showing, as was done last year, that in heavy loam the exotic cotton is a more paying crop than country cotton, even though the latter were to yield up to 200 lb. per acre; while in light loam it is country cotton which is most profitable. The cotton hand-books of Bombay, Madras, and Bengal, together with that for all India, compiled by Dr. Royle, have left little to discover in the way of experiments with exotic cottons, so far as the English home market is concerned; and it was established clearly that India could never hope to compete successfully at Manchester with America in American cottons· but since then times have changed, and the question now is whether the exotic cotton cannot be grown for local mills with success and with great profit to the ryot and to the spinning companies. The Farm experience is so far favourable to an affirmative. At the Rawatpur estate, which is but a short distance from the Farm, the success of American cotton has been very marked: the cultivators are, I understand, beginning to appreciate the high price obtainable, and the cultivation is likely to extend. Last year and again this year the American cotton plants at Rawatpur were stripped of their leaves by swarms of caterpillars, which left the adjoining fields of country cotton absolutely untouched, nor did they visit the fields on the Experimental Farm. It seemed at first as if the crops would be damaged, but I understand the yield has been fairly good. As the caterpillar was a stranger to the cultivators of the district, I kept some of the chrysalises until a moth emerged and then tried to get the latter identified. The Agri-Horticultural Society of Bengal returned a caterpillar first sent without being able to recognize it, their only authority having left for England. Then the moth travelled to the Panjáb and to Simla, and at last found a resting place at Poona, where it was kindly identified by Lieutenant-Colonel Swinhoe, Assistant Commissary-General, Bombay Army, who writes as follows to confirm a first opinion :—*Dated 21st February*—"I have to-day received from Mr. Arthur Butler, of the British Museum, the specific name of the little moth you sent me: it is *Glyphodes Multilinealis of Guenée.* Mr. Butler says it is common and it appears widely distributed. The cotton you sent me with your letter, 18th December last, I put carefully though a process of drying and heating, and have succeeded in hatching out three moths, all of one species, and each of them came out of the heart of a separate injured cotton pod; and I can't help thinking that this is the real insect that has been damaging the cotton. I took it myself out of a cotton-field near Karachi four years ago, and sent specimens of it to the British Museum. It was pronounced to be a new species of the tribe *Tortrices*, family *Nycteolidæ*, and was named by Mr. Butler *Erias tristrigosa*. I don't mean to say that *Glyphodes Multilinealis* has not been injuring your cotton. Probably both insects have been at your cotton, one in its leaves and the other in the pod." It may be interesting to others who may come across rare specimens to know that Lieutenant-Colonel Swinhoe has a collection of over eleven hundred species of moths.

CAYENNE PEPPER.

TO THE EDITOR OF THE "AMERICAN GROCER."

Your remarks in last week's *American Grocer* about breeding canaries and the use of cayenne pepper which change the color of their feathers and improve the song of the birds, I can confirm having seen the birds which had been so treated. I am a native of the country of Norfolk, of which Norwich is the capital. Messrs. Mackley Brothers have for years made the breeding of canaries a study, you will gain some idea of the success they, with other breeders in Norwich, have obtained by the following, which I clip from the Norwich *Weekly Press* of November 17, 1883:—We have received a telegram stating that Messrs. Mackley Bros, have won twenty-four prizes with twenty-seven entries. Mr. Howard has taken three-thirds and three-fourths, Mr. Spelman one-second, Mr. Andrews two-firsts and one-second. At Southampton Mr. Fred. Bullard won nineteen prizes on Tuesday. In conclusion would say I have known as much as $1 50 per pound to have been paid for cayenne for feeding canaries.—Respectfully, CAWSTORA.

BIRD PEPPER.

Capsicum Baccatum, or bird pepper, is a product of the West Indies. It is obtained from a shrubby bush growing four or five feet high, producing berries which are found at the division of the branches. These are small, oval shaped and of bright red color, from which the finest Cayenne is made. Birds and fowls are very fond of the berries, hence the name bird pepper. It is imported ready for use, in air-tight cans and bottles, and is prepared by the natives as follows:—When the berries are ripe they are gathered and spread out upon mats so as to get the full rays of the sun; when throughly dried, the berries are most carefully sorted by taking up a handful at a time, and throwing every defective berry aside. This done, the sound selected berry, or capsicum, is ground between two circular stones (as corn was in Egypt 2,000 years ago). After being so ground, or powdered, it is known as cayenne pepper of commerce, and is of a dark red color, and commands a high price through its most acrid and stimulating properties. It is frequently limitated in colour through mixing red lead with inferior growth of capsicum. That birds are fond of cayenne is well-known to those who reside where it grows. I had the pleasure of an introduction to Mr. Reid Trott, of Bermuda, who was on a visit to New York, and in speaking of the various productions of the Islands and in answer to my inquiry said capsicum shrubs grew there and produced a small pod, which, as soon as it was ripe, the birds quickly devoured; that no one cared to take the trouble to secure any for domestic use. W. D. BENNETT.

ADULTERATED PEPPER.—A new adulterant of ground pepper is a finely ground preparation of the kernels of olive berries. If a sample of the suspected mixture is scattered upon a mixture of equal volumes of glycerine and water, the pepper floats upon the surface, while the ground olive kernels sink.—*Druggists' Circular and Chemical Gazette*

TEA IN AMERICA

is thus noticed in the proceedings of the the Agri-Horticultural Society of India:—

As several papers in India have lately had paragraphs on the future of Tea in America, the following extracted from the American Annual Agricultural Report for 1881-82 may be of interest:—"A few remarks relative to the position of Tea culture in America as at present understood may assist us in arriving at an intelligent view of the matter, for the past 20 years the department has distributed a number of the plants in varying quantities of from 10,000 to 50,000 plants yearly, the object in view being to introduce the plant to the notice of farmers and planters, so that they could familiarize themselves with its characteristics, and its adaptability to climates and localities also that experiments might be made with the leaves, in the preparation of an article for domestic use. In many instances this was so satisfactory, as to encourage further plantings, so that small plantations, of one-fourth of an acre and upwards in extent, were here and there to be found.

Many of the samples of Tea prepared in a domestic way, were pronounced to be very good, and the Department for the past twelve years or more, has frequently been the recipient of Teas which were creditably manufactured and otherwise considered commendable. In the latter part of the year 1879, Mr. J. Jackson, the present Superintendent of the Tea farm at Summerville, who had been for many years engaged in the manufacture of Tea in British India, being in the United States on a pleasure tour, had his attention called to the efforts of the Department in the introduction of this industry; and looking over the matter he concluded to purchase one of the largest of these incipient Tea plantations, situated in Georgia, for the purpose of making experiments in the manufacture of Tea. His first effort at the manufacture was made in the spring of last year (1880), and the result was deemed encouraging, samples of his Teas were received by the department where they were exhibited and tested; but while the manufacture and appearance of the Teas were commended, they were pronounced to be deficient in strength.

During last fall and winter, Mr. Jackson gave a special attention to the plants in the way of pruning, manuring, &c. In consequence, the plants made a most satisfactory growth, giving five crops of leaves, which allowed Mr. Jackson a fair opportunity to test the cost of manufacture, which has convinced him that Teas may be placed on the market at a cost not exceeding 25 cents per pound. This crop has also been tested by experts, and their opinion again shows that the Teas are deficient in strength. About 20 pounds of this crop was sent to the department, from whence it was distributed for testing, as samples of American Tea. It is therefore evident that the great defect of these Teas is lack of strength.

It is an established fact that the strength of Teas depends upon the climate where the plant is grown. The warmest Tea climates produce the strongest Teas. Teas produced in localities where frosts occur, are always pronounced to be weaker than Teas which are produced in localities where the thermometer never reaches to the freezing point. This is well understood in all Tea-growing countries, and it certainly would not be wise to ignore the fact in making experiments in this country. The position may be considered as fairly represented as follows:—Having every reason to conclude that the locality near McIntosh, Ga; is too far north for the production of Teas, which possess sufficient of strength and pungency, to command the best prices, or even profitable prices, it is therefore considered proper to try the experiment at Summerville, S. C., which is one and a half degrees further north! However unfortunate it may be, it is clearly evident that the Tea experiments must be made in a more southern latitude. The state of Florida may be looked upon as presenting the most favorable conditions, and if the experiments are to be proceeded with, operations should be transferred to that State without delay. As to the future management of the Tea farm, following the conviction that no experiment which can be made in the culture of Tea at this place, will warrant a continuation of the undertaking, it may be suggested that expenses be cut down to the lowest figure admissible; and that all labor cease, except so much as may be found necessary look after the young plants.

In a general way, it may be stated that since 1st July 1880, $15,000 have been appropriated by Congress for encouragement of Tea culture. So far as is visible to the ordinary observer, the only practical, palpable result of expenditure from this fund, is what is to be found, and what has been done on this farm."

Again, the United States *Economist*, says, that—"this (Tea) is an industry which might very profitably be carried on in the South * * * *. In the Tea districts of Japan, there are but few agriculturists who devote themselves exclusively to the culture. The indications, both in the older systems of culture in oriental lands, and in the experiments of America, go to prove that the business may be pursued as a supplement to other agricultural enterprises. Each farmer may raise enough for his domestic consumption, for ten or twelve trees will furnish enough Tea to meet the wants of a family of eight persons, * * * the labor to cultivate a few Tea plants would only absorb the odds and ends of a farmer's time which might otherwise go to waste." [On all of which we may remark, that, looking to cost of labour as well as to climate, it is not probable that any appreciable quantity of tea will ever be grown in the United States.—Ed.]

GOVERNMENT CINCHONA PLANTATIONS.

A short time ago Dr. Henry Trimen, M.B., Director of the Royal Botanic Gardens in Ceylon, visited the Government Cinchona Plantations on the Nilgiris with the object of reporting upon the botany of those plantations. Although specially qualified for the task by his thorough knowledge of botany, his special study of cinchona in Europe, and his experience in Ceylon, he was accompanied by Mr. Lawson, the Government Botanist, Dr. Bidie, Major Campbell Walker, Mr. L. Campbell, and Mr. Gass. Mr. Trimen has written an elaborate report, in which many disputed points as to the origin of the varieties cultivated in India are discussed, and to a certain extent settled. Into the Doctor's notes on the various descriptions of cinchona we need not enter, simply recommending those especially interested in cinchona to secure a copy of the report. There is much, however, in Dr. Trimen's report which is of general interest. He pleads for uniformity in nomenclature. It is much to be desired that the same plants should bear the same names in India and Ceylon and elsewhere, instead of the present system of obsolete, incorrect, or duplicate names. As a rule, the spelling of this genus of plants is *cinchona*, although Mr. Markham has argued so strongly in favour of *chinchona*. With regard to the future management of the fine properties on the Nilgiris, and which have proved so remunerative to the local Government, Dr. Trimen takes it for granted that the recent appointment of Mr. Lawson to the office of Superintendent is evidence of a desire to maintain the plantations in a high state of efficiency. We have reason to believe that he is quite right in this conjecture, and that the interest taken in the subject by His Excellency the Governor will secure that for some years yet to come everything possible will be done to secure progress in knowledge and improvement in practice. This, it is urged, should be the main object in view, and not gain. The ultimate end of the enterprise is the production of a cheap and efficient febrifuge for this country and the East, and Dr. Trimen is of opinion that the final realization of that laudable scheme is more likely to be effected by private enterprise, in Europe or in India itself, than by any Government manufacture of alkaloids. "Meanwhile the Government possesses a very valuable property, which, worked without stinting the expenses necessary for the highest experimental cultivation, cannot fail to return a profit for many years to come." What is said with regard to past management is very true. While the Government have properly endeavoured to secure large revenue from their estates, they seem almost to have forgotten the object of such estates. The result has been that the estates have been overworked, and insufficient attention has been given to observations which might produce much valuable information useful to cinchona planters and quinine manufacturers all the world over, and especially in India. "Selections by cuttings or seed from the best of known ana lysed trees (by which system, steadily preserved in, the Dutch in Java have so largely increased the value of their bark) has not been practised, nor is propagation of the delicate sorts by grafting on more hardy varieties carried on." The necessity of adding a skilful propagator to the staff is suggested, and it is insisted upon that for any satisfactory progress to be made, the chemist as well as the experimental physiologist and botanist is a necessity. The appointment of a quinologist is therefore recommended; a man who would be on the spot always, constantly among the trees, and working in unison with Mr. Lawson. It will be remembered that Mr. Broughton did, some years ago, do much service in this direction, and his mysterious departure from the scene of his labours has always been regretted by those persons interested in the cultivation of cinchona. There is, as we said above, much to be done in the way of research, and Dr. Trimen contends that the Government of Madras is best able to carry on the inquiries. He says:—"All such researches, however, can only be properly carried on in a Government establishment, where the officers can devote themselves in a spirit of pure research to a work which must, of necessity, be spread over many years. And I will add that it is to the Government of Madras that all who are interested in cinchona in any of its various aspects necessarily look to take the lead. No other Government, in fact, will be likely to undertake it." The reasons are then given, and Dr. Trimen adds:—"It was Madras that was formerly in the front position. As the pioneer of cinchona-growing in India it proved that the best barks could be grown there, and initiated a great industry . . . . The excellent system followed has, from fortuitous circumstances, come to an end; under the very favorable present conditions, one cannot but expect to see it revived."

There is a recommendation at the end of the report which the Government should not forget; it is that all results in such matters as those dealt with above should be made promptly available to the public in annual reports, which ought also to be easily obtainable. Not only in annual reports should they be available, but also whenever papers of importance are printed for Government use. Such papers as Dr. Trimen's report ought to be made available to all who are willing to pay for the cost of printing. In affording publicity to such papers, much benefit may accrue to the planting community, and also, if only indirectly, to the Government. We regard Dr. Trimen's report as a very able and valuable one, and the Presidency is indebted to that gentleman for the trouble he has taken in writing it.—*Madras Mail.*

THE CARDAMOM FORESTS OF TRAVANCORE.

A correspondent who several years ago visited the cardamom forests of Travancore and made copious notes of everything he saw and heard writes:—Taking advantage of a long-standing invitation from a friend who was then Superintendent of the Cardamom forests, I found myself one December morning at a village called Combey at the foot of the Cardamom Hills, after a wearisome journey of 40 hours by transit and bandy from the station of Caroor. At Combey I received hospitality and assistance from the Travancore Agent stationed there (as he told me to watch cardamom thefts and see to prosecutions in the British Courts). After a short rest I mounted a pony and rode to the foot of the ghât. As the ascent was only 2,000 feet above the plains, I soon scrambled to the top, where I was glad to rest at the Travancore frontier watch-house. A guard of Nayer sepoys and peons were located here, and I was received with all honour by the native officer. The officer was in full war paint, but some of the men seemed to have been hurried in their toilette. They informed me they were stationed here to watch the pass and to make rounds north and south of it to other watch stations, the object being to intercept those who might be moving into the Hills for stealing cardamoms. Considering that a pound of the spice was worth from two to three rupees in the plains, these precautions were necessary, though not altogether successful, as the frontier was too extensive for the few sepoys and peons to guard. From the watch station I was able to ride to a camp at Othemenshola, distant about six miles. The first mile was over open grass land which took me up to a woody plateau, the view from which was very fine, comprising the finest stretches of forest and hill for thirty miles on the Travancore side to the Peermaad plateau, while to the right was a still more extensive view of the Madura plains, looking like a chess board with its squares of green and brown fields. From the top of the grass hill I soon entered the forest, and the remainder of my ride was through a long stretch of cardamoms under the forest shade. All or nearly all the undergrowth was removed and cardamoms substituted, and the contrast between the light foliage of the cardamoms with the varied foliage of the trees above was very pleasing. The busy part of the cardamom season was well on, and I was continually coming on gangs of coolies weeding, pruning, and collecting the spice, while ponies and donkeys kept passing me on their way back to the plains after dropping their loads at the various cardamom collecting stations. Altogether it was a new experience of forest life and different to the usually gloomy feeling that one experiences in passing through an Indian forest. I examined the clusters of cardamom fruit that had been collected in the gardens I passed through, and was struck with the careless way in which the clusters were gathered; while some of the capsules were ripe the greater part were green and immature. A native owner with whom I conversed explained that unless the cardamoms were gathered in this way, the polecats, monkeys, and rats would destroy the crop, and in proof he pointed out quantities of capsule shells under a neighbouring clump of plants, the result of their depredations. A friend to whom I mentioned the circumstance explained that it would not pay the growers to gather the crop as it ripened, and that the consequence was that a large amount of every crop was of an inferior description. Could the growers be induced to pick the crop as it ripened, a much finer sample could be produced, but he despaired of this while the Travancore Government paid the growers, as they did, without reference to quality.

The marks of wild elephants were plentiful everywhere, and at a hollow in the roads their foot-marks had left holes so deep as to make it necessary for me to get off my pony and walk. About a mile from Camp I found my friend superintending some road repairs, and very glad I was after my long journey to get into shelter in his little bungalow at Othemenshola. The Camp was surrounded by a deep trench for protection from elephants, and consisted of a mud and rubble bungalow and offices, and an iron-covered store for forest produce. The view was splendid, and comprised a mixture of grass hills and forest to the foot of the high hills to the north and to the south and west of a deep forest partially cultivated with cardamoms. A. had got some good bison and sambur heads, which looked like a promise of sport, but owing to the presence of large gangs of coolies in the neighbouring jungles for collecting the cardamom crop, game had been scared away, but elephants were, he said, plentiful, and to prove his words shortly after reaching Camp their near presence was announced by shrill trumpetting and screaming in a clump of reeds not five hundred yards from the Camp; late in the afternoon a herd of fifteen walked out into the grass lands, and A. and I were able to get within a few yards of them and for nearly an hour watch them. There was only one small male among them, with tusks as big as tent pegs, and the rest were females and calves. One of the latter was no bigger than a buffalo calf, and evidently caused its mother some anxiety by its helplessness. Two calves were pugnaciously inclined, and shoved and battled at each other with a good will till the mother of one walked up and separated them with what sounded to us a good scolding. Feeding up rather close to us A. and I showed ourselves, and the herd, after scanning us for a few seconds, moved away at a slow pace and re-entered the reed clump they had come from. A. said that though the elephants were very numerous about the cardamom forest, that they were seldom troublesome. They were strictly preserved by the Travancore Government and were increasing in numbers. Nothing was done to catch or trap them except by pits. About a dozen a year were caught, of which about one-sixth were saved. Many died in the fall and others subsequently, and except young animals few were of any use when caught in this way. A. had tried to get Ceylon noosers to come over, but the terms offered by the Travancore Government were not sufficiently good to induce them to come. Referring to the juvenile fight between the two calves, A. mentioned that he had on three or four occasions seen tuskers fight, and in one instance, near the scene of the juvenile fight, had witnessed the death of one. The victorious tusker never left his antagonist till he had killed him This was done by repeated thrusts of the tusk behind the shoulders. The dead tusker was a very large, powerfully built one with 100 lb. of ivory, but he was no match for his foe, who had the advantage in both height and long sharp tusks. The following day the victorious tusker was found by a large herd, the master-ship of which was no doubt the cause of the fight, and after visiting the defunct male—who was by them robbed of his tusks—they all marched away.—*Madras Mail*.

TEA MACHINERY.

Considerable interest has been taken in tea and tea machinery by your correspondents of late, and I have read with great interest the various articles which have from time to time appeared in your valuable columns regarding tea, its manufacture, and the machinery used for its production. I have heard that a complete revolution is about to be accomplished by Mr. Greig, a well-known inventor of tea machinery, who will exhibit a machine of a combined nature at the coming Exhibition. It is on the continuous principle, and from all accounts the leaf will be introduced at one end direct from the coolie's basket and manufactured "pucca" tea will emerge from the other, sorted, as well as classified, and the very dust extracted. Surely, this will be a great improvement on our present tedious system, and will be quite a boon to the tea house assistant; in fact, I doubt very much whether planters may not be able to dispense with his services altogether, should the new type of machinery about to be introduced by Mr. Greig perform the many duties claimed for it. I am quite surprised your correspondent did not refer to the link and lever rolling machine in his article on rollers, since he gave a very detailed account of the various types of machines at work in the tea districts.

Without a doubt the best machinery yet sent us for rolling is that of Messrs. Jackson, and I ask my fellow planters who have had any experience, whether bag machinery will give the leaf as fine a twist and produce the fine wiry. samples the "Excelsior" roller made by that firm does. The three varieties of machines supplied by Messrs. Jackson have proved themselves without exception the most reliable and durable machines for all round work, and have stood the test of time; many of the first introduced being still in good condition and likely to last many years; and I look to this firm who take more interest in us than any of their rivals, for further improvements in tea machinery, as they are untiring in their efforts, both at home and in the tea districts, to design and construct machines suited to our individual requirements; and with their long and varied experience of tea machinery seem to know our wants quite as well as we ourselves do.

Referring again to Mr. Greig's new type of machinery as described in the *Home and Colonial Mail*, it would appear as if he intended to take us by strom and completely revolutionise our existing system of manufacture. The description given was not of the clearest kind, or I might have been able to say more; meantime a few passing remarks will not be out of place regarding its principle, since so many advantages have been claimed for its novelty, and they may be interesting to your readers. First of all the withering machine is used, and, strange to say, it receives its hot air from the drying machine, so the dryer must of necessity be set to work to "pucca batty," or something of the sort, before the green leaf witherer will receive its hot air. Withering, as all tea-makers know, is one of the most important points in the manufacture; and how the rapid, or by the description, instantaneous, withering system will answer remains doubtful, seeing that, if at all possible, natural, cool withering is preferred by all who know how to make good tea. After the withering process the leaf is then put into the cutting machine, which has been tried and pronounced a failure by those who experimented with it, and abandoned as serving no good purpose, having india-rubber buffers inserted in square cutters on the cylinder so as to clear itself of the particles of cut and damaged tea leaf, these are apt to give the leaf an odour of rubber, which gives the tea anything but a good "nose" and removes all traces of malty flavour on its being tried in the cup. These might be made of a special rubber, perfumed, so as to impart a flavour somewhat resembling that of Ceylon or Darjeeling teas, to our rasping, pungent liquors from leaf plucked on "bheel" lands.

When cut into squares, or lacerated, rolling is, of course, impossible, no matter whether the leaf is soft or hard, unless the Link and Lever Roller possesses advantages peculiar to itself, which I hardly think is possible, seeing that it is a bag machine and behind this age of improvement; when we want something of more modren design, easily filled and emptied, and capable of doing some work, instead of taking a maund of withered leaf at a fill, apart from bags, with their enormous wear and tear, and necessitating the keeping up of an entire establishment of tailors to repair the bags, also a "soft goods store."

The drying part of the machine is puzzling, with its zinc-bottomed trays, and the application of the hot air after it has dried the tea to wither the leaf in cylinder for that purpose, as described, with say from 10%, 21% moisture in it, reverses nature; how can saturated green leaf be withered, or dried by hot air already impregnated with moisture? After drying the tea it may have a stewing tendency. But another and equally important question arises; would the supply of hot air, after it has dried the tea, leaving the question of moisture aside, be sufficient to wither the green leaf to keep pace with the other machines, without adding to its volume by some means? I think not, as the temperature that would be required to wither the leaf must vary with the moisture in the green leaf, which if plucked in very wet weather is much more than stated above, but the first question raised is quite sufficient to altogether remove existing doubts as to the soundness of the principle.

Last of all, there is nothing novel in the Greig Sorting Machine, as this sifter has been used over half a century ago for assorting seeds and flour, also many other materials, such as sand and coal, and we have machines quite as effective and simple, such as Jackson's "Eureka" sorter, and others of a similar nature, all of the self-delivery class, and possessing all the merits of the Greig Sifter.—*Indigo and Tea Planters' Gazette.*

THE ORGANIC AND INORGANIC CONSTITUENTS OF PLANTS.

[THE REASON WHY.]

The organic constituents of plants are those which are commonly known as vegetable substances, or vegetable productions—starch, gum, sugar, gluten, albumen, &c. They are the product of plants endowed with life, and cannot be produced without the operation of life. This mysterious power influences the elements, and recombines them in various forms. They are the products of living organs, and therefore termed organic. While they are being formed, the chemical laws affecting them are modified by the living principle; when that principle ceases—though in some cases it may be retained for a long time, as in the case of a seed—when the plant or seed dies—the substances are operated upon by chemical laws, and undergo various changes. Organic substances are for the most part compounded of four simple elements; never less than three. The elements which enter so invariably into these organic compounds are called organic elements, as carbon, oxygen, hydrogen and nitrogen, and the various bodies compounded of these are called organic substances.

The old notion—that which prevailed at the close of the sixteenth century—was, that there existed in animals, plants and soils one universal, vitalising and fertilising principle—namely, salt; and this miserable and vague theory was upheld by the most learned men of that age. It was thus expressed by the early writers upon agriculture:—"Salt whiteneth all thinges, it preserveth all thinges, it hardeneth all thinges, it giveth savour to all thinges, it is a mastike that gleweth all thinges together, it gathereth and knitteth all mineral matters, and of manie thousand peeces it maketh one masse. This salt giveth sound to all thinges, and without the salt no metall will ring his shirle voyce. Salt maketh men merrie, it whiteneth the flesh, and it giveth beauty to all reasonable creatures, it entertayneth that love and amitie which is between the male and female, through the great vigor and stirring uppe which it provoketh in the engendering members; it helpeth procreation, it giveth unto creatures their voyce, as also unto metalles. And it is salt that maketh all seedes to flourish and growe, and although the number of men is verie small, which can give any true reason whie dungue should doe anie good in arable groundes, but are ledde thereto more by custome than anie philosophicall reason, nevertheless it is appaurent that no dungue, which is layde upon barraine groundes, could anie way enrich the same, if it were not for the salt which the straw and hay left behinde them by their putrefaction." The inorganic constituents of plants consist of silica, alumina, potash, soda, lime, maguesia, phosphate of lime, common salt, sulphuric acid in the form of sulphate of lime, and some other sulphates, &c. Many of the inorganic substances vary according to the soil in which the plants grow, but a certain number of them are indispensable to their development. All substances in solutions in a soil are absorbed by the roots of plants, exactly as a sponge imbibes a liquid, and all that it contains, without selection. But there are alkaline and earthy phosphates that form invariable constituents of all kinds of grasses, of beans, peas and lentils.

The inorganic substances are generally combinations of two elementary bodies. They are wholly mineral; they are the products of the chemical action of the metallic or non-metallic elements of rocks. The existed before plants or animals. When vegetable substances are burnt, there remains behind a portion commonly called the ash, and this constitutes the inorganic portion of plants. The proportion of ash to the bulk of vegetable substance is very small, varying from 1 to 12 per cent. The smallness of these proportions has led some persons to the opinion that the mineral or inorganic constituents of plants are merely accidentally present, and are not necessary to their existence. This may be true as far as regards those matters which are not always found in plants of the same kind; but when they are invariably present the smallness of their quantity does not indicate their inutility. The phosphate of lime existing in the animal body does not amount to the fifth part of its weight: yet no one doubts that this salt is necessary for the formation of the bones.

It has been generally supposed that these materials act in the vegetable economy in the same manner as condiments or stimulants in the animal economy; and thus they render the common food more nutritive. It seems, however, a much more probable idea that they are actually a part of the true food of plants, and that they supply that kind of matter to the vegetable fibre which is analogous to the bony matter in animal structures. Thus those plants which are most benefited by the application of gypsum are those which always afford them upon analysis. Clover and most of the artificial grasses contain them, but they exist in very minute quantity only in barley, wheat and turnips. A knowleage of these inorganic constituents, and of the nature and chemical composition of soils, must necessarily regulate the practice of every branch of agriculture. Attention must be paid to the kind and quality of the crop, and the nature and chemical composition of the soil in which it grows. Are any of the salts of iron present? They may be decomposed by lime. Is there an excess of silicious sand? The system of improvement must depend on the application of clay and calcareous matter. Is there a defect of calcareous matter? The remedy is obvious. Is an excess of vegetable matter indicated? It may be removed by liming, paring and burning. Is there a deficiency of vegetable matter? It is to be supplied by manure.—*Leader.*

POISONING WITH SEEDS ("CRABS' EYES") OF THE INDIAN LIQUORICE PLANT.

Who would suspect the beautiful little red seeds, each with a jet black spot on it, of "the Indian liquorice" of being a deadly poison? Yet so it is:—

The Professor of Chemistry in the Calcutta Medical College, Mr. C. J. H. Warden, has reprinted from the *Indian Medical Gazette* some very interesting notes on the *Abrus Precatorius* familiarly known as the Indian liquorice plant, and in Bengalee as *Koonch* or *Goontch*. The seeds are employed in India for various purposes. The red ones, there are three varieties, are employed by goldsmiths and native druggists on account of their uniform weights. For medical purposes says Mr. C. J. H. Warden, the seeds are used as an external application in ophthalmia; and he quotes Rheede to the effect that, mixed with the roots and cocoanut milk, they are employed in the treatment of hæmorrhoids. In the Hindu system of Materia Medica, ruttee seeds are classed among the seven minor poisons, which are—opium, seeds of Abrus precatorius, dhatura, roots of Gloriosa superba, roots of Nerium odorum, juice of Calotropis gigantea, and Euphorbia neriifolia.

According to the Pharmaceutical Journal* an infusion of the seeds has long been used in the interior of Brazil as a popular remedy in the treatment of ophthalmic disorders. In some experiments by Dr. de Wecker (Comptus Rendus, xcv, 299) he ascertained that a weak cold infusion of the powdered seeds applied as a lotion, rapidly produced a purulent ophthalmia, of intensity corresponding to the number of applications. The factitious ophthalmia thus produced disappeared in the course of the ten days or a fortnight without any therapeutic intervention or danger to the cornea; and Dr. de Wecker is of opinion that this property, possessed by the seeds, of provoking a very intense ophthalmia of short duration could be utilzed in ocular therapeutics in the treatment of granulations, conjunctival diphtheria, &c.

Drury states that the seeds are innocuous if swallowed whole but dangerous in a powdered state; but he remarks, regarding the latter point, that there must be some mistake, as they form an article of food in Egypt, though considered hard and indigestible. Dr. Center, Chemical Examiner, Punjab, in his Annual Report for 1873, mentions that he administered the powdered seeds to dogs, in doses varying from one quarter to one ounce, the result being only "mild vomiting." Dr. M. Thomson,† Chemical Examiner, N.-W. P., also records evidence of a similar character. "The *Gunchi* seed, even when finely ground, does not seem to be a poison when given by the mouth. I have repeatedly given it to dogs in as large doses as two or three drachms, but with no ill effect." My experiments, made on cats, also indicate the inert nature of the seeds when introduced into the stomach.

