markham, Dr. Spruce, and others, did, with rare forethought, undertake the initiative in introducing the cultivation and acclimatisation of the cinchonas, and private planters, seeing the success achieved, have also taken up the matter. They have also taken up the Indiarubber question. The Colonial Government should now take up the question of gutta-percha. Borneo, Labuan, the southern portions of the Malayan Peninsula, are the natural homes of these trees; possibly the Nicobars, Ceylon, and some parts of Assam, would prove equally congenial, and Singapore could be used as a nursery for the young plants.—*Journal of the Society of Arts.*

PARTICULARS OF SEEDS AND PLANTS LATELY INTRODUCED TO JAMAICA BY THE DIRECTOR OF PUBLIC GARDENS AND PLANTATIONS.

Botanical Department, Gordon Town P. O., 4th Dec. 1883.

SIR,—I have the honor to report that while absent from Jamaica, on vacation leave, I was enabled to make collections of seeds and plants for the Botanic Gardens in this Island, most of which had not been previously introduced.

2. My chief aim was directed to obtain and introduce seeds and plants of economic and industrial value, in order that, ultimately, their produce might contribute a quota to the wealth and resources of the country.

3. Although the number and value of the seeds and plants thus obtained were considerable, I anticipate that, having established relations with new correspondents in different parts of the world, I shall obtain, by exchanges and otherwise, many other important plants which are not at present in the Island.

4. From the Royal Gardens, Kew, I was permitted, by the kindness and courtesy of Sir Joseph Hooker, to make a valuable selection of economic and ornamental plants, some of which came out by the mail of the 17th October, and others under my own charge by the mail of the 2nd November.

5. Amongst these valuable plants was a fine well-grown set of *Cinchona Ledgeriana* raised at Kew. These will be kept at the Government Cinchona Plantations as types of the best forms of this species. Other Cinchona plants were *C. Calopteru*, new to the Jamaica plantations, and *C. Calisaya var Josephiana.*

6. There was also included a good strong plant of Scammony (*Convolvulus Scammonia*), the dried root, as well as the resin from the root of which, is an important article in medicine. This is intended to be cultivated on the hills.

7. Amongst other plants obtained from Kew were *Aloe Succotrina*, one of the plants supposed to yield the famous Socotrine aloes of commerce; as also *Aloe Perryi*, the true plant; the latter, however, I regret to say has not survived.

8. *Garcinia Mangostana*, which bears the celebrated Mangosteen fruit of the Eastern Archipelago. Although plants of this were already established in the island, I was fortunately able to supplement them by half-a-dozen more from Kew, which, when recovered from the effects of the voyage, will be planted in favourable situations.

9. Owing to the interest taken, at the present time, in fibre-producing plants, I brought out with me two authenticated plants of *Agave ixtli*, the source of the celebrated Sisal hemp of commerce. The cultivation and extraction of fibre from this plant, in Yucatan, form a large and increasing industry, estimated to reach an annual value of £100,000. As much time and money is lost in fruitless experiments with many so-called fibre-plants, it is a matter of the highest importance to be able to determine accurately what plants are known to yield remunerative results in other countries; and, also, those for which satisfactory machines have been invented to extract the fibre. These plants *Agave ixtli* have been put out at the Parade Garden, Kingston, where they may be seen by persons interested in the subject.

10. In a subsequent letter I hope to discuss, fully, the means for obtaining large supplies of these plants, in order to distribute them widely amongst those anxious to undertake their cultivation.

11. *Quillia Saponaria.*—This is a large tree, native of Chili, rich in *saponine*, a vegetable soap-principle. A few plants have been introduced for experimental trial, as it is anticipated that a demand will arise for the bark for use in the arts and manufactures.

12. *Piper methysticum.*—This is described by Mr. Horne in "A Year in Fiji" as follows:—"*Piper methysticum* is grown to some extent by the natives for making their favourite beverage *ayona* or *kava*. When well grown it is a noble picturesque-looking plant, worthy of cultivation in our English hot-houses. The root is the part used, and the plant is easily propagated by cuttings. Of late, attention has been called to the medicinal properties which the plant is said to possess, and a quantity of it has been exported to the Australian colonies. The Fijians give presents of its roots to their chiefs, friends, and any one that they wish to propitiate. Between them and some of the traders it has a recognised market value, at which it is bought and sold, varying according to the supply and demand. The best quality is grown in the mountains where it grows most luxuriantly and in great abundance." The plant obtained from Kew arrived safely in Jamaica, in spite of its delicate character, and it is hoped it will be fully established at the Castleton Gardens.

13. Numerous other plants from Kew were also introduced at the same time, consisting chiefly of new, ornamental and decorative foliage plants for the plains. These in due time will, no doubt, find a congenial home in the numerous well-kept gardens which exist in the Island.

14. While at St. Helena I received much valued assistance in making collections of seed of the numerous indigenous and introduced plants at present thriving there. To His Excellency the Governor of St. Helena, Lady Ross, the Hon. George Moss, Lieut.-Colonel Phillips, Mr. Bazett N. Knipe and many others, I am indebted for great courtesy and kindness in these respects, which I am glad to acknowledge here.

15. Having been so long a calling station for ships from all parts of the world there are found, at St. Helena, plants from nearly every quarter of the globe; but more especially from India and the East, from Madagascar, Australia and the Cape.

16. Among the seeds obtained from St. Helena were the following:—*Royenia lucida* or wild peach—a pretty white-flowered bush, useful for hedges and shrubberies. It bears a fruit, a kind of purple plum, enveloped in an outer covering resembling the Cape gooseberry. *Royenia pallens* or poison peach—similar to the last but taller. The wood is of a like nature to ebony.

17. *Olea Europæa* or true Olive.—Two varieties of this important and interesting tree are completely naturalized in St. Helena, and by the kindness and courtesy of the Hon. George Moss I was enabled to bring with me about two bushels of fine ripe seed for distribution in this Island. Although so many other plants have been introduced to Jamaica from time to time, the Olive has apparently not been successfully cultivated here. Mr. A. W. Heron, of Shooter's Hill, has or had a couple of plants of the Olive which were obtained a short time ago, which if now alive are probably the first olives introduced to Jamaica. As the best varieties of the Olive are propagated by cuttings or slips, in order to supplement the present supply of seeds, it is intended to procure (through the Royal Gardens at Kew) a consignment of stock plants from known and reliable sources in Spain or Italy.

18. As regards the cultural treatment of the Olive I would quote the following extract from an article on "The Vine and Olive in Siena," in the Journal of the Society of Arts for October 19th 1883, pp. 1005-6:—"The Olive is cultivated on the hills. In some places it is grown in plantations, and in others the trees are generally planted in rows along the fields in combination with other cultures. The varieties most generally grown are the *correggiolo*, the *moraiolo*, which ripens early, and the *olivastro*.

19. "The trees are grown from slips cut in the spring, which are planted in holes in ground that has been well broken up and covered with mould and watered as re-

quired. The hardiest shoot is subsequently selected and may be permanently planted in three years. The Olive is also raised from seed. In the districts of Siena, when a tree is about to be cut down, the *ovoli*, or eyes, on the roots are detached and placed in a separate plot of ground, plants being obtained from them in three years, which can then be transplanted. In the wooded districts where the wild Olive is plentiful, grafting is commonly employed. The trees are usually planted in holes or ditches of more than two yards square, and a yard deep, drained with a layer of stones.

20. "When the olives are planted in row in the fields, they are generally pruned *a paneira*, nearly all the inner branches being cut away from the centre to enable air and light to penetrate freely. The trees are pruned every two or three years. The most careful cultivators apply a special manure, when the trees are between five and eight years old, composed of straw, mixed with wollen rags, the whole saturated and moistened with sewage, but this is not general, as the trees profit by the manure laid on the fields. It is estimated that in the province of Siena one acre of vines will produce 115 gallons of wine, and an acre of olives 20 gallons of oil; the quantity of the former actually produced in 1882 amounting to 10,898,000 gallons, and of the latter 780,000 gallons."

21. *Scotia tamarindifolia* or Coral Tree.—A shrubby ornamental tree ten or twelve feet high, with crimson flowers somewhat resembling *Fuchsia*; but bearing short legumes and large rounded seeds about one inch in diameter. According to Dr. Atherstone, the beans from the pods of this plant are roasted and eaten in the Albany districts where they are called Boerboom, and the powerfully astringent bark is used medicinally, as well as in tanning.

22. *Podocarpus elongatus* or Cape Yew.—A handsome timber and shade tree allied to the Yacca (*P. coriaceus*) of Jamaica. A fast growing tree, suitable for the higher lands, and yielding excellent timber known at the Cape as Yellow Wood.

23. *Melhania erythroxylon* or Red-Wood of St. Helena. A tree of twenty feet high, with handsome slender foliage of a pale green colour; the large bright flowers first appear pure white, changing after a day to pink, and finally to a brownish red. Flowers of all three colours are seen on the tree at one time, giving it a singular appearance. The wood is hard and of a rich brown colour. As one of the fast disappearing indigenous plants of St. Helena, this is a very interesting tree, and its naturalization in Jamaica would be an event of considerable botanic and economic interest.

24. *Pittosporum undulatum* or Tree Pittosporum.—One of the handsomest flowering trees of Australia, growing to a height of thirty or forty feet. The rich perfume of its white blossoms extends over a considerable area.

25. *Pittosporum viridiflorum* or Green-flowered Pittosporum.—A shrub which attains a height of ten or twelve feet. Though the flowers are not so handsome as in the last species, they possess an equally delicious perfume.

26. *Leucæna glauca* or Seed-work Acacia.—From the seeds of this shrub beautiful ornamental work is made at St. Helena which is largely sold to visitors. The tree is very common in the Liguanea plains and other places in Jamaica, and with taste and judgment ladies of small means might utilize the seeds for the manufacture of brooches, necklaces, etc. The seeds are coloured black by means of a little copperas (sulphate of iron).

27. *Acacia longifolia* or Port Jackson Willow.—This is one of the hardiest and most easily grown of all Australian plants. It is admirably adapted for clothing the bare barren slopes of the Port Royal Mountains, and through the kind offices of His Excellency the Governor of St. Helena, I have made arrangements to procure regular and large supplies of seed of this useful tree. The timber is close-grained and hard, something between Walnut and Salmwood and takes a fine polish. The bark, which contains a large quantity of tannin, is admirably adapted for the preparation of leather.

28. *Acacia (Albizzia) lophantha* or Black Boy.—One of the most rapid-growing trees in exposed situations: it produces seed abundantly which germinate easily. For exposed hill sides, steep barren lands and desolate places, generally, this tree is invaluable to create shade and so induce shelter and a copious vegetation (Mueller).

29. *Curtisia faginea* or Assegai Tree.—A hardy handsome shrub from the Cape of Good Hope. The natives of the region where it abounds employ it to form shafts for their javelins or assegai.

30. *Psiadia rotundifolia* or Bastard Gum Wood.—The chief characteristics of the indigenous Flora of St. Helena is the existence of tree-like plants allied to the English daisy, dandelion and the common aster. As once described by Sir Joseph Hooker "it is wonderfully curious Flora, a fragment from the wreck of an ancient world, resembling none other in the rarity of the plants of other countries, or in the number of species that have actually disappeared within the memory of living men." Of these plants the Bastard Gum Wood is the most interesting as, at the present time, only one tree is known to exist in the world, and that grows in a field near Longwood, formerly the residence of Napoleon I. I have gathered and distributed seed of this tree in the hope it may be naturalized in other countries. The seed brought to Jamaica is apparently good, and hopes are entertained that plants will be established here.

31. *Aberia Caffra* or Kei Apple.—A native of the Cape of Good Hope, belonging to the same natural order as the Anuatto of the West Indies, but yielding an edible fruit of a golden yellow colour about the size of a small apple. The plant is admirably adapted for hedges as it is densely clothed with strong dry spines, forming an impenetrable fence. The fruit is chiefly used for making preserves.

32. *Harpephyllum Caffrum* or Caffre Red Date.—A hardy and free-growing tree adapted for dry rocky and barren spots where it thrives abundantly. The foliage appears to be not liked by stock, and even goats do not touch it. The bright-red fruit, shaped like a date, is very acid, but of a pleasant flavour.

33. *Calodendron Capense* or Cape Chestnut.—A very handsome tree with clusters of pale pink flowers. Suitable for the hills.

34. *Hakea gibbosa* or Snail Tree.—A small fir-like tree, native of Australia, bearing fine needle-like leaves of a leathery texture. The woody fruit is in shape resembling the head of bird or land snail.

35. *Leucadendron argenteum* or Cape Silver Tree.—This is a handsome tree or shrub, whose leaves are covered with white silky hairs.

36. *Quercus Suber* or Cork Oak.—A few acorns from this oak were obtained, which are likely to grow. The Cork Oak, on the higher hill slopes, should become a common tree in Jamaica. It is both ornamental and useful.

37. *Casuarina equisetifolio* or Beef Wood. A handsome tall growing tree. Splendid for fuel, giving great heat. The timber is tough and nicely marked. The tree will grow either in sand near the sea or at high altitudes (Mueller.)

38. *Agave lurida* or Fence Aloe.—A handsome plant much used for fencing lands.

39. *Nephrodium Napoleonis*, a small handsome fern, found abundantly along the side of road from Longwood to Napoleon's tomb.

40. From Madeira, by courtesy of Dr. Grabham, I obtained seed of: *Ceratonia siliqua* or Carob Tree. This tree is extensively cultivated in countries bordering on the Mediterranean, and especially in such as suffer from periodical drought, its long roots penetrating to a great depth in search of water. It is called Algaroba by the Spaniards, and Karoub by the Arabs, whence comes our English name of Carob or Caroub, the pods being called Carob-pods or Carob-beans, or sometimes Sugar-pods. These pods contain a large quantity of agreeably flavoured mucilage and saccharine matter, and are commonly employed in the South of Europe (as the Guango is in Jamaica) for feeding horses, mules, pigs, &c., and occasionally in times of scarcity for human food. Two plants of the Carob were presented to the Botanical Department by Mr. William Lee, Administrator-General, a short time ago. One is growing near the Bungalow at King's House and the other at the Hope. Both are doing so well that there is no doubt the tree is well adapted for the climate of Jamaica; and further effort will be made to introduce and import large quantities of seed for general distribution. The gross export value of Carob-pods shipped from Cyprus during the last year, according to the *European Mail*, was over £100,000.

41. *Dracæna Draco* or Dragon Tree.—The famous Dragon

Tree of the Canaries, which derives it common name from a resinous exudation known in commerce as dragon's blood.

42. *Myrsiphyllum asparagoides.*—This is a pretty twining plant with glossy myrtle-shaped leaves (or rather metamorphosed branches, very suitable for pot culture in verandahs.

43. Amongst other seeds obtained from Madeira were:—*Oreodaphne fœtans* or Tél Tree; *Cytisus virgata*; and *Erythrina spp.*

44. From the Island of St. Thomas, through the kindness of Baron Eggers, I obtained several specimens of *Pontaderea cœrulea*, an interesting and ornamental aquatic plant not previously in Jamaica. This is described as "a singular plant from the West Indies (Porto Rico) having roundish heart-shaped leaves, borne on a thick swollen petiole full of air cells, by which the plant floats on the surface of the water. It produces offsets freely, soon extending itself over a large surface. It rarely flowers in this state, but when it becomes attached to the soil its footstalks become long and narrow, and it then produces its pretty blue flowers" For the present the plants have been placed in the tanks at the Parade Gardens, Kingston, and the Castleton Gardens.

45. Other plants obtained from Baron Eggers were:—*Malpighia coccifera*, a small ornamental holly-like plant suitable for the plains; *Chlorophytum sp.*, a handsome piece of *Philodendron sp.*; and the interesting proliferous orchid *Oncidium Lemonianum.*—I have, &c.,

D. MORRIS, Director of Public Gardens and Plantations.

The Hon. the Colonial Secretary, Kingston.

[NOTE ADDED.]—I would mention as of special interest a pot containing about 50 plants of *Dracæna Cinnabari*, which was brought out from Kew by the mail of November 2nd. These plants are valuable as yielding the true Dragon's Blood collected in the island of Socotra. Dr. Bayley Balfour, who obtained the seeds from which these plants were raised, refers as follows to the "Kinnabari," or the resin of the Dragon's Blood tree of Socotra:—"This 'Kinnabari,' which Dioscorides mentioned, was obtained from a species of *Dracæna* (now named *D. Cinnabari*) that grew on the island of Socotra, belonging to the family of the *Liliaceæ*. All the species of that genus did not yield resin, but four only, which belonged to a very peculiar type of the family, which branched very freely and formed a thick trunk. The peculiarity of this species was that not only did the trees branch freely, but the leaves were curiously stiff and sword-like, and it formed a very thick stem. The resin was secreted from the stem in the form of tears, exuding naturally from small cracks or crevices, and forming a large red mess. In Socotra it exuded most abundantly immediately after the rainy season. This was the true Dragon's Blood as collected in the island of Socotra, referred to by Pliny and many other old Authors."—(*See Pharm. Journ. and Trans.*, No. 698, pp. 372-374.)

Dragon's Blood is largely used in the arts; and about 50,000 pounds weight reaches England every year. The rich polished mahogany, in such great request, owes a great deal of its beauty to the colouring properties of Dragon's Blood.—D. M.

CULTIVATION OF THE SHUMAC TREE IN ITALY.

The leaves of the shumac tree are extensively used throughout Europe for tanning purposes, and a large amount of care and attention is expended on the cultivation of the tree in Italy, with considerable profit to the planters. It thrives best in Southern exposures and hot temperature; its life is from twenty-five to fifty years, according to the conditions of the ground, climate, and culture. It spreads through shoots rising from the bottom of the tree, and it is for this reason that plants two or three years old are selected for transplanting; the price for which they are to be obtained in Italy is 50 centimes per 100. In preparing a shumac plantation, ditches are dug in the ground about three feet three inches apart, with a breadth and depth of about 17 inches. In stony ground the plant is set in holes, the shoots are placed at a distance of about three feet from each other, so that every hectare ($2\frac{1}{2}$ acres) will have 10,000 trees. In digging the ditches, and more especially the holes, great care is always taken to prevent water remaining in the bottom, and when there are no other means to provide against it, the ground is cut transversely. The tree does not flourish in heavy or damp ground, especially when the substratum is impermeable. The plantation is made in December, and then, during the first year, the ground is dug up from four to six times, to preserve it from weeds; manure is but sparingly used. The first digging, which is the deepest, is made in January, and the following in March, May, June, August, and October. In September of the first year, the leaves are stripped off with the hands, a little before their falling. It is better, however, not to touch the young bark, but to allow them to fall off naturally. Young trees are sometimes too quickly stripped and damaged, while the crop of leaves will bring, when sold, half the price of that obtained in the following years, in which the shumac ground is dug over more frequently; this is done between December and January, and March and May, when the earth is heaped up round the stem, at the time of the first digging, and then smoothed down. In Sicily, they heap up the earth among plants, cultivated as vines, to ventilate it by increasing the surface through hills, to make the running off of water easy, and to facilitate the future transplantings. In the time of the greatest dryness the hills are always levelled. In the second year, open spaces left by dead plants are filled up. The harvest is made when the leaves have acquired all their development and consistency, and are about to change colour; it takes place between July and August, yet before the month of May the leaves of the lower branches grow yellow, and fall, and these are also gathered. Usually, in collecting the crops, secondary branches are cut off, leaving only the trunk of the tree for the new buds. Some planters strip off the leaves by hand in July, and lop the trees in December, but this has the disadvantage of causing the new buds to grow too soft and the leaves too flabby. The branches are either left in bundles on the ground, for two or three days, after which they are carried to the threshing-floor: or they are brought at once to the threshing-floor, where, after two or three days, according to the season, they are ready for threshing, and are beaten out with flails, or by means of horses. When beaten with flails, the twig is fairer and less torn, and sold in bales, but when trodden out by horses, it is crushed into minute particles before it is exposed for sale. When long leaves are required for the bales, the bales are threshed early in the morning, before the heat of the day has dried up the leaves; but for crushing, the operation must be done in the hottest hours, when the branches already threshed once are threshed again. Square linen sheets, six feet square, with a ring in each corner, to pass a rope through, are generally used for carrying the dried branches and leaves to the storehouse. The leaves for bales are carried to the storehouses, and the rest to the mill, which is similar to that used for olives. After being ground, the large lumps are sifted out, and the branches and other impurities thrown away, and the leaves, if any, are ground again. In this work, the leaf loses a seventh part of its original weight. The threshing-floor is always kept in good condition, paved and covered with cement or bricks, and the storehouse is generally exposed to the sun. When the shumac becomes old, and its verdure scanty, another crop is cultivated, and for this the vineyard is especially adapted by the previous preparation.—*Journal of the Society of Arts.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, January 26th.

Alimentary combinations for the feeding of stock make rapid progress, since farmers club together to purchase the materials at the fountain-head, through the banks which afford them accommodation; the analyses of the agronomic stations prove also a powerful means to have sound products, as the latter are analysed in sample, and then in bulk, before delivery be accepted. It is thus that cotton cake is making new way, not only mixed with maize flour for fattening, but with various meals—pea, vetch, and barley for milch-cows. The only cotton cake in favour is that from decorticated cotton seeds from

America. It is the safest and the only cotton cake that can be employed without danger for young animals. Unbarked cotton cake or its flour is offered at a very low price; it should be avoided as it contains filaments of cotton or cellulose, which from their indigestibility are inimical to the production of either milk or meat. Thus decorticated cake contains 15 per cent of fatty matters, and 43 of albuminoids; in the undecorticated state not more than one-half of these percentages. A mixture much in favour for milch-cows consists of $\frac{3}{4}$ lb. each of pea and vetches flour; half-a-pound of barley meal and one pound of cake. This feed of 3 lb. is given in moieties, morning and evening, on the cattle leaving and returning to graze.

M. Quatremarin has adopted the Neilson system for the desiccation of forage on his farm in Normandy; he dispenses with steam-worked machinery for the production of ventilating currents; he has invented a machine, worked by an ordinary labourer, which makes 1,800 to 2,000 revolutions per minute, can be trundled on a wheelbarrow, and set to work anywhere. The price of the machine is about fr. 168.

The ensilage of green fodder in silos or trenches continues to be one of the foremost questions in the agricultural world. It has now passed out of the domain of experiment and ridicule, and become a concrete fact. Yet it was only in 1852 that the discoverer of the plan, M. Goffart, of Burtin, in Sologne, first commenced his trials of the preservation of the green stems of maize in trenches made in ordinary soil. Agricultural commissions and inspections by unbelievers have since borne unanimous testimony to the success of M. Goffart's discovery. In order to encourage a system so fraught with practical advantages, several of the local agricultural societies of France have offered prizes for the trench-preservation or ensilage of fodders. Among other reports, that by the Meaux Society deserves special notice; the tests were chiefly applied to clover, and many of the competitors commenced as disciples of St. Thomas, but ended as is usual in presence of palpable conviction as zealots.

One farmer, Bénard, trenched the yield of $7\frac{1}{2}$ acres of red clover, in an ordinary silo 40 inches deep, 80 wide at bottom, and 120 at top and 55 yards long. The mass was reduced two-fifths by shrinking. A second trench 33 yards long contained the yield of 6 acres of red clover. The Commissioners found all the clover to be well conserved, of a clear brown colour, giving off the alcoholic odour; the animals eat it with avidity. M. Bénard recommends that the clover be cut when in full flower, and to select a time rather humid than dry for cutting and pitting the clover, the better to exclude the air and water.

A M. Gilles employed his pits, 22×10×7 feet, destined for distillery pulp, to the preservation of clover, cut between the 5th and 10th June, and when commencing to form seed: 56 tons of stuff were pitted. It turned out well. M. Guibert trenched four acres of white clover, and obtained a medal for his results, though he expected to find his clover "only a heap of manure;" he had the clover trodden down in the silo by bullocks.

A M. Martin pitted the yield of five acres of late red clover, in a trench 83 yards long: the men shook the clover, winnowed it as it were, as they spread it in the silo: the next day they renewed work late, and then covered in. The volume of the preserve lost 75 per cent, but was in an eatable condition, because the ensilage was not finished within the day commenced, and the forage was aired too much.

The Commission concludes that all clovers and aftermaths can be perfectly trenched, as well as other green forage; that the trenches exact no outlay of capital; that it is at the moment of flowering such forage ought to be mown as it then contains its maximum of vegetable humidity; that neither rain nor dew affects the pitting, but on the contrary, if too dry it does not keep so well. The employment of salt is not necessary, nor is a mixture with dry matters, cut straw, chaff, &c., required. Silos constructed in masonry and cement give good results, but no special system of trench can be recommended; that ought to depend on the region, the surface and subsoils, and the climate. The chief ends to secure consist in the exclusion of air and water, the pressing of the matter in the trench with regularity, and covering it with a pressure of 8 to 10 cwt. per square yard. Cutting, before trenching, is not indispensable, save in the case of forage with thick stems. In nutritive value, silo-food approaches most to winnowed fodder, but is more assimilative. In the case of milch-cows it is a beneficial ration.

It is the usual practice with housed stock to commence the rations with hay, and then, having cleaned the troughs, supply the water, to be followed next by roots, &c. This plan or order of giving food-supplies has been called in question. At the agronomical station of Kiel, where the cattle can drink when they please, the rations were distributed thus twice a day: hay; cake, roots and straw. It was observed that the cows only drank after having eaten the roots (mangolds), and that as soon as the special drinking trough was refilled, they commenced again to drink with avidity. Only occasionally an animal drank a little water after consuming straw.

The agriculturists of the department of Loiret have presented M. Pasteur with a splendid objet d'Art—subject "Youth"—in honor of the benefits his discovery of vaccinating cattle against the *charbon* malady have conferred upon them. Since they have practised his discovery, they fear no longer the disease. Impossible to have more striking testimony.

The herring boats on returning to France after the season's fishing, proceed to secure the fish; the refuse is available for manure. This is not in high request from the quantity of salt it contains, 50 per cent. It is suggested to wash the refuse two or three times in water, to carry off the excess of salt, and then dry the *débris*, which contains $4\frac{1}{2}$ per cent of nitrogen and 8 of phosphoric acid. The fatty matter, 38 per cent, and which is of no use to the plant, could be separated by treatment with sulphuret of carbon, that which would enhance the nitrogenous value of the manure.

Messrs. Lavallard of the General Omnibus Company, assisted by Professor de Muntz, have been occupied since two years experimenting on the relative value of saw-dust, peat, and straw, as littering for horses, and their importance as manures. The conclusion is, that saw-dust (from white deal) ranks first, then peat mould, and lastly, straw.

A roller-cart, though not exactly new in idea, is becoming a favourite in the case where the cutting-up of meadow land by ordinary wheels, during the transport of top-dressings, is undesirable, especially when mowing machines are intended to be used. It is an ordinary cart, arranged to be fixed on a roller of two or three joints.

The Society for the Encouragement of National Industry has awarded its first prize of fr. 12,000 to M. Faucon, for his plan of resisting the ravages of the phylloxera by autumnal submersion of the vines and good spring manurings. The plan is now applied to 50,000 acres of vineyards, that which signifies an assured production of more than half-a-million gallons of wine yearly. It is regrettable to learn that there are 200,000 acres of vineyards capable of being flooded, but that the proprietors decline to so treat.

M. Gaillat of Beaune (Côte d'Or) has produced the latest remedy against the vine bug. Accepting as true that fire purifieth all things, he has invented a small hand machine weighing three pounds, called a *flambeur*, which injects a flame of petroleum a distance of ten inches. By a system of cocks, this flame can be directed in any direction, and a hood protects it from being deviated by the wind. It is thus between November and February, and during a dry period, that he singes vines attacked with the phylloxera, destroying their eggs, &c.; the same cure can be applied to any trees affected with insects, regulating the action of the flame to the delicacy of the stems. It is capital for blistering off old coats of paint and scorching the walls of stables or apartments where an infectious malady has taken up its abode.

A proprietor of several farms asserts that since ten years he has prevented wild mustard and similar weeds springing up with his sowings. In March, he employs a peculiar harrow of finely-set steel teeth, combining the advantages of a scarifier; the soil, well-stirred, is carefully rolled. All the seeds of weeds that can grow will now shoot; when the latter have sprouted, he gives a few strokes of his harrow, which never allows the weeds to return to the soil, while "stirring" the soil, and the enemy lies everywhere dead. It is thus his flax is ever clean, while his neighbour's is filthy.

THE POSSIBILITY OF REVIVING THE SUGAR ENTERPRIZE IN CEYLON.

Our correspondent "Honolulu," (see page 657) whose experience in the volcanic island, whence he borrows his *nom de plume*, might well have given him the idea that rich soil was the first element of success, insists that the whole enterprize hinges on good varieties of cane. No doubt much depends on the selection of cane—an attack of "rust" having been got rid of mainly by this means in the great Queensland sugar district of Mackay, while some canes excel others in luxuriance and rapidity of growth, in quantity and density of juice and in amount of crystallized sugar produced. But the result of our reading and observation is, that the great essential to success is a soil rich not merely in humus but in such mineral constituents as phosphates and carbonates of lime. "Honolulu" in addressing us and "D. E." in writing to the local "Times," make rather light of climate and fall into an error of some magnitude in stating that a rainfall of over 50 inches is unknown in the Australian colonies. We suspect that well up on the anges of Mount Dalrymple, Mount Elliott and othre elevations in the northern and tropical portions of Queensland, twice 50 inches fall in a year. For at Mackay, on the flat delta of the Pioneer River, the annual rainfall ranges about 70 inches, while, for a large portion of the year, the atmosphere is saturated with moisture to a degree fully equal to that of Colombo, so that there, as here, clothes and boots become mouldy, and the covers come off books. Humidity is represented by so high a figure as 80°. Extremely saturated atmosphere lasts for three weeks at a time, while extremely dry atmosphere in the hot season lasts only for a few days. The mean temperature is 73° against our 80° in Colombo; the mean minimum being somewhat over 62° and the mean maximum somewhat above 81°. There are two rainy seasons, December to April or May, and again in October-November, the number of rainy days in the year being 130. That would be a small proportion but for the quantity of moisture held in suspension in the atmosphere for a large portion of the year. The climate of Mackay, therefore, is a good sugar climate. But here as in the delta of the Burdekin River (further north, nearer the equator but more distant from the high mountain ranges), the great feature is the rich, deep black alluvial soil—the deposits through countless ages of matter disintegrated from mountains above, themselves the products of ancient volcanic action. We have no such soil in Ceylon, whatever our advantages of climate, labour supply and means of communication may be. The climate of the Burdekin delta is drier than that of the delta of the Pioneer, but an immense series of swamps and lagoons, alternating with slightly elevated parklands, the latter rich in grass and interspersed with timber, afford great facilities for irrigation. Our good friend Mr. Macmillan, of Ardmillan (born in Argyllshire and educated at the Inverness Academy) tried the experiment of pumping up water into a cane-field, with marked success, the growth of the cane and the density of the juice being all that could be desired. A French neighbour, on hearing of this experiment, shook his head and exclaimed: "Monsieur Macmillan, he must *arrogate*; he vill nevare succeed!" But the accounts which have reached us since we saw the great steam plough at work on 800 acres which were brought into cultivation in one year, prove that success is certain without "arrogation," if only Mr. Griffiths, the new Premier of Queensland, does not ruin the grand sugar enterprize of the colony by rendering impossible an influx of cheap labour from India, while the supply of "Kanakas" is daily becoming more and more inadequate. If only this labour difficulty can be overcome, the Queensland sugar planters have the great advantage of a large and rapidly-expanding market at their doors. For the sweetening of tea and coffee, the preserving of fruits, the brewing of beer, &c., the consumption of sugar in Australia is enormous, the rate per head of the population being considerably higher even than in Britain, where sugar from all parts of the world is duty free. We had the advantage of visiting the Mackay sugar estates and those of the Burdekin in company with Mr. Jeffray of Melbourne, the head of the firm of Sloane & Co., to which "Honolulu" refers, and we understood that this one firm had invested half-a-million sterling in sugar-land and machinery in Northern Queensland. It is just possible that the fatuity of the Government of Queensland may compel Mr. Jeffray and others to look to Ceylon, and "D. E." draws a tempting picture of the rich soil about Dambulla and via Polonnaruwa down to the Bay of Kottiyar, while the floodwaters of the Mahaweliganga are represented as needing only the guiding hand of the irrigation engineer or expert to be converted into sources of laughing fertility. Granted the fertility of the soil, we should fear not merely the arid nature of the climate but its pestiferousness, especially near the banks of the great but erratic river. And does it not occur to "D. E." that, if the waters of the Mahaweliganga had been tractable enough to be utilized for irrigating in dry weather the soil they have deposited when in flood, the ancient inhabitants would not have neglected this source of wealth as they seem to have done. The overpowering strength of the occasional floods and the effects of malaria, singly or united, may account for the sparseness of population in a region described as distinguished for some of the richest soil in Ceylon. Such a region is surely capable of reclamation from the fever demons and the forest fauna, but, alas! for the pioneers! Will "D. E." accept the risks? But there is really no necessity to go into the depths of the desert to try experiments with the culture of sugar by means of irrigation. There can be no objection to sugar cultivation any more than rice "under" or by the sides of the irrigation channels or dams formed or in course of construction in the dry and arid regions of the north-eastern portion of Ceylon. Experiments on a moderate scale might be tried alongside the already restored portions of the Yoda-ela, and, if a trial on a large scale is ventured on, there is the fine soil under the Kantalay tank near Trincomalee ready to hand. The experiment of a native Rice Company having turned out such a miserable *fiasco*, Government can surely offer no objection to granting an appreciable tract of the land to a European capitalist, on conditions which will render it worth his while to give a full trial to sugar, and perhaps cacao, rhea grass and other similar products. The rice-cultivators having rejected or misused the advantages offered to them, it is only just and right that those advantages of rich soil, covered by good timber with water stored to irrigate the soil when tilled, should be offered to others who can turn them to the best account. Tobacco has been tried, and we suppose it has failed. We mention it only to turn up our nose at it, as the least useful and yet most wasting product of the soil. On the other hand, the more sugar the human race consumes, in preserves or with beverages, the better. But experiments in Ceylon towards anything beyond the supply of local demand must be qualified by at least two considerations. There is the emphatic repetition by our correspondent "C. S." of the oft-told but "owre true tale" of previous complete failure and disastrous loss, and there are the statistics of sugar production from cane and beet, showing that for the present supply has gone beyond demand, large and greatly increased as the latter is. Before dealing with the figures, we may just revert to what "C. S." says about the cheap coarse sugar grown in the Phillippines and other islands of the Eastern Archipelago. At the great sugar refining works on the banks of the Yarra below Melbourne (buildings, plant and material insured up to £200,000), we saw masses of dirty stuff which we could scarcely recognize as sugar, or even jaggery, and from which clay enough to be made into bricks was separated,—we saw this filthy black stuff so manipulated and subjected to chemical and centrifugal processes, as to yield saccharine crystals of snowy whiteness. The palmyra jaggery of the northern portion of Ceylon is certainly superior to the cheap and nasty raw saccharine matter we refer to, and we had felt long before Mr. Vincent's able Report on the Forests of Ceylon appeared that, to the encouragement of the culture of this palm which yields excellent timber, nutritious fruits and good sugar, the Ceylon Government ought to devote special attention. It will grow on ground where irrigation is impossible at the rate probably of six to ten times as many trees to the acre as in the case of coconut palms. While the trees are growing, the leaves are useful for thatch, writing olas, the manuring of fields and other purposes. When fruits are borne they are useful as food, directly or in the shape of "punattu" (the inspissated saccharine juice), while from the wounded flower spathe large supplies of sugar can be obtained. Finally, the trees yield a timber comparable to ebony for density and useful above all other wood as rafters and reepers in house-building. We do not see that Government would be travelling beyond its functions in planting regular forests of this tree, which they could ultimately sell in small lots, as demand arose. In any case, the overcrowded population of the Jaffna Peninsula ought to be tempted to the mainland of the Northern, North-Central and Eastern Provinces, by offers of unirrigable land on easy terms for the cultivations of this most useful leaf, fruit, timber and sugar-yielding palm. By its means alone, Ceylon might become an exporter of a very considerable amount of raw sugar, even if refineries were not ultimately established in the island. It is true that *Borassus flabelliformis* takes a long time before it yields sugar or timber, but "be aye sticking in a tree, Jock; it will be growing when ye are sleeping." Let us request Sir Arthur Gordon's special attention to the palmyra palm, the thousand uses of which were fully dealt with in Mr. W. Ferguson's monograph, of which a new edition would be very acceptable, to natives as well as Europeans. The population of this island as well as of the world at large is growing, and sugar will be more and more in request as wealth advances and comfort is appreciated. At present an interference with the natural laws of commerce by the German and other governments has placed sugar in almost the same position as coffee in regard to price as affected by overproduction. From the latest number of the *Sugar-cane* we quote an article on the subject, premising that the consumption of sugar, raw and refined, has risen in Britain from 206,472 tons, or 16·77 per head of the population in 1844, to 1,066,464, tons, or 66·36 lb per head in 1884. The increase per head in the 39 years has been 4½ times, which means an incalulable addition to food, comfort and health; for the consumption of tea and preserves has increased with that of sugar. But details in this direction we reserve for another article, merely quoting now the statement which shows the present overdone and depressed state of the sugar market:—

STATE AND PROSPECTS OF THE ENGLISH SUGAR MARKET.

Mr. Licht's first estimate of the beet crop for 1883-84 was 1,975,000 tons; his latest estimate is 2,240,000 tons—an increase of 265,000 tons! His estimate in December last was 2,050,000 tons—195,000 tons below his present estimate; and it now appears that the actual crop of 1882-83 is 2,146,534 tons, and not 2,062,043 tons, as previously given,—an increase of 84,000 tons. Assuming the substantial correctness of the present estimate for 1883-84, it shows a difference in favour of the present season of 93,500 tons.

It is quite evident that the cultivation of beet—especially in Germany—has outgrown the possibility of any reliable computation of its results being made before the yield in sugar has been ascertained: and the conviction is growing that these estimates are misleading and mischievous.

With such supplies, it is not suprüing that the great dulness, which has prevailed so long., continues unabated, and that prices both of raws and refined are again down.

							In January 1883.

SUGAR IN INDIA AND AUSTRALIA.

[Now that the question of sugar cultivation in Ceylon has been revived, the following article from the *Pioneer* will be interesting. Our soil is not equal to that of Australia, but we have other advantages, especially in labour supply.—ED.]

A few stalks of sugarcane, which may be detected by curious eyes among the raw products of Australia, now on view in the Calcutta Exhibition, are well calculated to suggest serious reflections to any man who is concerned in the welfare of one of the chief agricultural industries of India. They are long canes of a reddish colour and, even in their half-withered state (they were cut, of course, six months ago), are still remarkable for bulk and evenness of growth. It is to be presumed that they were selected as samples of the best, and probably there are many Indian districts from which equally good specimens could be culled; indeed, we know that some varieties of Australian cane, such as the "Red Assam" affected by Queensland planters, have originally been borrowed from India. As regards its sugar-giving qualities, however, the Australian cane is greatly superior to anything grown in this country. The causes seem to lie at once in the soil, in the method of cultivation, and in the processes of manufacture. Two descriptions of soil are especially adapted to sugar cultivation in Queensland. The so-called "scrub soil" may be compared to the forest clearings which are favourite spots for the growth of cane in the extreme east of India. The scrub is in fact a forest of tall soft-wood trees, fastened together by a dense network of vines, and presenting a shade through which the sun's rays are unable effectually to penetrate; no breeze ever waves beneath the huge branches, and the unsunned earth lies damp all the year round. Scrub soil is of a chocolate colour, sometimes verging upon red. Alluvial soil, on the other hand, is a rich brown loam, generally destitute of trees. In neither case is any manuring necessary, and the same field will go on producing cane year after year with apparently undiminished fertility, but the ploughing is very deep and thorough, hoeing and weeding are carried on at regular intervals, and the ventilation so necessary to the health of the standing crop is effected by "trashing" the full-grown cane, or stripping it of its superfluous leaves. It is this last operation specially which the advocates of cooly importation allege to be too severe for Europeans in the tropical climate of the sugar-growing parts of Australia, and in fact the majority of the hands on a cane plantation are usually Kanakas, though even in the hottest districts European settlers are to be found who cultivate their own little patches of land, and bring the produce to some large central factory to be crushed and converted into sugar. The amount of enterprize and capital which has been lavished upon the construction fo these factories presents a magnificent contrast to the beggarly progress of the industrial arts in India. An Australian sugarmill has not only the latest machinery for crushing, boiling, and refining, but all the auxilliary appliances necessary for saving manual labour in disposing of large quantities of raw produce—railways running overhead between the different buildings, and the electric light turned on the fields, so that work may go on by night during the busy season; and all this in places which were not heard of twenty years ago, and which are still mere oases of civilization in the immense wastes of an unreclaimed and unpeopled country.

It is not easy to render a reason off-hand why sugarcane cultivation should receive all this attention in Australia, while in India, so far as we are aware, it is absolutely neglected by European capitalists. If the refined sugars of India are incapable of competing with those of the Mauritius and other places, the fault is primarily to be found in an inferior stock, the product of random propagation and unenlightened culture, and consequently yielding a juice deficient in crystalizable quality. One cannot, indeed, accuse the ryot of any want of laboriousness. Every sugar-growing district has its rustic proverb, expressing in uncouth rhymes the toil and expense, the 'hundred ploughings' that are necessary to prepare the field for this valuable crop. But the ryot, after all, can only work according to his means and his lights. Deep ploughing is usually beyond his power, and his sense of the advantages to be gained by a careful selection of the plant is as yet deplorably undeveloped. The importance of seed selection is one of the points which agricultural departments are striving to impress upon the ryot as the best way of promoting the wheat trade which is becoming such a source of wealth to the country. There is plenty of room for the application of the same principle to sugarcane. In the Punjab, for instance, the weight of cane per acre is estimated by the Settlement Officers of the best districts at about thirteen tons, or one-half the rate of produce yielded by a good Queensland plantation, where the soil is much deeper ploughed than in India, but where, on the other hand, artificial stimulants are not employed, while in these Punjab districts each acre of soil receives eleven tons of manure. The Bourbon cane in Queensland is even capable of affording, from a second or ratooned crop (which is always decidedly inferior to the first), more than double the Indian average of sugar per acre of cane. It is impossible that these vast differences can be wholly due to the comparative unfertility of the Indian soil, or the inadequacy of the treatment it receives from the ryot. We cannot but believe that by introducing a better stock, and bestowing some intelligent care upon its propagation, the value of the annual cane crop might be very considerably increased. There is no reason in the world why a product must be inferior merely because it is Indian. In the matter of manufacture, the first steps towards improvement have been taken already. The success of the Bihia mill proves that the ryot has no unconquerable aversion to the use of a new-fangled machine which is demonstrably cheaper than his old traditional apparatus. Assuming that the Bihia mill enables the ryot to extract in juice 60 per cent. of the weight of the cane, instead of one-half its weight only (and a country mill must be one of exceptional power to extract so much as one-half), the value of the sugar harvest is immediately enhanced by one-fifth, and the total addition to the wealth of the country may be reckoned in crores of rupees. But satisfactory as all this is, it still falls far short of what might be effected in this branch of industry. While we are still pottering away with small machines driven by cattle or by manual labour, and crushing perhaps a ton-and-half of cane in a hard day's work, an Australian mill of unambitious dimensions turns out its three tons of white sugar daily, or 15 tons a week, allowing one day for clearing up. In the refining processes, indeed, India enjoys the benefit of the latest inventions, but no amount of skill and enterprise will enable the Anglo-Indian refiner to eliminate the essential faults in the raw material which comes into his hands. In co-operation with the Bihia mill, we want some simple machine which the ryot can be induced to use in the place of his own rude and wasteful method of converting cane juice into coarse sugar. An American apparatus, imported by the Cawnpore experimental farm last year, proved very successful, and if it can be reproduced in the farm workshops at a price that will place it within the means of the ryot, it seems likely to become popular.

There is, however, a great deal more to be done before sugar can begin to take its place with wheat as a regular article of Indian export. From planting to refining, every stage of sugar cultivation needs to be raised towards the level which has already been attained in other countries. A degenerate plant, imperfect crushing, and wasteful boiling, give between them a smaller outturn of sugar than is recorded in any other part of the world where cane is grown. A ton-and-a-quarter of *gur* per acre is considered a splendid return in Upper India; indeed, the recent Punjab papers do not estimate anything so high even for the best harvests. Converted into white sugar, the produce would certainly not exceed half-a-ton per acre. Comparing this with the records of a Queensland plantation, where 80 acres of cane yielded 288 tons of white sugar last year, we see at once how far India lags behind in the industrial race. The progress of modern science, unfortunately, tends to leave her still further in the rear, by increasing the distance between European machinery in its latest developments and such simple forms of improved appliances as the ryot is able to master. For instance, it has been scientifically proved, quite recently, that even the best steam mills fail to express a large proportion of the juice in sugarcane; the refuse, as it comes from the mill, still contains much sugar which is thrown away for want of a means of getting it out. Now, it is quite reasonable to expect that the general recognition of the loss thus incurred will in a short time lead to the invention of a mill which shall express the juice more thoroughly, but such a machine is not at all likely to be within the command of the Indian ryot, and it is quite possible, therefore, that even with his Bihia mill he may find himself at a greater disadvantage than ever in comparison with the capitalist sugar-growers of other countries. The same thing may be said of the improvements West Indian boiling houses, where the assistance of chemistry has been called in with such signal effect. So long as it was merely a question of cauldrons, great or small, one had at least the satisfaction of knowing that the Indian ryot was doing in his small way much the same kind of thing as the Demerara planter did on a more magnificent scale. But the vacuum-pan has lifted the whole matter into quite another sphere; the ryot and the planter are no longer on the same plane, and whatever progress the former may make along his present line, he will never get any nearer to the latter. If India is to produce refined sugar in quantities at all corresponding to the area under sugar-cane, European capital will have to be attracted once more to an industry in which it has hitherto achieved but a doubtful success. In the meantime, however, much can be done by introducing a superior plant, by encouraging the selection of cane, and by teaching the native sugar-maker to avail himself of a few simple lessons of practical chemistry, and to adopt a few simple modifications of the machinery he is accustomed to work with. Could the out-turn of *gur* be raised to even a ton-and-a-half per acre. the value of the sugar crop of the Punjab would be increased by two millions sterling.

MR. ROBERT THOMSON ON CINCHONA CULTURE IN COLOMBIA.

The many friends of Mr. Robert Thomson, the late island Botanist, will we are sure, be glad to hear that we have received the most pleasing accounts of his progress, and success in the cultivation of the cinchona and the India Rubber plants in Bogota U. S. of Colombia. Mr. Thomson writes us:—"Many thanks for the cinchona seeds you sent me, they have grown nicely. The plantations here are at a height of 7,500 to 8,000 feet. (Higher than the Blue Mountain Peak.) This great central Cordilleras as you are no doubt aware is the native home of the cinchona. Great quantities of C. Lanceifolia one of the best species have been largely exported, and a few degrees further north another very important species exists, viz:—C. Pitayensis. Another species, much interior to these, but with one and a half per cent of quinine abounds in this district. I have seen some trees with trunks over three feet in diameter, equal to a yield of 500 lb. of dry bark. But a far more interesting fact to me, is the way in which my plants on the plantation grow. Officinalis, the favorite kind in Jamaica, grows here with great rapidity, that is on the average four feet a year, indeed, many of them attaining over five and six feet a year. In Jamaica the average with officinalis is not more than one and a half foot a year. The result of this, is, that bark can be produced at half the price needed in Jamaica. Another example: we have a plant of officinalis at a height of 7,700 feet above the sea, at present growing *eleven inches a month*! The cause is easily explained. In Jamaica the strong prevailing winds seriously retard the growth of the plants, indeed, these winds not only retard growth, but the young trees are badly injured thereby. Here we seldom have even a light breeze."—Jamaica *Standard*, Jan. 8th. [If Mr. Thomson's representations are to be fully depended on, and no canker or other disease sets in, all that will be wanted will be a good labour supply, to beat India and Ceylon out of the field.—ED.]

THE BRAZIL COFFEE CROPS

are thus discussed in the *Rio News*:—

In another column we give an important communication to the *Jornal do Commercio* from Dr. Cesario Alvim regarding the condition and prospects of the coffee crop, to which we would invite the attention of our readers. Were it not that these reports of the unfavorable prospect for the next crop are only repetitions of what we have heard before with each recurring year, we should be inclined to believe that there is really a bad outlook for the next crop. Knowing, however, that this season has had no more nor worse accidents than any year before, except here and there in limited localities, we cannot understand just what basis there is for this universal cry of short crops. Those who have watched the course of events cannot have failed to notice how worthless the majority of these reports are. If there is a week's sun during the blossoming season, every planter gravely announces that the blossoms have been parched, or have withered for lack of moisture. So, too, when there is a two or three days' rain he is just as ready to assert that the blossoms have either been knocked off, or that they are moulding on the trees. Every year we have all these plaints dove-tailed one into the other, so that the nominal probabilities of a crop are always at a minimum, while the final result has been away at the other extreme. The bare truth is that the coffee planter never admits that the prospects of a crop are good. He is invariably a pessimist, either from some inherent quality of his nature, or from policy. If he were to consider that no year ever passes without a loss of blossoms from either heat, or rain, or both, he would see that this regular complaint of a normal occurrence is entirely without foundation. The wonderful fecundity of the coffee plant which exhibits three distinct blossomings, sometimes four, in a season, generally makes good all these losses and produces a good crop even when the season has been almost uniformly unfavorable. What is lost in the first blossoming is quite certain to be made good in the second or third, and even the supplementary blossoming—for the *café das aguas*—often comes in at the last hour and saves the situation. We do not forget that there are many old orchards whose exhaustion will render them unable to recover from even slight injuries during the early blossoming, but at the same time it must be remembered that a very large area of the existing coffee orchards is filled with young trees just in their prime, and that there are new orchards yearly coming into bearing. We had thought that the falling prices of late years had checked the expansion of this industry, but on picking up a São Paulo newspaper the other day we found an advertisement of the sale of a plantation at S. José dos Campos containing 71,000 coffee trees, of which 31,000 were young trees varying from one to eight years of age. This, of course, can not be an isolated case, especially so as the inducements held out for coffee growing in that place are less attractive than in many other localities of São Paulo, Minas Geraes and Rio de Janeiro. These new orchards must be accepted as determinative factors in Brazilian coffee production for many years to come. In São Paulo, where they are most plentiful, they are sending more coffee to Santos this year than in any year before, and they are now rushing coffee into this market at a rate little below that of last year. In view of these considerations, we are not yet prepared to accept the sombre outlook to which our attention is called from all sides. There may be a slight decrease in the next crop, but certainly not in the proportion claimed.

ENSILAGE.—Yestesday the first of four capacious silos constructed on the Horsley-lane Home Farm of the Peckforton Estate, Cheshire, by Lord Tollemache, was opened in the presence of a large number of agriculturists and dairy farmers. In order to make the experiment thoroughly exhaustive, Lord Tollemache filled two of his silos with grass cut in very wet weather, the third with dry grass, and the fourth with a mixture of vetches and grass. The grass was chopped by chaff-cutters into pieces about an inch in length. The fodder was then pitched into the silo and trodden down, and finally a pressure of 56lb. to the square foot was placed upon it. A month afterwards each silo had sunk about 2 ft. 1 in., and they were then refilled, about seven tons more grass being placed in them, making in all 24 tons in each. No. 3 silo was opened yesterday. For convenience a pathway had been cut about 3 ft. wide right through the silo. The appearance of the ensilage was that of dark brown, compact moss, with a sweet and pleasant aroma. Just at the top the ensilage was found to be mouldy and spoiled, as was the case when Lord Walsingham's silos were opened at Merton. In answer to a question whether the stock on the home farm were fond of ensilage, Lord Tollemache afforded those present a practical demonstration by offering some to a young mare that had been driven over from Peckforton Castle. The animal ate the ensilage greedily, as also did some cattle in the yard. Lord Tollemache said his experience of ensilage was that at first the animals did not care for it, but afterwards ate it with evident relish. It was stated that the 24 tons of grass placed in the silo would yield about 21 tons of nutritious cattle food. The experiment was regarded by practical men as completely successful.—London *Times*.

TEA.

STATISTICS, OUTTURN AND CONSUMPTION.

The position of Indian tea is apparently strong and very encouraging to investors in yielding gardens, but the question that is exercising the minds of people just now is, how it will stand tho strain when the present large extensions which are going on come into bearing, and a matter of several million pounds extra are thrown upon the market. The cry a year or two ago to stop extensions and pluck fine so as to keep the outturn down, seems to have been entirely forgotten or lost sight of. At no period did we consider that advice of this sort carried feasibility on its face, because if one planter was religiously carrying out such instructions, his next neighbour was simply taking advantage of it by plucking coarse whenever he saw an opportunity of getting any thing like a price to cover manufacture. No doubt the true solution is now being tried, namely, in the study of economy combined with the most improved machinery, and so long as this is kept in view we have no fear for the result. The better class of plant now being put out, the higher class of machinery being used, and the careful attention paid to manufacture, are bound to tell upon the consumption of China tea, simply because there is better value for the money in the Indian tea. We notice in our home contemporary, the *Home and Colonial Mail*, that a taste is developing for the higher classed teas pure and unadulterated, and that the rage for what we may term "People's Mixtures" at 2s. and 2s 6d per lb. is to some extent dying out amongst those who can afford a higher price for the finer grades: this is to some extent, our contemporary says, the reason of '*Fine lines*," carrying such high values compared to good sound mediums, although no doubt there is excellent values for the price in the class. We confess we often wonder what becomes of good medium Pekoes, large numbers of chests of which are sold at one shilling and upwards, and we very much doubt whether much of this class is retailed pure. A very large proportion finds its way into the market well mixed with, we fear, a China Congou bought probably at 6d to 8d per lb. That a large number of middlemen in tea must make a fine thing there is no doubt, but we feel pretty certain we are not far out when we say that the consumer of the article has never yet felt the full benefit of the low prices now ruling for Indian tea, but which nevertheless we should be content with, were there any surety that the present standard would remain as it is. A year or two ago, we believe, one house in London made a very large fortune, laying up all the red leaf and selling it as pure Indian tea, and advertizing largely that it was the only pure Indian tea, and went so far as to try to prove this by asking in their advertisement what color a withered leaf assumed if put out in the sun, as all Indian tea leaf was so treated. By such ruses are the British public taken in, but we wonder that many of our large companies do not start retail places and guarantee their produce. We are aware that a few do —but as yet the quantity sold in this way is trifling. We feel convinced that if America can only be enlisted on our side, that with their style of advertizing and by the means of travelling agents Indian tea will have a great future before it there. The American simply hoists his wares into the market by advertizing, or as it were driving his goods down his customers' throats, and we think the Indian tea Investor might take a leaf from Cousin Jonathan's book.—*Planters' Gazette*, Feb. 5th.

THE BUG.

The bug differs from the majority of insects in not passing through a quiescent stage previous to the assumption of its adult form. Those insects which pass through the stage familiarly known as the "chrysalis," are in their earliest life totally unlike what they are destined to develop into, and during their pupahood tho vast modifications that have to take place before the creature appears in its adult form, are elaborated out of the store of nutriment laid up in the body during the preliminary stages. Now the bugs are already, at the commencement of their life, so similar in general form to their adult shape, that the changes they have to undergo are comparatively trifling, and therefore no quiescent stage seems to be necessary. Bugs live entirely upon juices which they extract from plants or animals. The hard bugs seem to favour an animal, and the soft ones a vegetable diet; this, however, must not by any means be taken as a hard-and-fast rule. Some are attached to special plants, apparently because they either derive their nuriment directly from the plant, or indirectly from other insects that feed upon the same plants.

As a rule they are not to be regarded as coming under the category of useful insects. When a plant is, so to speak, tapped, and its juices gradually absorbed, it of course tends to become weak, shrivelled, stunted, and unhealthy; and, therefore, any creature that feeds on vegetable juices may be reckoned *a priori*, as likely to become injurious to man, since his welfare so largely depends upon the vegetable produce of the soil. There are a few plants which seem specially liable to the attacks of bugs. The different kinds of grasses are much infested, furze and broom have each their special inhabitants, nettles and thistles afford a home and food to large numbers, rest-harrow and heath are much frequented by species, and amongst trees, oak, hazel, sallow, birch, ash, and fir have each their own peculiar hemipterous fauna. If you would see the bug at home and pry into the secrets of their life, go in July or August to a flourishing bed or nettles or thistles, or to some luxuriant patches of ragwort, sit down beside the plants, and carefully look on without disturbing them. They will be chiefly green, a favourite colour with *soft* bugs, and may easily be recognized by the characters of wings and beak. If you wish to secure them, a bag of stout calico attached to an iron ring and stuck in a handle should be vigorously and rapidly drawn backwards and forwards across any patch of rank herbage, and in this way with very little trouble large numbers will be obtained.—*Knowledge*.

THE DEVELOPMENT OF TEA CULTIVATION IN CEYLON.

The *Planters' Gazette* states:—A proposal is being privately circulated by a Ceylon planter, the object of which is to obtain tho co-operation with him of one or more capitalists in the creation of a tea estate of 500 acres. For this purpose, it is calculated that a total capital of £15,000, or £30 per acre, will be needed, and of this sum the planter himself will lay down £1,500. He accordingly invites subscriptions for the other £13,500 upon terms which are not only novel and ingenious but perfectly just, and sufficiently attractive. For every £30 subscribed, he guarantees to open up an acre of virgin soil in Ceylon, and to hand it over to the investor at the expiration of three years from the date of payment as a tea garden, and as security for the due performance of this contract, he will execute a mortgage upon other estates in Ceylon in favour of trustees. for those providing the funds. Moreover, he undertakes to have the title to the land registered in the names of the several parties. At the option of the investor, the £30 per acre may be paid in three equal instalments spread over three years, or it may be paid up at once, and in the latter case it will bear six per cent. interest; should any of the subscribers be young men anxious to learn the business of tea planting, arrangements will be made for placing them with the tea planters, under whom they would have full opportunity for learning their work. They would be expected to pay for their board, and if prepared to live economically, £120 per year would be amply sufficient to maintain them, until they could take up their own property. In this way, an investor say of £3,000 would receive sufficient to maintain himself until the three years were over. It is generally estimated to cost about £30 to bring an acre of tea into bearing in Ceylon, and therefore it is not at first sight very obvious what the planter is himself to get out of it. But he explains that it is far more economical to work a large estate than a small one, and of course his available cash, amounting to £1,500, would be quite useless by itself. Moreover, there is very little doubt, we suppose, that out of the £30 an acre there would be sufficient to pay him a fair salary for the three years occupied in the creation of the garden, provided always that the whole sum asked for was subscribed, and the 500 acres therefore planted up. At the end of the three years, then, the originator of the scheme would have his own fifty acres of tea in bearing, and the chances are that his co-partners, if they were satisfied with his management, would wish him to continue at least a general supervision over the estate. In this indirect way therefore, we can see that it will answer his purpose, but at the same time he obtains no unreasonable advantage.

As to the probable returns from the undertaking, the statements put forward are not extravagant, but in precise accordance with ascertained facts. Well planted gardens at suitable elevations are now producing from 400 to 700 lb. of dry leaf per acre, at ages varying from three to seven years, the tea being placed on the London market, all charges paid, at a cost per lb. of 8d to 10d. During the past year, Ceylon tea invoices have frequently averaged above 1s 6d per lb., thus leaving a surplus of 8d to 10d per lb. to the producer. Taking a production of only 400 lb. to the acre, at the proportionate cost of 9d per lb., the profit to the grower would be at present rates £15 per acre. But if the average fell to 1s per lb., there would still remain a profit to the Ceylon producer of 3d per lb. or £5 per acre, and it must not be overlooked that at this price most of the Indian gardens would be working at a loss. At the worst then, the return is equivalent to about 16 per cent. on the capital outlay, and this with a fair prospect of obtaining 50 per cent. ought to attract investors. We sincerely hope that this novel attempt at co-operative planting will succeed and that it will mark the commencement of a new era in the prosperity of Ceylon.

THE CASTOR OIL PLANT

is thus noticed in the proceedings of the Madras Agri-Horticultural Society:—Read the following letter from H. R. Farmer, Esq., Acting Sub-Collector of Cuddapah, to the Acting Collector, dated Madnapalle, 10th November 1883:—

"In reply to your letter, No. 2,614, 13th September 1883, calling on me to furnish you with some information on the subject of the cultivation of the castor oil plant and the manufacture of oil as practised in this part. I have the honor to state that I have gathered the following information from the Tahsildars of the Sub-Division and Mr. Thomas Ward of Madnapalle. The printed note received with your letter under reply was circulated to them.

2. "*The Botanical Description of the Plant.*—Height 3 to 9 feet, stem round, hollow, and brittle, leaves large, and divided into 7 or 8 segments, capsules prickly, and seeds oval, shining and dotted with gray marks.

3. "*Cultivation.*—It is generally cultivated with other crops, but sometimes alone. The plant flourishes in soft loamy soil and requires ordinary ploughing and manuring. After a fall of rain in July or August, the land is first ploughed and the seeds hand-sown in parallel rows. The rows and the seeds are at a distance of one from each other. The shoots spring up in 10 days, and the land is turned up with the plough after 20 days. This is believed to secure a better harvest. The plant begins to bear berries in about 4 months. These berries are collected with the hand as often as they are ripe at about the end of January. They are heaped up for a couple of days, and then dried in the sun, and the seeds are separated from the outer shell. An acre of land takes from 4 to 6 Cuddapah measures of seed.

4 "*Varieties.*—In this part of the country there are three kinds of castor seeds. (i) *Chittamudalu*; (ii) *Chittamidalu*; (iii) *Peddamidalu*. The first is small seed, rarely cultivated; the second is medium sized, and chiefly cultivated in dry lands; and the third is the large seed usually grown in betel and sugar-cane gardens.

5 "*Outturn and Percentage of Oil.*—The average outturn is stated to be about ¾ putte or nearly* 4¼ cwt. per acre.† Twelve measures of seeds (27 lb.) produce by the process of home manufacture, 3 measures (7 lb.) of oil. A measure of oil generally weighs 144 tolas or 3¾ lb. Thus, 27 lb. of seeds produce (3×3¾) 11¼ lb. of oil. The percentage can therefore be stated to be nearly 11 per cent.

6 "*Extraction of Oil by Home Process.*—The seeds are first roasted and then pounded to a pulp, which is mixed with a large quantity of water and boiled. The oil is skimmed off as it rises, and when all the oil is thus collected, it is again boiled to remove any moisture and to precipitate impurities.

7 "*Scientific Process.*—No scientific process is known in this division.

8 "The oil is used for lamps and as an unguent. It is of course a well known purgative. After extracting the oil, what remains of the berries are used as manure for betel and sugar-cane gardens."

Read the report of the Head Assistant Collector of Cuddapah, embodying replies to his questions from the Tahsildars of Proddatoor, Jammalamadugoo, and Pulivendala to the following effect:—Castor seed is generally sown with other crops, though in Pulivendala usually alone and only rarely with "Anumulu" (*Dolichos lablab*) and "Alasandalu" (*Dolichos sinensis*). It grows and thrives best in red, sandy loams, and gravelly soil, but will also grow in black cotton soil; it is planted only once in the year in June, July and August; no special preparation of the land is made for it, and it is sometimes used as fencing for betel gardens; the seeds are not soaked before sowing; the plant lives in the dry lands from July to December, but may be kept alive nine months by watering; two sorts, large and small seeded are grown, large only in Pulivendala; the ryots extract the oil by boiling, and with the mill; the husks are used with cow-dung, as fuel, but in Pulivendala are generally thrown away; and the oil-cake forms an excellent manure for paddy fields.

* The Madnapalle putte contains 320 Cuddapah measures.

† 1 measure (holding 132 tolas of 2nd sort rice) of castor seed weighs 88 tolas, and 38 8-9ths tolas are taken as equal to 1 lb.

WHITE ANTS—Although white-ants are a pest as much to certain crops as to anything else, they are said to perform a service to agriculture on unoccupied ground, similar to that performed by the earthworm in England. They are specially destructive to sugar-cane, and have actually been the cause of stopping the cultivation of the cane in several *pergunnahs* of the Cawnpore and other districts. Mr. Ridley, of the Lucknow Horticultural gardens, however has found a remedy for the depredations of the white-ant in the field, which he has proved invaluable. Kerosine oil will not of itself mix with water, but if first shaken up with milk it will amalgamate with that, and can be then diluted with water to any desired extent. A little of this mixture, we are told, goes a long way and proves a very effective insecticide. A mixture of two parts of oil to one of sour milk, "churned" together, mixed completely, and this mixture diluted to the extent of one wineglassful to four gallons of water, will not injuriously affect either plants or grass, but will effectually keep off white-ants. It will probably be useful to many to know this simple remedy.—*Friend of India.*

NEW VEGETABLE PRODUCTS IN COSTA RICA In consequence of the unremunerative character of the Coffee crops during the past few years in Costa Rica, much attention, it is said, is now being given to the introduction and cultivation of other crops. New lands have been opened up on each side of the railway from Rio Lucio to Limon, where already there are about 240,000 Banana plants, which are calculated to yield 30,000 bunches monthly, besides which Tobacco Sugar-cane, Pines, and Yams are also largely grown, and becoming articles of export. Potatoes grow well in the highlands of the Republic, where they are cultivated, and are now being shipped to Colon, the West Indies, and the United States. "The Government is doing all in its power to promote the cultivation of new products, amongst which may be mentioned rubber, cocoa, ginger, vanilla, and ipecacuanha, the three latter of natural growth, and which it is to be hoped in time will considerably add to the prosperity of the country." A project has been submitted to Government for the establishment of a school of agriculture and a model farm. Instruction, it is said, is much needed "for the cultivation of the almost unknown and valuable products of Costa Rica."—*Planters' Gazette*

Correspondence.

To the Editor of the Ceylon Observer.

THE LATE MR. JOHN ELIOT HOWARD AND MICRANTHA CALISAYOIDES.

Lord's Meade, Tottenham, 19th Jan. 1884.

SIR,—I observe an editorial footnote to a letter of my late father's published in your issue of Nov. 26th, 1883, from which it appears that you are under the impression that a Micrantha Calisayoides is a "bastard grey bark." If you will refer to Dr. Weddell's Notes on the Quinquinas, you will see it is not so, for you will find it under Stirps Micrantha Ramus Eumicranthæ as a distinct variety. It may interest you to know that much bark of C. micrantha var. Calisayoides has been received in London and Paris of late years from South America, that it is always classed in trade as calisaya and is freely taken by manufacturers though somewhat uncertain in yield of quinine.—Yours truly, WM. DILLWORTH HOWARD.

[We are very glad to receive this information, which we publish in justice to the late great quinologist, and for the benefit of readers to whom the information is as new as it is to us.—ED.]

THE QUININE SYNDICATE.

London, 25th January 1884.

DEAR SIR,—We have to thank you for publishing our letter to the Ceylon planters, and, as a matter which we knew would be interesting to you, we cabled to you on the 21st instant:—"Quinine Howard seventy-five pence tins. Probably smash of syndicate." The effect of this drop will most probably be the smash of the syndicate in the more or less near future. As yet of course it is too soon to expect its official dissolution as the signatories must have time to take steps to release themselves from their engagements to each other.

It will only remain for the planters not to press sales too much at first, but allow the manufacturer time to realize the new situation.—We are, dear sir, yours faithfully, FRANÇOIS LE MAIR & RIVERS HICKS.

COFFEE IN COSTA RICA.

Edinburgh, 30th January 1884.

DEAR SIR,—Whether or not the feeling is a right one, is open to question. But it cannot be denied that when any are suffering from an infliction or affliction of any sort it is always some consolation to know that there are others as bad or worse than they are. I refer to the following short extract from a private letter, received the other day from America:—

"In Costa Rica, they are grubbing up coffee trees as being no longer profitable, and planting rubber instead, so Ceylon is not the only sufferer in coffee."

Now, in Ceylon we are not yet come to this, for, bad as we have been, I suppose few have either abandoned permanently their coffee or hope for the future in it—where the trees are neither wasted nor worn *from age*?

The decadence of coffee crops, generally, everywhere surely must eventually bring down the enormous stocks of coffee, both in London and Europe, which our small crops in Ceylon have failed to do in any marked extent?

In face of these heavy stocks it is really wonderful how first-class qualities of coffee continue to realize such good prices.—Yours truly, P. D. MILLIE.

THE EDINBURGH FORESTRY EXHIBITION.

Mysore, 2nd Feb. 1884.

DEAR SIR,—I enclose a cutting taken from the *Scotsman* of 22nd December last, with reference to the forthcoming Forestry Exhibition in Edinburgh. It struck me when reading it that it would be a good opportunity for Ceylon to show off her fine woods and her native furniture manufactures to our friends in "Auld Reekie." Why should it be behind Sierra Leone and Canada, in coming forward with exhibits? I think something ought to be done in the matter by your Government. Now that you have a Scottish Governor, I am sure he would do his best to further the interests of Ceylon, especially as the exhibition in question is to be held in Edinburgh.

Excuse this rambling letter; if you think it worth your while to publish it, please do so. RAMBLER.

(*Extract referred to.*)

THE INTERNATIONAL FORESTRY EXHIBITION.—At a meeting of the Executive Committee, held in Edinburgh on Wednesday, copies of despatches from the Governor-General of Canada and the Governor of Sierre Leone, addressed to the Earl of Derby, Colonial Office, were read and received with much satisfaction. The despatch from Canada enclosed a report of a Committee of the Privy Council embodying a report from the Minister of the Interior, in which the great importance and interest of the objects of the exhibition to Canada are fully recognised. The Government of Sierra Leone have also determined to take advantage of the opportunity offered by the exhibition to bring into public notice the valuable and ornamental woods and dyeing substances of West Africa. The War Department of this country will show a collection of wood used in the Surveyor-General's Department for ordnance purposes, and the Commissioners of Woods and Forests are preparing a representative exhibition of British timber.

SUGAR CULTIVATION IN CEYLON.

Koslanda, 10th Feb. 1884.

DEAR SIR,—There seems to me to be a question looming in the distance in the pages of the *Observer*, of some importance to the island: Can the sugarcane be profitably cultivated in the low-lying lands of Ceylon? I take it that is the enquiry several of your correspondents are making, and it is an important one. You and I can well remember the sugar estate near Kandy; it failed owing to too damp a climate.* Baddegama is *not* and never has been a great success, and you must have a drier climate than Baddegama if you want your 2 tons an acre for plant canes, and, say, 1½ for good ratoons. In Barbadoes they say: "Soil, sir, we make the soil," that is what the "Bims" say, and there is little doubt that, on fairly good soil, sugarcane in a dry climate can be well cultivated. The Bourbon or Mauritius I believe to be the best: the trash or straw of the sugarcane ploughed into the land helps very much to keep up the fertility of a sugarcane plantation. Wray's book on the cultivation of the sugarcane is the best I have seen, but much more *interesting* and valuable information could be got from Barbadoes, the highest and best cultivated island of the West. There is a "Planters' Society" there: it meets at Bridgetown, I think: they also consult on *yam* cultivation, sweet potatoes, Indian corn, etc., etc. To return to our subject. The cultivation of the sugarcane in the West—in Mauritius, Queensland, China and Japan—might be made very useful and pleasant reading and interesting in the pages of your *Tropical*. The kinds of cane, kinds of land, mode of cultivation, *class of labourers* employed, *terms of agreement*, yield per acre, etc., etc., and the planters would learn some matters worth their knowing. I am sure the information would be most interesting to them in many points. I cannot myself say if Ceylon has any large tracts of land suitable for the profitable cultivation of sugarcane, but I cannot help thinking it must have: in poor land plant the purple canes, and in richer lands the

* We were told that the cause of failure in this case was smallness of area.—ED.

pale yellow kinds. Trusting a new industry may yet spring up in Ceylon, I am, yours truly,

SACCHAROMETER.

[At present the market is swamped by beet and bounties. In Ceylon a great deal ot palm sugar is made from the juice of the kitul, palmyra, coconut, &c.—Ed.]

HOW TO GERMINATE NUTMEG SEEDS.

13th February 1883.

Dear Sir,—Will you kindly allow me to suggest to your correspondent "Anti-Humbug" the necessity of having his seed nutmegs sent to him with the rind on them.

Let him remove the rind and also the mace, but, in removing the latter, he must take the precaution ot cutting it off with a pair of small scissors in such a manner as to leave a portion adhering to the nutmeg at its point of attachment, about the size of a two-anna-piece.

In planting, the nuts should be laid on their side, for, like the jak seed, they put out a stud-like projection, and from this stud proceeds the stem and radicle, one up, t' other down of course.—Yours truly,

TRY AGAIN.

ANATTO (*BIXA ORELLANA*) A PAYING CULTIVATION IN CEYLON.

Dear Sir,—I have seen the name of this plant spelt in descriptive books in several ways: anatto, arnatto, arnotto and onotto. The most common and correct way probably is *anatto*, and this form of spelling it should, I think, be adhered to in future. Full details, as you say, have been published in your columns about the plant, but further information, particularly as regards its experimental cultivation ending in success in Ceylon, will it is supposed to acceptable to you and the public. The plant is common in Kalutara, and I have seen it bear fruit equally well at an elevation of 3 000 feet. It will be, therefore, worth a trial at much higher elevations, for then such land as are unsuited for chinchona and other products might be utilized, as all soils save swamps seem to suit. The plant is supposed to have been introduced by the Dutch along with cocoa, perhaps, as a necessary article for the preparation of "chocolate" as made by the Spaniards in South America. It gives chocolate a peculiar color and also imparts a certain flavor. It certainly was grown plentifully in Moon's time (1829) and was used then as it is now by the famed Kalutara basket-makers for dyeing. There can be no doubt that "it is an elegant coloring substance" The natives use it largely in obtaining different shades of red, orange, yellow, &c, by mixing it with other coloring substances. Besides, the substance has the property of indelibly fixing its own or altered colors on any article it is applied to, and has therefore an additional value beyond its mere color. That its *chief* use is "to dye butter and cheese" is a mistake. It is used for this purpose, but it is also used largely for dyeing silks, cloth and leather, and confections and in the painting of toys, and much in the same way as the natives do, to give different shades to other colors. The demand for it in the European market has never slackened, and is increasing. Statutory enactments in Belgium, Holland and Sweden prohibit the use of coloring substances obtained from metals and minerals (mostly poisonous) in the dyeing and coloring of wearing apparel, wall papers, toys, confections, &c, and there is every probability of similar acts being introduced into Britain and France. There is a demand for the article in Australia too, as not long ago a Mr. de Rinzy made special inquiries for the seed (not for cake or flag anatto), being prepared to buy it largely. I believe he made Messrs. Darley, Butler & Co., his agents, to purchase any offered for sale. This is a plant which deserves the attention of natives and those who are contented with a reasonable profit. It is a hardy plant requiring very little expenditure in planting out and in the upkeep. It grows in poor soil, yields a quick return and requires no trouble in preparing the produce for the market. A measure of seed costing a few rupees will give about 10,000 plants. In four months, the plant will be fit for putting out. In the lowcountry in 18 months the first crop can be gathered in. The plants can be planted from six to ten feet apart according to the nature of the soil. There are two kinds of plants in Ceylon: the common plant with the apple-like blossom and having hairy pods, spearhead shape and dull red in color: the other plant is similar in appearance but with snowy white flowers, pods spherical in shape and of a green color with a tinge yellow when ripe. The seed containing the dye is of a slightly lighter color and is preferred to impart a deeper tint to yellow.

Anyone wishing to see specimens of the former kind can do so by visiting the Circular Walk, where, at the suggestion of Mr. Wright, some are grown for the sake of their flowers. Mr. Advocate Cooke of Kandy has some growing remarkably well on his clearing facing his residence, and with his permission, I have no doubt, they can be inspected by anyone wishing to try the cultivation of the plant.