Though the pulverized seeds are harmless when eaten, they produce rapidly fatal effects—even in small quantity —when introduced into the cellular tissue.

Dr. Center of Lahore was the first, I believe, to draw attention to the fact that rati seeds were used for poisoning cattle. And for this purpose they are pounded, moistened with a liquid and shaped into needles,—"suis"—and when dry, forced beneath the skin of cattle. The *Chamar* or skinner caste, appear to be the only class who adopt this mode of poisoning; and their object is to obtain the skins. The practice of "sui" poisoning has apparently spread from the Punjab into Bengal; the Chemical Examiner to the Government of Bengal, in his Annual Report in 1875, remarks that that was the first year in which "spikes" or "suis" had been received in Calcutta for examination. Within the last six years, cases have frequently occurred in Bengal in which "sui" poisoning has been suspected; and in several instances "suis" have been forwarded to the Chemical Examiner for examination. It is probable, however, that the number of reported cases does not represent the actual extent of this system of cattle poisoning, because unless suspicion be aroused, and the skin of the animal very carefully inspected, the minute puncture caused by the spike is likely to escape detection.

The preparation of "suis" is an operation which apparently requires some little skill; and the following particulars are from an article in the Police *Gazette* for December, 1880, communicated, I believe, by an officer in the Police Department, who obtained his information from a *chamar* prisoner in the Patna Jail, who prepared "spikes" before him, with one of which a bullock was stabbed in the back of the neck, death ensuing on the second day. The shell of each seed is carefully broken and removed, and the seeds softened by soaking in water, and pounded on a stone in order to form a paste. The lump of paste is then rolled with the

* Journal Pharm. Soc., No. 656, page 184.

† Report of Chemical Examiner, N.-W. P., 1874.

palm of the hand on the stone until it is of a cylindrical shape, with a sharp point. The point, about ¾ of an inch long, is then cut off and forms the "sui," or "sutari," as it is termed in some districts, from its resemblance to the point of a cobbler's awl. After half a dozen or more "sutaris" have been made, some straw is cut into lengths of about 2½ inches, and a "sutari" inserted in each end; the straws are then put in the sun to dry, care being taken that the "sutari" points are not injured. As soon as a "sutari" is thoroughly dry and hard, the point is "edged" on a brick after which it is soaked in some animal fat for a night and the instrument is ready. Occasionally the point of the "sutari" is slightly curved. Suis weigh on an average 1½ to 2 grains, and vary in colour from dirty white to dark brown or nearly black. A handle of wood is then made, about 3 to 3½ inches long and like the handle of a bradawl. At the end of the handle, which is about an inch in diameter, two holes are drilled, about ¼ to ⅜ of an inch in depth, and about ⅜ of an inch apart, and into each hole the thick end of a "sutari" is pressed, a piece of cloth being first spread over the holes in order to afford a firmer hold. Bamboo wood is frequently used for a handle, a small cane being selected and a portion cut off so as to include town joints; one joint has the holes drilled for receipt of the "spikes," while the other is sometimes removed, exposing the cavity of the bamboo, in which the spare "sutaris" are kept wrapped in a rag. The blow given with this instrument is delivered with great force, so that the whole of the sutari protruding from the end of the handle is driven into the flesh; any attempt to withdraw the "sutari" by pulling at the piece sticking out, invariably breaks it, a portion being left in the wound.

In some cases "suis" are made with the milky juice of the Calotropis gigantea—muddar—instead of with water; and the effect is then supposed to be more rapid. Metallic mercury, dhatura, aconite, and arsenic are also occasionally incorporated with the paste from which spikes are prepared. When the subject of "Sui" poisoning first engaged attention, there was a suspicion that dried snake poison might possibly be the active principle; a number of spikes were therefore forwarded to Dr. Ewart, President of the Snake Committee, who came to the conclusion that the snake poison theory was untenable.—*Indigo Planters' Gazette.*

ORIGIN OF DOMESTICATED VEGETABLES.

There are two methods of studying the origin of our domesticated plants, the one historical, the other through investigation into the causes of variation. The first method has the disadvantage that events of this character but rarely find explicit record; the second, that we as yet have a deficiency of proper data. We are hence obliged, if we would attain truthful conclusions, to combine the two methods, and through painstaking consulting of scattered mention, the guarded interpretation of hints to be gained from tradition and vernacular names, and the recognition of changes due to the acts of man, to follow the protean changes from course to course, until we either attain the limit of our knowledge or indication of the original species.

We may in the furtherance of this course recognise certain truths which we must consider axiomatic; that variation is an indication of changed environment, and that departure in the plant from the natural motive towards a motive more subservient to man's wants is evidence of man's interference; that as through man's agency plants become removed from natural conditions, and have qualities dependent upon domesticated conditions impressed upon them, so when neglected by man these acquired qualities disappear in a large measure, and the plant changes, not reverts, to conditions which enable it to satisfy the requirements of Nature; that change of form, added to the plant through man's selection, if beneficial to the plant, when left to Nature will be maintained in the plant escape or garden wilding; that a large number of varieties is an indication of antiquity of culture, especially if such varieties are of different types.

Applying these thoughts to a case in illustration, we should at once infer a greater antiquity of origin for the Turnip than for the Ruta-baga; for the Carrot than for the Parsnip; and where the varieties and types are very many, as in Maize, Wheat, Beans, &c., we should infer very great antiquity of culture. So seedless fruits indicate man's ancient interference, and should only be expected to occur in regions which are, or have been, occupied by man.

If a highway leads from Jericho to Jerusalem, it is certainly proper to infer that the same road leads from Jerusalem to Jericho. If variations of a certain kind are produced only by man's interference, if the fact be well established, it is certainly proper to infer that if variations of this kind are found they indicate a former cultivation. We can even go further, and say that if the agency of man induces numerous variations favourable to a man's wants in a species, then that the presence of numerous variations in a species, of a kind favourable to man, indicate a previous agency of man. Thus, the peculiar distribution of the Vitis californica in rows, near Fort Whipple in Arizona, is considered conclusive evidence that the ancient Pueblo Indians were in the habit of cultivating it; evidence of a dissimilar character, but very nearly as conclusive, for the ancient cultivation of the Vitis Labrusca is seen in the variability of this species, which is strikingly in the direction of the improvement of the fruit in individuals, as is known to the many farmers in New England who have transplanted improved kinds to their door-yards, and is a matter of common repute, as well as evidenced in the various named varieties, as the Concord, which have originated from its seed. If we plant the seed of the Apple, as we note the varying quality of the seedlings, no two being alike, we can infer from this circumstance that the Apple is a domesticated fruit, and of human origin; if we likewise plant the seeds of the American Crab, we may properly infer that it is a wild or natural species from the power its seeds possess of coming true to name. This method of research, if supplemented by a historical record, offers much promise to the investigator.

When we consider the number of species of vegetables that America has furnished to civilisation, their number of variations, their high degree of improvement, and their constancy to type, we may infer, *primâ facie*, that a civilisation, capable of producing these results has existed in the past. We need but mention the Maize, the Bean, the Pumpkin and Squash, the Tomato, Peppers, the Potato, the Cassava, Chocolate, &c.

It is not improbable that many of our so-called natural species, to which our domesticated varieties are referred, are themselves but escapes from a cultivated state. I do not know whether the wild Parsnip of America has a close resemblance to the wild Parsnip of Europe or not. We cannot readily suppose that the wild Parsnip was really brought to America, for it appears more reasonable to believe that it is an escape from cultivation; as the Salsify certainly is about Geneva. In default of any mention, we certainly should be justified by common consent in referring our cultivated Parsnip for origin to our wild Parsnip, and yet how erroneous this would be. The same remark applies to the Carrot. Should we not, therefore, be slow to refer the cultivated Parsnip to the wild Parsnip of European fields, or the cultivated Carrots to the wild Carrots? Avena fatua is supposed to be the parent from of the cultivated Oat, but why not more reasonable to suppose it to be an escape, modified only from the cultivated Oat in order to meet the conditions necessitated by its struggle under Nature's conditions?

The history of Indians, after the discovery, shows that they were greedy for new sources of food supply, and the facts connected with their habits of living all show that they exercised a care over vegetable productions. Thus the Melon and the Peach received distribution over wide areas in advance of European discovery; the Onion was even mentioned by Cortez as found in Mexico; the Maize, the Bean, and the Squash, in varieties, all plants of tropical origin, and which could not maintain themselves without care, were staple crops throughout northern America, even to Lake Coulonge on the Ottawa river, and beyond the St. Lawrence, where the crops required seeding, protection and preservation of seed over the winter months. The Sunflower was grown for its seed by the Hurons, as seems also to have been the Jerusalem Artichoke for its roots. Bartram notes seeing in the South a plantation of Hickory Nut cultivated by the Indians. The Prunus americana seems to have been planted by the New England natives, and this seems also to have been the case with Prunus Chicasa in the South-west, although I find no district mention of the fact. Numerous other illustrations occur in my notes of a cultivation or domestication of plants throughout America, and a care and curious concern about forms and colours which must have caused selection to have been exercised; at any rate, when we have so-called wild species of the same varieties, the variability of these wild species in the portion which finds use is noticeable.

Indeed, the careful student must recognise that the American Indians were an agricultural people wherever natural conditions and tribal strength would admit, and that they were efficient agents, not only in the geographical distribution of certain plants, but also in the producing of varieties. Circumstances, as in European nations in times past, made the tribes usually hunters and agriculturists, often agricultural solely, and again devoted wholly to the chase, and living on wild productions.

The history of the origin of our American vegetables must come from a close study of the history of a people, as well as from a study into the causes and effects of variations. These two methods in time may admit of certain generalisations, and it seems safe to assume that the results of such a study will not be in accordance with accepted notions. The physiological method will bring a certainty so far as it accomplishes a conclusion, which the method of systematic botany does not supply. Until we can separate escapes from natural species—that is, until we can determine species apart from changes impressed upon plants by man—it seems unsafe to refer our cultivated plants to localities wherein occur wildings of like species. Far preferable the agrument from historical mention of the habits and movements or migrations of peoples. It seems probable that variability or trueness to seed may become the test as to the sufficiency of a conclusion in favour of or against an assigned species. This fact is an interesting one for the scholarly botanist, for it only needs the reading of De Candolle's work to realise the uncertainty at present existing.—E. Lewis Sturtevant, M.D., in *Botanical Gazette.*

A Texan Plague-plant.—According to gentlemen who have recently come to this country from Texas, a plant of which they have brought specimens to Kew is fast becoming the terror of graziers. Unfortunately the said specimens were not in flower, but as far as can be judged from the long silky pinnate leaves and the general aspect of the plant, it may be Astragalus Bigelowii; of course without flowers it is impossible to venture a possible opinion in such a case. The plant, whatever it is, is spreading rapidly from the south in a northerly direction. Great patches from half an acre to an acre in extent occur frequently, and, to render matters worse, cattle are very fond of it. As soon as they begin to feed on it, however, they lose flesh very rapidly, their eyesight is effected, and they soon die. A friend of the gentleman who furnished these details lost nine horses recently through their having fed on this plant, about which it would be desirable to have more information.—*Gardeners' Chronicle.*

Plants and Animals.—The analogy found to exist between plants and animals is remarkable, and to a great extent corroborative of the modern doctrine that the entire universe is composed of the same few simple elements, and ruled by the same correlative laws. It appears to be the case, both among ourselves and the lower creatures arround us, that those which have been raised in scant pastures, and inured to hardships, succeed much better on being moved to better places than those grown in the midst of abundance of rich food, when, afterward, they encounter restricted supply of what is poorer. It is argued that plants manifest a similar behaviour, that seed taken from poor ground to rich succeeds better then if it had been raised on good soil. It is an opinion very generally held, and one that seems to have reason in it. Many potato growers advocate the policy of raising sets for seed by themselves, in unmanured ground, and with late planting; and for nursery work it is admitted that soil of medium or poor quality is better for raising plants to send away than a rich soil which would bring them on more rapidly. Short-jointed cane also, the produce of poor land, makes better cuttings than when it is long-jointed. The rule is good and worth watching by all, and its principles can generally be applied advantageously.—*Queenslander.* [The principle seems plausible, but doubt its general applicability. From cinchona nursery beds, for instance, we think it would be hazardous to withhold good forest mould.—Ed.]

95

Marking Garden Labels.—In spite of the various ingenious adaptations of wood and metal, we do not seem to have got anything better, cheaper, and easier dealt with at short notice than zinc labels with an iron stem, such as were figured in the *Gardeners' Chronicle*, and those made of strips of lead to be stamped with letters or figures. Writing may be assumed to be not indelible. Let the makers of ink that is reputed to last as long as the metal say what they please, it does become obliterated, or at least to such a degree that the reading of the words, &c., becomes a work of difficulty. That being so, the next best method is that of stamping the letters or figures into the label by means of steel dies, which work is best done when the letters are arranged on the limbs of a pair of shears or pincers, eight or nine letters on each. Sometimes the whole alphabet is arranged on one pair, but then the letters furthest from the fulcrum can have but little force exerted on them, and the impression is therefore faint; but by having one-third of the alphabet on each, the jaws are not made needlessly long. The figures can be treated in similar fashion. As we know from experience loose dies are constantly getting mislaid, but pincers, being larger objects would be less likely to be missing when wanted. Under each die on the opposite limb a little boss or anvil is placed, upon which the label is held in making the impression, and the handles of the instrument being made of considerable length and strength, a great amount of pressure can be obtained, and which can be so regulated by the operator as will fit it for use on either lead or zinc.—*Gardeners' Chronicle.*

Asphyxiating Flying Foxes by Means of Sulphur Fumes.—The large bats known popularly as "flying foxes" are destructive to forest in Ceylon, but so few persons make their living by orchards, that much attention is not excited by the savages of these creatures. The case is different in Australia where fruit-growing is a most important pursuit, and in a very interesting account of an Orchard in Queensland, we find the following statement:—This orchard contains fine specimens of most tropical fruits; the mango in particular proves to be quite at home here, and the proprietor thinks so much of it that he purposes to plant much more largely with it. The persimmon in several of its varieties is also thrifty here, and from all the trials which up to the present have been made with this fruit it promises to suit any part of the colony equally well, for it is healthy, vigorous, and fruitful, north, south, and west; in fact everywhere that it has had a fair trial. Many varieties of the custard apple are grown in this orchard, and my attention was arrested by a cross between *anona squamosa*, the common rough-skinned one, and *anona reticulata* or *glabra*, the cross being a variety of very great promise. Its specialities are a very superior flavour, more than ordinary productiveness, and the tree attains quickly to a very great size. None of the custard apples known to me have so many good points as this, and all lovers of the fruit should endeavour to add this to their collection. In foliage and general appearance the tree resembles *anona squamosa*, the common rough variety, but it is much better in flavour, and as a giant to a dwarf in comparison to its size. Loquats bear profusely, but cannot be harvested owing to the ravages of that abomination, the flying fox. A war of extermination will need to be waged against this nocturnal pest before fruit-growers will be able to enter upon their industry safely. And it may not be so difficult of accomplishment as many suppose. A settler in New South Wales once wrote a private letter to a friend in Central Queensland stating that he had made a successful raid upon these animals by following them to their camp with furnaces extemporised out of old nail cans and a quantity of common sulphur. Choosing a calm day he kindled charcoal fires in his furnaces immediately under the foxes, and burnt sulphur in them, retiring to watch proceedings, and succeeded in bringing them down by thousands. I was relating this to the manager of a sugar plantation once, and he told me that he was in company with an aboriginal at one time where the foxes had a camp, and the nigger—true to his instincts—said, "Budgeree! me like 'em; plenty fat that fellow!" and set to work collecting rubbish to burn and raise a great smoke; the result of which was that the foxes began falling around stupefied, and the black had a good time of it bagging his spoil.—*Queenslander.*

ST. HELENA.

A Report upon the Present Position and Prospects of the Agricultural Resources of the Island of St. Helena,

BY D. MORRIS, ESQ., M.A., F.L.S., F.G.S.,

Director of Public Gardens and Plantations, Jamaica.

St. Helena lies in lat. 15° 55′ S., and long. 5° 42′W. It is 1,140 miles from the African coast. It is 1,800 miles from the American coast, 700 miles south of the Island of Ascension, 955 miles due south of the equator, and about 4,000 miles from England.

It was discovered 21st May, 1502, by the Portuguese; held by the Dutch until 1651, when the East India Company took it. It was transferred to the Crown in 1833. It has been in British possession about 232 years.

Historically, it is chiefly remembered in connexion with the exile of Napoleon I. After the defeat at Waterloo he was placed a prisoner at St. Helena from 15th October, 1815, until his death, 5th May, 1821, a period of 5½ years. His body was at first interred near Longwood, but afterwards (1840) removed to France.

The area of St. Helena is about 45 square miles; its extreme length, 10½ miles, and extreme breadth, 8¼ miles. Of the 28,800 acres of which the island consists, the greater portion suitable for cultivation is in private hands. The Crown lands, with the exception of Longwood Farm and a few other places, are barren wastes on the outskirts of the island, incapable of cultivation.

To understand aright the present condition of the surface of St. Helena it may be mentioned that three fairly distinct zones, each possessing its own special characteristics, are observable both in the geological nature of the soil as well as in the plants which affect them. These are:—

1. *The Coast Zone.*—This, in the present day, is "the dry, barren, soilless, frowning, lichen-coated, rocky outskirts of the island." At one time it is said to have been covered with abundant vegetation, and with trees drooping over the tremendous precipices that overhang the sea.

The barren coast zone, at present extends about a mile to a mile and a half around the island. Deep, wide valleys, and rocky, almost inaccessible, ridges run from the central ridge towards the sea, breaking up the coast zone into numerous, almost detached, prominences and ledges. It is absolutely devoid of vegetation except prickly pear, a few plants of *Mesembryanthemum*, and the rare indigenous *Pelargonium*, *Pharnaceum*, and *Tripteris*. On the Barn there are straggling bushes of the scrub-wood (*Aster glutinosus*, Roxb.), which is probably the most abundant of the indigenous plants of the rocky coast.

The plants on the coast zone are so scattered and for the most part so lodged in crevices and hollows that they do little to redeem the barren, burnt-up appearance which the island presents from the sea.

2. *The Middle Zone.*—This extends about three-quarters of a mile inland from the boundary of the coast zone. Its surface is less rocky, with shallower valleys, and more grassy slopes. The elevation is from 400 feet to about 1,800 feet; the temperature is lower; and numerous Australian, Cape, and American shrubs and trees have become established, forming thickets of considerable size. One of the chief features of this middle zone are the furze-clad slopes, with occasionally the indigenous gum woods, and, in moist sheltered hollows, the larger ferns. Longwood and Deadwood, Plantation House, and West Lodge may be said to occupy characteristic positions in this zone. The English brooms, brambles, willows, and poplars, Scotch pines and gorse bushes, Cape of Good Hope bushes, Australian trees, and American weeds have driven out most of the indigenous plants from this belt. The tendency of these introduced plants is to encroach more and more upon the higher lands where the indigenous flora still remains. As regards the larger trees, such as pines and willows (acacias), they appear to be spreading downwards in the direction of the valleys; following, no doubt, the distribution of their seeds by the action of the trade winds.

3. *The Central Zone.*—This occupies a certain extent of land on each side of the central ridge (once the rim of the Sandy Bay volcano). It is altogether not more than about 3 miles long and about 2 miles wide. In some places, as on the southern slopes of the central ridge, the rocks are very precipitous, while in others the land possesses an undulating "hummocky" character, with grassy slopes, meadows, hayfields, a few farms and gardens, and well wooded glens of oak and acacias. On the extreme crest of the central ridge, extending from High Peak to Rock Rose, there is still left a portion of the indigenous forest, with cabbage trees and ferns, the wild olive (*Nesiota elliptica*), angelica, lobelia, and the delicate campanulate *Wahlenbergia*. Generally the soil in the central zone is rich though not very deep; the climate is particularly cool, the sky being continually obscured by mist and cloud.

I have previously mentioned that St. Helena contains an estimated area of 28,800 acres. Of this area probably 20,000 acres, or more than two-thirds, are composed of barren rocky wastes or clayey slopes totally unfit in their present conditions for any agricultural operations.

Aloes, *Furcræa*, and plants of this kind may be induced to grow in the more warm and sheltered valleys; and possibly, several hardy trees may be established in other places under careful and proper treatment; but unless pioneering vegetation of this kind is first spread over these wastes to gradually reclaim them, they must continue to remain in their present condition.

About 8,000 acres are in pasture and hay land. The tendency is to throw more and more land out of cultivation and place it in grass. This is a retrograde step as regards the agricultural interests of the island, but it is inevitable under the influences which obtain at present.

The country houses which in the East India Company's time were inhabited by prosperous merchants and officials, and surrounded by well-kept gardens and orchards, are now fast falling into decay and becoming ruinous. The cultivated areas around them are simply converted into grazing lands, and a few cattle and sheep are the only indications of life for miles round.

Under forest, both of indigenous and introduced trees, in detached and struggling patches, there may be altogether about 400 acres.

Under cultivation, with root crops, forage, orchards, and gardens, there are not quite 300 acres.

This last area, viz., 300 acres, practically represents all the land now used for raising crops and for contributing to the food supply of the inhabitants.

It will be noticed that this is not all the land capable of being thus utilised. Under a more efficient system of agriculture, and with the introduction and application of capital, the area under crops and garden cultivation might be increased tenfold. In fact, fully one-half the land under pasture and hay land might be broken up and utilised for crops, provided a tangible and apparent purpose were in view, and a market found for the produce.

The present population of St. Helena according to the census of 1881, excluding the garrison and shipping, is about 4,500. Of this number more than one-half (2,435) live in Jamestown.

As regards occupation, there are only 70 persons (males) returned as farmers and small cultivators, and 477 (males) as labourers.

During the last 10 years large numbers of labourers and small cultivators have emigrated to the Cape and Natal, and at the present time labour is scarce and expensive. Wages range from 2*s.* to 2*s.* 6*d.* per day, but the quality even at this price is not quite satisfactory.

The rainfall at St. Helena is very variable. In Jamestown Valley and the coast zone it is probably as low as 25 or 30 inches. In the middle zone, as at Longwood, the mean annual rainfall (by observation) is 44 inches. On the central ridge it is no doubt higher and may be placed at 55 to 60 inches.

As regards climate St. Helena stands pre-eminent in possessing a remarkably fine and healthy climate. The temperature is uniform; observations at Longwood, at an altitude of 1,764 feet, record the mean temperature for five years at 61·4° Fahrenheit, the lowest being 52° and the highest 77·6° Fahrenheit.

The mean height of the thermometer in the different months ranged from 57·07° in September to 66·24° in March, making an average difference of only 9·17 between the hottest and the coldest months.

The trade winds from the south-east blow interruptedly for about 10 months of the year, keeping the air pure and cool.

In respect to its climate I regard St. Helena as a mos valuable station for recruiting health, and it is a matte of regret that its resources in this respect have not been more fully appreciated.

During the period when the East India Company held the island, owing to its being so important a station on the then route to India, "it was reared in the lap of luxury." Merchants and officials possessing large incomes were settled in the island; they occupied handsome residences situated in the country parts, and public works and buildings were maintained in a high state of efficiency. The number of vessels calling at the island were reckoned by thousands in the year. Being sailing ships they remained a considerable time in port re-fitting and re-victualling, and they spent annually large sums of money which circulated amongst all classes of the community.

When, however, the Suez Canal was opened and the Cape route was practically abandoned by the largest and best ships to India and the East, and when again the naval and military establishments were reduced to the lowest ebb, then there set in a period of financial depression and general distress which has extended to the present day.

The island has never been able to produce any article of exports, and owing to its geographical position and its close connexion with shipping, the attention of its inhabitants has been called away from any serious attempt to cultivate the soil for the sake of profit.

Hence now, when the number of ships calling at the island is becoming yearly less and less, there has settled upon the inhabitants a hopelessness of fighting against circumstances which is most distressing. Before they fully realized that they must look to local industries and to the resources of the soil for the true prosperity of the island, the spirit of enterprise, and with it the necessary capital for developing those resources, had fled.

I append herewith a return showing the number and tonnage of vessels which have called at St. Helena during the last 10 years:—

	No.	Tons.
1873	717	464,637
1874	684	469,231
1875	605	412,149
1876	582	393,761
1877	664	449,724
1878	669	505,750
1879	602	425,811
1880	564	430,925
1881	525	385,911
1882	497	409,400

From this return it will appear that the falling-of in the number of ships calling at the island during the last 10 ten years is very considerable. As compared with 1873 there is a falling-off of 220 in the number of ships which called in 1882, and a falling-off of 55,237 as regards the tonnage. The gradually substitution of large steamers for sailing ships is another very serious blow to St. Helena. And again, although steamers continue to call, they seldom require anything, as with the new improvements in ice-chambers and refrigerating machinery, they can carry supplies of fresh meat and fresh vegetables to last a long voyage.

Under these circumstances the outlook in St. Helena is a very serious one.

Unless the Home Government is prepared to give the island some assistance and to support it while endeavouring to develop the resources of its soil, I fear there is little hope in the future.

In the endeavour to keep the expenditure within the income, and to pay off a debt contracted some years ago, the present governor has been most careful in husbanding every penny paid into the exchequer, but in spite of his utmost endeavours the income is becoming less and less every year; public buildings, roads, and public works generally are suffering from want of funds; the establishment, reduced to its lowest standard, is small, ill-paid, and sharing in the general depression; education, religion, local institutions, and in fact all that make up the moral, social, and commercial machinery of a community are suffering from want of means, and are yearly less and less able to meet the demands made upon them.

I feel it my duty to speak thus plainly of the present state of affairs in St. Helena, as I trust that some means may be devised for bringing about a radical and decisive change in them.

Speaking from my point of view, and after a careful consideration of the soil, climate, and general resources of the island, I am led to take a hopeful view of those resources, provided they are developed in such a manner as to place the island in fair competition with other countries.

I look entirely to the soil for the elements necessary to bring prosperity to St Helena. But the people require to be shown what those resources are; they need to be taught how to use those resources aright, and they require to be encouraged and assisted, while so engaged.

I would recommend, in the first instance, that an intelligent and competent gardener be sent to the island to take up the entire question of the revival of agricultural pursuits, and that if the local government is unable to support such an officer and a small staff, that a grant be made for the purpose by the home government.

With regard to suggestions for the improvement of the general agriculture of the island, I shall, in treating of the plants now under cultivation there, offer such hints as may be conducive to their better treatment, and to a better return from the areas under cultivation.

Taking into account the remoteness and comparative isolation of the island, the reduced condition and great want of knowledge which characterises most of the cultural operations undertaken by the smaller settlers, as well as the need of the assistance which only a practical and well-trained gardener can give them, I am disposed to recommend that a small establishment be again organized with Plantation House as a centre, and that a good gardener be placed in charge of it. The work of such a man would combine the maintenance of nurseries and of a small garden at Plantation House with a keen interest in the general development of all cultivation undertaken in the island. He would introduce and raise for distribution the numerous valuable plants not already in the island; he would show experimentally the best methods adopted for their successful cultivation, and he would give every assistance to cultivators in teaching them how to prepare the land and plant trees; how to prune them and keep them in good health; how to treat the numerous diseases which unhappily have appeared and been allowed to attack unchecked the numerous industrial plants in the island; how to prepare the produce of plants for exportation; and, in short, to promote by every means in his power the revival of cultural operations in St. Helena and to endeavour to place them in a healthy and prosperous condition.

Under present circumstances I am unable to suggest any other means of accomplishing the objects above enumerated, and I fear that even with these means it will take a long time to bring things back to such a condition as will have an appreciable effect upon the finances of the island.

The probable yearly expenditure in connexion with the employment of a trained gardener will amount to about 400*l*. per annum. This would include his own salary and the wages of three or four men. There is a small cottage at Plantation House which might be converted into a residence for the gardener, and there is a propagating house and land suitable for nurseries close at hand.

At first little, if any, reimbursement in aid could be expected. Later, however, as plants became ready for distribution, and a keener interest was created in the cultivation of new products, a small charge made for plants sold to cultivators might bring in about 50*l*. per annum. Ultimately the wages of the men might be covered by the sales of plants; but in any case the establishment could not be expected to be self-supporting amongst so small and comparatively speaking so poor a community.*

In addition to the work above mentioned the Government gardener might do much towards placing the Crown lands in a position to bring in a larger revenue, and to assist in the planting of the large areas of denuded land which at present are becoming less productive every year.

It was noticed more than a hundred years ago that the excessive cutting down of the indigenous forest had had an appreciable effect upon the climate of the island; and especially that the springs rising in the highlands of the central ridge

* At present there is a small sum expended in the maintenance of a small garden in Jamestown which might be added to the above for working them under one officer.

had become gradually diminished in volume and regularity. Oaks and Scotch firs were introduced in 1749, and planted at an elevation about 2,000 feet, where they are growing luxuriantly to this day. Numerous acacias, and notably the Port Jackson willow, many Cape trees and Australian shrubs, have been established, and form the chief vegetation at a mid-elevation.

Since the time of the East India Company the lands above 2,000 feet have been gradually denuded, so that at the present time only inaccessible peaks and steep, precipitous, and rocky slopes, unsuitable for pasturage or for cultivation, remain in natural forest.

At about 2,000 feet, and down to about 1,500 feet, there is a belt, fairly well maintained of Australian and Cape trees; but as the tendency of these is to propagate themselves at lower elevations or down the slope of the hills, the upper areas remain untouched.

The lands on the higher slopes, inasmuch as they afford good hay grass, are eagerly sought by farmers, and hence the tendency is to extend as much as possible the area under hay grass, and to cut down in every possible locality the indigenous trees.

I would suggest that a boundary be marked from the top of the central ridge, extending, say 500 yards down the slope to the northward, and this should be permanently maintained in forest; and where at present denuded, that it be carefully and systematically replanted.

This belt might begin at the Old Picquet House, the eastern termination of the central ridge, and extend to the westward, under High Peak, Old Telegraph, Sandy Bay Ridge, Stitches Ridge, the Three Peaks, to High Ridge, and Long Ground Ridge. The high road running under the northern slope of the central ridge might form a convenient boundary for this belt; but in cases where it comes close to the ridge, as at Telegraph and Sandy Bay Ridge, the boundary might fall below the road.

Latterly, the island has suffered very severely from drought, numerous springs having been almost dried up. It is probable that such conditions may be repeated, if the process of denudation is not immediately stopped, and if the central ridge, where the chief streams of the island take their rise, is not reclothed with trees. The beds of the streams should also be well shaded by suitable trees to prevent excessive evaporation, and all ponds and reservoirs should be similarly treated.

It is needless to add that blue gums, or any member of the genus *Eucalyptus*, is very unsuitable to plant near springs and streams. These trees act practically as force pumps; and several instances have come under my notice where springs and small rivulets have been dried up by the wonderful powers of absorption possessed by their roots.

As the best and most economical means of reforesting the denuded slopes of the island would be to utilise the numerous native and foreign trees already yielding large quantities of seed, I append here a list of the principal trees which may be used for such purposes:—

Common Name.	Scientific Name.	Elevation suitable for Growth.
Kei Apple	Aberia Caffra, Hook. f. and Harv.	Mid.
Mahoe	Paritium tiliaceum, St. Hil.	Lower.
Redwood	Melhania erythroxylon, Ait.	Mid.
Margosa	Melia Azedarach, L.	Lower.
Caffre or Red Date	Harpephyllum caffrum, Br.	Mid.
Tree Pittosporum	Pittosporum undulatum, V.	„
Cape Coral Tree	Erythrina caffra, Thunb.	„
Red Coral Tree	„ Corallodendron, L.	Lower.
Coral Tree	Schotia, tamarindifolia, Afz.	Mid.
Fine-leaved Acacia	Acacia dealbata, Link.	„
Acacia	„ decurrens, Willd.	„
Port Jackson Willow	„ longifolia, Willd.	„
Black Acacia	Albizzia Lebbek, Bth.	Lower.
Black Boy	„ lophantha, Bth.	Mid.
Madras Thorn	Pithecolobium dulce, Mart	Lower.
Loquat	Eriobotrya japonica, Lindl.	Mid.
Rose Apple	Eugenia Jambos, L.	„
Red Gum	Eucalyptus viminalis, Lab.	„
Blue Gum	„ Globulus, Lab.	„
Indian Almond	Terminalia Catappa, Gærtn	Lower.
Assegai Wood	Curtisia faginea, Ait.	Mid.
Privet or Iron Wood	Canthium sp.	Mid. and Highest.

Common Name.	Scientific Name.	Elevation suitable for Growth.
Purple-fruited Olive	Olea laurifolia, Lamk.	Mid.
White or Wild Olive	Nesiota elliptica, Hook. F.	„
True Olive	Olea europæa, L.	„
Snail Tree	Hakea gibbosa, Cav.	„
Oak	Quercus Robur, L.	„
Evergreen Oak	„ Ilex, L.	„
Cork Oak	„ Suber, L.	„
Casuarina	Casuarina equisetifolia	„
Norfolk Island Pine	Araucaria excelsa, R. Br.	„
Brazil Pine	„ brasiliensis, Rich.	„
Cypress	Cupressus sempervirens, L.	„
China Pine	Cunninghamia sinensis, Rich	„
Bermuda Ceder	Juniperus bermudiana, L.	„
Cluster Pine	Pinus Pinaster, Ait.	„
Stone Pine	„ Pinea, L.	„
Cape Yew	Podocarpus elongata L'Her	„
Camphor	Cinnamomum Camphora, Nees.	„

It will be noticed that most of the trees mentioned above are suitable for mid-elevations, these being the areas which at the time of their introduction, required to be replanted. Since then, however, large areas on the highest lands have been cleared of their indigenous plants, and for these it might be desirable to introduce trees of a hardy character and capable of withstanding strong winds. Also in the hot and and dry valleys of Jamestown and Ruperst, several valuable trees might be planted, suitable for the conditions which obtain therein.

For the latter situations, the Divi-divi (*Cæsalpinia coriaria*) the Lignum-vitæ (*Guaiacum officinale*); the Cashaw (*Prosopis juliflora*); the West Indian Ebony (*Brya Ebenus*); and various species of *Ficus* might be planted to afford shade and shelter, as well as give some returns in economic productions.

Cinchona.—The proposal to introduce the cultivation of Cinchona into St. Helena appears to have been made, in the first instance, by the late Dr. Roxburgh, who, as far back as 1814, recommended that seeds of *Cinchona officinalis* be obtained from South America, and that after plants had been established at St. Helena they should be transmitted to India.

Sir Joseph Hookor, having on two occasions, namely, in 1839 and 1843, had favourable opportunities of forming an opinion respecting tho resources and climate of St. Helena, when Sir Charles Elliott in 1864 began to develop planting operations in the island by the introduction of new and valuable plants, it occurred to him that *Cinchona*, if properly tried, was likely to lay the foundations of a remunerative and successful industry.

To undertake experiments a skilled gardener, Mr. J. H. Chalmers, was sent out from Kew in 1869, who having been supplied with seeds, succeeded within a short period in raising several thousand Cinchona plants in nurseries at Plantation House. Soon after a nursery was established at Newfoundland (altitude 2,400 feet), in the immediate neighbourhood of the highest peaks and of the only uncleared natural forest remaining in the island.

Mr. Chalmers succeeded altogether in raising about 10,000 plants from seed; and of these possibly more than one-half were planted out either on the slope above Newfoundland and under Actæon's Peak; or, on the Peak itself.

This portion of the island, it may be explained, lies along the inclines of the central ridge, of which Actæon's Peak, Diana's Peak, and Cuckold's Pit Peak form the culminating points. The general elevation is between 2,500 and 2,700 feet; the mean annual temperature rather below 60° Fah.; and the soil composed of a rich black vegetable mould—peat—overlying marl or decomposed volcanic rock. At this elevation the ridge is bathed in moisture for at least three days of every week; and thus favoured, as pointed out by Sir Charles Elliott, it has become covered with a luxuriant growth of ferns and other plants usually found in the home of Cinchonas in South America.

The prospect for Cinchona at first was full of promise; and indeed if the cultivation had been attempted at an earlier period when there was a larger area of indigenous forest to select from, and when plantations might have been established on the northern and more sheltered slopes of the central range, the results might have been very different.

As it was, the plants put out on the terraces at the foot of Actæon's Peak began to die off, and, driven to a last resort, the cultivation was ultimately confined to the narrow ridges of Actæon's and Diana's Peak, which, in many places, are only a few feet wide and fully exposed to the strong trade winds which usually blow in St. Helena for about 9 or 10 months in the year. Here the soil on the surface was of a promising character, being composed of rich vegetable humus formed by the decayed leaves and stems of tree-ferns and native plants. Below, however, there was nothing but a cold, wet, indurated or slightly friable marl, very unsuitable for the growth of Cinchonas, and which in Ceylon and India is known by experience to develop rot or canker in the roots, and to destroy every plant in contact with it. In his last report on the subject, dated 12th December, 1871, Mr. Chalmers rightly attributes the large percentage of losses amongst his plants to the superficial nature of the soil, and reports that "they invariably died soonest in shallow ground, and, on the "contrary, lived longest where the soil was of greatest depth." Further, he remarks, "there is nothing, either in the climate "or situation, of an unsuitable character; the soil alone "seems to be at fault, being insufficient for the further de-"velopment of the plants."

Out of about 5,000 plants put out by Mr. Chalmers between January 1869 and November 1871, at the latter date there were only 540 of all ages then remaining. These were as follows:—

Cinchona succirubra,	over 2 feet	-	221
"	" 6 "	-	84
Cinchona officinalis	" 2 "	-	81
"	" 6 "	-	3
Number of both kinds under	2 "	-	151
Total	-	-	540

Further experimental trial was stopped by the reduction of the establishments effected by the late Admiral Patey, and Mr. Chalmers left the island.

From 1872 up to the date of my visit the Cinchona trees still living had received some attention, but practically their cultivation was abandoned.

I went up to the central ridge with the Governor and Colonel Phillips, R. E., on the 31st July, and spent the day examining the soil and noticing the condition and state of the Cinchona trees still remaining.

Of the trees planted by Mr. Chalmers there were 40 fine trees of *Cinchona officinalis*, from 8 to 20 feet high; of *Cinchona succirubra* there were 116 trees, from 8 to 20 feet high. The largest tree of all was a red-bark tree, *C. succirubra* which measured 18 inches in circumference at 1 foot from the base. Except a few trees in exceptionally sheltered spots, they were all much damaged by wind, and presented a stunted and half-starved condition.

The ridge on which they were growing formed a portion of the rim of the old volcanic crater of Sandy Bay. On the southern side there was a steep, almost perpendicular, wall of rock, about 100 to 250 feet deep, reaching down to broken lands and ravines clothed with ferns, briars, and the low, bushy growths of cabbage trees, jelico, wild olive, and lobelia. On the northern and wester sides, the slopes, in places, were somewhat easier, but in no place was the ridge more than about 20 feet or 30 feet across. In many places, indeed, it was so narrow that it appeared like an old castle wall, clothed with vegetation.

The length of the ridge on which Cinchona had been attempted was altogether under ¼ mile in a direct line.

Under the most favourable circumstances it was not possible to place more than about five or seven acres under cultivation in Cinchona; but in view of the very unsuitable nature of the subsoil and the large mortality which had taken place amongst the young plants, it is very undesirable to attempt any further experiments. According to the statement of a very intelligent native gardener, trained by Mr. Chalmers, who has been employed since at Plantation House, and in occasionally looking after the Cinchona plants on the ridge, more than 90 per cent of the plants put out were lost owing to the unsuitable nature of the soil.

I visited the ridge again on the 1st August, and spent the day in exploring the lands in the immediate neighbourhood of the peaks, with the view of finding land offering better facilities for Cinchona planting than the ridge itself. In this I was disappointed. Except on the crest of the ridge there is no vegetable deposit or surface soil likely to grow Cinchona, the soil elsewhere being very shallow and immediately overlying rock or cold impervious clay.

Summing up the results of my inquiry, I am of opinion that, while the first impression were favourable to the possibility of growing Cinchona on the highest peaks in St. Helena, the character of the subsoil, together with the exposed position of the locality, would entirely preclude the undertaking being commercially a success; and on other grounds it would be very undesirable to cut down any more of the indigenous forest, which already is reduced to such a small extent.

With regard to the cultivation of other plants, I devoted as much of my time as possible to a careful review of the capabilities of the island, and append herewith the remarks I have to offer.

The plant known in the island as the English aloe (*Furcræa, gigantea*) offers a very important means of establishing an industry by its extended cultivation, and the preparation of the valuable fibre which its leaves contain. This plant grows wild at mid-elevations, and its tall flowering stem, rising to the height of 30 feet or more, is quite a feature in the landscape. The leaves are often 8 or 10 feet in length; when freshly cut they possess a peculiar penetrating odour, from which the old name *Agave fœtida* was derived. On the flowering stem, instead of flowers, there generally appears a numerous progeny of bulbils; these enable the plant to be very readily propagated. This *Furcræa*, which appears to have spread naturally on the low-lying lands and deserted sugar estates in Mauritius, has been utilised in that island for the production of a valuable fibre known in commerce as Mauritius hemp. A machine invented by M. Gracieux was found to extract the fibre from the *Furcræa* leaves successfully, and a large business, amounted to an annual export value of 15,000*l.*, has consequently been established there.

Another machine, known as Smith's Patent Scutching Machine, manufactured by Messrs. Death & Ellwood, of Leicester, is being used for the extraction of this fibre, and with favourable results.

Those who contemplate embarking in this industry in St. Helena should, in the first place, obtain one of the machines above mentioned, and test its suitableness for the extraction of the fibre on the spot. The motive power might be obtained from horse-power, water-wheel, or windmill. For the circumstances of St. Helena the latter would probably be the most preferable. In the first place, the present supply of the *Furcræa* might be utilised; but sooner or later it would be necessary to establish regular plantations in the immediate neighbourhood of works, and with proper appliances for the rapid transport of the leaves.

It must be remembered that the proportion of fibre in each leaf is very small. It is generally admitted that the leaves of this plant give an average yield of about 3 per cent; that is to say, not three pounds of fibre for 100 pounds of leaves, but three pounds of fibre for 100 leaves. By actual experiment in Mauritius 50 leaves of average size, 4 feet long, weighing in the aggregate 56 pounds, produced 1·75 pounds of dry fibre. This would be at the rate of 3½ pounds of fibre per 100 leaves, or 3·12 pounds per 100 pounds.

A consideration of the above facts should lead to every effort being made to reduce the cost of transport of the leaves and to establishing works in a central position easily accessible on all sides.

While in the island I received samples of fibre prepared by Mr. Deason of Longwood Farm, by means of a machine of his own invention, driven by windmill power. On arrival in England I was enabled, through the kind offices of Mr. Thomas Christy, F.L.S. to submit them for report to Messrs. Collyer & Co., Fenchurch Street, London.

This result is as follows:—

"Aloe fibre (*Furcræa gigantea*) St. Helena. Good length: full strength: rather dull colour: generally well cleaned, but with some runners untouched and barky. Value, 28*l.* to 30*l.* per ton. This sample is very different in appearance to the *Furcræa gigantea* of Mauritius, owing probably to differences both of growth and treatment. It is in some respects apparently more suitable for cordage purposes; that is, more like Manilla hemp."

Considering that this fibre was prepared by simply passing it once though the machine, that no water was used, and that it was dried by simply exposing it to the sun, the report is full of encouragement and very suggestive. Owing to the limited supply of water in the island, it would be useless to attempt to wash the fibre, or indeed to do anything to it beyond drying it in the sun and beating some of the pithy substance out of it before it is packed for shipment.

To sum up my recommendations under this head, the chief points to which attencion should be given:—

1. To grow large quantities of the plants and utilise all waste lands so as to produce leaves cheaply aud economically.

2. To use simple and effective machines, the Gracieux or the Mauritius machine for preference, cheaply worked in the immediate neighbourhood of the plants.

3. To dry the fibre by exposure to the sun and air, and ship it in a perfectly dry condition.

New Zealand Flax.—New Zealand Flax (*Phormium tenax*) has been extensively planted over the island, and in some cases it occupies good and valuable soil. Some time ago an attempt was made to establish a factory for the preparation of the valuable fibre yielded by this plant; and many people were thus tempted to cultivate it. As the factory with expensive machinery was established at Jamestown, several miles away from where the plants were grown, the expense of transport—chiefly by means of the small breed of island donkeys—was so great as to swallow up all the profits.

This cannot be a matter of surprise when it is remembered that it would take more than 100 tons of leaves, and these carried in small loads, to yield about five tons of fibre.

If another attempt is made to extract fibre from the New Zealand flax, the machinery should be placed quite close to the plants; and it might be more profitable in the end to ship a lower class of fibre than attempt to work expensive machines requiring a large water supply.

I am encouraged in this view by the report of Messrs. Collyer & Co., the brokers who examined the *Furcræa* fibre, on a sample of New Zealand flax, roughly prepared by Mr. Deason's machine. This was passed through the machine in the same manner as the *Furcræa* leaves, and submitted without washing or the use of chemicals. Messrs. Collyer's Report is as follows:—

"New Zealand flax (*Phormium tenax*) St. Helena.

"Fair length: fair strength: poor brownish colour: fairly clean: some runners untouched and barky. Value, 22*l.* to 23*l.* per ton.

"Either this fibre, or that of the aloe (*Furcræa gigantea*) would be fairly saleable in large quantities."

If Mr. Deason's machine does not fully answer for the New Zealand flax, possibly the machines manufactured by Messrs. Death & Ellwood would do so. A single machine of their pattern may be had for abont 37*l.* 10s, and they are fitted with special appliances, so that they can be driven either by cattle or horses or by windmill power.

I commend the subject of the extraction of fibre from the New Zealand flax to the careful attention of proprietors in the island; and failing remunerative prices for the fibre, there is still an opening in shipping "half-stuff" for the paper manufacturers, and obtaining some return from the hundreds of tons of this material now growing uselessly on such extensive tracts in the island.

Barbadoes Aloes.—Another member of the aloe family, which is very abundant in the island, and capable of being largely utilised, is the Barbadoes aloe (*Aloe vulgaris*).

It grows freely in Jamestown Valley in volcanic ash, and on barren rocks. It is fast spreading also in Rupert's Valley; and I noticed it was there used, and seemed to flourish as a coping for a stone wall.

This plant, so hardy and prolific, produces the aloes of medicine, and it is cultivated, especially at Barbadoes in the West Indies, solely for this purpose.

It reproduces itself by means of suckers around the stem; these being removed when about 6 inches high are planted out on waste pieces of land about 2 feet apart. When fully grown, and just before flowering, the outer and older leaves are first removed; they contain an abundance of a thick yellowish juice, which is allowed to drain into troughs leading into a large iron pot or cauldron. When the pot is nearly filled it is placed over a fire, and the juice boiled until it has attained the consistency of thick glue; this when cool is the aloes of commerce, and it is usually exported to England in bottles or gourds.

Barbadoes aloes, prepared in the manner above indicated, is valued in the London market at 4*l.* to 8*l.* per cwt. It is usually retailed by druggists at 4s 6d per pound.

This industry, which necessarily must be very small might, commend itself to the notice of many people, especially fishermen and others, living in the lower valleys. The plant is abundant; its cultivation, if merely putting a few suckers in the ground can be so called, is of the simplest description; and the preparation of the juice requires only a few troughs, made by nailing a couple of pieces of board at right angles to each other, and an iron pot. If some local tradesmen were to give attention to the subject, and undertake to purchase the manufactured aloes from the cultivators in small quantities, the industry would soon be placed upon a satisfactory footing.

Walking Sticks, &c.—I noticed in many parts of the island that a considerable quantity of low brushwood, composed of privet (*Canthium* sp.) as well as numerous hedgerows of wild pepper (*Clutia pulchella*), were spreading by means of root suckers over large areas. Also the European gorse or furze bush (*Ulex europæus*), a naturalised plant in St. Helena, covered many acres of the somewhat barren slopes at mid-elevation. It occurred to me that possibly a small trade might be made in sending selected specimens of these to England for walking sticks, umbrella handles, &c.

With the view of testing the demand for such articles I brought with me a bundle of sticks, representative of the three plants above mentioned; and I had them submitted (through the Kew Museum) for examination by one of the largest firms in London interested in the subject.

The report which I received is as follows:—

Report by Messrs. H. Howell & Co., of 180, Old Street, City Road, London, upon sticks from St. Helena, collected by Mr. D. Morris.

24th September, 1883.

"We have given attention to the specimens of sticks from St. Helena which you kindly sent for our inspection, and the result is that we find it difficult to speak as to their commercial value from such a *small sample*, as from a long experience we find that the larger the sample in sticks the more nearly it is likely to represent the bulk.

"Each of the specimens, however, have characteristics which we like, and if you could get over a large sample, say 500 or 1,000 each, or even say 200 each, we could then estimate their probable value in the market.

"The wild pepper should be sent over *without having* the root peeled. We prefer the roots left as large and natural as possible, so that we can use our discretion in shaping the handles. This remark applies equally to the privet.

"If the furze, too, can be cut with a knob or crook of some sort it will increase their value.

"These sticks, viz., the *two each* sent us, are all very fairly selected; that is, they are good sizes, and they taper nicely from the root to the point. Moreover, they are free from *knees* or *acute* angles, which always, when present, depreciate the value of sticks.

"The diameter of sticks such as these can vary from ½ inch to about 1 inch (yours measure ½ to ⅞)."

HENRY HOWELL & CO.

Pyrolusite.—Pyrolusite, or black oxide of manganese, is occasionally found in veins amongst the finely crystalline felspathic greystone lavas at Horse point; and, I believe, at one time an attempt was made to export it to Europe. Tho price obtained did not, however, encourage the hope of making it a permanent industry. The ore is of a particularly hard description, and difficult to separate from the clay beds in which it occurs. More than this, the cost of transport is so great, that until some means can be obtained to ship it on the spot, there is little hope of placing it in the market, so as to compete with supplies from other countries. [*See* Appendix I.]

Clays.—The numerous clays, ranging from bright red to pure white, found at the higher elevations, as they all contain iron, would be quite unfit for potter's purposes.

Coffee.—Coffee is grown in small patches varying from one-fourth of an acre to two or three acres. At Plantation House, Terrace Knoll, Bambu Groove, Elliotts, Prospect, and Oaklands, I saw very fine patches of coffee, somewhat neglected and unpruned it is true, but indicating the capabilities of the island to grow, in sheltered hollows, a fair quantity of very good coffee. The extent of land actually suitable for coffee would, however, be so small that I do not anticipate it will, under any circumstances, be produced in sufficient quantity for exportation. If it would supply local demands it would do a great deal.

It would appear that *a large amount* of foreign coffee is imported to the island, the returns for the last 10 years being as follows:—

Year.	Quantity (Bags).	Value. £
1873	63	311
1874	74	433
1875	91	431
1876	37	171
1877	93	473
1878	76	222
1879	60	251
1880	82	348
1881	62	237
1882	31	121
Total	669	2,998

For the improvement of this industry, which is in a very languishing condition, induced no doubt by the smallness of the individual areas and the inability to give proper scientific treatment to the trees, I have little of practical utility to offer. There should, however, be no difficulty in digging the ground around the trees, and applying, occasionally, a good dressing of manure to them. Also the pruning which the trees require is a simple matter in itself, but it requires skill and intelligence above the average of that found amongst the small settlers.

The chief hope is, that if an intelligent gardener is appointed to take charge of the Crown lands and teach the people the elementary principles of cultivation, coffee will be included amongst the first objects to receive special attention.

Tobacco.—No tobacco is, at present, grown and prepared in the island. During the last 10 years 84,570 lb. of tobacco were imported representing an aggregate value of 5,272*l*.

In 1869, at the suggestion of Sir Joseph Hooker, Sir Charles Elliott thought it desirable to encourage the cultivation of tobacco, if not for exportation, at least to supply ordinary demands in the island.

A small plantation was accordingly started by Mr. Chalmers, who gives the following account, in his report dated 12th December 1871:—"The ground was manured and the "plants otherwise well attended to till they had arrived "at that state of maturity at which it is customary to "'cure' or prepare the leaf for use. They were then "carefully treated after the manner usually practised in "tobacco-growing countries. A sample was prepared and "submitted through Sir Joseph Hooker to the test of a "proficient London tobacconist, who reported upon it to "the effect that it was deficient in flavour and burning "properties, and bore evidence of having been grown on "a very poor soil. Some of the leaves were, however, of "fair quality, and he believed that by increased attention "to the manuring of the soil, and the preparation of the "leaf, St. Helena tobacco should become equal in quality "to that of Natal and other tobacco-growing countries."

The results of this experiment are exactly what might have been expected under the circumstances, and so far from discouraging the industry they afford very hopeful grounds for its ultimate success. There is no doubt that if Mr. Chalmers had remained in the island and carried on further experiments, tobacco culture would now have become an established industry. For good returns on a small acreage tobacco growing is the most profitable of any. The chief points to be attended to are the selection of soil, and its thorough trenching and working, so as to reduce it to the finest powder. The soil should be a fine, somewhat sandy, rich loam, with no trace of clay or marl, and thoroughly well drained. No soil that I noticed in St. Helena is sufficiently rich at present to grow tobacco, and it would be useless to attempt to grow it where good facilities do not exist for heavily manuring the land. Where the soil possesses the characteristics mentioned above, a portion might be enclosed and cattle or sheep penned and fed upon it for several weeks. When the ground has become throughly saturated with animal deposits, it should then be ploughed or trenched, and all the manure thoroughly mixed with the soil.

Land so prepared would produce tobacco of the finest quality, and I trust that another attempt will be made to start an industry which possesses so many advantages for limited areas and a small labour supply.

Forage plants.—As raising and feeding cattle is one of the principal industries in the island, the question of raising large quantities of forage is a matter of prime importance. At present owing to the poor quality of the pasture lands cattle require to be fed, especially in the winter months, with green forage, such as barley, oats, and Indian corn, supplemented by well cured hay made in the high lands. During periods of drought, such as those experienced during the last three or four years, several hundred cattle have died from want of proper nourishment; and at the time of my visit few, if any, island cattle were fit to be killed for food, the whole community being dependent on supplies from the Cape or the West Coast. Beef is usually retailed in Jamestown at 1s 1d to 1s 3d per pound.

The improvement of the grass lands and a larger and more abundant supply of forage appear to me to be the urgent wants of the island.

As regards the grass lands, they have all, for the most part, become impoverished by continued and ceaseless cropping and the entire absence of manuring.

To improve them, the hundreds of tons of manure wasted in Jamestown should by some means be made available for the purpose; or, failing this, farmers should look upon a compost or manure heap, formed by all refuse and vegetable *débris* near and around farm buildings and cottages, as a necessity in order to enrich the lands in their neighbourhood and develop their resources. In some few cases where this is done the results are so patent that they should commend themselves to the serious attention of all in possession of pasture lands.

For green forage possibly barley, Cape oats, and maize or Indian corn are very suitable for the soil and climate, and yield large quantities of useful and nutritious forage. To supplement these I would recommend the introduction and cultivation of several varieties of Sorghum, usually called millet or guinea corn. In the South of Europe, in Asia Minor, and more recently in the United States of America, the cultivation of Sorghum occupied a place similar to that which oats and barley hold in the field-culture of the northern parts of Europe; and its extended culture in St. Helena would, I believe, be attended with very satisfactory results as a forage plant.

I was much struck by the almost entire neglect of the celebrated guinea grass (*Panicum jumentorum*) in St. Helena. Speaking of the importance of this grass in Jamaica (Report 1880, p. 23), I mentioned that "most of the grazing "and breeding pens were originally created and are still "supported by means of this invaluable herbage, and per- "haps the settlement of the north side of the island is "wholly due to the introduction of this excellent grass. "Again, it has rendered many rocky and otherwise barren "spots in Jamaica, very valuable as affording support to "herds of cattle and horses."

To establish this grass in St. Helena the land should first be ploughed and manured. The grass-tufts taken from an older field should be planted about a foot or 18 inches apart each way and well fixed in the soil. If seeds are used they may be sown broad-cast or in drills. A large field of guinea grass in a sheltered spot at mid-elevation would be more productive than almost any forage plant. To keep it in good order the grass should be cut not grazed, and the field should receive periodical hoeing and a plentiful supply of manure.

To guard against drought and times of scarcity of water it would be very desirable to introduce several valuable trees, yielding nutritious pods or fruits, which in many countries possessing dry and arid climates supply the chief food stock for cattle and horses.

Among the first of these I would place the Carob tree (*Ceratonia siliqua*), a native of the countries bordering the Mediterranean, where it is extensively cultivated for the sake of its pods. These contain a large quantity of agreeably flavoured mucilaginous and saccharine matter commonly employed for feeding horses, mules, pigs, &c., and occasionally, in times of scarcity, for human food.

The tree can resist great drought, as its long roots penetrate to a great depth in search of water. I found one small plant of this tree at Oakbank; but as it is not likely to flower for many years, it would be better to import large quantities of seed from the south of Europe, and establish the tree everywhere in the island below 1,200 or 1,500 feet.

Another useful tree of this class is the Rain tree (*Pithecolobium Saman*) of South America. Its pods, produced in large quantities, are greedily devoured by cattle, and for the lower lands and the valleys of Jamestown and Rupert's Valley it would prove a handsome shade and shelter tree, as well as a useful forage plant.

The Cashaw (*Prosopis juliflora*) is found invaluable in the West Indies in time of drought, and being a hardy tree and easily propagated it should be utilised largely in St. Helena. The pods of this tree possess the nutritious properties of the Carob, to which indeed it is nearly allied; but they require to be gathered soon after they have fallen, and kept in a dry place as after they have begun to germinate, they are highly injurious to cattle.

St. Helena possesses three grasses which are peculiar to it, as I learn from Mr. Hemsley. They are:—*Agrostis simulans*, Hemsl., *Eragrostis saxatilis*, Hemsl., *Demazeria oblitera*, Hemsl. The former was abundant in pastures in the interior of the island, and was also collected by Sir Joseph Hooker and Mr. Melliss; the other two are probably unimportant as forage grasses.

These are the only native grasses in St. Helena, if we except the doubtful existence at the earliest times of the Bahama or Bermuda grass *(Cynodon Dactylon.)* The paucity of spe cies would probably be due to the fact that at one time the island was covered with thick forest with no open spaces suitable for grass. Be that as it may be, it is evident that it is very desirable to supplement the present forage resources of the island; and this can only be done by a more scientific and generous treatment of the grasses now in the island, and the introduction of the valuable trees mentioned above.

Oranges, Limes, Citrons, and Lemons.—Of this class of fruits St. Helena is practically destitute. It is true that a few orange trees grow in Jamestown; and, occasionally, a few limes and lemons are produced in Rupert's Valley. But any of these fruits produced in the island are looked upon as local curiosities, and as much as a shilling each is asked for them.

Mr. Melliss, speaking of the lemon, remarks:—"Formerly "the island was quite a lemon garden, producing fruit in "perfection, but now visitors and mariners after long sea "voyages look for them in vain. The trees growing old, "their roots penetrated through the upper soil to the rock, "and no new ones were planted, so that about 10 years ago "lemons became a scarce article. The tree once grew "plentifully in such places as Lemon Valley, Lemon Tree "Gut, &c., where now scarcely a vestige of one is to be "seen."

Speaking of the lime, Mr. Melliss relates the same story, and adds:—"The lime, once so abundant, suffered the same "fate as the lemon, and I doubt if a lime can now be "obtained in the island."

The sweet orange fruits fairly well, but the number of trees is so small that practically the fruit is little known, except as imported from other countries.

The shaddock or pumelow is found in one or two gardens, and appears to produce fine fruit. The citron is represented by one solitary tree in Rupert's Valley.

Most of the Citrus tribe are severely attacked by an *Aphis*, with the subsequent visitation of a *Capnodium* or sooty blight, similar to that which so ruinously attacked the orange trees at Madeira and the Canary Islands. There is also another enemy, possibly a small fly, which produces a knotted, crumpled appearance of the leaves, often attacking the entire foliage of a large tree.

These insects and fungoid blights are no doubt the cause of much of the failure of orange and lemon trees in St. Helena, but they are evidently not answerable for the whole of it. In former times great care was taken with the trees, and they were established under conditions very different with the present. As the old trees died no fresh ones were planted; or, if they were planted, they were not properly supplied with large, deep holes, free from stone and rubble, or with the necessary manure and good dressing.

I believe with proper precautions and management all the members of the Citrus tribe could be grown to a much larger extent than at present. The blights could be kept in check, and if the trees had only a tithe of the manure, wasted in their immediate neighbourhood in Jamestown, they would soon bear abundant crops.

Under this head, as well as in the culture of the finer vegetables, great assistance might be rendered by a well-trained practical gardener accustomed to the management of tropical plants. A large supply of grafted plants of all kinds requires to be placed within reach of the people, and they also require to be shown experimentally the results of scientific and careful culture.

Grape Vine.—Owing to the introduction of an insect from the Cape during the last 10 years, the grape vines in St. Helena have been almost entirely destroyed. The exact nature and habits of the insect should be investigated, and specimens should be sent to England for the purpose. On all sides I heard lamentations over the loss of grape vines which had grown splendid grapes for nearly half a century. To resucitate vine culture fresh kinds, and especially hardy American vines, should be introduced. It is quite possible that the worse attacks of the grape insect are over, and under these circumstances the culture might be resumed.