The anatto cake and roll anatto sell in the European market, but at present it is not necessary to extrace the dye here. It is not an advantage as the price in England of the imported cake and flag is only about 1s 3d a lb. and it takes more than 10 lb. of seed to make a lb. of the cake. The fact is the rough method in use in South America does not result in a satisfactory article being turned out, and the price is out of proportion to the value of the dye stuff in the seed, rendered inferior, in fact spoilt, by their rude process of fermenting, boiling, &c. The best anatto (seed) fetches in bulk 4½d a lb. in London, and near that price has been obtained for small shipments from Ceylon. There are trees in Kalutara said to be 16 years old. They are about 14 feet in height with trunks about a foot in girth a foot from the ground. As in other products, Ceylon will yet top the market, if proper care in the picking, sorting, &c., is used. The first crop will give 5 cwt. an acre of the seed (though more has been got from an experimental clearing), and the yield is likely to increase up to 10 cwt. the acre. Neither cinnamon nor coconut properties have for some time past given or are ever likely to yield profits which anatto promises to yield. It is a pity to see the determination with which the natives are continuing the growth of cinnamon notwithstanding the fall in price for some years back of this article. If the Government will use proper measures to induce the natives to try this easy-growing product, it will soon give relief to them as well as prove beneficial to the island and the Government.

W. PROWETT FERDINANDS.

ALKALOIDAL VALUE OF CINCHONA BARKS.

Colombo, 20th Feb. 1884.

Dear Sir—A correspondent in your issue of the 19th says:—"I sold some autumn bark on analysis (1·47 per cent sulphate of quinine) in Colombo, four months ago, and bark from the same place and three months older was said to contain only ·35 per cent sulphate of quinine when sent down last month."

These results are certainly very remarkable if the bark in both cases was from trees of the same species, and from similar parts of the trees. If your correspondent were to give a fuller description of the bark than simply "bark from the same place," his experience might add something to our knowledge of alkaloid production, provided no mistake has been made.

The analyses referred to were not made by me, but a few days ago I made two analyses which were sufficiently remarkable, as showing the great difference which may exist in alkaloidal value between root and stem bark from the same tree, to justify their being placed upon record. The planter for whom the analyses were made, in answer to my enquiries, furnished the following particulars :—"The bark I sent you of stem and root was all that could be collected from one tree. It was only about two years old seed from ———, Dikoya. The growth was fairly good for calisaya. The tree was about six feet high, grown amongst coffee at an elevation of about 3,000 feet. Leaf lanceolated, broadest at centre, pubescent beneath. capsule much longer than usual in calisayas. Cattle-manure was applied last year to the field of coffee, and this tree may have got some."

The following are the analytical results :—

	Root.	Stem.
Quinine alkaloid ...	2·47 per cent.	·31 per cent.
Amorphous alkaloid...	·95 ,,	1·29 ,,
Other alkaloids ...	·86 ,,	·43 ,,
Total alkaloids ...	4·28 ,,	2·03 ,,
Cryst. quinine sulph...	3·33 ,,	·42 ,,

In the above figures there are certain relations that are worth noting. The root bark contains, in round numbers, twice the amount of total alkaloids and eight times the amount of crystallizable quinine contained by the stem bark. The quinine and amorphous alkaloids taken together, bear the same proportion to the total alkaloids in each case. When we consider that quinine and its amorphous alkaloid quinicine are isomeric, *i. e.*, have exactly the same chemical composition as represented by the formula $C_{20}H_{24}N_2O_2$, we see in this case a striking example of the tendency which the same alkaloid has to assume the crystallizable form when protected from the light, and to become uncrystallizable when exposed to the sun. Besides the influence of sunlight, or in conjunction with it, we know that free organic acids in the bark have likewise the tendency to develop quinicine out of quinine. In the laboratory, quinine is easily converted into quinicine by heating the dried acid sulphate of quinine for a few minutes to a temperature of about 132° C. The pity is that no one has found out how to reverse the process and turn the amorphous substance quinicine into crystallizable quinine. Unfortunately, I had disposed of all the stem bark before it occurred to me to estimate which sample of bark had the largest quantity of free acid present in proportion to the amount of alkaloids. I believe all the cinchona barks contains some *free* organic acids. It does not come in the way of ordinary commercial cinchona analysis to examine the unture and amount of the organic acids present, esat in every case in which I have, from curiosity, betted an aqueous decoction of cinchona bark, I have found it to give a distinctly acid reaction.

In the two samples of bark analyzed, the sum of the alkaloids other than quinine and amorphous alkaloid, bore the same proportion to the total alkaloids in each case. M. COCHRAN.

[The enormously superior value of the root bark, in this case due, as Mr. Cochran believes, to the exclusion of sunlight, renders the more puzzling the widely differing prices obtained for root bark. For the first samples sent from India and Ceylon very high prices were given, and this was most important in view of Mr. Gammie's calculation that one-third of all their bark in Sikkhim from uprooted trees was root bark. Latterly, root bark has not obtained high prices, and the question is why? The dirtier condition of the bark could scarcely be the reason. Can it be that it is more intractable in the hands of the chemist? Mr. Cochran does not seem to have found it so.—ED.]

SUGAR CULTIVATION IN CEYLON : SUCCESS DEPENDENT ON GOOD CANES.

Kandy, 23rd February 1884.

SIR,—I notice in your issue of 20th inst. a letter signed "Saccharometer," in which the writer states the failure of sugar cultivation near Kandy to be due to excessive moisture or as he states it "too damp a climate."

Having with Mr. Toskey (the proprietor of Poloo estate) planted 222 acres of sugarcane at Navure, Fiji, I can certify that I have there seen 50 inches of rainfall during a month, the greater part of the estate being under water for a week of that. I never saw so wet a climate.

In that part of Fiji, Honolulu canes have given the highest density, viz. 11½ per cent, as obtained by Messrs. Sharp Fletcher & Co. of Navure.

In one of the letters on the subject of sugar cultivation lately published in your paper, the failures in Ceylon are attributed to the DRYNESS of the climate. How about Queensland with its nine months' drought?

In another letter, the poorness of the soil is mentioned as a probable cause. On Mango Island, Fiji, old, abandoned cotton-lands were planted with sugarcane, which gave a high density, and at the Colonial Sugar Company's estates on the Rewa River manure is used. While on the subject of failures, I may mention that some years ago a company was started at Suva for sugar cultivation ; the land they planted was what is called "soapstone," a slippery, barren soil, and the plantation was, in consequence, a dismal failure ; part of the machinery is lying around to this day.

In view of the various opinions expressed—none of which seem satisfactory—I venture to say that inferior canes are the real cause of failure. Introduce Honolulu and other new canes, modern machinery and experienced sugar-boilers ; and even supposing a density of 8 per cent or 9 per cent were obtained, the greater cheapness of the labour employed in Ceylon would make up any deficiency existing in the density of our canes as compared with those of Queensland and Fiji.

Our chief object should be to draw the attention of such large Australian Sugar Companies as the Colonial Sugar Company of Sydney and Messrs. Sloane & Co. of Melbourne, to the great suitability of Ceylon for this cultivation, and induce them to investigate for themselves, so that we may share their capital with the above-named countries.—I remain, sir, yours faithfully, HONOLULU CANE.

THE HISTORY OF THE SUGAR ENTERPRIZE IN CEYLON IN THE FORTIES.

Colombo, 25th Feb. 1884.

DEAR SIR,—The writers in the local newspapers who are advocating the renewed cultivation of sugar in Ceylon are, I suspect, unacquainted with the history of the island and with the present state of sugar-planting and manufacture all over the world.

When I first came to Ceylon, there was as great a mania for planting sugar, as there was a few years ago for planting cinchona, and as there now is for planting tea, and I was slightly bitten with it myself to the extent of buying 1,200 acres of land in the Rayigam Korale, which, however, I fortunately resold before the epidemic passed away.

If my memory serves me, the former proprietor of the *Observer* contributed to generate the epidemic, and

I think he suffered somewhat in pocket from an attack of the complaint.*

The first extended experiment was made at Peradeniya, then at Negombo, at Awisawella, in the Rayigam Korale, and largely in the Galle and Matura districts. I should think at least £300,000 was lost in the attempt to counteract the poverty of the soil in the west and south-west portions of the island.

Under the most favourable circumstances of soil and climate, the profits of the cultivation of sugar by Europeans is now so small, that the cost of increasing the yield from one ton per acre (which is the average yield of new forest land in the west and south-west of Ceylon after the first crop) to two-and-a-half tons by high cultivation not only swamps all profit but entails a loss which ends in disastrous failure.

Neither skill in manufacture nor modern appliances can counteract an outlay for manure of at least R100 per acre, to produce an article which in a crude state is now only worth in London £12, and, when crystallized by means of costly machinery, £22 per ton.

That the sugarcane will grow well in Ceylon, admits of no doubt whatever, and there are localities where the soil is rich enough to produce two tons an acre, but in these the climate is as antagonistic as the poverty of the soil is in the west and south.

In India, with its cheap labor and rich soils, though the natives produce enormous quantities of crude sugar, nothing but failure has attended the attempts of Europeans to cultivate the sugarcane on a large scale. As there is a protective colonial duty of R50 per ton, I quite believe it may be profitable to cultivate sugar and manufacture it in vacuum pans in Ceylon, to the extent of the local consumption; but when the production would exceed that limited quantity competition with beet sugar and the produce of richer soils is out of the question. Looking at the enormous increase in the production of beet in Europe, the rising cultivation of sugar in what will soon be called the Australian Confederation and in the Southern States of North America, all of which with the exception of Great Britain and a few other kingdoms have highly protective tariffs, I think the time will come when Brazil and the foreign and colonial exporting islands will have even a greater struggle to cultivate the cane profitably than they now have. In India, China and the Philippine Islands, great quantities of crude sugar will always be produced by the natives, because the cost of growing the cane and making the sugar is very little. R60 or 70 per ton on the spot affords them sufficient remuneration!

The misfortune of sugar cultivation by Europeans in Ceylon is, that they cannot experiment in it on a small expenditure of capital. The cost of the buildings and machinery required to manufacture the best descriptions and obtain the largest yield is prohibitory. Sugar may grow well and yield largely in the North-Eastern Province, but who will be bold enough to try the experiment with the risk of sinking R100,000 to R200,000?—Yours truly, C. S.

* No: Dr. Elliott sold his estate, [illegible], near Negombo, for a good price, to Mr. Fraser, an old West India planter, who was supported by Messrs. Arbuthnot & Co. of Madras. Mr. Fraser failed to make this place or Charlie's Hope (near Kalutara) pay.—ED. C. O.

NORTH BORNEO.

Sandakan, 3rd Jan. 1884.

DEAR SIR,—Since I last wrote, a great reduction of officers has been made, and is still going on, it having been found necessary to reduce expenditure by a considerable amount. The step taken has, I think, met with general approval, and has not in the least shaken the faith in the Company; on the contrary, the opium and spirit farms are double this year what they were last, and private enterprize, in the way of planting, hotels' etc., is going along right merrily.

Our Governor has been appointed acting Governor at Labuan and Consul General for Borneo, as well as his present appointment in the B. N. B. Company.

The agent for the Australian Sugar Company is expected here in April, to commence operations. A sugar mill and fibre machine have been imported.

Mr. Gibson an experienced tobacco planter, is expected to return here with some skilled labour, to commence operations at once. Mr. Robertson is busy cutting out land near Silam for the Australian Sugar Company.

The Government have abandoned the intention of having a large staff of Government surveyors, and most of the work is to be done for the future by contract.

Among the specimens collected by the late Mr. Hatton, mineralogist, is one containing silver, but, to ascertain whether it is in paying quantities, a larger sample is to be sent home. I feel quite certain there will yet be found valuable minerals in North Borneo, but in a country covered to a great extent with dense forest it must take time to find their whereabouts.

The experimental garden is finished, and the products planted are thriving well.

I hope to call in at Colombo on my way home, and Mr. Callaghan who has resigned his appointment accompanies me. I hope, however, to return to Borneo after having recruited my health.

I am glad to see Ceylon is holding its own notwithstanding the general depression, and trust that the cultivation of tea, fibres and sugar, besides many other new products, that will, I am sure, be discovered, will be the means of assisting those who are in pecuniary difficulties and also be the means of bringing capital to the country.

The Chinese are not favourites of mine, but I cannot help thinking there must be many parts in Ceylon, such as abandoned coffee-land, etc., where they could as small proprietors with the help of their beloved pig make a very decent living. There should also be a good opening for them in the gemming districts. L. B. VON DONOP.

G. W. ON SUGAR PLANTING IN CEYLON.

SIR,—As I am probably the only survivor, now in the island, of the old sugar planters, I venture to address a few words of caution to those enterprizing spirits who may be thinking of renewing an attempt to introduce sugar cultivation in Ceylon. Though no one would rejoice more than I to see another new resource added to the list of these by which the decline of our old staple is to be counteracted, I should be sorry indeed to see another added to the list of failures, especially in these critical times.

Whatever may be the conditions of rainfall, season, climate, and soil, necessary for the successful cultivation of the sugarcane, no one living can say with certainty that sugar could be produced remuneratively in any given place except by actual trial. I will not attempt therefore to confute those of your correspondents who fancy they see assured success in the conditions to be found in certain parts of this island, but will confine my remarks to the facts of the local history of sugar planting in this island.

The *pioneers* of this enterprize, be it observed, were practical sugar planters imported from, or specially trained in, old sugar-growing countries. They, therefore, understood their business, and were better judges than most of those who now seek to revive the cultivation.

The *lands* chosen for the early efforts were for the most part selected by these very experts, who did not all cluster round one spot, but tried the experiment in widely different parts of the Southern, Western, and Central Provinces, in times when almost the whole country was at their disposal. The lands so selected comprized virgin forests, and the alluvial flats on the banks of several principal rivers.

The *proprietors* for whom these experts were engaged included companies, and men of great wealth, such as Baron Delmar, Lord Elphinstone, Tindall, the great ship-owner, and others, who spared no capital that was necessary to ensure success. My own friends would willingly have supplied any reasonable amount of money, or modern appliances which promised success.

The *appliances* already known in those days comprized the vacuum pan, and several other less expensive contrivances for evaporating the cane-juice at low temperatures. Not having kept pace during the last 20 years with the process of improvements, I cannot speak confidently as to the exact amount of advantage or economy that may be gained thereby, but I know enough of the principles involved to feel perfectly sure that by none of them could the scale have been turned in favour of the abandoned estates in Ceylon.

Varieties of Cane.—Though unable to state what varieties of cane were tried on other plantations, I can testify that canes of every important variety then known were tried on the estate in my charge. We had canes from *China*, *Bourbon*, the *West Indies* and other countries, of numerous kinds. In fact, no pains or expense were spared to obtain success. The Bourbon cane succeeded best, on the whole, and attained a most luxuriant growth. I have measured many of 22 feet length exclusive of *top*, and as thick as my wrist. Of these canes a Mauritius planter exclaimed that this was the country for sugar, as Mauritius could not produce such cane. He changed his note when he saw how the saccharometer stood in the boiling-house. It would be tedious, even if I could trust my memory, to specify the details of peculiarity of the different kinds of cane. Some were large and others small, some were striped and others plain, some yellow and others purple, some grew well but would not rattoon, or they did so very badly. But all gave poor liquor! The common characteristic, however luxuriant the growth, was poverty in saccharine. The saying was that our climate was too forcing, and that the canes grew well, but would not ripen.

Soils.—Someone writing about sugar, lately, says that the one thing needful is *rotation of crops*. But what would *rotation* avail when virgin forest fails! Especially, I would ask, what good could *citronella*, the proposed alternating crop, do for *any* land? As well might you alternate with mana grass! Let those who please argue for black or any other coloured soil: sufficient is it for me to have seen canes cultivated with every care possible on virgin forest, on drained deniya land, on alluvial flats, and all with the same result, in varying degrees, of failure. The finest canes and best crops I ever obtained were grown on deeply drained deniya land, and the next best in my experience were on the Gin ara at Shandon, and the plain of Peradeniya. I never saw the canes at Dumbara: the estate there was abandoned before my time. Tytler, originally a sugar planter, had either opened or had something to do with it, and he was strong in the conviction that sugar would not succeed in Ceylon.

Pests.—Of all the products that have come under my observation, the large cane stands pre-eminent for the number and pertinacity of its enemies. Pigs, jackals, cattle and buffaloes need to be kept out of the fields by costly fences. But monkeys, rats and squirrels defy all precautions. Borer and a host of insect pests also infest the plant at all stages of its growth, but mainly at the critical time of harvest, when sometimes half your canes may be soured, more or less, by those enemies, and their sugar turned to molasses.

Season.—The sugar planter in Ceylon is sore troubled to bring his canes to harvest at a suitable season, failing which he must lose largely. The dry seasons are so short, and so uncertain, that his best calculations may be futile.

In conclusion, my experience, after a severe struggle for bare exsistence, was that even that small measure of success could only be ensured so long as *retail* prices could be obtained for the produce. In the end, I was fortunate enough to sell the estate to a gentleman whose convictions were so strong that he purchased the estate with a full knowledge of all my difficulties, and of the failures of all but two other estates, which existed, as mine did, on retail sales. This gentleman went energetically to work, spent about R70,000 on the estate, and then abandoned it *in toto*.

If, after this brief history, anyone with the courage of his opinions should choose to buy sugar in Ceylon, let him be content to do it on a scale to do himself as little *harm* as possible. G. W.

[On this subject "G. W." speaks with special authority, and his warning deserves respectful attention.—Ed.]

SUGAR CULTIVATION IN CEYLON.

(From the local "Times.")

Sir,—The question lately raised in connection with the revival of sugar cultivation in Ceylon appears to deserve greater attention than it has so far received. A desultory correspondence from one or two people who have heard this, that or the other, or who (like myself) have sent for half a gallon of treacle once a month to the Peradeniya sugar factory, will hardly elicit facts which are necessary to be known as such, before the matter can be put before those who hold the required capital for such an expensive operation as sugar-growing. Hitherto, the result of inquiry has been merely to point to past failure, and a recommendation to apply to some old broken-down gentleman, who was, at some antediluvian period, a sinna dorre under an inebriate old planter whose carelessness, or worse caused the enterprizing proprietors to retire without a fortune. Of course, I am not pointing to any particular instance, but that seems the general tendency when anything in this island is first put before the public—especially, if it be an old enterprize sought to be revived.

Past failures, when duly inquired into and explained, are useful as warnings and guides to those who attempt the cultivation in the present day. The great questions to be answered are three:—Have we the soil in a favorable position for cultivation and transport; have we the climate suitable for remunerative production; and have we the labour? Now, first, about the soil and how does it bear. Sugar, we are told, and some of us have seen it, to pay well requires a black rich soil in flats or gently undulating fields. Ceylon has millions of acres of land which apparently satisfy these conditions, but there is nothing volcanic about it, such as they have in Mauritius and Java. I have lately had the opportunity of meeting sugar-planters from Fiji, Queensland, Demerara, and Louisiana, and I have seen sugar-growing in Mauritius and Madagascar. I am told that lime is required; or, at any rate, that the black soil with limestone, such as we meet with in Ceylon in many places, is very suitable for sugar. If this is the case, and our large area of otherwise suitable soil is proved by analysis to be wanting in lime, it is very easy to apply it artificially in the situations to which I am now about to refer. The attempts which in former years were made to grow sugar were in the west and central portions of the island, principally, if not entirely, so. We all know that the soil there is cabook, or gravel, and hardly an acre of anything which may be called rich soil—at any rate on flat or gently undulating ground. Let any one look at Peradeniya and its surroundings, and say whether there is anything about the soil that would strike the attention as rich, black free soil. A crumbled half-burnt brick would be about as likely to grow sugar, and yet sugar at one time did pay there. Probably the only inducement for sugar to grow where it did formerly was the extra abundance of moisture in the climate, and at Peradeniya an occasional flood from the river, over certain portions of the estate. But what enabled the sugar to grow as cane was the very thing that prevented the secretion of saccharine matter. This argument applies more or less to Kalutara, Baddegama, and the other places in the Southern Province, according to their situation. If any one can find a rich plot of soil in that direction, the probability is it would grow sugar well. It being just 23 years since I visited Baddegama, my recollection fails me as to the details of soil, but, except may-be along the banks of the river, I don't think much can be said of richness of soil, and still it is made to pay. But where our rich tracts of land, suitable for sugar, lie in Ceylon is away down by Dambulla, Polanaruwa, and the Bay of Cottiar. The lay of the land is perfect, and the appearance of the soil superb, easy communication with cart-roads, or navigation by the Mahawelliganga to Trincomalee. Here are thousands and thousands of acres of land available, with all conditions of the situation favourable, only awaiting the plough and the cane. If sugarcane be made, has been made, and is being made, to pay on the wretched cabook and gravel of the west coast, how much more should it be remunerative in the East, and East Central portions of the island. Now comes the question of climate. In regard to heat, no apprehension need be felt as to an insufficiency of caloric; there will be plenty of that. Then we come to rainfall. If I am not much mistaken, the registration of rain shows a fall of about 50 inches on an average all over the low-country on that side of the island, and that principally falls in the months of the north-east monsoon. Now is 50 inches sufficient, and can canes stand 9 months' comparative drought? Cane grows wonderfully well, and is abundantly remunerative in Queensland where they have 9 months' drought, and a rainfall of 50 inches is unknown in any part of Australia. A West Indian planter, told me a day or two ago that 9 months' drought would do no harm if soil and climate were otherwise favorable. In Fiji I understand the same thing is experienced. We may then pretty well consider it settled that the rainfall is sufficient, and sufficiently well distributed for sugar; but then suppose it is not; we come to the question of irrigation. And here we shall find that, apart from certain fields along the banks of the Mahawelliganga periodically overflowed by floods, and which may, or may not, be suited for the cultivation in consequence, the great river comes down in flood, with abundance of fertilizing matter in the water, all through the south monsoon, when it is dry in the east part of the island. Here we have one of the most wonderfully beneficent provisions ever known, by which nature provides abundant water supply in the hot dry weather in an otherwise waterless country. It is astonishing to come across a great river bank full with flood water, rolling down millions and millions of tons of water and soil from the hills through a hundred and fifty miles of dry country, sometimes with the leaves lying on the ground, and the trees bare as it is in the winter at home. Hitherto this extraordinary provision of nature has been entirely neglected, not an anicut, not a pump, not a canal, nor an engine. This valuable, incalculably valuable, water-supply is utterly wasted and has been, for any thing we know, since Ceylon was an inhabitable island. We have one tradition, however, concerning the branching mouth of the river, called Virgil Oya. This was said to have been caused by one of the kings cutting a channel for irrigation purposes, and a flood in the river breaking through all restraints opened a channel for itself all the way to the sea. Be this as it may, there is an unlimited supply of water at little cost, and if irrigation of sugar will pay anywhere in the world, other condiitons being similar there can be no possible reason why it should not pay better here than any where else. I say "better," because of the facility of working and cheapness of labour supply. Irrigation of sugar cane is being practised in Mauritius, and perhaps some of your correspondents may let us know the result. I think we may conclude that there is a sufficiency of rainfall, and backed up by facility in irrigation, as well as (we may add) for water communication, such as does not occur in other sugar-producing countries of the known world. The third question, "Labour supply," may be answered in half-a-dozen words. Ceylon is the only country in the world which commands a plentiful supply of cheap labour. There can be no more difficulty in securing labour for sugar than for coffee or tea or any other product.

If, as suggested above, a suitable tract of country can be found in the west, or in the south, indigenous labour can be obtained by men who understand the Singhalese, in any number, at 16 to 20 cents a day 25 cents would be high pay. In other situations, Tamils at an average of 30 cents. would flock in by thousands. The supply of labour need not trouble any speculator. Here then we have soil, climate, and labour, suitable, if people will only go to the right place to look for it. We want a practical Queensland, or Fiji planter, to select the land, with an experienced Ceylon man to point out the advantages and disadvantages of each position, and there is little doubt that it would be made a paying business. It must not be forgotten that, not only have discoveries been made in the machinery which enables a greater proportion of the saccharine matter to be extracted, but, what is more important, experience has been gained of different kinds of cane as specially adapted for special soil and situation. In former days, a planter had to be content with whatever cane he could get, and that might or might not, be suitable for his position. Now the sugar industry has gained experience and can tell him from practical cultivation that Honolulu cane will be best, or white, or red, or any one or more of a dozen different varieties. He would not have to work in the dark as men did thirty years ago, and gain or lose according to luck. No, with the right man and the right cane in the right place, sugar should do as well in Ceylon as anywhere else in the world. It is hardly necessary to add that, on elevated portions of the estate, in wide belts separating fields, cocoanuts would eventually prove an unfailing source of profit, and go a long way towards preventing the spread of disease, or insect pests, which seem by some fixed law of nature to follow extended cultivation of any one product over large unbroken areas. D. E.

GUTTA-PERCHA.—A writer in *Gardening Illustrated* uses thin gutta-percha in his grafting operations. Pieces about two inches long square are put in hot water, and placed around the graft. He likes it better than the common mixture for the purpose.

DESTRUCTION OF WHITE ANTS.—A portion of one of the yards at the sheep quarantine, Indooroopilly, was attacked and partially eaten away by the white ant. The quarantine keeper, Beck, poured a bucketful of liquid from the sheep dip on one of the posts, and, noticing that the ants dropped dead immediately on coming in contact with the liquid, he applied it to all the posts and rails that had been attacked. A considerable number of weeks have since elapsed, and today I examined the fencing and found it perfectly free from the ants. The liquid used in the dip is Little's chemical fluid, mixed in water in the proportion of one of the fluid to 100 parts of water. The price of the fluid, wholesale, is only 8s. 6d. per gallon, so that if it is found to be effective, there can scarcely be found a cheaper remedy.—I am, sir, &c., P. R. GORDON.—*Queenslander.*

HOW TO MAKE A TEAK NURSERY.—I see some one in the "Observer" inquiring how to make a nursery of teak seeds. The system adopted in the Government teak forest near Calicut is to make nursery beds in the ordinary manner. The seed is laid on the top of these beds, which are then covered over with grass or leaves, these again being covered with light boughs to keep the grass or leaves from being blown away. If necessary, light bamboos can be strapped across to keep everything in its place. In these plantations Mr. Laurie's transplanters have been used with great success in removing valuable treeplants. The teak-trees there are planted in the first instance 6½ feet by 6½ feet apart—practically 1,000 trees to the acre.—ARBOR.—Cor. Local "Times."

PAPER-MAKING IN EGYPT

In the suburb of Boulak, the river-port of Cairo, is situated the Daira paper manufactory, which, before the late war broke out, used to employ regularly more than 200 hands, almost all natives. Most of the paper turned out is used for packing purposes in the Khedivial sugar factories; but there are also manufactured in the course of the year some 70,000 reams of very fair writing and printing paper, which more than supply the demand of the Government offices of Cairo and Alexandria and the requirements of the national press. The writing paper is manufactured specially for Arabic writing, and to suit the peculiar style of Oriental penmanship; and therefore what is produced of this sort in excess of the requirements of the country is exported eastward rather than westward, a good deal of it going to Arabia, and a few bales even to India for the use of our Moslem fellow-subjects. Linen and cotton rags are used to a certain extent in the Boulak factory; but the interior of the stalk of the sugar-cane supplies the Cairene paper-making with an inexhaustible supply of very workable material; while, in the production of what is called "straw" paper in Europe, the *hilfa* grass plays a very important part. The Daira factory at Boulak enjoys a monopoly of this industry in Egypt; and in connection with it is the National Printing Office, also under the control of the same administration. The extraordinary turn for paper-making displayed by the Boulak Arabs is, it need hardly be said, and hereditary accomplishment. They can point to a long line of ancestors who educated the East and the West in successive stages of this useful art. There is an Arabic version of the "Aphorisms of Hippocrates" in the magnificent library of the Escurial, written on paper said to be made of linen rags, which dates from the very commencement of the thirteenth century. This was an improvement on the *Carta bombycina*—or *Carta Damascena*, as it was vulgarly called, from its having been first imported into Spain from Syria—which was fabricated from silken as well as cotton material, and is known to have been in use as early as 1100 A.D. It superseded, in its turn, parchment made of the skins of sheep and calves, which if not also an invention of the Arabs, was one that was quickly profited by and improved in Arabia, Syria, and Egypt. The Egyptians appear to have been acquainted with the use of papyrus in the most remote Pharaonic peroids; and its manufacture was a Government monopoly, as paper-making is to this day at Boulak. The *Cyperus Papyrus* grew almost entirely in Lower Egypt, and rather in marshy places or ponds formed by inundations of the Nile than on the banks of the great rivers itself. Isaiah gives us also to understand that it was found in shallow brooks (presumably in connection with the Lower Nile), when the course of his denunciations of Egypt, he prophesies the withering and decay of the papyrus plant—"the paper reeds by the brooks, by the mouths of the brooks." The mode of its preparation was in this way:—The outer rind having been first removed, the inner bark was divided by a needle or some other sharp instrument into very thin and broad layers. These were placed side by side longitudinally and glued together at the ends, another strip of the plant being glued across the back to give strength. The papyrus, having been pressed and properly dried, was then ready for inscription. Pliny was mistaken in imagining that the ancient Egyptians employed portions of the same papyras in making sails, mats, bedding, and even boats. It was another species of the same family that was so treated, which Strabo was careful to distinguish from the "hieratic byblus." The monopoly of the papyrus in Egypt, which was only permitted to be grown in certian localities, brought its value up to a price which was practically prohibitive of its use by any but the very opulent. Official documents—especially wills and agreement for the purchase and sale of lands and tenements—were required to be written on this expensive material; but for ordinary purposes the Egyptian of the later empire and the Roman *régime* committed his hieroglyphs to the custody of a meaner medium, and to this day we often find in the dust heaps of Upper Egypt domestic memoranda, and especially the accounts of the Egyptian housewife, scrawled on the glazed fragments of some cast-away earthenware vase. On the conquest of Egypt its papyrus was introduced into Rome, and there its manufacture was conducted under improved conditions. Pliny says the Romans made all sorts of paper out of it. Still Alexandria continued, as of old, the chief centre of the industry; and in the third century the tyrant Firmus could write that "there was so much paper there, and so large a quantity of glue used in its preparation, that he could maintain an army with it."—*Globe.*

INSECT PESTS AND THEIR DESTRUCTION.

People seem to forget that by the act of importing seeds and plants not indigenous to the country, and in cultivating them they are virtually interfering with Nature, which, according to their contention, would have produced them on the spot if they were needed. They omit to remember that by so introducing new plants they are more apt to introduce along with them the parasites which infest them, but leave the natural enemies of those parasites behind; and they do not seem to be aware that when they undertake to nurse, rear, and cultivate these plants, they are removing them from their state of nature into an artificial life, and that it becomes as much their interest to devise means for their protection against parasitic and other depredators as it is to prune, water, manure, and otherwise cultivate them. The stupid cry that "you cannot alter Nature," is receiving a direct contradiction every time one puts on clothing, cuts his hair, or does any single act or thing to promote his comfort or convenience. How would the conservatories get on without a constant attention to destroy the red spider, thrips, scales, aphides, and other little pests, or what would be the result if our vignerons omitted to use sulphur against the ravages of that insidious fungus the Oidium Tuckerii? Have not our sheep farmers been enabled by dipping into suitable washes to cleanse their flocks from the attacks of the acarus causing the scab—without the adoption of which remedy it would have been impossible to keep a sheep alive upon this large continent. Indeed, there is scarcely anything in Nature over which man is not able to exercise some sort of control, and this power is given him to exercise for his own good—or evil.

Thus, then, with respect to the inroads of insects, &c., upon his cultivated crops, it is quite within his province to endeavour to arrest their progress. By careful watching over fresh introductions of seeds, plants, and cuttings from other countries, and a supervision during their first few months of growth, he can prevent the introduction and spread of new pests and diseases. While by the use of insecticides and mechanical appliances he can, with more or less success, prevent the ravages of those already established. Thus, with the Curculio beetle (Otiorhyncus picipes) which is now spreading so rpidly, he can trap them by thousands by merely wrapping a piece of canvas or cloth loosely round the stem of his trees, in the folds of which they will hide by day. This is the only effectual plan yet found for destroying the Codlin moth, which is so destructive to apples in the United States of America, and latterly in Tasmania, and has lately been introduced into Victoria. The curculio is also caught by spreading sheets under the trees by day, and quietly going at night and jarring the trees, when the wevils drop and are swept up and destroyed. Some insects, such as the Aphides, are covered with a fine powder, which rolls off any insecticides that may be sprayed upon them; but a little grease or soap in the water will destroy this propensity, and the grease itself, without the addition of the insecticide, will stop up the spiracles or breathing-places, and thus the insect will be suffocated. Upon the same principle a very thick smoke is sometimes found effectual in destroying some kinds of insects, and others may be destroyed with even clean water. Occasionally it has beeen found that there are particular stages in the life ofinseagts when one method is destructive which at another stage would be quite ineffectual. At one time merely shaking the plant upon which they may be feeding will cause them to fall and be starved, because unable to crawl back to their food, and at another time this course would have no effect. On most insects the leaves of the Anthemis group of plants have a fatal influence—it is not known to what principle this influence is due, but its effects are most marked. The powder known as "insect powder" is made from plants of this order, chiefly Pyrethrum cerneum and P. Dalmatica, but the whole group possess the principle in a greater or lesser degree. Upon some insects the powder seems to possess little effect, but when mixed in water, in even small proportions,—an ounce to nine gallons—it proves very fatal. Even when burned, the smoke or fumes given forth possess an influence, and some people burn the powder in rooms to destroy mosquitoes, through merely sprinkling it about will be as effectual and far more effectual and lasting. In the United States it has been necessary to pass laws compelling people owning insect-infested orchards, &c., to take measures for cleansing them, and these measures are found to be effectual. They use, amongst other appliances, a small force-pump, with which they force a spray of strong lye over their trees before they break into leaf, and when in leaf they use a weaker solution of caustic soda with most successful results. For Curculia, they use sheets as before stated, as well as bandages for these and codlin moth. The borers are attacked with a chisel and wire; the locusts (cicada) are attacked with horse scoops and kerosine, and a constant aggressive war is kept up with an innumerable host of enemies, which would soon, if left alone, put a stop to agriculture and horticulture in America—as they certainly will do here unless we get rid of the idea that we should do nothing else but fold our hands and pray for deliverance from our enemies.—*Adelaide Observer.*

FLORIDA.

The Governor of Florida estimates the settlers in the State at 20,000 a year, and the number is rapidly increasing. Improved lands are now worth from $4 to $20 an acre and unimproved from $2 to $4 per acre. But there are lands adapted to orange culture valued at $300 an acre. The State owns upwards of 10,000,000 acres of lands, divided into school and seminary lands, internal improvement, and swamp lands. There are also about 12,000,000 acres belonging to the general Government, which are held at $1 25c. per acre. From the surveys made by General Gilmore and the Okechobee Land Company, it appears that Lake Okechobee has an elevation of 22 feet above the Gulf, and that Lake Tahopeliga, the head waters of the Kissimee, has an elevation of 65 feet, so that there is every probability of the reclamation of millions of acres. The Governor considers that the influence of the great drainage scheme upon the future of the State can scarcely be exaggerated. The lands are some of the most valuable sugar lands in the United States. The timber lands exceed 30,000,000 acres, three-quarters of which is yellow pine, the best timber. The pine is estimated to reach 7,000,000,000 feet, and, according to the figures of the last census, during the year which ended May 31, 1881, no less than 208,054,000 had been cut. Railway construction has added to the population and wealth of Florida, and the enhancement in the land value is remarkable. The sea coast and many inland towns owe their increase to these railways, which cannot be overdone in the south or fruit-growing portion of Florida. Take the orange industry for example. An acre in full bearing will produce 200,000 oranges, which, boxed, will weigh 100,000 lb., or three car loads of 33,000 lb. each. Cotton will not average in the United States over a bale to three acres, and a single car will carry off 50 bales compressed, or the production of 150 acres. The conclusion is consequently reached that 120,000 acres in oranges in good bearing will require more cars to move them than it would to move 6,000,000 bales of cotton, the production of 18,000,000 acres. Orange growing is rapidly increasing, but the lumber manufacturing business takes the lead in Florida, which has, however, manufactories of cigars, ice, and cassava. There are also a few cotton factories and a few cotton-seed oil mills, together with fibre factories to utilize the palmetto plant. The financial condition of the State is represented to be very good. The assessment in 1882 was about $46,000,000, and the assessment for 1883 shows an increase of about $10,000,000. Four years ago the whole assessment was only $30,000,000. The only asylum in the State is one for the insane at Chattahoochee, where 110 patients are under treatment. The census showed 119 deaf mutes. Thre is no penitentiary, the convicts being leased out to a private individual, who receives the prisoners at the country gaols, and is required to pay all expenses after their conviction, furnish them with proper food, clothing, &c., and pay the State $9,200 fos their services during the next two years. The number was 135, but the sentences for 1882 decreased largely compared with those of the previous year.—London *Times.*

DURRA, DHURRA, OR RICE CORN, &c.

BY J. M. MCBRYDE, PROFESSOR OF AGRICULTURE AND HORTICULTURE, UNIVERSITY OF TENNESSEE.

In Kansas and portions of Texas, a new cereal is reported to be supplanting Indian Corn. It is also popular in California, having been introduced there, so it is said, from China. It is estimated that in Kansas 25,000 acres were devoted to this crop in 1880, and the Fourth Quarterly Report of the Board of Agriculture of that State, just published, puts the crop of 1881 at 520,531 bushels, worth $314,787·12. Its great merit, and one that makes it invaluable for those regions, is its power of withstanding prolonged drouths. It is perhaps as remarkable for its multiplicity of names. In the West it is called indifferently Egyptian Corn, Rice Corn, and Pampas Rice. It is a native of the warmer portions of the Eastern Hemisphere, and has been cultivated for ages in Central Asia, and the Nile Regions of Africa under the Arabic name of Durah. Webster gives no less than five different spellings of this word, dhurra, dhura, dura, dhoora, and doura. It is also written, by others, dhoura, dhouro, dourah, dora, and durra. As if these were not enough, it has received, besides the three mentioned above, the local names of Negro Corn, Guinea Corn, Negro Guinea Corn, Chocolate Corn, China Corn, Chicken Corn, Ivory Wheat, Tennessee Rice, Indian Millet, and Great Millet.

Its scientific synonyms are almost as numerous. It is *Holcus saccharratum* of Linnæus, *Holcus sorghum* of other early writers. Some botanists speak of it as *Sorghum cernuum.* As "Sorghum" is a "Smith," and "vulgare" a "John," of the vegetable kingdom, it is not saying much for the identity of the plant to give it its true name, *Sorghum vulgare.* The species breaks into numberless varieties, the two most important being the white and the red. The white, the kind mentioned in this article, is the great bread crop of the Soudan and other regions of Central Africa. English travellers familiar with the Arabic always speak of it as "Dhurra." It is frequently mentioned by Baker in his works on the Nile and its tributaries. In one of these, after describing the method of planting it in the Soudan, he says:—"Although not as palatable as wheaten bread, the flour of dhurra is exceedingly nutritious, containing, according to Prof. Johnston's analysis, 11½ per cent of gluten, or 1½ per cent more than English wheaten flour. Thus men and beasts thrive, especially horses, which acquire an excellent condition." It can hardly be considered a new-comer in this section of country, for N. T. Sorsby, of Greene Co., Ala., writing to the U. S. Commissioner of Agriculture nearly a third of a century ago, makes the following statement in regard to "Indian Millet or Dourah Corn" (U. S. Patent Office Report, Agricultural, 1854, page 160):—I first saw this plant growing in Georgia, in 1838. The year following I introduced its culture into this County, where it has been somewhat extensively cultivated since." He speaks of it in high terms, and declares that it grows well on poor soils and in spite of frost, rain, drouth, weeds, or grass. He regards it as exceedingly valuable "for soiling cattle and mules," and also for fodder. He says, "the ears are eaten entire by cattle and hogs." In view of its abundant yield of "stalks, fodder, and grain," he considers it "one of the most valuable of the cerealia," and as not exhaustive to the land.

Killebrew, in his "Grasses, Cereals, and Forage Plants" (page 339), uses almost similar language, and goes on to observe:—"Above 25 or 30 years ago it [Dhurra] could be seen on the plantation of almost every farmer in the State [Tennessee]. It gave very general satisfaction, and yet it went out as suddenly as it came into popularity. This was due to the cry that it impoverished the land. This verdict was accepted without question, and its culture abandoned; but it is manifest from subsequent experiments that it detracts as little from the fertility of the soil as any other cereal, much less than some." Numerous letters of Kansas farmers, published in the Report of the Board of Agriculture of that State for 1880, afford more recent testimony as to the value of this cereal.

In June, 1880, I succeeded in procuring a small quantity of the seed of the Dhurra, or so-called "Rice Corn," from Kansas, and on the 16th of that month planted it on stubble land, from which a crop of wheat had just been taken without manure. The Dhurra received no fertilizers. The portion, 0·22 acre, thickly drilled in rows 4 ft. apart, gave a yield of 45·4 bu. per acre, the other portion, 0·25 acre, planted in rows 4 ft. apart, and from 12 in. to 18 in. in the row, a yield of only 16·3 bu. per acre. The great difference in the two yields is explained by the excessive tillering of the thinly planted portion—the plants formed more heads than they were able to ripen. The stalks, of which no account was taken, attained an average height of about 8 ft. The grain was plump, and weighed 60 lb. to the bushel. As an abundance of rain fell, the drouth-resisting powers of the plant were not put to the proof. In 1881 a piece of stubble was thoroughly plowed and harrowed immediately after the removal of the wheat, and planted the first week in July, a very fertile portion, 2½ acres in Indian corn, and a very thin portion immediately adjoining 2 1-5th acres in Dhurra. No manures were used on the preceding wheat crop, but 400 lb. of the same fertilizer was drilled in with both the corn and the Dhurra. The two portions were planted on the same day, and their subsequent culture was the same. That the fertilizer in consequence of the drouth seriously injured both crops was shown by six unfertilized rows of Dhurra, the superiority of which could be noticed at a considerable distance. When the long midsummer drouth set in, the Indian Corn was in full tassel, from 8 ft. to 9 ft. high, and gave promise of a fine yield. The Dhurra was hardly half the height, but while the Corn was twisting and burning up from the want of rain and the terrible heat, it scarcely wilted, and continued fresh and green. The drouth dwarfed it, but did not interfere with the filling of the heads, which were almost as large as those of last year, while the stalks were but little more than half as high.

About the middle of September it became evident that all hope of a crop of corn was destroyed. Hardly one stalk in ten had even a green nubbin. It was therefore cut for ensilage on October 5th and 6th. The yield of grain did not amount to one bushel per acre. The Dhurra gave, when harvested late in September, 20 bushels of clean, plump grain to the acre. As this plant remains green and succulent after the seeds are ripe, this crop was also cut for ensilage on the same days as the corn. The Dhurra gave 5,543 lb. of green forage per acre, the corn 8,764 lb. In comparing the fair yield of grain of the first with the total failure of the second, we should remember the great advantage the latter possessed in the superior fertility of the soil of its plat. These experiments, which were very carefully conducted, are almost conclusive as to the remarkable superiority of the Dhurra in dry seasons. Every farmer should protect himself from the effects of drouth by planting at least a few acres in this cereal. Such a course last year would have saved the farmers of this section many thousands of dollars.

The feeding value of this grain is clearly shown by the results of experiments given in full in the August No. of the *American Agriculturist* for 1881. From these and other tests on a larger scale, made last winter, it appears that it was about equal, pound for pound, to corn meal, or cotton seed meal, as a food for farm stock. These practical tests are supported by the results of analysis. I herewith append the analyses of samples of grain of the crops of 1880 and 1881, recently made by my colleague, Prof. W. G. Brown, of the Chair of Chemistry, and his assistant, Mr. W. E. Moses.

Analyses of Dhurra grown at Misty Farm.

	1880.	1881.	Aver.
Water	12·61	12·74	12·67
Ash	1·63	1·42	1·53
Albuminoids	11·45	10·46	10·95
Carbohydrates	74·31	75·38	74·85
	100·00	100·00	100·00

In its percentage of albuminoids its compares very favorably with the other cereals. Wheat grown at the Misty Farm gave 12·79 per cent of albuminoids; Indian Corn grown in Michigan, 11·09 per cent; Oats grown in Connecticut, 9·77 per cent; Rye in Germany, 11 per cent; and Barley, 10 per cent. The grain, ground and bolted, makes a good article of brown flour, superior for cakes to buckwheat. This is not my testimony only, but that of several other parties who tried it last winter. It makes fair brown bread. The meal is, however, inferior for bread-making purposes to corn meal. The silo containing the Dhurra, and the corn ensilage has not yet been opened, and as none of the first was fed green, I am unable to pronounce upon the comparative nutritive value of Dhurra forage.—*American Agriculturist.*

ACROSS THE INDIAN OCEAN.

By Garnet Walch.

MAURITIUS—THE ROYAL BOTANICAL GARDENS.

Frequently during the voyage from Australia the conversation on board the Caledonien had for its subject the things worth seeing in Mauritius, and as frequently I was strictly enjoined not to leave the island without visiting the Royal Botanical Gardens, situated at Pamplemousses, seven or eight miles to the north of Port Louis. And the advice thus tendered at sea was even more strongly urged upon me when I landed—at the hotel, at the merchants' offices, in the train, on the station platforms, one of the first questions I was asked was, "Have you seen the Pamplemousses-gardens?" followed by an assurance that they could not fail to delight me. A thorough believer in the proverb, that what everybody says must be true, I made up my mind, that, come what might, I would visit the gardens. Hence I was much gratified when we Globe-Trotter & Co. received an invitation from Mr. William Scott, the assistant director at Pamplemousses, to take *dejeuner* with him, and afterwards inspect the place for ourselves.

Driving by the large and highly ornamental central gates, round the neat iron-railed enclosure of the gardens, we enter at a side door, and are on the threshold of Mr. Scott's hospitable home. He receives us with a cordiality that is a perfect tonic in itself. He utters a few cabalistic words to his Indian familiar, and, lo! *déjeûner* is ready. Our appetites being in a equally prepared state, we do full justice to one of the best meals we shall taste, in Mauritius, and can but compliment our host alike on his cook and his cellar. The last time I hobnobbed with a botanist—it was at a nursery garden in Sydney—we drank beer poured out of a watering-can into flower-pots, the holes whereof we stopped up with our fingers. But that was many—never mind how many—years ago, and now-a-days, when the grey hairs that betoken wisdom are making their appearance, I prefer *Haut Sauterne* to even Tooth's XXX. After *déjeûner* we enjoy a smoke in the flower-embosomed verandah, and admire the superb creepers that hide us from the outer world. Here is the clerodendron, with its pink and white blossoms; the ipomæa, with its deep-purple flowers; the Petræa volubilis, with its exquisite blue; and here, too, is the sire of all the Mauritian bougainvilleas, dressed in his truly imperial robes. Hard by, on each side, are magnolias, Dracænas with their ruddy leaves, a fine Braughmansia, and a huge tree of the New Guinea spathodea tulipifera, one glorious pyramid of brilliant orange blossoms from tip to base; and as far as the eye can reach stretch level swards of cool, green grass, great monarch trees, long avenues of stately palms, giant quivers filled with verdant arrows, and in between, soft ferns and downy mosses, glowing flowers and little, swift-flowing runnels of sparkling water. Amidst such surroundings, lulled to rest by the *frou-frou* of over-arching foliage, the tinkle of the streamlet, and the twitter of happy birds who would not feel himself—what's that? Only a snore from one of us, who has succumbed to the enchantment of the scene, and pays nasal homage to its beauty. But this serves to remind us that we have a long tour before us, so, waking the sleeper we start at once. And here I may as well caution the reader that I am about to hurl a few dozen assorted Latin names of supreme ponderosity at his devoted head. Forewarned is forearmed; *allons donc.* Behold the areca catechu, or betel nut of commerce; the Croton Tiglium, one nut of which would kill the strongest man; the Croton longifolia, the Quassia amara; the satinwood tree with its delicate bright green foliage; the mahogany tree, the rosewood tree of India, the table-wood tree from the Seychelles, the Morinda citrifolia, the anisette tree of Japan, the camphor tree; the common indiarubber tree, with its wide spread of leaves and its vast network of roots upon the surface of the ground; the Makak tree, wondrously slow of growth, and one of the oldest forest trees of Mauritius; the Badamier, or almond of Mauritius, with straight perpendicular branches starting up from those that lie horizontally; the Moreton Bay pine, in all its luxuriance; the deceitful fern tree, so named by Linnæus, who was misled by the appearance of its leaves; the mango tree; the Indian marking-ink nut tree; the allspice of the West Indies, also with its roots well above the surface; the strychnos nux vomica tree; the Litchi of China, and scores of others, all large, matured, well-grown trees, not puny specimens that require daily attention. Here is the Tanghinia venenifera, or ordeal-tree of Madagascar, with which the authorities of that cheerful country are wont to test the innocence or guilt of a prison. He is presented with a bean—about the size of an almond—being the kernel of a fruit as large as a hen's egg, and this bean he has to chew. If he survives he is innocent, if he dies he is guilty. As a single bean contains enough poison to kill 20 men, the chances, it will be agreed, are not overwhelmingly in his favour. Here is a Hibiscus discovered by Livingstone in South Africa, but not yet named. Here is the sour-gourd Baobab, or monkey bread tree of Senegal, also connected with the great explorer, for it was under a very fine specimen of this tree that he buried his wife on the banks of the Zambesi. Here are a group of hideous euphorbias, whose fleshy, dull-green, all-but-leafless stems exude a poisonous milk when stabbed, milk used by the Africans to make their arrows and their assegais deadly weapons without fail. Here is a great American aloe, between whose leaves a big, overgrown spider—large even for Mauritius, and they have some monsters here—has spun a series of webs. She resents interference with her vested rights, and fairly leaps at our intrusive walking sticks; but she has to succumb, and with her a capsule full of tiny reproductions of herself. Here is a Madagascar fig-tree—here a grove of Madagascar nutmegs, the outer envelope, like a flat yellow plum, just bursting apart to show the scarlet mace and dark-brown nut within. A pretty sight these ripe nutmegs when on the tree, but when picked the mace speedily turns to a dull yellow, and thence to the colour so familiar in the spice-boxes of our housewives. Here is a patch of the true sarsaparilla—here a great queer-leaved creeper, the Monstera deliciosa of Mexico, "swarming" up the trunk of an antediluvian badamier. Here is the creeping rubber plant of Madagascar (Vahea Madagascariensis); and here the Bois colophane batard, or Bursera obtusifolia of old Mauritius, from which the negroes were wont to make their torches, its wood being highly resinous and inflammable. Here are jack-fruit trees, the fruit itself, a foot or more in length, growing directly from the trunk. Here are durians, and here are colossal cinnamons, whose aromatic leaves we taste to our gratification.

But the chief glory of the gardens consists in its wealth of palms. No wonder Messrs. Besant & Rice, in one of their capital novels, christened Mauritius Palmiste Island. It is, indeed, the very home of this beautiful tree, and here at Pamplemousses are varieties from all the corners of the earth. Let me enumerate a few as seen in the long avenues through which we pass. The coconut palm; that is already familiar to us outside these grounds. The date-palm, whose produce is dear to every schoolboy worthy of the name. The wine-palm of the Moluccas, which furnishes arrack to the thirsty Indian. The sugar-palm, a very useful tree, for in addition to the sugar obtained from it, the coarse black fibre which hangs in clusters round its trunk is made into brooms, or, teased and broken up, is an excellent stuffing for mattresses. The wrinkled sago-palm. The dome-palm of Egypt, with its pear-shaped fruit, containing a hard interior like black ivory. The rofia-palm, Sagus ruffia of Madagascar, with its 20-ft. long leaves used by the natives as rafters for their huts, since the rofia withstands the attacks of the white ant. The lower fronds of these tall palms are cut off at Pamplemousses, as the tree grows, and are sold to the Malabars for 25 cents each. The tree itself has a very handsome appearance, while the flower spathes curling down from above like big brown elephant trunks, and then opening out to drop their showers of seeds, are extremely curious. The palm of Peru, from which the cabbage-tree hats are made, the young fronds only being used, and the whole process of plaiting carried on under running water, also attracts our special attention. So, too, do a fine row of young talipot palms, with their thick fleshy leaf-stalks, or petioles, 10 ft. long, and armed with teeth on the edges, and their great clusters of large leaves. The peculiarity of the talipot is that so soon as it flowers it dies. The palms known as Verschaffeltia splendida, growing here to about 40 ft. high, are natives of the Seychelles. At first sight they seem to be propped up by a number of sight buttresses, but on closer examination one finds that the tree has a habit of throwing out a number of roots from its trunk about 3 ft. above the ground, and when these roots have struck downward and secured a firm hold, the trunk itself ceases to be dependent on *terra firma*, so much so that one can pass one's hand between the earth and the body of the tree, which is now carried only by the slender roots. Yet this species, we are told, withstands the hurricane better than any of its compeers. The Latt palm of the Seychelles and the Nephrosperma van Houttenna of the same islands are also here in numbers; but of the Deckenia nobilis and the Roscheria melanochœtes the Pamplemousses-gardens possess the only specimens—one of each—out of Seychelles. A variety of small palm, indigenous only to Round Islands 25 miles to the north-east of Mauritius, is also grown here. The gargouet palms, which Colonel (otherwise "Chinese") Gordon christened the Armstrong gun palms, bear an extraordinary resemblance in their bole to one of those huge cannon placed upright with the muzzle in the air.

Very beautiful are the fan palms, and somewhat similar in shape but larger are the "traveller's trees" of Madagascar. Rising from the ground with a thick succulent stem the tree sends out long broad leaves, on either side, the stalk of the leaf being six or eight feet long, and the leaf itself as much as seven feet long by three broad. The leaves spread out in fan-shape, are grooved upon their upper surface, and thus serve to catch the rain, which runs down the leaf stalk and so into cavities where the stalk joins on to the stem. Here the water remains perfectly pure and fresh, and may be tapped at any moment by the thirsty traveller. By the aid of Mr. Scott's penknife we tested the trees at several points and always obtained a good jet of pellucid water, entirely free from any disagreeable flavour. The trees abound in Madagascar, and are useful in many other ways besides acting as reservoirs. A recent tourist there says:—

"In Madagascar this tree might with propriety be called the builder's tree rather than the traveller's tree. Its leaves form the thatch of all the houses on the eastern sides of the island. The stems of its leaves form the partitions and often sides of the houses; and the hard outside bark of the elder trees is stripped from the inner and soft part, and having been beaten out flat is laid for flooring; and I have seen the entire floor of a long well-built house covered with this bark, each piece being at least 18 in. wide and 20 ft. or 30 ft. long. The leaf, when green, is used as a wrapper for packages, and keeps out the rain. Large quantities are also sold every morning; in the markets, as it serves the purpose of tablecloth, dishes, and plates at meals, and, folded into certain forms is used instead of spoons and drinking vessels."

The tree evidently, like the heroine of the old-time novel, is as good as it is beautiful. At Pamplemousses it grows in large clusters, from the baby palm a few feet high to the tall and wondrously graceful fully-developed tree, whose leaf-clusters are far beyond the reach of ladderless humanity. Besides all the palms already described, I have yet to mention three or four others. Cabbage palms—the Dictyosperma alba of the island of Rodriguez—have an avenue all to themselves, and are a noble sight; but the *crême de la crême* of avenues in these gardens, and probably in the world, is that formed of the Royal palms of Cuba, Oreodoxa regia. Towering aloft to a height of 60 or 70 feet, with their smooth, round boles in some cases 11 ft. in circumference, these magnificent trees stand side by side like the columns of some lovely fairy temple—a house not made with hands—and the visitor as he passes between their giant ranks feels an involuntary impulse to remove his hat and walk bareheaded beneath their over arching glories. The popular fallacy that the age of these trees may be ascertained by counting the rings so distinctly marked on their trunks is here explained to us. We have been told that each ring represents a year. This can hardly be so when we find —the age of the trees in question to be 25 years, whereas they number upwards of 200 rings each. Alas! even here the hurricanes that have wrought such havoc throughout the island have not spared these kingly palms. Several of them have lost their leafy crowns, and palms, like men, once deprived of their heads, grow no more.

Leaving these trees, we walk awhile by the side of the ornamental lakes near the centre of the gardens. Fringed by the luxuriant tropical growth, the mirror-like surface of the water reflects the trees that border it, and every now and then a rustic bridge leads across to some enchanting little island, ringed round with broad-leaved arums planted at regular intervals in the water, with here and there a summerhouse or a pavilion, and here and there cosy seats suited for amorous couples. The gardens are a favourite resort of fashionable picnic parties, and the amount of desperate love-making that takes place in this part of the grounds is, we understand, something almost incredible. Many scores of happy families now flourishing in Mauritius owe their foundation to the whispering winds, the wooing wavelets, and the woodland witcheries of this lovely spot. Sir George Bowen was especially fond of it, and passed much of his time here composing speeches that were afterwards to make his name for ever remembered in the island. And *à propos* of the name of Bowen, not far from here we see the monument erected "to the benefactors of Mauritius," the usage being to engrave their names upon the obelisk after their death. Several ancient and honourable surnames were thus recorded, and Mauritians loved to read the titles o'er; but one fine morning they awoke to the fact that the name of their living Governor figured upon the stone, and that, too, in larger characters than any of the others. And there it remains to this day, and how it got there has never been satisfactorily explained. Those who know the modest and retiring, the truthful and chivalric nature of Sir George, know also that he himself could have had no hand in it. The monument stands in the centre of the broad walk leading to the principal gates, and on either side are beds full of rare and beautiful plants—azaleas, red, purple, and white, coleus, crotons, begonias, marantas, dieffenbachias, and a thousand other lovely blossoms or leaf-bearers are here in endless variety. Another walk, of older date, leads between rows of badamiers and mango trees to the ancient château of Mon Plaisir, where the French Governors of former days used to live, and where many a night of revelry was held. It is no longer used as a vice-regal residence, but the lower rooms are turned into a museum and a botanical library respectively, and here we find exhibits in course of preparation for the approaching Calcutta Exhibition.

Near the château is an enclosure in which are kept a couple of large tortoises, brought from the Seychelles by Colonel Gordon, and presented by him to the gardens. We pay the clumsy pair a visit, and, rubbing our sticks smartly on their backs, cause them to shuffle about, while the male resents our intrusion with serpent-like hisses. They are fed with chopped-up Jack fruit while we are present, and we notice that they peck up their food hen-fashion, and bolt it without masticating it. An interesting half-acre plantation of the veritable rubber-plant of the Brazils is visited, and we succeed in manufacturing a small sample of true caoutchouc by rolling some of the sap between our figures. Passing through a low hedge of *campeche* or logwood we next examine some coffee plants suffering from the *hemileia vastatrix*, and by the aid of a powerful magnifying-glass are able distinctly to discern the fungoid growth that has spread such ruin throughout the coffee plantations of Ceylon. Returning across the gardens by a different series of avenues, we are shown much more that interests and instructs us. Notably the large section set apart as a nursery, whence the young trees are supplied to the state forests now in course of planting. Here are upwards of a million baby eucalypti, to be shortly set out round and about Port Louis and other fever-haunted districts, in the hope that they will not disappoint the high hopes attached to them as malaria exorcisers. Here, too, is a fine plantation of cocoa-trees, and we see the large pods familiar to us in Messrs. Epps, Cadbury, and Fry's advertisements growing, like the jack-fruit, right out of the trunks of the trees. The pods are, in many instances, five inches in length, and the trees look very healthy. Passing once more by the margin of the lakes we notice shoals of gold fish and gouramis swimming leisurely about. A black swan sails slowly above them, as if in mourning for her mate, which has lately disappeared. Busy water spiders skim hither and thither, and gauzy-winged dragon flies flit from point to point. Near here, surrounded by a small grove of sago palms, is the so-called monument to Paul and Virginia, but all we can see is a ruined pedestal of brick and stucco, from the top of which an iron rod, once the central support of a vase or statue, but looking now merely like a displaced piece of garden railing, points blankly upwards. All signs of inscription or date have long since disappeared, and there is absolutely nothing to identify the unsightly ruin with the hero and heroine of St Pierre's romance. Their graves, afterwards shown us in an adjoining sugar plantation, are equally disappointing, and even less authentic. However, I deem it but my duty to send you a little of the earth. You can mix it with the ink for the issue of *The Argus* that contains this article, so that each of your readers may preserve a memento of the unhappy lovers.

We turn now to another part of the grounds, where a magnificent slope of verdure trends away to yet another lake, with a grand view of distant mountains. Here we see some fine kauri pines, more large cinnamons, sandalwoods, cypresses, and the boinsettia pulcherrima, with its scarlet bracts. And then we descend a zigzag path into a picturesque little gully where rare and valuable ferns are growing in profusion, and below, in a special wire-protected pond, we see a number of the exquisite lattice-leaf plants of Madagascar—Ouvirandra fenestralis. The structure of the leaf of this plant is curious in the extreme. It is more of a living fibrous skeleton than a leaf. To quote a technical description—"The longitudinal fibres extend in curved lines along its entire length, and are united by thread-like fibres or veins crossing them at right angles from side to side, at a short distance from each other. The whole leaf looks as if composed of fine tendrils, wrought after a most regular pattern, so as to resemble a piece of bright green lace or open needlework." The entire plant is under water, and presents a most beautiful appearance. It thrives best in a running stream. By the time we have finished with the fernery it is getting on towards evening. We have been several hours wandering round the gardens, we have by no means exhausted their beauties, but our carriole is waiting, and we must catch the last train to town. A final word or two with our indefatigable conductor, from whom we ascertain that the area of the gardens is 57 acres, with 20 acres in course of being added, that they date back far into the last century, and that they cost annually less than £1,500, and we take our leave, firmly convinced that travel where we may we shall never see anything in point of matured beauty and grandeur to surpass the Royal Botanical Gardens of Pamplemousses.—*Adelaide Observer.*

COCUS WOOD.

What Box-wood is to wood engravers Cocus-wood is to musical instrument makers, at least to the makers of wind instruments, such as flutes, clarionets, &c. No true substitute has yet been found either for Box-wood or Cocus-wood, the fine close grain of the former, and the metallic ring of the latter being as yet undiscovered in any other woods. Like many woods of great commercial importance, the botanical source of Cocus-wood was for some time quite unknown. In Holtzapfel's *Descriptive Catalogue of Woods* it is referred to under Cocoa or Cocus-wood, and is there said to be "imported from the West Indies in logs from 2 to 8 inches in diameter, sawn in lengths of from 3 to 6 feet, tolerably free from knots, with a thick yellow sap; the heart, which is rarely sound, is of a light yellow-brown, streaked when first cut with hazel and darker brown, but it changes to deep brown, sometimes to almost black. Cocoa-wood is much used for turnery of all kinds and for flutes; it is excellent for eccentric turning, and in that respect is next to the African Blackwood. An apparent variety of Cocoa-wood, from 2 to 6 or 7 inches in diameter, with a large proportion of hard sap, of the colour of Beech-wood, and heartwood of a chestnut-brown colour, is used for tree-nails and pins for ship work, and purposes similar to Lignum-Vitæ, to which it bears some resemblance, although it is much smaller, has a rough bark, the sap is more red, and the heart darker and more handsomely coloured when first opened than Lignum-Vitæ; it is intermediate between it and Cocoa-wood. Another, but inferior wood, exactly agrees with the ordinary Cocoa-wood, but that the heart is in wavy rings, alternately hard and soft."

The above is all that was known of Cocus or Cocoa-wood when Holtzapfel's little book was published in 1852, and since then we have by no means satisfactorily cleared up this point. The writer of the article quoted above says:—"It is really singular that the exact localities and the botanical name of the Cocoa-wood that is so much used should be uncertain; it appears to come from a country producing sugar, being often imported as dunnage, or the stowage upon which the sugar hogsheads are packed. It is also known as Brown Ebony, but the Amerimnum Ebenus of Jamaica seems dissimilar."

The Amerimnum Ebenus of Swartz is now referred to Brya Ebenus of DC., and the wood of this plant, which is known in Jamaica as Green Ebony, is now credited with furnishing the Cocus-wood of commerce. The woods, indeed, upon comparison are almost identical except in colour, the Cocus-wood being somewhat darker, but this may be due to the wood being older, and perhaps selected on account of its deeper colour, for the darker the colour is for flutes the more highly it seems to be valued, its principal competitor in the market for this purpose being a still darker coloured wood known as African Blackwood, the botanical source of which has not yet even been guessed at.

Another wood, so similar to Cocus-wood that it is difficult, if not impossible, to distinguish it, is furnished by a Euphorbiaceous tree of Northern and Eastern Bengal and Birma, known as Kokra-wood, and furnished by Aporosa dioica, Mull. Arg. (Lepidostachys Roxburghii, Wall.) The similarity of the Bengalese name, Kokra, with the commercial name, Cocus, or Cocoa as it was formerly spelt, is so remarkable that it would seem to point to them as being one and the same thing, and the question then arises whether, instead of Cocus-wood coming from the West Indies it does not in reality come from the East. Gamble, indeed, in his *Manual of Indian Timbers*, says (p. 355):—"This last (Aporosa dioica) has been identified with the tree producing the 'Coco-wood' of commerce, generally supposed to come from the West Indies." Gamble further says:—"The wood of Aporosa dioica should be carefully examined to prove that the Indian tree gives a timber similar to Coco-wood." A comparison of the two woods contained in the Kew Museum proves their similarity. —JOHN R. JACKSON, Museum, Kew.—*Gardeners' Chronicle.*

TEA.

According to some authorities, tea began to be drunk in the Liang dynasty, at the beginning of the sixth century. But it was earlier than this according to other accounts that tea came into use, and in the time of the Three Kingdoms, in the third century, it is spoken of as a substitute for wine. There are three kinds of drinks according to the Chinese theory. To quench the thirst, says an ancient writer, you take rice water, or those prepared drinks called *Tsuan*. To drown sorrow you take wine, by which he means the brewed yellow wine of antiquity. To refresh the body when fatigued, and take away drowsiness, you drink tea. This is the way in which the matter appeared to Lu Yu, who about a thousand years ago wrote the curious book on Tea, called Ch'a-king. This book may be recommended to those who wish to make inquiries respecting early methods of preparing tea and the domestic usages of ancient China. It is also rich in legends and stories of what those who plucked tea in each famous mountain met with of an extraordinary nature, from the time of the Divine Husbandman down to the days of blue jackets and wadded cotton gowns.

Tea was taken as a medicine before it was a daily beverage. The use of this now inestimable article of daily consumption began with the efforts of the healers of diseases to assuage human pain by administering infusions of leaves. Tea is early mentioned with examples of its healing powers. Four or five cups of this infusion will cure headache, restore vigour to drooping eyes, and re-establish the bodily frame when faint. Its invigorating nature is compared to that of wine, and to the nectar of the genii known as *Kan-lu*. It is also classed with Ginseng on account of the valuable properties of that root, which then, in the days of the author of the Book on Tea, was, as now, a famous product of Corea and of Manchuria, as well as of Chihli. The Emperor Wen-ti of the Sui dynasty dreamed on one occasion, it is said, that a god changed his skull-bone, and from that time he had headache. Unexpectedly he met a Buddhist priest who told him that there was in the mountains a plant called Ming. If he boiled some of this plant and ate it, he would be well. The Emperor followed this advice and was completely cured. From that time forward the people strove each man more than his neighbour to pluck tea-leaves, infuse them, and drink the tea as a medicinal beverage. Tea was anciently described as a cooling bitter without any injurious quality. It was regarded as a specific for large swellings and ulcers, and as useful for removing phlegm, thirst, and inflammation. The autumn tea, which is more bitter than spring tea, is recommended as beneficial for removing indigestion. It will prevent sleep, and therefore may be taken to cure drowsiness as also to increase the vigour of the thinking faculty. In other words it is a mild stimulant. Beside these milder medicinal effects it has been employed with advantage as an antidote to arsenic when taken as a poison. A strong infusion of tea dissolves in the stomach both arsenic and tartarised antimony. But it must be very early administered to have this beneficial effect. If opium poisoning is attacked energetically, and the chief portion of the opium removed by pumping, tea has proved very helpful in overcoming the secondary symptoms. Its tannin has a decomposing effect on substances difficult to dissolve and dissipate. Tea, being in some respects a stimulant, is in other respects a sedative, as is the case with other stimulants. Were it not for its sedative qualities it could not have attained its unexampled popularity.

In the year 1835 the export of tea from China was about two hundred and sixty thousand piculs. In the year 1871 it was a million piculs and three quarters. Last year it was over two million piculs. Such is the wonderful progress of tea-cultivation that China may both hope and fear on account of her trade. She might fear that Assam, Japan and other tea-growing countries may limit her market, and diminish her gains. But her hope may well dominate over her fear, because the extension of tea consumption advances with such amazing rapidity that China has enough to do to increase her tea plantations sufficiently fast to keep pace with the demands made upon her. Her western and central provinces constitute the mother country of the Tea tree, and the climate of that region suits its constitution to a hair. At the time when the dictionary Kuang-ya was written, or about the fourth century, the people of Pa and King, or the modern Szechuan and Hunan, were accustomed to make "brick tea," or rather cakes of tea-leaves. These were mixed with rice-cakes and boiled so as to produce a red liquid. The bitter was toned down by ginger and orange peel. It was then used as a stimulant. From all this it may be deduced that black tea, which the Chinese call red tea, came into use before green tea, and that it was thirteen or fourteen hundred years ago when the inhabitants of southern and western China began to find out the excellence of the infusion made from the leaves of the shrub which they called Ming, or Ch'a or Kia. It was a long time before it became universally adopted, and as a mode of preparing the article for sale, brick tea was known before, or at least quite as soon as, the modern packet of loose leaves. It was common then to hear of Ch'a-ping or Ping-ch'a. These two modes of speaking differed in their sense in a way similar to the difference of meaning when we say "chocolate cakes" or "cake chocolate"—*N.-C. Herald.*

RICE CULTIVATION IN JAPAN.

Autumn cultivation is interesting, as now the rice fields are drained and the rice cleared, and where the ground is sufficiently dry it is turned over with a long-handled spade. The handle is bent, so that when the spade is thrust into the ground—not by the foot, but by a thrust from the shoulder—the bent handle rests on the ground as a fulcrum, and the long handle is pressed downwards and the clog lifted and turned over. The ground is then finely raked down or harrowed. Sometimes a wooden plough drawn by one bull or one horse is used in lieu of the spade. In this prepared ground barley, pulse, buckwheat, rape seed, &c., are grown in drills and manured by liquid manure carried by the farm labourer in two wooden buckets slung on a flattened stick placed upon his shoulder. The liquid manure is collected twice a week from the residences and public conveniences by the farmers, who make arrangements with the residents, &c., and carry it away in deep wooden buckets with covers slung across pack horses or coolies' shoulders as before mentioned. This is emptied into wooden tanks upon the farms. The tanks are roofed with thatch to prevent dilution by rain, and the sides and ends of the shed are open to allow of the full play of the atmosphere upon the surface of the tank, which has no cover. In a few days the soil ferments and the solid matter rises to the surface and forms a crust; the gas from fermention passes away into the atmosphere, and the soil is used in about a week after depositing in the tank, before it becomes putrid. When poured in an undiluted state upon growing crops it does not scald or burn them as the nightsoil of this country does; this may be accounted for probably by its being kept in open tanks, and thus never allowing the sulphuretted hydrogen to poison the soil. The soil is never poured directly upon the vegetation, but along the drills beside the growing crops, but is often spilled upon the crops, and does not injure them. A second crop is not invariably obtained from the ground upon which the rice has been grown. The ground sometimes lies dormant for six months, and is manured for the rice probably between the drills, which are covered by two inches of water. On the plateau and ground elevated above the rice fields irrigation is not applied, and here dry cultivation alone prevails, and no rice is grown, as rice must be constantly covered by water. On this table land the crops consist of carrots and radishes (both grown a length of 2 feet), peas, beans, buckwheat, sweet potatoes (Dioscorea batatas), cucumbers, melons, the purple egg plant (Solanum esculentum), millet, &c. The cucumber plants are trained six feet high up brushwood, like peas, the cucumbers hanging down.

The staple production of Japan is rice, and rice can only be grown on land inundated by water. Small areas, from 50 to 100 feet square, are well worked into mud by rakes with teeth about 15 inches long being struck into the soft ground and pulled towards the labourer, thus overturning the sod. Water is then let in, and all is worked into mud. Upon the surface the rice seed is sown thickly, and about an inch of water is kept over the seed. The sowing takes place about the middle of May, and by the middle of June the rice is sufficiently strong for planting out. In the beginning of June the early crops of barley, pulse, &c., are ripe and reaped; these crops are grown on the dry ground, the rice ground having been drained for them. This dry ground, now free from crop, is entered upon by farm labourers who, with long drag rakes as before described, strike the long curved prongs into the soil and drag the sod over, and by this method completely turn over the whole of the ground; water is now let in, and a horse with a rake or harrow, with long handle resembling the plough handles, is worked through the plot, about an acre, surrounded by banks about 15 inches high by 9 inches wide on the top; these little banks prevent the water escaping from the plot. When the plot is worked 15 or 18 inches deep into mud, and about the middle of June, the seed plants are lifted by women and men from the seedbeds before mentioned, and dibbled out in rows, apparently 12 inches between, and 6 inches between each plant. Water is now run on to the plot, and is kept upon it about 2 inches deep, until the rice is matured in November. These plots do not appear to be manured for the rice, the manure which was given for the previous dry crop being apparently sufficient for the two crops, which are taken off within the twelve months. Irrigation is adopted for six months only, from June to November; the water is then run off. Irrigation is the grand resource of Japan, and probably for thousands of years Japan has constantly and annually produced rice upon the same land at the average of forty bushels to the acre. The rivers, as in most other countries, have their sources in mountain ranges, varying from 4,000 to 10,000 feet high, which are snow clad during some of the winter months, but snow only to small extent lies on these mountains, and the rivers are not fed through summer by the melting of the snow as in Italy and other largely irrigated countries. The principal rainfall is during the summer months. It is the summer rainfall which feeds the rice fields. The whole of the country from the mountains downwards to the sea, where the ground is not too precipitous—and a very large extent of the country near the mountains is too steep—is laid out in level plots, contoured so that one plot is slightly lower than the one above. Into the uppermost the water is led from a race taken from the river. These races are small, about 4 feet wide, and numerous, tapping the river at various points, and from these races arterial conduits are carried to the various contours. Each inlet to the plot is through the small bank surrounding it, and the water is admitted by passing over a small paling sluice which is removed when the plot is to be drained. The races are all provided with wooden sluices which are lifted by a rope passing over a barrel worked by handspikes. The whole irrigation is most efficient, and carried out at the least possible cost. The races being numerous, and of such comparatively small dimensions, effectually prevent floods or destruction of works. The rivers are all banked on each side, and many of the beds are higher than the land on either side, which is irrigated. Although the heat of summer at Yokohama and the more southern port, Kobe seldom exceeds 93 in the shade and 122 in the sun, yet the heat is oppressive, the atmosphere being so humid.—F. C. CHRISTY.—Melbourne *Age*.

OLIVE CULTURE IN AUSTRALIA.

At the last meeting of the Royal Agricultural Society, Adelaide, a discussion took place on a recent paper read by F. C. Barnard on the olive. Mr. J. Curnow said the paper put a very gloomy aspect on the industry of olive culture. The figures given by Mr. Barnard went to show that each tree belonging to Mr. Hardy and Mr. Everard was worth after being planted a number of years about 1s. 6d. per year, and if people were only to receive that amount after years of trouble it would never pay to grow the olive.

Mr. E. Smith said he had looked at the analysis made by Mr. Goyder, and he saw that he said he was able to produce a gallon and a half of oil per cwt. from olives costing [illegible] per cwt. His experience had been that he could produce three gallons from a cwt. of berries, but of course there were three or four crushings. With reference to the olives at Mr. Everard's property, they had been planted years before they were grafted. The trees were also alongside a lot of pines, and they could not be expected to do well there.

Mr. S. Davenport said he would give the committe a return he had made of the olive oil produced at his place since 1875, as follows:—

Year.	Weight Olives Crushed.			Oil per cwt.			Total Oil.	Per cent for weight.
	cwt.	qr.	lb.	gls.	qts.	pts.	gals.

He would like to draw attention in this return to the year 1878, when there was a very hot season, and the yield was consequently rather small, but strange to say the average quantity of oil per cwt. was much larger than any previous year. It should be remembered that the olive was a plant which became more valuable each year, as the yield became arger and larger. The olive was suited to a dry climate, and therefore it would be very valuable in a country like Australia. He had never troubled himself about disposing of the oil produce at his residence, but there was always a demand for it, the price given being 10s. per gallon for virgin oil, and 8s. for hot-pressed oil. He crushed the berries himself, and he paid children 5d. for each two-gallon bucket of olives picked. With regard to the picking, he would point out that the best table oils were produced from olives hand-picked, because it was well known that olives were particularly sensitive, and if they were allowed to lie on the ground the oil produced was not of the best quality, on account of the berry becoming impregnated with any smell that might be in the ground. The trees on his property were not planted in the best position, some of them being in hedges, but they had been most productive, as the return he had produced showed. Of course, as Mr. Barnard had pointed out, the great point was to plant good varieties, which would yield the best class of oil.

Mr. E. Smith agreed with Mr. Barnard that it was better to plant five good varieties of olives than fifty bad ones. He might mention that he had disposed of 700 or 800 plants produced from the olives brought to the colony by Mr. Boothby.

Mr. T. Hardy said with regard to the olive trees at Bankside they were planted ten feet apart, or in fences, or at the ends of rows of vines, and so that they had had to fight for their very existence. The plants at Mr. Everard's place were alongside pines, and so they had no chance of proving their productiveness. The expense of gathering the berries had been 3s. per cwt., but he thought the proper method of collecting the olives had not been carried out. He had of late spread cloths under the trees, and so kept the olives from being bruised or from coming in contact with the ground. Many people were deterred from planting olives on account of the time it took to grow trees. To lose the use of the ground for eight or ten years seemed to be a long time, but he suggested a plan by which the trees might be grown and the ground made use of at the same time. He would plant the largest worked trees to be obtained at about seventy to the acre and fence each tree round with a guard by driving in a circle of barked wattle or mallee stakes six or seven feet long, at eighteen inches from the tree, and from four to five inches apart, and securing them round near the top with fencing wire in two or more rings. The ground could be cleaned round inside the guards once or twice a year by lifting one or two stakes, or as may be required, and a space of one foot round outside the stakes might be dug with the spade. The land in this way could be depastured with sheep or cattle from the first.

Mr. C—now did not object to olive-growing, but on the contrary rather favored it. What he objected to was certain statements contained in the paper before them.

Mr. Hardy would like to add that he had been able to sell the olives he had gathered at 9s. per cwt., so that left him a profit of 6s. There was not a wheat crop in the country would pay so well as that.

Mr. J. Brown said the storekeepers and merchants always had a greater demand for the colonial oil than for the imported. The price he purchased the oil at was 12s. per gallon.

Mr. J. S. Bagshaw said he could purchase the imported oil at 6s., but he preferred to give 3s. or 4s. more for the colonial, as it was ever so much better for oiling the bearings than that sent from home.

Mr. Barnard said he was taken by surprise when he heard it stated that this papers put the matter of olive cultivation in a very gloomy light, as he thought he had put it in rather a too rosy aspect. Having referred to the rapidity with which the yield of the olive trees increased in value, he said that really the margin of profit left to the manufacturers was not by any means as large as that of the grower.—*Oil and Drug News.*

PLANTING IN MAURITIUS.—According to Mr. Horne's reports, the planting in the suburbs of Port Louis has been successful in improving the sanitary condition of sites formerly most unhealthy. Eucalypti of various kinds succeed well, and Cedrela Toona is highly spoken of for the rapidity of its growth and the value of its timber.—*Gardeners' Chronicle.*

THE VARIETIES OF GUM.

Gum is identical in all vegetables, and the different kinds vary only in the quantity and quality or the substances united with them. It exists naturally almost pure in gum Arabic and gum Senegal, and more or less mixed in the gum which exudes from the plum, cherry, and other fruit trees, as also in the mucilage of flax seed, slippery elm, etc. Various rosins and gum-rosins are commonly confounded under this appellation. In structure gum is quite amorphous or indeterminate in form, being neither organized like starch nor crystallized like sugar. It is believed that the acacias yield their gum abundantly when sickly and in an abnormal state, caused by a fulness of sap in the young tissues, whereby the new cells are softened and finally disorganized; the cavities thus formed fill with liquid, which exudes, dries and constitutes the gum. When dry it is transparent, brittle, not easily pulverized, and of insipid or slightly sweet taste. Although custom has inaccurately given the name of gum to several rosins and gum-rosins, such as gum copal, gum sandarach, gum ammoniac, and others, these differ in many particulars from real gum. The true gums are gum arabic, gum tragacanth, cherry-tree gum, gum of Bassora, and mucilage. Gum arabic is the product of the *Mimosa Nilotica* and some other species of the same genus, inhabiting the sandy parts of Arabia, Egypt, Senegal, and Central Africa. The principal kinds are distinguished as Turkey picked, Sedda, Talca, Senegal, Bombay, Cape, and East India (from Bombay and Aden). Another variety, but recently introduced into the market, is called gum mesquite. It comes from Western Texas and Mexico, and is yellowish in color, very brittle, and quite soluble in water. Gum arabic exudes spontaneously in a fluid state, and remains attached to the branches after it has concreted and become solid. This exudation takes place continually during the whole of the dry season, from October to June, but more copiously immediately after the rains. December and March are the two months in which this gum is collected by the Arabs, with whom it is an important aliment, those tribes that are continually wandering in the desert often making it their principal article of food during a great part of the year.

Gum arabic is obtained in rounded masses, transparent or of a light yellow color, capable of being easily reduced to a powder, insipid to the taste, or possessing a slight acidity, which, however, is only perceptible by those who use it habitually. It is easily soluble in water, and the solution has the property of conveying pulverized solids through a filter, which would separate them were they suspended merely in water; thus it is impossible, by this means, to separate powdered charcoal from gum water. In pharmacy gum arabic is employed to suspend in water substances which otherwise could not be kept equally diffused, as balsams, fixed oils, rosins, etc., but its principal consumption is in manufactures, forming the basis of crayons and cakes of water-colors, as well as of writting ink, and several liquid colors, serving to increase the consistency of these colors, and to prevent their spreading in calico printing, affording a clear cement for joining light substances, which may be prepared in a moment, giving a lustre to ribbands, silks, crape, etc. It is besides, used for a great variety of purposes. In medicine it is frequently employed, especially in dysenteries, as a demulcent, and enters into the composition of a variety of emollient preparations. It is also employed in the manufacture of confectionery, and for labels, etc., it is usual to mix sugar of glycerine with it to prevent cracking. The variety of gum arabic called gum senegal, occurs in pieces generally rounded of the size of a pigeon's egg, and of a reddish or yellow color. It gives, with water, a somewhat stronger mucilage than the ordinary Arabic species, from which it is distinguished by its clear interior, fewer cracks and greater toughness. It is imported from the river Gambia, from Senegal and Bathurst, and is collected in March and December yearly. Chagnal gum, a new variety brought from St. Iago de Cuba, resembles gum Senegal. By the aid of sulphuric acid it may be converted into a species of glucose.

Gum tragacanth, generally called gum dragon, is collected in Asia Minor, the principal port of shipment being Smyrna. Formerly only the spontaneous exudations of the tree called *Astralgus* were gathered, and these were of a brown color; now the flow of gum is aided by incisions cut near the root, and the product is the fine, white, flaky variety so much valued in commerce. The chief flow of gum takes place during the night, and hot and dry weather is the most favorable for its production. This substance is the variety chiefly used in calico printing as a thickener of colors and mordants; in medicine as a demulcent and vehicle for insoluble powders, and as an excipient for pills. Gum kuleira is another species of gum tragacanth, but is scarcely known in commerce. Cherry-tree gum occurs in shiny reddish lumps, resembling the commoner kinds of gum arabic. It is not much used commercially. Gum of Bassora is obtained at Bussorah, in Asia, and is sometimes imported into the London market under the name of the hog tragacanth. It is insipid, crackles between the teeth, occurs in variable-sized pieces, is tough of a yellowish white color and opaque, and has properties similar to gum tragacanth. Under the name of caranamica, gum is mixed with inferior kinds of gum tragacauth before exportation. Gum rosins apparently combine the properties of gums and rosins, being partly soluble in water, and partly in alcohol; but they are evidently compound substances formed of two or more vegetable principles, which, indeed, are often in a state of mere mechanical mixture. Aloes, ammoniac, assafœtida, galbanum, gamboge, oilbanum, scammony, and a great variety of concrete juices are referred to this head.

Gum substitutes are manufactured from wheat starch, farina, or potato starch, sap flour and other feculas by baking or roasting, so as to convert the starch into dextrine. This is now an important manufacture in which a large amount of capital is engaged. They are largely employed in dressing calicoes and other fabrics, also as a substitute for the more expensive gums in gumming paper, as in the case of postage and receipt stamps, which are made adhesive by dextrine. For this and some other purposes the gum substitutes are superior to the real gums, as they are easily dissolved and can be spread more easily over a smooth surface. Very large quantities of the starch of potatoes, called farina or potato flour, are made in this country, and are also imported from the continent to be used in this manufacture.—*Exchange.*

THE ORANGE TRADE.

Few importations have increased so rapidly as that of oranges during the last ten years. It is within the memory of many that they were really a scarce fruit, and comparatively dear, and when none could be got at all for many months of the year. But now we have oranges all the year round, and they can often be bought at the rate of three or four a penny in almost every street. The recognised season for importation covers, generally speaking, about nine months of the year, beginning in November and ending in July, but consignments continue to come in after that, though not large ones, and so the market is never without oranges. The revolution in, and development of, the trade has been brought about mainly by the employment in it of large steamers, the first of which exclusively engaged in the trade arrived in London, in November, 1867. In the recent Christmas week there were nine ships of various kinds laden with oranges in the port of London. The first mention of oranges being brought to this country is in the reign of Edward I., when it is recorded that in 1290 that the Queen bought various fruits from the cargo of a Spanish ship which came to Portsmouth, and that among them were seven oranges (*Pome de Orange*). But no mention of this fruit is found in the "Libell of English Policy" or the "Liber Albus of London," in which most articles of fruit and grocery find a record. We read, however, of oranges in the reign of Henry VI. (1432); and they are mentioned in the "Paston Letters" in 1470. They are entered in the "household expenses" both of Henry VIII. (1530), and in that of his daughter the Princes Mary (1539); and by the end of the 16th century they were recognised as a notable article of commerce, and, according to Stow (1598), Billingsgate was the principal quay at which they were landed. Sir Walter Raleigh, "the father of tobacco" is credited with having brought oranges to England, and it is said that Sir Francis Carew, who married his niece, planted their seeds and produced orange trees at Beddington, in Surrey; of which Bishop Gibson, in his additions to Camden's "Britannia," speaks as having been there for a hundred years previous to 1695. These trees perished in the "great frost" in 1739. At Hampton Court there are still several orange trees, believed to be 300 years old. The most interesting feature in the growth of the orange tree is that it bears at one time what may be called three different stages—the blossom, the immature fruit, and the ripe oranges. We read of oranges in Shakespeare; and the famous Mistress Nell Gwynne carried her orange basket in Drury-lane, and probably from an earlier period "bills of the play" were associated with oranges. When Pepys went to the "King's Playhouse" with an "order," the successors of "pretty, witty Nelly" with these orange baskets were a recognised institution; and to the present day the odour of orange peel has a peculiar affinity to the flare of the footlights, at least among the "gods of the gallery."

Our chief orange supply comes from Valencia and other Spanish seaports; but Lisbon, Villa Real, Ariero, and Oporto also contribute their quota. Other consignments hail from the Azores, Brazil, Palermo, and Malta, and other Mediterranean ports. The St. Michael's oranges are held in high esteem by connoisseurs, and they are pre-eminently the Christmas fruit, as they do not begin to arrive in this country till the end of November. The St. Michael's crop was, in 1882, almost a total failure, in consequence of a disease among the trees, caused, it is supposed, by some insect; and fears were entertained that eventually the supply from the island would almost cease, as it has from others of the Azores group, such as Terceira, Fayal, and St. George's, which once produced a large quantity of fruit. St. Michael oranges, as are most Brazilian, are separately wrapped, in the packages, in the leaves of Indian corn, while oranges from all other parts are wrapped in thin paper. The "blood" oranges, as they are called, come mostly from Valencia, but a few from Malta. The aromatic and delicious Tangierenes hail from St. Michael's, and also from Lisbon, and vary considerably in price, according to the supply. Seville oranges (specially alluded to in Shakespeare's "Much Ado about Nothing") come from the place of that name, and, as most people know, are now almost exclusively used for making marmalade and orange wine. For both these purposes, however, the Palermo "bitters" are really better adapted; and it may not be generally known that the best marmalade of all is produced from the shaddock, a sort of cross between the orange and the lemon, and named after a Captain Shaddock, who first brought it from China, or, as some say, from Guinea, and planted it in the West Indies, whence we derive our limited supply. It is the bitter element in the Seville and Palermo oranges which fits them for marmalade, as it preserves their skins while they are drying. We need not be much alarmed at the stories we hear of orange peel being collected at places of entertainment and in the streets for marmalade making, as the skins of ordinary oranges, instead of drying, simply become rotten.

The head-quarters of the orange trade is Pudding-lane, Lower Thames-street, where, during the height of the season, the chief brokers hold sales three or four times a week. Pudding-lane, where the Great Fire of London is said to have begun, is not exactly an orange grove, but the fruit trade makes it about as busy a spot as any in the City; and if an unwary passenger happens to get in the way of the "fellowship" porters carrying along it, without intermission, the wooden packages of oranges, he is not unlikely to become the object of some Billingsgate vernacular. The trade in oranges and other fruits has now become so enormous, that Lower Thames-street and its vicinity is all too small to accommodate it, even if the fish trade were removed. There are many things more unlikely than that this may be eventually the case, and that the more sweetly-smelling fruit trade may one day occupy the historical market of Billingsgate itself. A large quantity of the oranges sold in Pudding-lane afterwards finds its way to Duke's-place, a quarter of the Hebrew region on the west of Houndsditch, where it is re-sold to shopkeepers and costermongers. This locality is redolent of oranges, and it is no exaggeration to say that, in wet weather, you may walk literally ankle-deep in orange pulp and peel, mixed with cocoa-nut fibre. The appetite for oranges among the masses in London seems almost insatiable, and it is said that nearly half the retail trade in them is done by the itinerant street vendors. A package of oranges contains, on an average, 400; and in the season of 1881-2, nearly a million packages were landed in London; and not far short of that number were landed in Liverpool. Glasgow receives a large, and each year an increasing supply; while Bristol and Hull account for many thousands. Altogether, it was computed that in the season of 1881-2, two and a-half million packages were imported into this country, which would represent something like 1,000,000,000 of oranges for home consumption. This season will show a still greater advance, as in most orange-growing districts the supply is plentiful; and the market value of the total importation, including lemons, will represent something not far short of two millions sterling, first hand. The increase in the trade is due not only to increased facilities of transport, but to the abolition of the duty on the fruit. Formerly, 2s. 6d. per package was the impost; in 1853 it was reduced to 8d; and was altogether abolished in 1861. Happily, the orange is a very harmless, if not a decidedly wholesome, fruit.—*Journal of the Society of Arts.*

OYSTER CULTURE IN FORMOSA.

Mr. W. B. Russell, the Commissioner of Customs at Takow, has the following interesting note on the above subject in his report on trade for 1880:—"A very considerable proportion of the poor people on the coast gain their livelihood by the cultivation of the oyster, and, as I believe the method is peculiar to South Formosa, a brief history may prove interesting. Two varieties exist, the bamboo and the rock oyster. The beds are always found in lagoons or other inland waters which are susceptible to the ebb and flow of the tide, and it is a *sine qua non* that these spots must not be uncovered for a longer period than from four to six hours in the twenty-four. The spat floats in with the flood tide, and, attaching itself to bamboos and rocks placed for the purpose, takes up its abode until the oyster is sufficiently grown for the market. The stronger the current and the dirtier the water, the surer the chance of a good yield. The cultivation of the bamboo oyster may be thus described:—After a suitable spot has been selected, the cultivator chooses a quantity of flat oyster-shells, the thinner the better, and dividing them into two equal lots, he bores through the centre of one-half of them a hole $1\frac{1}{2}$ inches in diameter, the purpose of which will soon be explained. He next provides himself with as many bamboos as he requires—the number representing the amount of plants each of which is about 2 feet 6 inches long by $1\frac{1}{2}$ to 2 inches wide, and about half an inch thick. These are split up about two-thirds of their length, and when all are so prepared the planter takes one of the entire shells, and placing it between the bamboo, presses together the split ends and closes them by pushing over and down one of the bored shells, which acts as a padlock. Now being ready for the nursery they are taken to their destination and planted about 6 inches distant from one another, and are then in position to receive the spat. It is estimated that 2,110,000 plants are put down yearly. Each bamboo produces from four to five catties of oysters in the shell, but when opened and cleaned only about half a catty, so the total amount of pure fish produced annually is 10,550 piculs. The value varies in summer and winter, but the average price may be taken at 30 cash a catty, which gives 11,145,000 cash as the total value. This sum, converted at 1,400 cash to the dollar—the usual exchange—equals 39,386 dol. Although in most parts of the world the oyster is considered unfit for food during the summer months, here, where anything is welcome that gives one a change from chickens and shrimps, they are a luxury not to be despised, and even though they are not first-rate in the hot weather, they are always fresh and palatable. The bamboo oyster is edible seventy days after planting the bamboo, but is not considered in its prime until five months afterwards. The best are those planted about the seventh Chinese moon, thus reaching their maturity at Chinese New Year time, when they figure as a considerable item in the feasts of this festive season. It is stated that the colder the north-west monsoon and the fiercer the wind, the better the oyster thrives. They are usually eaten fresh by the Chinese; and so great is the demand for the bivalve, that the market has to be replenished by the importation of dried oysters from coast ports. Formerly this industry was taxed to the extent of 120 cash for every 1,000 bamboos planted, but some three years ago Ting Futai ordered all taxes on the fisheries of all kinds to be done away with. The rock oyster requires much less care than his fellow. Wherever spat is observed, generally in lagoons and at the mouths or sides of creeks, the natives lay down stones, rough or smooth, and varying in weight from a catty to half a picul, and leave them until sufficient oysters are produced to make it worth while gathering them. Every creek and lagoon in the neighbourhood has its oyster beds, as is the sad experience of all those who love boat sailing. Although these oysters do not look well on the table, on account of the ungainly ill-shaped shells, the fish is good, and oddly enough is at its best in those months which do not contain the letter R in their spelling.—*Hongkong Daily Press.*

THE BOTANIC GARDENS, MAURITIUS.—Ninety-four thousand persons are reported as having visited the gardens in 1882. The rainfall was 75 inches—March, with a fall of 24·83 inches, being the wettest month. The highest temperature recorded was 85°·6 Fahr., on January 21, and the lowest 53°, on June 1—the mean maximum for the year being 77°, the mean minimum 70°. The propagation of the Ceara rubber tree, Manihot Glaziovii, has been proceeded with satisfactorily. Trials are being made of other rubber trees, the great demand for caoutchouc stimulating cultivators in all tropical colonies. Liberian coffee is reported not to be a success in Mauritius. The propagation and distribution of new kinds of Sugar-cane were carried out satisfactorily, 131,700 canes having been distributed during the year.—*Gardeners' Chronicle.*

CEYLON.—Dr. Trimen has recently published a little hand-guide to the Royal Botanic Gardens, Peradeniya, Ceylon, which cannot fail to be very useful. * * * * The history of the existing garden, of its predecessors, and of its several superintendents, from the time of Alexander Moon to the retirement of Dr. Thwaites is given at some length. We have at various times given illustrations of some of the more remarkable trees in this garden, such as of the Talipot, Corypha umbraculifera, the noblest of all Palms, though in some sense an "annual," for like an annual it produces flowers but once, and then, having accomplished its mission, dies. The gigantic buttresses of the indiarubber trees (Ficus elastica) have also been figured by Captain Oliver. Dr. Trimen's narrative, strictly didactic though it be, makes "one's mouth water," if the expression may be allowed. Three other gardens in different climatic districts of the island are also under Dr. Trimen's charge.—*Gardeners' Chronicle.*

INFLUENCE OF LIME ON SOILS.—Professor E. W. Hilgard, in discussing the "Objects and Interpretation of Soil Analyses," gives, among other things, the following advantages resulting from an adequate supply of lime in soils:—1. A more rapid transformation of vegetable matter into active humus, which manifests itself by a dark or deep black tint of the soil. 2. The retention of such humus, against the oxidising influences of hot climates: witness the high humus percentages of such soils, as against all others, in the Southern States. 3. Whether through the medium of this humus, or in a more direct manner, it renders adequate for profitable culture percentages of phosphoric acid and potash so small that in the case of deficiency or absence of lime the soil is practically sterile. 4. It tends to secure the proper maintenance of the conditions of nitrification, whereby the inert nitrogen of the soil is rendered available. 5. It exerts a most important physical action on the flocculation, and therefore on the tilability of the soil, as heretofore shown by Scholoesing and by myself. Professor Hilgard adds that in the majority of soils (excepting those that are extremely sandy) the lime percentage is greater in the subsoil than in the surface soil. This is doubtless, he explains, the result of the easy solubility of calcic carbonate in the soil water, which carries it downward and thus tends to deplete the surface soil. This fact is strikingly shown in the results of Loughridge's investigation on the composition of the several sediments. The efficacy of lime in preventing "running to weed" in fresh soils, and in flavouring the production of fruit, is conspicuously shown in a number of cases.—*Australasian.*

NATURE AS A GUIDE IN GARDEN PRACTICE.—How we may follow nature in the artificial culture of plants in this country is a question which often presents itself to cultivators, and some have one opinion on the subject and some another. When anyone succeeds in growing any particular subject successfully, from the cultivator's point of view, and, as he may imagine, by following a course not exactly what the plant affects naturally, we are cautioned against the danger of imitating nature too closely; and when another succeeds by adhering to nature as closely as possible, we are told that we cannot disregard her teachings with impunity; while some advocate both courses, just as the spirit moves them, telling us one week to follow nature, and the next cautioning us against her teachings. For my own part, I venture to think that no cultivator ever succeeded or is likely to succeed in the culture of either plants or fruits who does not draw his lessons from nature, but such lessons must be drawn from the best examples which nature furnishes and not from the worst, if we desire to read her aright, and, above all, we must reckon the agents through which she accomplishes her ends. These are heat, light, air, moisture, and soil, &c. It would be easy to find inferior examples among nature's own productions, where some of those conditions were absent, but where they are combined in the right degree nature produces her noblest types. A tree or plant growing in a genial soil and situation, where it receives the light and air freely on all its parts, is a very different object from the same grown in a thicket, perhaps, when it has to maintain a continual struggle for existence. Need it be said that it is the first of those examples which the cultivator should copy, and not the last? If it be admitted that nature works by the agencies we have named, it is for those who say that nature's laws may be set aside occasionally, or disregarded, to prove that any of our horticultural operations or practices are not connected expressly with the view of utilising and adjusting the same forces by which nature acts, just according to the altered conditions and circumstances, it may be, in which the subjects treated are placed. Those who tell us not to imitate nature err, I am afraid, in misinterpreting her meaning, and unconsciously follow her teachings all the time.—J. S. H.—*Australasian.*

ON an island situated at the mouth of the river La Plata, in South America, there has been discovered a new esculent, which is a tuberous-rooted Solanum like the old-fashioned potato, an is therefore called a new species of potato. The tubers were taken to Brest and given into the care of M. Blanchard, gardener at the Seamen's Hospital in that town. The novelty is named, after its discoverer, *Salanum Ohroudi*, and M. Blanchard speaks of it as follows:—"From the time it came into my hands I have cultivated, or rather left this plant in the same place, and for the simple reason taht it was impossible to destroy it. Every year, at the end of June or beginning of July, I took up the produce. Notwithstanding all the pains taken in lifting there remained enough in the soil to ensure a crop the following year." Here it should be explained that this new solanum has three sets of creeping stems, one of which runs near the surface and throws up at intervals young growths, which flower almost as soon as they appear. Another strikes deeply into the soil and pronounces tubers, whilst others take a path midway between these two and content themselves with producing an enormous quantity of almost microscopical bulbets, which when detached effectually guarantee the plant against extermination. M. Blanchard adds: "I believe in would be easy, simply by means of good culture, to improve this plant. Already there is a great improvement in the size of the tubers compared with those received from M. Ohroud. The latter were no longer than a nut, whilst some of those grown by me are as a small hen's egg and good in flavour, having a chestnutty taste, accompanied by a slight amount of bitterness. We have used them both boiled and baked but they are best baked. The tubers are perfectly hardy, having passed the winter of 1881 in the open ground, and I may add that up to the present the haulm has shown no trace of disease." The plant is described as very dwarf, growing only a foot in height, exceedingly bushy, and in appearance like the common potato. Its probable value will be for crossing with the old stock for the purpose of securing its proved hardiness in new seedling varieties. It has thriven in a warm district in France, and is supposed to be tender to frost and severe cold.—*Queenslander.*

MELON MANURE.—The *Moniteur des Produits Chimiques* advises melon-growers to put coffee-grounds on their melon-beds. They form a very stimulating manure, and greatly improve the flavour of the fruit.

TO MAKE CANVAS STACK COVERS WATERPROOF take common resin soap, dissolve in cold water to the consistency of paint; give it a good coat thoroughly rubbed in; let dry forty-eight hours; then soak in alum water for another forty-eight hours, occasionally turning the cloth so as to expose every part to the action of the alum; dry, and the article is ready. This should be repeated at least once in two years when used and exposed to the weather, as an awning usually is.

POTTERY TREES.—One of the most remarkable of those trees which bear a stony or silicious bark is the "Pottery Tree" of Para, on the Amazon, termed "Carapia" by the Brazilians, and known to botanists as the *Moquilea utilis.* It is a magnificent tree, and sometimes grows to 100 feet before branching. The wood is exceedingly durable, being largely impregnated with flint; but the principal value of the tree lies in its bark, which is used by the Indians for furnishing the raw material of pottery. It is not that vessels are made from the bark itself, as they are sometimes made from gourds and calabashes: but the bark is burned, and the silicious ashes mixed with a proportion of river-clay make a strong and serviceable ware.—*Indian Agriculturist.*

TOMATO VINES FOR CATTLE.—In looking over a file of the New York *Tribune* for 1848 we came cross the following item from the Cheraw (S. C.) *Gazette* of September 3, 1848, which may be new to many of our readers and of practical value. It states that "in addition to the advantages of the tomato for table use the vine is of great value for food for cattle, especially for crows. It is said that a cow fed on tomato vines will give more milk and yield butter of a finer flavour and in greater abundance than any other long feed ever tried. It is thought too, that more good food for cattle, and at less expense, can be raised on a given quantity of ground planted in tomatoes than from any other vegetable known in the Southern country.—*American Grocer.*

BUD VARIATION.—Negative evidence is not usually good evidence, but when we know that countless millions of fruit and flowers have in the past 100 years been budded and grafted without the individuality of the variety being in any way affected by the stock, and that only a few instances, such as the Cytissus purpureus and the Bizzaria Orange, can be cited as exceptions, is it not fair to infer that these almost solitary cases are due to what Mr. Darwin calls "bud variation?" a condition by no means uncommon in scores of families of plants which are never budded or grafted. Nearly all of us see every season scarlet and scarlet and white striped carnations on the same plant. Dahlias are found crimson, crimson and white, and sometimes almost pure white on the same plant. Last spring we had plants of the double scarlet hibiscus with scarlet, orange, and scarlet and orange—three distinct kinds of flowers on the same plant; and that wonderful freak of nature, the striped tea rose, American Banner, was a "sport" from a plant of Bon Silene, and has no resemblance to it, either in flower or foliage. Scores of other instances could be cited if time would permit, but enough has been shown, I think, at least to throw doubt on the theory that the stock affects the individuality of the graft. In the past quarter of a century millions upon millions of Bartlett pears and Baldwin apples have have been grafted upon millions of stocks; and yet today they are as true to their individuality as the Concord grape or Wilson's strawberry that are perpetuated by cuttings or runners, and none of them are in any way changed from when they first appeared, unless by the temporary accidents of soil or climate. I believe that the smallest or the greatest of the works of creation has a separate and distinct individuality, and that they cannot be blended except by generation, and that the product of generation, whether in the lowest microscopic germ or in the highest type man, has an individuality distinct and separate that it cannot attach to another.—*Australasian.*

FOR MAKING CEMENT for leather, take of common glue and American isinglass equal parts, and place in a glue pot. Add water to cover the whole. Soak ten hours. Then bring the mixture to a boiling heat, and add pure tannin, till the whole becomes ropy or like the white of eggs. Apply warm. Buff off the grain of the leather where it is to be cemented; put the joint surfaces solidly together; let it dry a few hours, and it is ready for use. If properly put together the cement is as strong as the leather.—*Oil and Drug News.*

A FINE CALIFORNIAN BARBERRY.—At the first August meeting of the Academy of Sciences, of San Francisco, Dr. Kellogg exhibited flowering specimens of a most remarkable barberry tree from Big Canyon—the Berberis Fremonti—which grows 20 feet high, and its trunk is 3 inches in diameter. It was laden with golden blossoms, and may be cultivated and made one of the most desirable ornamental shrubs of California. It thrives well on poor, dry, rocky soils, and is celebrated for its medicinal virtues. Its sap furnishes material for making a most powerful yellow dye. He presented a fibrous plant, as yet unnamed, from Lower California, which pushes up a flowering stem from 5 ft. to 6 ft. high and bears an ample mass of small white blossoms. He also exhibited a plant of the Comandra umbellata, belonging to the family of sandal-wood trees, which has been found in the Sierra Nevadafoot-hills.—*Garden.*

TWO WORTHY BEE PLANTS.—There are two plants which are particularly prominent for nectar-producing qualities—neither perhaps equal to thyme, but in its absence the next best substitutes. These plants are the common mignonette (Reseda odorata) and the Sweet Melilot (Melilolus suaveolens. That this character is well deserved let us call in the Editor of the *Utah Pomologist*, who deposes:—"There is no plant for bees within the range of our knowledge as valuable for bee-forage as mignonette. And why? It will keep in bloom year after year if not disturbed by frost, and it gives a longer period of usefulness than any other plant. It gives more blossoms in a given space, and therefore gives more forage than any plants we have ever seen. Honey made from this plant has the most delicious fragrance of any we have ever tasted, and when it has been tested in market is far ahead of Californian or any other brands of honey in worth, and brings a much higher price. We think that one acre of mignonette will make enough of forage for one or two hundred colonies of bees, even when there is nothing else to work upon. We place mignonette in the lead of all other plants we know as a crop to cultivate as bee-forage."—*Australasian.*

SOTOL.—Sotol is a pure alcoholic drink, which is to the Mexican what whisky is to a Scotchman or an Irishman. It is limpid and colourless, with a peculiar penetrating odour and a taste which, though a little bitter, has been compared to the smoky flavour of Scotch whisky. It would seem to have little deleterious effect on the human system. The plant which yields it is a lily, known as *Dasylirion texanum.* It is perennial in its growth, having long green armed leaves, with a stout flower stem some 10 ft. to 12 ft. high which is produced every three or four years. Its home is Western Texas, South-Eastern New Mexico, and Northern Chihuahua. It sometimes covers square miles of arid, stony slopes, growing best at an elevation of some 500 ft. or 600 ft. The base of its leaves and young stems are full of a sweet, refreshing, and nourishing saccharine matter, which is both food and drink. The thick parts of the leaves are eaten baked or boiled, and the sweet taste of the inner portions makes these leaves much sought after for food. It is from these, after a process of boiling and fermenting, that the alcoholic liquor is distilled, and from one large head or basal part of the leaf nearly one pint of this is to be procured. The Mexican barrel of sotol, containing about 28 gallons, is sold at an average price of 15 dollars, and the liquor is retailed at from 30 to 40 cents a quart. In an interesting note on its use by Dr. Havard, of the United States Army, from which the above details have been abstracted, he mentions that it is now-a-days very largely consumed, the Mexican revenue laws being very lenient in their taxing of the sotol distilleries.—London *Times.*

KEEPING NUTS.—If you will simply bottle them—walnuts shelled, but nuts put into the bottles in their husks, corking tightly, and sealing with wax or roisn—you will find when opened for use that they only require wiping to be as good as when first put in. I have eaten nuts so kept in the following June or July perfectly good. In a dry cellar I have been told that thus treated they will keep sound for two years.—S. I.—*Australasian.*

FERTILIZER EXPERIMENTS.—In the discussion on fertilizers, at the recent meeting at Newtown, Conn., Mr. Sedgewick, of Cornwall, said he thought that Dr. Atwater's experiments had saved the farmers a great amount of money by teaching fertilizer manufacturers that less nitrogen is required for many crops than had formerly been supposed. Nitrogen is the most costly ingredient used in commercial fertilizers, and the most difficult at the present time to obtain. It would be wasteful, therefore, to use a greater quantity than is really needed, and such waste is exceedingly costly to the farmer. As it is found that less nitrogen is required, the price of fertilizers has been gradually dropping in market, and this gain is greatly to the benefit of the farmer. It enables him to buy more and to use more, with a fair prospect of obtaining a profit. One objection to the use of guano, he believed, was that it contains a larger percentage of nitrogen than is needed, and consequently a larger portion than farmers can afford to pay for. A saving of 1 per cent in the amount of nitrogen in a ton of fertilizer will cheapen the cost about four dollars. He thought the most profitable way to use fertilizers is in connection with stable manure, the fertilizers being compounded in such a way as to make the manure and fertilizer together just meet the wants of the crops to be grown. Exactly how the nitrogen is taken by plants he did not attempt to explain, but it is evident that soil which is well filled with the tops and roots of colover and other plants contain a large amount of nitrogen that the growing crop will in some way appropriate.—*New England Farmer.*

OVER-POTTING PLANTS.—Growers for market have long since discovered what kind of plant is best for indoor decoration, and they produce marvellously well-developed specimens in a minimum of root space, by means of high feeding with some of the soluble manures now so plentiful. It is well known to all who have indoor decoration to carry out how much better plants in small pots backed full of roots not only flower, but retain their flowers and foliage under the adverse conditions of light and air to which they are too often subjected, compared with those in larger pots only moderately well rooted, as they are so liable to get waterlogged, and to quickly lose both flowers and foliage. As a rule the pots become covered with moss, or are plunged out of sight, where evaporation is reduced to a minimum. There is not the same necessity for large pots now that existed a few years ago, when large specimen plants were frequently to be seen grown solely for filling the houses in which they grew, or possibly to figure once or twice a year at some neighbouring flower show. Now, the great increase in the matter of indoor decoration necessitates all available space being utilised by plants that are useful for that purpose. This has caused palms, dracænas, and other fine foliaged plants to be extensively grown, for in them we have a class of plants that withstand the usage that such materials get in crowded assemblies; and, moreover, they form fine plants in proportionally small pots, that fit vases and other receptacles in which they are required to be placed. The plea generally put forward in favour of the use of large pots is that they require less frequent attention as regards watering in hot weather than small ones; but that is overborne by the fact that a plant in a pot really too large, with a quantity of cold, inert soil about its roots, is in far greater danger of sustaining injury from careless watering than a plant in a small pot full of active fibres, for although the latter may flag or droop from lack of moisture, it soon recovers when water is supplied; but an overpotted plant that gets into bad health from over-abundant root-moisture is by no means so readily recovered. I would, therefore, strongly advise amateurs to rather under than over pot their plants, for with the drainage in good condition it is surprising what a small quantity of soil will sustain even a large plant if liquid stimulants be intelligently applied to it.—JAMES GROOM.—*Australasian.*

RHEA AND PINEAPPLE FIBRE.

A reference to Messrs. John Walker & Co. will enable our correspondent (page 679) to ascertain the price of one of Smith's machines. But we are all now waiting to learn the results of the trials at Calcutta of the rhea cleaning machines to be exhibited by Dr. Forbes Watson and others. Rhea plants can be obtained from the Botanical Gardens, and the plant grows readily in Ceylon, but it requires rich soil, and, after a time, liberal manuring to secure about two crops per annum. The fibre is very fine with a silky lustre, while it can be made flossy like wool. Chemicals are necessary, however, in order thoroughly to rid the fibres of fragments of cortical matter and gum. The long leaves of pineapples grown, as the natives generally grow them, under the shade of trees and in hedges, can, we believe, be thoroughly cleaned by a machine with a jet of water striking the fibres. These vary from thick to silky fine, the latter being a good substitute for silk. We confess to more faith in pineapple than in rhea here in Ceylon, but even pineapples, we suspect, would require manure if frequently cut. We ought to hear something definite and valuable from Calcutta.

THE QUESTION OF SUGAR CULTIVATION IN CEYLON.

Of the two grand difficulties specified by G. W. (page 658) one is common to cotton as well as sugar in Ceylon. With our recurring monsoons and our moist atmosphere it is difficult to obtain a good harvest season. This difficulty might, perhaps, be obviated by cultivating the cane by means of irrigation in the arid regions of the north-east of Ceylon, provided the soil should turn out to be suitable. But here seems to be the difficulty. According to G. W., who speaks from personal experience, cane grown on the most fertile soil in the south-west of Ceylon failed to yield juice with a sufficient proportion of saccharine matter. Even the soil of Dumbara, where coffee once gave a ton an acre and which is now found equally suitable for cacao, failed to yield profitable sugarcanes. In May 1841, we saw the late Mr. Tytler, who had had West Indian experience, doing his best, but the Dumbara experiment, like all others, ended in failure. The final, question, then seems to be whether, with our advantages, especially of a cheap and steady labour supply, we could afford to add to the soil the fertilizing ingredients, which chemical analysis or experience otherwise should prove to be wanting. We confess to doubt on this head, as well as with regard to cheapness of labour if the cultivation is to be a mammoty (hoe) cultivation. In Queensland, the carting principally and the ploughing, wholly, of the land is done by white men, and, although these get comparatively higher wages, yet, the day's task of ploughing compensates, we suspect, for this. Nothing surprized us more in the Mackay district than the comparatively small number of kanakas aided by white men (one of the latter to twenty of the former), who worked large sugar estates. There is the superior soil to begin with, and the possibility, from its flatness or gentle undulations, to plough every inch of it; first, in many cases, with the steam-plough and then with American ploughs pulled by horses which the ploughman guided from a seat. The maximum of work was thus performed with the minimum of fatigue. What the black labourers were really needed for were the operations of "trashing" and cutting the canes. If, therefore, Queensland is not deprived of the necessary labour, and we may add if the new laws do not bring about the same result in Java, we suspect it would be vain for us, with our poor soil of gneissic origin, to attempt to compete in sugar-growing with countries where the soil consists of comminuted lavas.

EUROPEAN ENTERPRIZE IN JOHORE.

In our last issue we mentioned that arrangements were in progress between the agents of the Lini-Soie syndicate in London, and the grantees of a large tract of land in the State of Johore, which would presently result in a powerful company, for the cultivation of rhea, and we are now in a position to give some further general information on the subject, but as the preliminaries are still incomplete, it would be improper to go into detail. We understand then, that the scheme includes the acquisition by the company of over 20,000 acres, or say thirty square miles of rich and fertile land, covered with virgin forest containing a large proportion of valuable timber, except 150 acres, which was cleared and planted with Liberian coffee three years ago, so that in the present season it will bear its maiden crop. This tract has been specially selected by Mr. Edwin A. Watson, formerly of Ceylon, and latterly a highly successful planter in Johore, and a lease of it for 999 years has been granted to him by the Maharajah of Johore, whose enlightened policy in the encouragement of European enterprize we have more than once had occasion to notice in these columns. The land is situated close to a nevigable river, thus rendering communication with the ports of Johore and Singapore cheap and easy, and it is declared by competent authorities to be capable of bearing heavy crops of rhea for an indefinite time, without either irrigation or manuring. Another feature of the project is the acquisition of the patent rights of the Favier-Frèmy processes, for the whole of Johore, and the consideration for this will be accepted entirely in shares of the company. More than half of the price of the land will also be paid in shares, so that the bulk of the capital will be available for cultivation, and it is said that this can be cheaply worked by Chinese labor at 1s per day, of small allotments of ten to twenty acres each can be leasde to Chinese on favourable conditions, including the sale of the produce to the company. It is calculated, we believe, that one crop of 200,000 stems per acre will be obtained the first year, two crops of the same extent the second, three the third, and four the fourth and succeeding years. When in full bearing these four crops should give a return of thirty cwts. of *filasse*, or clean fibre, prepared for the spinner by the Frèmy process, the profit upon which at a selling price of £60 per ton (or only one half the present value), would be £20 per ton, equivalent to £30 per acre. Now a very little simple arithmetic suffices to show that if this calculation be correct, and it is based upon Algerian experience, where the conditions are said to be less favourable than in Johore the return will be something enormous. Thus, if the land can be brought into full bearing for £20 per acre, which is an outside estimate, taking into account the three intervening corps, the returns would be 150 per cent. per annum! It is obvious, therefore, that with the allowance of a very large margin for contingencies, the industry ought to prove extremely profitable.

Within the last few weeks another company for carrying on planting operations in Johore has not only been formed, but actually floated. We refer to the "Pulo Lyang Planting Company of Johore," and we observe, by the way, that an article which appeared in this journal in 1882, under the heading "Johore as a Field for Planting Enterprize," was circulated as a fly sheet of the prospectus. The capital is £25,000, but the first issue consists of 2,000 shares of £10 each, whole of which has been subscribed. The directors are men of the highest position and respectability, and Mr. W. W. Bailey, a well-known Johore planter, is to be the local manager. The company acquires 5,000 acres of land suitable for Liberian coffee, cocoa, sago and numerous other tropical products, and it is intended to bring 1,600 acres under cultivation as rapidly as possible, the remainder being sold off as opportunities present themselves. It is estimated that there will be a net profit of £2,000 upon the fourth year's crop, or say 10 per cent. on the subscribed capital, which will increase in subsequent years. We do not for a moment doubt the soundness of this calculation, but we should like to see how the capital outlay is distributed; that is to say how 1,600 acres can be planted and brought into bearing for 20,000 minus the cost of the land, which can hardly be less than £5,000, or in other words for less than £10 per acre. There is one expression in the prospectus which we ought not to pass without notice:—"Planters (especially those who have failed in Ceylon) are now turning their attention to this country" (Johore). We presume the intention is not to intimate that the hill country of the Maharajah's State is gradually being occupied by Ceylon insolvents, but that as men who have acquired a reputation in Ceylon for sound judgment in such matters have pronounced favourably upon the soil and climate of Johore, the fact may be accepted as proof positive of the capabilities of the country.—*Planters' Gazette.*

TRIAL OF FIBRE-SHREDDING MACHINES AT CALCUTTA.

Yesterday evening, under the auspices of the Agricultural Department, between 3 and 5 p. m., a trial of machines for detaching fibre from various materials was held opposite the Zoological gardens. These comprized a a powerful steam power machine, by Sir Walter Desoza; a smaller compact, ditto, by Messrs. Burn & Co. two hand-power roller machines, by V. V. G. Hatti Barooah, of Assam, tea garden proprietor and mouzadar; one animal-power ditto, by the same exhibitor, and a manual rotatory machine, by Messrs. T. E. Thomson & Co. The fibres under test were as under:—

FIBRE YIELDING PLANTS.

Known as		*Scientific designation.*
Rhea	...	Boemhera Nivea.
Aloe	...	Agave Americana.
Pine-apple	...	Anannasa Sativa—Four
	...	croya Gigantea.
New Zealand Hemp	...	Sanseviera Zeylanica
Shoe-flower	...	Hibiscus Rosasinensis.
Sthalpadma	...	H. Mutabilis.
Roselle	...	H. Sabdaraffa.
Bala	...	H. Tiliaceus.
Plaintain	...	Musa paradisiaca.
Saolapadma	...	Yucca Gloriosa.
Nona or Bull's-heart	...	Anona Squamosa.
Ulat Kambal	...	Abroma Agusta.

The two steam power machines fell short of the results expected of them (the smaller not offering to work at all), for want of proper adjustment in their positions The same may be said of T. E. Thomson & Co's manual machines of the others the Baroah machines turned out fair specimens of fibre, but the operation has to repeat itself before a fair result is obtained, but this their invention promises to remove in time. This gentleman showed a specimen of drawn rhea fibre, which appeared very clean and glossy, and of very fair marketable quality, which is said to have been stripped by one of his machines. But he said also that it bad been subjected to the action of "certain chemicals incorporated with oil." This, however, is a secret at present.

Baboo Troylockho Nath Mookerjee and Mr. L. Liotard watched the operations on behalf of Government, and there were several European and native gentlemen on the spot representing the mercantile and Zemindary interests.

There will be another and more detailed trial on a future date, but not until the arrival in this country of the two machines now on their way to this country from Messrs. Death and Elwood and Mr. Forbes Watson. The latter has been represented at the Exhibition, but the one expected has some later improvements, and is considered complete.—*Statesman.*

KINMOND'S ROLLING AND DRYING MACHINERY.

The results obtained from Mr. Kinmond's visit to the Dunedin tea estate being of the greatest importance not only to the proprietors of that estate but to all who are connected with the tea enterprize, and consequently interested in the machinery which can do the best work at the least cost, we annex copy of the report by Mr. Forsythe, superintendent of Dunedin, on the work done by his machinery under Mr. Kinmond's personal direction. Mr. D. Fairweather, superintendent of Sembawatte, was present during the time Mr. Kinmond was working his machines so as to give the best results.

At Dunedin we find there are a Kinmond's No. 1 roller and No. 2 drier, worked by one of Robey's vertical 6-horsepower boiler and 4-horsepower engines. Neither the roller nor drier worked satisfactorily previous to Mr. Kinmond's visit: in working the roller, the leaf adhered to the surface of the rolling discs, and prevented, to a certain extent, the twisting action on the bulk of the leaf; the result was badly-twisted tea. Mr. Kinmond explains that this adhesion of the leaf to the discs is caused by the large amount of gummy matter and sap which, compared with Indian, is found in the Ceylon tea leaf. The remedy Mr. Kinmond applied was very simple and most effective. The battens on the surface of the rolling discs for turning over and twisting the leaf had the base widened by the insertion at each side of a triangular fillet; this thoroughly prevented the leaf sticking to the surface of the discs, and the result is that the tea has now a hard wiry twist better than anything we have ever seen; Mr. Kinmond has left with us a sample of the bulk of tea made on the 28th ultimo which can be seen at our office by those wishing to judge for themselves of the statement that his roller now gives an exceptionally fine twist to the leaf.

We understand that the Fairfield Ironworks Company, Mr. Kinmond's agents, have been instructed by Mr. Kimmond to furnish on application a sketch of the shape of the battens now used on the rolling discs, and to enable planters to thoroughly examine his rolling machine. A No. I, the same size roller as at Dunedin, will be on view at the Fairfield Works in about a fortnight. The alterations on the battens of the rolling machines now at work in the island can be carried out by a native carpenter in a few hours.

The improvement made by Mr. Kinmond on his drier was simply an alteration in the method of working: the speed of the fan was increased to 700 revelutions per minute and the layer of tea spread on the trays was much reduced in thickness, the result being that the tea was dried in 10 to 12 minutes, instead of about 30 as before. The difference of briskness between the sharp-and slow fired tea was simply astonishing, a sample from bulk of the sharp-fired was far superior to a sample from the *pekoe* of the slow-fired, and if the enhanced value put on the these sharp-fired teas by the superintendents of Dunedin and Sembawatte is realized in the London market, the benefit of Mr. Kinmond's visit to Ceylon cannot be overestimated; and apart from the profitable results to himself and primarily to those estates now working his machines tea planters generally will be benefited and encouraged by the knowledge of such important aids to their enterprize being obtainable, and, as may be seen from our advertisement column, at a reduced rate.

The quantity of tea dried by the Kinmond No. 2 drier was as near as possible two maunds of pucka tea per hour, and this might have been exceeded if there had been more space round the drier to enable the trays to be handled quicker. Those who may be setting up Kinmond's driers would do well to make a note of this and allow plenty space on both sides for the rapid working which sharp-firing necessarily entails.

Altogether the machinery now is a perfect success, and any information required as to its working will, we have no doubt, be gladly given by the superintendent of Dunedin, and as to supply and erection, &c., by the Fairfield Ironworks Company.

Report on the working of Kinmond's machine on the Dunedin Estate on the 29th February, under the personal direction of Mr. Kinmond.

Mr. Kinmond arrived here on the 27th February. On Thursday, the 28th, he went to the Factory and first examined, the roller. The principal fault in this machine has been the way in which the leaf used to catch and clog against the wooden battens on the movable rolling disc. To prevent this, Mr. Kinmond suggested filling in the angles at the sides of the battens with wooden fillets nailed on, and this was most successful, as the roller cleared itself entirely after each roll. I was afraid the alteration on the battens might interfere with their rolling and twisting action, but apparently such is not the case, as the machine turned out today 1,040 lb. green leaf in as good style as could be desired.

Mr. Kinmond seemed to think that the reason the roller threw out leaf was owing to the hopper not being properly fitted and made to overlap the iron plate, but I am inclined to think, if the manufacturers had done this work better in the fitting of the discs to the cylinder that the spilling of leaf would be reduced to a minimum not worth noticing. Two remedies were suggested by Mr. Kinmond to reduce the spilling, both of which I shall try and report further as to effect.

With the drier Mr. Kinmond conclusively proved that the machines could not only turn out the tea perfectly dry in 12 to 15 minutes, but also that the quantity of two maunds as specified in his circular could be dried in the hour. The two most serious errors made in the working of this machine are, not driving the fan at a sufficiently high rate of speed and spreading the leaf too thick on the trays. Following the printed instructions. I was spreading my leaf twice as thick as I used to do over charcoal fires; this is a great mistake. To ensure brisk and regular firing the leaf should only be spread ¼ to ⅜ of an inch thick on the trays. One lot of broken pekoe was fired off yesterday in five minutes; this is of course quicker than the coolies could work regularly, but as I have said I think eight to 10 minutes for the finer teas and 12 to 15 minutes for the coarser will be found to be correct.

I annex a table kept by Mr. Fairweather and myself of the time taken in drying the leaf in the two sides of the drier. The former took the side with the trays in top, I took the other or the lower tray side; the time was accurately noted by the factory clock; the quantity of tea dried was 290 lb., and the time taken was exactly two hours, or at the rate of 145 lb. dry tea per hour, which with more trays to spare might, I have no doubt, be easily increased to 160 lb.

For the days work the fuel account stands thus:—

Engine 9 cwt., drier 5 cwt.,—total 14 cwt. for 290 lb. dry tea. Engine wood cost 45 cents, drier wood 25 cents, or per lb. of tea rolled and fired ¼ cent.

After the firing was finished, five or six samples of the day's make were tasted by Mr. Fairweather and myself. We considered the tea increased fourpence per lb. in value chiefly on account of the brisk firing.

(Sigued) W. FORSYTHE, Superintendent.
Dunedin Estate, 1st March 1884.

Table of time taken in firing off 290 lb. of finished tea:—

	Put in dryer. hrs. min.	Taken out. hrs. min.	Time taken each set.	
Rroken pekoe ...	6·36	6·44	8 min.	by W. F.
Do ...	6·38	6·48	10 ,,	
arge leaf ...	6·46	7·00	14 ,,	
Do ...	7·04	7·15	11 ,,	
Do ...	6·42	6·55	13 ,,	by D. F.
Do ...	6·47	6·59	12 ,,	
Do ...	6·50	7·04	14 ,,	

Average time nearly 12 minutes,

Classification of the teas made on the 29th February:—

Broken Pekoe	62 lb	or 21 per cent.
Pekoe	180 ,,	or 62 ,,
Pekoe Souchong	40 ,,	or 14 ,,
Dust	8 ,,	or 3 ,,
	290 lb	100

No. of coolies working Engine ...	2
,, of do do Roller ...	2
,, of do do Dryer ...	6
	10

NOTE:—The table of time does not extend to the whole of the 290 lb. dried, but only to a portion; the total time, however, is two hours, and the details though not carried out will shew how an average of 12 minutes is arrived at for firing a set of trays—previously it took 30 to 40 minutes to a set. Regarding the defects in manufacture or in workmanship of the roller referred to by Mr. Forsythe, it was acknowledged by Mr. Kinmond that the manufacturers, Robey & Co., had not done the work as well as it should have been done, and that, if they had, there would be very little cause of complaint as to throwing out leaf. This defect in the rollers now in Ceylon will no doubt be avoided in any made in future.

ANSELL'S PATENT TEA SORTING AND WINNOWING MACHINE.

Colombo, 4th March 1884.

DEAR SIR,—We have the pleasure to enclose copy of a report received from A. E. Scovell, Esq., manager of Strathellie estate, Nawalapitiya, on the working of the above machine, which may interest many of your readers. With reference to the last paragraph of the report, we are glad to be able to state that the manufacturers have reduced the price of the machine from £80 to £70.—Yours faithfully,

W. H. DAVIES & Co.

Report on the working of Ansell's Patent Tea Sorter.

Strathellie Estate, Nawalapitiya, 12th Feb. 1884.

I have had one of your patent sifting and winnowing machines at work on this garden continuously for the whole of last year, and have pleasure in stating that the work performed has been very satisfactory, both as regards quantity and quality. By a re-arrangement of the sieves I have been able to arrive at excellent results as evinced by the prices realized for Strathellie teas. The average for the year is so far very good: the last invoice has yet to be sold; the two previous ones averaged 1s 9d and 1s 9½d respectively. Pekoe souchong selling at 1s 3½d to 1s 5d; pekoe 1s 9½d to 2s 4½d; broken pekoe 2s 5¾d to 2s 11½d, and broken orange pekoe at 4s 10d. These results have been attained with careful manufacture by Jackson's Excelsior and Universal rollers, Davidson's Siroccos and Ansell's sifter.

I have pleasure in adding my testimony to that generally expressed as to the efficiency of your sifting and winnowing machine, and, with a reduction of the present price, I have little doubt but that Ansell's will be the favorite sifter on the many Ceylon gardens now forming.

(Signed) ARTHUR E. SCOVELL, *Manager.*

In order to add completeness to the information regarding tea machinery, we insert, gratis, a portion of Mr. Andrew Thompson's advertisement regarding his "Challenge" roller. Testimony is borne to the value of this roller, but where did Mr. Thompson acquire his style, which is "peculiar in the extreme"? It certainly does not resemble his machine if that is distinguished for "the utmost simplicity of construction and detail." This and "a more or less individual and dividing (individual and dividing?) movement" is secured by the adoption of the conical form. The cones "*suck* the leaf under" and "*vomit* it up, the leaf passing irregularly from cone to cone, *working and moving like boiling-water*"! If we saw the roller, we might be in the position of the old woman who understood the Pilgrim's Progress and hoped *in time* to understand the notes. But, if our readers can clearly comprehend what follows, including the "revolving on one axis (*as in a bag*)," they have the advantage of us. Here is what Mr. Thompson says about his machine:—

The singular efficiency of the "Challenge" is obtained by the employment of the Conical form as a twisting, rolling, and compressing surface. Owing to their form, no elasticity or spring play is needful. The cones suck the leaf under (apply the pressure themselves when the machine is properly loaded up) and vomit it up, the leaf passing irregularly from Cone to Cone, working and moving like boiling water. The irregularities of movement, pressure, exposure to the air and the way in which the leaf is separated from one lot and dragged or sucked into another are peculiar in the extreme and at once prove the lines hitherto worked on (which have all been to keep the leaf in one mass or roll and move it bodily) to be at least unessential: revolving on one axis (as in a bag), or on more or on continuously shifting axes, entailing in some cases complex mechanism or peculiar disposition of parts; whereas, by the use of the Conical form, a more or less individual and dividing movement is secured, in conjunction with the utmost simplicity of construction and detail.

CULTIVATION AND LABOUR IN FIJI.

On page 677 we print one of those few and far between, but always welcome, because able and intelligent, letters, in which a former Ceylon planter gives full and reliable information on planting and labour conditions in Fiji, for which readers of the Fijian journals may look in vain. It seems quite certain that, as yet, coffee has not been an assured success in Fiji. *Hemileia vastatrix* may not be so virulent as it has proved to be in Ceylon, but the wet climate has developed another bad blight in the shape of "black leaf." Such coffee as is grown, too, is not well cured, although the single curing mill erected is but poorly patronized. Last season in Fiji seems to have been worse for excessive rainfall than even that of 1882 in Ceylon. From a rainfall of 110 inches, the quantity went up to 183 inches, an increase of 73 in one year, and it will be observed from the monthly returns that, as nearly as possible 100 inches fell in the four months, December to March. No wonder, although the coffee blossoms were destroyed. Of course, it would not be logical to judge the coffee enterprize by the results of one year, but we have now the experience of a good many years before us, and we have a right to say that the prospects of coffee in Fiji are not hopeful, any more than are Mr. Storck's prospects of destroying the leaf-fungus by means of the vapours of carbolic acid. The prospects of the sugar enterprize, and we may add of tea culture, are very different indeed, provided the labour supply does not fail, and it certainly is by no means in a satisfactory condition. Polynesians are hard to get, and so are Fijians, even under the new law. Coolies seem to have developed a talent for malingering, so that the sugar planters are resting their hopes on Chinese at 15s per week, that is £3 per mensem! It is added that the Chinese are to find themselves, but "lines" or "barracks" and medical aid must, we suppose, be provided for them. Such Chinese labour, therefore, if it can be depended on for field work, will cost three times the monthly average in Ceylon. The profits of sugar to the manufacturers may pay, but our correspondent shows that planters who are merely growers of sugar complain that already, in consequence of scarcity and dearness of labour, the contract price of 10s per ton does not pay. This price is the same as prevails in the Mackay District in Queensland, but in Fiji, it seems, the planter has to cut the cane and deliver it into the punts of the Manufacturing Company. The difference against the Fiji sugar farmer is considerable, and of course scarcity and dearness of labour will aggravate the disproportion. Putting aside exceptional yields, the average in Fiji seems to be the same as in the Mackay district in Queensland, about 30 tons of cane per acre, and the yielp of sugar is probably the same, from 1½ to 2 tons per acre. What is significant in its bearing on the discussion now going on in Ceylon, is that the excessive rainfall which in Fiji proved disastrous to coffee does not seem to have had any bad effect on sugarcane any more than on tea. All the evidence which reaches us, therefore, points to the one conclusion that successful sugar cultivation is not a question of climate but one essentially of soil. The soil of Fiji is, like that of Queensland, volcanic in its origin, and the canes grown on it yield a profitable proportion of saccharine. Had the occurrence of the abnormal rainfall led to any deterioration of the cane in this respect, we believe our keenly observant correspondent would not have failed to notice that fact. We may take it for granted, therefore, that sugar, equally with tea, will flourish in a climate too wet to be favorable for coffee, and we may add cacao, but that an essential condition to successful sugar-growing is a soil fertile in its mineral as well as its organic constituents. But even the presence of suitable soil and of liberal supplies of capital from adjacent Australia will not enable Fiji successfully to compete with Java, Mauritius, Demerara, Cuba and other great sugar unless countries there is a satisfactory solution of the labour difficulty. From what our correspondent says about white labourers, we suppose they plough the sugar-fields, the climate of Fiji apparently permitting outdoor exposure which would be fatal in Ceylon. But white labour, at probably £60 to £100 per annum, supplemented by Chinese (who are generally impatient of working for others), at £36 to £40, would scarcely seem the conditions for continued success. The curious part of the matter is that Indian coolies, who do well in Ceylon, in Mauritius, in the West Indies and Demerara, should have given so little satisfaction in Fiji. It may be, as our correspondent seems to indicate that the fault is in the courts of justice which under the legislation of Fiji do not adequately punish coolies for misconduct. If so, there ought to be a change of policy, for, while we contend for justice to the labourer, especially as regards the wages for which he has worked, we equally contend for justice to the employer, who is entitled to a proper return of labour for the wages he pays. In Ceylon, the custom of the country sets bounds to malingering and shirking work: for the days he does not work a cooly gets no pay. In Fiji, where the coolies are "indentured" for long periods, the case is different, and the difference is evidently by no means in favour of the Fiji planter. On the whole, even if it is finally proved that sugar for export cannot be profitably grown in Ceylon, our condition and prospects compared with those of Fiji and other places are not unfavourable.

Correspondence.

To the Editor of the Ceylon Observer.

CULTIVATION AND LABOUR IN FIJI.

Fiji, 7th January 1884.

DEAR SIR,—Since writing to you last I have made a short tour to Viti Levu, having a look at the coffee and sugar, both on the Navua and Rewa rivers. The former cultivation has made but little progress since I last visited the Navua, 4 years ago. The latter has made great strides on both rivers and seems very flourishing. Under their proper headings, I will say what I think of both industries.

Coffee.—In Taviuni. Our crops will again be short, owing principally to exceedingly wet weather throughout the year. The rainfall, particulars of which later on, was 183 inches during the year here. I am referring to an estate 1,000 ft. above sea level, situated on the north end of the island. Leaf-disease also paid us a visit, but did not do so much damage as on the previous occasion. My and my neighbours' coffee is also just now suffering from 'black leaf,' so, taken altogether, our prospects for this season are not very promising. In your issue of October 30th last, I see A. R. W. has been having a rap at me, *re* 'black leaf,' leaf-disease, labour, and crops. He clearly makes out to his own satisfaction, that his estate is so admirably situated, that it possesses an immunity from black leaf, leaf-disease, and also gives such crops as to enable him to write, "I should not wish to see the trees bear more heavily than they do." I am glad, for A. R. W's sake, he is so easily satisfied, and I sincerely trust his trees *will* bear so heavily, as to enable him to retire soon. Of course others may differ from A. R. W., and I am one of them. Although I have not seen his estate suffering from black leaf, I have seen it with leaf-disease and *very badly*, let me add. As for crops, I 'm afraid, A.R.W. does not yet know what a *good* crop is like: wait till he gets 10 cwt. or even 7 cwt. or 8 cwt. on his trees before he writes about not wishing them to bear more heavily than they do.

On the Navua.—No extension worth speaking of has been made to the two estates on this river. The coffee looks vigorous, but has not much crop on. I noticed signs of the black leaf on both plantations, but nothing to signify much. The season there seems to have been as unfavourable as ours was here, the rainfall being excessive. A good dry coming season would make these places bear well. I should say. I did not hear of anyone else going in for coffee cultivation. There 's a coffee estate far up the Rewa River, but I had not time to visit it.

Sugar.—On the Navua.—What used to be grass and "vico" land, *i e.*, wild cane or reed land, four years ago when I was last there, is now nearly one large expanse of fine cane, growing and looking well, with no disease. Extensions are still the order of the day, and in a short time a large acreage will be planted up. The work is well done, and good substantial buildings are and have been erected; one mill has been built and ought to be crushing by this time, another is coming out, and there 's some talk of a third being put up shortly.

On the Rewa.—Greater strides have taken place here than on the Navua, owing to the large mill erected by the Colonial Sugar Refining Company. This Company is said to have spent some £300,000 already, so this will give you an idea of what their establishment is like. A former Ceylon planter was sub-manager of the mill when I was up there, and, as I stayed with him, I had every opportunity of seeing everything, and fortunately it was their busiest time, working night and day, so I saw all that was to be seen in and around the mill. It is a great undertaking and well worth visiting. The managers' billets there are no sinecures, I can tell you. Their work during the season is very arduous and they occupy very responsible positions. The expected outturn this season was 5,500 tons sugar. This will be greatly augmented next season, as they are just doubling their crushing power, which will then make their mill one of the, if not the, largest cane mill in the world. The mill employs a great number of whites and blacks, about 1,000 altogether. Owing to there being a resthouse close by, where the whites can buy liquor, rows often take place amongst the labourers and cause a deal of trouble. A white employee was murdered the day I was there. Some Fijians were arrested and, I hear, have since acknowledged having committed the crime. The Navua proprietors are very lucky in this respect. There 's no place on that river where white employes can procure liquor, consequently, there are but few disturbances and the men work regularly. A large extent of country has been planted up in the Rewa with cane. The Company themselves have purchased a large acreage and are planting on their own account, and the planters are also under contracts to supply the mill with cane, at the rate of 10s a ton delivered into the Company's punts. A lot of the planters told me they were getting from 40 up to 60 tons off some of their fields. The latter return was off two or three good fields and must not be taken as an average over the estate. The average, as far as I could ascertain, over the whole river was a little less than 30 tons, about 28 tons per acre. This is without manure. All the planters seem to be dissatisfied with the 10s per ton. What they say is this: "When we entered into contracts, labour was very much cheaper and more plentiful than it is now, and we had a fair margin left for profit: now, even if we get good crops, labour is so scarce and dear, that it is almost impossible to make any profit at all," so they want the Company to pay them more. Whether the Company will do so remains to be seen, but I should say they will turn round and say: "No, a bargain 's a bargain, wait till you have completed your contracts and then we 'll enter into the question of an increase in the price per ton of cane." There 's no doubt that at the present price the Company will make money hand over fist, but it is at the planters' loss, and how long will the latter be able to carry on. The question which will arise will be: "Will it be better to pay the planters a little more and get them to go on planting and supplying the mill with cane, or, shall we let them rip, and plant cane for ourselves on our or their land if we have to buy it!" The same Company intended erecting a mill on the Ba, another part of Viti Levu, but owing to a dispute about the land this is in abeyance.

In Taviuni.—The cane looks well and is giving fair returns. Mr. Hedges' mill at Vuua is crushing away and turning out very good sugar. A large extent of tramway is being laid down in the estate to facilitate the transport of the cane. Up to the present the difficulty experienced in getting the cane down has been great, and crushing has been retarded in consequence. Mr. H. has resumed the management of the property.

Other parts.—A mill has just been completed on one of the Windward Islands, and I hear a Company has been formed to put up a large one in Vanua Levu and another Company, a smaller one, on the Navu.

Tea.—I have been manufacturing small quantities here, and the tea seems to be liked. There's a local demand for it, and all we can make goes at present to supply that demand. I should much like to get hold of a book or pamphlet containing information, of cheap machinery, viz., rollers and drying-off apparatus capable of turning out small quantities of tea. Do you know of any cheap and suitable machinery capable of rolling, and making, say 200 lb dry tea a day, without going in for expensive Siroccos, etc.? We have no disease amongst the tea as yet that I know of.

Weather for the last year has been horrible. The year not only set in very rainy, but it continued raining more or less throughout the year, destroying our coffee blossoms. The rainfall, as I mentioned before, was 183 against 110 the previous year, and greatly exceeded the one before that again.

North Taviuni.—Rainfall and temperature for 1883. Elevation 1,000 feet above the sea:—Temperature.

On the Navua I heard the weather had been as bad, if not worse, throughout the year. At present we are passing through the hurricane months. Last year we had two slight and one stiff blow, the latter doing a great deal of damage. This year it is hoped we shall escape.

Coffee Curing Mill.—Did good work. Unfortunately we could not tax it very much as the quantity sent down to cure was but small. Considering it was the first time the manager had ever done similar work, he did it well, but still it was not up at all to the Ceylon standard, as a lot of silver skin was left on most of the beans. It is to be regretted, the proprietor has not more work for it to do after going to the expense of its erection: we can only hope better days are in store for him, as well as ourselves.

Labour This vexed question as usual occupies most attention. Recruiting vessels have been most unfortunate this year, but few of them making more than two trips and even then returning with a short complement. Vessels have found it useless in most cases to go to the New Hebrides, the nearest ground for Polynesians, as the men won't readily engage and have gone to the Solomons and to New Britain and Ireland. I saw a lot of newly arrived New Britain men at the depot when I was at Suva: they were a fine lot of men, well formed and looked strong, but I hear they catch colds and coughs very readily and are in reality delicate. If so, it is a great pity, as the weather here is so changeable. On the Navua where there are a good many at work, I heard that in rainy days as many as 20 and 25 per cent were laid up. Government did not send out a single vessel during the season, all those that went were sent by private enterprize, by planters clubbing together. In some cases where vessels returned with only a few men, in one case I know only five came; the loss experienced was very heavy. In the case I refer to, the five men must have cost over £150 each! It has been such a risky undertaking that I doubt if many will embark in it next season. Companies and large proprietors with sugar mills must go on, either by getting the Polynesians or coolies, much as they may dislike the latter. The Polynesian business was so very expensive, that the Colonial Sugar Company have thrown it over altogether and are going in for coolies and Chinese. Some of the other companies also wish to get the last named labour, but as yet they have not settled the preliminaries with the Government. At present, if Chinese are introduced by anyone, they can leave you at the expiration of twelve months. This of course would never answer, and those who are willing to introduce that class of labourers wish the Government to pass some ordinance to compel them to serve as an indentured labourer for say, three or five years. I dare say, some arrangement of this sort will be arrived at. Chinese can be got, so one of the mill proprietors told me who had gone into the question, to come here and work for 12s to 15s a week, finding themselves. Till this question is settled coolies must be employed and a lot of requisitions for them have been forwarded this year. Coolies have, and are still causing a lot of trouble wherever they are employed, and will continue to do so as long as every trivial complaint of theirs is listened to, and men not punished when bowled out in instituting lying cases. I took care during my travels to go into the cooly question, and what I heard in the Rewa opened my eyes. The percentage of coolies really in (a small one by the bye) those who shammed illness and those who were lazy and would not go to work was from 40 per cent, the minimum, up to 50 the maximum. These returns, I know, are correct, because the managers themselves informed me. Just imagine 45 per cent of your labourers in their house every day! men who have cost you over £20 a head and are indentured to you for 5 years. The loss by their not working alone amounts to a considerable sum, leaving alone work uncompleted and getting behind. I remonstrated and said: "Why not take them before the magistrate and get them punished?" The answer was: "This had been tried over and over again. Managers had taken as many as 40 cases and over against their coolies in a day. The men would be found guilty and fined say 1s (the maximum is 3s, and this is not often inflicted). They would pay their fine and go back and be just as bad as ever." Travelling is so difficult and takes up such a long time, that the managers naturally say they cannot afford the time to go and be constantly instituting cases against the men, especially as it seems to have no good effect. If a man has to go 20 miles or more to court, it takes him a day to get there, as the roads are so bad; or, if, he can go by river, he has the tide against him sometimes, or there's a flood on; then there's the probability of the cases not being tried the day after his arrival at court; then there's the same bother getting back: in all three days are wasted at least. Well, of course, a manager cant be constantly at this little game neglecting his work most probably in his busiest time to get his coolies fined 1s, 2s and 3s each, with the certainty of their being just as bad as ever on their return to the plantation. If the coolies were to get a severe punishment for, say, the 3rd conviction it would be a different thing, it would then be worth one's while to go down constantly until the cooly got a proper punishment, saw it was no good malingering, and went to work.

Another thing which one looks forward to, more than any thing else out here, if he's always at court punishing his men who wont go to work, he gets a bad name, gets marked by the Government and most probably gets the sack by his employer. Cooly malingering is a serious evil and ought to be put down, but I don't see any chance of its being put down as long as a cooly can pay his fine and go back to his plantation. The cooly according to the ordinance, must get the option of a fine, before he can be sentenced to imprisonment.

The new Fijian labour ordinance, which I referred to in my last, has been passed and is in force now. Whether Fijians will be readily procurable under it, remains to be seen. There has been a regular squabble over the ordinance, between some of the unofficial members and the Governor. The former say, that alterations &c. which were promised have never been inserted and that they were misled by the Governor throughout the Council sittings. One member in consequence resigned his seat and another wrote a very stiff letter to the Governor on the subject, a copy of which was inserted in the *Fiji Times* and which you doubtless saw. The writer in question accuses the Governor of having been so verbose and ambiguous in his speech as to have misled him and others, and concessions which were fought for in the ordinance and which they took for granted, were allowed, were in reality withheld. The letter to say the least, was very hot.

A. R. W. I see, has a hit at me about the labour question, but really I can't make out what he is driving at. If he means to insinuate that Ceylon planters can treat their coolies anyhow because, as he says, they come over to Ceylon in a state of semi-starvation, it only seems, he does not know what he is writing about. It is not worth while defending the Ceylon planters. Their kind treatment of their coolies is too well-known to require anything being said to uphold their character. For every labourer employed in Fiji there have been thousands employed in Ceylon, and one *very seldom* hears of any cruel treatment towards a cooly, although there are magistrates everywhere—*verb. sap.* If he means to say that planters in Fiji, who were formerly in Ceylon, are in the habit of ill-treating their men, then again I disagree with him and say they treat their labourers as well, if not better, than the Fiji planters. The case which seems to have stirred up A.R. W., and which, he says, I chose injudiciously, was that of a planter who had put on four mustard plasters in a Fijian labourer's chest who complained of pain there and then put his legs into a sack, tying the mouth loosely round the man's waist. The Fijian complained to the magistrate, saying that the bag was tied round his neck and round his waist as well, thereby preventing his removing the plasters which caused him pain. This yarn, those who know the Fijian character would readily disbelieve. I saw the planter after he came out of prison (I mentioned in my former letter he got two months' imprisonment with hard labour for what he had done) and he told me what he stated were the actual facts of the case, and I see no reason to disbelieve him. He stated that the Fijian had been ill for some time, complaining of a severe cold in the chest. Several remedies were tried ineffectually, so one day he put on four plasters, two of them being very small ones, covering the man's chest well with them, and, as the man complained of having cold feet, he, the planter, picked up the nearest thing at hand which happened to be a bag, told the Fijian to lie down and then put his legs into the bag tying it loosely round the man's waist to prevent its slipping down. The Fijian took the bag and plasters off himself, so I was told by the planter, in about 20 minutes time, but, laid *his* version of the treatment received to the magistrate, whereby the planter got sentenced to two months with labour. There was a lot of ill-feeling against the planter on the estate, owing to scarcity of food, &c., or else I don't suppose there would ever have been such a case. Now, this planter happened a long time ago to have been in Ceylon for less than two years altogether if I remember right, but has been in Fiji for about 12, therefore according to A. R. W.'s reasoning he 's a Ceylon planter and has learned his system of working men there! And because, to carry his reasoning further, the owner, or part owner rather, of the property where the mustard plaster business occurred was a Ceylon planter for about two years, and because I happened also to have been in Ceylon and write to you about it all, therefore we are all in the habit of cruelly using our men. If he does n't mean this, I beg his pardon and must acknowledge I don't know what he means.

Leaf-disease.—Whilst up the Rewa, I took the opportuh i s of visiting Mr. Storck at Belmont to have a look at ui cure going on. He took me to some Liberian coffee trees 4 in number, all in a row, and under one of them I saw the tin which he so graphically describes in his letters,, with the mixture in it. I examined the tree, of course, and was sorry to see spores fully developed, so they appeared to the naked eye, although Mr. S. assured me they were inert and the leaves were yellow as if the disease was in the tissues, but had not developed outwardly at that time. The tree which had the tin under it had more disease and more signs of it than the other 3, and it struck me as being naturally a weaker and more backward one than its companions. After what I saw, I must candidly say I have no faith in Mr. Storck's treatment. Mr. Jardine's experiments ought finally to settle the question.

Miscellaneous.—Suva, the new capital, is quite a large place now. When last there, 4 years ago, one might count the houses on one's finger ends. Now it has several fine stores, hotels, private residences, etc., and presents quite a busy aspect. The Governor lives there and all the Government offices have been removed there, from

Levuka.—The latter place is very quiet and very different from what it used to be, I have been looking out for my copy of the *Agriculturist* with the map and Mr. Vincent's report on the Ceylon forests, but it has not reached me: was it posted? [Yes—ED. C. O.]