The Peaches have suffered equally with the grape vine from the ravages of insects during the last few years; and at present the fruit, once so common, is becoming rather rare. The apricot is present, but does not bear.

The Loquat is a plentiful and highly esteemed fruit.

The Date Palm grows well and bears abundantly in Jamestown Valley. One kind, called Bussorah date, without a hard kernel, is particularly good.

Of other fruits produced in the Island there are guavas, the common red and pear-shaped; the mango, a few trees only; the tamarind, two or three trees of an inferior kind; the rose-apple, a few trees; the pomegranate, plentiful and good; the granadilla and sweet-cup, rare; the papaw, a few plants only; the fig, fairly common; the mulberry, common; the avocado pear, rare; the Cape gooseberry, common; the raspberry and blackberry, common; the cherimoyer, a fine and delicious fruit, rather common; the strawberry, rare; the Otaheite gooseberry (*Cicca disticha*), rare, the Chinese gooseberry (*Averrhoa Carambola*), rare; Kei-apple (*Aberia Caffra*), somewhat common; the country walnut (*Aleurites triloba*), rare; the prckly pear, abundant; the Indian almond (*Terminalia Cattapa*), common; the sea-side grape (*Coccoloba uvifera*), rare, and the Barbadoes gooseberry (*Pereskia Bleo*), rare.

Pineapples.—It would appear that pineapple, the finest of tropical fruits, are only moderately successful in St. Helena. They are probably cultivated at too great an elevation, and in soil of too claycy a character.

Pineapples prefer a fine, light, sandy soil, thoroughly well drained. No animal manure should be applied to them, but the rich, black earth from the forest, or what is known in England as fibrous loam, is the best dressing for them.

New varieties should be introduced to the island; and, with proper treatment, the Jamestown Valley might raise pineapples of the finest kinds.

I append here some remarks on pineapples, from one of my reports:—

"The soil should be a fine, gravelly loam, free from clay, and perfectly drained. The plants, consisting of suckers from elder plants, may be put out at about 3½ feet apart, care being taken to keep them free from weeds, and give the land, in dry weather, a dressing of decayed leaf-mould or rotten turf; animal manure, unless very old and, in fact, reduced to black earth, is not suitable for pineapples, and should be carefully avoided.

"In rather moist lands pines may be planted in ridges with drains between, but in hot, dry soils, after a preparatory trenching of the whole surface, pines may be planted on level land.

"The best kinds to cultivate for export are the Black Antigua, Black Jamaica or Cow-boy, Ripley, Charlotte Rothschild, Smooth Cayenne, Scarlet or Cuban Pine, and British Queen."

Tea.—There are one or two tea plants in the island, but they are so poor and miserable that, judging from their age and appearance, tea is not likely to be successfully cultivated in St. Helena.

Roccella tinctoria.—This lichen or dye-weed, known as orchella weed or orchil, is very common on the exposed rocks of High Knoll, Ladder Hill, Rupert's Hill, and Sugar Loaf. It is an article of commerce in Ceylon and India, and much esteemed in England as affording a fine blue or purplish dye. If on investigation it is abundant in other parts of the island, it might be usefully collected and form an article of export.

Vanilla.—This valuable spice plant is being tried on a small scale, but the results so far are not satisfactory, owing chiefly to a want of knowledge of the requirements of the plant, and the proper methods for artificially fertilizing the flowers. The plants require warm *and well sheltered situations*, very moist, rich soil, and plenty of shade.

Vanilla is a valuable spice, which in some countries, as in the Isle of Bourbon, where it has been successfully introduced and cultivated, forms a valuable article of export. Well-cured vanilla-pods fetch as much as 30*s.* per pound. The following directions for establishing vanilla from cuttings, and curing the pods, have been lately published by tho Botanical Department, Jamaica, and I quote them as applicable in every respect to the circumstances of St. Helena.

"*Vanilla.*—This is a vigorous soft-stemmed plant, tho cured fruits of which are the valuable vanilla beans of commerce. If cuttings are taken, their upper end or the portion to appear above ground may be readily determined by examination of the base of the attached leaf, in the axil or upper face of which is a small growth bud.

"Cut the stem with, say, three or four joints, at one-fourth of an inch below the bassal node or joint, then place the base of each cutting shallowly in prepared soil, agiust the bole or trunk of a rough-barked, low branching tree, as, for instance, calabash; or on a low-trellised frame 3 to 4 feet high, the supports of which should be unbarked logwood, yoke or calabash.

"If tho insect which fertilises the flowers of this orchid, in its natural habitat, is not present, in order to securo a crop of fruit it is necessary that the flowers should be artificially fertilised. This may be easily accomplished as follows:—

"In the flower is a central white column, at the summit of which is a detachable cap or anther, which if touched on the lower front edge with a sharpened pencil or knife blade will adhere to the implement. The pollen masses contained in the anther must then be made to lightly touch the viscous (sticky) disk situated on the front of the column. Each flower must be so treated at or about noon of the day on which it opens.

"To cure vanilla beans gather when full; steep for about two minutes io boiling water and place in flannel to dry in the sun. When perfectly dry place them next day on plates of iron or tin, anointing once or twice with sweet oil, to keep them soft and plump. Complete the curing process by exposing them carefully in the sun for several days. When quite cured they should have a uniformly rich brown colour, and the full fragrance of this valuable product."

Olives.—Fine trees of the true olive (*Olea europæa*) grow in the neighbourhood of the Briars (the residence of the Honourable George Moss), and at certain times they are loaded with fruit. Extensive areas at similar elevation might be placed under cultivation in olives which are admirably adapted to the circumstances of the island. The best varieties of olives are grafted, and if a few plants of the finest and largest Spanish olives were introduced, grafts from these might be established on seedlings raised in the island. I have no doubt that green olives of fine quality might be grown in St. Helena, and from the present trees as they stand large quantities of oil might be prepared.

For further information respecting the cultivation I am indebted to Mr. W. T. Thiselton Dyer, C.M.G., for the following extract from an article on "The Vine and Olive in Siena," in the *Journal of the Society of Arts.* for October 19, 1883, pp. 1005-6.

The olive is cultivated on the hills. In some places it is grown in plantations, and in others the trees are generally planted in rows along the fields, in combination with other cultures. The varieties most generally grown are the *correggiolo*, the *moraiolo* which ripens early, and the *olivastro.* The trees are grown from slips cut in the spring, which are planted in holes in ground that has been well broken up aud covered with mould, and watered as required. The hardiest shoot is subsequently selected and may be permanently planted in three years. The olive is also raised from seed. In the districts of Siena, when a tree is about to be cut down, the *uovoli*, or eyes, on the roots are detached, and placed in a separate plot of ground, plants being obtained from them in three years, which can then be transplanted. In the wooded districts where the wild olive is plentiful, grafting is commonly employed. The trees are usually planted in holes or ditches of more than two yards square, and a yard deep, drained with a layer of stones. When the olives are planted in rows in the fields, they are generally pruned *a paneira*, nearly all the inner branchos being cut away from the centre to enable air and light to penetrate freely. The trees are pruned every two or three years. The most careful cultivators apply a special manure when the trees are between five and eight years old, composed of straw mixed with woollen rags, the whole saturated and moistened with sewage, but this is not general, as the trees profit by the manure laid on the fields. It is estimated that in tho Province of Siena, one acre of vines will produce 115 gallons of wine, and an acre of olives, 20 gallons of oil; the quantity of the former actually produced in 1882 amounting to 10,898,000 gallons, and of the latter 780,000 gallons.

Cork.—The cork oak grows so freely near Plantation, at Oakbank, Terrace Knoll, and other places that it may be said to be naturalised in the island. The bark, so far as I am aware, has never been utilised or its value tested in the English market. If the seed, produced so abundantly, were sown on waste banks and ridges, the timber at least would be very valuable, and an opportunity would be offered for placing the cork in the market for experimental trial.

Flower Cultivation for extracting Perfume.—The luxuriant manner in which many garden plants, such as *Gardenia* and others, flourish in the island has suggested the possibility of cultivating them for the sake of extracting their perfume. The difficulty hitherto has been to obtain a simple and inexpensive apparatus, by means of which the perfume can be extracted. From inquiries made, after my return to London, I believe, provided a sufficient quantity of flowers can be obtained, an apparatus designed and supplied by the firm of Eugene Rimmel would fully answer the purpose.

Arrowroot.—The cultivation of tho arrowroot plant (*Maranta arundinacea*) should be largely undertaken, as it would flourish in most gardens with very little care or attention. Arrowroot is a pure nutritious starch obtained from the roots of the plants when about 12 months' old. The starch is extracted from the tubers, by reducing them to a pulp in water, straining, allowing the fecula or meal to subside, again washing it, and ultimately allowing it to dry.

Turmeric.—This is a medicinal and tinctorial substance obtained from the root of *curcuma longa*, an East Indian plant belonging to the same family as ginger. The powdered root forms one of the ingredients in the preparation of Indian curry-stuff or curry powder, to which it imparts its yellowish hue. This plant might be cultivated under similar circumstances to arrowroot; and if not already in the island—a plant of it was supposed to be at Oakbank, but I failed to find it—it might be obtained through the Royal Gardens, Kew.

Oil Plants.—Among the numerous class of oil plants for which the island is adapted mention might be made of the gingelly-oil plants (*Sesamum orientale*), which is already cultivated to a small extent among the settlers; pindar-nuts (*Arachis hypogæa*), a productive plant in light sandy soils; croton-oil tree (*Croton Tiglium*), a common East India plant; castor oil plant (*Ricinus communis*), already a common weed near cultivated areas; physic nut (*Jatropha Curcas*), which yields a valuable medicinal oil; the African oil-palm (*Elæis guineensis*); the butter tree (*Bassia butyracea*), a native of Bengal; and the horse-radish tree, or oil of Ben tree (*Moringa pterygosperma*), a very free-growing and hardy tree, common in the West Indies.

Bird Pepper.—which is the source of the Cayenne pepper of commerce, should be cultivated in dry, hot neighbourhoods, especially in Jamestown and Rupert's Valley. It is a cultivation suitable for elderly people, and those unable to undertake much bodily fatigue; but if the pepper is prepared carefully and successfully, there is a very fair demand for it at good prices.

Bananas.—This fine tropical fruit is grown to a small extent, but owing to the destructive influences of wind they do not bear so abundantly as they should. The small Chinese banana (*Musa Cavendishii*) is admirably adapted for cultivation in St. Helena, but with the exception of one or two plants it does not appear to have been largely tried. Being a small plant, seldom more than 5 to 6 feet high, it would grow well under shelter of a wall or side of a house; and under these circumstances it would be more satisfactory to grow than the taller kinds.

Plantains.—This highly esteemad vegetable rather than fruit appears to be absent in St. Helena. At least no plants came under my notice. As a food plant it stands high in most tropical countries, and is very easy of cultivation. Suckers might no doubt be obtained from the West Coast of Africa in large quantities. It would require shelter, and a moist and somewhat rich soil. The latter conditions are easily attained in Jamestown, at least by means of irrigation.

Vegetables.—Of ordinary table vegetables there is a fair supply. Potatoes, cabbages of good quality, pumpkins in five or six varieties, onions, shallots, beans, peas, cucumbers, parsnips, carrots, beetroot, chillies, are all grown more or less, and flourish best in sheltered spots at mid-elevation.

What is called in St. Helena Yam (*Colocasis esculenta*), to be distinguished from the "Yam Flower," (*Richardia*), is only slightly cultivated, whereas the "Coast Yam" (*Dioscorea*), has almost entirely disappeared.

For the shipping, lettuce, radish, and water-cress appear to be receiving chief attention.

The Cassava plant (*Manihot utilissima*) is not present, although its cultivation might be attended with great success,

The Chiote or Chocho, the Pepinella of Maderia (*Sechium edule*), is a hardy vegetable, somewhat resembling the vegetable marrow, which should certainly be introdnced to St. Helena. In the West Indies it is reckoned extremely wholesome, and is commonly used as an article of food by all classes. The plant is propagated by seed, and when once established becomes a hardy self-sown climber, bearing nearly all the year round a fruit larger than a pear covered with soft prickles. It is boiled (or parboiled and fried) and eaten as a vegetable.

I noticed that pumpkins, vegetable marrows, cucumbers, melons, and all plants of this class were severely attacked by a fungus (*Erysiphe*) which covered them with a whitish floury deposit as if they had been powdered over with lime dust. This or a very closely allied disease also attacks peas, cabbages, roses, and other plants. The best treatment for this disease is the application of flowers of sulphur dusted over the plants immediately it appears.

Where the disease has taken firm hold of plants in a garden, the better plan is to burn them at once, and so destroy the spores, which would otherwise remain in the land and attack the plants of the next season.

Pumpkins, vegetable marrows, and melons should never be planted in old garden soil. These plants require freshly broken ground away from other cultivation, but it is not necessary that the land should be very rich or heavily manured. It is said that too rich a soil as a tendency to produce a large proportion of male—and hence barren flowers.

A native vegetable much resembling celery is found growing wild on Diana's Peak, which formerly was sold and eagerly bought in the market at Jamestown. This is the Angelica (*Sium Helenium*, Hook. f.), a handsome umbelliferons plant, growing to the height of six or eight feet amongst the cabbage trees and ferns on the central ridge. The inner portions of the stem, which is of a tender succulent character, may be eaten raw, and form an excellent substitute for celery. The native people eagerly eat it. As brought to market it is in short tubes, much like bamboo stems, and is sold under the name of jelico.

A plant growing in one of the economic houses at the Royal Gardens, Kew, shows that it might be easily cultivated if necessary.

Potatoes.—This is probably the staple production of the farmers and small cultivators in St. Helena, and if there were a convenient and abundant market, potato-raising might become the source of a considerable export trade.

Some time ago St. Helena potatoes were exported to the Cape and found great favour there. Owing, however, to the restrictions attending the introduction of the phylloxera, all vegetable prodnce, and even potatoes, are placed under a ban, so that the trade from St. Helena is hopelessly cut off. Potatoes are sold in fair quantities to the shipping and to supply local demands, but there is no incentive to grow such large quantities as the island could produce, as cultivators have often seriously lost thereby.

The potato disease (*Peronospora*), so well known in England, is at times very severe on lands at the higher elevations, but if the soil were more kindly treated and new stock introduced from England from time to time, this disease would not probably be severely felt.

I was informed that as many as three crops per annum of potatoes have been off the same land; as the use of manure is the exception and not the rule, and as some soils have been under continuous cultivation for the last two hundred years, it speaks well for the inherent quality of St. Helena soils that they are still yielding large, and where properly treated, abundant crops.

Hops.—While on a visit to Mulberry Gut, in the neighbourhood of Longwood, it occurred to me that in such sheltered, rich hollows as this hops might be cultivated with success. I discussed the subject with many of the cultivators, and the impression was that hops would do well in St. Helena. Plants might be obtained either from England or America. The cultivation, like tobacco, inasmuch as it yields a large return on a small acreage, is well worthy of attention.

Cotton.—A fine sample of St. Helena cotton was presented to me by Mr. Benjamin Grant, which attracted considerable attention at home. The sample has since been deposited in the Museum of the Royal Gardens, Kew. At present prices, I fear St. Helena cannot grow cotton to compete with other countries, but the subject should not be lost sight of in case the plants, growing almost wild, can ba utilized.

Coconuts.—Only a few coconut palms grow in the island, and these chiefly in the Jamestown Valley. Owing to there being no sandy beach, or any sandy hills or banks, along the coast of St. Helena, the coconut palm is unable to obtain the conditions so essential to it. Few, if any, of the plants are in bearing, and owing to the dry, gravelly, and poor quality of the soil, the stems are slender and weak, lacking the robust, luxuriant, habit so marked in the West Indies, and evidently showing is is not at home here. I would recommend a more generous treatment of the plants; plenty of manure being forked in among the roots, and an occasional application of salt water or of the brine out of pickled beef or pork barrels.

Sugar Cane.—A few plants of the ordinary varieties of sugar cane are found in Jamestown, but no attempt is made to cultivate them. For eating purposes many of the newer varieties might be introduced, as also for the purposes of fodder for horses and cattle..

Indian Corn or Maize.—This is cultivated to be cut as a forage plant in the green state, but is seldom grown as an article of food. To many people in countries where maize, either in the green state (cobs), or as meal, enters largely as an article of daily food, it would be a matter of surprise to find that it is hardly known here. Owing to custom and habit the people in St. Helena consume large quantities of rice; in fact, as long as a St. Helenian can procure a little rice to go with his fish he is quite happy. There is no doubt if maize could be substituted for rice as the staple food of the bulk of the inhabitants of St. Helena, the island could easily dispense with the present large importations of rice, and possess within their own resources the chief food supply of the inhabitants. The taste for rice has arisen from the former close connexion of the island with India, and the facilities which then existed for obtaining it by means of homeward bound ships. In case of war and the blockade of the island for any length of time, rice would be practically cut off, but maize if grown locally would be at hand and provide a good food supply for an indefinite period. Both on these grounds and the great adaptability of the soil for growing maize, when it cannot possibly grow a bushel of rice, it might be advantageons to do something to encourage the cultivation of maize in St. Helena, and so bring it prominently before the people.

At the present time oats and maize are imported from the Cape and America for feeding horses, whereas the latter at least might be produced locally in large quantities.

Fisheries.—Fish of all kinds abound in the neighbourhood of St. Helena, and are easily caught. A large industry might be established in fish curing for exportation, if sufficient enterprise were created amongst the inhabitants, and this wonderful resource of so isolated an island rendered conducive to its wealth and prosperity.

The American whalers obtain large supplies of oil within easy reach of St. Helena, while cod and mackerel might be caught in large quantities.

The chief food fishes found in the neighbourhood of St. Helena are:—gurnard, eel, cod, mackerel, tunny or albicore, bullseye, cavalley, flounder, hog-fish, mullet, skulpin; crustaceans, such as stump and crayfish; and the green turtle. The boats and appliances now in use are too small for deep sea fishing, and on this account chiefly many very valuable fish found on the windward side of the island are seldom caught.

Bee Culture.—The honey bee was, I believe, at one time introduced to the island, and it became quite naturalised. According to Melliss "it almost suddenly disappeared about 18 or 20 years since."

As there are so many flowers constantly in bloom, and all the conditions exist for profitable bee farming, I would recommend that bee farming as a regular industry be introduced and encouraged. The export of beeswax and honey from Jamaica, an industry chiefly in the hands of negro settlers, amounts to the annual value of 8,000*l.* per annum.

The Pride of India (*Melia Azedarach*), an Indian tree, now widely distributed all over the world, is one of the commonest objects in the island. About Christmas time it is covered with masses of blue-coloured, sweet-scented blossoms. These are generally succeeded by immense quantities of small spherical yellow coloured fruits, generally considered to possess poisonous qualities.

Although the root is bitter and nauseous and used in North America as an anthelmintic, the tree practically is of little economic value. It must be distinguished from *Melia Azadirachta*, the Neem tree or Margosa, which is a very valuable plant. From the latter a kind of toddy is obtained by tapping; and from the fruit an oil is extracted fit for burning and other domestic purposes.

The Peepul trees of Jamestown (*Ficus religiosa*) are remarkable for their great age and the peculiar contorted and weather-beaten appearance which they have assumed. These trees afford grateful shade in the streets of Jamestown; and it is much to be desired that more of these and other trees be planted on all sides to relieve the monotony of the purplish lava hue which pervades streets, houses, rocks, and everything.

The graveyards and waste lands between the houses and the steep cliffs of lava on both sides of Jamestown Valley might be rendered ornamental and even picturesque if planted with hardy trees and shrubs. The Peepul, two or three other species of *Ficus*, especially the Indiarubber tree (*F. elastica*), the Indian almond (*Terminalia Catappa*), the Caffre date (*Harpephyllum caffrum*), and numerous ornamental aloes would grow admirably in such situations.

The present governor has done a little in this way already, and it is with the view of strengthening his hands in so laudable a work that I draw attention to the subject in this report.

The Caffre date might be largely utilized also to relieve the monotony of the dreary waste at Half-Tree Hollow and Dallas Village, as well as generally on exposed barren spots in the neighbourhood of dwellings.

Amongst the plants of interest in the island I may mention a remarkable fine specimen of the Chili palm (*Jubæa spectabilis*), erroneously called the double coco nut (*Lodoicea sechellarum*) in the local hand-book published by Mr. Grant. This plant grows at Farm Lodge, and attains a height of about 40 feet. The stem at the base measures about 5 feet in circumference, and is crowned at the top with almost a globular mass of fine long pinnated fronds, somewhat resembling the date palm, but, if possible, with a more pronounced glaucous tint.

This palm fruits freely, the nuts being small and spherical, having much the characteristics of miniature coco nuts. Owing to the eagerness with which they are sought, for the sake of the white edible kernel, they appear to have never been sown. At least it is remarkable that, although the palm is well known and a very striking object in the country, not a single plant has been raised from it during the numerous years it has continued to produce seed.

The seed work acacia (*Piptadenia peregrina*, Bth.), is utilised for ornamental purposes. Its seeds are gathered, dyed black by means of copperas, and made into bracelets, brooches, and other ornaments.

The Cape Yew (*Podocarpus elongata*) is one of the handsomest and most successful timber trees in the island. It produces an abundance of seed, which grows freely in all places around the parent trees.

Bamboos in several varieties are established in the island. The handsome *Dendrocalamus giganteus* grows to a large size at Oakbank, where I had the pleasure of finding it in flower.

Sea Bean (*Entada scandens*). I saw several of these large beans which had been washed ashore on the windward side of the island. As the plant is not found at the Cape, it is probable that these seeds had been brought by sea currents all the way from the West Indies or the West Coast of Africa. It is said that these sea waifs have germinated in St. Helena and produced one or two fine plants. At present, however, I believe there is no plant existing.

APENDIX I.

Owen's College, Manchester,
November 16, 1883.

My Lord,—I have the honour to reply to the letter of Sir Robert Herbert's of November 7th with reference to samples of pyrolusite collected by Mr. Morris in St. Helena, requesting report and analyses.

Sample 1. (St. Helena manganese, soft, found in clay beds.)

Percentage of manganese dioxide, 35·41.

Sample 2. (St. Helena manganese, hard, found in clinker.)

Percentage of manganese dioxide, 63·19.

The value of manganese ore at the present moment is 70*s.* (3*l.* 10*s.*) per ton, delivered at Liverpool or Garston, for an ore containing 70 per cent of manganese dioxide. For poorer ores a deduction of 2*s.* 6*d.* for every degree or percentage is made. It thus appears that the material No. 1 is worthless, whilst No. 2 would be worth 52*s* 6*d.* per ton delivered.

Manufacturers of chlorine, the chief employers of this ore, rarely buy any manganese so low as 63 per cent.

Your Lordship will therefore see that should the cost of getting and transport amount to anything approaching the figures given by Mr. Morris, any economic use of the St. Helena pyrolusite is out of the question.

I have, &c.

(Signed) H. E. Roscoe.

To the Earl of Derby,
Colonial Office.

APPENDIX II.

Report on Three Samples of Earths from St. Helena submitted to me for Chemical Analysis.

The three samples submitted to me were numbered I., II., and III. respectively.

No. I.—This is a specimen of fibrous arragonite or carbonate of lime, containing 92 per cent of carbonate of lime, 1·1 per cent moisture, 3·50 per cent silica, and 2·3 per cent alumina. This, when burnt in kilns, would form quicklime, which, when slaked, is very useful for field purposes, and increases the production of crops in a high degree.

Nos. II. and III. are both specimens of gypsum, the former containing 20·62 per cent water and 79·38 per cent sulphate of lime, and the latter 21·3 per cent water and the rest sulphate of lime, they are therefore pure minerals. Quicklime cannot be obtained from this by burning, but it can be used directly as manure in the fields, and is very useful when judiciously employed.

(Signed) B. H. H. Hooker.

Royal School of Mines,
South Kensington, S.W.

ROYAL GARDENS, KEW: OFFICIAL GUIDE TO THE MUSEUMS OF ECONOMIC BOTANY.

No. 1.—DICOTYLEDONS AND GYMNOSPERMS.

From this publication we quote as follows:—

The collections occupy three separate buildings within the Royal Botanic Gardens.

Museum No. I. overlooks the Ornamental Water, and is directly opposite to the Palm-Stove.

Museum No. II. is at the northern end of the Herbaceous ground, three minutes' walk from No. I. Its direction is shown by a finger-post standing by the entrance of the latter.

Museum No. III., devoted chiefly to specimens of Timber and large articles unsuited for exhibition in the glazed cases of the other Museums, occupies the building formerly known as the "Orangery," at the north extremity of the Broad Walk leading to the Ornamental Water and Palm-Stove.

THE OBJECT OF THE MUSEUMS is to show the practical applications of Botanical Science. They teach us to appreciate the general relations of the Vegetable World to man. We learn from them the sources of the innumerable products furnished by the Vegetable Kingdom for our use and convenience, whether as articles of food, of construction and application in the arts, of medicine, or curiosity. They suggest new channels for our industry; they show us the variety in form and structure presented by plants, and are a means of direct instruction in most important branches of useful knowledge. We see from them the particular points upon which further information is needed, especially as to the origin of many valuable timbers, fibres, and drugs, in order to perfect our knowledge of economic botany; in brief, the Museums show us *how little*, as well as *how much*, we know of the extent to which herbs, shrubs, and trees contribute to our necessities, comforts, and numberless requirements.

ORIGIN OF THE MUSEUM.

The foundation and progress of these collections, not only by far the most extensive in existence, but the first of their kind established, may be briefly traced since the conception of their plan by the late Director of the Royal Gardens, Sir W. J. Hooker.

In 1847 the building now occupied by Museum No. II., which up to that year had been in use as a fruit storehouse, &c., was added, by command of Her Majesty, to the Botanic Garden proper. Permission was immediately sought by the Director to have one room of this building fitted up with suitable cases for the exhibition of vegetable products—objects which neither the living plants of the Garden nor the preserved specimens of the Herbarium could show. Sir W. J. Hooker's request was liberally met by the Chief Commissioner of Her Majesty's Woods and Forests, and the Museum was forthwith commenced; its nucleus consisting of the Director's private collection, presented by himself.

No sooner was the establishment and aim of the Museum generally made known, than contributions to it poured in from all quarters of the globe, until, in a few years, the ten rooms of the building, with its passages and corners, were absolutely crammed with specimens. Its appreciation by the public being thus demonstrated, application was made to Parliament for a grant to defray the expense of an additional building for the proper accomodation of the objects, and the house occupied by Museum No. I., opened to the public in the spring of 1857, is the result.

In 1881 the extension of Museum No. I. on the west side, containing a new and commodious staircase, was erected at a cost of £2,000, met by a grant from the India Office, in order to supply the additional accommodation required for the Indian collections mentioned below.

From the Exhibitions of 1851 and 1862, and from the Paris Exhibitions of 1855 and 1867, large additions were made to the Museums, both by the presentation of specimens, and also by their purchase, aided by grants from the Treasury and Board of Trade. Many eminent firms engaged in the importation and manufacture of vegetable substances, have most liberally contributed various illustrative series. By the different Government Departments, by our Colonial officers and foreign Representatives, and by numerous private travellers also, the most important esrvices have been and continue to be rendered.

Besides these sources of contribution must be mentioned the reinforcement of the Indian element in the Museum, first in 1878 by the collection of forest produce, presented by the Government of India (consisting of 1,113 specimens), and secondly in 1880 by the transference to Kew of the entire Economico-botanical collections, forming part of the India Museum at South Kensington. From these about 4,000 specimens were selected for permanent exhibition; these are distinguished by a light blue label bearing the words India Museum.

On the staircase, at the first landing, has been placed the stained glass window in four lights, removed from the Guildhall, and presented to the Royal Gardens in 1878 by Alderman W. J. R. Cotton, M.P. It represents the growth and manufacture of cotton.

THE ARRANGEMENT OF THE OBJECTS.

The specimens exhibited in Museums No. I. and No. II. are arranged in the order of what is termed the natural affinities of the plants which respectively furnish them. They are grouped under NATURAL ORDERS. These are, in some cases, very large, in others comparatively small. Some abound in economic products while others afford but few.

Between the members of each Order the rule is, that a closer relationship subsists than with the members of any other Order. This relationship or affinity amongst plants is based upon the amount of similarity, chiefly in the form and arrangement of the parts of their flowers and seeds; and the correctness of this method is confirmed by a remarkable general and corresponding uniformity in the character of the products and properties of the plants thus brought together. For example, note the tough, fibrous BARKS of the "Nettle" Order, of the "Mezereon" Order, and of the "Linden" and "Mallow" Orders;—the BITTER or TONIC properties of the "Gentian" Order, and of the "Quassia" and "Peruvian Bark" Orders;—the RESINS of the "Amyris" or "Frankincense" and of the "Pine" Orders;—the NARCOTIC or POISONOUS character of the "Nightshade" Order, which includes the Deadly Nightshade, Henbane, and Tobacco.

In dividing the extesive arranged collections between the two Museum buildings, advantage has been taken of the two grand Classes under which the Orders of flowering plants are to be grouped in nature. One of these great Classes occupies Museum No. I. The other Class, together with all the products, &c., yielded by those plants which are commonly regarded as *not* bearing flowers (as Mosses, Ferns, Seaweeds, Lichens, and Fungi), are contained in Museum No. II.

The same details of arrangement obtain through both Museums. The upright cases are numbered *outside*, above the glass doors: the numbers correspond to those on the margin of this Guide. The botanical name of each Natural Order is exhibited *inside*, at the top of the cases; also, wherever an Order *begins*, if on a lower shelf. A brief note on each Order is given in this Guide, preceding the enumeration of the noteworthy objects belonging to it.

To simplify and facilitate reference, every object of great importance enumerated bears, upon a card, mounted *close by* it, a conspicuous corresponding number [*e.g.*, 26]. One numbering runs through the whole of each Museum.

The proportion of *numbered objects* is very small to the whole; this is a necessity which a handy guide-book, intended for visitors rather than students, imposes. As nearly every object is properly labelled, the deficiency is rather apparent than real. This Guide is not intended to supplant a system of copious instructional labelling, which is being constantly improved upon, and printed labels substituted for those written by hand. Any suggestion bearing upon these, or hints respecting our deficiencies, those who have the charge of this important branch of the Kew establishment will be most happy to receive. Such should be addressed in writing, to the Curator of the Museums, or to the Director of the Royal Gardens.

MAPS are placed in the cases, showing in red colour the countries furnishing the products near which they are placed.