More steamers come from the Colonies here now than formerly. Two come regularly from Australia and one from New Zealand.

Wishing Ceylon a prosperous New Year and many of them, yours truly, A. J. S.

RHEA FIBRE MACHINE.

DEAR SIR,—Can you tell me what the probable cost would be of one of H. C. Smith's machines referred to in the *Tropical Agriculturist* for February? Will you also kindly tell me whether this fibre-plant can be got in Ceylon? We ought to be able to grow it. Pineapple grows wild with us in this country. Pineapple silk may, some day, become an industrial export from Ceylon with the aid of this machine—who can tell?—Yours truly, ?

MR. W. CAMERON'S TEA DRYING APPARATUS.

Ythanside, Dimbula, 20th Feb. 1884

DEAR SIR,—Your learned correspondent "J. B." in replying to my defence of the "Drier," begins another attack by complimenting me on the possession of a calm philosophic spirit. I thank him. The subject is truly a *hot* one, but so important that one may well keep *cool* over it. Volumes have been written on the subjects of heating, ventilating, &c., still the laws which govern these are far from being popularly understood—nor are they easily put in practice.

It is curious to think that the common chimney was introduced so late as in the time of Elizabeth, and it is marvellous to think on the waste of fuel which has been allowed to go on since the great development of arts and manufactures in the past half-century. So important is this that some of our best scientists have been seriously employed in trying to determine the probable duration of the English coal-fields!

To descend from great things to small: there is many an old worn out coffee estate which will yet grow splendid tea, and one of the difficulties will be the finding of fuel for the manufacture of it. This want will be met somehow, but the best way of meeting scarcity is to economize. I offer "J.B." no apology for answering his remarks at some length, careless as I am whether he or I prove right—it is the truth that we want to get at—but "J B." must give me fair play.

Now I have to complain that he seems to have had his mind so fixed and decided about the merits of the "Clerihew apparatus, that he did not examine my plans but in a very superficial way, evidently overlooking the fact that I use a greater amount of iron-heating surface than was likely ever employed in a "Clerihew" of the same dimensions In the ground plan is shown a large corrugated cast-iron plate, for the flames of the furnace to play on, then the covering of the brick flues is formed of sheet-iron, amounting to about 150 square feet—the brick-heating surfaces are fully double that. The whole is covered with broken stone, the hard granite of our hills—with quartz. These materials being in contact with the flues, form a large heating surface, for the air which is freely admitted below. Air is one of the lowest heat conductors, being only capable of being heated by convection, or carrying, *i. e.*, the portions in contact with the heating surface get heated and rise, giving place to others, much in the same way as water is heated. To conclude the description of the "Drier," the flues in the aggregate have an area about eight times as much as would be necessary for merely carrying off the products of combustion, decreasing thus the velocity of the smoke, &c., to allow of the radiation of the heat, which is kept in constant action by the cool air admitted below.

Now for *bricks*, "J. B." is quite right that brickwork is send for the retention of heat, and it has an advantage over stone in its low degree of expansion and so does not split, when used in furnace-work. But there are *bricks* and *bricks*. Soft porous bricks form the best low conductors of heat, while those of hard, close texture, conduct heat sufficiently well, to have been used for the heating of large plant conservatories, till quite recent times, when hot water piping has superseded them, but for other reasons than the difference of power in heat conduction.

What is attempted to be carried out in the "Drier" is the saving of fuel, consistent with effective working. There is no way of accomplishing this but by increasing the heating surfaces, regulating, at the same time, the distribution of the heat by the use of materials of different conducting powers, such as brick, iron and stone. Doubtless, the same effect can be obtained, by expensive arrangements, in metal; but why not do the most with inexpensive materials on the spot? Another point to which "J. B."'s attention may be directed. An apparatus of the "Drier" kind does not require regular firing, which in practice is a great advantage. When once heated, the drying goes on till the whole mass has cooled down to air tempeature. So there need be no night work, and a chimney damper keeps the flues from wasting the heat, at all times when the firing is discontinued.

I repeat that the loss of heat is just what is necessary for the drought of the flues. I have not tried it with the thermometer, but one can hold his hand in it. If it became hotter I would stop firing for some time. It need not be much hotter than the air heated for the drying-house, if properly constructed.

"J. B." will now see that I could not very well have this kind of heating apparatus in the roof of my drying-house, even to secure the problematical advantage of drawing the heated air *down*, as in the "Clerihew." I do admit that to draw the air *down* is the only way that the "Clerihew" could be worked: were it admitted below, it would simply strike against the nearest part of the floor, and with a scorching and destructive effect.

But to consider "up" and "down." I cannot see that, if the heated air is at the necessary drying temperature, equally diffused on either side of the materials to be dried, and under *mechanical control*, that it would make the slightest difference whether it was drawn *up or down*?

We need not look for the advantage of *drawing down* to lie in the gravity of the steamy air, as, while it is in the condition to hold the maximum quantity of vapour, it is in a condition to rise, as well.

I quote from a standard work on the subject:—

"Tension of vapours."............The maximum density of vapours is dependent on the temperature; it increases rapidly as the temperature rises. This is well shown in the case of water. Thus, taking the specific gravity of atmospheric air at 100° C. or 212° F.—1,000 that of aqueous vapour in its greatest state of compression for the temperatures will be as follows:—

Fahrenheit.	Specific Gravity.	
32°	5,690	
60	14,108	
100	46,500	
150	170,293	As above air.
212	625,000	1,000

I think, from the above figures, that a moderate temperature with a quick circulation will be found best for drying; and that the air must be discharged while hot enough to carry off the vapour economically. It is quite clear that the air is hot enough to rise very rapidly. When it is charged with all the vapour, possible, to be safely taken from most fruits, seeds, &c., likely to require drying by this means. Probably about 100° F. is about the heat that may be safely used for general purposes. At 120° coffee was bleached by the "Ceribew," which likely led to the abandonment of that form of drier. I suspect there had been a great want of circulation from malconstruction, resulting in a sort of low *stewing*. A high temperature with the attendant vapour would be sure to bleach some of our products. Want of circulation with too low a temperature might induce a sort of fermentation. These remarks refer to ordinary drying.

One more point, which "J. B." may think of. It is obviously wrong to draw vapour through what is already dried, or even through the materials being dried. If we can get each surface to clear off its own vapour, the greatest effect, will be obtained. This is so far met in the "Drier" by keeping the temperature a little higher at the furnace. end with a freer influx of air, then the current of vapourous air is pretty equally drawn *along* the six floors, and neither "up" nor "down" altogether, but up and along. Apologizing for taking so much valuable space, I am, yours faithfully, WM. CAMERON.

TEA AND CACAO IN TRAVANCORE.

Travancore, 22nd Feb. 1884.

SIR,—In your overland issue of the 7th inst. you refer to giant tea bushes on Abbotsford. It may interest your readers to know that Travancore is not far behind. When spending a short holiday there last month, I have seen a tea tree measuring in height 23 feet 5 inches, and girth of stem close to the ground 27 inches, and two feet from the ground 22 inches. These measurements, you will allow, compare favorably with the Ceylon giants. The Travancore planters are beginning to wake up to the necessity of having more than one string to their bow, and are now going ahead with tea: the older and more "canny" ones prefer giving it a fair trial in virgin soil to planting up the existing coffee land; the latter, no doubt, is more economical, but as to future results, I should think, bear no comparison to the former.

Coffee prospects are, so far as I could judge, favorable, and I think there will be fairly good crops all round. Leaf-disease has been knocking about as usual, but has not done more damage than on previous years.

Cacao promises exceedingly well, and will, I believe, be a great success. I have seen some trees 3½ years old, with 10 to 30 pods on each.

The railway survey through the Ariankow Pass is now being pushed on rapidly and will very soon be complete. There is an alternate route *via* Nagercoil in the south. The Travancore Government have not yet decided which to accept, but everyone with any knowledge of the country give preference to the latter.—Yours, &c., TRAVELLER.

CINCHONA BARK: DISCREPANCY BETWEEN COLOMBO AND LONDON ANALYSES.

Colombo, 1st March 1884.

SIR,—In September last a small parcel (1,280 lb) cinchona officinalis sharings from Ballagolla Ella, Haputale, was analysed in Colombo, and the result stated as 1·09 per cent crystallized sulphate of quinine.

The bark was shipped in the "Duke of Sutherland" and sold in Mincing Lane at one shilling per lb., a very high price for the reported quality.

I wrote for analyses, if possible, and, as the sample had been preserved, received it by the mail yesterday. It results according to Dr. Paul in 2·2 per cent of crystallized quinine sulphate, just over double the Colombo yield, besides 0·74 per cent of crystallized cinchonidine sulphate. Annexed is copy of Dr. Paul's analyses.—Yours truly,

SYLVESTER T. RICHMOND.

(*Copy.*)

Dr. B. H. Paul, Consulting Chemist and Commercial Analyst.

Analytical Laboratory, 13, Fenchurch Avenue E. C., and 1, Victoria Street, Westminster S. W., London 29th Jan. 1884.

CINCHONA BARK CERTIFICATE.

To Messrs. C. M. & C. Woodhouse & Co., 30, Mincing Lane.

The sample of cinchona bark received from you on the 24th inst. marked Ballagolla Ella ex "Duke of Sutherland" gives the following results on analyses:—

	per cent.	1 lb. (7,000 grains) of the bark. contains.
Crystallized quinine sulphate	2·20	154 grains
Crystallized cinchonidine sulphate	0·74	51¾ „
Cinchonidine (alkaloid)	trace	

(Signed) BEN. H. PAUL.

TEA PREPARATION IN CHINA.—The tea leaf is the same pretty well all over China, unless it be in the south-western districts in and bordering on Yünnan. The great tea-producing districts are however farther north, bordering in the Yangtszekiang and extending far into the interior. The small garden proprietors and farmers cultivate, gather the leaf and prepare it sufficiently for transport to the coast by native dealers, who go round buying up the produce on the spot. At the Treaty Ports, the European merchant buys from from large dealers, who refire the tea, assort it into grades and otherwise manipulate it. In fact, the "godown" manipulation is supposed to be the most important part of the tea breparation, differant flavours being produced at will, while the Chinese as we know are experts at adding colouring matters in order to give tea the handsome glossy "face" popular in some quarters; while it is well-known now all over the world, how freely they would they would, and do, adultetate, if left to themselves. Experts among Europeans, however, now find it most profitable to give their attention chiefly to really superior carefully-prepared and highly-flavoured teas as affording the most chance of a profitable return. In Canton, teas are artificially flavoured by flowers gathered from a variety of jasmine producing the white fragrant blossom familiar to us in Ceylon. A layer of tea is placed in the bottom of a large basket and a few flowers scattered upon it, then another layer of tea and another layer of flowers, and so on until the basket is full. The flowers are generally placed in the tea in the afternoon and allowed so remain there overnight, when it is found that the tea are absorbed most their fragrance. The flowers are removed by sifting, and the tea then refired to expel any moisture gathered from the blossoms. Both black and green teas are thus scented into the varieties known as "Scented Caper" and "Flowery Pekoe" which are largely used in England for mixing purposes.

DRIED APRICOTS.

TO THE EDITOR OF THE "AUSTRALASIAN."

SIR,—Dried apricots, like dried apples, are much prized in the far-off newly-settled regions in the Australian bush ; and if you or some correspondent would make known the correct process of drying them, a favour of no small moment will be conferred on others as well as on your obedient servant, BARCOO.

[Apricots may be readily dried on trays or sheets of iron in the sun. The trays, &c., are taken in-doors each evening. ED. "A."]

FRUIT DRYING.

SIR,—Can you please inform me of some book that treats on the best method of preserving or drying fruit for exportation, such as apples, &c., and whether you think it is possible to preserve bananas on the same principle. WYCHEPROOF.

[Since the Alden machine was invented in America, numerous improvements thereon have been designed, and such machines are much used. The makers usually send printed instructions for operating, but beyond those we know of no publications on the subject. All kinds of fruits can be dried, but all are not eqnally appreciated.—ED. "A."]

THE WHITE ANT *v.* THE SUGAR CANE.

SIR,—In your issue of the 24th ult. it is stated that the De Lissa Pioneer Sugar Company attribute their want of success to "the persistent ravages of the white ant." Some years ago I was pestered in garden and dwelling by ants of many kinds, and happening to notice the immunity enjoyed in this respect by a neighbouring country storekeeper, he informed me that by mixing arsenic with dissolved sugar he had destroyed millions, and the survivors had "cleared out." I tried the prescription, and was successful. Cannot the sugar company make liquid manure from their refuse, mingle the arsenic, and practically say to the insect pests. CAVE CANEM?

WATTLES.

SIR,—I have a selection that has been rung about two years. A forest of wattles has sprung up nearly all over the paddocks. Can you inform me how to get rid of them? WATTLE.

[Wattle bark being a valuable product, would it not be well to allow the trees to become large enough for stripping, a condition they usually attain in three years. The bark should not only pay for the clearing, but yield a profit besides, if you are not too distant from a market.—ED. "A."]

CHINESE INVESTIGATION OF SORGHUM SUGAR MAKING.

The State and Stripes with the dragon flag of China floated together over the Rio Grande Company's works today, for among the visitors on a special train from Philadelphia were the Chinese Ambassador and two of his Secretaries. For 2,000 years sorghum has been profitably grown as a cereal in the Flowery Kingdom, and if the clear gain of its sugar value can be added to the crop, the fact will be of vast economical importance to the Empire. It was, therefore, no superficial interest which the Embassador and his companions manifested. If they had been sugar experts inclined to purchase the whole concern as an investment they could not have studied the methods and machinery more intelligently and closely. They watched the cane through the rollers, and followed the expressed juice as it was clarified and boiled through the vacuum pans to the centrifugals, and by their searching inquiries kept Dr. Collier and Superintendent Hughes constantly explaining every detail through the entire process. When the day was over there is little doubt that they had a more comprehensive knowledge of sugar-making than any of the American visitors. The Rio Grande Company at present turns the seed into pork, boiling it, and for a change scattering it on the bagasse or pressed cane with which the floors of the pens are thickly covered. The swine, rooting and tramping this into compost, furnish manure for the crop, so that all the refuse, including the rich scum from the boilers, is returned to the soil, and nothing practically is taken from the land except the phosphate of lime in the skeleton of the pork. All this utilization of the waste was carefully inquired after by Cheu Tsao Ju and his Secretaries, as well as by the men of science and capitalists who made up the party.—*Rural World.*

THE SEYCHELLES ARCHIPELAGO.

Reported by U. S. A. Consul Mussey.

DESCRIPTION OF THE ISLANDS.

The Seychelles Archipelago lies in the Indian Ocean, about 1,400 miles south-east of Aden, and 1,000 miles east of the coast of Zanzibar, in latitude 4° south and longitude 55° east. The Seychelles group comprises about thirty rough, rocky, and mountainous islands, surrounded mainly by coral reefs. The group was discovered by the Portuguese in the fifteenth century, taken by the French in 1642, and captured from them in turn by the British in 1814, since which time they have been under the domination of Great Britain. The name is derived from a French explorer, Count Hérault de Seychelles, who visited the islands at an early period in their history.

The surface of the land is extremely rugged and mountainous, and but a comparatively small portion is available for agricultural purposes. Huge boulders lie thickly strewn on the surface everywhere, and great labor and capital must be expended to clear the steep sides of the hills and mountains of stones, trees, and tropical tangle of grass, vines, and undergrowth.

The soil is a hard, red, clayey loam, strong in plant-food and the elements that make a vigorous vegetable growth, and, given the adjuncts of heat, moisture, and almost perpetual sunshine, vegetation flourishes and riots in tropical abundance and luxuriance. The islands are, therefore, green and fresh at all seasons, and particularly so during the wet period, which extends from November to May. During this season, the tropical summer, immense quantities of water fall, the total for the year 1881 amounting to 113·50 inches.

The climate is warm and equable, the extreme range of the thermometer in 1881 and 1882 being only 22°, viz., minimum 71°, maximum 93°, Fahrenheit. The heat is seldom sultry and oppressive, as the air is tempered by the monsoon, which gives a cool breeze rarely broken. The "winter" season covers the months between May and November, and the climate is most agreeable, as the southeast monsoon obtains, and the mercury but infrequently rises above 85°. These islands are too far to the north to receive the frightful hurricanes which occasionally sweep over the sister islands of Bourbon and Mauritius, and even thunder-storms but seldom appear here.—*Indian Mercury.*

THE DESERT PALM.

The following description of the Desert Palm is from an American paper:—"All the tree, except the bark and leaves, are available for paper-making. The fibre bleaches easily, and what is very desirable in a paper-making substance, it felts well and cooks well, as the phrases are. The fibre contains no resinous substance, and therefore turns out a clear quality of paper. Mr. Walker has erected a mill in the Soledad Canon, six miles from the entrance to the desert."

My own immediate object is to attract the attention of experienced men interested in the India n Section of the Society's operations, with a view to raising the question whether it may not be highly desirable to have the *Yucca Draconis* introduced into India. I have high authority for the assurance that this "cactus would grow every where in India."

There is a further incidental excuse for my thus bringing the matter to the notice of Anglo-Indians. Just before the Session closed, Mr. Alderman Fowler—who is always ready to do India a good turn—put a question as to the probable advantage of propagating the esparto grass in that country. M. J. K. Cross replied, in general terms, that the attention of the agricultural bureau should be drawn to the subject. But the proposal at once suggests comparison as to the far greater fibre-yielding qualities of the *Yucca Draconis;* for whereas, I believe, the yield from esparto is only thirty per cent of fibre, the *Yucca* is said to yield sixty per cent. Then, again, the esparto requires so much and such tedious manipulation in its preparation for the market, that the value to any producing country of the Californian plant must be immensely greater. It is true that the tedious peeling and sorting of the esparto might afford suitable means of utilising the illimitable resource of domestic industry that India possesses. Hence it may be well worth while for the esparto to be cultivated in or near some of the more thickly peopled provinces of India; while the *Yucca Draconis* should be encouraged in the "deserts idle" that, mainly because of ruthless denudation, are so prevalent in vast tracts of Upper India. And, if the *Yucca* can be cultivated within reach of rivers or canals, which would afford cheap means of transporting it to the deltas or coasts, where it could be "pulped" and prepared for export as "half paper stuff," it seems to me that a very important new industry might, at comparatively small outlay of capital, be speedily established in India."—*Indian Mercury.*

DAM-MAKING.

For the benefit of those readers of the *Queenslander* interested in dam-making, I shall give directions how to make a dam which I have seen tried with great success. Select a gully running not more than a mile; choose a place where a level foundation can be got, if possible just below a bend in the gully—say to want a dam to carry 8 feet of water. Plant a stick 11 feet high in the lowest part of the watercourse, and level from side to side. In doing so shift the level back until you sight the top of the stick and the ground on the far side. You do not want any staff level or civil engineer to do this; use a common carpenter's level, and sight along it from bank to bank. Having done so take this as the centre line; then lay off a puddle trench to a 2 to 1 batter all the way across. Thus, allowing the bank to be 10 feet wide on top, and the depth at centre 11 feet, the puddle trench is 27 feet on the up-stream side of centre line at the deepest point, and so on as the depth varies. Sink the puddle trench 3 feet deep, and about 2 feet 6 in. wide all the way across. If you strike sand-drift you must sink through or give up the idea of a dam at this place. Fill the puddle trench with clay, rammed in 6 in. layers, up to 12 in. above the original surface of the ground. If the clay is dry moisten it till it sticks. When forming the bank excavate the muck from the up-stream side (thus giving additional depth), but don't work within 20 feet of the puddle. Use tip-drays, and work all from one end, as this traffic over the bank at time of making tends to consolidate it and make a good job. Let the muck take its own $1\frac{1}{2}$ to 1 batter on the down-stream side. When the bank is finished sow couch grass all over, and better fence temporarily to keep cattle from playing on it.

In making the bywash there must not be any messing, as this is the most particular part of it. Use your level from the top of the dam-head, and sight up the gully on to the lowest of the two banks, and toward the bend in the gully. In doing this make sure you are correct. Turn your level end for end, and sight from both points at the spot where your eye catches the ground. In the bend start your bywash, making it 3 feet deep at this point; carry it out toward the gully with a fall; let the highest point of the bywash be 3 feet below the dam-head. The width must be determined by the quantity of water the gully carries in flood time, but above all be sure and have it wide enough. Throw the muck excavated from the bywash on the side next the gully, where it may be readily got to make up the bank as it consolidates. Don't give the run of the bywash too much fall; 2 in. in a chain is enough. Have a clear 20 feet of solid ground between the end of the dam and the inner edge of the bywash. If a dam is built as I have directed, it will be safe and serviceable. It is a new plan to have the puddle wall at the toe of the bank. Yet I have seen splendid water stores made in this way, and I am prepared to undertake the construction, and stand the risk (but there's none). The cost of this dam varies according to size. It just means so many cubic yards of muck, to be shifted at so much per cubic yard, and the cost can be calculated beforehand.—*Queenslander.*

CINCHONA IN THE NILGIRIS.

Situated on the south-eastern slope of the Nilgiri Hills at the top of the Ouchterlony Valley, and directly overlooking the Wynaad and Mysore districts, are the Government Cinchona plantations at Nediwuttum. These plantations, about 20 miles distant from Ootacamund, have hitherto furnished the principal supply of Cinchona bark exported from Southern India. The plantations are three in number, viz., the Nediwuttum estate, the Wood estate, and the Hooker estate—the latter named, I believe, in compliment to the present Director of Kew Gardens. The amount allowed by Government for the keeping up of the plantations has of late years been principally expended on the Nediwuttum plantation, the two others being at present in a semi-abandoned condition, mainly attributable to the fact that the surface-soil containing the rich vegetable humus so essential to the growth of the Cinchona has been nearly all washed away by the heavy rains of successive seasons, and no regular attempt has been made at improving the soil by applying manure or any fertilizing matter.

The Nediwuttum plantation consists mainly of the red-bark tree, Cinchona succirubra, but contains likewise a good sprinkling of the crown bark, C. officinalis, and grey bark, C. micrantha, as well as C. pubescens, a well marked hybrid between the two former, and a few C. calisaya, a group containing such a host of sub-varieties and forms merging more or less into each other as to have formed the basis of a never-ending controversy concerning the proper name due to each particular form; and it is needless, perhaps, to add that the names applied or suggested are almost legion, whilst each fresh one only adds to the existing confusion.

Two well-built bungalows exist on this estate, as well as two of smaller dimensions for the use of the clerks and assistant overseers, the extensive drying sheds being well worthy of a visit. Here the Cinchona bark, after being collected from the living trees by the alternate stripping system, or the Java process of scraping or uprooting, is dried by fire-heat, and securely packed in bales of 100 lb. each, and marked ready for the market. A new system of drying and packing houses is now in course of completion, the main building being filled with bark on the occasion of my visit for the first time. Owing to some defect in the building of the flues generating the dry heat necessary to cure the Cinchona bark, the fires did not draw satisfactorily, and the flues not being properly set, had burst, filling the building with smoke, much to the deterioration of the bark contained therein, the brickwork and woodwork in general having been done by cheap contract labour improperly supervised, leaving much to be required before the buildings approached perfection. Near the drying sheds is erected a long span-roofed propagating-house, heated also by flues; this is used principally for the propagation of C. pubescens and C. Ledgeriana, the latter taxing the abilities of the officials to the uttermost from its shyness of propagation when in the younger stages of growth.

Fully one-third of this plantation has been uprooted during the last two seasons, and is now being replanted with C. pubescens, a fact which speaks highly for the far-sightedness of the manager in charge, as undoubtedly this will be the Cinchona of the future. At the elevation of 5,000 feet—the altitude of the Nediwuttum estates—in a plot well sheltered from the south-east monsoons, were to be seen two fine specimens of the "hard Carthagena" Cinchona, C. cordifolia, introduced to the Nilgiris by Mr. R. Cross, in 1880, from South America. These were fine sturdy young plants, upwards of 4 feet in height, the result of eighteen months' growth. It is a matter for regret that no energetic attempts have been made to extend the number of plants of this new kind, or that of its fellow novelty, the Calisaya of Santa Fé, not more than thirty or forty being alive at the present time, although most easy of propagation—private planters, from some unaccountable misunderstanding, being denied plants of these species when they apply to the responsible authorities for them, even though they may possess every appliance for propagating them successfully and extensively. Three or four large nurseries are kept well filled with plants and seedlings for supplying the estate and neighbouring planters who purchase at the very moderate rate of R5 per 1,000.—W. J. KEMP.—*Gardeners' Chronicle.*

IS IT GOOD TO DIG ABOUT TREES?

This is a question that will very well bear discussion. We know that of old tne question was answered practically in the affirmative in the parable of the unfruitful tree, where the head gardener pled for the tree that it might be suffered to remain until he had dug about the roots and manured it. There would probably be ninety answers in the affirmative to ten in the negative if the answer were asked offhand. But when we come to look around us and find that there are trees growing in certain places, green to the utmost point of the tallest branches, but which trees never are dug about the roots from year to year, whilst other trees that are regularly dug about, perhaps twice or thrice a year, with the result of a sickly habit and poor yields of fruit, it begins to make one doubt whether after all it may not be better, in some cases at least, to leave the trees a little more to nature. A very large number of our-fruit-trees—notably the orange—send out innumerable fibrous roots close to the surface, and every time the soil about these trees is dug, the spade cuts away or mutilates these roots, so that the foliage is either not sufficiently nourished and drops off, or an excessive call is made upon the few remaining roots, and as a matter of course the points of the shoots or branches fail and die. Such a phenomenon is often witnessed where trees are planted upon very stony and unsuitable ground or upon a shallow soil possessing a stiff subsoil of clay. The roots cannot get down deep enough, and the supply of moisture in dry weather is not sufficient for the growth that was made in spring; therefore some of the growth has to be sacrificed, and in a very few yers such trees assume an aged and worn-out appearance.

There are a very few persons who advocate a deep and thorough breaking up of the soil in the first case, but particularly retaining the relative positions of surface and subsoils, and then leaving the orchard alone, except as to weeding and pruning the trees. Some, indeed, go futrher, and maintain, with much probability in their argument, that the surface should be planted with grasses, which by permeating the soil, and through the operations of worms, &c., keep the surface aerated and sweet, and give the fibrous roots of the trees every opportunity of ramifying the earth. Once every year they wood give a good top dressing of old leaf mould or thoroughly decomposed manure from the stable, but beyond this and pruning they would do nothing. It is also maintained that the grass keeps the roots of the trees shaded and cool, but this office would be quite as effectually performed by the foliage and branches if the tree were in proper health and vigour. One great fault in some fruit-growers is that of trimming up the stem to make a tall tree, which exposes the trunk of the tree to the fierce rays of the summer sun, by which the bark becomes baked, hardened, and incapable of properly conveying the sap, and the roots are at the same time dried up from the same cause. As the tree gains age, the effective working fibrous roots are extended further and further from the bole or stem, and to properly shade these roots the branches should be near the ground and extend a considerable distances around. There are certain plants that will grow beneath the shade of trees, and if planted under a young tree it will be observed that the plants near the stem are stunted and dwarfed, while the outer rings increase in vigour as they extend from the centre. With an older tree a contrary effect is produced, the plants nearer the stem are full of vigour, whilst the outer rings dwindle away to the smallest size. This is due to the fact that the young trees have extended their fibrous root to only a very short distance from the stem, and of course absorb all the moisture and nutriment from the earth beneath the other plants, but under the older trees the opposite is the case, and the outer plants are drained, whilst those near the stem of the tree gain a full supply. Where the trees naturally send their fibrous roots to a good depth below the surface, it is highly probable that the practice of digging about the tree is beneficial; but it certainly is opposed to common sense to suppose that the annual destruction or mutilation of the effective feeding roots of a tree should promote its health and luxuriance. On the contrary, it appears calculated to inflict serious injury, and the dying away of the topmost branches of peach, apricot, and plum trees might perhaps in most instances be attributed to this practice. A good mulch of old litter around the roots of an old tree—not round the stem—has very often prolonged its life and vigour, whilst digging away its roots would have inevitably killed it.—*Adelaide Observer.*

THE BAMBOOS AND THEIR USES.

Having occasion to look up some matters relating to the Bamboo tribe of grasses, we were reminded that, after the cereals and the forage plants, no grasses were so useful to mankind as these. We have often wondered that no attempt has been made to cultivate the larger species in this country; a few, dwarf kinds, six or eight feet high, have been introduced as ornamental plants, but there seems to be no reason why the tall and useful kinds should not have been grown in the southern portion, at least, of our country, and we have no doubt that some may be found that will succeed in the Middle States. We have one native species of the Bamboo tribe, the cane (*Arundinarian*) which forms extensive brakes in the Southern States, and extends to Virginia and Southern Illinois. As several of the gignatic Bamboos grow in the colder parts of Japan, and others are found at an altitude of several thousand on the Himalayas, it is highly probable that some species are sufficiently hardy to succeed over a large portion of our territory. There are some 120 species of the Bamboo tribe, divided into about 20 genera; these are mostly natives of Asia, but one has been found in Africa, and several in South and Central America. The larger Bamboos grow from 30 to over 100 feet in height, and from 6 inches to a foot or more in diameter; like other grasses, the stem is marked by joints (nodes) at which point there is a transverse partition in the otherwise hollow trunk. These joints, from which the leaves arise, in time become bare below and give a peculiar appearance to a forest of Bamboos. The leaves are small in proportion to the size of the plant, being rarely much over 18 inches long, and 2 to 3 inches wide; are clustered at the top of the stem. When growing in an isolated clump, the leafy tops of the tall stems curving gracefully outward, the whole resembles a huge sheaf and is a picturesque object. The flowers are in branching panicles, and individual spikelets often being very small, not larger than those of the Oat, though larger in others; the seed is about the size of a grain of rice. Some Bamboos flower annually: others require 20 or 30 years to become sufficiently mature, and with these, the stems often become so much exhausted that they die after producing a crop of seeds, new stems springing from the roots. On more than one occasion the seeding of the Bamboos has adverted a famine; one of these was in 1864, in Soopa, a district on the west cost of India; it is stated that some 50,000 persons came from other districts to collect the seeds, which formed in many cases their sole subsistence. The leaves are used to cover the roofs of houses, to stuff beds, and afford a forage for horses. To enumerate the uses to which the stems of Bamboos are put would be as difficult as to catalogue the uses of wood. In some eastern countries, the stems enter largely into the construction of the house, and of most of the furniture within it. They serve as the masts and spars of the Chinese junks, and when split are the material of the sails, while the rigging is made from the fibres. Indeed, stems of different kinds and sizes serve from walking canes and sticks for supporting plants, up to nearly every purpose for which we employ scantling. The joints in the larger stems are from one foot to over two feet in length, and from 4 to 12 inches in diameter. These are sometimes nearly solid, while in others the hollow portion is much larger. They are converted into a great variety of receptacles, for solids and liquid, and serve as baskets, boxes, barrels, jugs, etc. Split in various degrees of fineness, the stems afford the material for mats, blinds, screens, etc.; the fibre makes strong cordage, and is good paper stock. The stems even afford an article of food, the young tender shoots being cooked and eaten. Some of the more tropical Bamboos bear, what is remarkable in grasses, a berry-like fruit. An envelope that surrounds the pistil, in some genera, becomes fleshy as the grain ripens, and in one species is, when mature, " the size of a largish pear;" this, when cooked, is edible, though without much flavor. Though Bamboos grow wild, the Japanese and Chinese at least, do not trust to chance for a supply of so important a plant, but cultivate it; in their languages are treatises entirely devoted to Bamboo culture.

Since the above was in type, we had a conversation with a young Japanese friend upon the Bamboo. He informed us that a year or two ago a relative of his sent something like 200 different varieties of Bamboos to our Department of Agriculture at Washington. Inquiry was made at the Department concerning these plants, in order to learn where they had been planted, and what success had attended the experiment. Reply came from one of the officers that all that was known about the Bamboos was the fact that they had been received. The former Commissioner, it is supposed, sent or took them to some Southern State, but there is no record of the matter at the Department. If any of our Southern friends know of where these Bamboos were planted and how they have succeeded, we shall be glad to hear from them.—*American Agriculturist.*

BUNT AND SMUT.

The names bunt and smut are indifferently applied to a class of fungoid diseases which attack all grain crops more or less. The chief predisposing cause of the appearance of these parasites is a warm, abnormally wet summer. The bunt of wheat, *Tilletia caries*, also known as brand, black-ball, and pepper-brand, attacks every kind of wheat, spelt having less to fear from it than other sorts, and winter less than summer wheat. The fungus fills up with its spores the whole of the ovary, so that at the time of ripening there is found in place of the grain an elongated, black, greasy body of most disagreeable odour. Smut, *Ustilago carbo*, more especially attacks oats, so that the phrase "smut of oats" has become familiar. The disease first shows itself on the organs of fructification, the epidermis of which is irregularly ruptured in a great number of places, a black powder then appearing through the slits. The different parts of the flower are attacked in a very unequal degree. The whole of the parenchymatous tissue is often destroyed, and so much is this the case in winter barley, that of the whole ear the common axis of the inflorescence alone remains, while in other cases, as in oats, the seed only is destroyed, the pales or glumes enclosing the grain remaining unaffected. During the progress of the disease, and especially towards its later stages, the black dust consisting of the spoals also emerges from the culms beneath the flowers, and even from the leaves. *Ustilago Maidis* is the smut of maize, which converts the grains into large tumours filled with the black dusty spores, the diseased part frequently exhibiting swellings as large as the fist, and sometimes the size of the head. *Ustilago occulta* fructifies in the leaves and haulms of the rye, while the millet-smut, *Ustilago destruens*, destroys the whole of the flower, even before the ears have emerged from the leaf-sheath. Besides wheat, barley, oats, rye, maize, millet, and dari, various species of grass are liable to the attacks of bunt and smut, so that the disease is often very widely spread.

These parasites were with rust *Puccinia graminis*, long included by fungologists in the division Hypodermii on account of their vegetating beneath the epidermis of the host-plant. Recently Ferdinand Cohn, a celebrated German botanist, has advanced reasons for assigning bunt and smut to a separate order, the Ustilagineæ (from *ustus*-burnt, destroyed), the rust being relegated to the order-Æcidiomycetes, this and the one already mentioned form, ing two orders of the highest group of fungi, the carpo, sporeæ.

The life-history of the parasites now under consideration is comparatively simple. When one of the microscopic spores germinates it gives rise to a delicate hyphal tube, the promycelium, which soon begins to branch, and after a while the branches conjugate, or become fused together; the place of union swells somewhat, and forms what is called a sporidium, and this developes the delicate weft or mycelium of branching hyphæ, which can always be found by the aid of a microscope beneath the epidermis of the infested part. The free ends of the mycelial hyphæ become constricted off into a series of spores which, one after another, fall away, and by thus establishing its independence within the host-plant each spore is capable of giving rise to the same series of changes as those we have just described. The life-history of the Ustilagineæ may, therefore, be represented thus:—Spore—promycelium—conjugating branches—sporidia—mycelium—spore.

The manner in which bunt and smut are enabled to infect the growing plant is by the introduction of the spores in the seed. Grains of wheat, oats, &c., may look perfectly sound, and yet may contain a few of the minute spores; these germinate at the same time as the seed, and, as the young plant grows, the mycelium is carried up with it, and vegetates most luxuriantly in the delicate parenchymatous tissue of the inflorescence, absorbing all the nutritive juices sent up for the nourishment of the grain, and producing at a prodigious rate crop after crop of sooty spores, which sometimes entirely usurp the position of the grain. The latter retains its shapes, but when pressed between the fingers it either crumbles like a mass of soot or emits an unctuous black pulp, which smells like putrid fish. In the process of harvesting, and in a boisterous wind the spores get scattered broadcast, and thus it becomes a difficult matter to insure that any grain that has grown in the neighbourhood of a field infested with bunt or smut shall itself be entirely free from the contagion.

It has long been known that bunt and smut are transmitted through the seed, and all remedial practices are based on this fact. The grains intended for seed are washed or pickled in various solutions before being sown. The uses of corrosive sublimate and arsenic for this purpose are now abandoned, because, though they destroy the spores, they also impair the vitality of the seed. A strong solution of Glauber's salt (sulphate of sodium) is undoubtedly of value, but by far the most useful agent is blue vitriol sulphate of copper), which is a blue crystallised substance, prepared by dissolving the worn-out copper plates from ships' bottoms in sulphuric acid. The blue vitrioil is powdered, and two ounces are dissolved for each pint of water, one pint of the solution being the quantity employed for dressing one bushel of wheat. The grain is laid on the floor, and while being spread about with a shovel, the solution is sprinkled over it and is absorbed, and so kills the spores without affecting the vitality of the grain. The application of sulphate of copper as an antiseptic agent in this way will probably be much extended, for an agricultural chemist has very lately adduced some valuable experimental evidence in justification of the use of blue vitriol.

Bunt and smut are, as we have shown, very widespread in their ravages, not only the cereals, but many grasses, and even other plants quite outside the order of natural Gramineæ being liable. Of the cultivated cereals, rye is perhaps attacked less frequently than any of the others; but Nature compensates for this in the fact that rye is most subject to the attacks of the dangerous ergot. The flour from bunted wheat will always fetch a price; it is generally used for making dark-coloured foods, such as ginger-bread, and no harm is known to arise to those who eat of it.

In conclusion, we may compare bunt and smut with rust. The two former have but one kind of spore corresponding with the teleutospore of rust. Rust requires two host-plants for the completion of its life-history; bunt and smut are confined to the same host throughout. Rust attacks chiefly the leaves and culms of the host-plant, so that the straw suffers most, while the grains only suffer indirectly, in consequence of the impairment of the efficacy of the organs which should prepare the nourishment for the grain; in bunt and smut, on the other hand, the grain itself is the victim. Lastly, the spores of rust are brownish and reddish, never quite black; while those of bunt and smut are best described as sooty.—*Mark Lane Express.*

FOREST CULTURE.

What is more specially regarded as Forest culture is not practised in our East or West Indian possessions; the only exception is with regard to the contracts entered upon for felling wood in Netherlands, India, and this only in Java and is exclusively limited to the Djati-woods. In these contracts the license for felling, is ever accompanied by the condition of *inboeting*, and so approaches the European idea of forest-culture. We give the following account of this subject, which may partly be considered as a branch of Commercial Industry, partly agricultural.

Djatti-wood is the staple building material in Java and indeed throughout India. It is used for all kinds of works for houses, ship-building, bridges, piers, railways, etc. as also for finer work, such as furniture, cases, etc. It is moreover largely used for lining the insides of the iron or steel plates of iron-clads, gun-carriages, etc.

The Djati, as to its scientific classification, belongs to the *Verbenaceae*, that order—the 173rd of Miquel, in his "Flora of Netherland India" (v. vol. II, p. 836)—which we have already made acquaintance with in treating of Cl. 10 Litt. E. "Sylvan Productions," as including among others the *laban*, *aras*, or *govasa* (Vitex pubescens). Hitherto only two species were known, 1° the *Tectona Hamiltoniana* of Further India (where it is called *Ta-la-hat*) and the Philipine Islands, but are not found in our Archipelago, a fine tree enough, but whose wood is only of relative value, no commercial or staple article, and of no signification in this account; and 2°. The *Tectona* (or according to some "*Tectonia*") *grandis* (Miq. II. 901). We owe this name, now in general use, to the younger Linnaeus; Loureiro called the tree with a small variation, *Tectona Theka*. It had already been named more than once, chiefly by the following names. In 1658 Bontius still thought the tree to be an oak, *Quercus Indica* (Hist. Nat. Ind. Orient. VI. cap. 16, p. 151), and this name prevailed here and there, as "*Indian oak*," "*Chêne de Malabar*," "*Chêne des Indes*" (even "*bois puant*"). Rheede, in 1678—1703, called it, (in his Hortus Malabaricus, IV, 57 and pl. 27) "*Theka*," after its name in Hindostan: "*Taik*, *Doda-taika*" in Malabar and further Westwards, "*Tek-chetoe*" in Teloegoe, "*Tek-maram*" in Tamil. This *Tek* or *Taik* is the English "*Teak*," corrupted in French and German to "*Tek*." Rumphius, in 1741—1751 transformed the name given to this tree in our Archipelago into "*Jatus*" (*s. djati, jati, caju jati*). This word *djati* came over to Europe and of course in Netherland also, *Kajoe-djati* or *ki-djati* became Kajoejati-wood, *kiati-wood*, and lastly *kiaten*-hout, and this word has prevailed hitherto in Dutch. The Hindoo name is "*Sagoein*" and *Sagoen*, modified along the East coast of the Bay of Bengal to Sêngon (the same name that the *Albizzia stipulata* bears in Java, the *Djeundjing* of the Sundanese); in Borneo it is called "*ki-oen*," in Cochin China, *Cay-Sao*, all more or less cognate names; in Siam, were Teysmann made a study of it, (Nat. Tijds. v. Ned. Ind. XXV, 205), it is called "*May-Sah*."

All these dates, the many names so extensively given to the tree, show how much and how long it has attracted the attention, chiefly on account of its great importance for social and domestic uses, and also for commerce and industry. The area over which it spreads is confined to Hindostan, Further India, and a part the Indian Archipelago; within this area it is confined to certain districts, not being every where met with; at Java, among the rest, with exception of a few small quantities in Banten and the Sunda-lands, only in Middle and East Java, further in the islands situated East of Java as far as Soembawa, included. The *Djati* of Mindanao, mentioned by Crawford (in Descript. Diction. of the Ind. Islands etc. 1856, p. 428), is apparently to be attributed to confounding it with the above-mentioned less important Tectona Hamiltoniana. The small numbers scattered pretty far over Sumatra, further in Celebes with Saleyer, in Timor, Boeroe, Amboina c. a., Rosengain near Banda, still less in Riouw, Bangka and Borneo, are all owing to a few attempts made at different times, but only partially successful, to introduce and acclimatize this tree, partly of old by the East India Company or private individuals, and lately by our Government.*

For some time it was thought that this spread was more extensive, and that the Djati occurred also in Africa, on the West coast, whence a kind of wood called "*African Teak*," is exported to Europe, chiefly to England, apparently just like the "*Indian Teak*" our Djati, but which long deceived the botanists. Brought from the woods of the low-lying interior regions, whose deadly malaria exhalations preclude all access to Europeans, it could only be defined from certain leaves, etc., ordered and sent over for the purpose; but almost with every parcel another set of leaves, blossoms, fruits etc. were received. Even now the problem is unsolved, and the only certainty arrived at, was that the African "*Teak*" is no "*Tectona*"; probably it is the *Oldfieldia Africana*, a *Euphorbiacea*. The wood is, in quality, pretty similar, if any thing, then only a little inferior to the *Indian Teak* or *Djati*, and is used for the same purposes, principally for the lining of the plates of iron-clads.

Both for industrial and commercial purposes, the Malabar and Coromandal *Teak*, which supply the building yards of Bombay in British India, are considered the best; then follows the Javan Djati (the supply however is rather insignificant, it might be considerably more), after that the sorts of the Districts Pegoe, Arahan, Moolmain, as the greatest shipping-places—along the East coast of the Bay of Bengal. In Europe, it is England that has the greatest import, and at the same time the only regular mart for Teak-wood. The above-quoted sortings are however not firm, and the fixing of the wood prices depends on the evaluation of each supply. The Teak or Djati wood is namely very different in quality, according to the nature of the soil on which it is grown; not only in the same tract does this diverge considerably, but even in one and the same small district, according as the tree grows on mountain ridges, inclines, or in valleys, in a sandy soil, or in a loam or lime soil, in rich soft mould growing singly, or in groves, or else in dense forests, thereby showing a finer or closer texture, or a looser and softer body. These deviations are sometimes so marked, as to have suggested the distinguishing of various species, which, after a systematic research, were again abandoned. Rumphius adopted two sortings—male and female—the difference only appearing in the wood: "that of the male is dark-buff with many longitudinal stripes, like pine-wood, tough, hard and easily splitting, very easy to saw and plane. That of the female is paler and has sparser stripes, softer and rather hairy under the plane, but difficult to saw, and not easily smoothed. Both have a strong bitterish smell when worked fresh, and an unpleasant taste, the smell remaining long when made into chests and cases. "(Rumph. Amb. Kruidb. III, 34). Blume, a century later, mentions ten varieties: *Djati doeri*, *soengoe*, *kombang*, *minjak*, *koenir*, *preng*, *goair*, *lenga*, *kapoer*†, which he collectively states as "*infirm*". Some of them are of limited local use, and not at all general. The Javan classification is the best.

1°. Djati *soengoe*, or horny Djati‡ a dark chestnut coloured wood, exceedingly firm and equal and free from fibre, the hardest and strongest sort, the best and most used for building-timber, ship-building, etc. and at the same time the most general.

2°. *Djati lenga* or *minjak*, *oily djati*, much darker, variegated and striated, in working rather greasy to the touch, so much so that now and then an oily matter in drops of the size of a pin's head exudes from the surface; thence the name of "*lenga*." This timber, as excellent as the foregoing, but less abundant, is especially in demand for joiners' and cabinet-makers' work; though rather troublesome to work. Both these varieties coalesce here and there more southerly towards Central Java. So there they speak only of *Djati lenga*, while the *Djati Soengoe* is with them only a variety from Rembang, known only by tradition. Improved intercourse is bringing a modification in this notion

3°. *Djati Kapoer*, *lime Djati*, lighter in colour and softer of grain than the former, brittle and less durable, and its tissues abounding in lime, mostly in a finely dispersed condition, visible as minute crystals between the fibres, sometimes, even frequently, grown into complete calcareous rings (which however occur also occasionally in the darker and firmer wood of the two fore-mentioned varieties), absorbed from the soil, where the tree grew in low-lying,

* The spread of the Djati-tree in Neth. India is circumstantially treated Chapt. II. p. 165 seqq. of the excellent monography "The Djati forests in Java" of T. W. H. Cordes, Insp. of the Forests in Neth. India.

† Not all equally recognizable or acceptable.

‡ *Cordes* calls this: Djati Soengoeh, "*i.e.* true or genuine Djati," but confounds here his Malay. "*Loengoeh*" is not a Javan word, nor is it understood in the rural districts. It ought then to be *Djati bener* or *temen*, as for instance one of the Javan oaks, "is called *Passang bener*"; but this distinction does not exist for the Javan, to whom all the varieties are real Djati. He called the varieties after the properties of the wood.

calcareous regions. This variety is naturally extensively spread, and follows immediately after the first.

The following varieties are all of them more limited, or occur more or less frequently here and there, as in Rembang, in other parts more rarely. These are:—

4°. *Djati doréng, marked, marbled djati*; the most beautiful of all, much preferred for furniture; it is hard and durable, but requires some preparation, otherwise it is subject to bursting and fissures, especially by long drought.

5°. *Djati eri or doeri, thorned djati*, with small thorny knobs and irregular fibre; durable, hard, troublesome to work.

6°. *Djati keong, shell-formed djati*, with rather larger knobs in the form of shells.

7°. *Djati oerang* (Cordes calls it *Djati daging oerang*) with ring-shaped weals on the surface of the trunks, like the articulations of lobsters or shrimps (*oerang*).

8°. *Djati weroe*, wood of a brownish yellow, somewhat glossy, with an equal, rather fine, fibre, which reminds one of the wood of the *Weroe* (*Ki hyang* of the Sunda-lands, *Albizzia procera, a Mimosa*, already treated of in the sylvan-productions and woods). All three good and useful varieties, especially the last. Finally:

9°. *Djati kembang, flowered djati*. Properly not a variety, more a common name for a few mostly casual deviations; some beautifully and peculiarly marked, others more or less fragrant, and such-like.

The enemies to the Djati-tree are not very numerous in sorts, but they are sometimes, as to numbers, and can then cause a great deal of devastation. As to the vegetable kingdom, the tree is rather dangerous to its neighbours, than they to it. Few other plants can thrive in the Djati forests; yet strange enough, a relation of its own, not long ago, (some say only 50 years) brought over from America, but which spread over the whole Archipelago in an incredibly short space of time, the *Lantana alba* (Miq. II, 904) or *tjintee*, less delicately called, on account of its peculiar odour, *kembang tembeleh, tembelihan poejena* etc. proved to be one of the most dangerous enemies to the young djatis. After this, but only on barren grounds, the *alang* p (Imperata spec. div.) it is greatest enemy; of the animal creation it is the white *ants, rajap* (Termes fatalis), and a kindred ant *wrangas* (Termes spec.?), and sometimes a large sort of genuine ants, *rang-rang-an*. Of these the white ant is the most destructive, as it sometimes attacks the tree from its first germ, and mostly nestles itself in the soft pith of the young shoots, which then never get rid of their guests, and though shooting up, remain pining and never reach a perfect, healthy growth. The rang p-an only attacks the tree externally, occasions much less devastation, and destroys or dispels, when once settled, all the white ants, so that it is much less dreaded. Temporary attacks of other insects do not damage to the tree, the annual growth of which, even endures the regular burning out of the brushwood shooting up between them, and thrives afterwards all the better.

On account of the great extent of the copsewood, and the little opportunity for a regular seasoning of the wood, a treatment has been adopted called "ringing", namely the notching of a groove round the trunk, by which the tree gradually loses all its sap, therefore it literally bleeds to death, as it is also sometimes called, and then dies away, when it is cut down. Now the question still remains unsolved, whether this treatment, or the ordinary seasoning in running water, is better. With us the first treatment is generally practised; in British India it has many opponents. One thing is sure, that dryrot which the djati was considered unsusceptible of, is made out to be possible with either process, and that other less dangerous germinating and fermenting processes had with either treatment, as insignificant results.

Artificial treatment with mineral salts, overheated steam, etc. is not applied by us, as applied elsewhere, though hitherto too scantily to be able to show definite results. As a general rule, however, they are favourable.—*Indian Mercury*. (*To be continued.*)

INDIA: CROP AND WEATHER REPORT

FOR THE WEEK ENDING THE 19TH FEB. 1884.

GENERAL REMARKS.—Rain has fallen in most Provinces during the week under report, but the fall has been light and partial.

In the Madras Presidency and Mysore, the standing crops continue generally in good condition. Harvesting is in progress, the yield being in most districts equal to or below the average. In Bombay the harvesting of the rabi has commenced, and prospects are good. The crops in parts of Sindh have benefitted by recent rain. In parts of Dharwar there is a scarcity of drinking water. In Hyderabad, Central India, Rajaputana, agricultural prospects continue satisfactory, although some injury has been caused by hail to standing crops in Morar, and rain is needed in Ulwar. In the Punjab, the south-eastern districts require rain; elswhere, the prospects are favourable. In the North-Western Provinces prospects remain unchanged Rain is much wanted in most districts for crops on unirrigated lands, and some injury has been done by frost. Irrigated crops promise well. In the Central Provinces prospects are excellent.

In Bengal the rainfall of the week has proved beneficial to the rabi, and moistened the ground for the cultivation of the ensuing rice and jute crops. The rabi crops are on the whole in fair condition, except on unirrigated tracts in Chota Nagpur and Behar. Pulses, &c. are being reaped with a fair yield, and the outturn from the sugarcane is also good. In Assam there has been over two inches of rain, (accompanied in some cases by hail) in Cachar and Sylhet. Standing crops are doing well, and mustard, sugarcane, &c., are being cut, and the land prepared for ensuing crops. In British Burma the rice harvest is over, and has proved an abundant one. Cholera continues severe in Tanjore, and smallpox exists in most parts of India, otherwise the public health is fair. Prices are generally steady, but have sustained a further rise in parts of Bengal.

MADRAS.—General prospects good.

BRITISH BURMA.—Smallpox still very prevalent, chiefly in the town of Rangoon and in Pegu; no cattle-disease to speak of; harvest reported to be a good one: supplies at ports in good quantity for the season; prices keeping fairly steady.

ASSAM (GAUHATI, Feb. 19th).—Weather seasonable; mustard being gathered; sugarcane being cut; lands being prepared for amun cultivation; public health fair.—*Pioneer*.

PLANTING PROSPECTS IN TENERIFFE.—The diminution in the cultivation of cochineal in Teneriffe is thus alluded to in a recent report from that island. The prices at which it is now selling will not cover the cost of its production, and according to the opinion of those expreienced in such matters not more than half the crop of former years may for the future be expected. The cultivation of the sugarcane and the production of sugar and rum is now considered a settled matter. Tobacco also is progressing by slow degrees, and the quality is gradually improving. The best way to increase the culture of this article, it is stated, is to buy it in its green state from the growers, so that the small producers who cannot afford to wait the time required for its preparation may thus have an opportunity of converting it into cash as soon as they cut the leaf, for which purpose a drying-house is being constructed. —*Planters' Gazette*.

FOREST FLORA OF JAPAN.—This, according to Dr. Yaroku Nakamura, may be divided into five zones, according to altitude, as follows:—(1) Zone of Pines, reaching to a height of 1,500—1,600 feet. In the lower part, Pinus Massoniana, with evergreen Oaks, Quercus glauca, Q. glabra, Buxus sempervirens, &c. Above these Pinus densiflora, Zelkowa Keaki, Gingko biloba, Sophora japonica, Populus Sieboldi, Ilex crenata, &c. (2) The zone of Cypresses, from 1,500—3,500 feet. Here occur the Retinosporas obtusa, pisifera, Podocarpus macrophylla, P. Nageia, Sciadopitys verticillata, Torreya nucifera, &c. (3) The zone of deciduous trees, from 3,500—5,100 feet. In this zone occur Magnolia hypoleuca, Alnus campestris, A. maritima, Juglans Sieboldiana, Acer palmatum, A. cratægifolium, &c. (4) Zone of Firs, extending from 5,100—7,000 feet. At the lower part occur Abies firma, A. Tsuga, and Larix leptolepis; while above occur Abies Veitchii, Picea Alcockinea, P. polita, &c. (5) Zone of Alpine Pines, from 7,200—8,400 feet. In this zone grow Pinus parviflora, Alnus viridis, A. firma, Betula alba, Sorbus aucuparia, &c.—*Gardeners' Chronicle*.

Sponge Cultivation has frequently been attempted, but hitherto without success. There seems every reason to believe, however, that the difficulty has been solved, and that henceforth nothing can prevent its profitable culture. An experiment has been made in the Gulf of Florida by taking cuttings from the living sponge. Through each of these a stick was thrust, and then stuck in the sand, the entire process being conducted under the water. Most of the cuttings stood the experiment, and one of them, dredged up seven months afterwards, had grown to a bulk of eight inches by seven, at it was perfect as a sponge in every respect. There is no reason why "sponge beds" should not be cultivated like "oyster beds," for the former animals, like the rest of the protoza, are remarkable for the amount of pulling about they will bear if only they are not taken out of the water.—*Australasian.*

Most Peach-growers are only too familiar with the disease known as the "yellows," whereby the fruit is mottled with red or orange-coloured spots, especially at the pit end. The skin also is usually spotted. Both are due to a fungus, whose structure is plainly visible under the microscope, and Mr. W. K. Higley, and American botanist, has just published the results of special researches on the subject. He says the mode of attack is as follows:—A spore of the fungus falls on some part of the branch, and sends forth its mycelium threads until they ramify and fill the tissues, crowding back the flow of sap to the parts beyond. This is only one, and usually the first, stage of the disease. Mr. Higley thinks that if the orchard is kept in a proper state of cultivation, the trees will not contract the disease very readily, and especially if they are occasionally manured with phosphate of lime. Impoverished soil is almost sure to have the peach trees grown upon it attacked in the above manner. The disease has caused much havoc in the United States since 1845 (up to which period it was confined to South Carolina) by its rapid spread, and itseems that exhausted soils are everywhere great encouragers to its development.—*Australasian.*

Chicory is not known to cultivators generally as a vegetable, although in addition to its value as a cheap adulteration of coffee it is known as a valuable forage plant for sheep. A Belgian agricultural journal gives the following with reference to its cultivation:—"A bed is made in a light sandy soil, dry rather than damp, 4 ft. or 5 ft. wide, and of a depth proportionate to the quantity of chicory that it is desired to force. The surface of this bed to the depth of 4 in. or 5 in. is thrown to either side, and the subsoil turned over 9 in. or 10 in. deep. The chicory roots are pulled up, and the tops are cut off, leaving only an inch above the roots. A cross trench is then made in one end of the bed, and the roots are planted therein upright, close together, so as to form a row 2 in. or 3 in. wide. The soil is then banked up against this compact row of plants, leaving only the leaves projecting. Another row is planted from 2 in. to 4 in. distance from the former and so on, until the whole bed is planted. All the surface soil that was before taken off and thrown on either side is then replaced, and, when it has somewhat settled and sunk, 4 in. or 5 in. more of light rich earth is thrown over, so as to cover the roots with about 9 in. of soil. When it is desired to bring chicory on, that end of the bed which is taken first is covered with 18 in. or 20 in. of fresh stable manure, well pressed down so as to heat. An equable temperature is maintained, either by adding more fresh manure, or by employing a straw covering. The young shoots, white and tender, soon force their way through the layer of earth and may then be taken up for use from one end, but carefully, so as not to break them. Every twelve or fifteen days a fresh portion of the bed is heated, its size depending on the consumption, and this goes on until the month of April, when the plants sprout without forcing. They are cooked like sea-kale—that is to say, boiled till tender, and served with gravy or white sauce. The chicory is chiefly eaten with fowl and white meats, and is especially recommended to invalids and convalescents. In Brussels the plant, deprived of refuse, is sold for about 2d. or 2½d. per pound in January." As a vegetable, it is said to be very agreeable to the palate and highly nutritious; it is also said to possess tonic properties. It can be readily grown in Queensland, one variety of it with yellow flowers being indigenous. The plant grown in Europe is an improvement on the common chicory—*Cichorium intybus.*—*Queenslander.*

It is the turn of the American agriculturists to suffer a scare from an imported insect which, if not as great as that produced in Europe by the potato beetle, is as important. A common European beetle, called Phytonomus punctatus, has made its appearance in their clover-fields, the leaves and flowers of which it destroys in great quantities.—*Australasian.*

Tea Cultivation in America.—From experiments that have been made in the cultivation of the Tea plant in North America, it seems scarcely to be expected to become a profitable crop: not that the plants do not thrive, but that the Tea itself, as prepared for the market, lacks strength. It seems to have been in the latter part of the year 1879 that the cultivation and manufacture of Tea was taken up in earnest at Summerville, in America, by a thoroughly practical and competent person, who had previously had considerable experience in the Tea plantations in British India. The plants grew well, and in the spring of 1880 the attempt at preparing or manufacturing the Tea was considered encouraging. The make and appearance of the Tea were all that could be desired, but it was found upon testing it that it was very deficient in strength. This, it was thought, might be remedied by special attention being given to the plants, and they were consequently carefully pruned and manured, with a result of a most satisfactory growth and fine crops of leaves. Upon again being tested by experts, the Tea was found equally deficient in strength, so that it is considered that if Tea is to be grown in America the State of Florida must be looked upon as presenting the most favourable conditions. The United States *Economist* recommends its cultivation as supplemental to other agricultural enterprises. "Each farmer," it says, "may raise enough for his domestic consumption, for ten or twelve trees will furnish enough Tea to meet the wants of a family of eight persons; the labour to cultivate a few Tea plants would only absorb the odds and ends of a farmer's time, which might otherwise go to waste."—*Gardeners' Chronicle.*

By the use of the lysimeter, it is learned that soil which is cultivated loses less moisture from evaporation than that in sod, or that which is bare and uncultivated. This fact has been often asserted but has not been proved. The leaching of water through the soil is, however, greatest on the part that is cultivated. —*American Cultivator.*

If trees are pruned at any season the larger wounds should be covered with gum shellac to exclude air. Many a valuable tree is lost by neglect of this precaution. Water gets into the wood, which begins to rot before the bark can grow over. It is the same as when mortification beings on a diseased or dismembered limb in animals.—*American Cultivator.*

New Source of Caoutchouc.—The attention of the Indian Government has been drawn to a new plant which is common in Southern India, and yields abundant supplies of pure caoutchouc. It is an apocynaceous plant called *Pramera glandulifera*, the native habitat of which appears to be the forests of Cochin China, where the liquid juice is often used in medicine by the Annamites and Cambodians. In China it is called *tuchung*, and is a frequent ingredient in the Chinese *materia medica*, in the shape of blackened fragments of bark and small twigs. It is imported into that country from Cochin China, the price of the bark after being smoke-dried being about 20s. the picul (133 lb.) When broken, the twigs are seen to contain an abundance of caoutchouc which can be drawn out into threads as in the East African Landolphias. The plant may be propagated by cuttings, and M. Pierre, director of the Botanic Gardens at Saigon, thinks that it may be planted in forest reserves when the trees are not less than 10 years old, and that an addition may be made to Indian forestry of great economic value.—London *Times.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, February 14th, 1884.)

IMPORTED FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White ...	Slightly softish to good hard bright ...	£7 a £8 10s

MR. H. KERR'S TEA-ROLLER.

We were very favourably impressed with the model of Mr. Kerr's important and useful invention, but we still more appreciate its value now that we have seen the completed machine. It is on view at the premises of Messrs. Maitland & Co., Limited, and we understand that already four orders have been received. And no wonder. The design is simple, and the efficiency of the roller at work has been testified to. The cost is only R350 ready packed at the Colombo station, and it performs, by the aid of two or three coolies, what it would take 16 cooly rollers to accomplish. It is just the machine for young or small estates, or persons of limited means. Amongst others, our correspondent from Fiji will find an answer to his question in this cheap machine which packs into a very convenient space. On estates where there are pulpers, the roller can be attached and worked by water or other power; while, if required, larger machines on the same principle can be prepared to do a larger amount of work.

Now that Ceylon is becoming a great tea-country, it is only fitting she should have tea-machinery of local manufacture, and we trust Mr. Kerr will reap the due reward of his ingenuity.

CALCUTTA EXHIBITION AWARDS.

The local "Times" has the following telegram:—

The tea and cinchona awards have been given at last with the following results:—Mr. J. E. Howard of London takes a gold medal for his splendid collection of cinchona bark, and Mr. Thos. North Christie the next prize a silver medal and Whittall & Co. a bronze medal, whilst Messrs. W. D. Bosanquet, W. F. Laurie and Wm. Smith each obtained diplomas. As previously advised, Messrs. Leechman & Co., take the gold medal for coconut oil, and Mr. Charles de Soyza the gold medal for citronella oil. A silver medal is awarded to Messrs. Williams Brothers for arrowroot, and a bronze one to Messrs. A. Von Possner for an ice box. The tea awards are as follows:—Mr. T. C. Owen a silver medal for Oonoonagalla; Kaduwella estate a bronze medal; Sembawatte, Galbodde and Avisawella diplomas.

Ninety medals or 15 per cent, of the Indian tea exhibits obtain medals, but of Ceylon only 10 per cent.

To the above the "Times" editor adds a note as follows:—"By this we presume our teas *have* been judged against those of India," which certainly no other reader of the telegram would "presume." The very essence of the complaint is, that, the Indian and Ceylon teas being judged separately, the judges (Indian tea-tasters, no doubt) gave medals to 15 out of every 100 exhibits of Indian tea and only to 10 out of every 100 of the Ceylon teas; in other words Indian teas were awarded 50 per cent more medals than Ceylon teas, and Ceylon teas as a whole are stamped with inferiority to Indian, just to that extent. That is the clear and distinct result, if the judgment and mode of judging are accepted. But this is the first time, we suppose, in the history of Exhibitions that such a mode of judging has been adopted. The teas sent from Ceylon were intended to compete with teas from all tea-growing countries, with all the world, in fact for what else is the meaning of an International Exhibition? People need not go to the ends of the earth to compete with one another. For the present Mr. Owen holds the Ceylon Championship, vice Mr. Armstrong who was No. 1 at the local Exhibition. Those who saw and tasted Ceylon teas at Calcutta are stated to have appreciated its merits, but the verdict of the judges is, indicated by proportion of medals awarded, "Ceylon teas inferior by 50 per cent to Indian." The decision will not certainly be accepted; indeed it is already reversed by the juries of Mincing Lane.

Since writing the above, we have seen the following correction in the "Times," which with a table of awards we quote:—

We find, by a letter which we have just received from the Telegraph Office, that our special telegram of yesterday from Calcutta was mutilated by the omission of a few words, which rendered a portion of it almost unintelligible, and even now we are uncertain whether Messrs. Williams Bros. have obtained a gold or a silver medal for their arrowroot. In consequence of the omission of these words from the telegram, we find we should have stated that Messrs. G. and W. Leechman obtained the gold medal for arrowroot and first prize, so we think that in all probability the second prize and silver medal fell to Messrs. Williams Bros. Messrs. Skeen & Co.'s photographs appear to have commanded much attention by the award of a special certificate as well as a gold medal and the next prize which we have to notice is that awarded to Messrs. Von Possner & Walker for their ærated waters and ice-box.

WEIGHT AND SIZE OF THE LEAVES AND FLOWERS OF VICTORIA REGIA.—Paul Marcoy, a plant collector, found, as we learn from the *Wiener Illustrirte Gartenzeitung*, a gigantic specimen of the great water lily in the inky-black water of Lake Nuna in Peru. One of the leaves measured 24 ft. 9 in. and 3 lines in circumference, and weighed between 13 lb. and 14 lb. A flower measured 4 ft. 2 in. in circumference; the outer petals were 9 in. long; the weight of the flower was $3\frac{1}{2}$ lb.; and that of a bud $2\frac{1}{4}$ lb.—*Australasian.*

THE INDIAN TEA AND SILK TRADE.

(From the *Times of India.*)

An interesting article on those two important articles of Baitish importation from the Far East, tea and silk, appears in the current number of the *London and China Telegraph.* In view of an import of 61,000,000 lb. of Indian tea, says the writer, it is curious to read in the latest edition of "M'Culloch" (1880) a doubt expressed as to whether tea culture will succeed in Assam. The imports of Indian tea have now attained, roughly speaking, to half the total from China. The experiments made in Ceylon have proved completely successful, and even the Javanese product is praised. Year by year, therefore, the competition which China teas have to sustain, becomes more keen, and the prices of the commoner kinds are so low that the duty is now almost in the proportion of cent per cent as in the last century. A 6d duty is equal to about 25 per cent on the higher kinds, while on common congou it seems so oppressive as to cause our contemporary to be surprized that the cry for the breakfast-table has not again been raised. The imports of tea increase every year, but it is not the China tea which shows an increase, but Indian tea, the importation of which advances "by leaps and bounds." Whether increasing or decreasing, however, the condition of the China tea trade seems healthy enough. There are, at all events, no rumour of disease in the plants, and no freaks of fashion are likely to disturb the consumption. It is otherwise with the other article named—silk. The fall of the crop from the 60,000 to 70,000 bales of former days to the 27,000 bales at which the China 1883 crop is estimated, is a matter for serious consideration. Unpropitious weather in the spring may, it is well-known, have very deleterious effects; but there does not appear to be any instance on record when the crop was thus reduced two-thirds; and therefore the report that the Chekeang silk-men are threatened with a visitation of the silk-worm disease, which wrought such havoc in France and Italy not long ago, is far from improbable. The disease appears to have been effectually overcome in Europe, thanks to Pasteur's discoveries, and the trade in silkworms' eggs, at one time an important feature in the Japanese export trade, has become a thing of the past. It will be remarkable if the disease has now broken out in the Far East. So far as European holders are at present concerned, the silk year has opened under favourable auspices for them. It is a significant indication of the depression in the China markets that even the comparative failure of the local crop did not appear to help the great mandarin speculator out of his enormous operation. According to the latest advices his endeavour to "corner" the silk market seems to have completely failed, and his holdings have now passed into the hands of foreigners, who have various chances in favour of making this year some of the profit which the Chinese speculator expected to make.

TEA: ITS CULTURE AND CONSUMPTION.

The progress of tea-culture in Assam, and in various other localities beyond the limits of China Proper, within the last half-century is of sufficient interest from many points of view to deserve notice. In Java, in Burma, and in our own Eastern possessions from Ceylon to Singapore and Perak in the Malay Peninsula, tea-culture is full of promise. The result affords a curious commentary on the fallibility of specialists prone to claim the authority of experts for their judgments. One of these, in the latest edition of McCulloch's "Commercial Dictionary," a work of great repute, says that, "notwithstanding the command of comparatively cheap labour and a close resemblance of the hills and table-lands of Assam to the tea districts in China," he is not sanguine as to the result. For this expression of doubt there might have been some show of reason thirty years ago, when Mr. Fortune's first experiments in the introduction of the tea-plant to Assam were incomplete; but it is quite misleading now, when by the latest returns we see that, while the estimated amount of tea imported from China was 114,955,000 lb., from India we received 59,097,000 lb. or 34 per cent. This great progress may well have exceeded all early anticipations. The importation of tea from Assam in 1874 stood at 17,780,000 lb. In 1878 it had increased to 36,776,000 lb. and in 1880 to 43,807,000 lb.

But not Indian tea alone competes with the Chinese in the English market; by so much rendering the tea-consumers here independent of Chinese produce. The experiments made in Ceylon have proved eminently successful, and the produce is reported not inferior to the superior qualities of China. In like manner the Java tea receives high praise. The competition, therefore, with China is becoming year by year more keen; and the prices now paid for the more common kinds will ere long raise a complaint of excessive charges for duty, which, at its present rate of sixpence per pound, does not fall far short of the cent.-per-cent. rate of fifty years ago when the duty fluctuated from two shillings to one shilling per pound.

The chief consumers of Chinese tea are still the British the Americans of the United States, [and the Russians. But in America it is chiefly green tea that is in request, as black is with us. The history of the growth of this taste in England is very remarkable. The East India Company sent out their first order to their factors in 1664 for 100 lb., after having offered 2 lb. of tea as a present to the King. But in 1660 Mr. Pepys tells us he went to take a cup of the "new Chinese drink—tea." From 1741 to 1745 the importation did not exceed 768,420 lb; during the next five years it increased to 2,360,000 lb. valued at £318,080. In that year a duty of 4s per lb. and an excise of 2s were levied. The fluctuations in duty since that period have been great; and there is nothing more obvious than the increase or decrease of sale as the duties and charges were lowered or raised, until at last a fixed Customs duty of 6d per lb. has been reached. Yet so much has the cost of tea in China fallen, that this reduced rate on all the more common classes of tea is even now little short of 160 per cent. What the effect of lowering this by one-half would be can hardly be doubted. A greatly increased demand, and a higher class of tea would probably come into general use; and this with no serious loss to the revenue: perhaps. That, however, would be a serious question for the Chancellor of the Exchequer. The quantity of tea now consumed per head on the whole population of the British Isles does not amount to more than $3\frac{1}{2}$ lb. per annum; which seems to leave a large margin for increase.—*St. James's Gazette.*

THE TEA TRADE OF CENTRAL ASIA.

(From the *Indian Agriculturist*, Feb. 16th.)

An extract from the *Oriental Review*, quoted in the *Moscow Gazette* of the 20th of November, and translated in the *Englishman*, contains the following observations regarding the tea trade of Central Asia:—

The consumption of tea is much more common in Central Asia than in Russia. In former times the tea trade was exclusively in the hands of the Chinese; their principal depot was Kuldja, to which place the tea came direct from China by caravan through Shikho, and from Kuldja it was carried to Konak, Kashgar, Turkestan, and to the Russian Semiretch province. The Shikho route having been closed by the rebellion in Kashgar, the Chinese merchants removed their tea stores to Verni in Semiretch, and from China the tea was brought *via* Kiakhta and Siberia. Nothwithstanding this lengthening of the route, the Chinese, retaining their monopoly of the trade, still derived enormous profits from it. In the meanwhile, however, Indian teas began to penetrate into Kokand (now the Ferghana province), and the Russian Kiakhto merchants started a competition in the Central Asian trade. The first attempt of these Russian firms was not successful, because they did not import the kinds of tea which are preferred by Asiatics, and those were despatched to Kashgar, where Yakub Beg, holding with the English, laid embargoes on the Russian trade. Two circumstances soon favoured the Russian traders: a regultion was passed for the refunding of the duty levied on tea passing through Kiakhta and Siberia to Central Asia, and the Anglo-Afghan war put a stop to the passage of Indian teas through Afghanistan. The Kiakhta firms of Molchanof and others thereupon increased their business, and improved it still more when the Chinese merchants, unable to compete with them, left the trade in Russian hands. Chinese Yambo silver was in a large measure taken in exchange for tea, and was sent to Kiakhta in metallic payment of duty;

thus the traders double their profits. The conditions of this trade are at present less favourable. On the one hand, there is a superabundance of tea on hand at the depôts, so that the merchants have been obliged to dispose of it on credit to the amount of several hundreds of thousands of roubles, the payments coming in the very small proportions. On the other hand, Indian teas are again flowing into Bokhara, and more particularly into Ferghana, notwithstanding the duties imposed on them. Owing to the nature and extent of our frontier, it is exceedingly difficult to guard against clandestine importation. Moreover, the Chinese tea merchants who have returned to Kuldja from Verni will not fail to re-open the direct route from China to Kuldja so soon as the way by Shikho is rendered secure. All this, coupled with the difficulty of obtaining payment of the money due to them, will compel the Russian merchants to limit their business. It is presumed that this condition of affairs can be improved by cheapening the means of transport through Siberia, by putting a check upon the smuggling of Anglo-Indian teas, and by adopting measures for the enforcement of the payment of their debts by the natives of Central Asia. The tea trade affords too large an item of profit in the Russian Central Asian trade to allow of any neglect in the application of measures for its retention in Russian hands.

THE POSITION OF FIJI IN 1884

is thus depicted in the *Fiji Times*. It will be seen, that the whole question of progresses depends on labour supply and that little hope of an adequate force is expected, unless the restrictions against the employment of local labour are removed. They had, in fact, been rendered more stringent, and the hopes of the European planters are directed to annexation to Australia:—Giving precedence to the staple industry of the colony, sugar culture and manufacture, there are on every hand signs of the advancement made during the past year, and contingently of that to be made during the year upon which we have just entered. The Deuba, the Nevua, and the Mago mills are fast approaching completion and will, before many months elapsed, be adding their quota to the material wealth of the colony. The little Pioneer mill now in course of erection on the Dreketi promises to do for that river what it has done for the Rewa, namely, demonstrate its productiveness by actual experiment; attract to it the attention of capitalists, and open up the way for the larger mills which, as a rule of progress, shall again push it to the further edge of the circle. For this the greater honor is due to the Pioneer, speaking both in the special, and in the general case, and when there is a chance of valuable public service meeting deserved recognition, something more will be heard of Mr. Leicester Smith and his Pioneer sugar mill.

Besides these instances in which preparations are almost completed, there are to be taken into account those in earlier stages of development. Foremost in point of magnitude comes the New Zealand Sugar Refining Company's undertaking on the Ba River. Here there are about 2,000 acres of splendid sugar land under preparation, to plant which the manager has a nursery nearly one hundred acres in extent. The Ellington fields at Raki Raki are in splendid condition, and there can be no doubt that when the mill is in working order, in point quantity and quality the yield will rival that from its Penang neighbor. The success of the enterprizes in present operation on the Rewa has determined the Colonial Company to increase its plant by additional machinery. shortly to arrive; the Rewa Plantation Company is extending its operations, and has also decided to increase its machinery; and lastly, as that in the earliest stage of inception, may be mentioned the proposed opening up by a Melbourne company of the Bua lands.

In other directions, and with respect to other products also the progress made during the pas year, and the prospect for this now current i fairly encouraging. At various intervals reports have recently appeared in these columns from competent authorities very highly commending the coffee and tea products of Taviuni, pointing out the directions in which improvements can be effected, and promising for more systematic cultivation and manufacture an extensive sale and improved returns. At Serua Mr. Hamilton Baillie is meeting with encouraging success in the cultivation of Cinchona, and at Bua Mr. Ganly has shown what can be done with cocoa. These for the future, but the concrete results for the past are evidenced in the surplus, small though it is, of actual receipts over actual expenditure for 1882; in the still larger surplus authoritatively promised with every prospect of realization for 1883; in the reasonable expectation of an increase in revenue for the present year, and in the prospect of progress with necessary public works which this additional spending power has opened up. Mention must also be made of the improvement in our means of communication with the outside world; of the increased postal and freight facilities we now enjoy, and of the still important additions to be made in this respect by the resumption of the interinsular service, and by the opening up of direct steam communication with the mother country.