Then follow the catalogues.

We quote a few descriptions:—

No. 8. ACONITE, MONKSHOOD, OR WOLFSBANE (*Aconitum Napellus*, L.). A perennial herb, with short fleshy rootstock, common throughout Europe, temperate and sub-Arctic Asia, and North America. The rootstocks are collected chiefly from wild plants, and used for medicinal purposes to allay pain or in rheumatic affections. It is a very virulent poison; deaths have occurred through mistaking Aconite root for Horseradish. A little care, however, might obviate this; the Aconite has a short dark coloured tapering root, from which numerous rootlets are given off; the Horseradish is much longer, of more uniform thickness throughout, of a yellowish colour, and without root fibres.

The rootstocks of *Aconitum ferox*, Wall. and other species furnish the Bish poison of India, used for poisoning the arrows in tiger traps. &c. A tiger trap of bamboo from Sikkim Terai is exhibited. Note also sheep muzzle from Sikkim made of split bamboo; when the shepherds take their flocks across the district where Aconite grows, they halt and a muzzle is made for each sheep to prevent it from becoming poisoned.

No. 21. FALSE CALUMBA (*Coscinium fenestratum*, Colebr.). A climber, native of the forests of Ceylon, Malacca, and Malabar. Wood bright greenish yellow, strongly marked in cross section by broad medullary rays; it is bitter. and has been used as a tonic.

No. 22. CALUMBA or COLOMBO ROOT (*Jateorrhiza Calumba*, Miers). A perennial climber with a short rootstock and numerous fleshy fusiform roots. It grows in the forests of Mozambique and Quillimane. Calumba root of commerce consists of the sliced and dried roots, and is shipped to this country either from Zanzibar direct, or by way of Bombay. It has a bitter taste, and is a mild tonic.

No. 27. LOTUS (*Nelumbium speciosum*, Willd.). Regarded by the early Egyptians, and by the Buddhists and Hindoos of the present day as an emblem of peculiar sanctity. Observe the seeds, or more properly fruits, imbedded in the dry top-shaped receptacle. These are believed to have been the "sacred beans" of Pythagoras. The seeds and stem, which contain much starch, are used as food in India and China.

No. 44. ARNATTO. An orange or yellow dye for silks, and for staining cheese; exported chiefly from South America and to the United States from the West Indies. It is prepared from the red coloured pulp which covers the seeds of *Bixa Orellana*, L. Dried specimens of the plant are also here shown having the red seeds still attached to the inside of the fruit capsules.

No. 54. Bark and young wood of the CEYLON GAMBOGE tree (*Garcinia Morella*, Desr.), showing the coloured juice which has exuded and dried upon the cut edge. In Ceylon Gamboge is obtained by incisions in the bark, or by cutting out pieces of it; the juice oozing from the wounds hardens on exposure, and is scraped off.

Observe wood, fruits, seeds, and oil of *Camellia Sasanqua*, Thb., a native of China and Japan, where the oil is used for a variety of domestic purposes. The dried leaves are fragrant, and are said to be used to mix with tea.

The most important member of the order is the TEA PLANT (*Camellia Thea*, Link.). It is a native of Assam, and probably China, though in the latter country so famed for its production, it is only known under cultivation. Black or green teas are prepared from the same plant by peculiar methods of drying or curing; the leaves made up into *green* being more rapidly dried, and not permitted to remain in a moist and flaccid state so long as those intended for *black* tea. Note a very fine series of Indian teas, now largely used in this country. Upwards of 165,079,881 pounds of tea were entered for home consumption in 1882, the total import exceeding 211,080,000 of which 53,927,998 pounds were from British India.

No. 59. A box of ingredients as used in China in the artificial colouring of lower kinds of green tea.

No. 60. Brick Tea of Tibet, pressed and dried in moulds. It is largely used in Central Asia, boiled with salt, butter, &c. Observe the "wheatsheaf," "lozenge," and other sorts of tea.

Upon the adjoining wall are hung Chinese drawings, upon rice paper, representing the history of the Tea-plant from its first introduction in fabulous times to human notice by a monkey, to the packing and exportation of the present period.

No. 65. ROSELLE (*Hibiscus Sabdariffa*, L.). An annual, cultivated largely in India, Ceylon, and the tropics generally, for the sake of the fleshy calyx and fruit, which are made into preserve, and also for the fibre.

H. cannabinus, L., and other species of *Hibiscus* yield useful fibres.

No. 66. OCHRO or GOMBO (*Hibiscus esculentus*, L.). An annual, largely cultivated in tropical countries as well as in the Mediterranean region. for the sake of the fruits, which vary in length from three to eight inches, and are used in a green state as an article of food and for thickening soups. Gombo soup is the characteristic dish of the Southern United States.

No. 67. CUBA BAST, the inner bark of the Mahoe (*Hibiscus elatus*, Sw.), a West Indian tree, formerly used for tying plants in gardens, as well as for tying up bundles of cigars.

In this case note fibre, fruits, flowers, and gum of *Thespesia populnea*, Corr., a small tree of India, Ceylon, Pacific Islands, Africa, &c. The fibre from the inner bark is said to be used in Demerara for making coffee bags. The wood is hard and durable.

A cotton plant, mounted specimens of cotton pods from China, Assam, Brazil, and Cuba, and a collection of Indian Cotton in various stages of manufacture, are shown in special cases near Case 5.

No. 68. COTTON consists of the delicate, tubular, hair-like cells which clothe the seeds; its commercial value depends on the length and tenacity of these hairs. The species yielding the cotton of commerce are *Gossypium barbadense*, L., known as Sea Island Cotton, *G. herbaceum*, L. and *G. arboreum*, L.; numerous varieties of these species are known. The Kidney, Peruvian, Brazil and Bahia Cotton of commerce are all produced by varieties of *G. barbadense*. Nankin Cotton is a naturally coloured variety. A portion of this case is devoted to the different sorts of commercial cotton, grown in the United States, South America, India, Africa, and the warmer parts of Europe; also to specimens of Cotton cloths in various stages of manufacture both by civilised and barbarous nations. The total imports of raw cotton amounted in 1882 to 15,794,566 cwt.

The use of Cotton dates from a very early period. Sanscrit records carry it back at least 2,600 years, while in Peruvian sepulchres cotton cloth and seeds have been found. No. 69 is a piece of cotton cloth from a Peruvian mummy.

No. 70. Oil, and oil cake for feeding cattle, from the waste seeds of the cotton plant.

Exhibited in this case is a tinder box and matches with tinder of burnt cotton rag. Such were in universal use throughout England before the invention of lucifers.

TRIBE IV. BOMBACEÆ. SILK COTTON TREES. They are nearly all tropical. some of immense size, as the Boabab (*Adansonia digitata*, L.), of Western Africa. The bark has been introduced for making paper, of which specimens are exhibited.

No. 71 is a portion of a small branch of the BAOBAB, together with fine specimens of the gourd-like fruit, which contains an eatable acid pulp. Trunks have been measured 30 feet in diameter. The wood is light, soft, and of little use.

Adansonia Gregorii, F. Muell. is the AUSTRALIAN BAOBAB or Gouty Stem tree.

Observe specimens of SILK COTTON, the silky covering of the seeds of *Bombax malabaricum*, DC. A large soft wooded tree of India, Borma, Java, &c. Ropes are made from its fibrous bark, and a gum called Mucherus is also furnished by the tree.

No. 72. SILK COTTON surrounding the seeds of *Eriodendron anfractuosum*, DC., of the tropics of the old and new world. Used for stuffing cushions, and the like, but not suited to work into cloth-fabrics. Another beautiful "Silk-cotton" (West Indian), from *Ochroma Lagopus* Sw., is exhibited on an adjoining shelf, with a nest of the "Doctor Humming-bird" made from it.

The bast from *Caranillesia platanifolia* H.B.K. is exhibited in this case.

No. 74. KOLA NUTS, the seeds of a Tropical African tree naturalized in Jamaica (*Cola acuminata*, R. Br.). Kola nuts are said to possess the virtue of rendering putrid water agreeable to the taste. They are chiefly used, however, for satisfying the craving of hunger and enabling those who eat them to endure prolonged labour without fatigue. From recent chemical investigation the Kola nut has been found to contain more caffeine in an uncombined state than the best samples of coffee, also theobromine.

No. 75. COCOA or CHOCOLATE (*Theobroma Cacao*, L.). A moderate sized tree of Central and South America, cultivated to a large extent throughout the tropics of both hemispheres, particularly in the West Indies, the chief places being Trinidad, Venezuela, and New Grenada, and latterly Ceylon and Jamaica. There are many varieties of this plant distinguished by the size and shape of the fruit and the quality of the seeds, of which each fruit contains a number very closely packed in pulp. These, after being fermented, rubbed and cured, constitute COCOA; if merely broken up COCOA NIBS; mixed with starch and very finely ground, SOLUBLE COCOA of the shops. CHOCOLATE consists of the same, made up into a paste and flavoured. A collection of specimens of cocoa from various countries, with its different preparations, by Messrs. Fry & Sons, is here exhibited. In 1882 over 18,990,000 pounds of Cocoa were imported into Great Britain, more than 11,996,000 pounds being entered for home consumption.

Illustrations of the fibrous character of many Indian species of the order are exhibited in this case, including *Abroma augusta*, L., *Guazuma tomentosa*, Kunth, &c.

No. 85. A bundle of the dried leaves of the COCA (*Erythroxylon Coca*, Lam.), the masticatory of the Andes and Peru. The Coca-bush is extensively cultivated by the Indians; the annual producing having been estimated at 30,000,000 pounds. The leaves are either infused as tea, or, as is usual, chewed with a little unslacked lime. The immediate effect is a gentle excitement, with sensations of high enjoyment. Its use lessens the desire for food, and enables the chewer to undergo an enormous amount of fatigue, from an increased nervous energy.

Observe the "*popona*," or lime-flask of the Indian coca-chewer, also "*Impadu*," the powdered leaf, mixed with a little tapioca, the ashes of Quinoa, *Cecropia*, &c.

["Coca" must be distinguished from "Cocoa" of the shops, the produce of *Theobroma Cocoa*, see Case 13]; from the Coco plum, see Case 42; and from the Cocoa Nut Palm (*Cocos nucifera*, L.).

QUASSIA ORDER (*Simarubeæ*). Trees or shrubs, growing mainly in the tropical parts of America and Africa, distinguished by an intense bitterness. Some species are employed medicinally as tonics.

No. 104. SURINAM QUASSIA WOOD (*Quassia amara*, L.) and cups made from same. This wood is the "Original "Quassia of the Materia Medica and the one upon which the "reputation of Quassia as a medicine was established, but as "the tree yielding it was of small size the demand for it soon "exceeded the supply," and it is now unknown in British medicine.

No. 113. NEEM or MARGOSA (*Melia Azadirachta*, L.). A large tree found throughout the greater part of India and Burma. It is held sacred by the Hindus, and idols are made of the wood, which is also used for furniture, ship building, &c. The bark is bitter and is a febrifuge. The leaves are used for poultices, and the clear amber coloured gum is considered stimulant. From the pulp of the fruit is expressed a yellow coloured fixed oil, which is bitter and acrid, and used both for burning and in medicine.

Note flowers of *Aglaia odorata*, Lour., used by the Chinese for scenting tea. Also edible fruit of the LANSA or LANGSAT (*Lansium domesticum*, Jack.) of the Malay islands.

No. 114. CARAPA or CRAB OIL, obtained from the seeds of *Carapa guianensis*, Aubl.,and used by the natives of British Guiana for burning and also for anointing their bodies.

No. 115. MAHOGANY, the wood of *Swietenia Mahogani*, L., a large forest tree of Central America and Cuba. One of the most valuable of furniture woods. It is stated that a single log lies near the south coast of Cuba, too heavy to carry to a port, measuring 9 ft. broad, 6 ft. high, and 12 ft. in length; supposed weight about 18 tons. It has been there many years, and is likely to remain till it rots. Upwards of 36,000 tons were imported in 1882.

No. 116. Model of a truck, laden with Mahogany, as employed in bringing the logs to the works, from the interior of Honduras.

No. 120. CEDAR WOOD of NEW SOUTH WALES, TOON, of India, (*Cedrela Toona*, Roxb.). A tall handsome tree, found also in Sub-Himalayan forests, Bengal, Burma, South India, &c. The wood is durable and beautifully marked, and is used both in Australia and India for all kinds of furniture, door panels, and ornamental work. The bark is astringent and is used in India as a febrifuge. It yields a resinous gum. The flowers yield a red or yellow dye, and the leaves are used to feed cattle.

[Although called "Cedar," these are totally distinct from the true Cedar (*Cedrus Libani*, Loud.), which belongs to the Pine Order, Case 121.]

No. 121. SATIN WOOD, afforded by an East Indian tree (*Chloroxylon Swietenia*, L.). The wood is durable, close-grained, and will take an excellent polish, preserving a handsome appearance for a long time. Largely used for the backs of hair brushes and for inlaying.

No. 125. "YERBA DE MATE," or PARAGUAY TEA, the leaves of *Ilex paraguayensis*, St. Hil., (and allied species according to Miers): in the province of Paraguay and Brazil cultivated to a great extent. The leaves are scorched and dried, while still attached to the branches brought in by the collectors; they are then beaten, separated, coarsely ground by rude mills, and packed in skins and leathern bags. The leaves are infused in small teapots, of which several forms are here shown, and the tea imbibed either from the spout or by:—

No. 126. a "BOMBILLA," or tube with wire network or perforations at the bottom. The consumption of Maté in South America is enormous; upwards of five millions of pounds, it is said, are annually exported from Paraguay alone. On a lower shelf are exhibited two packages of Paraguay Tea, one inclosed in the skin of the "great ant-eater."

CASHEW-NUT ORDER (*Anacardiaceæ*). Chiefly large tropical trees, often with a resinous or caustic juice; several species bear very valuable fruit. They occur both in the Old and New Continents; some extend into temperate countries, a few reaching the south of Europe. The flowers are usually very small.

No. 151. MANGO (*Mangifera indica*, L.), is a large umbrageous tree cultivated very generally in hot countries, though especially common, under a multitude of varieties, in India. The fruit is most delicious; unripe it is used in tarts, preserves, &c. Fruit and drawings of several varieties are exhibited in this case and in Case 27.

No. 152. CASHEW-NUT. Fruit of *Anacardium occidentale*, L., a tree of Brazil, Central America, and the West Indies. The edible portion is the swollen pear-shaped stalk (peduncle), which supports the nut. The kernel also is eatable when roasted. From the stem a gum exudes, and an oil is obtained from the kernels. Specimens of both are shown.

No. 153. CUDDAPAH ALMONDS. The kernels of *Buchanania latifolia*, Roxb. They resemble pistachio nuts, and are largely used in native sweetmeats; an oil is extracted from them. The fruit has a sweetish acid flavour, and is eaten by the hill tribes in the central provinces. The bark is used for tanning.

MORINGA ORDER (*Moringeæ*). A small family of deciduous soft wooded trees. Natives of Northern Africa, Western Asia, and East Indies.

No. 157. Fruits of the HORSERADISH TREE (*Moringa pterygosperma*, Gært.). Common in many parts of India, and cultivated, as well as in various tropical countries for the sake of the fruits which are eaten as a vegetable or pickled. The seeds yield oil. The root is pungent like horse-radish, and is used in India as a vesicant. The reddish gum, which exudes, is used in native medicine.

Observe seeds without wings, of *Moringa aptera*, Gært., of Abyssinia, Upper Egypt, Syria, and Arabia; it is said to be the source of the true Oil of Ben.

No. 164. INDIGO. Obtained principally from two or three species of *Indigofera* (*I. Anil*, L., *I. tinctoria*, L., &c.), by soaking the plant in large masses in tanks. After its removal, the water is stirred and beaten by paddles, its colour passes to a blue, and the suspended particles settle to the bottom, forming a blue mud, which after the water is drawn off, is dried in the sun and cut up into cakes. Of this valuable dye-stuff, 95,488 cwt. were imported in 1882. Specimens are exhibited from Egypt, Nicaragua, Siam, and East and West Indies. The "blue" of the laundress is prepared from Indigo. Specimens are shown. A colouring matter similar to true indigo is furnished by several other plants, as *Polygonum tinctorium*, Lour. (*See* Case 83), and *Wrightia tinctoria*, R. Br. (*See* Case 73). Artificial indigo has recently been manufactured on the Continent by chemical means.

On the upper shelves in this Case are specimens of the hard wood and seeds of the Umzimbiti tree of South Africa (*Millettia Caffra*, Meisn.)

No. 170. GROUND NUTS. Pods and seeds of *Arachis hypogæa*, L., an annual herb. Remarkable from the plant, after flowering, forcing the young pods underground, where they ripen. Extensively grown in warm climates as an important article of food, and for the sake of its oil which is largely used as a substitute for olive oil, also by perfumers in the preparation of pomades, cold cream, &c., and for soap making, burning in lamps, and by watch makers. Its native country is doubtful; but it is probably of American origin.

On the lower shelves are seeds of Gram or Chick Pea. (*Cicer arietinum*, L.), an annual herb, cultivated from an early period in warm countries, especially in India, where it is used in cakes, curries, &c. It was known to the ancient Egyptians, Hebrews, and Greeks. It contains much acid oxalate of potash.

On the lower shelves are various products of the genus *Cassia*. Amongst them seeds of *C. Tora*, L., an annual weed widely spread in India and the tropics generally. Pods, seeds, and bark of *C. auriculata*, L., a shrub, common in Central and Southern India. The bark is used for tanning and dyeing leather. Negro Coffee, the seeds of *C. occidentalis*, L., used in tropical Africa as well as in Central America and the West Indies as a substitute for coffee.

On the bottom shelf are specimens of the wood of *Cassia siamea*, Lamk, a moderate sized tree of India, Ceylon, the Malay Peninsula, and Siam, the heartwood of which is dark brown, and often beautifully marked. It is used in Burma for walking sticks, mallets, &c.

On the upper shelves of the first compartment of this case is shown the woody pods of *Cassia grandis*, Linn. f., the produce of a tree of Brazil.

No. 193. Pods of the Purging Cassia (*Cassia Fistula*, L.), an ornamental tree, 30 to 50 feet high, bearing numerous racemes of bright yellow flowers. It is a native of India, Ceylon, Java, the Philippines, tropical and sub-tropical Africa, and is frequently planted in the West Indies, Central America, and Brazil. The pods are pendulous, often 2 feet long, cylindrical, and when ripe, of a dark purplish brown. They contain a large number of small seeds, each embedded in pulp of a blackish brown colour, which has a sweetish taste, and is used in medicine as a mild laxative. It is imported from the East and West Indies, but chiefly from the latter. Wood, powdered bark, and gum of this species are also shown.

No. 194. Arabian or Tinnevelly Senna (*Cassia angustifolia*, Vahl). A small shrub of Southern Arabia, Somali Land, Scinde, and the Punjaub. The leaflets, when gathered and dried, form part of the senna of commerce, known as Arabian, Mocha, Bombay, or East Indian Senna. These sorts are exported from Mocha, Aden, and other ports of the Red Sea to Bombay, from whence they are re-exported to Europe and America. They are regarded in commerce as of inferior quality in consequence of their being carelessly dried, and often mixed with portions of legumes, stalks, and flowers. All the Sennas are purgative.

The kind known as Tinnevelly Senna is furnished by the same plant grown in Southern India, and on account of its more luxuriant growth and careful preparation, it is considered in commerce as a fine kind. The best Senna, however, is that next described.*

No. 203. Tamarinds. The pulp of the pods of *Tamarindus indica*, L., imported from India and the West Indian Islands, preserved in sugar. The Tamarind-tree grows to a height of 60 to 80 feet, with a wide spreading head of dense foliage. It is now found in all tropical countries, but Africa is, in all probability, its origin. Cultivated chiefly for its fruits, in warm countries it is often grown as a shade tree or for the fragrance of its flowers. Tamarinds have an agreeable acid taste, and in hot countries are used to make cooling drinks. Dried fruits, gum, and wood of the Tamarind, are exhibited. The latter is very heavy and sinks in water; a table and chair made of it are shown in Museum No. 3.

No. 217. Pods of the Rain Tree (*Calliandra Saman*, Griseb.). Native of West Indies and South America. The name Rain tree is derived from its occasionally in South America distilling moisture to such an extent as to wet the ground beneath. This is described as being caused by "multitudes of cicadas sucking the juices of the tender "young branches and leaves and squirting forth slender "streams of limpid fluid." The pods are sweet, and used for feeding cattle. The plant has been introduced into India and other countries. A photograph of the tree is shown, as well as a specimen of the wood.

Myrobalan Order (*Combretaceæ*). All tropical trees and shrubs, growing in both hemispheres. They are characterized by some degree of astringency.

On an upper shelf note fruits of *Terminala Catappa*, L., from Bombay, Venezuela, Africa, &c., also samples of oil expressed from the seeds.

No. 238. Myrobalans. The fruits of *Terminalia Chebula*, Retz, and *T. bellerica*, Roxb., large deciduous trees common in India, Ceylon, and the Malay Islands. The hard woody fruits of both species are imported in large quantities for the use of tanners. Specimens are exhibited from various parts of the East Indies. Astringent galls are often formed on the twigs of *T. Chebula*, used in India for making ink, as well as for dyeing and tanning. Specimens of these are exhibited; also samples of the hard woods of both species, used for a variety of purposes in India.

In the last compartment are gum, leaves, and wood of *Anogeissus latifolia*, Wall., a large tree common from the Himalaya to Ceylon. The gum is extensively used in cloth printing in India, and the leaves in tanning.

No. 241. Wood of Blue Gum (*Eucalyptus globulus*, Lab.), of Tasmania and South-east Australia. One of the largest known trees, occasionally reaching a height of over 300 feet, and of remarkably rapid growth. It has become familiar of late years, having been introduced and cultivated largely in many parts of the world, especially in the Mediterranean region and in malarious districts in Italy. The leaves of this and other species of *Eucalyptus* have been supposed to possess febrifugal properties. Smoked in the form of cigars they have been recommended in asthma. The oil obtained from the leaves is antiseptic, and the hard wood is very valuable in Australia for shipbuilding, railway sleepers, mill work, &c.

No. 244. Allspice, Pimento, or Jamaica Pepper, the dried, unripe fruits of *Pimenta officinalis*, Ldl. (*Myrtus Pimenta*, L.), a tree common in Jamaica; from whence large quantities are imported into this country. Pimento is very largely used as a spice, also in medicine for its aromatic and stimulant properties. Oil of Pimento, obtained by distillation from the fruits, is often used for similar purposes as the Oil of Cloves, as well as in perfumery. Sticks of the pimento are imported in very large quantities for walking sticks and umbrella handles.

From the leaves of an allied species (*P. acris*, Wight.), the oil of bay or bay berry is obtained, used in the manufacture of Bay Rum, employed in the United States as a refreshing perfume in faintness, or to sprinkle about sick rooms, as well as for hair washes.

No. 245. Cloves. The dried, unopened flower-buds of *Eugenia caryophyllata*, Thb., a tree originally brought from the Moluccas; now cultivated for this valuable spice in Zanzibar, West Indies, Guiana, Brazil, and most tropical countries. Cloves are collected for market in the Moluccas either by gathering them by hand, or by beating the branches with long bamboos, cloths being placed beneath the trees to receive them. They are simply dried in the sun. They are gathered in the green state, before they ripen or turn red, and in drying they change to the familiar brown colour. Many varieties are known in commerce, those from Penang being considered the best. Cloves contain a large quantity of oil, which is procured by distillation, and extensively used by soap makers, perfumers, and in medicine. Cloves themselves are very largely used as a spice, and in medicine, on account of their stimulant and aromatic properties. Observe the curious and fragrant ornamental models from Amboyna made of Cloves strung together. Also silvered Cloves, and Clove confectionery from India.

The dried fruits of the Clove Tree, under the name of Mother Cloves, are sometimes imported. They contain, however, less oil than cloves, and are inferior in fragrance.

No. 246. Rose Apples, the fruits of *Eugenia Jambos*, L. A small tree of India, and cultivated in many tropical countries. The tree is planted for hedges, shade, and ornament, as well as for the sake of the fruits, which have a fragrance similar to rose water, but a very insipid taste. They are usually about the size of a small apple, but vary in colour, some being white, others rose pink. Candied Rose Apples, preserved with sugar, are exhibited.

No. 254. Pomegranates, the produce of *Punica Gran-*

* Alexandrian or Nubian Senna (*Cassia acutifolia*, Delile).

atum, L., cultivated from early antiquity for its fruit; naturalised in the Mediterranean region, but a native of Western Asia, south of the Caspian, and not of Carthage, as its name would denote (*Malum punicum*). It was known to the Hebrews under the name *Rimmon*, and is mentioned in Deuteronomy as a product of Palestine. The root is an excellent vermifuge; the bark gives the colour to yellow morocco leather, which is tanned with it. The dried rind of the fruit is valued as a remedy in India for diarrhœa and dysentery. The flowers, under the name of Balaustine flowers, are sometimes used for their astringent properties. Walking sticks are made from the stems of young plants imported from Algeria.

No. 256. PAPAW, fruit of *Carica Papaya*, L. (*Papaya vulgaris*, DC.). Though now scattered widley through tropical countries in both hemispheres, it is believed to have originated from the warm part of the American continent. The fruit is edible. The Papaw possesses the remarkable property of rendering meat wrapped in its leaves reduced to a pulp tender in a few hours, causing a separation of the muscular fibres. It has lately attracted a good deal of attention in Europe for medicinal purposes, in dyspepsia, diphtheria, &c.

PERUVIAN BARK ORDER (*Rubiaceæ*). A very large Order of trees, shrubs, or herbs, numbering about 2,800 to 3,000 species; common in tropical countries. Characterised by opposite undivided leaves, having scales (*stipules*) between the bases of the stalks. A small section (*Stellatæ*), differing in having their leaves in whorls of from four to eight, represents the Order in cool countries. Several species afford most important economic products.

Various species and varieties of *Cinchona* and *Cascarilla* barks are exhibited in this Case. Cinchona bark comes into commerce in several forms, the chief, however, are *quilled bark*, which consists of that from branches and small trunks, which by drying roll up into pipes or quills, and *flat bark*, which is mostly from larger trunks, and the bark is submitted to pressure. The barks of the several species or Cinchona contain in varied degrees alkaloids of a valuable character, the most important of which is sulphate of Quinine, a highly prized tonic and febrifuge.

No. 281. PALE CINCHONA, or CROWN BARK (*Cinchona officinalis*, L.), a tree of 35 feet or more, but often found as a shrub, native of the mountain slopes of the Andes, at an altitude of 6-7,500 feet, in the district of Loxa, on the confines of Peru and Ecuador. It is known under several varieties, the most distinct are *Uritusinga*, *Condaminea Bonplandiana* and *Crispa*. Very little pale Cinchona bark is now imported from Loxa, the plant being extensively cultivated in India, Ceylon, Java, and other countries. Specimens of Root-bark, stem-bark, and renewed bark are exhibited from the Government Cinchona plantations, Darjeeling, from Madras, Ceylon, and Jamaica.

Note also specimens of *C. lancifolia*, Mutis, *C. Pahudiana*, Howard, from Darjeeling, *C. nitida*, R. and P., *C. peruviana*, Howard, *C. Humboldtiana*, Lamb., and *C. lanceolata*, R. and P.

On the upper shelves of the next compartment are barks of *C. pubescens*, Vahl., *C. micrantha*, R. and P., from Darjeeling and Jamaica, *C. rosulenta*, Howard, *C. macrocalyx*, Pav., *C. rubra*, Howard, *C. ovata*, R. and P., *C. scrobiculata*, H. and B., and *C. purpurascens*, Wedd.

No. 282. YELLOW CINCHONA, or CALISAYA BARK (*Cinchona Calisaya*, Wedd.). A large tree, native of the valley forests on the borders of Bolivia and South Peru, at an elevation of 4,500 to 5,400 feet. The plant is very variable in form, and several varieties have been cultivated. The richest, however, in quinine, is that known as *C. Ledgeriana*, Moens, which is grown both in the Dutch plantations in Java, and in the Indian plantations at Ootacamund, and in Sikkim. Fine specimens of the bark of this variety are shown from Darjeeling and Ceylon, and of ordinary *Calisaya* from Bolivia, Peru, Darjeeling, and Jamaica.

No. 283. RED CINCHONA BARK (*Cinchona succirubra*, Pav.), a tree from 20 to 40 feet high, but sometimes attaining 80 feet. It was formerly common in the province of Huaranda, in Ecuador, but it has long been becoming scarce, and at the present time is found only on the Western slopes of Chimborazo, near Guayaquil, at an elevation of from 2,500 to 5,000 feet. This species has been very extensively cultivated in India, and also in Ceylon, Java, Jamaica, and elsewhere. Barks, mossed, unmossed, and renewed, are exhibited. Also various samples from Sikkim, Madras, Jamaica, Java, Ceylon, St. Helena, and South America.

No. 284. A series of ALKALOIDS obtained from Cinchonae barks, consisting of Quinine, Cinchonine, Cinchonidine, Quinidine, &c. Also samples of CINCHONA FEBRIFUGE, obtained from bark of *Cinchona succirubra*, made and sold in India; the Crystalline febrifuge, also prepared and sold in India, and the Sulphate of Quinine, manufactured at Mungpoo, near Darjeeling.

Observe on lower shelf of the last compartment of this Case specimens of CUPREA BARK, furnished by *Remijia Purdieana*, Willd., and *R. pedunculata*, Trian., from the States of Colombia.

On the upper shelf of the first compartment note wood and bark of *Hymenodictyon excelsum*, Wall., from the East Indies, where the wood is used for agricultural implements, &c., and the bitter, astringent bark as a febrifuge, and for tanning. Observe also specimens of WEST INDIAN or Princewood BARK (*Exostemma caribæum*, R.S.), from the Bahamas, used the West Indies as a tonic.

No. 285. COFFEE, the seeds of *Coffea arabica*, L. A tree, native of Abyssinia and tropical Africa, now widely cultivated in hot countries. Ceylon, Java, the West Indies, Brazil, and Central America, afford the principal supply of this important product. The fruit of the Coffee-tree, which resembles a cherry in size and colour, contains two seeds (beans), which are separated by mechanical means from the pulp. After fermentation and washing, the seeds pass through a rolling-mill, which removes the parchment-like husk and silver skin immediately enclosing the seeds. The commercial value depends on the size, form, and colour of the beans, and their flavour. Specimens of Coffee in the berry, and of the different Coffees of the London market are here exhibited. A series of photographs illustrating the cultivation of Coffee in Central America are exhibited in the central compartment, and in the last compartment are shown Coffee sticks from Ceylon, sometimes used as walking sticks, and tea made from the leaves of the Coffee tree, from Jamaica and the East Indies.

As an example of the fluctuation in the prices of Colonial produce, it may be pointed out that in 1870 921,506 cwt. of Plantation Coffee were exported from Ceylon, of the value of 2,488,082*l*., while in 1875 the quantity exported decreased to 813,401 cwt., and the value rose to 3,812,817*l*., and in 1881 only 407,222 cwt. were exported, valued at 1,908,854*l*. The total importation of Coffee from all countries in 1882 amounted to 1,358,966 cwt., upwards of 285,000 being entered for home consumption.

On the bottom shelf of the first compartment is a model of a coffee peeler or cleaner from Ceylon, and of a coffee sizer, by the use of which berries of three sizes are sifted.

No. 286. LIBERIAN COFFEE (*Coffea liberica*, Bull and Hiern), a glabrous shrub, native of Liberia. This plant has been introduced into many Coffee growing countries in consequence of its more robust habit than the *Coffea arabica*. The beans are much larger, and it thrives at lower elevations.

The principal part of this Case is devoted to illustrations/of the various diseases to which the Coffee plant is liable, especially *Hemileia vastatrix*, Berk. and Br., a parasitic fungus common in the Ceylon plantations, and *Cemiostoma coffeellum*, Mann, a small moth which has caused almost the entire destruction of the Coffee plants in Dominica.

No. 287. IPECACUANHA. The root of *Cephaëlis Ipecacuanha*, Rich., a Brazilian plant, the cultivation of which has been introduced into India. The roots afford the important emetic, and the only known specific for dysentery. The annual imports of Ipecacuanha into this country amount to about 65,000 lb., of the estimated value of nearly 15,000*l*. The bulk is imported from Brazil, but some comes from Carthagena. Samples are exhibited from Brazil, and from the plantations in British Sikkim.

No. 314. GUTTA PERCHA, from *Dichopsis Gutta*, Benth., a tree of 40 feet high, native of Malacca, Singapore, Sumatra, &c. Various samples of crude Gutta Percha of different qualities are shown from Perak, Borneo, Singapore, &c.

The first division of this Case contains numerous articles made from Gutta Percha; also a dried specimen of the plant in a Gutta Percha frame. To collect Gutta Percha the trees are cut down and consequently destroyed in large quautities. This destruction was stated in 1878 by Dr. Dennys "to be so enormous that it seems impossible for "the supply to long continue. It is computed that over "7,000 trees were cut down during 1877 in the neighbour-"hood of Klang, while 4,000 must have perished near Sel-"angor in a single month to furnish the 270 piculs (a "picul=133⅓ lb.) returned as exported. The estimated "annual exports from the Straits Settlements and the "Peninsula was given as 10 millions of pounds in 1875. which "at the high average of 15 lb. to a single tree would give "600,000 trees. The demand seems always to exceed the "supply." The quantity of Gutta Percha imported into this country in 1882 was 72,681 cwt.

Observe on the upper shelves of the central compartment the edible fruits of the NASEBERRY (*Achras Sapota*, L.). A native of the West Indies (where the wood is known as Sapodilla), but cultivated in all tropical countries. An elastic gum furnished by the plant and known as Chicle Gum is imported into New York from Mexico for use as a masticatory.

No. 315. MAHWA FLOWERS (*Bassia latifolia*, Roxb.) and spirit distilled from the same. *Bassia latifolia* is a deciduous tree 50 feet high, indigenous in the forests of Central India, and cultivated and self-sown throughout India. The fleshy corollas of the flowers form an important article of food both for men and animals in Central India, and yield by distillation a coarse spirit. The average yield of flowers per tree is estimated at 2½ maunds, and they sell at about 12 annas per maund. The fruits are eaten raw or cooked, and from the seed an oil is obtained which is used for culinary purposes as well as for soap making. An oil cake for feeding cattle is made from the residue of the seeds after the expression of the oil.

No. 316. Seeds and Oil of the MEE or Illupi (*Bassia longifolia*, L.), a large evergreen tree of India. The flowers are eaten in the same way as those of the last-named species, and an oil is expressed from the seeds used also for similar purposes. The leaves, bark, and young fruit are used medicinally.

Note also seeds and vegetable butter of *B. butyracea*, Roxb. The solid white oil obtained from these seeds is of the consistence of lard. It keeps a long time without deteriorating, and is said to make good soap and candles. It is perfumed and used as an ointment in rheumatism.

No. 321. EBONY. The best sort is obtained from *Diospyros Ebenum*, Kœnig., a native of Ceylon. Ebony, characterised by its extremely dark colour and hardness, is (as specimens here exhibited show) the "heart-wood" (*duramen*) of the tree; the "sap-wood" (*alburnum*) of which is white and not durable. The Greeks and Romans were acquainted with Ebony; it is mentioned by Dioscorides, Pliny, &c. Indian caskets, inkstand, and other articles, carved in Ebony are shown.

No. 322. CALAMANDER WOOD, afforded by another Ceylon *Diospyros* (*D. quæsita*, Thw.), a most beautiful cabinet wood taking a high polish; it is so hard that edge tools can scarcely work it. Boxes and similar articles made from it are exhibited.

No. 335. YERCUM or MUDAR FIBRE, obtained from *Calotropis gigantea*, Br., common in waste places in India. The fibre obtained from the inner bark is very durable, and is used for bow-strings, fishing lines, and nets. Attempts have been made to weave the hair or floss from the seeds, without, however, any satisfactory results. The plant abounds in acrid milk which has powerful medicinal properties. Stems of the plant with the fibre partially removed are exhibited, also twine made from the fibre, and a specimen of woven fabric made from the floss.

The fibre or floss from the seeds of an allied species (*C. procera*, R. Br.), is also known as Mudar fibre. The dried bark of the root is an alterative, tonic, and diaphoretic.

NUTMEG ORDER (*Myristiceæ*). Trees confined to the tropics, often characterised by their red viscid juice and aromatic properties.

Observe fruits and seeds of various species of *Myristica*, amongst them *M. surinamensis*, Roland, *M. angolensis*, Welw., *M. guatemalensis*, Hemsl. Seeds and butter obtained from *M. Otoba*, H.B., from Antioquia and *M. malabarica*, Lam., from India.

No. 379. Nutmegs, the seeds of *Myristica fragrans*, Houtt. A beautiful tree of the Moluccas, scattered also in other islands of the East Indian Archipelago, and introduced into Mauritius, West Indies, and South America.

The fruit of the nutmeg, which resembles a Peach, consists of a fleshy exterior, which is edible and splits into two, disclosing the solitary seed or nutmeg surrounded by the scarlet aril, which latter is the spice called mace. Specimens preserved in fluid show the entire fruits, some of which are partly open, exhibiting the shell of the nutmeg and the "Mace" covering it.

Other spices allied to *M. fragrans* yield inferior nutmegs. Observe instrument used in Banda for gathering nutmegs from the trees. "By far the largest supplies of nutmegs "are derived from the Banda Islands. These are all at "first shipped to Batavia." About 560,000 lb. are annually imported into the United Kingdom and about 500,000 lb. to the United States of America. The principal consumption of nutmegs is as a condiment, but they are also used in medicine for their aromatic and stimulant properties.

No. 380. Concrete OIL OF NUTMEG, obtained in the Moluccas, from the seeds, by heat and pressure.

No. 382. CASSIA BUDS. The unripe fruits of *Cinnamomum Cassia*, Bl., a tree of Southern China, used as a spice chiefly in confectionery.

CASSIA LIGNEA, or CHINESE CASSIA as it is sometimes called, is the bark of the same tree furnishing Cassia Buds. Specimens are exhibited of different ages and qualities from Pakhoi and from Tai-wu and Luk-po in Southern China. Cassia Bark is used for similar purposes as cinnamon, it is however more astringent. Note, instruments used in collecting the bark, also samples of Cassia oil.

On the top shelf of the last compartment are exhibitnt-specimens of the wood and bark of *Cinnamomum Tamala*, Nees. The bark is aromatic and is collected in large quaed ities in India, and sold under the name of *Taj*, and the leaves under those of *Tez-pat* and *Taj-pat*.

No. 383. CINNAMON, the bark of *Cinnamomum zeylanica*, Breyn., a tree of Ceylon. Specimens of unbarked branches, affording the different qualities of this valuable spice, with the instruments used in peeling it, are exhibited, also a series of photographs illustrating the growth and preparation of Cinnamon in Ceylon; 1,835,039 pounds of Cinnamon were imported in 1882.

No. 384. CAMPHOR, obtained by distillation, from the wood of *Cinnamomum Camphora*, Nees, a tree of Japan and China. The root, trunk, and branches, broken up, are heated with water, in closed vessels, the volatilised Camphor being sublimed upon Rice-straw. It is further refined on its arrival in Europe. Samples of crude and refined Camphor are shown, also specimens of Camphor wood. (*See also* Borneo *Camphor*, Case 11, No. 62.)

No. 409. CASSAVA OR MANDIOCCA Meal, obtained from the root of two species of *Manihot* (*M. utilissima*, Pohl, and *M. Aipi*, Pohl), the former, Bitter, the latter, Sweet Cassava.

The juice of Bitter Cassava (which contains Hydrocyanic (Prussic) acid is highly poisonous. Cassava is grown chiefly in Brazil, Peru, and on the African coast,—forming a main article of native food. The roots of Bitter Cassava, which are often large, weighing from 30 to 40 pounds, contain much farinaceous matter. They are grated, after washing the poisonous juice separated by pressure, and the residue made into thin cakes (No. 410), which are baked. Prussic acid being volatile, the heat dissipates the remaining poison.

Observe "CASSAREEP," the concentrated juice of Manihot roots rendered harmless by boiling. It is largely used in the West Indies for culinary purposes, and in this country as the basis for many table sauces.

No. 411. TAPIOCA. A very pure form of Starch, which settles from the water employed to wash Cassava meal. It is granulated upon hot plates. A close imitation of Tapioca is prepared from potato starch.

No. 412. Mandiocca strainers. Long, cylindrical, plaited baskets in which the grated pulp is put after washing and pressed by torsion.

No. 413. Mandiocca grater, studded with particles of granite, secured in the tough wooden frame by the viscid juice of *Couma dulcis*, Aubl., one of the Dogbanes.

No. 435. JACK-FRUIT (*Artocarpus integrifolia*, L.). Grown from time immemorial in Southern Asia. The fruit attains an enormous size. Certain varieties are highly esteemed as an article of food by the natives of India. The name "Jack" is derived from the Sanscrit name of the fruit "Tchackka." Fruits from the East and West Indies are exhibited. Specimens of the wood, which is valuable for furniture, are shown on upper shelves of Case 101.

No. 436. BREAD-FRUIT (*Artocarpus incisa*, L.). A staple food of the South Sea Islanders. Introduced into the East and West Indies. Observe biscuits, &c., made of slices of the Bread-fruit. Also Bread-fruit Meal.

On the bottom shelf are fruits of other species of *Artocarpus*.

The upper part of this compartment contains woods and fruits of various species of *Artocarpus*, and in the lower part of this and upper portion of the next compartment are a series of native cloths (some ornamented), made of barks of *Artocarpus*, spp.

No. 438. Stems of CHINA-GRASS (*Boehmeria nivea*, H. and A.), a Nettle of China, India, and the Indian islands, affording the valuable RHEA fibre, specimens of which and fabrics made of it are exhibited in the next Case, No. 103.

On the upper shelves of the central compartment of this Case note sections of the extremely light and open-grained wood of a gigantic nettle of Australia (*Laportea gigas*, Wedd.), sometimes exceeding 80 feet in height.

COFFEE PLANTING

"Singapore soil is good for nothing." Such was the expression in the mouth of superficial observers, until M. Chasseriau proved the contrary, and others followed in his wake. This glibly uttered formula did Singapore an immense amount of harm, for it discouraged any attempt at plantation work. We all know that to give a certain animal a bad name is to hang him, and this was certainly the case with our lovely little island. M. Chasseriau, true to the faith that was in him as regards the possibilities of the careful scientific cultivation of Singapore soil, ventured on coffee, and what he has achieved is now a twice-told tale. Those who want to see what watchful and careful cultivation can do had better go and inspect his trees, many of which are laden with young berries, others in flower, the whole the picture of health. Another has been of M. Chasseriau's opinion, and he is our esteemed townsmen Syed Mahomed bin Alsagoff. His house and grounds are well known, we venture to say that directions thereto are superfluous, so we will pass on to the brief notice of how his coffee looks. Five or six years ago, more or less, he planted Liberian coffee, on a comparatively small scale, in the firm belief that it would pay well, if properly attended to. The soil was bad, nothing could be more unpromising; and to the superficial planter, in other words the soil-ticker who smokes his pipe and leaves the rest to Nature, it would appear that he who put money into the ground might wait till the resurrection of the dead for a return. Syed Mahomed planted Liberian coffee into this soil, or rather in large deep holes in it, which were well manured, twelve feet space being given to each tree; they were carefully and thoughfully attended to and what is the result? Failure. No, a success. Already he has made $20,000 from these trees by selling the seeds, at, we believe, a cent apiece, besides the returns from the sale of the coffee. Some of the trees are now in their sixth or seventh year, and what a picture they present, to gladden the eye of the planter? They are laden with berries, many of them having in the opinion of an unbiassed expert, as many as forty pounds of fruit. The healthy look of these trees, their vigour, and the beautiful way they have been looked after are subsidiary features that strike the visitor. But of course the great thing is the result, the yield of coffee. We saw some Arabian coffee which looked very well, but we should imagine this to be an experimental lot judging from the limited nature of the cultivation. If Syed Mahomed Alsagoff can with a small piece of ground produce such results with his coffee, solely by superior cultivation what is to prevent others doing the same thing. What is to hinder small native planters, if it comes to that some of the *gens de pays* cultivating coffee on a small scale? They could make a small fortune out of it, specially the industrious natives, who could get from a patch of land, worked by them and their picaninies, the living of a lord, and a small fortune in the future. The worst of it is that people will let the idea that the soil is bad run away with them; forgetful of the fact that we have proof positive what the soil can yield when properly looked after. Some will not let common sense or thought have a share in their planting transactions: that is why many come to grief. Others are so careless as to leave everything to chance. The land wants tending as carefully as the wife of your bosom, and must be watched quite as narrowly; and those that love their land, and keep a watch over it, and attend to every little want and wish, like many French peasant cultivators and Italian growers do, will reap rewards in bountiful yields and sure prosperity. —*Straits Intelligencer*. [We do not know what the ultimate fate of coffee may be, but this we know that Mr. Chasseriau, after trying coconut palms for fourteen years, and seeing no signs of fruit, cut them all down.—ED.]

TEA—PLUCKING.

The first thing to be taken into consideration is what the style of pruning is, whether it has been light, heavy or medium, as upon this must the plucking depend for the first month or two. We have seen in the case of very heavy pruning, the flushes allowed to grow out to a tremendous length, until they were waving in the wind like a field of corn at home. No doubt the planter thought he was doing a wise thing by this arrangement, but we consider he could not have done anything more prejudicial to either giving good wood to prune upon in the following season, or to giving a good crop in the meantime. When a flush or flushes are allowed to run away in this fashion, neither will the wood grown be as good, nor will the axils, from which the next flush is to be expected, be as numerous as if the flush had been carefully taken off. In cases of this kind six leaves will probably have formed on the main shoots, and so on from the other shoots resulting in the necessity of going over the bushes once in a week or ten days at most, and of course only getting a comparatively meagre return in the way of leaf at first. When, therefore, heavy pruning has been done, the plucking entails necessarily more careful supervision, and in the beginning of the season gives more unsatisfactory results, than some people are willing to put up with, and the consequence is that there is very often a tendency to over-pluck. We do not consider that it is safe to pluck more than three leaves from a six-leaf flush under ordinary circumstances after heavy pruning until the end of May, when after that a five-leaf flush may be plucked, say till the middle of July, and after that date to end of August a four-leaf flush. In September a three-leaf flush may be begun, that is taking off two leaves and a bud and leaving one full-grown leaf, and what is known as the "gool," or round leaf at the bottom of the shoot. In November everything should be taken off that is soft, as by that time the bush has made quite sufficient wood to prune upon, if it has to make it at all. And, moreover, there is no time left for a flush to develop from any axils should they be left. With lighter pruning of course there is not the same necessity to allow leaf to remain on the bushes to form into wood, as the height of the bush, and consequently its vigor, is not so much a point of consideration, in such cases of course a five-leaf flush can sooner be taken off. Now-a-days when plucking has been reduced more to a system than it was, it is necessary to go round the plantation as quickly as possible in order to obtain the best results, and so far as we can learn, once a week is considered about the correct thing. In former times once in the twelve days, and sometimes once a fortnight, was considered quite often enough, but now-a-days it is supposed that much of the substance is lost by allowing such a lengthy period to elapse between the pluckings, and the best information we can obtain on the subject points to a weekly pluck as the best. No doubt this entails a closer supervision from the European staff, and it may, we think, be safely affirmed that to the extra supervision may be attributed to some extent the superiority of Indian over China Teas.—*Indigo and Tea Planters' Gazette.*

TEA—DRAINING.

In our last issue we hurriedly noticed the subject of draining as being a little connected with hoeing. It may appear somewhat incongruous to say so, but the ordinary planter will no doubt agree with us. Draining is necessary in certain soils, and under certain conditions it is absolutely necessary for the primary existence of the plant. In commencing draining—and there is probably no plant which will more quickly point out where it is necessary than tea—the first point to be taken into consideration is the nature of the sub-soil before it is determined at what intervals or distances it is desirable to have the drains put down. In addition to the intervals the question of depth has also to be taken into account, and this is perhaps the more important of the two, as upon the depth principally depends the cost of the operation, because every extra foot in depth means a very considerable extra expense, far more than if six intermediate extra shallow drains were required to be put down. The subject of draining has been brought to a great pitch of perfection in the high style of farming that has lately been the rage at home in order to get the best results from a soil which was carrying a heavy rental with it. So far in India the subject has had but little attention given to it until the last few years, principally from the fact of abundance of tea land existing, which could be brought under cultivation without drainage. Now-a-days concentration has become necessary and hence the need for taking up those patches that divided the different teelahs or plateaux of the old cultivation, and the draining of which was considered too expensive, besides it was doubtful whether they would grow tea or not. It has now been satisfactorily proved that tea if properly drained will grow in any soil down to the stiffest clay, although, of course, the yield is not so great in stiff soils as in light loams. Many parts planted ten or twelve years ago and abandoned as unfit for tea, are now being taken up and replanted with "Indigenous plant" This, as well as careful draining, is perhaps part of the secret of the success. The China variety abhors anything approaching a stiff soil, and is useless for leaf production, although it may exist for a time in such soil. Where the sub-soil is stiff clay the general rule now observed is light shallow drains, say 2 to 3 feet deep, and 12 feet apart; and as the soil approaches a loam or little better than a peaty substance the distance apart can be increased, but the drains require to be deeper, say 4 to 5 feet deep. It would, however, be difficult to lay down any hard and fast rule on the subject, because everything depends upon the existing fall, and in many instances if a planter were to stick to what we have given above, many good patches of tea now yielding well would not be in existence. That tea subject to occasional inundation, for say a few hours, will flourish and yield in a way is undoubted, yet we are far from advising any such experiments as planting lowland of this sort, and we imagine that last year's floods taught many a lesson. We heard of one firm of Calcutta agents who, we think wisely had flood marks put up for future reference. However, if a fall sufficient to meet the requirements we have given is not to be had, this must be remedied by having the drains brought closer together; and in draining a great deal of fall can be gained by the placing of the drains. The first and most important point to be considered is the situation of the leader, and when this is right, a great assistance can be given to draining by the proper placing of the diagonal or side drains. We have often seen a piece of draining pretty to the eye utterly bad in reality, and the great point to be avoided in running in diagonal drains is their meeting, that is to say, the diagonal drain of the right side should run into the leader intermediate to its neighbour of the left hand side. Should the diagonal drains run into the leader opposite one another, the result is invariably a bar at the mouth, and the assistance one diagonal lends to another is nullified. In writing as we have done on the subject of draining lowlands for tea cultivation, we should not altogether ignore the utility of drains on slopes in stopping waste and in retarding the quick running off of water in the rains on sloping lands. In cases of this sort we can only say that it is almost impossible to have them too close. To prevent wash, bold rainfall terracing is a favourite method, and this is only a very high style of draining. Another style of stopping waste, by virtually draining is what is known as pit terracing. All these methods or "dodges" of saving soil, although called by different names, are really different ways and means of drainage, and are all more or less essential to getting the best results out of the soil. —*Indigo and Tea Planters' Gazette.*

THE SEAWEED HARVEST IN JERSEY.

The whole of the island of Jersey is encircled by a continuous chain of granitic rock, more or less exposed at low-water, and more or less distant from the shore. These rocks, the bugbear of the local navigator, rendering, as they do, his harbours so difficult to approach and so unsafe to move in, are to the local agriculturist "ports and happy havens," so to speak, for upon them grow perpetually and luxuriantly the seaweeds with which year after year he fertilises his lands, and which, under the old Norman-French name of *vraic*, he so generally and freely uses.

Etymologists trace the root of the word to the Arabic word *warak*, meaning the leaf of a tree; from *warak* they derive the old Latin nouns *varescum*, or *variscum*, signifying shipwreck; to either of these bases they go for the French word *varech*, which stands in that tongue for seaweeds, or for wrecking at sea; *vraic* is but another and more modern spelling for *varech*, and therefore implies, say these experts, "leaves torn from the rocks and cast upon the shores," as it also denotes ships subject to the same calamities. The argument is ingenious if nothing more. Need it be said that our own once common name *wrack*, for wreck, and the still used one wrack, for marine algæ, have the same parentage as *vraic?*

This *vraic*, then, consists chiefly of plants of the genera Fucus and Laminaria, with a few others sparsely mixed with them. The Fucaceæ are composed of F. vesiculosus, F. serratus, and F. nodosus. The Laminariæ are L. digitata and L. saccharina, and the other much less abundant kinds are certain sorts of Sphacelariæ and Ulwa. The Fuci grow upon the rocks, from which at certain seasons and under certain restrictions, which we shall presently hint at, they are cut forming what is technically called *vraic scié;* the Laminariæ, with moreover some Fuci and other algæ, are drifted on shore from outlying reefs in the Channel, or even from the Atlantic Ocean, and for this reason go by the name of *vraic venant* or *venu*. Upon this flotsam and jetsam we shall also touch. Rich in many of the salts of potassium and sodium are most of these seaweeds; the Laminaria saccharina has been found to contain in every hundred parts of its soluble ash no less than 60 per cent of various compounds of these bases, and the Fucus vesiculosus has yielded 51·49 of similar ones from an equal quantity of its ash. Free sulphuric acid, iodine, calcium, and potassium also exist minutely in almost all of them, and in the simply dried weeds the percentage of organic matter is from 70 to 83 per cent. But we may add, that it has been found by a local experimentalist that at different seasons of the year the quantities of organic and inorganic matter materially differ, and that certainly in the Fuci used in Jersey for manure the summer cuttings are more abundant in mineral fertilisers than are those of the spring.

Now, as it so happens, the soil of Jersey, and indeed of the Channel Islands generally, is singularly deficient in lime and other earthy salts, and this want was recognised even in those bygone times when agricultural chemistry was in its infancy. Then by a sort of happy-go-lucky "find" the worthy islander discovered that the seaweeds springing up so thickly about him, and thrown upon his beach by stormy winds, were the very things he needed to supply the default in his land. So he set to work to cut and to gather, and what he did centuries ago he continues to do in the present day. Quaint Mr. Falle, chaplain to William III., and the historian *par excellence* of Jersey (1694), alluding to this want of "chalk-lime and marle" in the island, says, "but Nature has supplied us with what fully answers the end in husbandry. It is a weed, but a weed more valuable than the choicest plant cultivated in our gardens, and the vast and amazing chain of rocks that environs our island is the grand garden of the *vraic*." Nearly 200 years have slipped away since this divine said his say; the "chalk-lime and marle," to repeat his words, are still *non inventi* in the ground, and the *vraic* is still its staple fertiliser; but its fertilising properties are now added to by phosphoric and ammoniacal composts; and where the Jersey farmer wants lime he will not trust to his Fuci or Laminariæ to get it from.

The *vraic venu* consists mainly of the Laminariæ. Storm-waves have torn them forcibly from their beds, and brought them shorewards, where they become any one's legitimate property and right of capture at any time or at any season. So, after the godsend of a heavy gale, the fisheries for *vraic venu*, armed with large wooden rakes, are many and eager. But with the *vraic scié*—the cut weeds—it is quite another matter. This must be cut with a sickle from the gardens of the wrack, as Mr. Falle words it, cut under certain legal permissions, emanating twice a year—in spring and in summer—from the Royal Court, and then only for a definite number of tides, cut between certain hours, and cut under certain agricultural conditions. All these are too numerous to detail, but woe betide the delinquent, or the poacher upon the *vraic* preserves, for fines, never under five pounds, and mounting to as many as fifty, await him. Until, therefore, *la'bandon du Varech,* as the law styles it, is announced publicly and legally, touch it, we repeat, who dare! And even when the permitted harvest is going on, there are many salutary restrictions as to precedence, proprietary, seignorial and parochial rights to be religiously complied with before the general *oi-polloi* swoop, and disposal can be made. This cutting and gathering is a very picturesque scene, and is worth a word of outline. At low spring-tide the reapers may be seen by scores, a mile or two from the seaboard, cutting and shearing where the crops are heaviest. Carts having been dragged through sand and slush soil, over low roofs, by pools and other impediments to these busy spots, and loaded—loaded to the utmost of horse-power—return in long strings of Indian file to the shore, thence to different farms, the water streaming from the dripping algæ. This *vraic* will sell for 10s. and more per load of over 1 ton, whereas the drift *vraic* may be bought at from 2s upwards, according to the distance it is carted from the shore.

The *vraic scié* of the spring cutting now going on is generally applied wet as it is to all grass and pasture lands, and left untouched to decompose and soak in. It seems in this condition to render the grass crisp, tender, and highly palatable to cattle. The weeds of the summer cuttings in July and August become available for roots and again for herbage.

The drift wrack—*vraic venant*, gathered just now and a little while back—is ploughed deeply into the fields for Potato crops and general gardening purposes; later in the season, say after April and until August, it will be collected, every scrap of it, by cottagers along the shores, dried, stacked, burnt as fuel, and the ash sold to the farmers as a top-dressing for corn lands.

It will take from 10 to 12 tons of *vraic* to fertilise as richly as the Jerseyman does fertilise an acre of his ever-being-utilised ground, but besides *vraic* some small proportions of artificial manures will be required to produce the heavy crops he habitually calls upon his land to bring forth.

It is said that, excepting the Faroe Islands, seaweeds are more extensively used in Jersey than in any other part of the world for agricultural purposes.—H. L. C.—*Gardeners' Chronicle.*

BRAZILIAN COFFEE.

The continued improvement in market value of this article is a feature not to be overlooked, as it shows a steady increase of consumption in those countries where Brazil coffee is most appreciated, namely, the United States and the Continent of Europe, and that the Rio coffee exhibitions held on the spot and in England have not been without a result in making the article better known and appreciated. It was thought at one time that the large production of coffee over the world would go on increasing, and Mexican production brought forward as a bugbear wherewith to frighten Brazilian growers, but like most other Mexican predictions this one has proved to be delusive, nor has there been any notable increase elsewhere.

The fact is that few countries are so well adapted to coffee-growing as Brazil, with its table lands, or command so large an area of suitable territory for growing it, and this, combined with railway facilities on a large scale which are now being carried out, must greatly facilitate the transportation of coffee to the ports of shipment, as well as open out new districts for its culture. It is one of those cases where (unlike sugar) mechanical means are not required (but simply growing and picking, the latter process a comparatively easy one as shown in our last number by the extraordinary result of the working of eleven families with free labour on the Santa Clara estate near Rio de Janeiro.

The improved condition of Brazilian coffee is all the more satisfactory as it has come about by natural means, and not caused by any speculative movement. It will tend to inspire planters with confidence, and materially benefit their financial position, at the same time there is no reason why other agricultural pursuits should not be resorted to, particularly as regards the food supply of the Empire, a subject to which we have frequently drawn attention.—*South American Journal.*

[A representation much too *couleur de rose.* The planters are not only suffering from the production, but the abolition of slavery hangs like the sword of Damocles over them—ED.]

DARJEELING.

I am sorry to hear that fever is very rife amongst the tea planters on the Western Dooars just now. Many have had to go to sea, while most have been more or less prostrated. Cholera has made its unwelcome appearance in the Terai, and there have been dropping cases of small-pox in the neighbourhood of Kurseong.

We had a smart fall of snow here on Friday afternoon, and the weather has been decidedly raw and unplaesant ever since. It is admitted on all sides that this is the most severe winter we have had in Darjeeling for years past. There have been an unusually large number of changes in the management of tea gardens in the district this year—chiefly in the Terai and Western Dooars. It is satisfactory to be able to say that the past tea manufacturing season in this district was pecuniarily a very successful one, as prices ruled high all round, and thus the fall off in quantity was more than made up for by enhanced prices. It is early in the day to speculate as to the prospects of next season, as so much depends on the weather. One thing is certain, and that is, should war break out between France and China, the result must be a very considerable advance in the price of Indian teas, and especially of Darjeeling. Pruning is well in hand throughout the hill portion of the district, and it seem to me that even more than ordinary care has been taken in carrying on very important operation. Male labor is still very scarce owing to the embargo put on its subjects by the Nepaulese Government, but as usual, there are any amount of women and children available for work in the hill.

The Dooars' gardens and many of those in the Terai are very badly off indeed as regards labor, especially the former. It remains to be seen whether it will be possible to keep the enormous tracts of lands put out under tea in the Dooars within the last twelve months clear of jungle during next rains. Most people doubt it. It has now been conclusively proved that even with the aid of machinery it is impossible to work a tea garden at a profit, unless there is an adequate supply of labor for outdoor work, and I think I am well within the mark when I say that it pays better in the long run to keep an average of one and-a-half coolie (or ought it to be coolies) for each acre of cultivation. I have heard no complaints of red spider this year so far.

Mr. Christison, the General Manager of the Lebong Tea Company, returned to Darjeeling a few days ago after a well deserved holiday trip round the world, and yesterday (14th Feb.) Mr. Curtis, Manager of the Tukvar Company, left Darjeeling on nine months' leave.—*Indigo and Tea Planters' Gazette.*

TEA IN BENGAL.—The area under tea during the year 1882-83 increased from 42,217 to 48,092, the number of separate gardens at the same time rising from 271 to 300. The total approximate yield of the Bengal Province was 11,170,504 pounds, of which nearly ten millions came from Darjeeling and Julpigoree, and the bulk of the remainder from Lohardugga. The average outturn in pounds per acre of matured plants was in Darjeeling 302, Julpigoree 390, Chittagong 322, and Lohardugga 170.—*Indigo and Tea Planters' Gazette.*

THE QUININE SYNDICATE AND MR. HOWARD.