The above rehearsed items constitute the most important entries on the credit side of our ledger, and go far to show a grand total in our favor; but the debit entries have also to be taken into account, and these unfortunately very seriously affect the result. Speaking generally, the per contra may be stated under the comprehensive head of "Labor Supply;" but this involves so much that in itself it holds the balance between profit and loss. Thanks to the prejudical influence of a system of government whose guiding spirits prate of progress while they strain every nerve to prevent progression, the restricted native labor supply with which we started last year has been still further restricted, and the small planters are now at their wit send to obtain workmen. The costly Indian system yielded about one half the number applied for; some 800 odd out of 1,600 odd; and these were all distributed among the half dozen wealthy firms and companies which alone can afford to engage them. The Polynesian recruiting season has not been a fortunate one, and the men have been introduced at a rate which places them beyond the reach of small planters; so that the advancement made is that which a few strong planting combinations have been powerful enough to achieve despite all opposition, and it bears but a meagre proportion to that which would have been made under ordinarily favorable conditions.

In concluding his recent message to the Legislative Council his Honor the Administrator expresses himself as entertaining no doubt as to our future prosperity and advancement if an increased supply of laborers can be obtained from India, or if the Chinese source can be tapped. His Honor may be asked:—What prospect is there of placing the expensive Indian laborer within the reach of the small planter, or what likelihood exists of his obtaining recruits from China? The answer is:—None whatever. Then failing his Honor's "if," what is to ensue? This he has discreetly avoided, nor was there any necessity for him to dilate upon that which must be patent to all. The individual planters that have made Fiji will go to the wall; the business population dependent on them will of necessity follow suit, the colony will be converted into an arena for the operation of a few monopolist companies and sugar exported, not a thriving ever increasing population, prosperous and happy, will be regarded as the conclusive evidence of progress.

FIBRE MACHINES AT THE CALCUTTA EXHIBITION.

There has been such a great sounding of trumpets about Dr. Forbes Watson going out to the Calcutta Exhibition with Death & Elwood's much-vaunted fibre machine, that, day by day, we have been waiting anxiously for news of the awards. Hitherto we have waited in vain, and we should judge, from the following extract from a Calcutta paper, that the Exhibition has closed without an appearance having been put in by Dr. Forbes Watson or his perfected machines :—

FINAL TRIAL OF FIBRE MACHINES.

The Jury appointed to try and report upon the various fibre cleaning machines in the Exhibition have deferred their final trial for awards in the expectation that Dr. Forbes Watson would ere this have arrived with his improved patented machine of which so much has been written, and from which such excellent results were anticipated. The holder of this new machine not having arrived by the present mail, it was felt that the trial for awards could not be any longer delayed, and accordingly yesterday morning was fixed upon as the time when Mr. Cogswell, Mr. Liotard, and Mr. Mackilligan should proceed to put the four machines in the premises at Alipore to a final practical test.

Rhea was the favorite fibrous plant operated upon, on the ground, we presume, of the large reward offered by the Government for a machine that should effectually clean the fibre. There were however aloe leaves, and plaintain stems also which were equally operated upon by one or two of the machines. The large rotatory machines of Sir Walter de Souza of Bordeaux was first set at work on a quantity of Rhea stalks, and these it disposed of effectually so far as regards depriving them of their thin outer bark, but there was no doubt a large amount of waste with this machine; the work was moreover slowly performed, and there was after all a good deal of the green coloring matter of the epidermis remaining in the fibres which gave them a darkish hue. Slices of a plantain stem were then introduced, and these it very rapidly and effectually disposed of, leaving the fibre well-separated and clean, but the waste was far too great, and this trial was regarded as unsatisfactory.

The little Assam hand-machine was able to show very indifferent work, and the larger one worked off the engine, though slightly better, could not be said to have given satisfaction in any respect. The work was very slow, and the fibre put through was very imperfectly cleaned, and evidently required a good deal of hand treatment with water afterwards.

The machine from New Zealand was tried upon Rhea stalks and aloe leaves, but though it was undoubtedly a very effective machine, so far as rapidity of work is concerned, the outturn was far from satisfactory. As in a previous case the fibre came through but partially freed from epidermis, and was in a state which needed a good deal of treatment before being pronounced really clean. The aloe leaves were rapidly taken in and disposed of by this machine, but in this process they were cut very much, and the fibre came out in a very ragged condition

On the table in the long building in which these operations were being carried on were a number of parcels of fibre which had been prepared by these machines on previous trials, and these were submitted to the Jury as examples of what could be done; but in not a single instance was the sample satisfactory. Without wishing to forestall the decision of the Jury, we cannot help arriving at the conclusion that not one of the machines on trial was capable of turning out a fairly merchantable sample of fibre which we presume should be the test to apply to them. The incompleteness of the work done and the waste of material rendered their value very questionable indeed. The conclusion which we are forced to arrive at is that judging by the samples of indifferently prepared Rhea fibre shown yesterday there has been no improvement whatever in the mode of preparing this fibre, and we much regret the non arrival of the new machine which was expected to do so much.

It would thus appear that not only were Death & Elwood's machines absent from the competition, but that Smith did not put in an appearance with his, while the machines which were shown are described as utterly unsatisfactory in their performances. Even those which succeeded in separating the fibre from the cortical, gummy and mucilaginous matter, did so at the expense of an enormous amount of waste. It looks, therefore, as if we were as far as ever from possessing a really good and effective fibre machine, simple and inexpensive. The delay in Dr. Forbes Watson's case seems unaccountable on any other hypothesis than the discovery that Death & Elwood's machines were not, in actual operation, the great success they were represented to be. What is wanted is a process of combined crushing, washing with water and application of simple but effective chemicals which will clean fibres rapidly from foreign matter, without the necessity of resorting to the "retting" process, which in hot climates is fatal to colour and strength. If it is the opprobrium of mechanical and chemical science that it has discovered no cheap and effectual method of consuming the smoke of coal, it is equally the opprobrium of engineering science that, even with the temptation held out of £5,000 reward, it has not been able to invent a simple, effective and inexpensive method of dealing with such fibrous plants as rhea, aloes, pineapples, &c. We confess to exceeding great disappointment at the absence from the Calcutta Exhibition of evidence of success in solving the problem. It may be, however, that Dr. Forbes Watson's delay may be explicable on some other ground than that which has occurred to us, and that those interested in fibres may shortly hear of something more to their advantage than we are as yet able to announce. In any case that engineering skill which has done so much for the preparation of sugar, coffee, tea and other products, including cotton, is not surely going to allow itself to be baffled in dealing with nettles, aloes, pineapples and other long-stapled fibrous plants, and their varying proportions of bark, mucilage, gum and water. We trust, therefore, speedily to be able to speak more hopefully than we are able to do now.

MELBOURNE BOTANIC GARDENS.*

We beg to thank the Director of the Melbourne Botanic Gardens for a very handsome and valuable volume containing a list of the plants growing in the extensive gardens and grounds under his able supervision.

The contents of this work are the following :— Introduction ; description of the Botanic Gardens from Hayter's Year Book 18[?]1-2 ; plans of the Botanic Gardens and adjoining grounds with explanatory notes : A. Eastern lawn, B. Western lawn, C. Buffalo Grass lawn, D. Central lawn ; General Catalogue pp.

* Catalogue of plants under cultivation in the Melbourne Botanic Gardens, alphabetically arranged by W. R. Guilfoyle, F.L.S., C.M., R.B.S., London, Director. With plans and illustrations. Melbourne, 1883.

1 to 170; List of Florists' Flowers; List of natural orders grouped, with list of general and species in each; lithographed views of the garden: No. 1 Western extremity of the Eastern or Palm House lawn, No. 2 Pagoda and small rustic bridge across Lake, No. 3 South side of central lawn, with rustic summer-house, No. 4 From the foot of the Fern Gully; and Index of common names.

For many years the Melbourne Botanic Gardens had a world-wide fame as the residence of Sir Ferdinand von Mueller, PH.D., M.D., K.C.M.G., F.M.S., an eminent botanist whose labours in connection with the Flora of Australia are so well-known, but with the view of enabling him to give undivided attention to his already important scientific labours as Government Botanist he was relieved of control of the gardens, and Mr. Guilfoyle was then appointad Director and at once began to remodel the grounds in accordance with a plan designed by him on English landscape principles which we can certify have been very ably carried out, and our readers will not be surprised to learn that these gardens are thronged with thousands of visitors on Sundays and holidays, the lawns being crowded by the public, for whose benefit the institution is maintained, not only, however, as a resort, but as a school for useful and scientific information.

The several plans and views which embellish this book give to even a stranger a very good idea of the arrangements and contents of these gardens, which are so beautifully situated on the banks of the river Yarra and adjoining the Goverment domain.

But it is to the list of plants growing in these gardens that we beg to to call particular attention, and when it is remembered that Melbourne is situated in 37° 49' south latitude, our readers will not be surprised to learn that a vast number of the ornamental and useful plants of the world have been introduced and are growing freely in them. This list occupies about 169 full pages, and, taking an average of about 40 separate plants enumerated on each, these gardens contain from 6,000 to 7,000 different plants, or nearly three times the indigenous plants of Ceylon. Each page of this list is divided into six columns with the following information:—1st Botanical name, 2nd Authority, 3rd Common name, 4th Description, 5th Order, 6th Habitat. With reference to the attempt here made to give *common names* to such a vast assemblage of plants, we have no doubt that Mr. Guilfoyle will receive the hearty blessings of a large portion of the visitors to the Melbourne gardens, as well as the reader of this list of plants, but we fear at the same time that the majority of botanists, and those who have some idea of the meaning of botanical terms and specific names, will consider that Mr. Guilfoyle and those who assisted him in this laborious work have wasted a large portion of time and space on the desert air! Nevertheless there can be no doubt that this work is a very valuable contribution, which will be appreciated by the directors of botanical and other gardens all over the world, as well as by travellers interested in plants, because it will enable them to see at a glance what plants they can procure from and what to send in exchange to the Melbourne Botanic Gardens, and we hope that every other person in charge of colonial gardens will follow Mr. Guilfoyle's example and issue lists of the plants growing in them. In our own case, for want of such a list of plants growing in Ceylon, when sending seeds and specimens of interesting plants from Java, on our return from Melbourne, we were twitted with sending "coals to Newcastle"! But our readers will readily admit that it was not our fault, but our misfortune not to know the very plants had been introduced into and were growing in the Peradeniya Botanic Gardens. We should be sorry to add to Dr. Trimen's multifarious labours, when we know how much his time is occupied, but a list, such as the one under review, of the exotic plants growing in the Royal Botanic Gardens at Peradeniya and in the island, as far as they are known, would be a very valuable contribution, and would save considerable expense in introducing plants which this list would show had already been growing in the island. As an instance of this we recollect our former Colonial Secretary, the Hon. W. C. Gibson, showing us some plants of Duranta which he had introduced from Bombay at a cost of £4 to £5, whilst we knew the plant was in the Peradeniya and other gardens in Colombo and elsewhere.

To persons like ourselves who do not profess to a knowledge of a large number of the scientific genera and species of plants, Guilfoyle's alphabetical arrangement with the index of common names affords a very ready means of ascertaining what plants may be had in the Melbourne gardens and of course the reverse.

As a specimen of the information given in Mr. Guilfoyle's list we select one of the Eucalyptus or Blue Gums, of which there are no less than 66 species growing in the Melbourne Botanic Gardens. "Eucalyptus globulus, Labillardiere, Tasmanian Blue Gum, hardy evergreen tree; height 50 to 400 feet, Victoria and Tasmania." Most of our readers are familiar with this plant, as it has been extensively grown in Ceylon and other parts of the world.

It would occupy too much space to quote passages from this work, which we feel much inclined to do, and we must therefore conclude with a hope that "the exhaustive work in preparation by Mr. Guilfoyle which will embody a summary of each order, with the history, properties, and uses of the more remarkable plants growing in the Melbourne Gardens," may soon be completed.

CANKER IN FRUIT TREES.—Mysterious at all times, and if Mr. H. Weir's assertion of insect agency should prove to be well founded, and an antidote invented, we should be well on the way towards stamping it out. Mr. C. J. Nicholson, a large fruit grower at Loughgall, near Armagh, and a most persevering and observant man besides, and who has suffered much loss from time to time through canker, tells me that he has quite got rid of it by never making holes when planting his trees. He simply spreads the roots out upon the surface, no matter how hard it may be, and places new soil over them. He also states that in the case of established trees he has got rid of it by double grafting. Some sorts are much more liable to canker than others, say, for instance, you have a large tree of some comparatively worthless variety. You head it down and graft it with another, which becomes cankered at once; whereas, if you place another kind between it and the stock, no canker ensues. A *résumé* of his experience would be most interesting and instructive to your readers, but the misguided man does not read the *Gardeners' Chronicle*!—T. SMITH.—*Gardeners' Chronicle.*

SUGAR FROM BAGASSE.

Some experiments have been made by the Department of Agriculture in order to see how much sugar might be obtained from bagasse. A series of barrels were so arranged that, having been filled with bagasse, water was allowed to flow in at the top until the barrel was full, and then by means of a pipe leading from the bottom of the barrel the water flowed into a second, and thence to a third, and so on. The overflow from the successive barrels was taken when it first ran off, and the result was that the water as it gradually passed through each barrel of bagasse, increased very regularly in density and its contents of sugar, and it was found that after four barrels of water had passed through the bagasse, the water, afterward passed through, took up no sugar, the bagasse having been exhausted of it. It was found as the average of nine experiments that it was possible to recover 8·12 per cent of the weight of the bagasse taken in sugars, and that finally, by these successive leachings, there was obtained a juice as rich in sugar as was the juice expressed from the cane by the mill. —*Indian Mercury.*

SUGAR CANE.

The following short sketch of the history of the Sugar Cane is published in the Louisiana *Sugar Bowl*:—"The cultivation of the sugar cane and the manufacture of sugar were introduced into Europe from the East, by the Saracens, soon after their conquest in the ninth century. It is stated by the Venetian historians that their countrymen imported sugar from Sicily, in the twelfth century, at a cheaper rate than they could obtain it from Egypt, where it was then extensively made. The first plantations in Spain were at Venetia, but they were extended to Granada, Murcia, Portugal, Maderia, and the Canary Islands, as early as the beginning of the fifteenth century. From Gomera, one of these islands, the sugar cane was introduced into West Indies, by Columbus in his second voyage to America in 1493. It was cultivated to some extent in St. Domingo in 1506, where it succeeded better than in any of the other islands. In 1518, there were twenty-eight plantations in that colony, established by the Spaniards, where an abundance of sugar was made, which, for a long period, formed the principal part of the European supplies. Barbadoes, the oldest English settlement in the West Indies, began to export sugar in 1646, and as far back as the year 1676, the trade required four hundred vessels, averaging one hundred and fifty tons burden."

THE TOBACCO INDUSTRY OF THE UNITED STATES.

This industry is now of large dimensions, for it appears that there are 764 establishments engaged in the manufacture of tobacco in its various forms. Of these 477 are engaged in the manufacture of chewing and cigarette tobacco, and 52 in stemming tobacco. The total number of persons employed, according to the census returns, is 85,597, of whom 20,480 are females. The total amount of money paid annually in wages is 25,054,000 dols., or about 300 dols. each per year. The value of the material used in manufactures is 65,384,407 dols; the total value of produce 108,660,166 dols. The largest amount of material consumed is for chewing and smoking tobacco, and snuff. The amount of taxes paid on tobacco of all kinds, including all special taxes for manufacturing, dealing, etc., for the two years ending September 1883, was 89,496,238 dols. Smoking and chewing tobacco paid the heaviest tax, viz., 47,170,141 dols; cigars and cigarettes paid 35,141,076 dols. The cultivation of the plant plays an important part in the industry. In 1883 there were 646,232 acres planted, which produced 449,880,014 lb. of tobacco, of the value of 43,374,360 dols. Kentucky produced the largest porportion, Virginia coming next. South Carolina was the lowest. The total exports of the leaf for the statistical year ending June 30, 1883, were 235,628,360 lb., as compared with 223,665,980 lb. for 1882, and 19,438,066 dols. in value, against 19,067,721 dols in 1882. The exports of cigars for the last statistical year amounted in value to 96,901 dols., against 113,717 dols. in 1882. In manufactured tobacco, however, there was an increase in the exports which amounted to 2,555,677 dols. in value, as compared with 2,246,692 dols. for the year 1882.—*Indian Mercury.*

PRESERVATION OF WOOD.

Dr. Joseph Jones, of New Orleans, has, after an extended series of experiments, inaugurated eighteen years ago, in 1864, succeeded in developing a method of preserving wood from decay for great periods of time, and even for centuries. The first series of experiments related to the preservation of animal structures; and in the Museum of the Medical Department of the University of Louisiana are preserved in the open air, the most delicate and destructible animal tissues, and entire animals, apparently as fresh as at the moment of death.

The second series of experiments related to the arrest of decomposition in diseased and gangrenous ulcers, cancers and gunshot wounds, and the results were none the less striking and satisfactory.

The third series of experiments related to the preservation of wood from decay and the destructive action of marine animals.

The process, as finally developed and perfected by Prof. Jones, consists in saturating wood with certain bituminous, resinous and antiseptic substances and compounds. The sap and moisture of the wood are transformed into steam, and the albuminous constituents coagulated by heat, and the wood thus treated is immediately plunged into a boiling solution, the most important ingredients of which are asphalt or solid bitumen and carbolic acid. The combination may be varied according to the age and density of the wood. As the preservative liquid and wood cools the vapor is condensed, and the solution of asphalt is driven into the pores and also permeates the wood by imbibition. The solvent of the asphalt rapidly evaporates from the surface of the wood after it is removed from the preservative fluid, leaving a smooth, polished surface, impervious to moisture and water. The antiseptic substances are thus locked up within the fibres of the wood. Thus, if it be desired to subject a railroad bridge to this process, the individual portions, after they have been completed, are first heated, in order to drive out all the moisture, and then plunged into the solution of asphalt; and after remaining from two to twelve hours, are removed, and each individual part is protected by a complete coating of asphalt, impervious to water, and itself one of the most powerful of wood preservers. When the bridge is erected every portion of it presents a coated surface, and the whole structure presents the appearance of having been carefully painted by hand with durable black varnish.

The saving of expense alone, in this mode of painting an entire bridge simply by plunging its component parts into a preservative fluid, it is claimed, will more than equal the expense of the materials used. Wood may be subjected to the hot solution of asphalt without preliminary heating.

A drying room for the wood, and a tank heated by steam for the preservative liquid, are the only forms of apparatus needed. Solid bitumen, or asphalt, is found in most countries of the globe; but it is to the West Indies that the United States must look for inexhaustible supplies.—*New Orleans Democrat.*

CANE SUGAR AND BEET SUAR.

Quite recently it has come to light that cane sugar and beet sugar, which have always been looked upon as indentical, are in fact quite different. The terms sucrose and betose have been used to designate these two sugars—for two isomeric sugars they certainly are, if all we hear about them be true. They show the same composition in a hundred parts, the same percentage of carbon, hydrogen, and oxygen, and yet their properties are different. They act differently in the polariscope; their sweetening powers are different. The superior sweetness of cane sugar, as compared to beet sugar, has been well-known for some considerable time past to those who are intimately acquainted with both sugars, though the general public has not yet been made aware of it. As to their relative sweetness it is found, of course, that as "tastes differ," opinions vary as to the amount of difference; but with all persons who have any facuty for tasting worthy of the name, and who have tried the two sugars together, nothing can be clearer than the fact that beet sugar does not sweeten as well as cane sugar. But, though individuals may differ in their judgment in this respect, here is a test which will be considered tolerably conclusive: At Mr. Gregory's College, near Blackpool, where a large number of youths are educated, and where the boarders are not stinted in their allowance of sugar or anything else necessary to life, it was found that when beet sugar was substituted for cane sugar, that "for household purposes it is at least 30 per cent inferior to cane sugar." Several other similar instances might be cited to show that wherever beet sugar is used instead of cane sugar, more of the former is required.

There has not yet been time to investigate minutely into the different solubilities and chemical reactions of these two kinds of sugar, but it is already known that they act differently on polarized light. And in this respect a very curious fact has come prominently forward, namely, that as the polarizing power of the sugar increases, its sweetening power diminishes. This shows, of course, that as regards the commercial analysis of sugars, the polariscope is an instrument which cannot possibly teach the exact value of a sugar. It appears very probable that betose or beet sugar holds an intermediate place between cane sugar (sucrose) and dextrose or dextrine.

"We venture to think," says a modern writer on this subject, "that beet sugar is a depraved sucrose, that betose stands midway between sucrose and dextrose, which last may be considered as a depraved betose, which has got so low in the scale of sugars as to be affected by the copper test (thus resembling glucose). Though it has nearly half as much again of 'polariscopic strength' as its stronger parent betose, it has not much more than half the sweetness of the latter, and not very much more than one-third of that of sucrose," as will be seen by the following table:—

	Degree of Polarization.	Sweetness.
Pure sucrose	100 deg.	100 deg.
Pure betose	103 deg.	70 deg.
Pure dextose	147 deg.	40 deg.

Now, the question arises whether any amount of refining can bring these different varieties into one kind of sugar. Up to the present time nothing has been brought forward pointing to such a conclusion. In the next place, we may ask whether the different processes of extraction from the cane now used in the West Indies all yield the same sucrose. We have certainly met with cane sugars having different degrees of sweetness, some of which may have been partially converted into betose. This is an important subject which deserves great attention, both on the part of the manufacturer and consumer.—*Chemical Review.*

THE FIBRES OF JAMAICA.

I desire through these columns to inform those connected with the manufacture of paper, that in Jamaica and its dependencies, can be obtained an unlimited quantity as well as an extensive variety of raw material suitable for the manufacture of the best grades of paper, whether to be made from wood pulp, palm, bast, or other fibres or rags.

In the month of September last, I was invited by one of the leading experts in the paper trade to visit the United States, whither I went and spent some eight or nine weeks very agreeably, visiting some of the largest and most important paper mills in the State of Pensylvania.

It is my humble opinion that all fibre-producing plants yield a larger percentage of pure cellulose in tropical countries than they do in colder climates. I noticed in one of the late issues of *The Paper Trade Journal* an article headed "Ginesta" (*spartum Scoparum*, or common broom weed). I think something was said about an attempt that was being made to cultivate it and jute in the State of Pennsylvania as material for paper stock, &c.

Now, if some of your enterprising paper manufacturers would only come down here and see for themselves the vast quantity of raw materials now lying waste on every hand, such as banana and plantain fibre, bamboo, &c., I feel pretty certain that American capital would soon find its way here to turn all these now useless things to profitable account.

At this moment the Ginesta is a nuisance to the planter. Abundance of it is to be found all over the island, as also a variety of fibrous plants of the same order.

Not long ago Thomas Christy & Co., of London, published a pamphlet entitled "New Commercial Plants and Drugs," No. 6 "Fibres," and in it the statement was made "that the supply of bamboos was exhausted in Jamaica, which caused the paper-pulp factory in St. Elizabeth to stop work."

I have made careful inquiries as to the cause of the failure, and find that this was not the cause, but something else common to many such enterprises; namely, reckless extravagance and mismanagement. I would refer you to the *Jamaica Gazette* by authority, of November, 1883, a return of all imports and exports during the quarter ended July 31, 1883, compared with the corresponding period of 1882. It will be seen from the schedule there published that the bamboo plant is not extinct, as has been stated, and I venture to state, and challenge denial of these facts, that there is just as much of the plant in the country at the present time as ever there was at any previous time. Only on one property has the plant been intentionally destroyed, and this has been done from want of knowing better. There is this much for congratulation and for the information of your readers, that the growth of the plant is very rapid, and the cost of cultivating it comparatively trifling. It flourishes in all damp situations and along the banks of rivers the luxuriance of its growth is very remarkable.

It would be out of place here to say all I have been told as to the cause of the failure of the Fairfield Paper Pulp Factory, but this much I can inform you that may be of interest—most of the machinery and buildings are still remaining on the spot in good condition and may be purchased at a low figure.

I would like to understand how bamboos, only partially crushed and imperfectly packed, can now be shipped from Jamaica to Europe to yield a profit, while a regularly organized institution with proper appliances, turning out half pulp in a compressed state, failed to show a profit. Besides this, the present shipments of chemical wood fibre from the States to Europe, support my statements. I am fully convinced in my own mind, and I can see no reason why a small paper mill could not be run to pay handsomely, there being every facility at hand for doing so. Water is plentiful in every locality, and we should never have to shut down because of ice. Wood for fuel, lime, and all other materials are to be had in abundance. Besides this, labor is cheap.

The experts who have examined the samples of raw materials have pronounced them to be of first quality, and if you can bring these remarks to the notice of the paper trade, and induce parties interested to visit this island and see for themselves, you will be doing a double service to the trade generally as well as to this beautiful island, the resources of which are so little known at present.

You can with every confidence assure your countrymen who have any dread of the climate that there is no more salubrious climate in the world than that which Jamaica possesses. I send you a paper in corroboration of these statements, containing the expressions of our late Governor, Major-General Gamble. They will speak more than I could say.

In conclusion, I beg to say that I shall be glad to furnish any information on this subject, that you or any of your readers may require, as one who is indirectly interested in the paper trade and the future of Jamaica.—W., Cabessa. Jamaica, W. I., Jan. 1st, 1884. —*Paper Trade Journal.*

A NEW RUBBER-PRODUCING PLANT, *prameria glandulifera*, has been brought forward in India. It is common in Southern India and Cochin China, and yields abundant supplies of pure caoutchouc. The liquid juice is often employed in medicine by Annamites and Cambodians.—*Paper Printing and Trades Journal.*

A COLORADO paper says that Pueblo is soon to have a paper and textile mill for utilizing the "soap weed" plant that grows so abundantly in the southern part of the State. This mill is the result of experiments made three years ago, when large quantities of the weed were sent to Hadley, Mass., to test its adaptability.—*Ibid.*

ALFA GRASS is a natural production, of which numerous articles are made such as cordage, mats, carpets, paper, tubs, railway wheels, and a number of other articles. Alfa is found in North Africa growing at an elevation of 300 or 400 metres in Algiers, Tunis, Morocco and elsewhere. Formerly it was also found in Spain, but now the culture is neglected there. Alfa grows luxuriantly without cultivation, requiring three years to grow to maturity. The plant grows to a height of about half a metre, and one or one-and-a-half metres thick. It is not cut down, but pulled up out of the ground by the stalks.—*Ibid.*

UNCUT AMERICAN TIMBER.—The rapid growth of paper-making from wood pulp has caused enquiries as to the stock available for the purpose. It is found that according to the forestry bulletins there were but about 82,000,000,000 feet of mercantile white pine standing in 1880 in the lumber states of Michigan, Wisconsin, and Minnesota, and only about 85,000,000,000 long-leaf pine in Florida, Georgia, and the Carolinas. But the estimate of long and short leaf in Alabama, Mississippi, Louisiana, and Arkansas, was above 134,000,000,000 feet, and this reserve has scarcely been touched yet. Louisiana alone has 48,000,000,000 feet standing.—*Ibid.*

A PATENT has been issued for the manufacture of paper from common grass. The inventor claims that he can work up into paper the grass grown in fields, meadows, and lawns, and from the green grass pulp produce a paper remarkable for strength imparted by its length of fibre, tenacity and flexibility. He claims that the new grass paper will be softer and more transparent than that made from linen stock; it is to be cheap, as well as strong, and of superior quality. An acre of ground, the inventor tells us, will produce from 30,492 to 66,840 pounds of green grass. One pound of green grass makes one-fourth to one-sixth of a pound of fine, bleached, finished paper, or 3,711 pounds of superior marketable paper to the acre.—*Ibid.*

THE "DWARF PALM" of Algeria, which is a nuisance to agriculturists in that country, is being experimented upon by a French manufacturer as a paper-making material. The substance is said to answer well, and even to possess unique advantages. Another plant is suggested in the "Giant Cactus of the Mohave Desert," or *Nucca Draconis*, which makes paper of a very good quality. It grows luxuriantly in California —an out-of-the-way source of supply, much against its adoption in manufacture. It is asserted, however, that it would flourish well in India, and the suggestion is thrown out that the plant should be introduced to some of the sandy wastes of that peninsula, where it might take root and ultimately prove an exportable product. The *Nucca*, it is said, yields double the percentage of fibre to that of esparto.—*Ibid.*

SUMAC IN AMERICA.—One of our neglected or ignored industries is the culture and preparation of sumac as a material for tanning and dyeing. It is admitted by experts that American sumac is quite as valuable for these purposes as the foreign article, which sells for nearly twice its value, and that the difference is merely in the preparation of it. Sumac is a very widely distributed and abundant shrub, and is gathered and prepared for market at a respectable profit, even at its present inferior price. As an indication of the quantity gathered in some localities, we read of a sumac mill in Virginia which was recently burned, but the owner congratulates himself that he has 350 tons of leaf still left ready for grinding. As it is a light substance and is wholly gathered by negroes, this seems a respectable quantity as the stock of one mill. How much more profitable it might be, however, if the gathering of the sumac could be done by more intelligent people, who would know the right season and conditions for gathering it.—*New York Times.*

FOUR-FLOWERS TEA.—The virtues of simple remedies, long obscured by the claims of more pretentious drugs, are again beginning to attract some degree of public favour. Amongst them is an ancient nostrum much commended by antique authorities of the less learned kind, and still believed in by many of the village housewives, and perhaps a few village doctors. This is four-flowers tea, a potion or "tisane" which is given for the alleviation, at least, if not the curing, of cold, and which a more or less eminent French doctor, well-known in literature, is bold enough to honour with his praises. It is made, as its name implies, of an infusion of four very simple wild flowers—poppy, wild mallow, cows' lung-wort, and violet. The properties of each of these plants or herbs are, of course, different, but they are said to mix together so kindly that the potency of each is improved by amalgamation with the others. The virtues of the poppy are those for which it is so celebrated by the classic writers, its somnolent and calming effects. The mallow is said to be rich in mucilaginous juices, which soothe the bronchial tubes. Although the critics of antiquity are not so universally eloquent as to the merits of this plant, Pythagoras at least gave it all its due, and perhaps more, by maintaining that it was good for moderating the passions. The cows' lung-wort, which is also called by various other names, and amongst them "high taper" in English, and "our lady's taper" in French, is declared to produce an oil having anti-spasmodic properties, and thus to be most useful in allaying the irritations of the throat. Finally, the violet is credited with much virtue as a sudorific, and, when it cannot be obtained, the pansy is substituted for it. The tea is made by taking the petals only and not the calix of the flowers, and steeping them in hot water, which must afterwards be flavoured with syrup of Tolu, and taken very hot.—London *Times.*

GROWING CABBAGES IN SUMMER.

TO THE EDITOR OF THE "AUSTRALASIAN."

SIR,—Will you be good enough to inform me through the next country edition of the *Australasian* if cabbages can be grown to perfection by dropping the seed where the cabbage is intended to be grown without resorting to transplanting, as in hot weather the latter process is almost sure to kill them? I have heard that without transplanting the cabbage will run to seed.

IGNORAMUS.

[Cabbages can be grown in the manner proposed with good success, but we consider transplanting preferable. In order to carry out the former plan, let the soil be well enriched and deeply worked. Draw wide and deep drills (three inches deep), drop the seeds two or three at intervals of three feet (if the variety be a large one), cover very slightly, and water. As the plants grow draw out the surplus, and fill the earth in to the level. Throw the plants you have drawn imto a bucket of puddle clay. Let each be thoroughly covered with the clay, and plant out immediately. This is the best method of transplanting cabbage plants in hot weather. If you can give them a watering at the time of planting, it will increase their chance of living; you will, at all events, have those that were not tran planted.—ED. "A."]

COMPOUND TINCTURE OF CARDAMOMS.

BY FRANK WILSON.

This preparation has always been considered one of the elegant tinctures, highly esteemed therapeutically for its carminative properties, either by itself or in combination with stomachics, it is largely employed as a flavoring and coloring agent with or without viscid ingredients; hence, it is one of the important tinctures of the pharmacopœia. Our query truthfully says the officinal tincture "precipitates badly," and inquires for a remedy, a substitute for the honey, to which it attributes the precipitation. Inasmuch as the carminative and stimulating properties of the ingredients, cardamom, caraway and cinnamon, consist in their volatile oils, and knowing that alcohol was the better solvent of these active principles, I reasoned that an increase of the alcoholic strength of the menstruum would not only make a better solution, but tend to prevent precipitation. I could see no therapeutic objection to thus increasing the volume of alcohol, as the tincture would hardly be administered in large doses; accordingly I prepared a tincture by the following formulæ:—

Tinct. Cardamomi Composita.

Cardamom	4 parts.		No. 50 Powder.
Cinnamon	4	"	
Caraway	2	"	
Cochineal	1	"	
Alcohol	133	"	To be mixed in the proportion of.
Glycerine	12	"	
Water	44	"	
To make	200		

Mix the solid ingredients, powder them together, pass through a No. 50 sieve. Moisten the mixture with half an ounce, or qs. of the menstruum, pack in a cylindrical percolator, gradually pour the remainder of the menstruum upon it, afterwards diluted alcohol to obtain 200 parts. This sample was completed June 15th, and placed with the other three; it has stood a test of seven months and presents an elegant appearance, free from sediment. I would offer the above formula as the best solution of the query my limited experiments have enabled me to deduce.—*Oil and Drug News.*

COLONIAL NOTES.

SINGAPORE.—We have received the report on the Botanical and Zoological Gardens for 1882, detailing the work of the year, the most important of which was the relabelling of the plants in the garden, a matter that had, it is alleged, been very inefficiently attended to. The sons of H.R.H. the Prince of Wales, each planted a specimen Martinezia caryotifolia on the occasion of their visit to the garden.

Mr. Cantley has also issued, under date July, 1883, his report on the forests of the Straits Settlements, in which attention has been called to the scarcity of forest and forest produce in the Settlements from want of forethought and reckless felling. A description of the island of Singapore and its physical features is given, including some meteorological details, from which it appears that the highest temperature observed is 91°, the lowest 66°, the relative humidity of the atmosphere (counting saturation as 100°) varying only from 78° to 80°, the annual average being 79°·4. The rainfall averages 91·6 inches per annum, as much as 6·25 inches falling within twenty-four hours, and serving to flush out the drains. No forest rules at all exist in Singapore, and indeed, no timber seems to be now available, as all that is used for constructional purposes is imported from Johore and the neighbouring Dutch islands. Most of the fuel used is also derived from the same source.

MALACCA.—The meteorological phenomena are practically the same as those experienced in Singapore. There are still some 40,000 acres of forest land in the hands of the Government, but the forest conservancy is "as meagre as in Singapore."

PENANG is more hilly than the previously mentioned districts, and more subject to drought, though the annual rainfall is still cited at 107·7 inches, and the mean temperature at 88°, the mean minimum being no lower than 75°.

PROVINCE WELLESLEY.—An island separated from Penang by a narrow strait, has a somewhat cooler climate, the temperature having been registered as low as 65° Fahr., though the mean is still 79° Fahr. Mr. Cantley makes suggestions as to the creation of forest reserves, the enactment of a proper system of conservancy, and adds a list of the species still remaining in the districts visited by him. The list of timber trees given in one of the appendices is interesting, but unfortunately the number of species, enumerated only by their Malay names, is very large. A Forest Flora would, therefore, seem to be a desideratum. —*Gardeners' Chronicle.*

SUITABLE FRUITS FOR QUEENSLAND.

In the country along the coast from the southernmost point of Queensland many tropical and sub-tropical fruits thrive, such as the banana, pineapple, mango, custard apple, tamarind, jackfruit, alligator pear, wampee, litchi (or leechee), rose apple, Herbert Vale cherry, and perhaps a few more; but when going further north, decidedly within the tropical zone, these will be found to flourish amazingly, on the coast line more especially. But there are a few decidedly tropical fruits which will eventually be confined to the far north. They have been experimented on in many places, where they eventually succumb to the cold of winter; in the far north—that is to say from Bowen northward—the breadfruit, durion, mangosteen, cocoanut, and the cacao (from which cocoa and chocolate are prepared), nutmegs, and many of the spices may be grown profitably, and here will prove to be the real home of the banana and pineapple, plants which should never experience cold lower than 45° or 50° Fahrenheit. True coffee lands must alsobe beyond the reach of frost, for anything that nips the young wood and checks its growth, prevents it from doing anything like its best and takes away from the chance of working it profitably. These remarks tell with even greater certainty when the Liberian coffee is taken into account, for Liberia is a region on the west coast of Africa, near the Gulf of Guinea, and not far removed from the equator. In hilly country the highest and steepest land would suit coffee well if it were terraced, as these situations would be exempt from frost, even when the valleys at the foot were visited with several degrees of it. But we have fulfiled our intention in penning these lines, and in conclusion would advise our readers who intend to plant an orchard, and are afraid of trusting their own judgment, to select some trustworthy and reliable nurseryman from whom to purchase their trees, and after stating their case to him as plainly and fully as possible to follow his guidance, for such men, having a reputation to win or lose, cannot afford to mislead customers.—*Queenslander.*

THE SQUARE BAMBOO.

One of the chastest and most elegant ornaments provided by Chinese ingenuity for the library or study consists of bamboo boards, the ground being elaborately carved in fretwork and inscribed with characters, generally quotations from the classics, cut from the wood of the same plant. They are to be obtained from the Chinese in Shanghai, and are valuable by reason of the peculiar character of the material from which they are made. Bamboos are divided into a large number of species, and well repay the study of those who take an interest in obtanical researches. There is one sort of a remarkably unique character, called the "square" bamboo, specimens of which have, we understand, been forwarded by Dr. Macgowan at Wênchou to the United States Consul-General at this port, together with a sample of the ornament above described, the device in this instance, however, consisting of a representation of the bamboo itself. Some of the plants received from the Doctor are destined for the Park at San Francisco, while others of the same nature are intended for the Public Garden at Shanghai. The following description of this novel-shaped product of the vegetable kingdom will, we think, be found of interest by our readers.

There is no plant except cereals proper which has received so much attention as this graceful grass. Early Chinese botanists enumerate seventy varieties of the bamboo, but if quest were now made in local gazetteers that number would be found greatly augmented. They describe the bamboo as diecious. Pre-eminence is assigned to the square variety of this most useful as well as ornamental plant, which has been a favourite in Imperial gardens whenever its acclimatisation has been effected in the North. The Emperor Kao Tsu once inquired of his attendants who were planting bamboos, concerning the various kinds. In reply he was informed respecting several remarkable species. Chêkiang in particular furnished one that was an extraordinary curiosity, in that it was square, and for that quality and its perfect uprightness was much esteemed by officers and scholars. They also told him that it was used for many purposes of decoration and utility, including, among others, that of being made into ink-slabs. Subsequently specimens were obtained, polished, and sent to His Majesty, who thereon signified his respect for the article by rubbing ink with his own hand on the ink-stand, and inditing an essay on the curiosity. In 650, A.D., the reigning Emperor sent a eunuch to Chêkiang to obtain specimens for the Imperial Park. Besides being furnished from scattered portions of this province, it is found in Honan, Szechuen, Yünnan and Hunan; in the latter province it appears to present its peculiar characteristic in a marked degree, being as square, with corners, and as well defined, as if cut with a knife. The Chêkiang species have slightly rounded corners, and moreover they are more slender, being used only as pipe-stems, whereas the western kind is large enough to serve as staves for the aged. In its early stage of growth the square bamboo is nearly round, assuming the anomalous figure it afterwards presents as it advances toward maturity. Like several other kinds of bamboo it is thorny, abounding in small spines. If we may credit accounts which have reached China from Western Turkestan (Ta-yuen) there is or was produced in that region a square bamboo which is a curiosity of a curiosity. The Prince of that country possessed and highly prized a square bamboo, on the faces of which were eyes, beard and teeth. Art no doubt contributed to the production. There are considerable varieties in the colour of bamboo—white, yellow, reddish, purple and black. Besides being ornamental it is useful, very pretty chairs being made of it. A native writer says of this plant that it "injures its mother," which means that its shoots must not be planted near the parent clump. In mentioning these curious bamboos we must not forget the useful description of all. We refer to what is generally known as the "hair" bamboo, the shoots of which constitute an excellent esculent which is largely exported from the neighbourhood of Wênchou; the bearded appearance of the shoots giving it the hirsute designation. It is not like square bamboo, which is adapted to limited areas only, but it will flourish almost wherever there is a due amount of heat, moisture, and a fertile soil. The uses of this kind of bamboo have been often described, but there is one purpose to which it is applied, and at Wenchou only, and therefore but little known. It is rendered plastic by being boiled half a day in potash and lime; the alkalies having done their work, a slit is made in the cylinder (which is of any required length, usually a foot), and it is then pressed out into a sheet form by heavy stones. These sheets of bamboo, which are sometimes a foot in width, are then carved, cutting them through, and in this way are formed representations of flowers, birds, various forms of characters in verse, and the like, which, glued to delicate filagree work of bamboo, and framed, make the unique and elegant pictures to which we have referred above.—*N. C. Herald.*

KITCHEN GARDEN: LAYING OUT A GARDEN.

There is not much artistic taste required in laying out a cabbage-garden, nor is there much poetry in culinary vegetables—except perhaps in the sympathetic onion, over which we often shed tears when it is sacrificed to the requirements of the savoury stew or the toothsome stuffing. Still, in laying out a plot of ground for a kitchen garden it needs a little thought to arrange the beds and paths in the most convenient manner. There are no meandering paths wanted, but it is needed to go straight from point to point without deviation. Then there is necessity for one path at least being wide enough to accommodate a wheelbarrow, and probably the weeds that may be thrown off the beds during the process of cultivation, for in a properly made kitchen garden it will be strange indeed if there are no weeds growing on the deeply dug and richly manured beds. It is not meant that these weeds are to lie on the wide path, but that they may perhaps be thrown there until they can be gathered up into the barrow and wheeled into the corner kept expressely for the weeds and rubbish to be stacked, where in time the heap becomes a most valuable manure. Suppose the plot to be only forty yards long by twenty. It would not be worth while to make three paths down it, so we should make one path down the centre about four feet wide, and across the middle of the plot there should be another path of the same width, leading at one end to an empty space upon which the rubbish heap should be kept, and at the other end to the tool shed. The rubbish heap space would need to be at least 15 feet long by 10 feet broad, and the space for the toolhouse would require about the same area of ground, because it would most likely be thought desirable to grow some kind of creeping plant over the toolhouse, and it would need that there should be some kind of a footpath outside. These main paths should be raised a little above the level of the beds, and sloped on each side, so as to throw the rainwater off quickly.

The reason for having the rubbish heap and the toolhouse near the centre of the garden will be obvious, for that is the most central spot, and therefore nearest to all parts, either for depositing rubbish, obtaining manure, or obtaining or putting away the tools. Wherever the rubbish heap is stationed it is only decent to try and hide it, and this can be done by the erection of a rough enclosure, to be shortly covered with somd kind of climber—by preference something suitable for the kitchen garden, such as the Cape gooseberry, which likes a rich soil, and does well amongst rough brush.

The beds should be trenched to a depth of about two feet ultimately, but there is no necessity for doing it all over to that depth before commencing to utilize the garden. A commencement may be made by ploughing or digging it all over as deeply as may be convenient, and making the soil as fine as circumstances will permit. Put on a good deal of manure, unless the ground is already pretty rich.

When the whole of the ground is dug over, except the central and cross paths, it should be laid out into beds of four feet in width, with paths a foot wide, running across from the main central path to the boundary on each side, which will divide the whole garden into thirty-two beds, the greater number of which will be 28 feet long by 4 feet in width. Such beds as are to be devoted to deeply-rooting vegetables must be dug deeply, and in most cases the manure will need to be buried at the bottom. Thus carrots, parsnips, salsify, chicory, yams, asparagus, celery, beets, and rhubarb should not be grown upon ground less than 20 to 30 inches deep; but potatoes, peas, turnips, cabbages, onions, beans, sorrel, spinach, thyme, tomatoes, and many others may be grown upon shallower soil, although all do better when they have plenty of room beneath in which their roots can run riot.

If the beds are made much wider than four feed it is difficult to get at them for weeding and watering, and as it never improves the state of the beds to be treading on them whilst the plants are growing, it is much better to multiply the paths upon which we may tread than to put our feet where they have no business to be. The perennial herbs—of which there are a very large number that ought to be found in our gardens, but which are not so to be found—would best be placed near to the boundaries outside, next the wall, and in digging the beds they will be out of the way of damage through too much disturbance.

If it is thought necessary to utilize the kitchen garden as a nursery for bulbs and flowers for the decoration of the flower garden, it is best to devote one or two of the beds nearest the latter place, but as far as possible the two departments should be kept separate. Some gardeners recommend a spot right in the centre of the garden for the toolhouse and dungheap, but there are many obvious objections to that plan, not the least of which is the bad smells close to the house, where perhaps it will be necessary for the gardener to be working for hours occasionally; and the break in the direct line of the path is not advisable.

The enclosure all round should, if possible, be 6 to 9 feet high, and consist of a stone or concrete wall by preference; next to this a good, close, broad paling fence would be desirable, and the gate should close with a spring, so that it should never be open except when designedly kept open by means of a catch placed expressly for that purpose.—*Adelaide Observer.*

PRACTICAL HINTS FOR PREPARING LAND FOR ORCHARDS.

As with the orange tree, so with other descriptions of fruit trees. The ground must be first well drained and trenched ere the grower can in any way hope to succeed, and the present drought will give satisfactory proofs of the appearance of vegetation in trenched and untrenched land. It is of the utmost importance where choice varieties of trees are grown that not only should the land be trenched and drained, but also all tree-roots should be carefully picked out and carted away to the wood-heap. It is almost impossible to drain land too much; and after heavy rains, if any one will take the trouble to examine and fairly estimate the quantity that issues forth at the exits, it will be seen that if the water is retained about the roots of the trees how very injurious it must be, causing without doubt root-rot and consequently the decaying away of the top branches. The more hybrid the tree, the more delicate will be its constitution, and therefore the more perfect the under tillage to prevent diseases, the more likely the chance of the tree producing fruit. The better kinds of plum trees, cherry trees, apricot trees, and other varieties of stone fruits specially come under this doctrine, and as up to the present time our growers have not succeeded in producing crops, we must naturally conclude that the ground has not been properly prepared. The system of trenching land by means of the plough, especially when done by contract, is very reprehensible. The same also may be said of the undermining system of trenching whereby large masses of soil are removed at one time in each trench, with the consequence that the mass simply remains intact, and therefore might as well have been left alone. Trenching, to be effective, should be done only by the spade, shovel, and pick, and so turned over that every particle may be fairly broken up. Those who have bonedust at command should give a good dressing on the top of the first spit of soil turned over. This would serve as a feeding-ground for the roots after they had passed their first stage of growth, and thereby throw vigour into the tree at its second season. In choosing a site for choice kinds of plum and apricot trees, select a portion that is warm and free from winds, as many crops of valuable varieties are lost from the simple fact of the flowers or just-set fruit being nipped by late frosts or blown off by cold, harsh winds.—As large acreages of vines are annually planted, we purpose to give a few ideas on the subject of planting. For some years we have cautioned the vigneron against planting vines required for wine purposes on rich land. Where this caution has not been attended to, the result is well known. Probably, however, the produce of the vineyards, owing to the excessive drought, will give fair wine, as the grapes will have not been able to make themselves into quantity but quality. The Duke of Manchester, who evidently was a keen observer of Australian resources, said in plain terms that our vine-growers were on the wrong path if they wished to produce wines that would command respect and a high price, as the vines, instead of being planted in poor stony soils, were planted in the richest land possible. Vignerons will no doubt say we plant on hillsides; but it is a peculiar feature of the country that it is on the high hills that the richest soil is to be found—at least it is so up to the present time where the vine is cultivated for wine-making. But the time will come perhaps when vignerons will be more alive to their own interest, and select land for vine cultivation in accordance whether the crop is required for wine or for table grape purposes. To produce good grapes suitable for the table, draining and trenching are as necessary as for other trees; and, probably, had the vineyards from which the supplies are obtained been trenched, the markets, even although the season has been bad, would have been supplied with better samples of grapes. Draining and trenching simply mean letting off surplus supplies of moisture during very wet weather, and the storage of moisture during very dry weather. Referring to the subject of preparing land for general gardening, there cannot be the slightest doubt that, if those about to make a garden were to moderately drain and trench even that part set out for the lawn, much benefit would accrue. It is scarcely possible under present conditions that hard land having the surface merely broken up can be expected to produce green grass, unless in very favourable weather. As an instance, we quote the material difference noticed in the appearance of the grass on made land, and that where the surface has been merely broken up. A little expense first incurred will amply repay itself. In fact, as most persons who lay out a garden of any extent are gentlemen of means, the best plan would be either to wholly or semi-trench the whole of the ground intended to be devoted to the lawn and the flower garden. This done, much future trouble would be avoided, and the present foolish system of trenching holes for the flower-beds entirely dispensed with. Flower-beds for general purposes or for carpet-bedding could be made, with the assurance that the ground was properly prepared, and that in wet weather the plants would not suffer from too much moisture, and that in dry weather the plants would be healthy and green, even although no water was available for supply.—*Sydney Mail.*

WATTLE CULTURE.

TO THE EDITOR OF THE "ADELAIDE OBSERVER."

SIR—"That which is well worth doing is worth doing well." Permit me a little space in your valuable paper for the simple treatment of a subject, which, in my opinion, the sooner it is drawn into full light the better. It being obvious that the mode of farming hitherto carried on in South Australia will not much longer stand competition with other wheat-producing countries more favourably situated in regard to soil, climate, labour, distance from the market, &c., than ourselves, we have to turn our eyes to such culture of plants that will stand the inclemency of our dry weather as well as they will regularly yield under proper management remunerative returns, and be less subjected to diseases and to havoc through pernicious quadrupeds—insects. No other plant I presume answers to these requirements better than the broad-leaved or golden wattle (Acacia pygnantha Benth.), from which the best mimosa bark of commerce for tanning purposes is obtained. Being a native of quick growth it is content with almost any kind of soil—even the beach sands not excepted—while its culture is no cumbersome task. From upwards of three or four years old it produces easily and plentifully germinating seeds for its propagation, and rewards the comparatively small trouble with a handsome and earlier return—more so than most of the tan-bearing trees and shrubs. Besides its ability to resist the effects of any severe weather, we have to appreciate in the wattle a plant the culture of which probably affects the soil in only small degrees' if at all, as it has been proved by authorities like Liebig, Mulder, Schleiden, and others, that the tanning substance contains no mineral ingredients, its formula being $C_{14} H_{10} O_9$. This is an important point, as we run no risk to exhaust the soil of the necessary ingredients for further cultivation by keeping it under wattle crops for from five to eight years. I may, nevertheless, be allowed to quote a passage from Schleiden's "Principal Lines of Scientific Botany." He says, page 141—"Many plants seem to be apt to produce organic acids whenever they are in want, of saturating an inorganic base, and, *vice versa*, an organic base when they are destitute of an inorganic acid. This is, for instance, the case with quinine in the cinchona-bark, a substance so similar in its representation to tannin. Tannin seems to be modified according to the various plants in which it occurs, and appears to lodge in 'cellulæ' defective in vitality."

Dr. Krause, chemist in Berlin, has carefully examined over forty prominent kinds of tanning material in use on our globe, and published an elaborate treatise thereon, from which we learn that the highest percentage of tan is derived from plants grown under the influence of sea-breezes. This we find also confirmed by reliable investigations of the Board appointed by the Government of Victoria in 1878 to consider and report on the subject of wattle-bark. The report states that the highest degrees of tanning have been obtained from broad-leaved wattles grown in the Geelong, Portarlington, and Queenscliff districts, all coast lands—certainly important hints for our future wattle-culture. In various localities of this colony, situated almost as low as the sea-level and up to an elevation of 2,000 feet, we find the wattles very different in their growth, verdure, and *extérieur* altogether. The reasons for this may be attributed chiefly to the more or less congenial soil, partly to the difference in the quantity of rainfall, and last but not least, to the variable contents of vapour in the air. The forest reserve of Woolundunga, more elevated than any other, bears me out in this assertion by interesting data, not unlikely, that the highest located belts of wattles therein, showing the most luxuriant verdure, will also produce the highest percentage of tannin. I may mention here that careful analysis of the above Board have clearly shown that limestone formation has a deteriorating effect on the percentage of tannin in the wattle, as the quantity of it obtained from wattles cut in such localities show a decrease of 13 per cent. Most likely very few of our farmers when casting their eyes, perhaps with contempt, on the rugged-looking wattles in their paddocks, may imagine to what extent and magnitude of business, wealth, and comparative happiness, private as well as public, the cultivation of these insignificant plants may lead if carried on under a system of uninterrupted rotations, and worked in a proper forestial style. I may therefore urgedly request the farming class before things turn to the worst to give this apparently trifling affair their serious and mature consideration, and finally a scrupulous trial, as dilatoriness has often been the ruin of many a well-laid scheme, and delay has often caused a failure where prompt action would have resulted in unbounded success.

If the locality in which an intended wattle plantation is to be established shows no material difficulties, an equal division of a certain area of such land into as many culture-sections as we have years in view to keep the wattles in growth—say, eight or nine—to attain a full size and maturity of the trees, and consequently to obtain the possibly highest peacentage of tannin, the introduction of a rotation system of crops and consecutive sowings will be necessary. This may be simply accomplished in such a way that, commencing with the first crop of bark at five and a half years old, the next year will turn out two crops, and the following—*id est*, after the seventh year reckoned from sowing—three, and being now in full swing, every year ought to yieldthree crops of bark, whilst fresh sowing in their places is a matter of course. A systematical mode of cultivation ought to be also the leading rule in such plantations. Careful ploughing, for instance, not less than six inches deep, of three combined furrows for the reception of one seed row at the time and in distances of six feet apart from another, would not only furnish the young plant with sufficient loose soil (harrowing same not to be forgotten) but it would at once introduce regular proportions in the plantation, would admit easier work and management, and above all give the young wattle an impetus to form a straight trunk, matter so important for facilitating the stripping work, and meantime allowing an income from the valuable wood. Before I conclude I may be allowed to allude to the value of our wattle bark in comparison to others. The bark of Acacia pygnantha, our golden wattle, is as yet surpassed by no other in the world in regard to the high contents of tannin and the facilities offered in its culture, the former having amounted under different tests up to 45 per cent. The demand for tan substances is yearly increasing in the European markets; and in Germany, for instance, it has grown to such a critical extent that, according to trustworthy forest journals, it has been found necessary to cut down fine oak trees of thirty years growth to obtain the so much appreciated glossy bark, the contents of which showing only from 13 to 16 per cent of tannin, whilst our wattle bark, according to latest accounts, received in the London market, the highest price given to any tan materials.

Trusting that you will excuse this rather lengthy attempt on account of the importance of the subject.—I am, &c., W. L. HOMEYER, Upper Mitcham.

A GREAT DISCOVERY IN FRUIT CULTURE.

Pure food makes pure blood, and no food is so pure as fruit. An abundance of fruit ensures the health and prosperity of the people. No crop is so rich and productive. Few objects in nature are so beautiful as a fine tree adorned with blossoms in spring, or laden with fruit in autumn. Our troubles have been that the proper culture of fruit has not been understood, and that our gardens and orchards have therefore been uncertain and often unproductive. The science of Fruit Culture has not existed. Its discovery, just now, we consider one of the most important events of this century of great discoveries—really more important than the discoveries of steam and electricity. The new method of fruit culture, or more probably a revival of an old one known and practised perhaps for ages in China and Japan, comes to us from North Wales in a letter by Mr. E. K. Kynaston, and an illustrated pamphlet by "Head Gardener," the pseudonym of Mr. Kynaston, entitled, "Out-Door Fruit for the Million. How to grow it in large and continuous quantity by simple and inexpensive means." with the motto—"Who loves not fruit, ripe glorious fruit—a priceless boon from the great Creator's hand?"

Mr. Kynaston, who modestly calls himself "Head Gardener," appears to be a gentleman of education and property, who has devoted himself to fruit culture with the enthusiasm of a discoverer and benefactor. If the man who makes two blades of grass grow where one grew before is a benefactor, what shall we say of Mr. Kynaston?

At the opening of his pamphlet Mr. Kynaston tells us that after long years of practical horticultural experience he succeeded in growing English fruits in unprecedented quantities, continuously, by simple, inexpensive means. He was always his own head-gardener. Living on property of his own, after some experience abroad, he planted more than twenty years ago a choice and varied selection of fruit trees. He says:—

"In about three years' time the young trees commenced bearing, and have borne from that period annually increasing crops, until at last the fruit hung for thickness like leaves upon the trees; and shelf after shelf, closet after closet, room after room had to be devoted to its storage and preservation.

"In the autumn of 1875, the garden being as usual loaded almost to its utmost, the writer hand-picked himself three trees to ascertain the exact count of fruit upon each. The tree (a dessert pear of excellent flavour), nailed to a wall 7 feet high, yielded 704 marketable pears. The second tree, also a pear, somewhat larger than the first, yielded a count of 718, and as the fruit was of the preserving order—very large and solid—the crop filled four huge baskets, each one a load sufficient for an average man to lift and carry. From the third tree, an espalier apple, of very moderate size, 700 choice russets were gathered, leaving some seven or eight dozen behind as being below a regular marketable standard. Thus for three young and comparatively small trees, no less than 2,152 count of good sound keeping fruit was gathered, and as there were some 25 distinct varieties of pear trees in the garden—all fairly well loaded accord ing to their respective sizes and weight of fruit—for instance, one of them of no great size, whose fruit had easily been forced up to a pound in weight, yielded upwards of 400—the general crop from this source alone may in some degree be imagined—in fact, the hand-picking of the fruit, together with its storage and disbursement, formed about the heaviest as well as the most pleasurable job connected with the garden.

"The fruit grown consisted of Apples (good dessert sorts, Pears, choice varieties, such as Marie Louise, Duchesse, Beurré Diel, Muscatel, Jargonelle, etc., Peaches, the trees bearing immensely—the count of good well-ripened fruit going up to 300 on a single tree, Apricots, Plums of several varieties—the New Orleans kind cropping extra largely, and the Magnum Bonum going up to a quarter of a pound in weight, Melons, Grapes (out-door sweet water), Strawberries, Currants and Gooseberries, Black and White Grapes, with other tender fruit, were grown under glass with similar success, and weight of fruit, but this kind being expensive to grow is not, nor probably ever will be, for the million in this country.

"Now none of this splendid fruit ever went to market—it was grown purely for the love of its growth, use and distribtiuon—besides the *ad libitum* supply for his own table—(which was supplied as tables seldom are) "Head-gardener" sent weekly baskets for the greater part of each year to his own relations, who having more than they could consume, distributed in their turn, and his friends and neighbours were likewise liberally remembered. One lady not long ago told him that she felt sure that her aged mother's days had been lengthened by the constant supplies of delicious fruit sent her. But what surprised people more even than the unprecedented yield of fruit was the following circumstance, viz., that whenever blight (so-called) destroyed or partially destroyed (which it too often did) the fruit prospects of the neighbourhood and country at large, "Head-gardener's" trees were never once affected by it. Blight or no blight, fruit to almost any extent was always to be found in his garden.

"Not long ago, a near relative of mine, possessing a fine large standard apple tree of a good dessert kind, non-bearing, begged me as a favour to take it in hand, and the following autumn the tree was so loaded with fruit that a cart (baskets being of little use), had to be backed up under it to convey away the crop—so that even half-a-dozen good trees well looked after, would constitute a respectable orchard, and become certain and valuable property."

In another case he restored an old, worn out, neglected orchard to such vigorous bearing that the trees had to be propped up to keep them from breaking down with the weight of fruit. Trees that had not borne fruit for fifteen years were restored to vigorous bearing in a single season.

A man who has done such work may well magnify his work. Mr. Kynaston says:—

"As fruit is one of nature's best medicines—being at one and the same time cooling, digestive, and health-giving—and is besides the direct alternative to the white bread, tough meat (as a rule) and other astringent food, which we daily and so largely partake of—its moderate constant use is therefore absolutely essential to our well and perfect being—consequently its proper cultivation would greatly add to our individual and national interests. Now I have found fruit easy enough to grow in marvellous quantity by the simple and inexpensive means which I have adopted: my plan being, after thinning out small poor fruit, to let the trees then bear to their very utmost, and the sure sign that they were equal to their work was, because they never dropped their fruit."

Mr. Kynaston says he has never exhibited or "paragraphed" his pears, nor sought for any publicity; but having proved his work, he thinks it his duty to teach his method to the public.

What that method is we will show as clearly and briefly as we can.

A fruit tree, Mr. Kynaston says, has three kinds of roots, each with its own special function.

1. A tap root, going down perpendicularly from the trunk, simply to give a firm support to the tree. This should not be meddled with.

2. Long roots, corresponding to the branches of the tree, which supply the nutriment for woody growth. These should be pruned to limit and regulate such growth.

3. Flower and fruit feeding roots, which are small and thickly clustered round the trunk of the tree. These are to be cultivated and nourished that they may supply the fruit-making materials.

To restore a fruitless tree to its proper function, prune away surplus wood among the branches, but leave enough for fruit. This may be best done in autumn. In the spring, when the tree is about to blossom, dig a trench about it from four to six feet from the trunk—according to the size—and about a foot in depth, and cut off the spreading roots. If the tree be small this can be done with a sharp spade. This will check the growth of wood and allow the life force of the tree to be chiefly expended upon its fruit.

The next point is to feed the starving fruit rootlets. As soon as the blossoms appear, do what the gardener in the parable of the barren fig-tree proposed to do—dig about and dung it. Carefully open and loosen the soil within a yard of the trunk, and moisten it daily with liquid manure, a bucketful to a small tree, and two or three to larger ones—half common manure and half water; and, Mr. Kynaston insists, all sewage and suds from the house, which, as the waste matter of human, fruit-eating creatures, is just the material needed by the tree to manufacture into fresh fruits. Guano also does well, and the sweepings of the hen-house. The great point is to provide the matter of which fruit is made *at the right time, in the right place, and in sufficient quantity.*

The right time is from the flower to the full grown fruit.

The right place is near the trunk of the tree where the fruit rootlets thickly cluster.

The right quantity is *Enough.* The roots will not absorb more than they need. What remains will be good for next year. The trees will be none the worse for a winter crop of cabbages or other hardy plants.

Trees may be cleansed from parasites by washing with soda or lime. But a healthy, vigorous tree takes care of itself. It is the weak that suffer from parasites.

We give Mr. Kynaston's facts and his method. We have no doubt that the facts are true; and no doubt that the adoption of his method everywhere would add millions to the wealth, and greatly increase the health of the English people.

In one case where an old, neglected, unbearing orchard, had become a mere thicket of tangled branches, Mr. Kynaston—or "Head-gardener" as he likes to be called—took it in hand. It was a tough job, but "next year every tree responded grandly to the call of good cultivation—the trees cropping, in many instances so heavily, that props had to be placed under several of their branches, to prevent the weight of fruit from breaking them down—and the year after the crop was still heavier."

Fruit trees, Mr. Kynaston insists, cannot be injured by his process, and also cannot fail to bear abundant fruit. Trees which had not borne fruit for fifteen years, but only "made wood," have been perfectly covered with fruit in a single season.

Such being the fact, what is to hinder the whole country being covered with fruit, and every town supplied cheaply and abundantly with the best, most delicious, and healthiest food?

Speaking of the advantage which his discoveries may be to Agriculture, Mr. Kynaston says:—

"People living in London can form but a poor idea of the distress (ever-increasing) that exists in agricultural districts; both landlords and tenants are everywhere in large numbers, being either hopelessly-ruined or else miserably reduced in circumstances. It really appears as if one section of the people were about to be starved, in order that the other might have cheaper food. We have, I fear, departed from the safe and happy medium course, and ventured on extremes, which always, as a rule, end badly."

Since writing the above we have been favoured by Mr. Kynaston with the following letter.

Mr. Kynaston writes:—

"Yes, advanced fruit culture is, as you rightly term it, *untold wealth for the future,* and can be, and has been, with amazing success, applied to all kinds of fruits, and to vegetation generally. The Bala garden, yielding but lately so poorly, is now exceedingly productive. A grand-daughter of mine, a well-grown, active girl, of twelve years, said to me last summer, 'Why, grandpapa, our garden is like a big shop where we get such a lot of good things every day, and have nothing to pay for them!'

"'Although I have had upwards of twenty years' experience of advanced fruit culture, I never, to this day, stand before my fruit-covered trees, without feelings of gratitude that are truly indescribable, on seeing how wonderfully faithful and thoughtful Nature ever is in all her work, if we be but true in ours. We have the fruit tree in almost endless variety, and the wit (if rightly directed) that will enable us to largely and constantly 'eat the fruit thereof'; but how customary it is for those who fail to obtain it, to blame God's weather for the mischance. But see how He, by His own grand words in Genesis, rebukes us for our unbelief, or want of faith, in His infinite goodness—

"'And God said, Let the earth bring forth grass, the herb yielding seed, and the fruit tree yielding fruit after his kind, whose seed is in itself upon the earth, and it was so!'

"From the very first man had to '*dress and keep*' his garden, which clearly shows that 'good cultivation' was as necessary then to obtain its benefit as it is even now.

"You have, indeed, a grand and almost inexhaustible theme to write and expatiate upon, and one that is not tinged, as far as I am concerned, with a single mercenary feeling, for I have given my life's real labours and these discoveries gratuitously to the whole world."

Mr. W. S. Roberts writes:—"I am well acquainted with Bala, and its many drawbacks with respect to climate, frequent rains, bath springs, and cold piercing winds; but I can bear testimony to Mr. Kynaston's most wonderful success. Trees and shrubs which before scarcely bore any fruit are now with bended boughs and branches overloaded with fruit. Apple, plum, currant, and gooseberry trees all speak: If you but cultivate us aright, we will produce abundance and plenty for all. No doubt many thousands of pounds are lost annually through a lack of this knowledge of how to cultivate our fruit trees. Doctors of the highest standing have declared that the juice of ripe fruit is an antidote in cases of fever."—*Herald of Health.*

THE TRANSPLANTING OF THE CINCHONA-TREE FROM SOUTH-AMERICA TO JAVA.

(*From the Indian Mercury.*)

The Quinine-factory at Amsterdam has brought its first product to market. In itself this announcement would seem of little importance, for what this new establishment produces is no new article, but one long known. On a small scale it has been made here for more than forty years, and at Paris the quinine-factory of Pelletier exists almost half a century. The circumstance, however, that this Amsterdam manufacture owes its existence to a new Dutch-Indian culture raises the fact to an event. For on the one hand it proves that in Netherland capital is still forthcoming for good and solid enterprises, and on the other it is a positive proof of the excellent results that the planting of the cinchona-tree in Java has achieved.

Nobody then will deny the apportuneness of the subject, if on occasion of the above-mentioned fact, I give an historical sketch of the culture.

Its history, fortunately, does not lose itself in high antiquity; but though the idea of disengaging the cinchona-tree from its habitat is not much older than half a century, it is less easy to make out who has the honour of priority. This point has been much disputed and written upon, even before a presentable cinchona-tree had been planted in Java, and for my part I hold it for certain that this effusion of human vanity has done much harm to the good cause and to the treasury.

It seems that Dr. C. L. Blume, the well-known botanist of Java, who abode there from 1820 to 1834 as a Botanist and Inspector of the Civil Medical Service, made the first step about 1829 to the Government to transplant the cinchona-tree to Java, but unsuccessfully. A few years later, the subject was broached anew by Reinhart, Korthals & Fritze, the first two naturalists in Java, the last-mentioned chief of the Military Medical Service from 1835 to 1840, with whom Junghuhn, then medical officer, amply discussed the matter during a journey he made in 1837 through the Preanger Regencies. The latter gentleman tells this himself, and does not neglect to add that the merit of this priority is of little consequence, because such an idea as the one in question might occur to many at a time. Dr. Fritze, it is said, had already recommended Junghuhn to the Government for a voyage to Peru.

But this proposal remained in abeyance.

Meanwhile a new sphere of action, that of naturalist in Sumatra and Java, was opened to Junghun, so that the plan of the cinchona culture seems to have been abandoned. At leat in India nothing more would be heard of it till 1852. About this time the affair had passed into other hands, and thereby entered upon a new phase. It was through the exertions of Professors G. Vrolik, G. J. Mulder, W. H. Vrieze and F. C. Miquel, that, encouraged by the successful attempts of the French, the Netherland government was urgently made to see the great importance of this question. It is therefore but fair that we should first relate what the French had done, that roused our scientists, and awakened Netherland to action.

France sent in 1844 the botanist Dr. Weddell to South America commissioned to trace the cinchona tree to its habitat, and to study it with attention. A purely scientific mission.

Weddell devoted more than four years to this task, and propounded the fruits of his research in his work: Histoire naturelle des quinquinas ou monographie du genre Cinchona. A truly standard work, and an issue most creditable to the French Government as well as to the French publishers and draughtsmen. Not less than 30 plates, partly beautifully coloured, a topographical map and an engraving of a primeval tropical forest illsustrate this work. The introduction of the work is devoted to the travels in the native country of the cinchona-tree, of Condamine, Van Humboldt and others. Then the exploitation of trees by the natives is described, and finally follows a detailed botanical pharmacognostic treatise of the genuine and kindred cinchona species.

It is especially the manner of exploitation of the wild-growing trees, and the ever increasing want of cinchona bark, that opened the eyes of European *savants* towards finding means to prevent the thoughtless extirpation of the trees, as was long practised in Peru and Ecuador. Mostly the trunks, more than twenty metres high, were cut down at the base, and then stripped of the bark. Not a thought was even given to the rearing of new trees from seed or slips.

Against this vandalism two remedies are feasible:—"l'un est de limiter l'exportation à un chiffre proportionné à la puissance productive des forêts; le second est d'en faire l'objet d'une culture régulière."

"Limiter l'exportation serait sans doute le plus sûr; mais n'est-il pas à craindre que la disproportion entre la consommation et la production ne soit déjà trop grande pour qu'il soit possible de rétablir la balance; et nos besoins d'autre part ne sont-ils pas devenus trop exigeants pour se plier à des considérations qui ne regardent qu'un avenir éloigné?—Reste la source de la culture, et il faut l'employer. S'il est un arbre digne d'être acclimaté dans une colonie française, c'est certes le quinquina, et la postérité bénirait ceux qui auraient mis à exécution une semblable idée."*

This happiness, however, was not reserved for Weddell or his country. The trial made in 1850 to acclimatize the cinchona-tree in Algiers miscarried, and it would seem that the affair is no longer on the programme of the second Empire. Fortunately Paris possessed in the Jardin des Plantes, some seed and even young plants, brought thither by Weddell. The horticulturists Thibaut and Keteleer were also provided with some. From these Professor De Vrieze, Director of the Academical Botanical Gardens at Leyden, had obtained a cinchona plant (*Cinchona Calisaya*), and this specimen, which in 1851 had already attained a height of 0·75 metre, was in fact the very first that was introduced into Java. The young tree arrived there in April 1852 with the ship *Prins Frederik der Nederlanden*, Huidekooper commander, and was entrusted to the care of the able Teysmann, and this tree is the progenitor of the first two cinchona trees in the open ground at Tjibodas, from which afterwards 1,900 slips were taken.

I find it of importance to insist upon this last fact especially, just because this has not been appreciated at its just value by Junghuhn, anent the question of priority

* Weddell, Histoire des Quinq., p. 13.

No one can deny that this honour is due to De Vrieze. Yet Junghuhn affirms that it was the Minister of Colonies Pahud who gave the orders for this; but it is more presumable that the first and only plant obtained by exchange, was reared in the Leyden Hortus out of love of science. For surely if the government had taken the initiative, the trial would not have been begun on so small a scale as to render the success dependent on a single specimen. Not till then did Government interfere, and Mr. J. Hasskarl, cidevant Director of the Government Botanical Gardens at Buitenzorg, was charged with a mission to Peru to collect seeds and plants for the culture in Java. The commission was first offered to Junghuhn, but however flattering this was for time, and however, much he desired to make acquaintance with the soil—the country that had become so celebrated by Von Humboldt's travels—he declined, and recommended to the Government his friend Hasskarl.

Junghuhn himself tells the story in the following words: "My old acquaintance of Java, the botanist J. K. Hasskarl was snatched from his sphere, as, in order to provide for himself and his family, he had accepted of a mercantile employment at Dusseldorf. He was unhappy, and pestered me with entreaties to endeavour to procure him some situation again in Netherland India. No shadow of a prospect had presented itself hitherto, and no other opportunity could be seized upon but this, viz., the intended mission to S. America, which I should *so much have liked* to undertake myself. I am not ashamed to confess, that two contending motives long struggled within my breast, and that when at last the unselfish motive conquered, and, instead of executing the newly formed plan in person, I recommended Mr. Hasskarl, this proceeded from pure philanthropy, Cantas, and from no other motives."*

And so it happened that Hasskarl set foot on shore the 31st of January 1853 at Callao, lingered in Peru till July 1854, and arrived at Batavia the 13th of December of the same year with a collection of plants, of which, however, only 78 remained alive, and a quantity of seed of different kinds of cinchona, a part of which had already been sent to the various Dutch Botanical Gardens. Both at Leyden and Amsterdam as also at Utrecht the germination had succeeded, but at Buitenzorg the first seeds failed entirely. The young plants of Hasskarl were set in the ground at Tjibodas, but these, too, soon began to pine, and in spite of the continual supply of young plants from the Gardens at Leyden and Amsterdam, the culture at Tjibodas did not prosper. From good authority the observation has been made that it was a mistake to sow the light winged seeds like those of the cinchona in the open ground, a point that certainly did not escape the attention of Hasskarl and Teysmann. Afterwards recourse was had to germinating houses. The choice of the ground, too, on the slopes of the Gedeh-mountains, was, according to Junghuhn, an error. The stratum of humus was not deep enough, so that the roots soon abutted on an impenetrable layer of alum-slate (wadas) and the plants began to pine. The Buitenzorg hortulanus F., however, has contradicted this, and shown that several plants were sound and throve vigorously.

Another observation of Junghuhn's, and perhaps not an ill-founded one, was regarding the elevation at which the nursery was placed at Tjibodas and a consequent too high average temperature. It lies 4,000 feet above the sea, and the average temperature is 19 C°.

Finally H. is said to have committed the fault—at least according to Junghuhn—of clearing the ground so as to make it quite open, that is stripping it entirely of the sheltering trees, whereby the tender cinchona plants where exposed to the full rays of the sun. In short, the condition of the cinchona-culture had advanced so little in the two years that it was under the direction of Hasskarl, and the observations of Junghuhn were in the eyes of the Government so well-founded, that the former "compelled by illness," had to give up the task he had hardly begun.† At the express desire of Government, Junghuhn, who had meanwhile returned from his leave of absence in Netherland to Batavia, took the supervision and conduct of the cinchona-culture upon himself, while Hasskarl, discontended with his position, returned to Europe."* These are Junghuhn's own words. On me they make the impression of some other impulses having probably been at work than the Cantas, with which, a couple of years before, the mission to Peru was so generously ceded. But we will drop the curtain here; the first act is played, and Junghuhn was to be the hero of the second.

He, then, transported the young trees to the wood and higher up the mountains, but it was especially the slopes of the Malawar and the Tangkoeban Proe in Bandong (Preanger Regencies) that he selected for the growth of the cinchona. The nursery already laid out at Tji-miroean, must be removed higher up, and fresh ones were made at Lembang and Nagerak. He fixed the limits of the culture from 4,300 to 7,000 feet above the sea, where the average soil temperature is 17° C.