SIR,—We have just read your editorial of Thursday, 24th January, on our telegram announcing the drop in Howard's Quinine and our opinion that it would result in the smash of the Syndicate.

We feel sure you will oblige us by making public that the interpretation you have put on part of our circular is quite foreign and opposed to the inferenc we wished to be drawn, and which we thought must necessarily have been drawn from it.

After quoting our words ending :—

"At the cost of the planter, and to the profit principally of that manufactory with which is connected the name of the man who is above all others answerable for the present deplorable state of affairs,—"

You say :—

"This of course refers to Mr. Howard."

Now we wish most emphatically to deny that we intended this to apply to Mr. Howard deceased or to Messrs. Howard. We wish to add to our denial the assertion that we consider that our words would be applicable to no one less than they would be to either the late Mr. Howard or to Messrs. Howard.

In fact, our opinion of the manner in which these gentlemen do conduct, and always have conducted, their business is such that we consider that, had all manufacturers worked on the same lines as Messrs. Howard, the Syndicate would never have existed, and that the consumption of quinine would be at least fifty per cent more than it now is.

You also draw from our circular that Messrs. Howard would have to forfeit a deposit. Kindly take note that there was, so far as we know, and we believe we *do* know, no question of ever asking a deposit from *these* gentlemen, and we do not for a moment think they ever entered into any written agreement of any sort, and we should rather describe their connection with the Syndicate as refraining from opposing it for a time, than as an actual participation in it.

Why! We asked Messrs. Howard to work with us to effect the dissolution of the Syndicate, only a few days before their quinine drop, and we found from their answer that they were already debating the matter themselves.

We should have thought that our words could only point to a foreign manufacturer, seeing that it was by continental buying in Ceylon that the planters' prices are spoiled both for the Colombo and London markets.

Kindly also allow us to express our surprize that Mr. Howard deceased should have been considered a monopolist by any one. The only thing in which, in our opinion, he may have been considered to create a monopoly was in his keen interest in and contributions to all that concerned the scientific aspects of the trade, and his willingness to give very valuable information to all who were seeking to improve the quality of bark grown.

We feel sure we can count on your publishing this explanation without delay, as we exceedingly regret that our name should even in the most indirect way be coupled with any imputation on the conduct of Messrs. Howard's business.

FRANCOIS LE MAIR & RIVERS HICKS.

London, 16th Feb. 1884.

—Local "Times."

COFFEE AND SYNDICATES

are thus noticed by the *Rio News* :—

In another column, we print a table communicated to the *Jornal do Commercio* in reference to the coffee production and consumption of the world. These figures have met with criticism on the part of Messrs. Berla, Cotrim & Co., of this city, who question the estimates printed by the *Jornal* and offer a radically different statement, which, condensed amounts to about the following :—

Over estimate of production in Brazil	...	1.250.000 bags
do do do in other countries	...	987,050 ,,
Under estimate of consumption	...	714,000 ,,
Total	...	2,951,050 bags

Now the *Jornal's* figures give as a probable stock on 30th June, 1885, 3,155,000 bags, and if Messrs. Berla, Cotrim & Co.'s deductions be made, this stock would be reduced to 204,000 bags, or a little less than a week's consumption. This may be called a starvation point in the coffee trade. We have no interest in the bean, worse luck, but we have some interest in endeavouring to keep our readers more or less cognizant of the movements and manipulations of the coffee market in Rio; and this seems a fit occasion to call their attention to the formation of syndicates and corners to the manifest detriment of legitimate trade. It is quite utopian to suppose that speculation can be done away with: nor do we consider it at all for the benefit of commerce in general that it should be. But there are speculations and and speculations and it seems far from legitimate speculation that combination should be formed with the openly expressed intention of sustaining the price of any article, without regard to its position statistically, nor to the great law of supply and demand. And still worse does it seem, to endeavour by a shrewd management of figures to bolster up an article in a position which is false and treacherous. The fate of the great coffee operator in the United States (to whom the Brazilian planters should present a golden coffee tree), and of all those who have based their calculations on untrustworthy reports from the interior, should suffice to prevent consumers abroad from listening to the syren's song of "short crops," and should serve as a lesson for those who are rapidly following in their footsteps. As we have frequently observed in these columns, crop reports are more or less untrustworthy. However honest the informant may be, his observation is made as to a very small part of the zone of production, and when interest, either personal or nearly so, is to be served, we may almost defy any man, however desirous he may be, to be perfectly frank and free in his estimates. We have seen examples of this everywhere. American cotton planters *never* make more than a fair crop. English farmers *rarely* have average crops. And yet in the United States and England, the Government takes note of these crops, and the planter and farmer know that their estimates will be checked and proved by officials who have no interest in the matter. How different here in Brazil! Rain in one district has played Old Harry with the bloom; drought in another has reduced the crop to "200 *per cent less than that of last season*"; and yet the unbelievers see the coffee coming in and each succeeding crop, as shipped, proving the fallacy of estimates. We can suggest nothing. Every good will has been shown us in our endeavours to keep posted in this matter of coffee crops, and in almost desperation, we can only say: "Believe nothing that you hear and only one half that you see."

REPORT FROM A LOWCOUNTRY ESTATE NEAR HENARATGODA.

17th March 1884

The drought lasted from the 24th December to the 11th March: during those 75 days there were three showers, 17th Jan., 7th and 17th Feb., aggregating, probably, from $1\frac{1}{2}$ to 2 inches. Through the whole period, a strong, dry wind for six hours daily aided the bright sunshine in dessicating the soil. Since the 11th there have been thunderstorms nearly every day, some of them very violent.

What with the previous action of the *Hemileia*, the almost total suspension of growth, and the fierce wind, the coffee looks awfully bare, but the one shower on the 17th January saved a very full blossom, a considerable proportion of which set even on the bare branches, and a second opened three days ago, the greater part of which has fairly set. Great numbers of the trees had their leaves drooping and appeared to be in heavy distress in the long intervals between the showers, but very few perished outright.

The older cacao trees suffered much from the wind, but did not seem to care for the drought, till towards the end. The young seedlings in the field enjoyed the first three weeks of dry weather, and grew rapidly, but gradually gave in as it continued, and finally all perished that had been sown later than June.

Out of about 1,000 pepper vines, planted during the N.-E. rains, and that seemed to have got a fair start, one-half or more are dead, and the survivors look seedy.

The cardamom patch planted in October had made a promising start before the drought set in, but the check has been a severe one, and about 15 per cent have died outright.

The tea in the field has not grown, but very little of it has actually died, and I believe it will now take a vigorous start. The nursery has been watered daily, and we have had no little trouble in deepening the well, to get enough of water to merely keep the plants alive, for they have grown none; but very few have died. I am now clearing off odd jobs, so as to be able to attack the holing vigorously and persistently.

I put out a few imbul (tree cotton) plants late in the season along the roads; as the seedlings were very small, one-half of them died, but the survivors have thriven bravely through all the dry weather, and some of them are now two feet high. I propose to extend them along all the roads and to plant up a guinea grass patch that the village cattle have ruined. I believe this product (tree cotton) will become far more important than Ceará rubber. Civilization is rapidly opening its mind to the fact that *pulan** makes a sufficiently soft bed, at a comparatively small cost, while in it the manufacturers of gun-cotton have found a cheaper and equally efficient raw material, as a succedaneum, to that used formerly. No statistical materials exist, on which to found an estimate of the cost of droduction, and local prices have not yet found their level by the operation of competition. The small local demand has hitherto been met by chance-grown trees in the villages, and no fixed value has ever settled down on it. In the neighbourhood of the towns, the villagers have found it worth gathering, but far out in the country it has generally been allowed to pass away on the wings of the wind, but this is not likely to happen in future, as the kadei Moormen are always prepared to barter for any product that has a certain market in Colombo. The amount of crop will, no doubt, be proportionate to the richness of the soil, but the tree will grow and yield more or less crop on almost any soil. In tolerable soil, it begins to bear in the second year, and anywhere in the third. It does not seem likely that it requires any very great care in cultivation, but it does not thrive on grass land, and very evidently detests jungle. I have had almost daily opportunities of studying these trees for twenty-seven years, but not twelve months have passed since I began to avail myself of them: such is the carelessness with which we pass by things that offer us no return for our pains; but as soon as it promised to be worth my while, I began to look on it in a new light, and have stored every fact concerning it that close observation supplied. My knowledge is still defective, but will daily improve. I have seen at least one tree, this season, bearing over a thousand pods; I have learned that the general crop has suffered this season, to the extent of 50 per cent from drought. I have read that the produce has been valued in France at 8¾d per pound, and I am credibly informed that R8 is offered in Colombo per cwt. including the seed. My knowledge in this department of the subject will be complete, when I have had an opportunity of ascertaining how many average pods make a pound, and the proportion between the weights of the seed, and the *pulan* (cotton). Whether the seed has any separate value is another point worth investigation, and, if fit for no other purpose, it must be worth crushing for manure.—*N. B.* Submit a sample to a chemist for analysis.

The *rata puwak* (foreign areka) has stood the drought wonderfully; I only lost ten out of the six hundred, and as the plants have now a pretty good hold on the soil they will probably come on rapidly.

The talipot and wax palm are very slow-coaches: at their present rate of growth, neither you nor I have any chance of ever seeing their stems; though both have taproots running four feet deep, all they show above ground resembles a few large blades of grass.

The Ceará rubber is taking out its wintering, and is utterly bare. I will be ready to give it its last chance with the new instrument, as soon as I can spare time. There is no use in counting the cost, and crediting returns, till by careful experiment the one is reduced to the lowest, and the other raised to the highest possible result.

The Indian bamboo has shown itself such an ill-neighbour to every other plant, that the cheapest and earliest means must be used to exterminate it. Its systematic robbery extends in area continually, and every plant within five and twenty-five feet suffers. It makes a very secure boundary fence, but its growth should be kept down to five feet, instead of the forty-five to which some of it has attained. Many of the stems are large and very strong, being very nearly solid; there may perhaps, be a paying market for them in Colombo.

* Sinhalese for cotton wool.—ED.

DATE PALMS.—As an instance of the time Date Palms require to develope into fruit-bearing trees, says Mr. Prestoe in his report on the Trinidad Botanic Garden, "I might mention the flowering and fruiting of specimens planted out by me in 1869 from tubs in which they had grown—having been small plants in Bamboo pots in 1864—about twenty years. Their stems are now 12 feet high, having magnificent heads, large bunches of fruit having been produced last year."—*Gardeners' Chronicle.*

ANTS IN TRINIDAD.—British gardeners, who often complain, and not without reason, of the damage done by ants, may congratulate themselves to a certain extent after hearing what Mr. Prestoe, in his recent Report on the Botanic Gardens, Trinidad, has to say concerning the ravages of these objectionable insects in the West Indies. "As locusts in North Africa and rabbits in Australia," says Mr. Prestoe, "are a national calamity for their destructiveness to herbage and corn crops, so are the parasol ants in this island for destructiveness to trees and shrubs of all kinds, particularly exotic ones." The labour of combating these ubiquitous pests is very heavy in Trinidad, as they occur in colonies of large area, and are composed of thousands of nests, extending over 1,000 or 2,000 square feet. The destruction of a colony some 50 feet over, employs four or five men ten to twelve days, according to the depth and nature of the strata. Where the use of boiling soap-water is impracticable sulphurous fumes are blown into each chamber, as it is opened by means of a machine with fan and tube. Care has to be observed to keep the ground clear of insects, otherwise the feet and legs of the workmen would be severely bitten. Mr. Prestoe thinks that it is unlikely that the island will ever be free from these pests; for, though all within range may be destroyed, there is a continuous supply from without, impregnated females being brought in myriads to the shores on the Orinoco current. These are to be seen occasionally in the Gulf, floating in patches several inches thick, 1 to 2 feet wide, and many feet long. So far the habits and economy of these West Indian ants are only imperfectly understood, the best account of them known to Mr. Prestoe occurs in Belt's *Naturalist in Nicaragua*, a work which has been frequently mentioned in these columns. Mr. Prestoe agrees with Mr. Belt, that the ants in question feed on "a kind of fungus, for growing which they obtain the leaves of certain trees or plants, when suitably dry, and apply them to the fungus mass for its sustenance and extension." Even in the neighbourhood of a small colony "no plant is secure from attack, and its leaves may disappear in a single night; for, the workers being in infinite number, could clear a large tree in a single night, each making but one journey.—*Gardeners' Chronicle.*

COMMERCIAL MUSEUMS.

The above subject has been recently discussed in the *Deutsches Handelsblatt*, in connection with the progress made in the direction indicated by England as well as by other European countries. In France the idea has found an energetic defender in M. Felix Faure, who advocated it in his proposal for the budget of 1884. According to the project of a so-called *Musée Commerciale Consulaire*, it would contain—1. A collection of raw material from foreign countries. 2. A collection of objects which are required in various foreign markets, accompanied by details as to prices, duties, &c. M. Faure's opinion is that private enterprise could not successfully carry out such an idea, and he therefore proposes a museum of this kind to be established at the Ministry of Commerce, and for a committee of manufacturers, exporters, and commission merchants to be formed under the presidency of the Minister. The establishment of such a museum in Paris would be followed by similar museums in other business centres.

In Germany, the formation of a museum of commercial geography was proposed in December, 1881, when (with promises of support from the German Foreign-office and Admiralty), the Central Association for Commercial Geography of Berlin sent out a formal request for co-operation to persons likely to promote the idea either by subscriptions or by exhibits. The responses to this appeal have been numerous and valuable as to the latter portion of the subject, but the funds available are not sufficient to cover the expense of arranging the collections. In Wurtemburg, however, the efforts made have been much more successful, private enterprise having established at Stuttgart a so-called "depôt of export," samples in which every branch of Wurtemburg industry is represented in a systematic manner. A catalogue has been printed, 4,000 copies of which have been distributed amongst various consulates, hotels, &c., in different parts of the world. It is printed in German, French, English, and Spanish. About 450 firms have joined in this enterprise.

The idea thus successfully carried out at Stuttgart has been partially adopted at Vienna, where the Oriental Museum deals with Eastern trade.

Belgium inaugurated a Commercial Museum at Brussels in April, 1883. This is not only a collection of Belgian industrial products, but much care has been taken in suitably classifying the samples, forwarded by Belgian consuls in all parts of the world, for the purpose of illustrating the articles capable of being imported by Belgium from various countries. The Belgian Parliament supplied the necessary funds for this undertaking.

Although not having made such an advance as Belgium in the solution of the question at issue, Italy has made progress of a satisfactory character, the Government having decided to open such institutions at Milan and Turin. The first contributions towards the Museo Commerciale Consolare were exhibited by the Minister of Agriculture at the Milan Exhibition, and at its conclusion, the claims of both Milan and Turin were brought forward in such a prominent manner that the collections were divided. Since then, the various Italian consulates have been invited to furnish articles for exhibition.—*Journal of the Society of Arts.*

INDIARUBBER AND GUTTAPERCHA.

Hardly has the cinchona culture gained a footing in Java, when two new produce articles for the European market begin to attract attention. These are Indiarubber and guttapercha. Both, almost unknown a century ago, play now an important part in industrial enterprise. The former product is the coagulated milky juice of a great number of trees belonging to different botanical families (*Artocarpaceæ*, *Apocyneæ* and *Euphorbiaceæ*). The second, on the other hand, is chiefly obtained from plants classified among the family of the *Sapotaceæ*. Both rubber and guttapercha are in great demand among traders, they being indispensable materials for submarine telegraph lines, the number of which is steadily growing. In these days of electro-magnetic motors rapidly coming into use, substitutes for them are hard to find. Many of the instruments used in medicine which are made of these vegetable gums, are besides turned to account for numerous other purposes. It is hence no wonder that botanists have been making inquiries as to the sources of supply yielding these products so greatly in demand. Very soon convincing proofs were brought forward, that the greater demand had resulted in the destruction of the trees on a great scale from tapping them being proceeded with recklessly. Immediate gain was the only guiding principle in the collecting operations. No heed whatever was paid to the future, so that export from the producing countries (Central America, Brazil, and India) to Europe fell off greatly. The export from Java has wholly ceased for instance. At the Electricians' Congress held at Paris in 1881, it was determined to draw the attention of the Governments concerned to this subject. Mr. Ten Brummeler, Head of the Postal and Telegraph department in Netherlands India, meritoriously exerted himself by forming a collection of samples of the different indigenous kinds of rubber and guttapercha; and forwarding it to exhibitions at Amsterdam and Buitenzorg. On the recommendation of the Director of the Government botanical garden, inquiries were conducted regarding the *Karet Munding* and *Karet Anjing*, two guttapercha yielding trees found in Java. Dr. Burck, the Assistant Director of the Government botanical garden, made a journey to the West Coast of Sumatra to conduct researches on the spot respecting the guttapercha trees to be found there. Mr. Berkhout, a forester, has set forth in a planting newspaper the great importance of growing caoutchouc trees in order to draw a larger revenue from the Government forests. He also dealt with the appearance, the cultivation, and the yield of the principal caoutchouc trees. Hence no one can complain of want of interest in the two new cultures on the part of Government officials. What should be done now is for the Government to take action in experimenting with rubber and guttapercha cultivation. It has readily available the funds and means needed to make head sufficiently against the difficulties likely to be met with at the outset. We note with pleasure that the Government has taken the first step in this, by directing a search for land in the Preanger Regencies suitable for planting young trees of the kinds brought under notice. But we hope that private planters will support the Government in its undertaking, that the example set by several of them, including the manager of the Chikandie Udik estate in Bantam, will be followed, and that by united efforts success will attend the endeavour to call rubber and guttapercha culture into being, alongside the tea, coffee, tobacco, and cinchona culture now carried on.—*Batavia Dagblad*, 23rd February.

EUROPEAN PLANTS IN THE TROPICS.—In spite of the wealth of floral beauty which lies ready to the hand of the gardener in tropical countries, the resources of temperate climates are largely drawn upon for the decoration of the flower garden in strictly tropical climates. In his report on the Trinidad Botanic Gardens, Mr. Prestoe says that for some years more attention has been paid to the importation of such English spring and summer flowering plants as Gladioli, Dahlias, Phloxes, &c., with results that have much improved the display and resources of the flower garden. It has been found that though these plants are so little tropical, and bear tropical conditions so indifferently that they either revert to the original species type, as in the case of the Dahlia, or in two or three years die out—they grow and flower for a single season in a manner that is little inferior to the productions in Europe.—*Gardeners' Chronicle.*

NEW TEXTILE PLANTS.—In the French journal *La Ramie*, M. Pailleux calls attention to a Japanese plant named *Kusu* (*Pueraria Thunbergeana*), the roots of which contain starch, while the leaves and shoots are used as food. Its fibrous portions are adapted for use in the manufacture of cordage. It is a lofty and hardy plant, attaining within a year a height of from 12 to 25 feet. It yields fruit, and grows upon the most unfruitful dry ground where nothing else would thrive, provided there is a sufficiency of warmth. It requires no care, and can be propagated by seeds or by planting. A plant named *Kappe* was shewn at last year's Amsterdam Exhibition. It is indigenous to Java, and when its fibres are carefully prepared they resemble wool, and when curled, at a moderate cost, can be used for stuffing mattresses. It can also be spun and dyed, but the fibrous appearance it retains shows that a radical improvement in the method of treating it has still to be discovered. All who examined the fibre at Amsterdam were satisfied of its contingent importance as a textile material.—*Journal of the Society of Arts.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, February 28th, 1884.)

IMPORTED FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White ...	Slightly softish to good hard bright ...	£7 a £8 10s

CHINA GRASS, RAMIE, OR RHEA.

From a gentleman who has taken great interest in the development of the rhea fibre industry, we have received a communication which we quote below:—

Ragalla, Udapussellawa, 2nd April 1884.

Dear Sir,—Enclosed are two letters from manufacturers of fancy cloths about "China grass." They speak for themselves, but one may hope to hear before long that fibre turned out by the Favier-Frémier or other processes is being worked up by the manufacturers in quantity. The fact, if correctly stated, of M. Favier having taken, in payment for the use of his machines in Johore, a number of shares in the new Company in Johore, is a proof of his belief in the machinery and the fibre as investments.

As Messrs. Mark Dawson & Son say, "the thing is too tempting" but "the moment a machine is invented that will *thoroughly* strip the outside bark *without breaking* it, then" &c.

Let us hope that time has come, but, until we are sure, let us take the warning expressed so strongly in the letter above quoted.—Yours faithfully,

S. M. KAY-SHUTTLEWORTH.

This is just what we have been saying recently, in the face of the extraordinary non-appearance of Dr. Forbes Watson at the Calcutta Exhibition with the machine which Death & Elwood had patented, and the miserable fiasco in the case of the fibre-clearing machines which were tried. The difficulty about all fibre-yielding plants is the enormous proportion of water and waste to commercially valuable fibre. The machine must, therefore, be brought to the material instead of the material being carried to the machine-house, while in the case of "China grass" or rhea, the bark is in such large proportion and so intractable that the mere products of the engineer's skill can never alone be successful in effecting the process of decortication: the chemist must be called in to aid the engineer, especially as there is much gum mixed with the ramie fibre. And after all is done, it would appear that the fibre, though much superior to jute in fineness, possesses some of the objectionable features of that fibre, especially its hardness and the liability of fabrics made from it, if crumpled, to remain so. No person can speak with more authority than Messrs. Dawson & Son of Bradford, and their letter sent to us by our correspondent runs thus:—

Dear Sir,—We have been asked by Messrs. Wm. Ecroyd & Sons to give you what information we could about "China grass." We may state that we are the only spinners of the above article in this country and have used it now for some years, and at the Paris Exhibition of 1878 we had the gold medal awarded for yarns out of China grass. Up to the present time it has only been used for fancy articles because of the price, which is caused through the bark having to be stripped (in China) by hand labour. We may also state that the India Office sent us all the samples to examine that had been used in the competition in India for the £5,000 award offered by Government, and there was not a single sample deserving of the prize, and we wrote to the India Office to that effect. We consider that there has been more money got out of the public by theorists, with the object of pushing the sale of "China grass" than any other article we know. For years past we have been asked for our opinion *re* "China grass" from various people, and, when we have given them a true statement of facts, the bait has been too tempting, and they have of course lost their money. We may state that the whole thing lies in a "nutshell"; the moment a machine is invented that will *thoroughly* strip the outside bark *without breaking* it, then it will be a commercial success; but, to judge of that, it requires to be seen by some one used to the material. Its growth is very rapid—three or four crops per year—and the above is the only difficulty we know of. We ourselves shall be only too glad if it can be done, but we must see it before believing. We shall be only too glad to give you any further information you may require, and, if you should be in Bradford at any time, we can explain to you more fully than it is possible in writing.—Yours truly,

MARK DAWSON & SON.

When Messrs. Dawson & Son speak of four crops of this nettle per annum, they may not be aware that to procure such crops, rich soil to begin with and very heavy manuring must be premised. The second letter enclosed by our correspondent runs as follows:—

I am expecting on Saturday to receive full particulars in reply to your enquiries about "China Grass." I have not been able until this week to meet with any manufacturer who could give me much reliable information Some years ago, we tried it at Domeshaye in one or two cloths, but it did not answer the purpose intended, and was abandoned. It has one great defect. When it is crumpled, it retains the creases. This is a serious defect as regards its use for dress-goods. It has latterly been used for curtains. I believe the trade is only of a very limited character.

Such is the testimony of English manufacturers; but amidst the floods of rhea literature which pour in upon us, are testimonies from continental authorities of a much more sanguine character. Amongst the latest is a prospectus of a proposed Syndicate, intended for the double purpose of making advances to Indian cultivators of rhea, and of carrying to every field where the plant may be grown, steaming troughs represented as just perfect in their effect on the hard bark and the fine fibre, the one being effectually separated from the other. It is unfortunate that the paper sent to us is anonymous, but we shall quote some of its statements, leaving our readers to judge for themselves as to the *bona fides* of the writer. The project for the "Lini-soie Syndicate," though not signed, in consequence probably of the modesty of the writer, is dated from 220, Gresham House, Old Broad St., London, E.C., and the statements put forth are qualified by no such "element of doubt," as the letters of Messrs. Dawson and the other manufacturer might raise. Listen!

China-grass gives a yarn from which is produced the strongest canvas; the finest gossamer; rich curtain stuff of every shade and colour, and its noils mixed with sl ldy, make an excellent cloth, strong and durable.

The marvellous strength of China-grass Fibre, its adaptability to every manufacture, whether used alone or in conjunction with other material, and the facility with which it takes every shade of colour, are qualities very precious to the spinner.

The basis of this enterprize consists therefore in the fact that China-grass contains fibres capable of being used in commerce, but that their cohesion to bark and wood has hitherto rendered their separation a process so slow and difficult as to make the cost too high to permit any hope of commercial profit from their treatment on a large scale.

China grass has nevertheless been for many years imported into England. It is put in the market after a prolonged handling by the Chinese, who have never been able to take from the stem more than a portion of the fibre, leaving the finest and most valuable part on the wood. China grass in this state is sold at from £45 to £50 per ton, loaded with at least one-third of its weight of a gummy matter, and the separation of this gum from the fibre entails not only loss of weight but an expensive and tedious process, calculated by Bosky at £32 per ton, making its cost price £100 per ton.

All efforts to secure a regular reliable supply of the raw material have hitherto failed, and whilst it is admitted that many of the British possessions (India more particularly), are especially favourable for the growth of the plant, no method of treatment on a scale commensurate with the possible production has been found practicable. We have studied every machine known (some forty) and have found none to fulfil the conditions, we believe, indispensable for the purpose under notice. Wherever cheap labour is obtainable it is in every way preferable to the best machine.

Only those conversant with the fact that all the fibre obtainable from a stem of Ramie is according to its length one-tenth to one-twentieth of an ounce can understand that the magnitude of the work comprized in machining hundreds of tons, renders the adoption of a system of steam and water power, serious to a large cultivator, and impossible to a small one; we are, however, principally influenced by the knowledge that the *Ryot* (on whose co-operation we count largely) with his small holding, could spare neither the capital to purchase nor the space required for plant of any kind, and the system of the Lini-Soie Syndicate requires of him neither capital nor space; besides, machinery includes machinists, and to create in new countries such a vast body of machinists as would machine the quantity produced, would be too slow and expensive a work, demanding an amount of space and motive power impossible to procure, and an outlay for plant, on which no satisfactory results would ever be realized.

Therefore, recognizing the objections to machinery in India where labour is so plentiful, we submitted to Professor Frémy, Member of the Institute of France, the difficulty in which we were placed, having to deal with an enormous quantity of ribbons obtained by Favier's process (*vide appendix*), begging him to supply, if possible, a means of completing M. Favier's discovery. We stated our requirement to be a process so simple as to resemble Favier's process, which requires of the cultivator neither skilled labour nor plant of any kind, and particularly a process whose result would be *absolutely reliable*, and also that on reception from the cultivator of his crop, it should not be subjected to machinery, the concensus of opinion denoting that, even if machinery could be made to act on the enormous quantity of raw material necessary to produce a given weight of filasse (ungummed fibre), the delicate fibres would be injured and their textile strength diminished.

Professor Frémy undertook this task and associated with himself his chief assistant, M. Urbain. He has succeeded in satisfying every requirement.

Our readers will observe that every element of doubt is eliminated: Professor Frémy has "succeeded in satisfying every requirement." If this statement is sustained in practical application, it is most important, and this is what we are further told:—

A whole year has been occupied in experiments, the inventors insisting, as a preliminary to permitting their names to be associated in any commercial enterprize, that the processes should pass through *all tentative stages* to their satisfaction. This has been done on a scale sufficiently large to approximate with the actual working of the two patents, and manufacturers are specially invited to visit the works in France, and to send there any quantity, up to one ton, of freshly cut rhea, sending at the same time a sample of the finished product required, so that, on return of the rhea converted into yarn the senders may judge for themselves of the remarkable simplicity, wonderful celerity, and absolute perfection obtained.

We have thus overcome all difficulties and reduced the cost of treatment, (particularly in countries, where, as in India, labour seeks employment at low wages.)

We increase the amount of fibre obtained, and that without its being torn or beaten by any contrivance, and produce yarns of any number, with the suppleness, marvellous strength, silky brilliancy and the numberless advantages of China-grass at half the cost of flax.

The "we" who profess to have done all this, sign themselves merely as "The Lini-Soie Syndicate," the very body they wanted to form. It may be all right, but we naturally desiderate names. The Syndicate, or rather the projectors of the Syndicate, go on to say:—

We propose that with the production and cutting of the stems, the work of the agriculturist ceases, and that these stems be purchased by the Company we desire to form, at such a price as would give the cultivator *a better profit than any other crop he could raise.*

It is not proposed that the Company insist on purchasing any crop. It would willingly arrange with each producer to allow the advances made to remain until the crop had been converted into fibre and sold in the open market, charging him merely interest, commission, and an agreed price for the conversion, just the same as a miller would charge for converting wheat into flour.

In the case of purchase of crops, it is within bounds to assume that there would soon be at least 5,000 acres in cultivation, which would give in the first year one crop of about 2,000 tons of ungummed fibres; doubling the quantity the second year; trebling it in the third, and quadrupling it the fourth, from which time four crops a year would be regularly obtained, and *if the Company sell at £60 per ton what is now sold for* £100, a most satisfactory result would follow.

We propose (and we have already provisionally accepted important propositions) to have in each district a responsible Agent, who would be supplied with plants of the most approved growth; with very small portable boilers, and with money to advance on the growing crop, and that at every cutting, each Agent would go round his district, steaming the produce of each holding, (the ashes of the wood burned for fuel for the boiler, and the dead leaves, forming excellent manure for the next crop,) and paying the owner on the spot for the quantity of ribbons produced. The process used (Favier's) requires merely wooden boxes, and the small portable boiler sent by the Agent, wherewith to make the steam required. Thus, instead of carrying 10 tons weight of stems, but *one* ton of ribbons have to be transported. The agriculturalist is not troubled with any calculations as to royalty, patent rights, or purchase of machinery. He utilizes every foot of his holding, and the transaction is limited to an operation familiar to him viz:: the raising a crop, and the selling it on the ground, and he has four crops in each year, no seed to buy, and cuttings to sell.