Later experience, however, has shown that these limits are to restricted, and that some sorts of cinchona take kindly to a region even a thousand feet lower. But at that time everything had to be learnt and therefore it shocks us the more that Junghuhn was so hard and unfair upon Hasskarl and Teysmann.

What was planted by him on the Malawar and the T. Praoe slopes, were slips from Tjibodas, and the seed also came from thence. By his talents and energy, however, he contrive to give a more vigorous impulse to the enterprise, made scientific observations, made fresh trials, built nurseries and inspector's dwellings, and made regulations for *personel* and material. Thus matters stood a year later, in 1857. The number of trees in the open ground amounted then to 298, of which 98 were at Tjibodas. Among these last there were two that were 15 or 16 feet in height, which favourable circumstance did not speak to the discredit of Hasskarl. At Tjimiroean some had shot up to 8 feet, but most of the plants were only from ½ to 1½ foot high.

The Governor-General Pahud, under whose ministry the cinchona culture in Java was effected, interested himself already sufficiently in the cause to go and inspect the youthful planting in Bandong. On the 29th of June 1857 he set out from Buitenzorg. The train that marched from Bandong to the mountains might well be termed splendid, and it has been described to the life by Junghuhn in his report.† The shrubs, the underwood, the high trees and their garlands of trailing plants, are not only mentioned by name, but he depicts them in form and colours, how they look in the shade, or when lit up by a glancing ray of sunlight. He engages you, as it were, to rise at dawn, when the feathered songsters hail the first morning rays with their hymns, or monkeys and squirrels gambol in the trees. Or, when darkness falls upon the ravines, he lets hundreds of coolies away their torches, shedding their glare on the train and making the diamonds sparkle again on the doublets and krisses of the village chiefs. Then we are fain to follow Java's greatest traveller, and revel in the glories of nature. But when the last tones of the Javan nightingale have died away, and the eye is surprised by the sunny nursery-grounds of Tjimiroean, then the civil officer steps forth, charged with the direction of the cinchona culture, and for us all poesy vanishes.

With a flourish of trumpets the fact is proclaimed that here, now, stand the very cinchona-trees, transported to Java in 1855 by the ship *Minister Pahud*, that the planting out at Tjibodas was indeed a couple of years older, but started on a very unfavourable spot, and that he had been obliged to advise the Government urgently to transfer the plants brought over by him to Tjimiroean. And once more we have to hear that here too, the almost irreparable fault was committed of hewing down the sheltering trees, in consequence of which many young plants perished, as wanting the natural shelter against the scorching rays of the sun.

We are next told how the Governor-General was agreeably surprised by the announcement that some little trees 6—8 feet high, were slips which His Excellency had seen half foot high in the Botanical Garden at Leyden, and which, at his command had been handed over to him (Junghuhn) to be transported to Java.

If we consider that the number of trees was not more than sixty, besides the slips in the nurseries, then we

* Natuurk. Tijdschr. v. N. I. 1859-60.

† Oudeman's Pharmacognomie 1880.

* Natuurkundig Tijdschrift v. N. I. 1859.

† Natuurkundig Tijdschrift van N. I. 1861.

must laud the interest shown by the Governor at so early a stage of the affair. Nor was the leader of the culture wanting in zeal and activity. Thousands of slips were planted—a method of propagation, which when seed is wanting, answers very well, but which under Junghuhn's treatment did not always succeed satisfactorily. Professor Oudemans pretends that he took his slips too long, instead of as small as possible, *i.e.*, a little larger than the bud.* McIvor in British India had learnt this as early as 1861, but then he was a nurseryman by profession.

Fortunately for Junghuhn, one tree came into bloom in 1858, which also produced seed, by which a quicker extension could be given to the culture, than had been hitherto possible. Thousands of seeds were then directly deposited for germination. But the seed was not of the best sort. At first it was taken for *Cinchona Ovata*, or *C. lucumaefolia*, but when the new plants blossomed and made fruit, they were pronounced by Howard, a cinchonologist at London, to be quite a new and unknown species, which on Junghuhn's suggestion received the name of *Cinchona Pahudiana*.

This sort, so intimately connected with the founder of the Netherland Indian Culture, was henceforth considered as a paragon, the tree of the future *par excellence*. It grew rapidly, blossomed and made seed; even the spiky shooting up was called a virtue. Though the stems remained miserably thin, and the bark not thicker than paper, all this would come to rights in time, for, as it was, the root-bark at a very tender age showed already a large proportiom of quinine—the quintessence—and more than had been met with in any other sort.

To the propagation of this species almost all exertions were expended, so that the number of plants in the open ground soon amounted to more than a million. On the other hand, the other sorts—among which were some very good ones, if not the best—only increased by hundreds and numbered scarcely 10,000 on the whole. The reason of this was in the first place that they produced no seed, and had therefore to be reared from slips, which under the shade of very tall trees, as Junghuhn was used to do, very often miscarried. Hence perhaps his preference is to be explained for the sort which conformed so easily to his notions, and in which he was not a little strengthened by the relatively favourable results of the chemical analyses of the Inspector charged with the chemical tests, Dr. J. E. De Vrij. I call these results *relatively* favourable, because the presence of quinine in the stem-bark was not proved, but supposed; it was the root-bark that contained almost 2 p. Ct.

(*To be continued.*)

* Oudeman's Handboek der pharmacogn. 1882 2nd Ed.

COLA NUTS.—The trade in cola nuts is an attractive feature in the commerce of the Gambia. The cola nut is the product of the Sierra Leone district, and the trade in it, both at Sierra Leone and the Gambia, is almost entirely in the hands of women, to a large number of whom it affords the means of livelihood, and in many instances the acquisition of considerable wealth. The nut is largely consumed by natives of the Gambia; it is of a bitter taste, and produces no exhilarating effect, but is said to possess the power of satisfying for a considerable time the cravings of hunger. For this purpose, however, it is much less used than it is as a luxury. The British trade in the article is rapidly increasing. In the year 1860 the import into Great Britain was about 150,000 lb.; 1870, 416,000 lb.; 1879, 743,000 lb. The trade in cola nuts has also spread to Central Africa, and even to the African shores of the Mediterranean. The plant has been introduced to the West Indies, Seychelles, Calcutta, Ceylon, Dominica, Demerara, Mauritius, Sydney, and Zanzibar, from the Kew Gardens.—*Oil and Drug News.*

PROFESSOR ASA GRAY says, in a private note quoted by *Home Farm*:—"Plants on the whole liberate to the air vastly more oxygen than they take away; and as to the last, an infant or a night light in a room uses up ever so much more oxygen and gives out ever so much more carbonic acid than would a room full of plants."—*Queenslander.*

CEDAR OF LEBANON.—Few trees, and certainly no other conifer, form singly such a magnificent feature in the landscape as the cedar of Lebanon; but it seems to have been considerably neglected by the planter in recent times, as comparatively few are to be observed in the plantations and ornamental grounds formed within the past 30 or 40 years. This may be partially attributed to the great influx of exotic conifers of an ornamental character which has taken place during that period, and partly to the slow progress made by the cedar in its early stages. When once it is fairly established in its permanent site, which it often takes 10 or 15 years to accomplish, it grows with great vigour, and often reaches a large size before it is a century old, especially if planted in a good soil and sheltered situation. It thrives best in a deep rich loam, and an open or well-drained subsoil; but it is by no means fastidious, and it will thrive in almost any soil which is neither stiff clay nor waterlogged. Planted as a forest tree the cedar makes a straight clean stem, towering to a height of 80 ft. or more, and having much resemblance in the bark and bole to a gigantic larch crowned with an evergreen top. Such a grand tree deserves to be much more extensively planted than ever it has been in this country, and planters will do well to bear it in mind when arranging for future operation.—*Journal of Forestry.*

WHITE ANTS.—Having been several times asked about a cure for these, found very successful here, it occurs to me that it might be useful to make it more generally known through your paper. The substance employed is Yellow Arsenic, *Hartal*, which is sold for 12 annas a seer in the bazar. Pound it very fine on a stone, and mix it as for colour-washing rooms (the Chancel of the Church and Apse of the Mission Chapel here are coloured with it, a very bright yellow) with water—3 seers of Hartal will suffice for a large jar (Naud) full of water. Apply freely with a brush to wood work or the surface of floors, or mix up with the mortar which masons are using in fresh work, or paint mats or carpeting, or the bottoms of boxes with it. It has been found, after a trial of quite 6 years, a perfect cure. The ants cannot "abide" it; indeed this house which used to be called 'Ant Hill Lodge' is now almost entirely free from them, though built a good many years ago and of inferior materials. Its smell is not very plesant for the first 3 or 4 days when extensively applied, but it passes off entirely, very unlike in this and other unpleasant respects the customary remedy, pitch. I have slept in a room a few days after its liberal application without unpleasant consequences.—Cor. of *Indian Churchman.*

WHITE ANTS IN AUSTRALIA.—The white ant prefers the soundest of timber. The white box, the strongest timber native to Victoria, is its most fancied home. Few of the larger white box trees in the forest but what are eaten at the heart by this minute enemy, though externally they may look sound enough. Should a storm of wind break a branch, however small, that is sufficient for a swarm of white ants to make a lodgment, and from that time the tree is doomed. Where timber houses are built on studs the white ants are certain to attack it; where a stone foundation is laid they seldom attack the house. Post-and-rail fences, barns, huts, the stoutest timber of all descriptions, nothing is safe from them. There is but one effectual way to protect timber from their attacks, and that is to dress it with kerosene, after which they will not touch it. Some time ago Mr. Henley found that a strong pillar of white-box, which supported the floor of the hop-kiln, was attacked by white ants. The cracks in which they had gained entrance were scraped out, but without succeeding in dislodging them. Having experienced the value of kerosene in preserving wood from the white ant, Mr. Henley determined to employ it on this occasion. He cut through the floor above, and bored a hole with an auger into the head of the post, into which he poured a small quantity of kerosene. The oil penetrated every fibre of the wood, and the white ants at once effected a rapid retreat, and were seen no more. In all the timber in his house, and in the permanent buildings on the farm, every piece of timber is now carefully dressed with kerosene before it is used.—*Australasian.*

FIBRE MACHINERY.

It is rather a curious coincidence, that, as we were writing in despondent terms respecting the production of a really cheap and efficient fibre-clearing machine, the following statement should be ready to appear in our morning contemporary. We give the details as we find them, only remarking that information is yet wanting as to the amount of work which Smith's machine can do and the cost in labour, &c. Such details are absolutely necessary before we can arrive at a final decision.

FIBRE-CLEARING MACHINERY.—We have been favored with samples of various kinds of fibre which have lately been cleaned at Baddegama estate by one of the "Universal Fibre Cleaner" machines invented by Mr. H. C. Smith and manufactured by Death and Ellwood, and commonly known by the name of that firm. We have already described the working of this machine in a former issue, Messrs. John Walker & Co., having had one at work in their factory, which was tried with aloe leaves in the presence of many who took an interest in fibre-cleaning. As regards the samples sent and their appearance, we have before us, as we write, three samples of different aloe fibre, one of plantain, one of pineapple, and of shoe-flower. They are all of exceptionally fine appearance, being clean and perfectly free from mucilaginous matter. The threads of the fibre are well separated and of good length. Of the aloes, the ordinary green aloe is not nearly so clean and fine looking as the other two, whilst the excellent sample of plantain fibre should command a very high price, if shipped in good quantity. Its threads are stronger and finer in texture than those of the aloe and, and in this instance, much longer, but nothing comes up to the beautiful specimen of pineapple fibre before us. We have seen several samples of this fibre, but never one so perfect in every respect as this. It is about 3 feet in length, of snowy whitness and as soft and flexible as "fairy flax." The sample of shoe-flower fibre is not at all in the same category, being short and coarse with the threads adhering one to the other. Of course, the success or failure of this machine depends not upon the primary fact whether or not it can extract clean fibre from plantain trees and aloe and pineapple leaves, for that fact is abundantly proved by the excellence of those and other samples we have seen, but upon the cost at which this can be done. The inventor claims that his machine can turn out from 140 to 250 lb. clean fibre per day of ten hours. We quote as follows from a prospectus forwarded to us:—"The machines are sold in pairs, and will turn out from 140 to 250 lb. of clean fibre per day of ten hours. The amount of out-turn varies with the proportion of fibre in different plants, and with the more or less care and assiduity exercised in feeding the machine, which is in itself so simple that any unskilled person can readily work it after practising for a very short time." We presume that not more than three coolies would be required to work the machine, and, if they can turn out as much as 150 lb. of dry and *clean* fibre a day, the result would be most satisfactory. But from what we ourselves have already seen of the machine the fibre, of whatever kind, has to be washed and cleaned of the gummy vegetable matter which the machine is unable altogether to remove, and practical experience alone can say how may coolies will be requirsd to keep the machine going. The cutting and carrying will also have to be added to those actually at work on the machine, but, even when we take all these into consideration, there is a very large margin of profit, if anything like the quantity described by the inventor can be turned out by it. We do not know whether the machine at Baddegama is being kept regularly at work or not, but, if it is, we hope in the interests of all, some one will come forward and give us particulars of the actual quantity harvested in one day and the cost. Of course to this, in order to arrive at a practical test of its paying capabilities, we should add the cost of producing the fibrous plants acted upon, but as many planters have thousands of aloes on or near their estates which have cost absolutely nothing to produce we need not do this to prove that it would pay them to cut down their aloes and convert them into fibre. Transport is after all the heavy item in the bill, and it is made more grevious than necessary by the want of railway relief in various parts of the country. That a remunerative cultivation of fibrous plants is but a question of time in the East, we are perfectly confident of, and, if so, Ceylon should lead the van in any such project; but we must be first assured by practical proof on a small scale that there is money in the venture. As regards the machine we have been referring to, Messrs. Clark and Co., of No. 17 Philpott Lane, London, have been appointed sole Agents for its sale here, and Mr. T. S. Clark of Galle will be glad to forward any orders for it.

NORTH BORNEO: ITS POSITION AND PROGRESS.

Sandakan, 14th Feb. 1884.

Since the country was first started, some 200,000 acres of forest lands have been selected by Cantonese, European and Australian planters. Of this land, some 40,000 acres have now been surveyed in blocks varying in size of ½ acre to 12,000 acres In all about 1,000 acres have been cleared, and about 400 acres planted up The gardens at Silam are, I hear, looking very encouraging, especially as regards what you call "new products." A trial of cacao and Liberian coffee on a small scale here, and planted in Ceylon style, is looking well, as also the few Liberian trees "put in" by the Cantonese, whose estates, owing to having "gone in for" extravagant cleaning-up (much beyond that which is usually done), will take a long time to pay. The place requires some of your Ceylon men to make it a success. With our splendid and well-proportioned rainfall, everything grows extremely well, especially cacao and Liberian coffee, for which our soil and climate seems to be well suited. A great many of the clearings here owned by both Europeans and natives are managed by men who have scarcely ever seen jungle and hold extraordinary ideas as to "clearing-up" and weeding and think as the Malays do: "Man plants ('sticks in' it is appropriately called here), and Providence looks after the plants." It is hoped that some of these people will soon see the error of their ways and obtain practical assistance.

We are fairly well supplied with labor from Brunei, Labuan, Singapore and Hongkong for thirty dollar cents per day (which we hope to reduce); the coolies from the latter place are, however, "at sea" in the jungle or on plantations, and consequently not much use, but may, perhaps like their employers, with the aid of practical assistance and advice, become better in time.

Our timber trade with China is likely to be a good one, the demand there being great and the supply of all sorts of timber here almost inexhaustible.

I may add that the greater part of your correspondent's letter on "The Ups and Downs in North Borneo" is untrue and likely to mislead as to the true state of the Government departments, &c., especially the survey department, everything here working much more smoothly than is usual in countries under similar circumstances, and with but one exception the "weeding-out" of officials has been a decided benefit. I write this, as the truth should be known, and am a private individual. In conclusion, I can safely advise that practical men (who are not afraid of work), aided by capital, could do well here, but those with capital only without practical advice or practical men without capital should *not* come here. A.

COFFEE AND TEA.

Tea and coffee both contain the same alkaloid and their action is almost indentical. Do they differ in any way and if so how?

To answer this question I must invite your attention to the following analyses of tea and coffee.*

	Coffee.	Tea.
Water	12·000 ...	11·49
Cellulose	34·000 ...	20·30
Caffein	0·800 ...	1·35
Nitrogenous matters excluding caffein	13·000 ...	21·22
Non-nitrogenous matter..	15·500 ...	23·88
Tannic acid ...	5·000 ...	12·36
Fat, &c.	13·000 ...	3·62
Volatile oil	0·003 ...	0·67
Ash	6·607 ...	5·11
	100·000	100 00

Looking at these two analyses there are certain points which at once strike us. First in equal weights there is more alkaloid in tea than in coffee, and nearly $2\frac{1}{2}$ times as much tannic acid.

Coffee on the other hand contains four times as much fatty matter as tea.

The absolute analysis, however, as conducted in a chemical laboratory, is only a partial guide to the dietetic value of an article. We, as consumers, are mainly interested in those matters which are soluble in water.

Now König† estimates that in an infusion of coffee we get 25·5 per cent of the coffee used, whereas in an infusion of tea we get 33·64 of the tea used, and that these percentages are thus constituted.

Alkaloid	1·74 ...	1·35
Nitrogenous matter ...	...	9·44
Non-nitrogenous matter { Oil	14·52 } 5·18 } ...	19·26
Ash	4·06 ...	3·65
	25·50	33·64

It will observed that the amount of alkaloid found in the tea infusion represents the total amount in the tea. The amount of alkaloid in the coffee infusion is rather more than double the total given in Payen's analysis. Coffees, however, differ immensely in the amount of contained alkaloid, and this well marked discrepency between the analyses of two chemists will serve to impress the fact of variability in quality very forcibly on the mind.‡

We have not yet exhausted this question of dietetic value as tested by analysis, and the most important question of all remains to be answered. What is the relative dietetic value of a cup of tea as compared with a cup of coffee? König has attempted to answer this question. For making coffee infusion a much greater weight of material is used than in the case of tea.

König assumes that to make what he calls a "portion" of coffee fifteen grams (a little over half an ounce) of coffee is used, and that of these fifteen grams, 3·82 are dissolved in the water. To make a "portion" of tea 5 grams are used, and of these 5 grams, 1·68 are dissolved in the water:—

CUP OF COFFEE.

Alkaloid	0·26 grams:
Oil	0·78 ,,
Non-nitrogenous matter ...	2·17 ,,
Ash	0·61 ,,
	3·82 ,,

* According to a statement emanating from Brazil (*Le Brésil à l' Exposition d' Amsterdam*) the Brazilian coffees are very rich in Caffeine, and from an analysis recently made by Ludwig of Vienna, the amount appears to vary from 1·16 to 1·75 per cent (See Church's Analysis page 6.)

† *Die Menschlichen Nahrungs-und Genussmittel*, Berlin, 1880.

‡ An analysis of Brazilian coffee by Professor Church, dated May 10th, 1882, gives the following results:—

Water	11·22
Oil and fat	14·27
Matters soluble in water	24·87
Albuminoid	6·96
Caffeine	1·18
Ash	3·51

CUP OF TEA.

Alkaloid	0·07 grams:
Proteid	0·47 ,,
Non-nitrogenous matter ...	0·96 ,,
Ash	0·18 ,,
	1·68 ,,

It would be rash to assume that the analyses are absolutely correct, but they are recent and they emanate from Germany which is *par excellence* the land of accuracy.

It follows from these analyses that, supposing all the dissolved matter to be available for the needs of the body the dietetic value of a cup of coffee is more than twice that of a cup of tea, and if we assume that the stimulating power is due to the contained alkaloid, then *qua stimulant* the cup of coffee has more than three times the value of the cup of tea.

Further, Binz observes in the third edition of his *Elements of Therapeutics* that "the alkaloid which tea contains appears to be less easily absorbed than that of coffee owing to the very large quantity of tannic acid present."

The tannic acid in tea is doubtless one of the causes why it is as a drink so attractive. It is slightly astringent and clean in the mouth, and does not "cloy the palate," an expression for which I can find no scientific equivalent. Tannic acid is also one of the dangers and drawbacks of tea. It is largely present in the common teas used by the poor. Now the rich man who wishes to avoid an excess of tannic acid in the "cup that cheers" does not allow the water to stand on the tea for more than five, or at most eight minutes, and the resulting beverage is aromatic, not too astringent and wholesome. The poor man or poor woman allows the tea to simmer on the hob for indefinite periods with the result that a highly astringent and unwholesome beverage is obtained. There can be no doubt that the habit of drinking excessive quantities of strong astringent tea is a not uncommon cause of that atonic dyspepsia, which seems to be the rule rather than the exception among poor women of the class of sempstresses.

Tea more nearly approaches to a pure beverage than coffee does. Coffee makes a very slight approach to the class of liquid foods.

The specific gravity of good tea is about 1,003, and of a cup of good coffee about 1,009.

Excessive tea-drinkers are more common than excessive coffee-drinkers, because the heavier coffee more easily produces satiety than the lighter tea, and it is not possible for ordinary stomachs to tolerate more than a certain amount of coffee, even when pure, and only a very small amount of the thick, sweet adulterated stuff which too often passes for coffee in this country.—*From Dr. Poore's paper on Coffee and Tea.*

THE TEA ENTERPRIZE IN JAVA.

Our Ceylon readers will see, from the following extract from the *Straits Times*, that tea culture in the great Dutch Colony is placed under many disadvantages:—

(*Translated from Java Newspapers.*)

The disadvantages of tea-growing in Java are thus set forth in a petition to the Second Chamber of the States General by several leading tea-dealers in Holland against additional import taxation on that article:—

"The undersigned having great interest in tea, owing to their direct importations of that article from Java into Amsterdam and Rotterdam, most respectfully bring under notice that both with surprize and regret they have heard of the proposal made by the Minister of Finances to raise the import duty on tea in the Netherlands from the excessively high rate of 25 guilders per 100 kilogrammes, at which it now stands in our tariff, to the amount of 40 guilders. Our surprize on hearing of it arose from the same suggestion having twice before been brought forward by former administrations, but each time it proved fruitless owing to strong representations from Java and the Netherlands against the scheme, while the present proposal is unsupported by any evidence whatever showing that what in two different years has been rejected as unadvisable, has now become fully advisable. They view it with regret, because, as victim of this purely fiscal measure, one of the principal products of our East Indian possessions has been selected, the cultivation of which could hitherto be only carried on by the utmost exertion. In fact, planters in Java have to bear, besides the import duty in this country, five additional and different taxes in that Island, while their rivals in British India, now so formidable, though they have to pay in the mother country a higher import duty than that now suggested here, are, on the other hand wholly free and untrammelled in their planting operations. The British authorities follow a sound policy regarding tea-growing in their colonies. They levy duties on the consumer but leave the producer wholly untaxed, and even energetically encourage production. The Dutch treasury not only taxes the product but the producer as well, and now that this burden threatens to become heavier still, the undersigned protest against it. Moreover, the present time is an unfortunate one to choose for laying on tea heavier charges than those now prevailing. In 1868 and 1876 the proposed increased duty could have been more justifiably imposed than now. The average price of Java tea was then 77½ and 62½, but now it is no higher than 40 cents per half kilogramme. Naturally, the increase suggested would now press much more heavily, and, that too, on Java tea in particular, than then. As the tea sold here consists half of that from Java and only the inferior qualities of it are available to consumers in the Netherlands, while the few better kinds are exported to the Levant, the increase of the import duty would drive most of the Java tea out of our markets, if it does not make the production of the same impossible to many of our Java planters. Tea from Java is so seldom classified among the better qualities of that article that some planters there can realize not more than 20 cents per kilo. for their product. Such persons will thus be burdened with a duty of 100 per cent in the mother country! More probably they will abandon the cultivation of that product. Those, however, who endeavour to defend the suggested enhanced duty by pointing to Britain, that preeminently tea-drinking country, where the import duty amounts to about 67 guilders per half kilogramme, will simply bring out more prominently into notice the sounder policy of the British in taxing consumers only, while the Netherlanders tax both consumers and producers, to which arrangement the undersigned have objected above. In Java, the tea planter pays no less than five imposts, namely, ground rent, assessment, poll-tax, license tax, and export duty. In Assam, on the contrary, land is granted to tea planters on 99 years leases free of quit rent on one-fourth of the area during the whole of this period, and on three-fourths during 15 years, and on payment then for the ten following years and the remaining 74 years, of amounts respectively equivalent to 59½ and 68¾ cents per bouw. The land leased under these conditions amounts to 338,000 acres, or 221,000 bouws. Moreover, 402,825 acres or 230,000 bouws have been made over to the tea planters in free ownership at prices of from 1½ to 5 rupees per acre, on the express understanding that the State would never demand any land tax on the same. Finally, tea planters there are exempt from the license tax. When it is also borne in mind that, besides the 100,000 acres under cultivation in Assam, ten times that quantity are available to the planters, and that fresh estates are continually being laid out, the difference of the conditions under which planters work in Assam and Java truly becomes strikingly evident. A few years ago many of the now flourishing tea estates in Java were unproductive forest, unsafe for the whole population from beasts of prey harbouring therein, while at the present time work and wages are abundantly given on them, to women and children especially. Yet planting enterprize of this kind has to bear heavy taxation both in the colony and mother country. The satisfactory results of the British system are clearly manifest, when Java in 1858 produced two to three million kilogrammes of tea, the production not having since risen much above these figures. British India yielded 350,000 kilos. What the yield there is now may be inferred from the fact that in 1882 it amounted to 27 million killos. Against this untaxed competition the taxed planters of Java have now to carry on their cultivation."

The petitioners, in conclusion, point out that the suggested enhanced duty is the more unadvisable now, owing to the danger impending over tea-growing in Java from the increasing production of tea in Assam, and that the abandonment of the cultivation of that article in Java would be a great loss to the people, from the prosperity it spreads wherever it is established. Hence they pray the States General to withhold sanction from the proposal to increase the import duty on tea in Holland to 60 guilders per hundred kilogrammes.

The Java planters might have strengthened their case by referring to the additional and formidable competition of Ceylon. We have an export duty, to be sure; but it is only 5 cents of a rupee, say 1d, per 112 lb.

THE BRITISH NORTH BORNEO COMPANY.

The *North Borneo Herald* of the 31st December contains the following review of the prospects of the British North Borneo Company for the present year :—

The old year out and the new year in. The old one has passed away. Its record is perhaps not so brilliant as we expected, but, before forming a definite opinion, we must wait for the various official reports which will no doubt, soon appear. In a new country, in the tropics, where European outdoor labour is impossible, progress does not make such rapid strides as in, let us say, Australia or Canada. The forest (or, are we to call it, the *jungle*?) is, however, falling fast before the planter's axe in the Sandakan district, and the principal company there established is, at last, taking vigorous steps to develope the resources of the large tracts of land it has acquired, utilizing the soil by planting and the forest growth by exporting timber.

The energetic Agent of the Australian Borneo Company of Melbourne, after travelling incessantly through all parts of the country available for cultivation during half the past year, has selected and paid the first instalment on close upon 100,000 acres in different localities, at Bangney island and on the East Cost.

In the Government Experimental Garden at Silam fifty acres are now under cultivation with coffee (Arabica and Liberian,) cocoa, cardamoms, cinchonas, and tea, and another thirty are ready cleared. The various plants, with few exceptions, are doing well, experience has been gained and seedlings have been distributed amongst English and Chinese planters.

Trade was not good during 1883, and there was a large falling off in the quantity of gutta exported. There have however, recently arrived from Sarawak over 100 sea Dyaks, who have discovered a good gutta district in the Kinabatangan, and the result of their energy will become apparent in the trade returns of the new year.

The want of increase in the trade was to some extent due to the absence of native collectors of jungle produce, the Sultan of Sulu, whence formerly large numbers came over, having taken steps to put a stop to emigration by making a permit compulsory, for which a fee is charged. Apart from this, trade in all Malayan countries appears to have been indifferent during the past year, and we hear complaints from our neighbours in Labuan and Sarawak and elsewhere.

Samples of rock sent for assay to England on the recommendation of Mr. A. H. Everett have given indications of silver and copper. The ore is the same as that which has been profitably worked by an English company in Sarawak. It was found near Tambuyukan, a spur of the mountain Kinabalu, in the neighbourhood of Kudat. In the interests of the Company and Government, it is sincerely to be hoped that some little energy will be shown in following up this indication. Professor Milne, of the Imperial College, Tokio, Japan, recently saw in Mr. Daly's collection at Kudat, specimens of the rocks to be found in different parts of the country and states that they are certainly "the rocks in which one would be encouraged to look for minerals." There is now also fair ground to expect that minerals, including a native ore of bismuth, will be discovered in the Segama district, on the East Coast.

Coal, as was to be expected, has been met with in several localities. The finds, however, have not been of a nature to induce the Government to work them, and probably no attempt will be made until the result of Messrs. Cowie Bros.'s experiment at Muara, near Brunei, becomes known.

The rush of Hongkong Chinese to Sandakan has settled down to a steady thirty or forty by each voyage of the steamer. Many of the first comers were dissatisfied with their introducton for the first time to a tropical forest-covered country, so different to their preconceived ideas and to what they had been accustomed to in their native land. They have returned to their own country. Those who remain shew every confidence in the Land they have adopted. The interest of the Straits Settlements Chinese in the country has been well maintained from the very first. These enterprizing people, from long residence in Singapore, Malacca, Penang and the Protected States, are fully acquainted with the characteristics of Malayan countries and do not expect impossibilities. The result is a steady increase in the revenue.

The Spirit Farm has been well sold; the Opium Farm for 1884 has been leased for a little more than double the figures reached in 1883: for a Farm of Pork for consumption, a large number of tenders were received and a revenue half as large again as that which had been estimated for the new year has been obtained.

An offer of $9,000 for the Gormanton bird's nests for 1884 has been received, which will leave a nett profit to the Government of $6,000—an encouraging increase when it is considered that the revenue from this source for the years 1880-83 only totalled $6,077. This was exclusive of the export duty of ten per cent ad valorem, which will be receivable also during the present year.

Communication with China will probably be undertaken, during 1884, by the China and Manila Steam Ship Company, and thus North Borneo will be placed *en rapport* with the Philippine Islands as well as with Hongkong. We can only hope that some of the former islands will now be induced to turn their attention to our territory, with its wealth of virgin soil.

Efforts are being also made by the Government to induce one of the lines running between Hongkong and Australia to touch at Sandakan, near which port their usual route leads them.

The Court of Directors having resolved to defer opening for the present the more remote parts of the interior and to confine their attention rather to the coast line, a re-arrangement of the staff has been necessitated and several valuable officers have been thereby lost to the country. It is not for us to question the wisdom of this decision, but taking it for granted that the Directors know their own business best, we merely express our regret at the loss the territory has sustained in the officers who are leaving us, taking with them that experience of the country which they have so laboriously and zealously acquired. Mr. C. A. Bampfylde has resigned his post of Sub-Resident of the East Coast. We are not exaggerating when we say that, taking all nationalities into account, he is the most popular officer in the Company's service. A rumour having spread that both the Governor and Mr. Bampfylde were about to retire, extensively signed addresses were presented by the Chinese and by the Malay community, begging them to reconsider their decision. We are glad to hear that, on receipt of a telegram from the Court of Directors, the Governor has consented, with the approval of the Colonial Office, to remain at his post another year. There is an old adage as to the inadvisabilty of swapping horses while crossing a stream.

The attention of the Straits gambier and pepper planters who are now experiencing a difficulty in finding suitable land in the Straits Settlements, Johore and Rhio, is being gradually turned to North Borneo, where large tracts, well adapted for this cultivation, are to be found. The Government prepared to offer liberal terms. The importance of this question cannot be exaggerated, as the example of prosperous Sarawak has proved.

For the race of 1884, Sandakan is a long way first favorite, Gaya and Kudat are neck and neck for the second place, with slight odds in favor of the former unless care is taken in the latter's training. Silam suffered neglect when, in its infancy it most required support, and will have considerable trouble in overtaking its opponents.

The prospects of the New Year are altogether encouraging, but much depends on the officers, from the highest to the lowest, pulling hard, and pulling well together, as heretofore.

Ground Nuts.—A gentleman in this station has, we hear, shipped a thousand rupees worth of ground nuts for Europe. A fine oil can be extracted from the kernels, and the shipment will possibly come back to India as the finest Olive or Lucca oil, and be bought as such by the people here. It is only one more example of the produce of India being carried to a foreign market for the want of local enterprize to utilize it. Is it ever to be so?—*Bangalore Spectator.*

Rhea Grass.—For many years past endeavours have been made in various directions to utilize this natural product of India for the production of textile fabrics, but without general success, owing to the difficulties attending its profitable decortication. Four times within the present century—quoting from *The Times* of the 22nd ultimo—has rheea been the subject of official action, while with in the last fourteen years a prize of £5,000 has been twice offered by the Indian Government, twice competed for, and twice withdrawn in consequence of all the mechanical means submitted for trial having failed to meet the requirements of the Government. Within the past two or three weeks, however, it has been demonstrated that there is a machine of recent invention which effectually separates the fibre from the woody stem of the green rheea, and at the same time cleanses it from all extraneous adherent matter, producing it in good condition for the market, and this without any previous or subsequent treatment. This machine, which is the invention of Mr. H. C. Smith, consists of an iron framing about 3 feet high, 2 feet wide, and 3 feet deep from front to back, carrying a revolving drum about 18 inches in diameter and 12 inches wide. The drum is fitted with a series of beaters which pass near to the edge of a small feeding-table about 12 inches wide, the drum being covered in with an iron hood. From beneath the feeding-table a thin sheet of water is made to play in a constant stream against the drum at a certain pressure and angle, and this constitutes the whole of the apparatus. The fibrous plants are fed in by hand on the feeding-table, and are simply held up to the beaters by a cushion or backing of water, by which means the whole of the extraneous matter is removed, and the fibre produced in a remarkably short time, and in excellent condition. The machine was invented about a year ago, and some specimens of it have been made and sent out to India, where they are now doing good work upon various kinds of fibrous plants. Until about three weeks ago, when the machine was first brought under the notice of Dr. Forbes Watson, it does not appear to have occurred to any one to try the effect of the appliance upon the fibre of the rheea plant. This gentleman's long practical acquaintance with fibrous plants at once suggested the idea that with the water backing it would successfully treat the rheea. The machine, on being put to the test satisfactorily answered his expectations, and a few days a private demonstration took place at Messrs. Jennings's Works, Stangate Wharf, Lambeth, the experiments being conducted by Dr. Forbes Watson. It may for the moment suffice to say that the results were such as to fully satisfy those present—gentlemen interested in the natural resources of our Eastern Empire, and of great practical knowledge. Thus it it is only reasonable to assume that the problem of the mechanical preparation of rheea fibre has been solved, and that the prospects of the utilization of this valuable but hitherto useless are now fairly established.—*Home and Colonial Mail.*

THE PORTUGUESE COLONIES OF WEST AFRICA.

BY H. H. JOHNSTON.

* * *

Of course the first Portuguese possession off the Western Coast of Africa is Madeira, but this is too well-known for me to touch on, so I will pass on to the Cape Verde Islands, an archipelago lying about 300 miles out at sea opposite Senegal, between the parallels of 14° and 17° N. These islands are ten in number, not counting many smaller barren rocks, and their entire population is about 100,000 or 30 to the square mile. In spite of their apparently barren and sterile look from the sea, they are productive, and in the interior of most of the islands there are springs of water which, with careful manipulation, irrigate large quantities of fertile soil, and compensate for the almost entire absence of rain. The productions of the Cape Verde archipelago consist of superior coffee, cacao, orchilla-weed, castor-oil, rum, maize, salt, cotton, indigo, oranges of fine quality, limes, lemons, pine-apples, cocoa-nuts, bananas, and most tropical fruits, sugar-cane, tobacco, coral, and much cattle and other live stock, including a hardy and very serviceable breed of horses, which are constantly exported to the neighbouring continent.

The largest island of the group is Santiago, whereon is the seat of government for the whole archipelago. Its superficies is a little under 500 square miles. The interior is fertile and well cultivated, and traversed by excellent roads, with strongly made bridges across the many ravines. The mountains rise to over 4,000 feet, and from their sides gush springs of delicious water which is carefully husbanded, and used to irrigate vast plantations of Indian corn, castor-oil plant, sugar-cane, pine-apples, and tobacco. Water is also conveyed in leaden pipes from a considerable distance into the town of Praia, the capital of the island, where it is stored in an immense reservoir.

Though Santiago is the largest island of the Cape Verdes, it is but little known to English people, for only Portuguese steamers call at its port, which is not a remarkably safe one; on the other hand, the miserable little desert islet of Sao Vicente, owing to its splendid harbour, is become a place of cosmopolitan resort, where the Anglo-Brazilian Telegraph Company has a station, and where many great lines of steamers have their place of call. The jagged coast of Sao Vicente is grandly awful in its sublimity of desolation. Sharply peaked and precipitous mountains descend to the water's edge; and in between their masses are little inlets of blue foam-streaked sea. The mountains are variegated with the long sloping lines of their different strata; they are scarped, and worn, and twisted into fantastic shapes, and they look like the earth's throes of agony hardened into stone. There is not a sign of life, not a bird or a plant visible about them. As they stand out in their dead neutral tints against a glaring blue sky, they might represent a landscape in a lifeless planet. In the interior of Sao Vicente there is one spring of water where a little vegetation grows, and a few people live and try to raise fruit and vegetables for the town, but, as a rule, Sao Vicente is entirely nourished by the great island of Sant Antao opposite, from which it receives not only food and water, but even the very soil necessary to grow the few plants and trees which decorate its sandy streets.

* * *

When we leave the prosperous and civilised Cape Verde Islands and arrive at the Portuguese possessions in Senegambia, which lie some 500 miles to the south-east, the contrast is very great in every way. We find ourselves in a most typically African part of Africa. The high and arid mountains of the Cape Verde archipelago are exchanged for a flat, marshy country, covered with the densest forest, and civilisation yields to utter savagery. Portuguese Guinea, which extends from about the 13th parallel to the 10th, just comes in between our colonies of the Gambia and Sierra Leone. This territory has about 200 miles of coast line, and offers many ways into the rich interior, by means of the great and navigable rivers, Casamança, Geba, and Cachen. Portuguese Guinea is, in fact, little more than the vast delta of these three great rivers, which communicate with each other by many natural canals. There is also the large archipelago of the Bissagos Islands, lying close to the mainland, and on one of these is placed the capital of the province, Bolama, where the Government and principal merchants reside.

* * *

Amongst the white inhabitants, those of Portuguese nationality naturally prevail, owing to the soldiers and officers of the garrison, but all the principal merchants are French, and the commerce of Portuguese Senegambia is almost within their hands. They have many commercial houses, not only in Bolama, but in most of the neighbouring islands, and the greatest trade is done in the export of ground-nuts, of which shipful is sent to Marseilles, there to be turned into spurious olive oil. Besides this, wax, coffee, cacao, indiarubber, sugar, ivory, and wild beasts' skins are also exported. Gold is found in the interior.

The principal centres of Portuguese rule and trade in Senegambia are Bolama, the capital; Bissau and Cachen, fortified places; the rich island of Gallinhas; Colonia, at the mouth of the Rio Grande; Géba, a hundred miles inland on the river of that name; Ganjarra and Fâ, on the same river; Farim, on the Cachen; Bolor, on the Casamança; and Jafunca, and Zeginchor.

The temperature of this part of Africa is very high, and the heat is more oppressive than in most parts of the continent; nevertheless, Portuguese Guinea is not very unhealthy. Yellow fever is quite unknown, and marsh fevers with rheumatism and ague are the most prevalent forms of disease. Everywhere the most perfect drinking water, cold and sparkling, is to be procured, not on the surface, but from wells of about 20 ft. in depth. Time forbids me to descant on the extreme richness of this possession, or, more strictly, on the latent richness of its soil and productions. Vegetation here reaches a development almost unparalleled; and I might state that Portuguese Guinea for the naturalist and anthropologist is one of the least known and most promising fields of study.

Though many traces of ancient Portuguese occupation may be found on the Gold Coast and the Niger Delta, the only remaining relic of their former possessions in this part of Africa is the solitary fortress of Sao Joao d'Ajudá, in the kingdom of Dahomé. "Whydah" it is called by the English, and it is the principal or the only seaport of that still independent kingdom.

* * *

At the present time, Whydah, or, as the Portuguese call it, Sao Joao d'Ajudá, is under the administrative government of the colonial dirtrict of Sao Thomé and Principé. These latter are two islands of singular natural wealth and incomparable natural beauty, lying from one to two hundred miles from the African coast, about the region of the equator.

Principé, which is distant from its sister island about a hundred miles, offers to the delighted gaze of a Nature worshipper one of the most beautiful spectacles in the world. As you enter the fine lake-like harbour of its only town, a wealth of vegetation is spread before you. On the spits of projecting rock and sand, coco palms grow in sturdy groups, while the rapidly rising land is one dense mass of dark green forest. Immediately behind the town, a great sugar-loaf peak rises nearly 3,000 feet into the sky, clothed up to the very top, save for one small streak of grey rock, with velvety forest which, from its proximity to the shore, presents a most imposing spectacle.

In the town, there is a general appearance of desolation and decay. Soon after landing on a stone quay projecting into the water, and evidently a fortunate relic of the magnificence of former days, you pass through some ramshackle streets, and cross a stone bridge over the little river. Here, there is a charming view of the distant peak reflected in its still waters. Many coco palms droop over the stream. Women come here to wash clothes, and their little naked children chase the mud fish and land crabs through the ooze. There are, in this town, no less than five ruined churches, their roofless interiors choked with ferns. But whichever way you turn, nothing but ruin, abandonment, decay, meets the saddened eye. It is like a dead town surprised by some calamity, and offering its ruined houses—many of them of magnificent proportions—and its deserted public buildings as a mute record of the disaster. The river, in its different branches, was once spanned by fine stone bridges, whose massive foundations attest their former stability; now, shaky and miserable structures of planks and ropes offer a hazardous method of crossing the stream dry shod. A little way in the interior, immense cacao plantations begin where the undergrowth is a thick brake of pine-apples, loaded with deep red fruit. Very little of the land in Principé is under cultivation; the principal estate belongs to a merchant in Sao Thomé. Cacao is the chief product of the island. Coffee hardly exists, although to encourage its cultivation the Government has made its exportation free of duty, whereas in Sao Thomé, coffee exported pays 5 per cent. The interior is very mountainous, and covered everywhere with unbroken forest. The uplands enjoy a fairly healthy climate, although occasionally the whole island is subjected to attacks of marsh fever, caused by the emanations from the dreadful Niger delta, which the north wind blows over to Principé.

* * *

The prosperity of Principé fell, because the sugar-cane plantations which caused its wealth were forbidden by the Portuguese Government, some two centuries ago, in case they should interfere with the rising sugar trade of Brazil. The island, however still continued wealthy until the middle of the present century, when the abolition of slavery gave the finishing touch to its ruin.

The population of Principé was once 30,000; it is less than 3,000 at the present day. Its palaces and churches of former days have become magnificent ferneries, and if it were possible to forgive this retrogression of civilisation, it would be so from the beautiful mask of vegetation that everywhere conceals the ruin and decay.

Sao Thomé presents a much more cheering prospect. While in its natural beauties and its great fertility it rivals Principé, it far exceeds that island in population, cultivation, and development. The superficies of Sao Thomé is about 700 square miles. It is traversed by the equator. The character of the island is extremely mountainous, some of the peaks reaching 6,000 feet in height, and many of them assuming the most fantastic forms. The climate varies greatly. In the lowlands it is hot and unhealthy, on the upper plateaux it is salubrious and warm, and high up on the mountains, it is mild and sometimes even chilly. Europeans can live in perfect health and comfort in the uplands, and, indeed, the Portuguese that reside there are most favourable specimens of colonists, with their pretty wives and their large families of fresh-coloured children.

* * *

Shortly after my arrival at the island, I made an excursion into the interior to visit some of the "roças," or country houses situated between two and three thousand feet above the sea, on the thickly wooded mountain sides. My guide and companion was a kind and erudite Portuguese, who was a Government doctor and medical officer to many of the great coffee and quina plantations in the interior.

In the cool of the afternoon we left the city of Sao Thomé, and journeyed along an excellent road, bordered with the most splendid vegetation, amidst which nestled the little wooden houses of the coloured inhabitants. Sao Thomé must be the ideal of a black man's paradise, and the negroes of Sao Thomé the happiest in the world. These little homesteads are surrounded by innumerable bananas, with plantations of manioc and sweet potatoes. Pine-apples form the rank undergrowth of their gardens, and the ground-nut is a weed. Here and there is an old chapel with lichen-stained belfry and silent bells. A civilised feature amid these little hamlets is the general shop, where a quaint assortment of things is sold, and where it is curious to see advertisements of English sewing-machines hung up to decorate the walls. By the side of the road are magnificent trees from most parts of the tropics, but principally from Brazil. Africa is represented by the baobabs, mimosas, fig trees, dracænas, and the bombax, or cotton wood. There are also guavas, oranges, limes, and papaws, and both the coffee and cacao are beginning, as the distance from the town increases, to take a prominent place. We crossed many brawling streams, and soon—were it not for the civilised-looking road—we might have believed ourselves in virgin Africa, for signs of cultivation began to disappear, and we would higher and higher up the hills, through the most magnificent forest. The air was musical with the continued sound of falling water; but, except now and then a glint of spray amid the foliage, the tumbling brooks were invisible. The soil was a rich red colour, and when, as we ascended to some height, the bracken fern began to show itself, and to cover with its dewy fronds the steep banks that bordered the road, the scenery, with its red soil and intense greenery, recalled very forcibly the Monmouthshire lanes which border the River Wye in England.

The roças, or country houses, that now began to crown the heights, were very Swiss-like in appearance, generally several storeys high, and with many little outside ladders going from storey to storey. Sometimes the houses are dazzlingly white, and remind one of the charming little quintas of Madeira, like which they are pleasantly embosomed in bright flowers and vegetation of dark velvet green.

We passed the night in one of these little châlets, meeting with a most hospitable reception from its occupants.

* * *

Early the next morning we started to visit the quina plantations, high up the hills, ascending to about 3,500 feet. The quinine plant, or quina, exhibits several varieties, all of which are cultivated in Sao Thomé. The propagation of this precious tree is fortunately easy. Besides growing it from the tiny and abundant seed, the new leaf-buds or "rebutes," as the Portuguese call them, are turned down by their long stalks, and fastened into little boxes of earth, raised, from the ground to the proper height, and in these boxes the buds throw out roots and become new plants.

The price of quinine bark brings in, on an average, £4 per tree, when the tree has attained the age of six years. So that a man who plants 100,000 quina plants, at a preliminary cost of £100, stands to gain in six years' time £400,000. Nor does his fortune end there, for after stripping the tree of its bark, it is cut down, and in some five years more has sprung up again from the roots, and gives an even greater yield. Land is sold for a mere nothing in Sao Thomé, for only about one-third of the island is under cultivation; labour, thanks to the excellent system of Government apprenticeship, is cheap and plentiful; the climate on the uplands is perfectly salubrious; there are pleasant society, glorious scenery, and good horses are to be had. Why do not some of our younger sons try quinine growing in Sao Thomé?

* * *

Since I left West Africa, the Portuguese have formally taken possession of a point on the South-west Coast, a little to the north of the Congo. This is generally called Landana, and is situated close to the *embouchure* of the River Chiloango, an important highway into the interior. Landana is nearly a hundred miles from the mouth of the Congo, but receives a great deal of the Congo trade, which follows the course of the Upper Chiloango. It is a prosperous place, with four or five large trading establishments, a flourishing Catholic mission, a church, and a doctor. It is, in fact, a readymade colony, into the possession of which the Portuguese have entered for no particular reason except that they were preferable to the French in the eyes of our Government. English Ministers seem to have the vaguest notions of geography; and when Portugal asked their permission to occupy Landana, they assented willingly, because they had no knowledge where Landana was. South of the Congo the Portuguese have, at present, no recognised possession before we arrive at Ambriz; unless, indeed, there be any fresh arrangement with the British Government empowering them to occupy territory north of the River Loge, in 7° 40', S., their present limit. Ambriz has been a Portuguese possession ever since 1855, when they annexed it to Angola for the purpose of more effectually suppressing the slave trade which, to do them justice, they have really done.

The habitable town of Ambriz rises to the top of a bold red cliff, at the base of which great rollers dash themselves into foam. Ambriz is sandy, and infested with the horrible "jigger," or burrowing flea, originally introduced here from America, and now fast spreading over West Africa.

The local commerce of this district is in coffee, which grows wild on the neighbouring hills, and is also cultivated by the natives. Ambriz is the natural outlet for the trade of all the interior lying about the 7th and 8th degrees of S. latitude, and stretching inland to the River Luango; but it does not seem to prosper somehow, in spite of being the only kind of port between Loanda and the Congo.

Many of its merchants have migrated across the Portuguese boundary to Kinsambo, where, perhaps, the landing is the most dangerous on all the South-west Coast, in order to escape the duties imposed by the Portuguese custom-house. Though these duties are much fairer and lighter than at Loanda or other Angolan ports, they are much complained of by traders; still in Ambriz, at least, there is some excuse for them, as the Portuguese have spent considerable sums in order to construct a pier, and render the landing of goods both safe and easy. Going south from Ambriz, we must travel by sea for a distance of thirty miles to reach the settlements on the River Dande. The intervening district between the Dande and Ambriz has never been conquered by the Portuguese, and still remains impossible to Europeans. A force of twenty armed policemen would suffice to clear the road, but although Portugal can dream of military expeditions to the Congo, she cannot afford a few soldiers to connect Loanda and Ambriz by land.

The estates in the fertile valley of the Dande are magnificent properties, growing immense quantities of sugar-cane, bananas, pine-apples, and oranges. The climate is good, and the scenery beautiful. Horses are successfully bred here, and supplied to the colony of Angola.

Continuing southwards from the Dande, we pass the great River Bengo, and soon afterwards, if the journey is by sea, arrive at the fine bay of Loanda.

* * *

The trade of Loanda is greatly in the hands of a well-known English firm, who also manage the navigation of the Quanza.

The Quanza has been termed by many writers "the gem of Angola," and with reason, for this navigable river offers a great highway to the rich regions of the interior. The Quanza rises not far from the source of the Ku-nené, that other great great river of the Portuguese Lower Guinea, in Lat. 14° S., and flows south and then westward to the sea, which it enters a little to the south of the Loanda.

It is navigable by river steamers of some burthen for over 200 miles from its mouth, and at this extremest point, just below the last falls, Dondo, an important commercial town, is placed. The old capital of the Quanza was Cambambe, founded by the Portuguese in the 16th century. Its ruins are still remaining, and lie about ten miles distant from the present site of Dondo. This latter place is extremely hot, and certainly unhealthy; whereas Cambambe was placed on the breezy heights, and was infinitely more salubrious. However, Cambambe was abandoned for the present capital on account of the difficulties of navigation that prejudiced the older city. Dondo can with ease be reached by steamers, but to ascend the river higher, to Cambambe, is difficult, and full of risk. As the point at which the commerce of the interior is focussed and concentrated in its relations with the coast, Dondo is a great emporium of Central African trade, and attracts to its markets the products of the far interior, of the Rivers Quango and Kassaï, both of them huge affluents of the Congo (the Kassaï being Stanley's Mobindu or Ikelemba), and all the outward trade of the Muata Yanvo's Empire. In fact, one may say, without exaggeration, that the trade of the Upper Quanza has relations with Nyangwé and the East Coast.

* * *

South of the Quanza river, as far as the 12th degree of latitude, the Portuguese rule is confined to the strip of coast. The interior, where the powerful tribes of Kissamas, Libollos, and Ba-ilundo have their territories, is quite independent of Portugal, although on all but the careful German maps it is coloured Portuguese. Between the Quanza and Benguella, there are, however, several important places on the coast, such as Novo Redondo, and Catumbéla. This is the most wonderful country for wild animals. Benguella itself is quite an *entrepôt* for the supply of wild birds and beasts to divers Zoological-gardens and to dealers. Every homeward-bound steamer is laden with monkeys, parrots, cage birds of all descriptions, and occasionally even a lion or leopard may be seen.

Benguella is an important place, especially as regards trade. I have spoken of Dondo, on the Quanza, having relations with the far interior. How much more Benguella, whose merchants range all over Central Africa, encounter their countrymen from the East Coast on the Upper Zambezi, and even penetrate to the copper country of Katanga and Lake Bangwéolo, whence rises the Congo. The rule of the Portuguese extends nearly 500 miles inland from Benguella, and their political influence even further. From Benguella, now, there is a road to the mountain ranges of the interior, where a healthful and bracing climate is to be found, and where the scenery is of great beauty.

Benguella itself is said to be unhealthy. It has, at any rate, a bad reputation, although its sanitary condition has certainly improved since the surrounding marshes were drained.

* * *

Benguella, like Ambriz, Loanda, and Mossâmedes, is the capital of a separate district, and has a governor and administration of its own. Between Benguella and Mossâmedes there is scarcely any place of importance. The coast becomes increasingly barren, and assumes an absolutely desert character.

Mossâmedes is the most flourishing town, perhaps, in all Portuguese Africa. It is situated in a tract of absolute desert, with a fine deep bay in front of the town.

* * *

On the map, this part of Africa seems anything but devoid of water, and it appears incredible that the district of Mossâmedes should be what it really is, a great offshoot of the Kalahari desert; but the fact is, that the three principal rivers of this province, the Giraül, the Béro, and the Croque, are but occasional torrents, flowing for about two months in the year, when the heavy rains of January and February drain off the distant Serra de Chella. During the other months, the body of the river dries up, the water sinks some feet below the sandy bed, and only occasional great lagoons retain a portion of the flood which at one time covered acres of level plain. It is in these great river beds that lies the richness of the country. Their splendid soil can be made to grow cotton of superior quality, sugar-cane, maize, castor oil, oranges, limes, and vegetables of every description. But in most places, especially in the valley of the Croene, cotton is lord of all, and fetches such high prices, on account of its quality, that scarcely an inch of ground is spared to anything else. Forty miles south of Mossâmedes there are several rich plantations on the River Croque, which are at present the farthest extension of Portuguese colonisation to the southward, except the fort and settlement at Humbi, on the Cunéné. As this latter place was one of the furthest limits of Portuguese possession, I was anxious to visit it, and accordingly joined Lord Mayo's hunting party which was journeying in that direction. We travelled at first due west from Mossâmedes, crossed a desert tract of 40 miles in width, and then arrived at the first spurs of the Chella mountains. This range, which lies at a varying distance of 70 to 100 miles from the coast, is part of the mountain barrier or girdle which encircles the interior plateau of Tropical Africa. Some of the Chella peaks rise to 8,000 or 9,000 feet in height, while the forest scenery on their slopes is of unparalleled beauty. When the mountain chain is crossed, you arrive on the other side at an elevated plateau, some three thousand feet above the sea, eminently healthy, and possessing a delightful climate. Here there are several important picturesque settlements and garrison towns, such as Huilla and Quillengues, and here, too, are settled a colony of Tranwaal Boers. This new and important element has lately been introduced into the somewhat sluggish province of Mossâmedes. The Boers that "trekked" away north from the Transvaal, as far back as 1874, after undergoing, thanks to their own obstinacy and ignorance, trials far more terrible and incredible than those of the boasted pilgrimages of antiquity, began gradually to approach the banks of the Cunéné in the year 1880. Here they halted for some time, and had many squabbles with the natives, from their overbearing behaviour and unscrupulous dishonesty, and on one or two occasions their enraged opponents nearly cut them to pieces. In the meantime, some of the less ignorant among them were negotiating with the Portuguese Government for permission to cross the Cunéné, and settle in the fertile lands beyond. An answer was some time in arriving. It needed a little consideration before the Angolan authorities could agree to the entry into their sleepy peaceful lands of these quarrolsome, turbulent, though energetic people.

The Boers grew impatient and sent word to say that if the local authorities could not arive at a speedy decision they (the Boers) would "trek" farther north, and interview the King of Portugal himself. However, consent was at length given, and the Boers were assigned territories at Humpata, a district in the vicinity of the Chella mountains. Thither they proceeded, and have since settled down, and find little to grumble at in the indulgent rule of Portugal. Their lands form one of the finest corn-growing districts in all Africa. There is abundance of running limpid water, a rich soil, and a perfect climate. The great elevation of the Humpata plateau above the sea produces a European temperature, and the thermometer is frequently at freezing point before dawn. Here some sixty families of Boers have settled down to corn-growing and cattle-rearing, hoping to dispose of their agricultural produce in the markets of Angola. From Humpata to the Cunéné is a distance of about 200 miles, traversed by a waggon-road, and dotted at raro intervals with Portuguese forts and garrisons. There is a Government postal service along this route once a month, and it is everywhere safe travelling except, perhaps, for the abundance of lions that at certain times infest it. The game is wonderfully abundant and varied in character. Great herds of giraffes, elands, zebras, and antelopes may be encountered, together with occasional elephants, rhinoceroses, and buffaloes. In fact it is one of the finest sporting countries in the world. —*Journal of the Society of Arts.*

BIFACIAL ORANGES.—In the *Provence Agricole* M. Heckel tells us how the fruits which on one side present the characteristics of oranges, and on the other those of lemons, are produced. A nurseryman at Cannes, M. Tordo, takes scions (*bourgeons*) of various species of citrus, orange, lemon, &c., and grafts them circularly around the trunk of a citrus, arranging the scions closely together in pairs so to bring about complete fusion of the scions. When the grafts have adhered the tree is headed down to within a short distance of the grafts, and in spring branches are seen which give rise to monstrous fruits, having the characteristics of the different grafts blended together. The branches which originate from the ingrafted shoots produce leaves which are greatly changed in form and differ from those of either species, thus affording a striking proof of graft-hybridisation. The flowers of the two species are also fused.—*Australasian.*

PRACTICAL KNOWLEDGE.—The more we see of farming the more are we struck with the importance of practical knowledge. The difference between practical and theoretical knowledge appears to be this—that practical knowledge enables its possessor to deal with special difficulties as they arise in the simplest manner, and with the least possible confusion to other departments of his business. Theoretical knowledge by itself is apt to cause a man to treat special difficulties by applying to them general principles, which, however true in themselves, may possibly derange his other plans. Without practical knowledge, it is very difficult to apply our theories. It is of little use to know how sheep ought to be fed if the master has not a keen perception as to whether his sheep are going the right way or the wrong. He may have rules at his fingers' ends as to the proper stage at which to cut grass, cart hay, reap and harvest wheat or barley, sell bullocks, roll land, &c. The question which tests his practical knowledge is, however, always, "Is this grass, or hay, or wheat, or barley, or bullock fit?" Such knowledge can only be gained by long-continued and constant observation, and it is soon lost from want of practice. Young men should especially cultivate it, and never think time wasted that is spent in working among live stock and crops. Another aspect of a farmer's business in which practical knowledge is of great importance is seen in his dealings with men. Under no circumstances, perhaps, will mere theoretical knowledge more completely break down than when brought into such collision with the prejudices of the working man. It cannot stand for a moment, for unless you can say you know by experience that the course recommended is the best, he has the advantage in the argument over the master. —*Agricultural Gazette.*

HAZEL NUTS, which form an important article of export from Trebizond, are stated in a recent report to be produced in Kerassond of a superior quality to those grown in any other parts of the vilayet. The values of the exports of nuts to Great Britain during the second part of the decade exceed by nearly £9,000 those in the former years.—*Gardeners' Chronicle.*

THE TOMATO AN INSECTICIDE.—It has often been asserted (says a correspondent of the *Garden*) that aphides have such a strong aversion to the tomato that the mere suspension of a few branches of this esculent on peach trees, or indeed on anything infested by them, would in some cases suffice to clear it of them in a few days. In others the effect has not been so satisfactory. It is, however, interesting to learn that a French nurseryman is making practical use of the tomato as an insecticide. By infusing the leaves at the rate of about one pound to ten quarts of water, adding thereto twenty quarts more water, he obtains an efficient insecticide. By planting tomatoes amongst his melons he keeps away the aphides which attack them.—*Queenslander.*

ASHES AS A FERTILISER.—Unleached wood ashes contain all the constituents of plant food that the ordinary or worn-out soil needs, except nitrogen. By their chemical action, they render much of the inert nitrogen in soils available and in that way may be said to furnish nitrogen. This is true of lime, and on this power of making nitrogen avilable the greatest value of lime, when applied as a fertiliser, depends. Ashes also have a good mechanical effect upon tho soil, especially heavy clay soils, which are made lighter and more porous, so that air and water circulate more freely. Ashes do not suffer waste by being washed out to the extent that is true of the more soluble and concentrated fertilisers sold in the markets —their effects are therefore more lasting.—*Australasian.*

COFFEE.—The active principles of tea, coffee, and cocoa are, as to chemical composition, almost if not actually identical. Physiologists are now, I believe, unanimous in the conclusion that tea and coffee, and, *à fortiori* cocoa and chocolate, are more than grateful solaces to the nervous system, actually conducing to blood and strength. Curiously, too, in support of these scientific deductions, is a testimony of Bruce, the celebrated Abyssinian traveller, a man suspected of drawing the traveller's long-bow at the time when his travels were written, but whose accounts of the strange things he saw in Abyssinia have since been fully verified. Bruce narrates that the Abyssinians, when starting on war excursions, and desirous of not overburdening themselves with commissariat stores, were in the habit of mingling butter and powdered coffee, rolling the compound into balls about the bigness of a billiard-ball each, and living wholly for long continuous periods on the compound. Consideration of the actual nutritive property of coffee is of importance in establishing the dietary of gaols, union workhouses, and other institutions supplied with a fixed dietary. In laying down the food regulation of these places, the rule has been acted upon of giving all necessary food, but withdrawing all mere stimulants—in a wider sense, all nervine solaces. Accordingly it will be found—looking at the published dietaries of these places—that gruel has been made to supplant tea and coffee almost exclusively. This would seem to be physiologically wrong, as it is socially cruel. To the case of union inmates well stricken in years the charge of cruelty with fullest force applies. The quantity of tea and coffee with dry bread that certain old people —more particularly old women—will consume and thrive upon, to the exclusion of meat, would surprise anybody who had not been witness of it. There is good warranty for affirming that the digestive organs get acclimatised to particular foods and modes of living by practise, as the whole human body does to regions. People long accustomed to tea and coffee cannot well do without those more than solaces to existence. One word now about the roasting of coffee. In England this operation is seldom conducted in private families, but is done by the coffee-roaster. Still, if coffee be desired to have the highest flavour of which it is susceptible, it should be roasted just before using. There is no difficulty in the matter. A frying-pan answers quite well; and in Germany—the Rhine provinces, at least —is mostly used for the purpose. The raw coffee being put into the pan with the least pat of butter, is set over the fire and stirred till of a delicate brown.—*Leisure Hour.*

A SOUTH SEA ISLAND SILO.

(TO THE EDITOR OF THE "FIELD.")

SIR,—It may interest many of your readers at the present time to know that the silo system has been long known and practised by the natives of the South Sea Islands.

In many of the islands of the Southern Pacific the natural products of the soil, such as cocoanuts, bread fruit, bananas, taro, and yams, are almost the only means of subsistence; and, as a year of plenty is frequently followed by a year of great scarcity, the inhabitants provide for the latter season by preserving the surplus of the former. Their mode is as follows:—

A large rectangular pit, 6 ft. or 7 ft. deep, is dug in the ground, and the sides well lined with plantain or other thick leaves sewn together. The fruits or vegetables are then stripped of their skin and thrown into the pit, which is then covered with more leaves, and heavily weighted with large stones.

Small spaces are left between the stones so as to allow the gas generated by fermentation to escape, and this fermentation is sometimes assisted by the introduction of pungent fruits and strong-smelling herbs.

Sometimes the pits are very large, and in one of the Samoan Islands I was shown one 8 ft. square and 14 ft. deep, belonging to a chief, and, when orders were given, it had to be filled from the contents of the smaller pits owned by his subjects. I was told that its contents would remain good for three or four years, and that "mai" (as it is called in Samoa), like good wine, improves by age.

In allusion to the stones employed, the Samoans have a proverb, "Wise chiefs are the 'mai' stones that repress the evils of society."

In Fiji the contents of the pit are called "madrai."

The smell arising from the pits is very disagreeable, but when "madrai" is cooked it forms a favourite native dish. In taste it is slightly acid, and not unlike a sour cream cheese.

The different sorts of "madrai" are said to possess different qualities, but the Fijians prefer that made from taro, as they say it makes them dive well. "Madrai" is not eaten in its raw state, but is taken out of the pit in small quantities, mashed up, mixed with coconut [milk, wrapped up in leaf packages, and baked in an oven.—J. W. BODDAM-WHETHAM.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, February 23.

Discussion is taking place as to the relative value of carbolic and salycylic acids in the treatment of foot and mouth disease. There really does not appear to be much difference, save, that the carbolic acid is five times less dear. The salycylic acid is applied in the form of a solution, 5 grammes to a quart of water, for the mouth, and applied to the nose and foot ulcers in the form of powder. The solution of the carbolic acid is employed two or three times a day, following the gravity of the disease; ten hours after the first application, the fever diminishes and the appetite returns.

A veterinary surgeon writes that the Pasteur process of preventive vaccination has not always succeeded with him in the case of pigs; that the cause might be attributed to difference of race, degree of fatness, and nature of food. Indeed, he has found that the terrible malady, *rouget*, disappeared where the pigs were let run on a grass field and fed on a vegetable, not a milk diet. The same gentleman draws attention to the astonishing fact that a farmer in the neighbourhood of Vervins, who introduced the most improved breed of English pigs, was refused the first prize by the Local Farming Society, because the pigs had too small ears!

The Commission appointed by the government, to try all the remedies they believe practicable, for combating the phylloxera, and if a perfect cure was found, to recommend the payment of the reward of 300,000 fr., has made its annual report. Some eccentric remedies were addressed to the committee, such as the secretions of snails in salt water, the employment of venomous plants, of electricity, and lastly, blessing the seeds of the grape before sowing. The committee recommends the employment of the only efficacious means known thus far, viz., submersion, sulphuret of carbon, and sulpho-carbonate of potassium. It draws attention to the astonishing results obtained by M. Mares, that of strong manurings of the vineyards followed by "summer"—not "autumn" which is the Faucon process of irrigation. The same body has courageously admitted the beneficial advantages resulting from employing American stocks—for heavy lands the wild Riparia, Solonis, York-Madeira, Vialla and Jacquez. The stocks are best to employ, as they resist, by their roots; grafting American cuttings is not so good.

In Sweden there are villages with low houses whose roofs are covered with grass, and which serve to graze goats. In Norway trees are planted on these grass roofs, so that at a distance the village looks like a little wood. Often the roof is a kind of kitchen garden.

Fodder in Germany frequently runs short for sheep; in such a state of affairs, hay and much straw are cut up, and mixed with chaff, leaves, and some roots sliced; all is placed in a vat, water poured in, the cover pressed down and weighted, then steam is turned on. A handful of hay at night will correct any tendency to laxity in the animals.

FORMATION OF GUM IN TREES.

Sir James Paget, whose interesting papers on abnormal growth of plants attracted so much notice some time since, has drawn attention in the *Medical Times* (Feb. 16, p. 206) to some remarkable investigations made by Dr. Beijerinck in connection with the formation of gum in trees, lately published by the Royal Academy of Sciences at Amsterdam. Dr. Beijerinck found that in the peach, apricot, plum, cherry, or other trees bearing stone fruits, the formation of gum may be caused by inserting a portion of the gum under the edge of a wound through the bark. The observation that heated or long-boiled pieces of gum would not produce this effect, and that wounds made in the bark of the tree did not produce gum unless a portion was first introduced into it, led him to suspect that the formation of gum was due to the presence of bacteria or other living organisms. On micropscopical investigation he found that only those pieces of gum containing spores of a highly organized fungus, belonging to the *Ascomycetes*, had the power of conveying the gum disease or gummosis, and that these spores, inserted by themselves under the bark, produced the same pathological changes as did the pieces of gum. The fungus has been examined by Professor Oudemans, who has ascertained it to be a new species, and has named it *Coryneum Beijerinckii*. Its chief characters consist in the fact that it has a cushion-like stroma, composed of a bright brown parenchyma, on which stand numerous conidia having colourless, unicellular and very slender stems, about as long as themselves. The conidia are small, cask-shaped, about one-thirtieth of a millimetre in length, and usually divided by slightly constricting septa into four cells, of which the two terminal are longer than the two middle ones. From these cells germinal filaments may proceed, from which are developed yeast-(like?) cells, or brown thick-walled and many-celled mycelia. The first symptom of the gum disease is the development of a beautiful red colour around the wound due to the formation of a red pigment in one or more of the layers of the cells of the bark. Dr. Beijerinck believes that the fungus produces a fluid of the nature of a ferment, which penetrates the adjacent structures, since the disease extends beyond the parts in which any trace of the fungus can be detected. This ferment he believes to act on the cell walls, starch granules and other constituents of the cells, transforming them into gum and even changing into gum the *Coryneum* itself. The influence of this fluid is also exerted in the cambium, causing the formation of morbid parenchyma, the cells being cubical or polyhedral, thin-walled and rich in protoplasm that is in its turn transformed into gum. It is further stated that "a similar disease produces gum arabic, gum tragacanth, and probably many resins and gum resins." Gum tragacanth is known to be produced by the pith as well as the bark of the stem, and to ooze out from the pith when the stem is cut; and if it be indeed due to a disease it would seem as if the disease infects the whole plant. Gum moreover, may be found in the uninjured husk of the almond, and it seems at first sight more probable that the irritation caused by a fungoid parasite should cause a greater flow of the natural product, just as the irritation caused by an insect causes the development of galls. Whether this be so or not, the discovery that it is possible to produce artificially a free flow of gum is a valuable discovery, since it may now be found advantageous to cultivate certain trees for the purpose. This is a point which might well attract the attention of the Forestry Department, since the importations of gum arabic at the present time consist largely of a variety that gives a ropy, slightly adhesive and very unsatisfactory mucilage.—*Pharmaceutical Journal.*

ROOTS.

The investigation of the inner life of the Roots—their structure, what they do, and how they do it—though obviously points of the very highest importance to cultivators—demands special qualifications and special means, neither of which are at the disposal of the ordinary gardener. It is unfortunate that it should be so, but it is our duty to make the best of the conditions under which we are obliged to work rather than lament over the impracticable. The observation of the development and growth of roots, so far as they can be seen by the naked eye, is a matter quite within our range, and we cannot too strongly urge upon young gardeners and others the necessity of carefully examining and noting the nature of the root-growth in all plants that come under their hands.

At first, perhaps, they will find that little interest is to be got out of isolated observations, but when they begin to compare the root-growth of one plant with that of another they will very soon become possessed by that most valuable of human faculties, the desire to know the reason why. Their interest will get excited, and will increase as their observations accumulate, while practical inferences will begin to suggest themselves, which latter must be rigidly tested before they are made articles of faith. One hint we may be allowed to give, and that is, as the problem is a very intricate one, that they attack it not all at once, but in detail. To sit down before a great leash of roots, and endeavour to disentangle them physically and mentally—to trace what, if any, connection there is between them and the branches or leaves, and so forth—is a disheartening task.

By investigating seedling plants, or watching how, when, or where, and under what circumstances the roots are produced, there is a better chance of arriving speedily at some useful result. The student in this as in most other problems of a similar nature, must act as the arithmetician does in working out a complicated sum—reduce his materials to the lowest possible denomination. This is what the microscopists and the chemists do in their laboratories—they endeavour to isolate each constituent, detach it from its associates, and study it in its isolated state. By treating each constituent in a similar manner they find out what is peculiar to each, and are very soon led on to see how they act and react on each other when in combination. As we have said, what the microscopist can do minutely, the ordinary observer can do roughly. To give an illustration. One particular branch of a tree we will assume dies, or becomes unhealthy, the rest remaining sound. This happens constantly with the Moor Park Apricot. Why that one branch? Is it that the roots corresponding to that branch are diseased, or placed under unfavourable conditions?

The reply to the question, it will be seen, turns upon the question whether or no there is any such connection between certain branches and certain roots. In the full-grown plant the inosculation and intercommunication that goes on between the several parts are so great and so complex, that the question can hardly be satisfactorily answered; but if the problem were attacked before all that complexity arose, we might get a definite reply. M. Clos,* in a treatise now before us, has gone into this question of root development to an extent beyond any of his predecessors, and botanists who have hitherto paid little attention to the subject will be surprised to find the degree of variation there is in the mode of production of what are called adventitious roots in different plants, and the constancy which prevails in individuals of the same species. M. Clos groups these roots accordingly as they spring from the nodes, beneath them, above them, around them, or at a distance from them, and he indicates very numerous variations in different natural orders—details into the consideration of which we cannot now follow him, but which clearly are of great practical interest to the propagator. We may, however, reverting to the question above raised as to the connection between the branches and the roots, mention that M. Clos has been studying plants of Myosurus minimus, a weed of the simplest structure, consisting of a root, a tuft of leaves from which uprises a single flower-stalk or several. If there is only one, then there are no adventitious roots; but if more than one, then the number of roots is equal to that of the flower-stalks, as if there were one such root to each flower-stalk. It must be remembered here that M. Clos is speaking, not of the original roots derived immediately from the seedling plant, but of the adventitious roots developed subsequently. M. Clos' paper is written from a purely botanical point of view, but it is very suggestive of the store of most important practical information which lies ready for utilisation by those who will take the trouble to do so.—*Gardeners' Chronicle.*

THE SILKWORM DISEASE IN CHINA.

The gradual diminution of the exports of silk from Shanghai during the last few years is a subject which has been attracting interest, but of which a definite and consistent explanation has been wanting. From 1875 to 1880, the export of silk from the port in question varied between 65,000 and 85,000 bales a year. During 1881 and 1882, the annual quantity was only 50,000 to 55,000 bales; while the shipments for the season of 1883 will fall short of 35,000 bales; this limit (which was at one moment regarded as an exceptional one) not being even reached, on account of the complete failure of the second crop. The loss to the country is about £4,000,000 sterling, in addition to the diminution of customs receipts, valued at about £340,000.

These circumstances, and the facts which have brought them about, were detailed in a comprehensive manner by M. Paul Brunat, of Shanghai, in a letter addressed by him, on July 12, 1883, to his Excellency Li-Hung-Chung, Viceroy of Tientsin, and Minister of Commerce for the North of China. The district which is referred to is specially that which exports its products from Shanghai, and which (notwithstanding its important yield of silk) is of relatively small extent. M. Brunat has communicated to a Lyons journal a copy of his interesting statement, and explains the ignorance which has hitherto been general, as to the silkworm disease in China, by the fact that the foreigner is kept in the dark, as far as possible, by the natives of that country. The partial reduction alluded to in 1881-82 naturally pointed to the existence of disease, but it was not until the impending results of the present campaign became known, that microscopic research proved the existence of the malady known as *pébrine*, in a form resembling in gravity that which devastated at one time the silk-producing districts of France and Italy. That the disease existed in China in a latent form was well-known to all concerned, but it was an equally recognised fact that the hardiness of the Chinese worm, and the favourable climate in which it was developed, kept in check any such grave consequences as would now seem to have resulted.

Attention is called to the fact that the diminution in shipments arise from no falling-off in the foreign demand, as all the silk which arrives upon the Shanghai market is, as a rule, disposed of for export. The cultivation of mulberry trees has been on the increase, and the preliminary steps taken each season have been with a view to an augmented production. The reduced yield is attributed to the fact that a great proportion of the worms die before having made their cocoons, or make weak cocoons, poor in their quantity of silk. This season it would seem that, in certain localities, the production has only been 25 per cent of the normal crop. Bad weathe would, of course, exercise a certain influence, but th remark is pertinently made that bad weather is an accidental circumstance, the influence of which is proved to be unlikely by the regularity with which the diminution of yield has progressed of late years.

The facts quoted by M. Brunat, as to the silkworm disease in Europe, are of value in appreciating the situation of matters in China, as depicted by his further explanations. In 1853, the annual yield of silk in France was 40,000 bales, but the effects of a malady similar to that now existing in China gradually reduced the production, until a minimum annual quantity of 3,000 bales was arrived at. At first, it was thought that the disease was in the mulberry leaf, but subsequent investigations established the fact that the malady was hereditary in the silkworms themselves. It was attempted to import seed from lands where the disease had not yet appeared, but all the producing countries were gradually attacked, and although in China the disease only existed in a latent form, it manifested itself clearly in such Chinese seed as was imported into Europe.

During the period from 1865 to 1870, M. Pasteur was engaged (at the instance of the French Government) in carefully studying the causes of the disease, and in devising means of curing, or at least preventing it. His investigations allowed him to report to the following effect:—1. That the most destructive malady was *pébrine*, or disease of the corpuscles, which had caused the ravages of previous years. 2. That this disease is hereditary and contagious, and that it is developed by want of care in the rearing of the silkworms, &c. 3. That the distinctive character of this disease is the presence in the body of the diseased subject of small corpuscles, which can be seen with a microscope, and which increase in number as the malady develops itself. Further, that microscopic observation should be made use of in the selection of seeds or eggs for preservation.

This malady is compared with consumption in the human subject.

It is remarked that M. Pasteur's theories were at first met at times by disbelief, but it is upon the principles thus laid down that the measures were subsequently taken, which have resulted in the French and Italian yield of silk having recovered a good deal of the importance of former times. In addition to *pébrine*, there is a disease named *flacherie*, which effects the intestinal canal of the silkworm, and which has also to be combated in China.—*Journal of the Society of Arts.*

GUMMING IN FRUIT TREES.

An essay, by my friend Dr. Beijerinck,* on the contagion of the gum-disease in plants, which has lately been published by the Royal Academy of Sciences at Amsterdam, contains so many facts likely to be useful in the study of contagion that I venture to ask you to insert a brief notice of its chief contents. The gum disease (gummosis, gum-flux) is only two well known to all who grow Peaches, Apricots, Plums, Cherries, or other stone fruits. A similar disease produces gum-arabic, gum-tragacanth, and probably many resins and gum-resins. It shows itself openly in the exudation of thick and sticky or hard and dry lumps of gum, which cling on branches of any of these trees where they have been cracked or wounded through the bark. To any students of medicine or pathology who live within range of such trees, Dr. Beijerinck's observations may suggest some interesting researches.

Dr. Beijerinck was induced to make experimental inoculations of the gum-disease by suspicions that, like some others observed in plants, it was due to bacteria. He ascertained that it is in a high degree contagious, and can easily be produced by inserting the gum under the edge of a wound through the bark of any of the trees above-named. The observation that heated or long-boiled pieces of gum lose their contagious property made it most probable that a living organism was concerned in the contagions; and he then found that only those pieces of the gum conveyed contagion in which, whether with or without bacteria, there were spores of a relatively highly organised fungus, belonging to the class of ascomycetes; and that these spores, inserted by themselves under the bark, produced the same pathological changes as did the pieces of gum.

The fungus thus detected was examined by Professor Oudemans, who ascertained it to be a new species of Coryneum, and has named it Coryneum Beijerinckii. Its characters, which are minutely described, are chiefly that it has a cushion-like stroma, consisting of a bright brown parenchyma, on which numerous conidia stand on colourless, unicellular and very slender stems, about as long as themselves. The conidia are small, cask-shaped, about one-thirtieth of a millimetre in length, and usually divided by slightly constricting septa into four cells, of which the two terminal are longer than the two middle. From these cells germinal filaments may proceed, from which are developed either yeast-cells, or brown thick-walled and many-celled mycelia.

The inoculation experiments are best made by means of incisions through the bark of young branches of healthy Peach trees or Cherry trees, and by slightly raising the cut edge of the bark and putting under it little bits of gum from a diseased tree of the same kind. In nearly every instance these wounds become the seats of acute gum disease, while similar wounds in the same or other branches of the same tree, into which no gum is inserted, remain healthy, unless, by chance, gum be washed into them during rain. The inoculation falls only when the inserted pieces of gum contain no Coryneum.

By similar inoculations similar diseases can be produced in Plum, Almond, and Apricot trees, and with the gum of any one of these trees any other can be infected; but of many other substances which Beijerinck tried, not one produced any similar disease.

The inoculation with the gum is commonly followed by the death of more or less of the adjacent structures; first of the bark, then of the wood. Small branches or leaf-stalks thus affected in winter, or in many places at the same time, may be completely killed; but in the more instructive experiments the first symptom of the gum-disease is the appearance of a beautiful red colour around the wound. It comes out in spots like those which often appear spontaneously on the green young branches of Peach trees that have gum-disease; and in these spots it is usual to find Coryreum-stromata, or mycelium-filaments. The colour is due to the formation of a red pigment in one or more of the layers of the cells of the bark.

But in its further progress the disease extends beyond the parts at which the Coryneum, or any structures derived from it, can be found; and this extension, Beijerinck believes, is due to the production of a fluid, of the nature of a ferment, produced by the Coryneum, and penetrating the adjacent structures. This, acting on the cell-walls, the starch-granules, and other constituents of the cells, transforms them into gum, and even changes into gum the Coryneum itself, reminding the observer of the self-digeston of a stomach.

In the cells of the cambium, the same fluid penetrating unites with the protoplasm, and so alters it that the cells produced from it form, not good normal wood, but a morbid parenchymatous structure. The cells of this parenchyma, well known among the features of gum-disease, are cubical or polyhedral, thin-walled, and rich in protoplasm. This, in its turn, is transformed into gum, such as fills the gum-channels and other cavities found in wood, and sometimes regarded as gum-glands. And from this also the new ferment-fluid constantly produced, and tracking along the tissues of the branches, conveys the Coryneum infection beyond the places in which its mycelium can be found. —Communicated by Sir JAMES PAGET, Bart., F.R.S.—*Gardeners' Chronicle.*

* *Onderzoekingen over de Besmettelijkheid der Gom-ziekte bij Planten;* door Dr. M. W. Beijerinck. Amsterdam, 1883, 4to

ST. HELENA.

Mr. D. Morris, the Director of Public Gardens and Plantations in Jamaica, has written a *Report upon the Present Position and Prospects of the Agricultural Resources of the Island of St. Helena*, which has just been printed by the Colonial Office, and which contains much matter of interest, as our readers may infer from the short account we are now able to give.

St. Helena has an historical interest to every Englishman, in consequence of its being the island home of the exiled Napoleon I. after the battle of Waterloo. Mr. Morris, in his introductory notes, briefly refers to this fact, and points out that the island was discovered on May 21, 1502, by the Portuguese; it was held by the Dutch until 1651, when the East India Company took it, and it was transferred to the Crown in 1833. The area of the island is about 45 square miles, 10½ miles long. and 8¼ miles broad. "Of the 28,800 acres of which the island consists, the greater portion suitable for cultivation is in private hands. The Crown lands, with the exception of Longtown Farm and a few other places, are barren wastes on the outskirts of the island, incapable of cultivation." The special characteristics of the island are, Mr. Morris says, observable both in the geological nature of the soil as well as in the plants which affect them.

The coast zone, which at the present day is dry and barren, was at one time covered with luxuriant vegetation, "and with trees drooping over the tremendous precipices that overhang the sea." The barren coast zone is described as at present extending about 1 mile to 1½ mile around the island. Deep wide valleys, and rocky, almost inaccessible ridges run from the central ridge towards the sea, breaking up the coast zone into numerous almost detached prominences and ledges. It is absolutely devoid of vegetation, except Prickly Pear, a few plants of Mesembryanthemum, and the rare indigenous Pelargonium, Pharnaceum, and Tripteris. On the Barn there are straggling bushes of the Scrub Wood (Aster glutinosus, Roxb.), which is probably the most abundant of the indigenous plants of the rocky coast. In this zone the plants are so scattered and so buried in crevices and hollows that they are scarcely seen from the sea, and do little to relieve the parched and barren appearance of the island.

The middle zone extends from the boundary of the coast zone to about three-quarters of a mile inland; its surface is not so rocky, and the slopes are more covered with grass. Here Australian, Cape, and American shrubs and trees have established themselves into thickets of considerable size. The slopes are often covered with Furse, with an occasional plant of the indigenous gum woods, and in the damp hollows some of the larger Ferns. "The English Brooms," Mr. Morris says, "together with Brambles, Willows and Poplars, Scotch Pines and Gorse bushes, Cape of Good Hope bushes, Australian trees and American weeds have driven out most of the indigenous plants from this belt. The tendency of these introduced plants is to encroach more and more upon the higher lands where the indigenous flora still remains. As regards the larger trees, such as Pines and Willows (Acacias), they appear to be spreading downwards in the direction of the valleys, following, no doubt, the distribution of their seeds by the action of the trade winds."

The central zone is described as being not more than about 3 miles long, and 2 miles wide; in some places the rocks are very precipitous, while in others the land is undulating, with grassy slopes, meadows, hay-fields, a few farms and gardens, and well-wooded glens of Oak and Acacia. On the extreme crest of the central ridge, extending from High Peak to Rock Rose, there is still left a portion of the indigenous forest with Cabbage trees (figured in *Gardeners' Chronicle*, 1880, vol. xii, p. 401) and Ferns, the wild Olive (Nesiota elliptica), Angelica, Lobelia, and the delicate campanulate Wahlenbergia. Here the soil is for the most part rich, though not very deep, and the climate is particularly cool.

Mr. Morris suggests that Aloe, Furcræs, and plants of a similar character, together with some hardy trees should be established in warm and sheltered valleys as a pioneering vegetation to spread over these wastes to gradually reclaim them. About 8,000 acres are in pasture and hayland, and the tendency is to allow this to increase. The country houses, which in the East India Company's times were inhabited by prosperous merchants and officials, and surrounded by well kept gardens and orchards, are fast falling into decay and becoming ruinous. The cultivated areas around them are simply converted into grazing lands, and a few cattle and sheep are the only indications of life for miles around.

About 400 acres are under cultivation with indigenous and introduced trees, and nearly 300 acres with root-crops, forage, orchards, and gardens. The census of 1881 showed the population of St. Helena, exclusive of the garrison a shipping, was about 4,500, and of this number more than half live in Jamestown.

After giving the rainfall, temperature, and other meteorological conditions of the island, Mr. Morris thus refers to the future:—"Speaking from my point of view, and after a careful consideration of the soil, climate, and general resources of the island, I am led to take a hopeful view of those resources, provided they are developed in such a manner as to place the island in fair competition with other countries. I look entirely to the soil for the elements necessary to bring prosperity to St. Helena. But the people require to be shown what there resources are; they need to be taught how to use those resources aright, and they require to be encouraged and assisted while so engaged. I should recommend, in the first instance, that an intelligent and competent gardener be sent to the island to take up the entire question of the revival of agricultural pursuits, and that if the local government is unable to support such an officer and a small staff, that a grant be made for the purpose by the home Government."

Mr. Morris further recommends the formation of a small establishment, with nurseries, &c., at Plantation House, for a gardener and a small practical staff, who should introduce and raise for distribution plants not already in the island.

We have quoted thus freely from this interesting report to show its nature and character; the remainder treats of economic plants under their separate heads, and is of equal, if not of greater importance, to that to which we have specially referred.—*Gardeners' Chronicle.*

Adulteration of Spices.—At the Pharmaceutical Meeting in Philadelphia on January 15, Professor Maisch exhibited a root called cinnamon root, which was said to be used in Europe for the purpose of adulterating powdered cinnamon. The root had a flavour of cinnamon and cloves. Dr. A. W. Miller stated that in the neighbouring city of Camden there was a factory for roasting and grinding coconut shells, the powder of which was used for adulterating spices; it sells at 2½ cents per lb., and enables the fraudulent operator to dilute the spice and obtain large profits (*Amer. Journ. Pharma.*, Feb., p. 224.)—*Pharmaceutical Journal.*

The Preservation of Flowers.—Our readers may have read in the newspapers recently the account of the interesting discovery of the bodies of the Egyptian Pharaohs and their Queens, and also of that of the daughter of Pharaoh who was the finder and protector of the infant Moses. Round the necks of two of these illustrious people were found wreaths of the sacred lotus and other flowers, still, after the lapse of 4000 years, preserving their form and hue as when they were first plucked to decorate the dead. They were probably prepared by loving hands, with no thought of the future time which was to see their repose disturbed and the sacred remains exposed as curiosities in a museum. The following recipes will show how the preservation was probably accomplished, and will solve the mystery which surrounds the subject. One of the processes consists in enclosing the flower or flowers in a glass jar provided with an airtight, hollow, ground-glass stopper, the cavity of which is filled with quicklime wrapped in leather. The object of the lime is to absorb the small quantity of humidity already existing in the jar, or which might enter on the removal of the stopper. The dry air, deprived of its carbonic acid, occupying the jar seems to brighten the colour of the flowers, and preserve them in their natural colours. The other method consists in burying the flowers carefully in sand, and then drying them. The most convenient receptacle that can be used for this purpose is a piece of paper wrapped in the form of a cone, the point bent over so as to form a truncated cone. The desiccation may be effected at a temperature of 90 to 100 degrees; but the method which gives the best results is desiccation in a vacuum in the presence of commercial sulphuric acid, or any other substance which absorbs water with avidity, such, for instance, as chloride of calcium or caustic potash. The flower once dried, which will be in eight or ten days, it must be removed from the sand with very great care, for it is very fragile.—*Ladies' Gazette of Fashion*

MOVEMENTS OF SAP IN PLANTS.—Observations made by V. Marcona on the movements of the sap in plants in the tropics indicated that in the plants examined, viz., *Carica Papaya* and a liana, there are two periods of maximum rapidity in the twenty-four hours, one between 8 and 10·15 a.m., and the other between 1 and 3 p.m., the rapidity in the latter being less than in the former and sinking gradually to zero, the activity commencing again after sunrise.—*Pharmaceutical Journal.*

CHINA CLAY IN AUSTRALIA.—Kaolin in by no means uncommon in many parts of New South Wales, and a deposit of kaolin, suitable for the manufacture of the best porcelain, is reported to occur at Lambing Flat, King's Plains, county Bathurst; while another of a dazzling white colour has been found on a hill near to Rocky Ridge, which is in association with a bright and pretty coloured lavender clay derived from decomposed bassalt. The substance is also found near Barraba, County Darling. —*Journal of the Society of Arts.*

BONES.—DR. J. R. Nichols, of the *Boston Journal of Chemistry*, gives this about reducing bones:—"Break 100 pounds of bones into small fragments and pack them in a tight cask or box with 100 pounds of good wood ashes, which have been previously mixed with 25 pounds of dry water-slaked lime and 12 pounds of powdered sal soda. Twenty gallons of water will saturate the mass, and more may be added as required. In two or three weeks the bones will be soft enough to turn out on the barn floor and mixed with two bushels of good soil."—*Australasian.*

TIMBERS OF NEW SOUTH WALES.—The collection of specimens of indigenous woods, prepared by direction of the New Zealand Government for the Calcutta Exhibition, includes various kinds of cedar, boxwood, gum, wattle, myrtle, and pine; also of ironbark, native willow, myall spearwood, and other kinds known only by name to Europeans. Many kinds of native wood are valuable for fancy work. For instance, the wood of the myall is used for cabinet work, pipes, picture frames, veneer, &c. Colonial cedar is said to be as beautiful in appearance as the best Spanish mahogany, and is much used for building purposes throghout the colony, the wood being cheap, durable, and easily worked. Red pine, the wood of which is beautifully mottled, and striped with black, white, and yellow, is used in many places in a similar manner. —*Journal of the Society of Arts.*

THE ALLEGED VIRTUES OF THE BLUE GUM.—Botany has made no such precious gift to therapeutic science as the Eucalyptus globulus. From all parts of Europe, as well as from the two Americas, pours in a flood of medical testimony to the remarkable value of the chemical preparations which are obtained from the leaves of this trees the properties of which would have been regarded as miraculous in the middle ages. Baron von Mueller has been at the pains of collecting and collating this testimony from the scientific publications of many countries, and he cites recorded cases, resting on the authority of practitioners of eminence, to show that eucalyptus oil possesses almost unique virtues as an antiseptic, as an agent for the reduction of the pulse in phthisis and typhus, for the diminution of bronchial catarrh, for the successful treatment of intermittent and malarian fever, for combating incipient or threatened gangrene, and for healing certain ulcers. Dr. Wooster, of San Francisco, enumerates 129 cases of various diseases, 96 of which were cured by the administration of the fluid extract of encalyptus foliage. In 23 cases of remittent, intermittent, and typhoid fever, every one yielded to the treatment. The American faculty are using the extract largely in cases of diphtheria and scarlatina with the most gratifying results; and in severe cases of cystisis it has effected cures when all ordinary remedies had failed. In the practice of a single physician in New York, 100 diphtheritic cases have been successfully treated by the fluid extract; and plants of the young eucalyptus are now being introduced for disinfecting purposes into the wards of European hospitals. Eucalyptus inhalations are capable, it has been found, of over-coming catarrhal asthma and hooping cough, and of arresting pulmonary consumption. In fact, if we may accept as trustworthy the tributes paid to the eucalyptus by medical men in Europe and America, it approaches more nearly to a panacea or a catholicon than anything that has been discovered.—*Australasian.*

CALAMANDER WOOD—or, as it is sometimes called Coromandel Wood—which is so much valued for small ornamental articles on account of its beautiful figure, is, as is well known, the produce of Diospyros quæsita, Thw., a large tree of Ceylon. Considering the value of this wood, both in Ceylon and also for exportation to Europe, it is not satisfactory to learn, on the authority of Dr. Trimen, that the tree has become extremely scarce. Gamble, in his *Manual of Indian Timbers*, also describes it as the most valuable ornamental wood in Ceylon, which is much in demand, but now scarce.—*Gardeners' Chronicle.*

PARAGUAY TEA.—Yerba, or Paraguay Tea, seems to be coming to the fore as a beverage in this country, if we may judge from the way it is being advertised by a firm in one of the large Midland Counties, who style themselves importers of this Tea. The following appears in the *Church Times*:—No more bad tea! Drink Yerba (trade mark), as adopted by the most fashionable circles in Paris. Descriptive catalogue post-free. Yerba, the finest quality of the famous Brazilian tea (Maté), is very nutritious, and has all the stimulating property of India or China tea, but no tannin, consequently never produces indigestion, and can be safely taken with meat. A light, thin, refreshing drink like tea, with fine fragrance and flavour, yet as nourishing as cocoa. Millions of pounds are used annually in Brazil. Price 2s. per pound." It will be interesting to see whether the leaves of Ilex paraguayensis will ever become an acknowledged beverage in this country. Readers of the *Gardeners' Chronicle* will remember the persistent attempts of Mr. Forsyth to introduce the use of the leaves of the common Holly for this purpose.—*Gardeners' Chronicle.*

A LARGE APPLE TREE.—Probably the largest Apple tree in the world is to be seen on the farm of Delos Hotchkiss, in Marion, Conn., U. S. A., the exact measurements of which are as follows:—

Circumference of trunk near the ground	...	15 feet 3 inches.
,, ,, 3 feet from ground		13 ,, 9 ,,
,, ,, at the forks	...	16 ,, 2 ,,
,, two main branches, from 10 ft. 4 in. &		8 ,, 8 ,,
,, of nine smaller branches, from	...	4 ft. to 6 ft. each.
Height of tree	...	60 feet.
Diameter of tree-top	...	104 ,,

A peculiarity of this tree is that it is what is termed "an alternate bearer," five limbs bearing one year and four the next. The usual yield from the five limbs is about 85 bushels, although in a single instance it reached 110 bushels; and the four limbs vary from 35 to 40 bushels. The fruit is said to be excellent for winter use, though on this point I can only speak from hearsay. The age of this venerable Apple tree is estimated at about 175 to 180 years. Curiously enough the patriotic old tree marked the centennial year by bearing fruit on all its branches, tho first time it has been known to do so in its life, and it has continued to do so down to the present time. Some of the limbs are now dying, others are broken down, signs of decay appear in many places, and it is thought that this noble specimen of Pyrus malus will soon be numbered among the things of the past.—Rev. C. H. HOVEY in *Scientific American.*

THE DIFFUSION PROCESS OF SUGAR-MAKING.—At a meeting of the Barbadoes Chamber of Agriculture, a paper was read on this subject of which the following is an abstract:—The speciality of the Robert diffusion process is that we require no cane Mills nor the immense power to work them, that we get out fully 20 °/ₒ more juice than by use of Mills. In this process the cane is cut in slices merely and steeped, so that out of the closed cells we take the juice by the well known law of Exomosis and Endosmosis. Hence the juice is much purer, since it is freer of albumen and of the fermentable matters of this juice which are left behind in the cells. The purity of diffusion juice may be judged of by the fact that a clarifier of 500 gallons when defecated would not give "Scum" sufficient to fill a slop basin! The drawbacks to diffusion are the large quantities of water required for its use (much of this can be utilized however for condensing purposes) and the addition to the juice of 20 or 30 % of water which means so much extra evaporation and so much extra cistern space but the larger yield of 20 % more than compensates for these minor disadvantages. The Aska sugar works is the only spot in her Majesty's dominions where the process is at work.—*Planters' Gazette.*

REPORT ON ANALYSES OF SPECIMENS OF CINCHONA BARK.

Forwarded from Madras, through Her Majesty's Secretary of State for India, to the Pharmaceutical Society.

(1) This and two following samples are from *C. Condaminea*, How. variety.

(2) These botanical specimens and also the bark were taken from coppice shoots.

(3) The bark belonging to this specimen is renewed, after the tree had been subjected to the Java shaving process In this the outer cellular portion is shaved or pared off, the inner vascular layer being left intact.

(4) Bark covered externally with a thick corky layer, very peculiar, of officinalis type but undetermined species.

(6) Large leafed or *C. Uritusinga*, Pavon type.

(7) This is the No. 2 variety, in the estate nomenclature, of the variety *C. angustifolia*, How.

(14) This species was discovered by Hasskarl, cultivated on a large scale in Java and found to be worthless. From Java it was introduced into India, where its culture never went beyond the stage of an experiment.

(17) This plant was said by Cross, on his recent visit to the Nilghiris, to be the *C. crispa* of which he sent seeds from the Loxa Mountains. That it came from Loxa there is no doubt, as the few specimens of it on the estate of Dodabetta are growing amongst the "crown" barks introduced from that region. It differs, however, very much from the *C. crispa* of Tafalla, which belongs to the *C. officinalis* group of Weddell. In general appearance it is more nearly allied to Weddell's section *Pahudianæ*. Its bark is also very peculiar, in fact unique.

(20) This form of the *C. Calisaya* grows to a considerable size and has bright green shining leaves, some of which measure from 6 to 7 inches in length by 3½ to 4 inches in width. Flowers pink, very sweetly scented.

(21) This plant approaches the *Boliviana* form of Weddell, but the *Calisayas* are most variable.

(23) This plant, according to Howard, is a hybrid between *C. Calisaya* and *C. succirubra*. On the other hand it is said to come perfectly true from seed. Mr. Surgeon-Major Bidie thinks it to be only a variety of *C. Calisaya*.

(26) This is not the *C. pubescens* of Vahl, but a plant which was considered to be a hybrid by the superintendent of the cinchona estates, the late Mr. McIvor. Mr. Cross regards it as the pubescent form of "Cuchicara," referred to by Dr. Spruce in the Parliamentary Blue Book of 1863, p. 116. Mr. McIvor stated that it is a hybrid between *Cinchona succirubra* and *Cinchona officinalis*.

(29) Pata de gallinazo of Cross.

When the valuable series of specimens of Madras cinchona bark was presented to the Museum of the Pharmaceutical Society by the Indian Government, through Dr. Bidie, it appeared to be important that analyses should be made, in order that the specimens might be rendered thereby more useful for reference, and that the analyses might be available for comparison with others which might be made subsequently on the plantations. Therefore having learnt from Mr. Holmes, the Curator of the Society's Museum, that portions could be spared from the Museum specimens without destroying their value for reference, I undertook to carry out the examination. Unfortunately, the smallness of some of the samples precluded the possibility of dividing them. Only eleven specimens, however, out of the forty-nine received were too small to be divided. The preceding table gives the results obtained. The footnotes are taken from remarks written on the Herbarium specimens by Dr. Bidie. The specimens No. 39 to 43, marked "India," are barks which were forwarded last year from Darjeeling by Dr. King.

These specimens of bark illustrate very well the influence of hybridization in masking the characteristic features of the bark of particular species of *Cinchona*, and the difficulty of forming an opinion as to the source of samples as well as their value in regard to amount of alkaloid.

I learn from Mr. Holmes that a comparison of the samples of *C. officinalis* bark indicates that the only one which could be easily recognized is No. 4. In this sample the bark presents an extraordinary development of the suberous or corky layer, which is divided into angular pieces about half an inch square, each piece exhibiting a stratified appearance. It is totally different from Nos. 17 and 18, in which the suberous layer, although very much developed, presents a rough granular appearance more like toasted bread-crumbs and is very friable. The corky *C. officinalis* also possesses more quinidine (0·45) than the other varieties, and a good percentage (4 08) of quinine. No. 4 is evidently the bark referred to by Dr. Trimen in his report "On the Nilgiri Plantations," as being the "crispa" of McIvor and Beddome, of which a vigorous propagation was going on by seed. If it can be shown, therefore, by futher analyses on the plantations that these percentages are tolerably constant, this variety would appear in every way to be specially suited for pharmacy.

On examination of the several specimens of renewed bark of *C, officinalis*, Mr. Holmes is of opinion that it would not be possible to recognize by physical characters bark rich in alkaloids from a poor one, and that however valuable such bark may be to the quinine manufacturer, it would not be expedient for pharmaceutical use, unless a guarantee as to alkaloidal strength were supplied to the retail pharmacist. It is also of interest to note that in Nos. 2, 6 and 8 the smaller amount of quinine found by analysis is associated with an increased amount of cinchonidine. The fact that No. 2 was obtained from coppice shoots adds weight to the supposition that the age of the tree may have something to do with the yield of cinchonidine; while the fact that the renewed (No. 6) and the natural (No. 8) *Uritusinga* varieties yield less quinine than the *angustifolia* and *Condaminea* points to the latter as being the better varieties, *i.e.*, so far at least as can be gathered from a limited number of analyses. The bark of *C. Pahudiana* might easily be mistaken by an unpractised eye for that of *C. officinalis*, and it seems desirable that such an inferior bark should be eliminated from the plantations as speedily as possible, lest by cross-fertilization it should deteriorate the seed of more valuable species. The same remark applies to the corky barks, Nos. 17 and 18, which, although very different in appearance from *C. Pahudiana,* are produced by a tree which has on its young shoots and capsules the peculiar coarse hairiness of that species, although in a less degree, forming a feature by which it is easily distinguished.

The specimens of the bark of *C. anglica*, from the Nilghiris, are not easily recognizable by physical characters, and Mr. Holmes considers that they bear evidence of the hybridiztion of the plants with *C. succirubra*, particularly No. 23, which gives 1·90 of cinchonine. This, he thinks, is further confirmed by the large leaves, resembling in size, shape and venation those of *C. succirubra.* The capsules also more nearly approach in size those of that species, being much larger than those of *C. Calisaya*.

With respect to the barks from Darjeeling, No. 39 to 43, Mr. Holmes is of opinion that the samples, judging from their physical appearance, were evidently collected from several different varieties of each species, and therefore the analyses cannot reveal anything special concerning them.

Judging from its physical characters the Ledger bark, No. 42, is good typical *Calisaya* bark, and does not at all resemble the thick bark with scattered warts which was recognized by Mr. Howard as Ledger bark, and of which samples presented by him exist in the Museum of the Society. Taken in conjunction with the analysis, the characters of the No. 42 bark indicate that it approaches most nearly to the *Boliviana* variety of *Calisaya*.

The Niighiri *Calisaya*, No. 21, appears to be identical with that of Darjeeling. The herbarium specimen of the latter is marked 2,000 feet, an elevation that is hardly high enough to develop the alkaloidal richness of the *Calisaya* to its utmost degree.

In Dr. Trimen's recent report on the cinchonas of the Nilghiris he lays great stress on the importance of analysis as a guide in the selection of plants for cultivation, and he expresses his conviction that in the present state of our knowledge, selection based on analysis is the most promising direction for the improvement of the trees as alkaloid yielders. From this point of view he recommends the isolation of trees with high analysis, together with other precautions to prevent cross fertilization, care in collecting seed, analysis of a selection of the resulting plants and destruction of all that do not reach the standard of their parent. It is by the continuation of this mode of procedure in the cinchona districts of the Madras Presidency that Dr. Trimen considers the interests of the great industry of cinchona growing in India can alone be efficiently promoted.

The attempt to draw deductions from the figures of the analyses now published of a limited number of specimens must, of course, be regarded as subject to correction by results of further examinations of a larger series of similar botanical specimens and barks that may come under future notice; but it may be hoped that the facts brought out by analyses of these specimens may prove of some value to the pharmaceutical public and to the energetic Directors of the plantations in India and elsewhere.—*Pharmaceutical Journal*.

THE FALSIFICATION OF QUININE IN PARIS.—We reported at some length in July last the trial of Henri Constant Lacombe before the Tribunal Correctionel de Paris, who was charged and convicted of the crime of having supplied to the Pharmacie Centrale des Hopitaux a fraudulent mixture of cinchonidine with quinine. Lacombe was sentenced to imprisonment for one year, a fine of 50f., and to pay for the insertion of the judgment in twelve journals. We afterwards stated that Lacombe had appealed. The *Gazette des Tribunaux* of January 20, 1884, reports that the Cour de Cassation has rejected the appeal, and Lacombe, therefore, now enters upon his punishment.—*Chemist and Druggist.*

COFFEE AND COFFEE "EXTRACT."

TO THE EDITOR OF THE "CHEMIST AND DRUGGIST."

Sir,—Last month you alluded to a letter which appeared in the *Times*, from Mr. H. S. Carpenter, bearing the above title. We venture to ask the favour of space for this communication, on the plea that, as manufacturers of essence of coffee for now fully forty years, we may not unjustly lay claim to a "vested interest" in the subject.

Not being makers of coffee "extract," if Mr. Carpenter's aspersions had been confined thereto, we would not have felt called upon to notice his communication. To anyone, but undoubtedly to an analyst, the addition "to his cup" of "a colourless liquid," on the plea that it was the substantial ingredient in the beverage which he had called for, that beverage being coffee, would not unnaturally suggest "juggling"; and, following up his own suggestion, the restaurant in question would appear to us to afford an excellent field for the exercise of Mr. Carpenter's professional attainments for "proceedings under the Adulteration Act."

When, however, Mr. Carpenter goes on to add that "the fact simply is this—coffee possesses stimulating properties, and these imitations do not, and I am of opinion that their substitution is distinctly a fraud," we feel ourselves called upon to notice a public statement which, if allowed to pass unnoticed, not only directly discredits, and is calculated most gravely to damage our trade, but which also impugns our character.

We hereby, therefore, challenge Mr. Carpenter to prove that our essence of coffee—

1. Can be classed with "imitations," or with such preparations as "contain no coffee," and that its substitution is "distinctly a fraud."

2. That it "does not possess stimulating properties," nor such "stimulating properties" as are derivable from absolutely unadulterated coffee.

For these purposes Mr. Carpenter is at liberty to procure in the open market anywhere, for his guidance —and for the exclusion of the faintest suggestion of collusion, say, from Messrs. Crosse & Blackwell—an unopened, authentic bottle of our "essence" in question, we stipulating that, in presence of Dr. Attfield, chemist to the Pharmaceutical Society of Great Britain, Bloomsbury Square, he open the same, and that he retain the one-half of the contents, the other to be immediately sealed up in Dr. Attfield's presence and to be preserved by Dr. Attfield.

If Mr. Carpenter prove our contentions to be untrue, to Dr. Attfield's satisfaction, we hereby undertake, not only to discharge Mr. Carpenter's fee, but also to place, sir, in your hands the sum of 50*l*. to be by you handed to any London charitable institution that you may select. Failing, however, Mr. Carpenter's ability thus to substantiate his said allegations—in which case we shall be liable in no expense whatever —we call upon him, as an honourable gentleman, so far as our firm is concerned, equally publicly to withdraw them.—We are, &c., T. & H. Smith & Co., Edinburgh, and 12, Worship Street, London, February 6.

The vapour of tobacco juice has been tested in France as an insecticide in greenhouses with great success. Instead of burning or smoking the tobacco, which is a very offensive process to some persons, the tobacco is made into an extract by soaking or boiling; and the juice is then placed over a chafing-dish, a fire, or the flame of an ordinary lamp, and deposited in the green-house or conservatory. Delicate plants which are very sensitive to smoke are not injured by this vapour, and it leaves no offensive atmosphere, while it effectually disposes of thrips, lice, scale insects, and slugs. One quart of tobacco-juice vaporised in a house containing 350 cubic feet is an ample amount.—*Queenslander*.

Dammer and Piney.—At the instance of Sir Joseph Hooker, the Governor of Madras was requested by the Secretary of State to order compliance with a request made as follows:—"I am desired by Sir Joseph Hooker to inform you that he is anxious to procure for the Indian Economico-Botanical collections at Kew, samples of the dried fruits and also of the kernels of the white Dammer tree of Malabar and Canara (*Vateria Malabarica*). 2. He also wishes to obtain an authentic sample of Piney tallow said to be procured from the fruit as well as of the candles made from Piney gum-resin on the Malabar coast."

The Ramie or Rhea Plant, which yields one of the most valuable of fibres, requires for its cultivation good soil, moisture and manure. It will not, like aloes, grow anywhere. Mr. Morris of Jamaica writes:—The Ramie plant requires a rich, deep soil, plentifully supplied with water; and to produce good fibre it should be kept under careful cultivation and in a continuous and active state of growth. As shown in the treatment of the Ramie by the Chinese, it can be propagated either by seed or off-shoots. Where seed is used, nursery beds carefully prepared, supplied with rich soil, and regularly watered are essential. Care should be taken to mix the fine small seeds of the Ramie with soil, and sow on the surface of the ground. If the seeds are covered with soil they will probably not germinate. The plants raised in these beds may afterwards be transplanted and put out at distances varying from 1½ to 2 feet apart, according to the nature of the soil. The better the soil, the further apart the plants; and, conversely, the poorer the soil the closer the plants. Where off-shoots or suckers can be obtained they are to be preferred to seeds, as being more expeditious, and yielding better results, especially within the first year after planting. Where off-shoots or suckers cannot be obtained in sufficient numbers, young plants may be obtained by "layering" the taller stems, that is bending them down (without breaking) close to the ground and covering the joints with soil. From every ripe joint plants will be produced. The burden of the treatment of Ramie, in all its stages, by the Chinese, is the plentiful use of manure and water. Unless the soil is rich and moist, the cultivators of Ramie must be prepared to supply their plants largely with manure, and keep them in a "moist, vigorous, perpetual state of growth." As regards the time when the stems should be cut, and the subsequent treatment, it may be mentioned, as noticed by Major Hannay, that the Ramie is fit for cutting *when the stems become of a brown colour for about 6 inches upwards from the root.* Care should be taken in cutting the ripe stems not to injure the young shoots springing from the root-stalk which are to form the succeeding crop of stems. It is beneficial to the roots after each crop is reaped to manure them heavily as well as to supply abundant moisture. When once the Ramie plants are established the stems are produced more abundantly with age and also grow much faster. Where too thick they should be carefully thinned so as to promote the growth of large healthy stems. The duration of life of a root of Ramie depends (as on the duration and yield of bananas and other similar plants) on the strength and character of the soil, the relative quantity of manure supplied, and the amount of moisture present, as well on the general cultural treatment received by it. There is no reason to doubt that where these favourable conditions exist, a plantation of Ramie will last for many years (ten or twelve at least) and prove very productive. The portions of the plant which yield fibre are cortical layers of the stem. The Chinese divide these layers as follows:—The outer green layer is generally coarse and hard, and only good for making common materials. The second is a little more supple and fine; while the third, which is the best, is used for making extremely fine light articles.—*Planters' Gazette.*

INTERCOLONIAL TOPICS.

Mr. R. W. Emerson MacIvor has recently analysed several samples of ashes from Australian timber, and we learn from the *Leader* with the following results: The specimens of wood were obtained from the Western district of Victoria, and for the purpose of analysis they were reduced to thin shavings (bark included), and those were burnt to a white ash, which was weighed. Bluegum gave 2·22 per cent. of ash, equivalent to 49·37 lb. per ton of wood. Redgum yielded 2·35 per cent., or 52·64 lb. per ton. The following are analyses of the ashes:—

	E. Globulus.	E. Rostrata.
Potash	16·00	9·65
Soda	8·59	4·05
Lime	35·41	42·50
Magnesia	6·08	7·21
Phosphoric acid ... / Oxide of iron ...	1·56	1·03
Silica	0·45	0·18
Sulphuric acid	1·58	2·01
Chlorine	1·05	—
Carbonic acid, &c.	29·28	33·37
	100·00	100·00

A ton contains in lb.:—

Potash	358·4	216·2
Soda	192·4	90·7
Lime	792·2	852·0
Magnesia	136·2	161·5
Phosphoric acid ... / Oxide of iron ...	34·9	23·0
Sulphuric acid ...	35·0	45·0
Chlorine	23·5	—
Other substances ...	667·4	851·6
	2,240·0	2,240·0

Reviewing these results Mr. MacIvor says:—"The most abundant constituent of gum ashes is carbonate of lime, which is familiar to all farmers in its natural forms of chalk, limestone, and marble. Thus the amount of this substance in the two specimens of ash is about 63·23 and 75·89 per cent. respectively. Hence, a farmer using a ton of redgum ash as manure applies to his land no less than 15 cwt. of carbonate of lime. The quantity of potash in this weight of ash is under 2 cwt. In the case of bluegum a ton of ash contains about 12½ cwt. of carbonate of lime and 3 1-5th cwt. of potash. It will be noticed that the percentage of phosphoric acid in both specimens of ash is low, and, hence, that the manure would not be effective in soils deficient in phosphates."

THE ADULTERATION OF COFFEE.

(From the *Planters' Gazette*, Feb. 16th.)

Messrs. Patry and Pasteur, the well-known brokers, of 38, Mincing-lane, call public attention once more to the prejudicial influence of adulteration on the consumption of coffee in this country. In a recently published circular, after demonstrating that there has been no expansion in the deliveries of coffee for home use, they say,—" Nor is this to be wondered at whilst the ingenious system invented by Mr. Chamberlain and Mr. Courtenay remains law. Under the regulations which these gentlemen imposed in July, 1882, the honest trader who wants to sell pure coffee is almost put out of court by the manufacturers and sellers of spurious mixtures, who are allowed to prepare any trash they like in imitation of, or for the purposes of being used as, coffee, and sell it under any attractive name, such as French or Belgian coffee, providing they put themselves in order by attaching to the packet one of the new excise or adulteration stamps, destined to bring in a little revenue as well as to leagalize cheating. An eminent medical authority, Dr. G. V. Poore, in the course of a most interesting lecture on coffee and tea given recently at the Parkes Museum, said: 'There is no doubt whatever that the present state of the law leads to the wholesale cheating of the working classes. It is to be hoped that those who have striven so hard to give the labouring man what is called a "free breakfast table," will make some honest endeavour to free it from adulterations, and cease to put in the way of tradesmen the leagalized temptation of giving a totally inadequate value for the poor man's pence. The countenancing of these admixtures is distinctly antagonistic to the spirit of the Adulteration Act, and surely it should be the main principle of all legislation to encourage the honest man rather than give opportunities to the rogue. I cannot help thinking that it would be wise to attempt a policy with regard to coffee similar to that which has proved so successful with regard to tea. Honesty is the best policy, and I believe the Chancellor of the Exchequer would find it so. At all events, nothing can be more disastrous (financially) than the present policy with regard to coffee. Here is work which the temporence party might well take in hand. When I can step into a coffee tavern and get a really first-rate cup of stimulating coffee, and not an insipid mess, than I shall believe in the chances of a permanent establishment of temperate habits among the masses of the people.' We commend these words to Sir Wilfrid Lawson and those apostles of the temperance movement who, strangely enough, have been among the most strenuous supporters of the adulteration policy of Mr. Chamberlain. The injustice and unfairness of that policy become more apparent still when we compare the increase that is taking place from year to year in the consumption of tea and cocoa, with the paltry increase on coffee and chicory, as the following table, taken from the Board of Trade Returns, will show:—

Home consumption in twelve months.

		1883.	1882.	1881.
Tea ...	lb.	170,812,000	165,079,900	160,225,00
Cocoa ...	cwt.	114,892	107,107	97,2950
Coffee ...	„	289,700	285,400	285,200
Chicory ...	„	102,900	100,000	113,900

Everywhere else, in Europe and America, the consumption of each of the three articles, tea, coffee, and cocoa, is increasing largely; alone, in the United Kingdom coffee does not find favour with Mr. Gladstone and his colleagues, who discourage its use in every possible way, by making it almost impossible for the labouring classes to obtain the pure article."

TREE PLANTING IN VICTORIA.

The report of Mr. William Ferguson on the State Nurseries, and the forest regeneration at Mount Macedon, is a very interesting document, not only as showing the work that has been done, but also what may be done in that direction and the case with which it may be accomplished, and proving that the very important work of forest regeneration rests entirely upon the Government and the Parliament of the colony providing the necessary funds. Had these been dealt out more liberally, there is no doubt that instead of one or two hundred acres, as many thousands would, by this time, have been progressing. It appears that an area of 75 acres on the Mount has been fenced and cleared during the last two years, but only 40 acres have been planted; though we know that the trees were ready for being planted in that ground three years ago, but the means were not forthcoming. It is gratifying to find, though not surprising, that the trees first planted, eight years ago, on the Mount are doing well, thousands of Californian pines having attained an altitude of 20 feet; while hard wooded European trees have done equally well, according to their kinds. Though a growth of 20 feet in eight years is not excessive, the bleakness of the situation must be taken into account, for that is most unfavorable to the progress of young, and especially of transplanted, trees.

The most effective, mode of re-afforesting is that tried "in the Majorca State forest reserve, where about 200 acres were sown this year with Acacia pycnantha, and about 20 acres of blue gum, which have done well, and promise to become a valuable plantation. Altogether there are about 400 acres of wattle plantations formed in the district."

As a proof of the efficiency of sowing the seeds where they are to remain, it is stated that—"The plantations of blue gum (30 acres) sown broadcast about four years since in the State Forest Reserve have now attained the height of about 20 feet and 25 feet and 6 inches in diameter, and promise soon to become of considerable value for mining and other purposes." Also at Longerenong a paddock of 60 acres, adjoining the nursery, was set apart for wattle cultivation, and 30 acres have been sown with black wattle (Acacia decurrens), and are growing very well. And Mr. Ferguson recommends the remaining 30 acres to be sown with golden water (Acacia pycnantha), which, he believes, will prove the most remunerative for cultivation. "In the nursery department during the past year a great amount of the available labor was employed in taking up and packing trees for public bodies, water supply, and State schools in all parts of the colony. From Macedon Nursery during 1882-83 upwards of 85,000 trees were distributed gratis to 550 public bodies, State schools and Government institutions and works; and from the Wimmera Nursery, at Longerenong, 1,145 trees were supplied to shire councils and public institutions. This work employed one half of the nursery staff, and sometimes more." The portion of the report relating to the ill-chosen Longerenong Nursery is not at all unfavourable, and, considering the arid nature of the climate, many Europeans and other trees "have succeeded well," even including the Sycamore. Among those transplanted in that nursery the Catalpa, which produces very valuable timber, is worthy of every encouragement, but we fail to see the use of propagating such things as Laburnums or Amorpha fruticosa. The wattles on the railway reserves are alluded to, and Mr. Fergnson considers they have made rapid growth.

From the appearance of the wattles along the Geelong line of railway, it would seem that they are not likely to prove a profitable speculation, as they are making a comparatively poor growth, although the soil, for the most part, is of good quality. We think the variety used is of the wrong kind to yield a profitable return, for though the bark of the Golden Wattle (Acacia pycnantha) is more valuable than that of the Black Wattle (A. mollisima), the tree is much slower growing, and requires double the time to yield a given quantity of bark than the Black Wattle, which has been known to attain a height of 14 feet the first year, whereas those on the railway will require five or six years to reach that height. We are not aware in what manner the ploughing of the ground was performed, we only know that it cost an immense amount of money. However that may be, it has certainly not been properly treated since, so that the wattles have not had a fair chance. The seed ought to have been sown in rows rather thickly, so that the ground might have been ploughed once a year so long as requisite to loosen it and keep the weeds down; these would have acted as manure, the roots would have had a better run, the trees would have drawn each other up, and less pruning would have been required. Then the plants could have been gradually thinned out as they attained sufficient size for barking. There is another obstacle to the well doing of wattles on such a situation; they are sociable trees, thriving best in company, and therefore succeed better in a large group than in a narrow strip; they also love shelter, but here they are exposed to winds both cold and cutting. So that, taking all circumstances into account, the probability is that the money expended will never be returned.—*Leader.*

ORCHARD AND OTHER INSECT PESTS.

(From the *Queenslander.*)

Of the many difficulties which cultivators of the soil have to contend against in this colony the attacks of aphis and other parasitic forms are by no means the least; yet, as has been pointed out repeatedly, those who suffer most and who complain most loudly have to a large extent the remedy in their own hands if they would avail themselves of it. These troublesome pests are more numerous here than in the southern colonies, probably because our climate offers special encouragement to their propagation. The disgusting grub which so frequently lies concealed in, and turns one with aversion from, our best peaches has been known in some parts of New South Wales for many years, but it is limited to a comparatively small area, while here it is so well acclimatized that it does not confine its depredations to peaches only, but directs them against many other kinds of fruit, including apricots, plums, guavas, bananas, mangoes, and even the less pungent kinds of capsicums. It may not be possible to get rid of such nuisances as this absolutely, but they may be kept within reasonable bounds if the fruits which are affected, and which easily fall to the ground, are destroyed at once by being given to pigs for food, or disposed of in such other manner as to kill the grubs before they advance to a more developed stage of existence. When they are permitted to lie and rot on the ground they soon arrive at maturity, and increase in number to an enormous extent. From those places where such precautions are not taken they soon extend their ravages to orchards in the vicinity that are properly attended to, and thus the thrifty man is often made to suffer through the supineness of his negligent neighbour. There are many kinds of parasites the attacks of which become more or less active according to the resisting power of the object attacked, and that power is increased or diminished in proportion to its healthy or unhealthy condition. The aphides which sometimes swarm on a patch of cabbages which have been left to struggle against poor hard soil and dry weather would probably never have appeared had the ground been well tended and the plants kept in a healthy condition by a supply of some fertilizing material and sufficient moisture. For want of this attention they become unhealthy and lose the power to resist the insects, which then multiply rapidly. When black blight or scale appears on fruit trees it invariably indicates an unhealthy state of the tree. The orange, amongst others, is peculiarly subject to these attacks, and this is perhaps about the worst treated of all our fruit trees. It is generally known that those roots of the orange from which it derives its chief sustenance keep near the surface of the soil; indeed the tree depends largely upon superficial nourishment; yet it is quite a common practice to carefully dig up the earth immediately round the stem, and by this means thousands of fibrous roots are destroyed, and the tree is perceptibly weakened, and thus offers greater facilities to the attacks of parasites. It is a common practice, too, when planting out oranges to cut off the taproot, and to place a large slab of stone beneath the plant to prevent a substituted root from piercing the ground to too great a depth. This is done under a very proper impression that when the taproot gets into the clay subsoil the tree will begin to go off; but a wiser precaution, and one which Nature herself points out, is to select soil of such depth that this main support of the tree will be able to penetrate downwards as far as it requires. The taproot is there for a good purpose, otherwise it would not have such strength, and although the practice referred to may be tolerated to a certain extent in some places its general adoption is inexcusable, and can be of no service to the tree itself: for where the clay is near the surface orange trees cannot succeed, but will soon prove themselves nurseries for the propagation of those diseases which every gardener should endeavour to eradicate, and the result will be loss and disappointment. Deep drift soil, the sand in which always retains a certain amount of moisture, is perhaps the best adapted for orange-growing; the surface within some feet of the stem should only be disturbed with the rake, and fertilizers should be applied on the surface. It is where these precautions are neglected that the plants become diseased most readily, and withering branches, scale, and black blight soon supply evidences of decay in hundreds of young trees in spite of every means which may be used to check them. Nor are the attacks of parasites less common where animals are concerned. The power which renewed health gives animals to overcome these attacks is familiar enough to drovers and bushmen, whose cattle and horses are sometimes in hard seasons reduced to extreme poverty and become literally infested with vermin. In such swarms do these pests exist that it would seem almost impossible for any animal to free itself from them without assistance, but when it gets on to good pasture and regains condition the dark patches of vermin begin to decrease, and in a few weeks will have completely disappeared. By the substitution of hardier, because healthier, kinds of cane the plantations have been freed from rust, which at one time threatened them with destruction. In the wheat-fields, too, a stronger kind is being introduced in place of those which were constantly cut off by rust; and it will probably be discovered in course of time that the conditions under which these plants have been treated for many years have made them more delicate, and therefore more susceptible to disease, as is the case with animals which have for a long time been indiscriminately inbred. The information which has hitherto been gained in connection with this subject is yet far from perfect, but it seems certain that one law operates in al cases, whether plants or animals are concerned. All ar subject to great improvement at the hand of man; but to be successful much intelligent observation must be exercised, and the result of all experiments should be recorded. Private individuals could do much in this cause, but it is one which might with advantage be taken in hand by pastoral and agricultural societies. The production of a good animal or of good fruit is no doubt an evidence of success so far as it goes, but the specimen is only useful because it shows what the class generally may be raised to. The establishment of a class of animals, or of plants, having the power to resist the attacks of disease would be a much greater achievement than the production of a limited number of perfect specimens, the only effect of which is to prove how much yet remains to be done.

THE WILD CROTON PLANT AND EPIDEMIC DISEASE.

(From the *Straits Times*, March 8th.)

Capt. W. J. Taylor, Master Attendant at Madras, writes as follows to the *Madras Mail* regarding the baleful influence of this plant. We publish his communication, as it may tend to throw some light upon the cause of the mysterious cattle disease to which we called attention a short time ago on the information of Dr. Little, who now informs us that he has lost 71 bullocks from it on his Siglap coconut plantation. Native owners have also, we are informed, suffered severely from it, and nobody seems able to diagnose its cause or to devise a remedy, and it is almost, if not entirely invariably fatal, and in a very short time:—

"The prevalence of disease in the town and suburbs of Madras is an alarming fact that should call forth all the energy and intelligence of its citizens to overcome it, and as far as possible search out its cause. It is therefore with the hope of contributing something towards this useful purpose that I beg to draw the attention of our readers to some correspondence initiated by me about two years ago regarding the deleterious properties of the plant, commonly called wild croton, that is of rapidly increasing growth in all our water courses, and has had already access to our wells and tanks during the heavy rains that up to a few days ago almost inundated Madras. The question was taken up at that time in a few quarters, but soon dropped from want of interest and the suppression of sickness. I was, in the first place, corrected as to the bontanical name of the plant, which it seems is a genus of Euphoriaceæ, and is known to botanists as Cureas Purgans, formerly as Gatropha Curcas. It seems to be admitted that every part of the plant possesses some medicinal quality if its use is restricted to very small quantities; but the same remark applies equally well to Prussic acid, Strychnine, Arsenic, and in fact all poisons. Dr. Benaet, in his 'Gatherings of a Naturalist,' writes that in administering medicine from this plant, the effects were vomiting, purging, a burning sensation in the stomach and bowels, with a determination of blood to the head, many of which symptoms directly resemble cholera; and the Civil Surgeon of Midnapore, a place infested with the plant, in reporting upon a malarious fever that had decimated parts of his district, mentioned that he considered this rank and pestilential growth no insignificant factor in the general unhealthiness of the villages. It flourishes again largely along the pilgrim road to Jaggernaut; and in the villages along this route cholera and malarious fever are never absent. Its character therefore is undoubtedly open grave suspicion. In my former letter I drew attention to two experiments I had made in connection with this plant upon fishes and frogs. Four large chatties were filled with Red Hills water, in two of which some portions of the wild croton were soaked for a short time; fish and frogs, about one dozen to each of the four chatties, were then introduced separately. The fishes died in a very short time counted by hours in the foul chatty, but remained alive and active for days in the other. The frogs which belong to a warm blooded family and are known to possess very strong constitutions, were all found dead next morning in the poisoned chatty, but in perfect condition in the other. The bodies of the dead frogs were discoloured, bloated and swollen from the effects of the poison. Considering the rapidity with which water runs through courses during heavy rain dragging this plant under water, and threatening to uproot it, and its constant crowded presence, I do not think the solution I used was very much stronger than that which drains into the wells and tanks, and overflows the compounds in Madras and neighbourhood. A very grave misgiving is becoming wide-spread regarding the milk supply, which is said to promote malarious fever. Now during the period when rain was daily falling, and ditches running, any traveller on our roads could see the milkman's cow drinking at these ditches, and even now their chief supply is drawn from the same polluted sources, and will continue to be so until the fine weather and presence of the sun has dried them up. Milk is such a vital necessity among Hindus as well as Europeans that some experiments should, I submit, be conducted in this direction with a view to the detection of any deterioration. Cholera of a certain type, and, fever, probably typhoid, may, I consider, be directly traceable to the above conditions, but there remains the extraordinary increase of small-pox to deal with, which increase I cannot help connecting in my own mind with poisoned milk. Cows, cow-pox and small-pox, with vaccination, have a direct association in our ideas, though one not readily explained, but if experiment should prove that milk is now in a state prejudicial to health, the fact would be another link in the chain of circumstantial evidence against this plant, but I am not in a position to press this indictment. I must leave that to scientific analysis. But I may mention that one naturalist and physician reports that in some places it is used in the medicinal quantities to promote the secretion of milk. We know that we have a hidden foe in our innermost circle of domestic life of Nihilist proclivities. His exertions are widely extended at certain periods, when wet and cold affect the water-supply, and compel the population to herd together in huts and hovels, where light and air never enter. He intrudes also into our highest and best protected families and palaces, which through the agency of servants, dhobies, milkmen, &c., can never be properly isolated. Every death occurring under unusual conditions, and where the habits of the individual and the nature of his food supplies, can be investigated, ought to be traced, and in most cases tracked as satisfactorily as a murder can be by the Police. The 'strong connections,' nice dependencies, gradations just of human life, are so mysteriously blended, that we are being constantly surprized by new communications that are discovered between them. And the unexpected in this our days generally happens. In a few days, when warm genial weather is established, and natives can freely take the air, as is their custom, and evaporation has removed the exciting causes the sickness now of so alarming a type will disappear, and we shall be told that it is stamped out, but it will surely return when the recent conditions of weather are restored. Meanwhile, the cause might be carefully investigated. Many places we might reasonably expect to be free from sickness, like Palaveram, the Mount, Guindy, &c., suffer as much as the crowded parcherries of Madras, and the former are infested with the wild croton plant. My duty as a Municipal Commissioner, equally with my sympathy in the general distress, urges me to bring this matter forward."

CHEMISTRY OF VEGETATION.

Why do plants grow?

Because they possess an organization which enables them to incorporate with their own systems certain elements by which they are surrounded. Air, water and earth are obviously elements of nutrition to plants. But "air," "water," and "earth," are only general terms; the air consist of gases; water of gases; and earth of various chemicals, such as carbon, oxygen, hydrogen, nitrogen, lime, sulphur, silica, &c. To comprehend, therefore, "how plants grow," we must examine their organization and study the nature of those substances which constitute their food.

Vegetables may be truly said to be living systems, in this sense, that they possess the means of converting the elements of common matter into organized structures, both by assimilation and reproduction; but we must not suffer ourselves to be deluded by the very extensive application of the word life to conceive, in the life of plants, any power similar to that producing the life of animals. In calling forth the vegetable functions, common physical agents alone seem to operate; but in the animal system those agents are made subservient to a superior principle.

Agricultural chemistry has for its objects all the changes in the arrangements of matter connected with the growth and nourishment of plants; the comparative values of their produce as food; the constitution of soils; the manner in which lands are enriched by manure, or rendered fertile by the different processes of cultivation. Inquiries of such a nature cannot but be interesting and important both to the theoritical agriculturist and to the practical farmer. To the first, they are necessary in supplying most of the fundamental principles on which the theory depends. To the second, they are useful in affording simple and easy experiments for directing his labors, and for enabling him to pursue a certain and systematic plan of improvement.

The presence of a growing plant. of the root of a seed, where life is, impresses on the soil, both on the organic and inorganic elements, power to enter into new arrangements. The soil, then, is not external to the plants; so far as life is concerned, it is as much internal as if the plant had a mouth and a stomach,through, and into which the soil might be fed.

What are the principle simple chemicals that influence the growth of vegetables?

They are carbon, oxygen, hydrogen and nitrogen. The other substances of plants, it will be seen, are compounded of two or more simple elements.

There is no reason why the agriculturist should not be as familiar with the names and properties of carbon, oxygen, hydrogen and nitrogen as he is with those of coals, lime and salt. Being familiar with the primary elements, he will the more readily comprehend the functions of vegetables, and the conditions favourable to their development. Who, without any formal scientific instruction, is not familiar with the names of iron, sulphur, potash, soda and lime? No one; for they are of every day occurrence. And who does not know that coal is carbon? And who has never heard that oxygen and nitrogen form the air we breathe; or that water is composed of oxygen and hydrogen?

With alumina or alum all are familiar. Silex or silicia is but the name of portions of hard stones. Most persons, too, are no strangers to what is called ammonia, which is a combination of nitrogen and hydrogen, is sometimes called sal volatile, and is what gives the sharp smell in the smelling-bottle, or the manure heap. It is the ammonia in manure which is so efficacious in agriculture. And if the reader is less familiar with the name of chlorine, it is easy to give him some hints of it. This is the substance used in bleaching cotton goods, and on opening them the smell is very pungent for a long time. And what is still more in point, chlorine united with soda makes our common salt; or, if united with ammonia, the product is what is called in the shops sal ammoniac. The circumstance that chlorine is a constituent of common salt is in itself sufficient to give it an interest in impressing it on the memory of every individual.

Chlorine is important also from being used to disinfect the air when impregnated with foul vapors, as in the case of cholera and other diseases. Here, then, is nearly the whole catalogue of these obnoxious terms, save manganese, which is simply a dark-coloured metal, used in the manufacture of glass as well as in agriculture.

What is "an element?"

A body that is constituted of one kind of matter only, is called an element. One that is composed to two elements, is a compound.

If a body consists of three elements, it is called a ternary compound; if of four a quarternary compound. Binary implies two-fold; ternary, three-fold, and quarternary four-fold.

Iron, being composed of one kind of matter, is an element; the rust of iron is a compound, being formed of oxygen and iron. Put a little drop of water upon a piece of bright iron; after a short time, wipe it away, and there will remain a spot of rust. The oxygen of the water, or a part of it, will have combined with portions of the iron, and formed an oxide of iron, a binary compound, or compound of two elements. Water is composed of two elements; Epsom salts of three; alum of four, and so on.

We must distinguish between a compound and a mixture. When two substances combine of their own accord, as if self-moved, the result is a compound. If they are only put together by mechanical force, it is a mixture. In the first case, the properties of the ingredients are entirely changed; in the last, they remain unaltered. Thus, if you bring chlorine and sodium together, a substance totally unlike either is produced—from two virulent poisons, a wholesome condiment, common salt, is formed: this is a compound. But if you put water with milk, no new substance is formed—the properties of the ingredients remain unaltered; they are water and milk still, and nothing more: this is a mere mixture.

What is carbon?

Carbon is a chemical element, abounding in nature, the most familiar form of which is charcoal. How large a proportion of vegetables consists of this substance may be ascertained by charring a piece of wood.

When wood is burnt with a smothered flame, the volatile parts are driven off by heat, and there remains behind a substance exhibiting the exact form, and even the several layers of the original wood. This process is denominated charring, and the substance obtained charcoal. As it is the woody fibre alone which resists the action of the heat, while the other parts of the substance are dispersed, it is plain that charcoal must be the residium of woody fibre, and that the quantity of the one must depend upon the quantity of the other, if they are not to be considered actually the same. Charcoal may be obtained from almost all the parts of plants, whether solid or fluid.

The properties of charcoal are, insolubility in water, of which however, it absorbs a portion when newly made, as also of atmospheric air. It is incapable of putrefaction. It is not altered by the most violent heat that can be applied, if all air and moisture are excluded. But, burnt in air, it combines with the oxygen of the atmosphere, forming carbonic acid gas; and it is important to bear in mind that this gas is one of the natural constituents of the atmosphere, by which plants are surrounded.

What is oxygen?

Oxygen is an element known only in the state of a gas, or in an air-like condition. It is void of color, taste and smell, and therefore cannot be distinguished from common air. It exists in the atmosphere, in water, and in minerals, and is necessary to the life of both plants and animals.

What is hydrogen?

Hydrogen is also known to us only in the state of gas, and when perfectly pure is scarcely distinguishable from common air, being without color or taste, and possessing but little smell. Although we can easily obtain it as a gas, it does not usually exist as such, but it combines with all animal and vegetable substances, abounds in water, and is found largely in coal, but is not found in any other of the large mineral masses.

What is nitrogen?

Nitrogen, also, is known to us only in the form of gas. It is without color, taste or smell. It is found most abundantly in the atmosphere; and forms a part of many animal and some vegetable substances.

Such are the simple elementary bodies of which the organic, or destructible part, of vegetable substances is formed. With one exception, they are known to us only in the form of gases; and yet, out of these gases much of the solid parts of animals and of plants are made up. When alone at the ordinary temperature of the atmosphere, they form invisible kinds of air; when united, they constitute those various forms of vegetable matter which it is the aim and end of the art of culture to raise with rapidity, with certainty, and in abundance. How difficult to understand are the intricate processes by which nature works up these rare materials into her many beautiful productions; yet how interesting it must be to know her ways—how useful even partially to find them out.—*Leader.*

THE EUCALYPTUS.

TO THE EDITOR OF THE "SYDNEY MAIL."

Sir,—In the December number of the *Medical Gazette* I was pleased to notice an article on the above subject from the pen of Baron Mueller. It is a subject that I have long taken a deep interest in, and therefore, on the present occasion, I crave your indulgence while I offer a few remarks on the matter. I have no desire in the sequel to say one word with the view of detracting in the slightest degree any honour that may be due to Baron Mueller for the painstaking labour he has bestowed in advancing botanical knowledge and research in these colonies. What I complain of is that he should have passed by those in this colony who have "originally" been instrumental in establishing by practical proof the medical virtues possessed by our gum trees long before he or any of the many authors quoted ever dreamt of the matter. It is all very well at this late hour of the day to compile statistics and array a string of names or authorities in support of the valuable properties possessed by the eucalyptus oil, eucalyptus leaves, and eucalyptus extract, etc., whereas these facts were known and fully established by practical information—information which is beyond the possibility of dispute—between 20 and 30 years ago. I believe I am the first medical man in these colonies that ever drew public attention (through the press) to the therapeutic properties and hygienic value of the "eucalyptus," so abundantly disseminated all over these colonies. I challenge Baron Mueller, or any other person, to show to the contrary, day and date, when it was used as a therapeutic agent or for medicinal purposes prior to the date it was first used by me in the case of "spear wound in the abdomen" in 1864, and subsequently fully reported by me in the November number of the *New South Wales Medical Gazette* of 1870. Let those who can disprove it, or show a prior or better claim to its discovery than myself and I am sure I will willingly feel satisfied in the matter. Until this is satifactorily done, whether the honour be worthless or not, I think I have a right at least for the present, in saying that the paternity of the discovery belongs to New South Wales. By all means give honour to whom honour is due, but it is a rather remarkable fact why the Baron should have passed by these patient facts in dealing with this question. The *Sydney Mail* in the columns has even repeatedly alluded to the importance of this question, especially in February, 1873, when it said, in writing of the eucalyptus, "that there is a large and unoccupied field of study in the medical botany of Australian plants. Hardly anything has been done as yet in this direction, though a few volunteers have disclosed some facts."

Mr. Phelps, M.P., also as far back as February, 1873, moved in the Parliament of New South Wales for a select committee to "inquire into the alleged virtues and theraputic properties of our eucalyptus or gum trees in medicine; but which unfortunately was negatived by 19 to 16, in a House of 45 members." Why are these facts overlooked by Baron Mueller in dealing with this matter? The virtues of our gum trees are not confined to any one particular species (Eucalyptus globulus of Tasmania) as is supposed, for I believe nearly all of them possess, less or more, peculiar medicinal properties. I am even forced, from careful observations and long experience of bush life, to believe that the majority of our gum trees, no matter in what form used, whether in the shape of the leaves in their natural state or dried, in ointment, in powder, decoction, extract, oil, gum, or alkaloid, all inherit virtues equal, if not superior, to quinine. Time alone is bound to bring them into more general repute in the treatment of intermittent fevers, an invaluable antiseptic and agent for counteracting lethal or malarial poisonous exhalations, a febrifuge and a cooling, healing application to wounds, ulcers, excoriations, burns, or rheumatism; a salutary remedy in parasitic disorders in sheep, especially the apple tree species, the leaves of which sheep are very fond of nibbling, owing to the tonic, bitter, pungent, aramatic principle which they possess.

I shall now submit the following short extract of this remarkable "spear wound" case in corroboration of this statement, viz.:—"On the 28th December, 1864, found the plaster and the whole of the stitches had been removed, the anterior (or abdominal) wound wide open and gaping and 'bowels protruding,' accompanied by a quantity of ichorous serum oozing from the large orifice. Took no medicine since my last visit. The posterior wound to all appearance healed. His gin sitting by his side in the bough gunyah attentively bathing the wound and swollen abdomen with a few of the most tender undershoots and leaves of the yellow box and red gum tree, wrapped together in the form of a wreath, and now and again dipped into a billy (a tin vessel capable of holding from half-a-gallon to a gallon) of hot water and the leaves, which is constantly kept hot by the fire. In consequence of this unexpected interference and the untoward appearance of the wound (now greatly enlarged owing to the swelling, the slight chance of his recovery seemed now to be completely taken out of my hands; for to attempt to again close the wound under the circumstances would not only have been perfectly futile, but adding to the danger, as the swelling had so rapidly increased that the case altogether now seemed quite hopeless and pulse sinking. I was somewhat, then, reluctantly forced to abide the issue of what seemed not only a clumsy but an unnatural and cruel sort of application; but as I was determined to carefully watch the case to the end, I continued the medicine and left the patient. On returning in the evening, to my surprize and astonishment, I found what I had previously considered a useless application had not only lessened the size of the wound, but had positively had the effect of reducing the swelling. Seeing such promising results, of course I made no further objection to the use of this strange application in the shape of the gum leaves, and simply then continued the medicine. On the 29th, or five days after, the wound gradually closing, and very little discharge. On the 'sixth day,' the 30th, found the abdominal wound closed, and, with the exception of the swelling, surprizing to say, it looked almost as well as when first dressed. In submitting so remarkable a case to the medical profession I do so more to stimulate research in the matter, and to attract special attention to the wonderful effects of so novel and simple a remedy, than with the view of pluming myself with any degree of credit for the recovery of the patient, a circumstance more indebted, I fully believe, to the efficacy possessed by the eucalypti than any services which I may have rendered the unfortunate sufferer. As a topical agent in cases of severe punctured wounds it certainly appears to possess many useful and valuable properties, properties which I think are worthy of being further investigated, and thus my sole desire to give the matter publicity through the medium of your columns. In fact, the leaves of the various species of the eucalypti, it is well known, possess a peculiar aroma, especially when bruised, somewhat resembling the odour of camphor. To those who may have chewed them the fact is palpable, and scarcely needs corroboration, for they are not only observed to possess a bitter but a rather pungent taste, followed by a kind of benumbing or cooling sensation in the mouth. It is probably due to these aromatic ingredients, combined with some kind of astringent mucilaginous extract or principle that it owes such extraordinary therapeutic properties—properties, I believe, that are not only sedative, antiphlogistic, but even catalytic or antiseptic."

Further, in my essay on the climate of Australia, which was published in the *New South Wales Medical Gazette*, vol. I, I have again particularly referred to the efficiency and virtue of the Eucalyptus in the health of man and animals. From these few quotations it is quite apparent that the valuable and now widely extending therapeutic properties of the eucalyptus were known in New South Wales prior to the time they were known or discovered in any other colony. If there is any real credit attached to the matter, so far as it is yet known, I have never heard of its application for medicinal purposes until I first saw it applied by the blacks in the manner I have described in the case of the "spear wound in the abdomen," as previously alluded to. The title, surely then has a right to belong to the New South Wales, unless some other person can prove a better claim to its earlier application than in the successful case which occurred to me in 1864. In cases of wounds, ulcers, rheumatism, burns, gonorrhœa, uterine affections, and perhaps some types of fevers, &c., its therapeutic efficacy, I believe, when it has become more generally known, will yet be found invaluable and incontrovertible. I hope, therefore, the interest I have shown in striving to give publicity to so valuable an indigenous plant will more than counterbalance any unnecessary space which I may now have occupied in your journal with the length of this letter. I shall be glad, too, to see the general press taking the subject in hand, so as to give the matter a still wider and greater field of publicity and research than what hitherto it has either yet received or deserved.

Why should I, Mr Editor, labour and toil, and tacitly allow others to get the credit of my works? I say honour to whom honour is due. Baron Mueller has not given me any honour. I believe I am the first person to report the discovery, through the press, of the therapeutic properties and hygienic value of the eucalyptus. It is for Baron Mueller or others who may think proper to show to the contrary—point out to us the history of such a case, or when the eucalyptus was ever used prior to the case of "spear wound" which was reported by me in the *N. S. W. Medical Gazette*. Would the question, I ask, have received the same amount of notice this day at the hands of Baron Mueller or others but, probably, for the trouble I took, twenty years ago, in watching this important and most remarkable case, and the many miles I had to ride to and fro in order to do so?

The importance of the matter is pleaded as my excuse for trespassing on your valuable space.—Yours, &c.,

Molong, January 24. ANDREW ROSS, M.D.

SUGAR CANE CULTIVATION IN HAWAII.

(From the *Fiji Times.*)

The following report on the above subject has been submitted to the Hawaiian "Planters' Labor and Supply Company," by the committee for that purpose appointed:—

The most casual observer who visits our plantations will not fail to notice a decided improvement in the present mode of cane cultivation, as compared with what it was a few years ago, or with what it now is in most sugar-cane countries. This improvement consists in a better preparation of the soil, and greater care in planting and in cultivation of the young cane; or, in other words, more thorough plowing, closer planting of the seed, and constant use of the hand and horse hoes. When these essential points are well attended to, and where water for irrigation is abundant, paying crops can be regularly harvested from year to year.

But all our plantations are not equally favored in this respect. At least one-half of them have to depend solely on rain to mature their crops. Were the rain more evenly distributed throughout the year, falling as copiously in the warm months, when the cane grows most rapidly, and needs it most—as it does in Mauritius and other more favored countries—our largest island of Hawaii might produce twice or three times what it now yields.

Aside from this irregularity in the rains, planters have another disadvantage to contend with; that most of our winter rains come in torrents, carrying to sea the rich surface soil, leaving little else for the roots of the young cane to subsist on but the hard red subsoil, which the plow has never disturbed. This will account for the poor crops on many fields that have had as thorough cultivation, and as much work bestowed on them as others which have given far better returns, with regular and abundant irrigation. For this reason it may be best to re-plow and re-plant after each crop is harvested, especially where the cane is grown on hilly or sloping land, liable to wash in heavy rains. The re-planting of a field need not cause a loss of more than three or four months for two plowings and planting, attended with an outlay of twenty to twenty-five dollars per acre more than the cultivation of the rattoons would have called for. But it leaves the soil in first-class condition, and ensures a fuller plant-cane crop in lieu of a [illegible] rattoon crop.

In some localities rattoon crops can be relied on in districts watered only by the rains, as well as in irrigated fields. These districts consist mostly of the low bottom lands that receive the wash from the hills, and consequently consist of deeper and richer soil that retains its moisture. Wailuku, Waihee and Hana, on Maui; Naalehu on Hawaii, and Kekaha on Kauai, not to name other places, have produced heavy rattoon crops as the plant cane. But of the value of rattooning, each planter must be the judge after fair trials. As a rule, we recommend re-planting after every field of plant-cane has been harvested.

In the [illegible] paragraph of this report, reference was made to a noticeable improvement in the cultivation of cane, and the [illegible] our Committee [illegible] for instancing several plantations which [illegible] the present [illegible], which afford [illegible] through [illegible] [illegible] the Paauilo, Hamakua [illegible] Nearly [illegible] the former [illegible] with [illegible] or Tahitian cane, in rows 5½ feet apart, with the plants averaging from 2 to 3 feet apart in the rows. One field of 90 acres below the road and the other of 120 acres above the road—but particularly the latter field—presented an appearance which it would be hard to surpass, though it may have been equalled by a field of 117 acres on the plantation of Messrs. Alexander and Baldwin, at Paia, on Maui, both of which are equally luxuriant and handsome, and give promise of extraordinary returns. At Naalehu, Kau, the experiment is being made of planting very close—the rows less than 5 feet apart—and continuous rows of seeds or plants. Some of these fields are remarkably fine in appearance, and will yield a heavy crop. All of the fields noticed above are of the growing crop, to be harvested the coming winter or spring. Among the fields harvested this last season, the Grove Ranch on Maui and the Kekaha on Kauai, have given large returns, the plant-cane on each having yielded 5¾ tons to the acre. Notwithstanding these exceptional cases, the average yield for the whole group for the past season is under 3 tons to the acre, as will be seen from statistics presented hereafter.

Respecting the effect of periodical droughts, Mr. W. H. Rickard, of Honokaa, Hawaii, writes:—

"You will observe that the yield from our plant crop is low, which is, no doubt, the result of the long drought that prevailed in our district when the canes were young, and from which effects it never fully recovered, although favored with rain at later dates.

"We find from past and long experience that all canes, if checked by drought when very young and tender, never fully recover from the effects, even if the weather should afterwards prove favorable.

"We find, on the contrary, that if our young plant crops get a good start, we are then very likely to have a good yield—at least a fair yield.

"We calculate, with favorable, ordinary Hamakua weather, on getting four tons from our plant crops, which take from eighteen to twenty-four months to mature, planting generally in May, June and July, according to elevation of land.

"Up to the present time, we have used no manures, as we have had new lands. But we notice that canes on lands that have been planted before do not yield so well as in the first planting, which means that we shall be obliged to manure eventually in order to keep up our yield.

"And then planting in proper season, and taking off the crops in proper season, have a great deal to do with the yield per acre, as well as thorough cultivation of the crops; and also proper care in planting, getting the lands evenly planted, and proper cutting of the crops, not leaving short stumps of the best of the cane standing in the field, which not only tends to lessen the first yield, but affects the rattoon crops."

Respecting the durability of soil, Mr. A. Unna, of Hana, furnishes the following interesting information:—"In order to give you an idea of the durability of our soil here, I would state that ground was first broken here for a plantation in September, 1851, when Mr. W. Needham planted forty-five acres of cane. In 1862 a lot more of cane was planted, and with an intermission of three to four year's rest, the same ground has been planted all along until now. In spots less productive some rotten rind, ashes, or a mixture of [illegible] and cane-tops (rotten) have occasionally been applied, but no regular manuring has ever been used. In December, January and February last we took off a crop of [illegible] from 47 acres (measured) of this, the oldest and most used land belonging to the plantation, and it yielded [illegible] lbs., or 8,700 lb per acre. This land is stony, [illegible]: the soil is black; and not inclined to packing. There is considerable [illegible] in our soil here, and therefore the same results cannot be expected everywhere in this district. The frequent rains, followed up by a hot sun, cause both rapid growth and decay. Returning to the soil a part of which it produces helps to preserve its strength for a number of years.

Thorough plowing is a very important matter, without which good crops cannot be produced.

Mr. A. H. Smith, of Grove Ranch plantation, Maui, communicates the following:

"The subject of cultivation, as to time of planting, number of times to be stripped, etc., I think, is a question of difference of locality rather than of difference of opinion as to any one locality. Different localities use different cultivation. On high lands, or where the soil is poor, or where there is no irrigation nor much rainfall, it is the custom to plant very early in the season, and sometimes let it have a two years', or even three years' growth.

"But where the soil is rich, and irrigation is carried on, it is safe to plant later in the season, and sometimes a yield of 5 tons is obtained from a fifteen months' growth.

"In this district planters have rather come to the conclusion that it does not pay to cultivate rattoons. That where the supply of water is limited it is better to put it into plant cane, which will yield 4 or 5 tons to the acre than on rattoons which will yield on an average only 2 tons or less per acre.

"I think it is generally thought best to plant as early as possible, without the cane tasseling, in the November following; to use the best seed obtainable, and keep the weeds out. Irrigate every ten days if you have water enough, and strip it from one to three times, according to locality.

"In this district the planters give their cane all one stripping, and, if possible, a second. But I have noticed that if the first is done when the cane is from 4 to 6 feet long—that is pretty late—it does not matter so much about the second stripping. When the cane is planted late on rich soil, and irrigated where the climate is dry, and has a quick growth, I think a second stripping is a most unnecessary, especially if the stripping is done pretty late. Where the cane grows quickly, the joints are all long, and there are consequently fewer leaves than where the cane is short-jointed. In marshy places, however, and where the rats are troublesome, or where there is much of the borer, the cane should be stripped oftener. This remark applies also to districts where the cane grows slowly.

"I think it is generally conceded that it is best to plow land before planting, and where the soil is heavy, or there is much manienie grass, to give it two or three plowings. There are localities, however, where it seems scarcely necessary to plow before furrowing out.

"Of the crop just taken off on this plantation, and which yielded about $5\frac{3}{4}$ tons per acre, not an acre was plowed before furrowing out. It was, however, virgin soil.

"The year previous, I planted a field without plowing, which had been planted once before, and the yield was very poor—about $2\frac{1}{2}$ tons per acre. I think the soil was not worn out, but the former planting and irrigation had hardened the soil. I think the localities where it is safe to plant without plowing are very few; and that in no place is it safe where the land has had a previous planting and irrigating. I feel a hesitancy in writing on the subject of cultivation, for it is one with which nearly all the members of the company will hear your report read are as familiar as I am; and it is a subject, as I remarked above, of difference of locality."

Mr. W. H. Bailey, of Wailuku, Maui, writes:—"I find the best way of applying bone meal, which I have used on about thirty acres, is to place it in pits at the side of the hills of young cane. I think the Lahaina cane deteriorates if not cut before July. Plowing rattoons has the best effect if done after the cane is 2 or 3 feet high."

Mr. C. C. Kennedy, of Waiaka plantation, writes:—"Our best time to plant is May, June, and July. We plant continuous rows of seed, plow our land twice, and get it in good order; then furrow it with the large half furrow plow."

A suggestion has been made in one of our local papers about cane-planting, which it may be well to insert here—that the whole stalks of cane be dropped in the furrow, then with a sharp *oo*, or other implement, cut the stalks into the usual lengths of seeds, say four to six eyes each. This will give continues rows of seed, does away with much of the hard labor of handling it, and the consequent breaking of the eyes. We have not seen any planting done in this way, but would recommend its trial, as it seems to have some advantages over that usually practized. In districts where cane-tops can be secured at the planting season, we consider these as the best, most reliable, and economical of any. Tops, however, can only be had when harvesting; and as planting follows harvesting in most districts, stalks have to be used from necessity. *Lalas*, or branches, should not be used for seed. Their continued use will result in reduced crops, and it should be the object of every planter to improve the quality of his cane by planting the best seed obtainable.

Your Committee have endeavored to ascertain the exact yield of sugar on each island for the past crop, with the number of acres actually harvested, but, up to this date, have not been able to complete the table. They still hope to accomplish it before the publication of this report.—Respectfully submitted, H. M. WHITNEY, Chairman.

EXPERIMENTAL CULTIVATION OF INDIA-RUBBER AND CINCHONA PLANTS IN THE WYNAAD.

We have received from the Madras Government papers recording the results of certain experiments entrusted to Mr. T. J. Ferguson of Messrs. Hinde & Co., Calcutta. Major Campbell Walker, the head of the Madras Forest Department, reporting on the results up to December 1883, stated:—

I inspected the *Cinchonas* and *Landolphias* in the Manantoddy garden at the commencement of last month.

The former, which were chiefly *Calisaya*, were received, as Mr. Morgan reports, in anything but good condition, and had to be planted out in very heavy rain, the continuance of which appears to have been unfavorable, as very few survive and these are not in a healthy condition.

The *Landolphias*, of which twelve plants were purchased by the district forest officer from Messrs. Hinde & Co., a year ago at R2 each, were at first kept in large bamboo pots, in which they made no growth. Seeing this, they were put out in the open, but the nine which remain alive are sickly and do not appear likely to succeed at Manantoddy. No *Ipecacuanha* plants were received, though the Curator, Government Parks and Gardens (Mr. Jamieson,) had promised to send them.

Mr. Ferguson reports so fully on the condition of the *Castilloa*, *Hevea*, and *Cinchonas* received by him on Government account, and on the *Landolphias*, which are his private property, that it appears unnecessary to supplement his letter, especially as I have not seen the plants. It will be observed that his experience with the *Landolphias* is similar to ours at Manantoddy and Nilambur, but that "a few plants retained under shade promise better and show a peculiar growth." The *Castilloa* and *Hevea* plants received from Ceylon are, on the whole, healthy, and Mr. Ferguson proposed (3rd October) to commence propagating from them shortly.

The Board and Government will gather from the above abstract and the copies of letters forwarded that the experiments have not gone beyond the initiatory stage and that no planting out in the sites originally selected has been attempted, the main reason for which having been want of plants.

No expense beyond the carriage of the seedlings to Calicut, the R24 for twelve *Landolphias* and their carriage to Manantoddy has been incurred.

The Collector now reports that Mr. Ferguson wishes to hand the experiments over to the forest department, but is still willing to provide land, if required, and it is suggested that a forcing-house and nursery will be required at Calicut and that 15 acres may be opened out in the Chenat Nair forests near Palghat, which is now in process of settlement as a "reserved forest."

Major Walker then goes on to shew, that the Forest Department could not undertake the experiments without neglecting other duties. Mr. Ferguson's report, dated 3rd October 1883, was as follows:—

I received from Ceylon six young plants of *Castilloa*, each about 4 to 6 inches high. Five of them have come forward remarkably well and measure as follows:—

(1) 3' 3" high, 6 branches, foliage luxuriant.
(2) 3' 3" do. 2 do. do.
(3) 2' 6" do. 2 do. do.
(4) } 2' 0" do. no do. do.
(5) }
(6) 10" do. sickly and stunted.

I hope very soon to commence propagating from the above: the leaves of thr best trees measure 12" × 5".

Twenty-seven rooted stumps of *Hevea Brasiliensis* were received from Ceylon, and sent out shoots very shortly after arrival. Two plants subsequently died; of the twenty-five surviving plants—

2 have suckers 6' high.
15 ,, averaging 3' 6" each.
8 ,, do. 2' 6" ,,

These plants have from two to four suckers each, and I am going to commence propagating at once.

Landolphias.—I received about 200 young plants, many of which were distributed in Wynaad, Coorg, Madras and elsewhere: some I planted in my own garden, but so far the reports on the growth of these plants have been very unsatisfactory. A few plants which I retained in pots and kept under shade promise better and show a peculiar growth.

Cinchonas.—I have received from the Superintendent of Government Chinchona Plantation the following plants:—

500 *C. magnifolia* seedlings.
250 *C. pubescens* ,,
250 *C. succirubra* ,,
125 *C. calisaya* var. *Ledger.*
10 *C. Carthagena.*

On arrival here, all but the *Carthagena* seedlings were immediately sent to the Ellembellary estate. Mr. Powell, the Superintendent in charge, reported as follows on 24th July:—

"I find the *C. magnifolias* sent are mostly plants, and not seedlings fit for a nursery. Can I therefore plant them at the top of the Upper Ellembellary new clearing?

"I see I have a lot of them here, and know that if these are put into a nursery for another year, they will be over 3 feet high and too big to transplant."

In reply, I pointed out to Mr. Powell that these plants being intended for a special experimental clearing could not be planted out, and must be carefully put in nursery beds as originally arranged. On the 1st August I received the following report:—

"I have to inform you that the *C. magnifolias* were duly put out in nursery beds 6" apart in best soil, and shaded with fern, at an elevation of about 4,000 feet; out of the 500 plants sent 30 were dead in the basket. A few more look rather bad, but the rest, I think, will come on."

On 3rd idem Mr. Powell wrote me—

"I have to inform you that out of the 250 *C. succirubra* seedlings you sent me, 174 were alive when they reached this.

"Out of the 250 *Ledgeriana* seedlings you sent me, 242 were alive when they reached this.

"Out of the 250 *Pubescens* seedlings you sent me, 240 were alive when they reached this.

"These have been put out in beds adjoining the *Magnifolias* in new land 6" apart, and shaded with fern."

As the monsoon has been light I hope these seedlings will have done well.

Of the ten *C. carthagena* seedlings five have been delivered to you and four sent to Wynaad; one died shortly after arrival here.

I understood that it was the intention of Government to make experiments in Wynaad with *C. calisaya* only. I cannot therefore understand the object in forwarding seedling of *Succirubras* and other varieties which are commonly grown throughout the district. Indeed, the *C. calisaya* is now grown extensively, and on the "Kersbrook" and "Nedimbally" estates are to be seen very successful clearings containing *C. ledgeriana*, *C. verde*, and *C. morada*, all of which are now grown most successfully in the Moopenad valley.

The Collector of Malabar reported on 23rd Nov:—

The cultivation of such species of Cinchona as *Succirubra*, &c., has passed beyond the stage of experiment in the Wynaad, and private individuals have planted up large tracts everywhere.

Those sent to the district forest officer were planted out in beds in the Botanical Garden, Manantoddy, only 50 per cent. survived, as the baskets in which they were packed were delivered in Calicut *upside down*, having apparently travelled some distance in that position.

The ones sent to Mr. Ferguson he reports fully on in his letter, which I enclose.

The *Landolphias* were Mr. Ferguson's private property. The district forest officer purchased twelve plants from Messrs. Hinde and Co. last year, and there are ten alive now at Manantoddy, but they have made no growth whatever. There is one at Nilambur, which looks sickly and stunted. Mr. Ferguson has a few in his verandah in pots which have made a little growth of late, having thrown out long trailing shoots.

The *Castilloas* and *Heveas* are promising,—*vide* Mr. Ferguson's letter, but the stock is very limited, and nothing can be done in the way of planting out till it is increased by propagation. A further supply is requested, and funds will be necessary to establish a small forcing-house for striking cuttings and a nursery at Calicut, as the work must be done under careful supervision.

Estimates will be forwarded in due course.

Mr. Ferguson now wishes to hand the experiment over to the forest department, but will provide land at Tamaraherry, &c.

The district forest officer suggests also opening out 15 acres in the Chenat Nair forests, where suitable land is available.

No clearing of forest is contemplated this year, as the stock of plants at our disposal is inadequate for planting purposes. If a further supply is received from Ceylon, and the nursery and forcing-house sanctioned early, it is hoped that a sufficient number of plants may be raised for planting up blocks in 1885.

No *Ipecacuanha* plants have been received yet.

They will not be required till planting operations are commenced.

The Board of Revenue in its report on the foregoing, stated:—

Of the 125 *C. calisaya* (var. *Ledgeriana*), as many as 242 are said to have survived and to have been planted out, which shows that some mistake has been made in reporting upon the variety of Cinchona in which Government takes special interest.

The Board support the proposal contained in paragraph 7 of the Conservator's letter to entrust these experiments to the forest officer at Nilambur and to erect there a forcing-house.

The orders of Government are requested regarding the further supply of *Castilloa* and *Hevea* plants from Ceylon.

Mr. T. J. Ferguson wrote again on 29th November:—

Government Cinchona Experiments.—In continuation of my letter of the 3rd ultimo, I beg to inform you that I have today received from Mr. Powell the following report on the Government nurseries:—

"I now have the pleasure to send you a short report on the Government Cinchona plants you sent me; the number alive now is as follows:—

"First lot ...	Magnifolias	... ...	474
"Second lot	Ledgerianas	... ...	242
	Pubescens	... ...	240
	Succirubras	... ...	174
"Third lot ...	Carthagena	... ...	4

"These plants are in a nursery on the Upper Ellumbellary estate at an elevation of about 4,300 feet in heavy forest land cleared for Coffee and Cinchona in 1882-83 with a north-east aspect and a heavy rainfall; the first and second lots are planted in open beds six inches apart and are shaded with fern and watered when necessary; they all look very healthy and vigours, and have all thrown out two or three pairs of fresh leaves.

"Lot third, the Carthagenas, that came last in baskets, were planted, baskets and all, two feet apart under a thatched sloping pandal and watered lightly every day; these are not looking at all healthy." One of them has lost its lower leaves, and the leaves of the others are drooping.

I may state for your information that we have on the Ellumbellary and Upper Ellumbellary estates 75,000 Cinchonas, including *C. ledgeriana*, *C. verde*, *C. condaminea*, *C. robusta*, Condaminea hybrids, *C. succirubra*, and Succirubra hybrids; these plants are growing at from 3,000 to 5,500 feet above sea-level, *vide* map enclosed. On adjoining estates we have growing successfully all the above varieties of Cinchonas, aggregating on two estates alone upwards of three lakhs of plants.

The Board of Revenue naturally enough, reported:—

As private enterprize has established cinchona cultiv ation, there would seem to be no need for further experiments at the public cost.

Finally came the order of Government:—

The Government observe that the young *Castilloa* and *Hevea* plants received from Ceylon are doing remarkably well on the whole under the intelligent care of Mr. T. J. Ferguson, and that propagation from these plants may shortly be expected to commence. It would seem from the Collector's letter that Mr. Ferguson has expressed a wish to hand over the further conduct of the experiment to the Forest Department, but the Conservator rightly points out that while there can be no objection to the making of small experiments at Nilambur, Manantoddy, and Chenat Nair, under the direction of the local forest officers, it would at present be impossible for the department to spare the time required for the conduct of direct operations on anything like a considerable scale. While fully concurring in this view, the Government think it very desirable to proceed at once with an experiment which has been so well begun, and would much prefer to make no change whatever in the existing arrangements unless compelled to do so. The Collector will therefore be requested to communicate further with Mr. T. J. Ferguson and to arrange, if possible, for a continuance of the experiment on its present satisfactory footing. Meanwhile steps will be taken to obtain more plants, if procurable from Ceylon, and the attention of the Director of Government Cinchona Plantations, Parks and Gardens, Nilgiris, will be drawn to the omission of the Curator, Ootacamund Government Gardens, to supply *Ipecacuanha* plants, as promised, either to Mr. Ferguson or to the District Forest Officer at Manantoddy. Mr. Lawson will also be requested to report his views as regards the suggested establishment of a forcing-house and nursery at Calicut.

As regards the *Calisaya* and other varieties of cinchona, the cultivation of both red and yellow barks is reported to be so well established now in South Wynaad that, in the opinion of all concerned, further State experiments are unnecessary. The experiments already commenced will therefore be discontinued, and the Conservator will advise as to the best method of disposing of the plants of Government now under Mr. T. J. Ferguson's care.

It would seem, therefore, that, while the cultivation of rubber-yielding plants is still in the initiatory stage in Wynaad, all the leading sp cies and varieties of cinchona are grown largely and successfully, except *C. carthagena*, which does not seem very promising. While dealing with cinchona culture we may mention what a planter mentioned to us in regard to cinchonas planted amongst coffee and growing so luxuriantly as to prevent the latter from bearing. Now that the cinchona have been cleared out, the coffee flourishes not merely in proportion to the benefit derived from the removal of its rival, but from the long rest it received while kept in the shade. Such bushes are likely to be more vigorous, he believes, and to bear better crops than those grown in the open and putting on regularly their full crops of foliage only to be attacked virulently by leaf-disease. We should like to hear the opinions of other planters on this matter.

CROP-MANURES.

It is certain that we are becoming better acquainted with the action of manures, and know now how to apply them to special crops with expectations of obtaining the best results. Professor Atwater's views correspond with those we entertain, and they have been formed from experimental observations and researches extending over a quarter of a century. Corn need little nitrogen beside what it can draw from natural sources, while its yield is largely increased under the influence of mineral fertilizers; the most effective being those in which the chief oppo ent is phosphoric acid, or potash according to the soil and the season. Potatoes respond uniformly to all the fertilizing ingredients, and they are less able than corn to gather from natural sources. The same appears to be true for turnips. Not enough experiments have been made with other crops to justify conclusions concerning them. Practically the largest yield for all crops is secured by the use of fertilizers containing all the essential elements of plant-food. Used alone, nitrate of soda is rarely useful, sulphate of lime frequently, muriate of potash very often, and the superphosphates generally. Soils vary in their capacity for conveying food to crops, and careful observation and experiment are necessary to determine the needs of a particular soil.—*Popular Science News.*

EMULSIONS OF PETROLEUM AND THEIR VALUE AS INSECTICIDES.

By C. V. Birley of Washington, D. C.

The value of petroleum for the destruction of insects has long been recognized, and I have for years been endeavouring to solve the question of its safe and ready use for this purpose without injury to plants. This paper contains the results of extended experiments carried on under my direction by several of my assistants, and particularly by Professor W. S. Barnard, Mr. Jos. Voyle of Gainesville, Fla., Mr. Clifford Richardson, assistant chemist of the Department of Agriculture, and Mr. H. G. Hubbard, who has for over a year been devoting his time to practical tests in orange-groves at Crescent City, Fla.

Passing over the ordinary methods of oil-emulsions by phosphates, lacto-phosphates, and hypophosphite of lime, and various mucilaginious substances, experience shows, that for the ordinary practical purposes of the farmer and fruit-grower, soap and milk are among the most available substances for the production of pretroleum emulsions. Ordinary bar-soap scraped and rubbbed into paste at the rate of twenty parts soap, ten parts water, thirty parts kerosine, and one part of fir-balsam, will make when diluted with water, an emulsion stable enough for practical purposes, as the slight cream which in time rises to the surface or the flakiness that often follows, is easily dissipated by a little shaking. Soap-emulsions, are, however, less satisfactory and efficient than those made with milk. Emulsions with milk may be made of varying strength; but one of the most satisfactory proportions is two parts of refined kerosine to one part of sour milk. This must be thoroughly churned (not merely shaken) until a butter is formed which is thoroughly stable, and will keep indefinitely in closed vessels, and may be diluted *ad libitum* with water when needed for use. The time required to bring the butter varies with the temperature, and both soap and milk emulsions are facilitated by heating the ingredients. Ordinary condensed milk may also be used by thoroughly stirring and beating it in an equal or varying quantity of kerosine.

The diluted emulsion, when prepared for use, should be finely sprayed upon the insects to be killed, its strength varying for different insects or plants, and its effect enhanced when brought forcibly in contact with the insects.

Of mucilaginous substances, that obtained from the root of *Zamia integrifolia* (a plant quite common in parts of Florida, and from the stem of which the Florida arrowroot is obtained) has proved useful as an emulsifier.

These petroleum-emulsions have been used with success by Dr. J.C. Neal of Archer, Fla, against the cotton-worm, without injury to the plant; but their chief value depends on their efficacy against the different scale-insects which effect citrus plants. Experience so far shows that such plants do not suffer from its judicious use, but that it must be applied with much more care to most deciduous fruit-trees in order not to injure them.—*Popular Science News.*

TO KILL LICE ON PLANTS.—Professor Glacer recommends the following in a German journal. Dissolve 2 oz. soft soap in half-pint of rain-water, make an infusion of 1½ oz. tobacco in half-pint water, mix together; add 2½ oz. fuse-oil, and half-pint of methylated spirit, and make up the mixture to a quart. Sprinkle the leaves of infected trees with it, and it will kill the lice without injuring the plants.—*Popular Science News.*

SULPHATE OF CINCHONIDINE IN INTERMITTENT FEVER.—We have been favored by Dr. B. J. Manasseh, a Syrian physician who has studied in London and is practising at Brumana, Mount Lebanon, with an interesting note on the utility of sulphate of cinchonidine in intermittent and remittent fever. It relates to ninety-three cases which he has been able closely to watch, out of more than two hundred in which he has given it. The dose with which he commenced (three grains four times a day) he found to be inefficient, and this probably accounts for its failure in twenty-four cases. In larger doses, five or six grains repeated four or five times a day, he found it most effective. The statistical result which he gives are as follows:—Ninety-three cases were cured from the first dose, and of these thirteen were of remittent fever; thirty-four of quotidian, forty-three of tertian, and three of quartan intermittent. Longer treatment was needed in seven cases. Cinchonidine failed (from insufficient dose) and quinine succeeded in five cases of remittent, and nineteen of intermittent fever. In three cases quinodine was successful, although cinchonidine failed. In two both these failed and quinine succeeded. In two cases all three alkaloids were employed without result and iodide of potassium succeeded.—*Lancet.*

A NEW FIELD FOR AMERICAN ENTERPRISE.—A correspondent of the Galveston *News* gives some information regarding the Territory of Soconusco, the possession of which is now a subject of dispute between Mexico and Guatemala. It is a strip of land lying on the Pacific coast southeast of the Gulf of Tehuantepec, and extending from the Bay of Tonela to the Bay de Ocos, on the present line of Guatemala, a distance of about 200 miles, and reaching inland to the summit of the mountain range, from forty to fifty miles, containing about 8,000 square miles. It includes the entire water front of the State of Chiapas, Mexico. The reason why Guatemala desires this territory is its marvelous fertility. It was celebrated before the inquisition for its heavy yield of coffee and fine quality of chocolate. The correspondent says that the Spanish Government reserved the right to exclusively purchase the chocolate crop of this Soconusco Territory, and that until recently the natives supposed that they had no right to sell chocolate to any other than merchants of Spain. On the Guatemalan side of the boundary these lands are held at very high prices. The valuable product of coffee chocolate, sugar, rice, cotton, vanilla and indigo, is building up the cities, beautifying the country and enriching the commerce. On the Mexican side rich lands in the State of Chiapas have all been conceded to Dr. Edward C. Wise, of Virginia, and others, who have organized a colonization company. An American city is laid out, and a number of Americans being already on the ground. Grant's Mexican Southern Railroad will penetrate this fertile region within two years. The correspondent says that there is a perfect stampede for its possession. The invigorating temperature, pure water, mahogany, rosewood, walnut, coffee, rice, sugar, etc., all combine to make it attractive. There are said to be single coffee trees ten or twelve years old yielding from twenty-five to fifty pounds of coffee annually. Labor is cheap, and lands are sold to colonists by the Company on ten years' time, without interest.—*American Exporter.*

GERANIUMS AND SNAKES.—Under this heading a contemporary draws attention to a new value for geraniums. In South Africa, we are told, the geranium has the reputation of being proof against snakes, which, it is said, avoid the plant as though it were poisonous. We are reminded that though the flowers of the geranium are scentless, the leaves contain a quantity of volatile oil with more or less pungent odours, and it is stated that no snake will come near a bed of these flowers. A missionary in South Africa has surrounded his house with a cordon of geraniums, with the result that it is never visited by these unwelcome intruders. To the Kaffirs is attributed the discovery of this property in the geranium.—*Planters' Gazette.*

A USE FOR SNAKE-SKINS.—While the skins of nearly all kinds of wild animals killed in sport or in self-defence are preserved for use or ornament in some form or other—even the thick, armour-like hide of the crocodile and alligator being pressed into the service of the purse manufacturer and the bootmaker—the adaptability of the skins of snakes to similar uses has been overlooked. The markings of many kinds of snakes are beautiful in the extreme, and the colours can be perfectly obtained after death, as the preserved specimens in museums amply testify. The skin, though thin, is exceedingly tough; and, if properly tanned, would make an excellent material for the manufacture of purses, ladies' bags, &c., and for the covering of fancy boxes and other ornaments. In this respect snake leather would be far superior to alligator leather, which shows how effectively the markings of so unpromising-looking a skin as that of this ungainly saurian in its natural state may be displayed in being turned into leather. A great advantage which would result from the use of snake-skins in the manner suggested would be that they would become of marketable value, and an additional inducement would thus be given to the natives in India and elsewhere to kill the reptiles which are so formidable a pest there and in many of our Colonies—*Colonies and India.*

UTILISING THE SHARKS.—In the list of exports from Queensland, Western Australia, Fiji, and other parts of Australasia, "shark's fins" figure as a considerable item, along with other articles with the names of which the European merchants are scarcely familiar. Sharks of various species are abundant in the warm waters of these tropical and sub-tropical regions, and the natives and settlers turn them to good account in various ways. The first process is to cut off the back fins, which are of great value, fetching in the market from 90*l*. to 100*l*. per ton. They are extensively used in making gelatine. The back fins are the best, yielding gelatine of a superior quality, but all the fins are more or less valuable. The operation is easily accomplished by merely placing a knife at the bottom of the fin, cutting it off level with the bark. The fin is then allowed to thoroughly dry in the sun. When afterwards placed in warm water and the rough skin scraped off, the result is almost pure gelatine. But the fins are by no means the most valuable portion of the fish, the liver yielding an immense quantity of oil, which is largely used for medicinal and other purposes. The extraction of the oil is also an easy matter. The best method of obtaining the utmost oil from the liver is to place it in a steam-tight receptacle, and force in steam to the pressure of four atmospheres; but a large proportion can be obtained by simply cutting up the liver and allowing it to drain, or placing it under pressure. In this case the oil often becomes thick, but that obtained by the former process has a beautiful amber colour, which fades on exposure to the light. It is often used instead of cod-liver oil, being equally efficacious. It has, however, an unpleasant taste and disagreeable smell, which may be slightly improved by allowing the oil to drain through charcoal. A good deal of the oil sold as "Dugong" is really shark oil. The carcase of the shark is also sometimes utilised, and is of considerable value. If, instead of being thrown away and allowed to putrefy in the water, it is subjected to the same process as the liver, a quantity of oil may be extracted from it, and the residue may be used as manure.—*Colonies and India.*

THE POSITION OF CINCHONA BARK AND QUININE.

The following memorandum on the position and prospects of the market for cinchona bark and quinine was drawn up by one of the first authorities on the subject, with reference to the letter which appeared in our columns recently from Messrs. F. Lemair & Rivers Hicks and the movement in which Mr. Felix Broun took an active part. The statements made seem reliable and are worthy the attention of those interested in cinchona. Our own feeling is that the influence of Cuprea bark on the fortunes of the cinchona planter has been almost equivalent to that of leaf-fungus in the case of the coffee planter:—

In the last months of 1881 the supply of bark was evidently becoming too large for the wants of the market, notwithstanding that those wants had been on an unprecedented scale owing to large purchases of quinine on speculators' account. German manufacturers were offering quinine for March 1882 at prices very much under the spot price.

This moment was positively considered a propitious one by a party of capitalists to form a corner in bark and quinine with the object of driving up the price. The manufacturers were not, however, to be caught, and the movement upwards was small and insufficient for the purpose. The position remained with little alteration till the summer of 1882, when a party of manufacturers took, it is said, a large share of the syndicate's stock of bark and quinine on their shoulders, and, having thus loaded themselves tried by free buying to raise the market. This effort failed to do more than maintain about the artificial level at which the combination-stock stood. Meanwhile, outside speculators in quinine kept the market frequently supplied with their stocks, parting with them, very wisely, on seeing the unmanageable state of the stock of bark which all this time had been steadily growing especially in South American sorts.

The importers of South American bark, notably those interested in the Cuprea kinds, could only realize their purchases satisfactorily at the old high prices and were most reluctant sellers. In consequence the business doing during the fall was chiefly East Indian, to the planters' great advantage.

Dropping markets followed, and the position steadily kept changing for the worse.

Last summer, a large convention of manufactures was formed, the object of which was to contract the make till the large accumulations of quinine went into consumption. The English makers were not members, but were not unfriendly to the operation, as by this time it had become clear that very large losses would have to be faced, and a panic must always be injurious to planter and manufacturer alike.

The convention having all "gone to water" owing to the action of the London Houses, it is not much use discussing what it might have done; it is more to the point to look the position in the face and see what the open market means as to the planters' prospects.

Stocks.—There is the largest stock of bark now in London and Paris the world has ever seen, principally South American, and not *all* inferior. There is bark harvested in South America ready to come over at a price. In addition, an enormous quantity of quinine is believed on good authority to be in existence ready for use, the surplus of the overmanufacture of late years.

Consumption.—There has been no very especial demand for quinine of late years in America, and as that country gets steadily more cultivated, so will the consumption per head of quinine decrease.

The Indian Government now supply all their wants from their own plantations.

No doubt, at prices between 4s and 6s for quinine, which is the probable outlook, very low prices will be obtained for low barks, and twigs will become quite unsaleable. Those planters who have *true* officinalis and calisaya trees, or who produce really fine renewed red, will command the market; while plantations of inferior barks will be best left to grow for a time, till the effect of low prices on South American wild bark has become visible.

When quinine ranged between these limits, years ago, with a perfectly open market, there was little profit for South American importers of wild bark, and information recently received inclines one to think that it costs more now to collect than it did then. The paucity of sales tends to confirm this view.

Replies to some of Mr. Broun's points.

No effort was made to keep quinine at 4s by the manufacturers when it ranged down to that figure some years back.

"Distributors" unknown in the London trade by that name; perhaps the wholesale druggists are meant.

Units in low bark worth less than in rich ones. At present the unit is worth from 5d to 7d net. Howards' price for quinine is in bulk, net 5s 5d. Usually on a falling market the weakness is felt first in the raw material.

All the manufacturers buy on their own analysis and examination of the samples.

SUGAR CULTIVATION IN CEYLON.

The correspondent who signs himself "Vedda" (p. 736) seems very anxious to prove that no weight is to be attached to the failure of previous experiments in sugar cultivation in Ceylon, even though conducted by men with experience acquired in the West Indies and Mauritius. He seems positive that with better varieties of cane and improved appliances success would now be achieved, and he wants, not the trial of small experiments, but cultivation on a large scale by Australian capitalists. We should be very glad indeed if such capitalists would come and risk their money on the strength of "Vedda" 's good opinion and without reference to the past. But it would be impossible, if it were right, to conceal the facts. We certainly feel strongly inclined to believe that sugar cultivation under irrigation might succeed in Ceylon, on the banks of the Mahaweliganga and other rivers, if only prices rose to a higher level and the climate did not interfere. At present, however, sugar is as much depressed as coffee. As regards the average rainfall of Australia being low, we never disputed that patent fact. What we did state was that the climate of the leading sugar district, Mackay, was distinguished by nearly 70 inches of absolute rainfall, while the atmosphere for most part of the year is so saturated with moisture, that clothes, shoes and books suffer from mould as they do in Colombo.

The case of Fiji, as we pointed out the other day, shows that sugar will flourish in a very wet climate, provided the soil is fertile. If soils fertile enough can be found in Ceylon, we do not see why sugar should not succeed in a dry climate as well as in wet,—in the former case by means of irrigation. What the Province Wellesley planters said to Mr. Forbes Laurie is very interesting, but it is a significant fact that Mr. Wray, author of a standard work on sugar, does not seem to have succeeded practically at Penang. He seems now to be in Government employ in Perak. Dr. Trimen may, perhaps, accept the challenge of "Vedda" and give his opinion of sugarcanes and their cultivation. As to beet sugar in Europe, not only is the highest possible scientific skill brought to bear on its production, but several of the Continental Governments aid the product by means of protection and bounties. They have ruined English sugar refiners but have benefited the English people by giving them, at the expense of their own exchequers cheap sugar. We by no means wish to discourage a revival of the sugar enterprize, but it is our duty to marshal all the facts, *pro* and *con.*

CASUARINA PLANTATIONS.

It seems strange that neither the Government Forest Department, the Railway Department nor private individuals have tried plantations of casuarinas for fuel purposes in Ceylon. There is a fine avenue of these trees leading to the new Lunatic Asylum, and as yet casuarinas seem to have been utilized only for ornamental purposes. Besides private plantations, there are nearly 2,000 acres of Government plantations of casuarinas in the Madras Presidency, from one to ten years old, and Mr. Gamble, the head of the Forest Department, remarks that

It will be seen that, considering only the regular plantations and not the small plots, the annual production of wood per acre of closely planted Casuarina three to nine years old varies from 2·6 to 6·3 tons, the average being 4·5. And it is probable that if, until more accurate data are available, we estimate the annual increase of wood per acre up to an age of ten years as four-and-a-half tons, we shall be under the truth rather than over it. I feel sure that many of the Madras private plantations will, for the same age, give more. In paragraph 25 of the report it is stated that Mr. Lushington found the acre-increment of a Madras plantation thirteen years old to be three-and-a-half tons, but it is not stated what thinnings had been made, and how much had been removed by loppings and cleaning of ground shoots. Mr. Woolridge's calculations made in South Arcot give 4·5 tons at eight years of age, which is the age at which I understand it is considered most profitable to cut the plantations near Madras. Mr. Lushington's measurements, though insufficient for a real basis of calculation, seem to point to the decrease of the acre-increment after ten years, and ten years is the term of rotation which I would recommend to be applied to the Nellore plantations, at any rate until further experience and greater accuracy of statistics enable us to reconsider the question.

But there seems to be a prejudice amongst the natives against this wood as fuel, for Mr. Gamble adds:—

This wood must of necessity be sent to Madras for sale, for, as is well known, the native consumers will not purchase Casuarina wood for fuel if it is possible to get any other kind. It may be possible to dispose of small quantities in Nellore and Ongole, but the greater proportion must go to Madras for sale, where it may possibly fetch a *net* price of R5 per ton, *i. e.*, 25,000 rupees per year. The cost of the plantations up to date has been, according to Somasundra Mudali's table, and, as before, omitting minor areas, very nearly 2 lakhs, so that the plantations may be expected to yield 12½ per cent. interest on the capital. This does not however account for cost of establishments which will probably reduce the rate to 10 per cent.

While referring to the cost I would mention that the rate of planting per acre has lately fallen considerably, the figures of Somasundra Mudali's list, corrected up to December 31st, 1882, giving R66 per acre as against R138 given in paragraph 342 of Mr. Brandis' suggestions.

From statements given me in Nellore the cost of the 1880 and 1881 plantations up to the 31st March 1883 had been per acre on an average:—

	R.
1880	41
1881	18

The 1880 plantations at any rate will not require now much more expense in watering and the later made ones are being now managed more economically, so that there is not much fear that the cost per acre of those made in and since 1880 will go over R50, while there is every probability of its being much less, at any rate for future years.

The experiments of the weight of Casuarina wood are also valuable; they give the result as follows:—

Green wood 69 lb. per cubic foot.
Dry „ 45 „ „

both with bark, which may account for the low value for dry wood compared with the 55 lb. given in Skinner's "Description and Strength of Indian Timber," which was calculated on large pieces of squared dry timber afterwards used to determine the co-efficients of transverse strength and elasticity, and may be taken as a fair value for the cubic foot of seasoned timber.

But if, as is stated, the tree comes to maturity in from eight to ten years, it would probably pay to grow casuarinas for timber for tea-boxes and other purposes. The statistics of an acre planted in 1877 and bearing 285 trees, showed a girth of trees from 9 to 27 inches; height 24 to 46 feet, and cubic contents 0·61 cubic feet to 11·02. The casuarina flourishes best when exposed to the sea-breeze. At nine years old, some trees were 31 inches girth, 60 feet high, and cubic contents 16·89 cubic feet. Mr. Hutchins, in his report, stated:—

Within the limits of my experience the growth of Casuarina does not perceptibly vary for elevations up to 3,000 feet. There are a few well-grown Casuarinas on the Nundydroog Hill near Bangalore at an elevation of 4,600 feet, but the growth at that elevation is observably less than at the plateau level, which is there 3,000 feet above the sea. In West Mysore the tree flourishes in a few situations, where it has been planted up to a rainfall of 40 inches. Beyond this, on coffee estates the growth is not good; but I believe Mr. Dickson is planting Casuarina successfully at 4,000 feet and in the heavy rainfall of Mercara in Coorg. The lower the elevation, the more severe must be the transpiration from an ever-green and a rapid grower, such as Casuarina. On the deep red loams of the Mysore plateau, where the level of well water is 30 or 50 feet below the surface, Casuarina exhibits a growth nearly equal to that on the mixed alluvial soils of the Madras seaboard (the Sríharikót Island for example) and superior to the average of growth on the sand dunes of the coast. With moderate subsoil moisture in Mysore, as in Sample-areas A of Kadgodi and Nelal plantations (*vide* Mysore report on rate of growth of Casuarina) the growth is equal to the best Coast Casuarina. Generally the Mysore Casuarina plantations are on bare or scrub covered plains, where the subsoil moisture in the dry season is at a great depth, and it is a remarkable fact that in the terrible droughts of 1876 and 1877 the casualties amongst these trees were practically nil.

OUR attention has been directed by a correspondent to a paragraph in the *Journal of Horticulture*, having reference to the value of bees to fruit-growers. Mr. Warren, a market gardener at Isleworth, near London, is also, it is said, a practical and scientific bee-keeper, and his opinion on the subject is worth the consideration of gardeners and fruit-tree growers. He considers that the large crops of fruit he has obtained, even when his neighbours have been complaining of scarcity, have been chiefly due to the influence of the bees in distributing the pollen. In this respect he considers bees return a handsome profit for the attention and care they need.—*Australasian.*

Correspondence.

To the Editor of the Ceylon Observer.

ANALYSIS OF CINCHONA BARK.

Colombo, 4th March 1884.

DEAR SIR,—In last night's issue of the *Observer*, I notice Mr. Sylvester T. Richmond complains of a parcel of Ballagolla Ella cinchona bark, consisting of 1,250 lb. officinalis shavings, having been analysed in Colombo in September last with the result 1·09 per cent quinine sulph., and that Dr. Paul afterwards found it to contain 2·2 per cent or fully double the quantity. As a Colombo analyst, permit me to state through your columns that the analysis referred to was not made by me. I find, however, that in November last I analysed a parcel of 1,219 lb. Ballagolla Ella officinalis root and stem chips and shavings with the result 2·31 per cent quinine sulph. M. COCHRAN.

[The analysis was made by the authority on whom purchasers rely, as well they may if the results generally resembled those in this case. There may be some circumstances peculiar to the case, which it may be well the public should know.—ED.]

Colombo, 4th March 1884

DEAR SIR,—Mr. Richmond's letter in yesterday's issue publishes a solitary instance of a Colombo analysis of bark having been lower than Dr. Pauls's. Allow me to send you a list, supplied by a German manufacturer, in his report on bark shipped by my firm, made of each lot by two analysts in which he gives the averages of two separate analysts in his employ and compares them with the Colombo analysis upon which the bark was invoiced.

Average of analyes made in Germany.	Colombo averages.
1·44 per cent	2·06 per cent.
1·03 ,,	1·12 ,,
1·58 ,,	1·96 ,,
1·55 ,,	1·95 ,,
2·64 ,,	3·23 ,,
0·87 ,,	1·32 ,,
1·75 ,,	2·78 ,,
1·37 ,,	2·05 ,,
0·79 ,,	1·08 ,,
1·00 ,,	1·46 ,,
0·74 ,,	1·18 ,,
3·52 ,,	4·08 ,,
1·37 ,,	1·66 ,,
1·34 ,,	1·82 ,,
0·72 ,,	1·36 ,,
1·26 ,,	1·66 ,,
1·35 ,,	1·82 ,,
3·19 ,,	4·42 ,,
0·84 ,,	1·97 ,,

I may add, that another German manufacturer found the Colombo analyses 30 per cent too high in the two shipments he received, and similar statements have been made to me by several others.—I am, sir, yours faithfully, PH. FREUDENBERG.

CINCHONA BARK ALKALOIDS.

Theberton, Maskeliya, 7th March 1884.

DEAR SIR,—I have noticed in your paper remarks, on the difference of the analyses of cinchona bark made in Colombo and London. The enclosed may be of interest to your readers, showing the difference, also, of Colombo analyses :—

No. 305.—Analysis of Theberton renewed succirubra cinchona bark, off trees 4 years old :—
Crystallized sulphate of quinine .. 2·78 per cent.
Total alkaloids ... ... 4·01 ,,

No. 306.—Succirubra, original bark, off 4 years old trees :—
Crystallized sulphate of quinine ... 1·97 per cent.
Total alkaloids ... ... 6·14 per cent.
Colombo, 3rd March 1883.

Analysis, Theberton bark. Colombo, 29th Feb. 1884.
Crystallized sulphate of quinine, net 1·75 per cent.
Renewed and original succirubra chips from trees 3 to 5 years old.

Succirubra original bark off trees 3 to 5 years old: —Crystallized sulphate of quinine net 1·05 per cent.

The above analyses were taken from a mixed lot of bark, the larger portion of which was from trees 5 years old.—Yours truly, T. J. GRIGG.

MR. WM. CAMERON'S DRIER.

DEAR SIR,—I have been reading carefully over Mr. Cameron's remarks in defence of his "drier." It is true that I did not observe with approval the fact, that he used a good deal of iron, to take the heat out of the smoke, &c., in the flue. There are also a great many other ingenious contrivances in his plan, which I did not take note of by way of expressing approval. It is not to be inferred from that, that they are not excellent, or that I did not think them so. I only noted what seemed to me defects.* However it seems we are agreed about the superior advantages of iron over brick, as Mr. Cameron explains that he only uses the brick flue in *addition* to the iron covered one.

I should doubt much, that it is any addition in effect. If the iron has taken out all the heat of the fire-heat in the flue, till the smoke, &c., is reduced to 120 inside the flue, he won't get much through the brick flue afterwards to be of any service. And if the air outside the flue, *i. e.* in the drying, house, be hotter than smoke inside, the heat will pass from the air to the flue, more than from the smoke to the flue.

However, it seems to me that there are merits in his scheme, if followed out in its main principle; the defect seems in trying to combine two different principles that won't combine. A main feature of Mr. Cameron's plan is to heat a large surface, and to lay the bark to be dried on that surface *to get heated* Now there is no question, that, if a damp thing be heated, the moisture in it will get heated, and evaporate; and very little motion of air will be needed to carry off the moisture evaporated. The process is chiefly this. The hot surface heats the bark on it and the moisture in the bark. The moisture passes off into the air, and heats it, and is thus carried upwards by cold air taking its place. A great deal of drying can be done, and is done, in that way. And in so far as Mr. Cameron's plan carries out that process, its merits are great.

Drying by heated air has also much to recommend it. Heated air gives out its heat slowly. Air heated up to 200° or more would not burn the hand, while water or iron so heated would. I am told tea will stand heated air at 400°. Of course iron at that would burn it.

There is, therefore, not much danger of over-heating a substance to be dried by hot air. A planter I knew used to keep the air in his clerihew at 160°, and he was not alarmed when it got to 180° as the coffee did not suffer.

Heated air holds more moisture than cold air, and it is maintained that more advantage is gained by using the air a high temperature, as equally great or greater advantges are to be gained by heating up a small quantity of air to a high temperature than a large quantity to a lower temperature. If the drying effect is the same for fuel there is the advantage in time, and space, and mechanical power, less air being required to be removed to effect the same result. In drying by heated air, of course the sooner

* True to human nature as well as to science.—ED.

and the more effectually the used air is removed the better. Also the more thoroughly the heated air *permeates* the substance to be dried the better. Mere *contact* above and below is not at all equal to *passing through.*

There is of course the objection to the highly-heated air system, that a good deal of heat is lost, all below 400° in a drier working at a temperature of 400° being lost.

There was for long a controversy raging in the engineering world regarding the merits of high and low pressure steam. I understand that the question has been disposed of by making the steam first work a high pressure cylinder and then a low pressure one, the combination of two cylinders giving excellent results.

Might I suggest to Mr. Cameron that he might turn his attention to a similar arrangement in his drier? Have one chamber for the highly-heated air process, and after the air has done its work there, coming out at 150° or 200°, pass it through his flues with the iron cover, quartz, &c., also utilize the extra heat (fire heat) in his smoke flues for the same purpose in another chamber. He would thus have the two principles working effectually, neither interfering with the other, and secure the greatest economy to fuel.

There is one point it seems to me, I must mention regarding Mr. Cameron's argument in re "up or down."

He says:—"We need not look for the advantage of drawing down to lie in the gravity of the steamy air, as while it is in the condition to hold the maximum quantity of vapour, it is in a condition to rise as well." There seems to be a confusion in his ideas here. Air rises only being by lifted. Hot air, being lighter, is lifted by colder air, and *vice versa*; cold air, being heavier sinks among hotter air. Now hot air dries by imparting some of its heat to the moist substance; also a good deal of heat is needed to turn moisture into vapour. Air at say 200 coming in contact with a moist substance at (say) 100 has to spend several degrees of its heat in warming the substance, and much more in turning the moisture into vapour, so that the air after the process is greatly cooler, 150 or 110 as the case may be, part of the heat having gone into the substance, and part become *latent* in the vapour. Now suppose a volume of air at 200 comes in contact with a moist substance, *the portion* of the air so coming in contact gets cooled by drying it, and being cooler than the neighbouring air, say 150° to 200°, it will necessarily sink in it.

It is not because it holds moisture in it, that it is cooler or heavier. If the hot vapour passes from a boiler into the cold air, it heats the air it mixes with (while itself is cooled thereby and becomes visible), and that air, being hotter than the surrounding air is lighter, and so is forced up by the cooler air around it.

In drying with heated air, as we have seen the process is reversed. The air has to impart of its heat to the substance and its moisture, and so gets cooler and heavier, and sinks.

If Mr. Cameron will take this into his consideration, I think he will not hesitate for a moment in admitting the advantages of drawing *down* the used air.

The clerihew like other machines needed to be understood to be wrought effectually, and the number of blunders possible for an unskilful man to make in the repairing of one are many. I have seen some of them, very wonderful in their way, and surprising in their results. And I can well believe that the genius that could make these, could have made more, and more surprising ones on occasion. Were the clerihews Mr. Cameron alludes to in proper order? or had they been *improved* (?) by untutored genius?—I remain, yours truly, J. B.

MEMORANDA FROM MYSORE.

DEAR SIR,—I sent you a letter about the transport of seed from north to south and south to north as referred to in an article in the *Field*, but it does not seem to have reached you, as it has not appeared in your paper.

I had to go to a meeting of the Parent Association Council at Chickmuglur; and I had an opportunity of seeing something of the country. Chickmuglur is the metropolis of the Mysore planters just as Sucklarpore was when there was a large number of estates in Munzerabad,—a case similar to what has occurred in Ceylon. A lot of new estates have sprung up around the Baba Budan hills, and there are a lot of planters altogether in Kadur. So the centre of Associations has been removed from the South, and there are now the South Mysore Branch Association, the North Mysore ditto and the Mysore Parent Body. There is a nice little club at Chickmuglur, and they have good fun at the annual sports after the coffee is all off. The Baba Budan Hills tower up to 7,000 feet, and are thus about 4,000 above the level of the maidan surrounding. These are the famous mountains which take their name from an old Musalman who lived about 200 years ago (now dead, I believe) and brought back in his "maddee" some coffee berries, or beans rather, after a visit to Mecca where he had gone on a pilgrimage. He sowed the seed beside his house, and from these few seeds the fine old Munzerabad or Mysore coffee came. Well done, old Baba! If you had not died, we might have made you Chairman of our Association as the pioneer planter of Mysore. On these ranges of mountains Mr. Cannon formed an estate, and his relative Mr. Allardice (our Chairman) still carries on the properties and upholds a name in Mincing Lane which is unsurpassed in the coffee markets. You in Ceylon are apt to fancy yourselves a bit and think you can beat creation. Well the Mysore climate is such that it defies you to lick it in coffee or cardamoms. You are not in it.

By-the-bye, I saw a good thing the other day in the *Weekly Times* (London). At a meeting of the Linnæan Society, a Mr. Baker read a paper about a new potato. The following remarks are interesting:—"The ordinary potato is grown as if its sole object were to produce tubers, and, moreover, it is grown under artificial conditions of climate and soil. Under these circumstances, the plant naturally loses its vitality, as indicated by the fact that after a time it ceases to produce flower and seed, and it then readily becomes a prey to the potato disease. *The same rule applies to other plants where one function is stimulated at the expense of another.*" Well what have you to say to that? Paddy would say: "Yes, the sole object of growing potatoes is to get potatoes," and then he would scratch his head and puzzle over the disease when it came. Now, I consider I have found here an antidote to leaf-disease. As I told you before, the men here were first thrown off their feet by *borer*. They did two things: they began the careful cultivation of shade, and they tried a new coffee. With the long droughts common here (sometimes five months on end) they found that the coffee must have an umbrella—and yet must not be too dark. Was not that pluck to start to *grow shade* and a *new kind* of coffee? Ceylon pluck is more of rashness. It sometimes needs more pluck to stick quietly to the task of overcoming a seemingly unsurmountable obstacle than to speculate on the "sink or swim" style.

Don't prune your tea to force an already forcing climate, and then brag of the prices before they are well out of the brokers' throats. In Coorg they are pulling in rupees by the cart-load. They don't study shade very much as far as I hear. They are hard at it, and we will hear of *Hemileia vastatrix* having broken out badly very soon. Men are like sheep. Start one over the precipice, and it 's a sure bet that veryone will follow.

I want to ask you to find out—say from Mr. Pyper of Hantane who is one of the very few who has had experience of shade in coffee in Ceylon: has he studied the proper trees that suit coffee, the proper supply of light to enable the coffee to bear a paying amount of fruit, the different degrees required for (say) a northern as distinguished from a southern aspect, the annual lopping in order to maintain the originally desired quantity of light, and the planting of suitable trees where light was over-abundant? Mr. Holloway, who is one of the few planters who have planted artificial shade (that on Hantane being natural growth prior to the planting coffee), I trust, will speak out. I would rather have as an inspector a man like Holloway than any fancy V. A. beloved of Colombo agents. I feel sure that the two gentlemen I have referred to will reply, but I am also sure that shade has never been made a study in Ceylon. If Mr. Holloway has thoroughly studied shade, then let him try Coorg coffee. It will pay him, and it will pay planters in general who still stick to coffee.

Now here are two coffees:—1. Munzerabad or Mysore brought by an old planter 200 years ago. 2. The Coorg or Nalknaad brought by the Moplahs from Mocha. (See *Tropical Agriculturist* page 966 Vol. I.) Besides these, there is the Ceylon kind. Planting operations commenced first in Ceylon and Mysore. Stewart, Mann, &c., got seed from both these localities and started in Coorg, and all went on nicely till 1866, when the borer came, and 1871 the leaf-disease. The insect and the fungus resulted from *unnatural culture*. 20 years ago Mr. Mann started "Nalknaads" and all this time these have flourished. Then Munzerabad planters got seed from Coorg, and they also are beginning to lift their heads and rejoice. Now it is an interesting point whether the Moplahs' coffee will top that of the aged pilgrim Baba Budan in price.

As for sport, you can with good retrievers get through a good deal of ammunition and load up a number of carts with duck and teal in the tanks between Chickmuglur, Hassan and Sucklaspore. You can get antelope-shooting without much trouble. You can stalk a bull-bison (none of your "cow-butchers") without going very far out of your way. You can get bears as plentiful as is necessary, and you can have a tiger marked down and pot it from a staging erected up a tree as it prepares to feast on the bait. You can get a fine tusker if you look for him, but you will have to pay through the nose if you have not a license: R500 is a stiff fine and a stiff price for a pair of tusks. But in all this I do not think there is anything here to come up to a week at Bintenna with an agreeable companion or two, ponies and snipe in the day and cards and pipes in the evening and a jaw in the hammocks before going off to sleep.

All the effervescence about the coolies' pay bill seems to have ended—the law is for the terror of evil-doers and for the protection of those that do well. All sensible men will be quite willing to afford much information to Government as will prevent scandals arising which have in this instance helped to publicly wash the dirty linen.

I wish you all success with tea. You have failed with coffee and cinchona. "Let that flea stick to the wa'." Go ahead but don't *force* the pace. It 's the pace that kills. With every good wish for Ceylon planters and their organ the *Observer*, I remain, yours faithfully, ABERDONENSIS.

P.S.—In Hall's *Coffee-planting in Southern India and Ceylon*, page 90, you will find the following:—"The natives always cut bamboos for building purposes when the moon is on the wane, as they then contain less sap, and are consequently, less liable to early decay." I think you were too hasty in dubbing the conclusions of a man like Mr. Graham Anderson as the petty notions of a native superstitition. You may depend on it, Mr. Anderson has satisfied himself, and Mr. Hall too, that there is something more than superstition. [We said nothing in disparagement of Mr. Anderson, who merely mentioned a notion which seems to us to be unscientific.—ED.]

ECONOMY OF FUEL AND EXPOSURE TO LIGHT IN TEA PREPARATION.

Nilgherries, S. India, 7th March 1884.

DEAR SIR,—Now that so many tea estates have (unfortunately) had to resort to steam for lack o water-power, you would confer great benefit no doubf to many of your readers if you could furnish us witt a few practical wrinkles on effective stoking anh economy of fuel; also the best and cheapest meand of utilizing the waste heat from boiler and dryings machines for our withering lofts.

A few hints on these matters by a practical engineer would be a great boon. Manuals by Reynolds, Clark and others give us a good deal of information regarding the advantageous and economical use of coal and coke, but little is said regarding wood-fuel.

Can any of your Ceylon tea authorities kindly inform me whether full exposure to light, during the fermenting process, is requisite to obtain a good "colour"?—Yours faithfully, NOVICE.

[Perhaps some correspondent may give the information desiderated.—ED.]

YIELD OF TEA BETWEEN 5,000 AND 6,000 FEET ALTITUDE IN DIMBULA.

Abbotsford, 14th March 1884.

DEAR SIR,—I have already sent and you have published the yield of a five-acre field on the above estate, showing an average of 405 lb. made-tea per acre. I have now the pleasure to enclose still fuller and more satisfactory statistics concerning the remaining 105 acres, showing an average of 424 8-12ths lb. per acre. It will be noted that we only worked 236 days out of 365. This means that on this estate there never is (and never will be, I trust) Sunday picking, and only in the hottest season does any Saturday picking take place, so as to avoid Sunday making. That God rewards those who honour Him I have not the slightest doubt, and I am perfectly certain that this estate has not suffered through striving to keep one day in the week holy to the Lord.

The rainfall for 1883 was 110·10 inches, but for the 12 months from 1st March 1883 to 29th February 1884 it was only 88·82. The drought seemed to suit the upcountry tea, for ,while I hear of a serious decrease on estates lower down, we have registered to end of February an *increase* of 10,443 lb. over the corresponding two months of 1883.

The "excess in bin" is easily accounted for. Each day's tea (or week's tea) is weighed roughly in boxes, sacks or baskets, before emptying into the bins, and care is taken to under-rather than over-weigh. For instance, if a box 18½ lb. weight is used and the gross is 171 lb., the amount of tea would be entered as 150 lb.

I may state in conclusion that the whole of the tea is planted up with cinchona, three years old, between every five rows, and that, while the cinchona does not seem to harm the tea, the latter certainly immensely improves the former.—I am, yours faithfully,

A. M. FERGUSON, JR.

SUGAR CULTIVATION IN CEYLON.

Kandy, 15th March 1884.

Sir,—The subject of sugar cultivation in Ceylon should not, by any means, be dismissed with a few last words from persons who have not only failed with sugar but with coffee and everything else they have attempted to grow, because their methods of cultivation, always theoretically perfect, were often practically useless, and extremely expensive. Carrying out capricious whims—such as roading and draining an estate in jungle before a tree was felled and then destroying the roads and drains by felling and burning, and spending thousands of pounds in turbines, etc. for irrigating—is not the way to make anything *pay*. It is a pity that the sugar enterprize should have been started by those who *wasted* so much money for want of a little more of the practical and economical method of cultivating.

"G. W." says the men who planted sugar in the old days were "experienced and practical men": Mr. Montclar, of leaf-disease-really-curing-mud-hole-constructing fame was, I find, one of them. We all know what a *practical* man he was! The others, doubtless, *were* very experienced men in the West Indies, but when they came here they had to learn all over again and adopt different methods of cultivation to suit climate, &c., as coffee-planters experienced in Ceylon culture find when they go to Brazil, Java, Fiji and other coffee-producing countries. "G. W." also asserts that they did not all cluster round one spot. What, I ask "G. W.," is this, but clustering round one spot, Galle?

1. Oodagama sugar estate, 30 miles from Galle.
2. Hanagam do 12 do do
3. Telicada do 9 do do
4. Kohilawajura do 18 do no
5. Mr. Robt. Craig's estate near Galle.

Nearly all the plantations, except Peradeniya, were down about sea-level, and no allowance had been made for latitude. The canes were planted here at the same elevation, as they had been planted in countries much farther from the equator, where the growth was not so rapid, and the quantity of saccharine matter, in consequence, more in proportion to the bulk of the canes. I may also add, that the *elevation* at which the boiling was carried on might make a difference in the facility with which the juice crystalized, even with vacuum pans, for the boiling point is lower, the higher the elevation. Why not experiment with canes at 2,500 feet or even higher?

To use a familiar illustration, cabbages heart well at sea-level in Fiji, but will not do so here; and again, broad beans in Ceylon shoot up rapidly to a great height and give no crop unless *topped*, when, the too luxuriant growth being checked, they bear well. Why not check the too rapid growth of sugarcane by some artificial means?

Gum trees flourish in Ceylon at 6,000 feet above sea-level, grow badly at 2,000 feet, and near the sea-level I doubt if they grow at all. In Australia the gum and the sugarcane flourish *together*: this should be suggestive.

In the *Observer* of 1st March, the poorness of the soil is blamed. I thought the subject of soil had been settled. Certainly, near Galle the soil (largely cabook) is poor, and both soil and rainfall are more suited for *tea*, but we have soil growing fine cacao and tobacco—both rich feeders—and, in parts of the lowcountry mentioned by "D. E." in his able letter, the soil is magnificent, while at Trincomalee, I believe, *volcanic* soil will be found, else why the hot spring, &c.?

It is absurd to say that the climate is too moist in a country where the rainfall and humidity of the air range, as they do here, between 227 inches rainfall at Padupolla and 33 inches at Hambantota.

Surely this is a large enough range in which to find a suitable climate! What "G. W." means by "the planter being sore troubled to bring his canes to harvest in the dry season which is so short and uncertain," I cannot imagine, seeing there are parts of Ceylon where there are months of fine weather with scarcely a break, and that even in the wettest parts the cane would be cut in the morning, carried off by portable trams to the mills, and crushed before night.

The writer in the *Observer* of 27th Feb. questions the statement made by "D.E." and Honolulu, as to the average rainfall of Australia viz. 50 inches. I annex figures from the Directory of 1878 which will prove it to be correct, viz.

Queensland	51 inches	per annum.
New S. Wales	50 "	
Victoria	26 "	
S. Australia	21 "	
and Tasmania	23 "	

In Barbadoes—a sugar country—the rainfall and humidity of the air are almost the same as in Ceylon—viz.

	Barbadoes.	*Ceylon.*
Mean temperature	75·0	80·07
Absolute max.	85·0	95·00
Absolute min.	64·0	68·03
Absolute range	21·0	26· 7
Mean daily	6·8	9· 0
Mean humidity	83·0*	83· 0*
Average rainfall	67·0*	76· 0*

The above needs no comment!

With new varieties of cane, improved machinery and our abundant supply of cheap and efficient labour, the produce of canes grown in Ceylon, sugar, rum, and molasses, would all compete with the sugar, etc., of Fiji in open markets, the Fiji produce having to pay import duties equally with Ceylon and in addition being hampered by want of labour which, unless overcome, must eventually ruin all small planters there.

The Director of the Government Botanical Gardens at Peradeniya seems to be unacquainted with sugarcanes, their varieties, yield, etc., or he would have written giving us some information on this subject, which is of such vital importance to both Europeans and natives, and in particular would have given us his opinions on Honolulu cane etc. as suited for Ceylon.

I quote Mr. Laurie's letter:—"One and all of the 'Province Wellesley' sugar planters were unsatisfied with my reply, and were unanimous in their opinion that with a rainfall of 80 to 90 inches, and high cultivation on FAIRLY GOOD soil the first 'want of saccharine matter in the canes' could not exist, and with modern means of boiling crystalization could no longer be a difficult." If the Province Wellesley planters were unsatisfied how much more unsatisfied the *Ceylon* planters ought to be, if they allow themselves to be beaten for want of a little more pluck.

A valuable extract in the "Times of Ceylon" states that beet-root only yields half the amount of sugar given by canes, and yet hampered though it is by expensive European labour, scientific methods of manufacture and improved machinery, much of which can be used for the manufacture of *cane sugar*, has enabled it to compete with the more favoured cane in the markets of the world.

The object of the Ceylon planters should be to prove that, given the right *cane, right elevation* and situation, the yield of Ceylon canes would be sufficient, (taking our cheap labor into account) to make *a little* profit for those who planted them. We do not want small capitalists to experiment and lose their little all in trying to make profit on growing ONE TON of sugar, as "D. E." says, and thus to give the enterprize a bad name, but what we do want is to induce the large Australian companies, backed by *vast capital*, to come here and make a profit by growing 5,000 or 50,000 tons of sugar. The Colonial Sugar Refining Company of Sydney, for instance, could put up refineries at Colombo, and refine the vast amount of *palm sugar* now shipped to England for that purpose. Ceylon alone has at least 80,000 acres of sugar palms, and makes 20 or 30,000 cwt. of jaggery, while Madras and Bellary have probably 150 to 200,000 acres of sugar palms, dates, etc.; sugar from all of which could be refined in Ceylon in addition to cane sugar, which the natives would grow for the mills, if they obtained even a small margin of profit. Such *large* companies as that above referred to could as well stand the fluctuations of the market if working *here*, where the *labour difficulty* does not exist, as in Queensland, etc., and would be content with a small profit until the swing of the commercial pendulum "supply and demand" brought present temporary low prices up again, and would besides give employment to Ceylon planters, etc., who would thus share in the advantages which would follow their coming.

It is for the Planters' Associations to discuss the above facts with a view to experiments by their members at various elevations, with various canes, with different soils, rainfalls, and methods of treatment, and if any encouraging results are manifest to make overtures to the *large* sugar companies, who are now fighting a hard battle with the labour difficulty in Australia and Fiji and seeking investment in countries like Borneo and New Guinea which have not half the advantages possessed by Ceylon.

A line of steamers direct to India calling at Colombo has been started, and will every day bring us nearer to the future great market for tropical produce, Australia.

In conclusion, Sir James Longden, who was in Demerara, said: "It has never been my privilege to see a more inferior lot of canes than I have seen in Ceylon," and he TALKED of introducing *new varieties* and reviving the sugar industry here.—I am, sir, yours faithfully,

VEDDA.

WOOD ASHES AS A FERTILIZER.—The following from the *Prairie Farmer* with reference to the great value of wood ashes as a fertiliser is worthy of the best attention of our selectors and farmers:—"The effects of potash upon the soil are well known to be remarkable. One hears continually that "the land never forgets a dressing of ashes," and cases are continually spoken of where the effects are apparent after thirty or forty years. This is not surprising when the action of potash in the soil is considered. Much error is taught in this respect. Potash is held by the soil very firmly, and so is phosphoric acid; and both of these are the principal fertilising elements of wood ashes. Dr. Lawes states that potash and phosphoric acid remain in the soil for at least thirty years, and an application of these fertilisers made thirty years ago at Rothamstead is still recognised by its effects upon the crops. Potash is one of the most necessary ingredients of the soil for plant food. It is at the same time very abundant in the soil, but unfortunately is held in its combination with silica, in the form of a silicate, in an insoluble and inert condition, and therefore it is that an application of potash, in whatever form it may be, to the soil has such remarkably favourable effects. It is because of their effects upon the soil in rendering the potash available by dissolving the silicate that lime, salt, chloride of potash, and perhaps gypsum, or the sulphuric acid released from this in its decomposition, are so beneficially used as fertillisers; and it is this effect, also exerted by the atmosphere and the weather upon the silicates in the soil, that makes fall ploughing, fallowing, and cultivation of so much use."—*Queenslander.*

COTTON SOWN IN DRILLS AND THE RATTOONING OF COTTON BUSHES are thus noticed in the Report of the Cawnpore Experimental Farm:—The sowing of cotton in drills was tried for the first time on the farm this year. The result showed an increase of 39 per cent in cotton and 30 per cent in seed over a crop raised on the plan which is generally used in these provinces. The experiments will be repeated next year. Another system, which, as far as I know, is never practised by the native agriculturist, yielded most satisfactory results. New Orleans and Upland Georgian cottons rattooned, and in the second year of their growth gave double and half as much again as the produce of plants sown this year. The American cottons maintained their very high price in the Cawnpore market at a time when native cottons were suffering a most serious decline, and realized R23-12-0 per maund, while good Bengal only commanded R13-12-0.

ORANGES, SUGAR, AND CORK.—In his report on the trade and commerce of Cadiz, Consul Gerald Perry mentions that the orange grows at Algeciras in considerable quantities, and might become an article for exportation were the means of transport more favourable. A large number of oranges, however, are sent to the Gibraltar market. The sugar-cane is said to grow well in the sheltered and watered valleys of this vicinity, and several tracks of land have been planted with it, giving the owners so far favourable returns and encouraging them to extend their plantations, and it is hoped that in the course of time the sugar-cane may become an important produce of the district. The cane is sent by sea to La Sabanilla, close to Estepona, the nearest place where a sugar mill is established. There are also extensive cork woods near Algeciras. In years past the destruction of these trees was enormous, but now the owners take care to foment their growth in view of the fair and increasing returns they bring, and as the demand for cork wood is very great, it is believed that the exportation from this place will augment. The prices of the article are as follows:—

	Pesetas per Spanish Cwt.
Cork in clean panes—	
First quality	30
Second quality	22
" " rough... ...	from 8 to 12

The Spanish cwt. is equal to 46 kilos.—*British Trade Jorunal.*

LUBRICATING AND ILLUMINATING OILS IN ENGLAND.—In a review of the oil market in London the *Ironmonger* of recent date says that contracts are now being entered into freely for the delivery during the winter months of petroleum oil. Colza oil is less in demand for domestic use each year, but for lighthouses it is still the only material employed. Where colonial indents for hundreds of barrels were formerly received, the numbers are now received only in tens. The expense and difficulty of properly lubricating moving machinery has led to many materials being employed. The old fashioned sperm oil is still used in many workshops, and for tricycles and bicycles it is much in request. Neatsfoot oil, when it can be got genuine, is an excellent lubricant, but is liable to be sticky. The ragosine oil, a natural lubricant introduced from Russia, is rapidly coming into use in England. It is uncongealable in cold weather, as it remains liquid at 50° below freezing point, and is neutral as regards its chemical qualities. Therefore it has no action on the metals. In the course of some exhaustive trials made in the English and French navies, the corrosion of the boilers and tubes was found to arise from the condensed water passing from the condensers into the boilers after having been used in the cylinders, and passing through the valves and copper tubes in the form of steam, taking up on its passage acids set free from the lubricants used, and causing a galvanic action between the two metals, and increasing the corrosion of the boiler plates. To overcome this chemical action, and suppress the acid portions of the lubricants, recourse was had to mineral oils, and they are now used compulsorily for lubricating cylinders and slides. The government at Woolwich are using "metalline" for high speed shafting with great success; the journals are taken down and bored with a number of small holes in every part, into which the metalline is fixed in small pellets, taking the pressure of the shaft off the metal of the journal, and requiring no further attention.—*Oil and Paint Review.*

CINCHONA CULTIVATION IN TRAVANCORE.

"Bark" writes from Travancore:—

I notice in a recent issue, your *Ooty Chronicler* says he understands "that the Travancore cinchonas are a failure. Planted in laterite, their roots become water-logged, the bark peels off, and the plant dies." As your *Chronicler* writes from a praiseworthy desire to keep the public well posted up in all planting news, and his chronicles are read with interest by the planting community of the presidency, and elsewhere, surely his correspondents might use due care when sending him "planting" information. Travancore is no mean territory, and because in some parts the soil is chiefly laterite, and the cinchonas planted in it have died, it does not at all follow that cinchona cultivation here is a failure. In this district we have at least a million, if not nearly double that number, of young cinchonas of every age, from a few months to three years, and, so far as I am aware, there have been no failures amongst them on account of "*wet toes*" except where they have been planted in worn-out coffee soil, in the hopes of getting some return from them before they died from being water-logged. On one estate that has a clayey laterite soil in which the coffee all died out through some root-disease attacking it, every cinchona plant has gone the same way, or is fast doing so after attaining the age of two or three years, for it is simply impossible for the roots of any but the strongest trees to spread and find nourishment in such *ground*—really not *soil* at all;—but this is the only case of entire failure that I know of. Ledgers and Calisayas do not seem a success on account of our heavy rainfall at high elevations, but succirubras, and all the more hardy varieties have every appearance of promise. Our large nurseries do not give one the idea that Travancore cinchona cultivation is a failure, if suitable soil is selected and care be taken to plant the varieties now found to answer at the different elevations, as some varieties are evidently susceptible of the least variation in temperature and rainfall. One planter here has registered orders for about two-and-a-half lakhs of plants to be ready by next planting season, and to supplement his own extensive nurseries. So we are not yet convinced that Travancore will not some day export its fair share of bark.—*Madras Times.*

INDIAN TEA IN AMERICA.

If ever rejoicing over misery was to be accepted as allowable, it is most certainly so now, and Indian tea owners and growers can chuckle openly over the woes of their falling foes—China and Japan shippers, for while a few accidental *faux pas* might have called for pity, a long series of dishonest practices has at length brought down condign punishment in a very tangible form. The workings of the "Tea Adulteration Act" passed by Congress, have most plainly declared their value, and a determination to enforce their provisions speaks highly for the United States authorities. During 1880-81 we are informed that 80,000 packages, shut out of English Ports as adulterated, were sent on to America for consumption, and it is needless to add that a very large proportion of it is still on hand unsold in this country. While "gift" tea companies are offering their "watches," furniture, and presents, to Americans to try and work off the rubbish by hook or by crook. The steamship *Flintshire* brought upwards of a million pounds of teas from China and Japan lately, and of her cargo 3,100 chests of China rubbish were condemned as impure by the United States' Appraiser, while 512 chests of Japan trash shared a like fate. One hundred chests of China tea (!) have recently been rejected as adulterated in San Francisco, and ordered to be returned to China.

About 3,000 packages of "Pingsueys" were condemned in New York some months ago, and an estimate appears in print, in a reliable publication, that 10,000,000 pounds of Japans and Chinas will be refused a market in this country. The effect of all this publicity has marked itself, and consumers have grown more cautious, and either cease to drink tea at all, or look around for any tea having an appearance of pureness, no matter at what a cost. Enormous quantities of Japans and Chinas must be stored in America, awaiting sales almost at any price, and we are informed that the Japan tea circles are panic-struck for money. Never was there such a moment as the present for Indian Teas to step in and gain a footing on their own merits nothing will afterwards upset, and yet what do we know to be a positive fact? that teas which were made as a speciality for the American market, or rather for consumption by land introduction to the masses, have simply been made a subject for speculators to work upon at a dead loss to Indian growers and a clear double gain to themselves.—*Indian Tea Gazette.*

TEA AND SILK FARMING: AN EXAMPLE WORTH FOLLOWING.

It will be gratifying to the promoters of tea and silk farming in New Zealand to learn from the printed Parliamentary debates for August, which reached this country a few days ago, that the Colonial Government has recently taken active steps towards the inauguration of at least one of these industries among the Maoris. Some months ago a small consignment of silk worm's eggs were forwarded to London in the ice room of the S. S. "British King" for distribution among the sericicultural experts in England and on the European Continent, partly with the view of testing the value of "graine" regared in New Zealand, and partly with the important object of ascertaining from the best authorities if the eggs were really free from disease. The results are not yet known, but they are looked for immediately with the keenest interest. Meanwhile, in the Colonial Parliament on the 21st August, in reply to some questions put by Mr. Bathgate, the Hon. Mr. Dick intimated that the Government had offered a bonus for the production of cocoons; that a gentleman acquainted with the subject had been putting the matter into a practical shape, and had succeeded in rearing silkworms and showing excellent samples at the recent Christchurch Exhibition; and that reports had been published with the view of instructing any one desirous of carrying out the propagation of silk-worms. He also said that in regard to the establishment of the industry among the natives the Government last April issued a circular to teachers in native schools, asking them to encourage the growth of the mulberry among the Maoris; that mulberry plants had been distributed to thirty-four schools; that the inspector of native schools had reported favourably regarding Government encouragement towards a company undertaking to assist in teaching the business to the natives; and that if there was any company prepared to make a special offer, the Government would be happy to consider it. With reference to tea-growing the Government had not yet been able to see their way to any arrangement. Considering that questions put by Mr. Bathgate to the same Minister only last year elicited little else than some mild official chaff, the improved and even serious tone of the reply on the present occasion seems to augur well for the enterprise so long advocated by one of our fellow-townsmen.—*Ladies' Journal.*

PRODUCTION OF TEA IN CHINA.

Can it be possible that China produces 2,000 millions of pounds of tea? We doubt it, but the statement is positively made in an article on China and Indian Tea in the *American Grocer*:—

China produces between 2,000,000,000 and 3,000,000,000 pounds of tea annually, all of which, except one-tenth, is consumed within its borders. Its tea-growing area covers 435,000 square miles, besides the Island of Formosa. The product of each district is different from that of the others, and is due to variation in soil, climate and mode of preparation for market.

Tea cultivated under a moist, southern sky grows more luxuriantly than farther north, where the leaf is thinner and more delicate in flavour.

We divide China tea into three general classes, viz:—

Green, or unfermented tea.

Black, or fermented tea, sub-divided into Oolongs and Congou, the former subjected to slight and the latter to great fermentation.

Scented, also fermented.

Fermentation turns the leaf black, and in a measure destroys that quality in the tea which produces wakefulness and affects the nervous system. Hence it is that unfermented or green tea is a greater excitant of the nerves than fermented or black tea. Therefore Congou tea is preferable to Oolong, and that in turn to green.

Upon the island of Formosa is grown the Oolong variety bearing the island's name It is extremely popular in this section of the United States.

Scented teas are known as Foochows or Cantons, the former divided into scented orange pekoe, scented capers, the latter the same.

Formosa Oolong tea was introduced into the United States in 1869 by Mr. John Dodd, an Englishman, who was the pioneer in the introduction of the plant in the island of Formosa, which, in 1862, was a pirate-infested island, where the tea plant grew in a wild state; the trees eight to ten feet high and the leaves about four inches long. The virgin soil produced a leaf which, when cured, was entirely different in flavor from that grown upon old soil on the mainland.

In Japan the first picking of tea is the finest, while in Formosa it is the poorest, being deficient in strength and flavor. The second crop is better, but the finest tea is gathered in August. This is due to climatic influences. In the late summer heavy rains occur, after which warm weather causes the plant to grow luxuriantly. The leaf is full of sap, and the moisture in the atmosphere causes the plant to ferment quickly.

AMERICAN COTTON IN INDIA AND COTTON INSECTS.

From the report of the Cawnpore Experimental Farm for 1882, we take the following extract :—

Comparing the value of the exotic cottons with the produce of country cotton grown at the Farm, we find a follows:—

Kind of cotton.	Class of land.	Produce per acre of cleaned cotton.	Value per acre of cleaned cotton.	
		lb.	R.	a
Country cotton	Light loam.	178·6	35	2
Exotic New Orleans and Upland Georgian	Ditto	... 92·0	25	4
Do. do. do.	Heavy loam	... 167·6	45	15