The grand merit of this scheme is that it proposes to carry a portable boiler and a steaming trough to every field; the weak point is the anticipation of four crops per annum in perpetuity. Even with the ashes of the stems and the aid of the fuel used for heating the boiler, there would not be manure enough, and, to prevent utter exhaustion of soil, rotation of crops would have to be resorted to. But scepticism is shamed out of the field by a quotation made from Sir William Wedderburn, to the effect that

Of all debtors in the world, the Indian ryot is the most frugal, the most industrious, and the most religiously desirous to pay all that he owes.

This is entirely new to us, and will be, we suppose, to the vast majority of members of the service to which Sir William belonged. But to quote again:—

The ribbons containing all the fibres would be conveyed to the works of the Company, fixed at some convenient and central spot, and would there, by the Frémy-Urbain process be converted into filasse ready for the spinner. This system would be adopted wherever Rhea-grass can be advantageously grown, and would secure to the Company three results:—

1st. The obtaining, at a price remunerative to the grower, and advantageous to the Company, of an enormous supply of the raw material.

2nd. A limitless field of operations in transforming, as already shewn, the raw material obtained into perfectly clean filasse for which it would, as an invariable rule, accept the market price.

3rd. The small capital sunk in plant would enable the Company to treat a maximum of produce with a minimum of cost.

With the progress of years and the consequent extension of the Company's business, its profits from treating purchases, and its commissions on sales would of course grow with the extension and cultivation of the plant.

As to the cultivation of the Rhea and its markets it is only by a visit to our offices that a just idea can be formed of its future.

We exhibit:—

1st. Ramie decorticated by Favier's process.

2nd. Ramie decorticated by Favier's process and then treated by the Frémy-Urbain process.

3rd. Ramie so treated and converted into fibre, divested of its gum, so that no loss of weight is incurred by buyer, this we call Filasse.

4th. Filasse converted into slivers, yarns and thread.

5th. Trowser material of excellent quality and texture produced with the most indifferent shoddy worked together with China-grass, which can be made to closely resemble wool.

The Rhea is also so capable of being worked with silk, that already in velvet-making it enters for a large proportion, notably at Lyons, which takes all the produce of Louviers for this purpose; for curtains as well as the finest articles of haberdashery, large fields are opened for the use of this noble fibre, whilst for sail-cloth it has this invaluable advantage, that whilst flax, when wet, becomes stiff and rotten, sail-cloth made from Rhea-grass is always soft and sound, and though *half* the weight, is of *equal strength.*

Samples of all the articles above-named may be seen at our offices, and the actual production of some of them may be seen at extensive works in France, and Belgium.

In France China-grass is bought as now imported from China, and is treated by the Frémy-Urbain process. It is then converted into yarn as high as No. 100 *i.e.*, about 50,000 yards to the pound, specimens of which arealso exhibited, and any quantity can be supplied for experiment.

These yarns are produced at Louviers, and also at the Liniere Gantoise, in Belgium. In order to show the capabilities of China-grass we also exhibit curtains, drapery, sail-cloths, handkerchiefs, shirting, and fancy articles made from China-grass at Huret-Lagache, France.

That certainly sounds very satisfactory, only that we should like to know the cost at which the China grass was decorticated, dyed, spun and woven into fancy stuffs. So far from being prejudiced against the China grass enterprize, we are most anxious for its success. All we want is to feel that the enterprize recommended for adoption and the investment of capital in carrying it out are on sure ground.

As to rate of growth, frequency of crops and proportions of stems and "ribbands," the statement is:—

The following statements are, it should be said, taken from actual working in Algeria, and although modifications for or against may be necessary, according to the country in which the work has to be carried on, yet they are confirmed by the superintendent of the Government establishment for the growth of Rhea at Hamma, near Algiers, and this gentleman adds, "our experiments made on a sufficiently large scale to ensure substantial grounds for calculating returns, have no unusual character."

The first year gives crops which are *doubled* the second year, *trebled* the third year, and *quadrupled* the fourth year, one thousand pounds of green stems giving about 100 lb. of ribbons. So soon therefore as the regular crops, *i.e.*, in the fourth year are reached, the ton of green stems will cost about 4/- a ton brought to the steaming box, and give at least 10 per cent. of ribbons, the cost of which is consequently: 10 tons of green stems at 4/- = £2.

The above figures may be in excess as to production of one country and below that of another. The mean, however, may be easily reached, and, addressing ourselves as we do to experts in the matter, we shall be happy to receive any well-supported information (founded on the treatment of at least one ton of stems), correcting any figures we may have given inaccurately.

Finally the projectors say:—

In inviting you to interest yourself in the formation of this Company, permit us to lay before you the following considerations:—

The two patents (both the property of the Lini-Soie Syndicate) in Great Britain and Ireland and every English Colony, effect the following:—

1st. Decorticate Ramie by Favier's process.

2nd. Dispense with retting and scutching.

3rd. Remove with unerring accuracy such an exact proportion of the Cutose, Pectose, and Vasculose (bodies discovered by Professor Frémy to be contained in the substance hitherto known merely as *gum* or cementitious matter) as may be necessary to produce the strongest sail-cloth, cordage, etc., or the finest gossamer filament, giving to this fibre so treated the strength and durable gloss of silk, so that its true name is Lini-Soie.

We have not heard whether the representations quoted resulted in the formation of a Joint Stock Company as was desired. Can any reader tell us?

Appended to the pamphlet from which we have quoted so largely, are extracts from the London *Times*, which, with a vast mass of other matter on the subject, have been already quoted into the *Tropical Agriculturist*.

EASY METHODS OF MAKING PICTURES OF LEAVES, FLOWERS, ETC., ETC.

(BY S. K. LAWTON, OF JAFFNA.)

Nothing can be more interesting and satisfactory to the distant proprietor, than to receive exact and truthful pictures of the leaves of the different trees on his estate, which, in addition, as representations of the various aspects of leaf and other diseases, would prove more useful than mere word descriptions. A pencil sketch, besides requiring considerable skill in drawing, is liable to be deemed inaccurate and untrustworthy. By the following methods, beautiful and clear images, with delicate tracings of the nerves of leaves, and gradations of shades, can be produced, and the manipulations are so simple that anyone can expect to succeed at the first trial. Besides producing pictures of leaves, the process can be applied for many purposes useful to planters and others. Drawings of machinery, plans, &c., engravings, letterpress printing, &c., and even ordinary photographs, can be reproduced any number of times. With a little artistic skill, grasses, ferns and flowers can be arranged and grouped to form very beautiful designs, mottoes, &c. Those who occupy themselves with fret-sawing can multiply their designs by it, and the unfortunate planter can revenge himself by putting in the duplicating frame the "poochies" and winged insects that thwart his enterprize.

The chemicals required for the work can be found in all dispensaries, and the appliances can be improvised out of the articles found in any bungalow. Have four clean white bottles, and put into one 100 grains chloride of sodium (or common table salt) and 10 ounces of water, and mark it "Chloride." In another, 100 grains of crystallized nitrate of silver and 2 ounces of water, and mark "Silver." In the third 1 ounce of hyposulphite of soda and 10 ounces of water, labelled "Hypo." It would be well also, though not indispensable, to have another bottle marked "Gold," with 30 grains of acetate of soda, 1 grain chloride of gold, and 10 ounces of water. The best water should be used, and in the case of "Silver," distilled or rain-water preferred. The paper to be used is the ordinary glazed foolscap, without water marks if possible, but the albumenized paper used by photographers would serve much better, if the expense is not an objection. A few ordinary porcelain dishes and a photographic printing frame complete the kit necessary. A fair substitute for the frame can be arranged with a smooth board, a few pieces of felt or flannel of close texture, and a piece of plate glass. Cut the foolscap or other *plain* paper into sizes and immerse them one by one into a dish, filled with the "Chloride" solution, and leave to soak for about two minutes, and, after slightly removing the superfluous moisture with a clean cloth, pin them on to strings to get dry.* Mark one side to show the unprepared surface, and coat the other with the "Silver" solution, evenly and well, using a brush. It would answer better to float the paper on the "Silver" solution in a dish, if a larger quantity than what is given above be prepared. This part of the operation should be done in a dimly-lighted room, or preferably by candle-light, as the paper gets spoilt in daylight. Hang up to dry and preserve in a book till wanted. Care must be used in coating with the "Silver" solution, as it causes a stain on everything it come in contact with.

In copying leaves, select those that are free from imperfections and of as dark a colour as procurable, and, if the stems are also to be included, reduce their thickness with a knife so as to equalize the pressure throughout. Having evenly spread the felt or flannel over the board, lay the prepared paper over it, unmarked side facing up, and place in contact with it the leaf to be copied. The upper sides of leaves are always flat and smooth, and therefore should be in contact with the paper. The stronger the pressure the clearer the impression; it is therefore necessary to keep the whole pressed down with a piece of plate glass and elastic bands. The whole arrangement is taken out of the room, and placed in sunlight, when a a change takes place in the paper; the exposed parts

* Albumenized paper should not be put in the "Chloride" solution. It requires only to be *floated* on the "Silver" solution.

assuming, by degrees, a dark-brown tint, in from 15 minutes to half-an-hour, according to the strength of light. The exposure should extend so long as to make all the nerves of the leaves shine, and the whole impression is darker than it is required to be, when finished, as it loses depth in the subsequent operations. When well-printed, withdraw the paper, in a dimly-lighted room, when a most beautiful impression will be found on it, with all the branching veins and shades of the leaf, brilliantly defined in white on a dark ground.

The picture is washed in a large dish of clean water and transferred to another dish, filled with the "hypo" solution, from which it is removed after a few minutes, and left to soak in three or four changes of water, for several hours. After drying, the picture is completed and can be examined in strong daylight. A brown or black colour can be given to the impression, by floating the paper in the "gold" solution, till the desired effect is attained. This is best done before immersion in the "hypo" solution.

For reproducing drawings, engravings, photographs, &c., a strong printing frame is required. This instrument ensures absolute contact, and allows the progress of printing to be examined from time to time, till the right point is attained. Engravings in the *Graphic*, *Illustrated London News* and other papers, should be damped at the backs and the printed letters removed by lightly rubbing with an ink eraser. Engravings without printing on the back, like *Punch*'s cartoons, can be copied as they are. The printed side must be placed in contact with the prepared surface, and exposed to the light till the lines of the copy are a little dulled. The subsequent operations are similar to those in copying leaves.

The copies are all reversed with white lines on dark grounds. Exact copies of the original engravings, drawings or leaves can be obtained by making prints from the reversed copies.

The only daawback in the above processes is the time occupied. By keeping several frames in operation, and washing and fixing a number of pictures at one time, quick copying can be done. By a variation in the process, from 40 to 60 copies can be printed in an hour, in bright sunshine, but the manipulations are not easy for a beginner.

Drawings or writings to be copied should be done in deep opaque or orange-coloured ink; Indian ink would also answer, if very thick.

AN EX-CEYLON PLANTER IN MANITOBA.

(*From a private letter to a friend in Ceylon.*)

Box 117, Brandon Post Office, Manitoba,
Canada, 15th Jan. 1884.

I came on to this country from Australia as you may possibly have heard. I found my brother here; he has been farming in partnership with a friend, and as things go has done well.

I have taken up two blocks of Syndicate land, one of 320 acres and the other 160 acres. They are well situated and in time will prove valuable, as one of them is only about 1½ mile from a station and the other about the same distance from a siding and they are only about 12 and 6 miles west of Brandon. Of course, the value of land in this country will entirely depend on how the crops turn out and also on the market for its wheat. At present, there is great dissatisfaction in Manitoba and the North-West: this is chiefly due to the poor returns which the farming has given during the past season which was partly caused by early frosts which damaged the growing crops in many parts of the country, but this was not exceptional to Manitoba as it also did harm in Ontario and in many of the wheat-growing lands in the States. I am told that these frosts are quite unusual and may not occur again, so we must hope for the best. Another cause of the dissatisfaction is the high rates of freight which are being charged by the C. P. Railway which has the effect of keeping down the price of even good wheat, and, owing to the conditions of the railway charter by which the Company has a monopoly, no other railway can be built south of the present line by any other Company. We are therefore in the hands of the present Company, unless we can get the Government to break the contract. Another cause of grumble is a duty of 35 per cent which is charged on all foreign machinery: this is a very heavy tax on the farmers as they use a considerable amount of machinery which is manufactured in the States. The dissatisfaction caused by these and several other grievances is at present being shown by meetings being held all over the country, and an association has been formed which is called the "Manitoba and North-West Farmers' Union." A great meeting was held in Winnipeg lately, and it was decided to send a deputation to the Government at Ottawa, and if satisfaction is not got from the local Government they will then be sent to England to the Privy Council, and, failing there, I believe this country (Manitoba) will go in strong for annexation to the States,* which would be a state of things I would be sorry to see, as I think few Governments are equal to the English, and perhaps none are.

The life here is pretty rough, but no doubt will improve in this respect in time; the work is hard and as much as any man would care for. On the whole, I consider I did fairly well last season, as I got nearly 100 acres broken on one place and 30 acres on the other, so I ought to have a fair return next crop if all goes well. This work was done with two teams of horses, and generally with the help of only one man about 110 acres of this land was backset (or reploughed), so that really 240 acres were gone over in the season—when the land is backset, it is ploughed about 2 ft. deeper than the first ploughing. What crop I had last season did not give any return except that it will help for horse food and seed. I did not expect to sell any wheat, as I had only a small acreage and so was not disappointed as to that crop, and, in fact, it did as well as I could expect, considering the season. I do not think fortunes are going to be made out of farming, but no doubt, with good seasons and prices, a fair living may be obtained.

My land has been taken up from the Syndicate on cultivation and payment terms, and these terms will have to be complied with before I get my patent for same. I had a letter some months ago from Mr. ——— from Tasmania, but have not heard from him lately. I hope he and his are all well and that they find the farming life suit them. The climate here is very pleasant in summer, but I must say I do not like the long and very severe winters; when the thermometer is low and a wind blowing the cold is almost unbearable. Of course, the monotony of the winter is broken at times by a spell of fine pleasant weather. On the whole, I would not care to settle down for good in this land, and I will probably try to sell or rent my farms and will then make a move either to a tropical or temperate region if I saw a fair opening for making a living there.

COCONUT PLANTING.

I have often wondered why, in these times, when there are so few really good openings for men with small capital, coconut planting has hitherto claimed so little attention. Yet, for those possessing sums of £1,000, or even less, there is perhaps no more reliable investment.

Take Fiji, for example. There you may purchase for little more than £100 a tract of land, of which a

* Where there are heavier duties on imported machinery than even in Canada!—ED. C. O.

hundred acres at least are suitable for coconuts. In nine cases out of ten this land has originally been the property of a cotton planter, and has therefore been cleared, so that the purchaser has simply to burn down a few straggling bushes and commence to plant.

Great care must be taken in selecting the ground, for on certain soil in Fiji coconut trees grow well but do not bear; but native judgment should be taken in a matter of this sort, and, apart from that, there are almost sure to be some full-grown trees already on the land, which would give one a fair idea of its adaptability for coconuts. Where clay is a prominent feature in the soil, the trees will not bear well, and, above all, should be avoided—planting where the tree known in Fiji as the "nokonoko" grows. There is only one other danger, viz., hurricanes, and, to provide against this, a spot fairly well sheltered from the north-west wind is desirable; but the risk of full-grown trees being wrecked by hurricanes is so slight that, taking other advantages into consideration, the situation, if not an unusually exposed one, should not stand in the light of the intending purchaser.

The *modus operandi* is very simple. The coconuts are placed in a hole in the ground, of no particular depth, but the distance intervening between each nut should be at least twenty-two feet, as plenty of sun and air is necessary.

In many cases coconuts have been planted only eighteen feet apart, but this cramping process is rarely successful, as the trees do not bear well.

In eight years from the time of planting the trees should be in full bearing, and each acre of land ought then to produce at least one ton of copra per annum. The average value of copra is, I should say, about £20 per ton, and the fibre should more than pay the whole working expenses of the plantation; so that 100 acres, when in full bearing, would bring in a clear profit of £2,000 per annum.

The cost of planting 100 acres would be at the most £100; and ten hands (natives), at an annual cost of £10 each, would do the necessary work. At the expiration of three years the plantation might be left to look after itself, for coconuts only require to be weeded for that period, so that the sole remaining expenses would be the actual living of the planter, which, if he be content to follow the scale of diet adopted by the early settler, is not a very serious item. An occasional cask of salt beef from Levuka, a little tea, flour, and sugar, and, in a climate like Fiji, little else is necessary. Fruits and vegetables may be bought for a mere song, yams ranging from 2s. a hundredweight. The rivers swarm with fish, and poultry rare themselves.

So here we have paid £100 for our land, £100 for planting it in coconuts, and £300 for three years' labour; so that out of our original capital of £1,000 we have a balance in our favour of £500, which certainly ought to pay all incidental expenses.

Most people object to coconut planting because of having to wait seven years without any returns; but it should be remembered that the fact of the land having been planted in coconuts does not hinder the planter from turning his spare soil to other uses. Maize, yams, sweet potatoes, or indeed almost any other vegetable may be planted between the young trees without in any way interfering with their growth; nor is it at all necessary for the investor to remain on his land after the first three years, when, in the event of his desiring more active employment, he might seek it in the Australian colonies, and return in a few years to find his plantation in full bearing, and himself on the safe road to a speedy fortune.—Coconuts.—*Field.*

Effect of Paraffin Oil on Fruit Trees.—The recent Apple Congress called attention to the need for extending and improving the growth of apples in this country, and an article on "Our Orchards and Paraffin Oil" in the current number of the "Nineteenth Century" shows how one of the most serious drawbacks to the profitable growth of orchard fruit may be remedied. The author of this article relates his experience in the application of paraffin oil to the trunks and branches of fruit trees for the purpose of cleansing them of the lichen and other parasitical growths by which their vital energies are sapped, and premature barrenness is caused. The trees on which the successful experiments were carried out were painted with paraffin in the Autumn, and in the early Spring, before the sap began to rise, the dead bark and lichen were scraped or brushed off the trunks and branches. The result was to restore apparently worn-out trees to full vigour and fruitfulness.—*Standard.*

Rust Preventive.—All who live by tilling the land would do well by bestowing a little—or rather, a great deal—more care and attention upon the tools and implements they use than is the rule. Rust is a costly thing to maintain, and when once it commences its work it is hard to keep in check afterwards. The simple preparation employed by Professor Olmstead, of Yale College, America, for the preservation of scientific apparatus, and which he long ago published for the general good, declining to have it patented, is made by the slow melting together of six or eight parts of lard to one of resin, stirring till cool. This remains semi-fluid, always ready for use, the resin preventing rancidity, and supplying an air-tight film. Rubbed on a bright surface ever so thinly it protects and preserves the polish effectually, and it can be wiped off nearly clean, if ever desired, as from a knife-blade; or it may be thinned with coal oil or benzine. A writer in *Forest and Stream* says that if oxidation has begun, no matter in how slight a degree, it will go on under a coating; it is therefore essential that the steel surface be both bright and dry when filmed over. Our Queensland farmers and gardeners would do well to keep this mixture by them for use when wanted.—*Queenslander.* [So with those who have articles of iron and steel in Ceylon.—Ed.]

Seeds from Ceylon.—In our advertising columns will be found a notice from Messrs. J. P. Williams and Brothers in Ceylon from which it will be noted that this firm are now prepared to despatch to Queensland a variety of Tropical Plants and Seeds. We have received testimonials from various persons in Queensland speaking highly of the quality of shipments of plants and seeds hitherto received from the firm mentioned, and we think that such persons as desire to experiment with tropical products new to Queensland cannot probably place their orders in better hands than those of Messrs. Williams and Brothers. There is no question whatever as to the desirability of introducing new plants of economic value to the tropical and semi-tropical parts of Queensland, as the practice of depending on one class of produce alone cannot be regarded as a judicious one. We shall with pleasure hear that some of our local agriculturists intend striking out in a new path and shall watch with considerable interest any experiment which may be made in this district whether it be with Ceara Rubber, Cinchona, Divi Divi, or others of the numerous industries for the adoption of which our climate is highly suitable.—*Mackay Standard.*

Sugar in New South Wales.—It has been, and continues to be, frequently asserted that if sugar can be successfully grown on the Clarence and Richmond with white labor that it can consequently be equally successfully grown in tropical Queensland under similar conditions. Putting aside the question of the great climatic difference existing between New South Wales and Queensland, a very pointed contradiction to the assertion alluded to was given by the Clarence and Richmond growers recently. It was proposed by the Government of New South Wales to make an alteration in the tariff which would include a reduction of the £5 per ton import duty on sugar in that colony. The Clarence and Richmond growers at once lodged a strong protest against this, maintaining that a reduction of the protective duty under which they are enabled to produce sugar profitably would ruin the industry in that colony. For every ton of sugar they make they to all intents and purposes receive a bonus of £5, and we have no doubt that if our Government were prepared to pay to our growers a similar bonus, on condition that nothing but white labor was employed, some of the planters and farmers might be tempted to make the experiment, at the same time we are by no means prepared to say it would be a successful one.—*Mackay Standard.*

THE CULTURE OF FIBRE PLANTS IN S. INDIA.

TO THE EDITOR OF THE "FIELD."

SIR,—I notice a letter with the above title, signed W. J. Kemp, in your issue of the 16th inst., from which it appears that the writer is not quite clear as to where Johore is, and couples it with S. India.

Johore is the southern part of the Malay Peninsula, between Malacca and Singapore.

Though I agree with the remarks regarding the unfitness of the plains of S. India, I must take exception to the statement that the climate of Johore is "too hot, and otherwise unsuitable," for the cultivation of rhea.

Ramie being indigeuous there, I think sufficiently answers this statement—in fact, the French term for the fibre, "ramie," is simply a Gallicised form of the Malay word "rami," the rhea plant.

The only other point in the letter that I wish to call attention to is regarding the "ryot," or "apathetic Hindoo agriculturist." With him, I am glad to say, we shall have nothing to do, as we rely almost entirely on Chinamen—the most skilful of agriculturists, who eagerly flock to the Malay Peninsula.

Now that the process for utilising the plant has been discovered, we are face to face with the scarcity of rhea; and I can imagine no better source to turn to for a supply than its very cradle, Johore.

The figures given by Mr. Kemp, favourable as they seem, are quite in accord with other calculations that have been made.

I claim, as it were, a right to address you on this subject, as I have spent some years in Johore, and, in fact, was the pioneer European planter there.—E. A. WATSON, 19, Cullum-street, E. C., Feb. 21.

OLIVE OIL.

The quality of the oil depends greatly upon harvesting the olives at the proper time. If this is done either too early or too late, the product has a fatty favour or odor.

Italian Oil.—The oils of Lucca, Calci, and Buti, are the best in the world, and those of Umbria and Liguria are but little inferior. The best article is produced in moderately warm regions. Thus the oils of Italy are more esteemed than those of the Orient, and of the former the oils of Pisa, Lucca, Arrezzo, Perugia, and San Remo, are better than those of Sicily and the Neapolitan provinces. While soil, climate, and the variety of the plant affect more or less the quality of the oil, much more depends upon harvesting and pressing the olives properly. That is done much better in Central Italy than further south.

Spanish Oil.—Next to Italy comes Spain in extent of olive cultivation. According to Mueller, the production of oil in that country is about 1,135,750 hectoliters per year. It is chiefly cultivated in the basins Guadalquivir, Ebro, and Guadiana, and the product constitutes an important branch of commerce for Andalusia, Aragon, Catalonia, Murcia, Navarra, and the Balearic Islands. Spanish oils are very little esteemed, and their exportation is rather diminishing.

French and Algerian Oils.—In France the cultivation is confined to the southern districts, and covers 94,000 hectares. The production is about 250,000 hectoliters. In Algeria about 150,000 hectoliters are produced, of a quality inferior to that of Italy, but better than that of Levant, Spain, or Portugal.

Austrian Oil.—In Austria the olive is a little cultivated in the southern Tyrol, and in the territory Gorixia, Gradisa, and Trieste, more extensively in Istria and Dalmatia. The yearly production is about 264,000 quintals. Of the production in Greece accurate statistics are wanting, though it is known that the cultivation is extensive.

Ottoman Oil.—In the Ottoman Empire it is cultivated in Syria, Brussa, Roumelia, and in the islands of Candia, Cyprus Metilino, Samos, and Rhodes.

Greek Oil.—Grecian and Turkish oils are, however, only used in Europe for the manufacture of soap.—*Consular Reports.*

THE GROUND NUT TRADE.

A few days ago we extracted a paragraph from a Bangalore paper in respect to the progress made in the growth of ground nuts in that part of Southern India and the export trade carried on between Madras and Europe in the produce. Ground nuts do not need much, if any, care in cultivation. They grow on dry, sandy soil, and need no water nor particular care as to the time when supplies of seed are put down and when they are reaped. The dry season is best adapted for the growth of the nuts, because when rain falls and water is available, expensive crops are grown and better returns obtained. With the close of the grain reaping season, extensive plots of land, especially in the Chingleput, South Arcot, parts of the Tanjore and Trichinopoly districts are sown broad cast with ground nuts. The Pondicherry merchants deal extensively in this article, and their representatives go about from district to district making advances to ryots for supplies of the nut. At certain seasons the price of ground nuts varies from R15 to 19 per candy, but, last year, when the season was at its height and every available bag was bought and shipped to France, the quotation advanced to R24. Of late years the Pondicherry merchants have dealt chiefly in ground nuts, as it has been found that the French markets are not so well suited to the indigo trade as they once were. Ground nuts shipped at Pondicherry find their way to Barcelona, Marseilles and Genoa. These are the chief emporiums of the trade on the continent. Formerly it was considered necessary, with sailing vessels to take the supplies to market, to send the nuts in kernels. The bulk of the nuts was great, but a good deal of what was rejected as refuse was sent, so that the trade suffered somewhat. Every sailing vessel occupied at least four months on the voyage from Pondicherry to France, so that it did not pay to send ground nuts kernels only—as supplies were rendered almost useless when they were landed at the Mediterranean ports. With, however, the introduction of steamers which now monopolise the carrying trade, it has been found advantageous to ship ground nut kernels: the voyage does not, by the Suez Canal, occupy more than forty days, and the nuts arrive in very good condition. With cheap freights large supplies are now sent, and ground nuts not only attract the attention of the French merchants, but small Hindu capitalists readily enter the market and make advances to the growers so as to secure supplies as they are gathered by the ryots. Large supplies of ground nuts find their way to the Mediterranean ports from Senegal, which, being only fifteen or twenty days' sail by steamer to Genoa and Barcelona, is able to land the nuts in far better condition than they can from the ports in Southern India. Thus there is healthy rivalry between the ground nuts grown in the southern districts and those available on the west coast of Africa, and an importance is attached to an article of produce which ten years ago was almost unnoticed by merchants dealing with Europe. The nuts shipped at Pondicherry are used chiefly in the manufacture of oil which, it need hardly be said, is used extensively all over the European continent and especially in the south of France, Italy, Germany and in the Mediterranean ports. The first supply of oil extracted from the Southern Indian ground nuts is of very superior quality, and after undergoing certain processes in distillation is retained for local consumption. After a time, additional heat and pressure produce a second class oil which is shipped to India and other parts under the name of Lucca oil and salad oil. It appears that a third quality of oil is also extracted and retained, while the remnants of the nuts, the cake, is given to cattle for fodder. Thus the uses to which the ground nut of Southern India is put in the commercial parts of southern and central Europe are such that the trade in it keeps many agency firms in the French Settlements in India agoing, while Hindu dealers make fairly large profits by advancing sums of money to the growers and securing the bulk of the crop when it is gathered. The entire trade in ground nuts has now been diverted to the southern districts, and Pondicherry has become the head centre of it. Some years ago, the nuts grown in South Arcot, Tanjore and other places were converted into oil and sent to France. But it has since been found that the system under which the oil is extracted in Genoa and Barcelona is far superior to that adopted here, that the two or three different qualities of oil obtained materially influence prices and trade, and consequently with the existence of the Suez Canal and steamers ready to take cargo on the most advantageous terms, it is felt that the shipment of the seed is of greater importance than the oil itself.—*Madras Standard.*

YELLOWING OF LEAVES.

A yellow coloration of the leaves is too sure a sign of want of vigour in a plant, and is often rightly enough attributed to some mismanagement upon the part of the gardener; but, although this truth is generally recognised, it is not so well known to what precise causes the sickly condition is due. Some recent experiments of M. A. Leclerc, performed, as it would appear, with all the attention to details, and all the care requisite to eliminate possible sources of complication and error, tend to throw considerable light upon the matter; and, although Mr. Leclerc's conclusions are based to a large extent upon plants grown in the open field by the farmer, yet it is clear that, if well founded, they must apply equally well, and indeed in many respects more definitely, to plants grown under the more neatly-defined conditions under which a gardener places his plants. M. Leclerc's experiments in the first instance were purely laboratory experiments, undertaken with a view of ascertaining the amount of watery vapour exhaled by plants, and the conditions under which that process takes place, but he was afterwards led to apply the conclusions at which he had arrived in the laboratory, where conflicting elements were eliminated, to the rougher test of the field, where all sorts of complications less under control of the cultivator arise.

Experiments showing the vast amount of fluid lost in the form of vapour or otherwise, have long been familiar to physiologists in this country from the time of Hales to that of Lawes and Gilbert, not to mention experimenters of other nations. We need not revert to these, nor to the confirmatory experiments of M. Leclerc. It may suffice to give some of the main conclusions arrived at by the last-named observer as detailed in a recent number of the *Annales des Sciences Naturelles.* As the results of his delicate and precise experiments, M. Leclerc shows that light by itself has no influence on transpiration, and that, as might have been expected, it ceases when the atmosphere is saturated with moist vapour. At first sight it would seem as if a plant exposed to the light must necessarily evaporate more fluid from its surface than one not so exposed, and that is so; but the effect is not due to the light only, but partly to the heat-rays which act conjointly with the light, and by heating the tissues cause them to give up their vapour, and partly to the chemical action which goes on in the leaves during the process of assimilating the carbon from the carbonic acid gas, and the consequent elimination of oxygen—functions which, as is well known, are exercised by all the green parts of plants when exposed to solar or electric light.

Turning to matters of more direct practical importance, M. Leclerc proceeds to speak of the yellow appearance so familiar to Wheat growers in certain states of the atmosphere. In his numerous experiments on evaporation M. Leclerc always found that plants grown for a certain time in a saturated atmosphere, or one which was near saturation point, soon became yellow. This yellowing was evidently caused by the atmosphere being overcharged with moisture. Previously he had considered that effect as the consequence of excess of water in the soil; but on examining into the validity of these two opinions, so radically different, and by the aid of easily repeated experiments, he arrived at the conclusion that the cause of the yellowing was intimately connected with transpiration, and consequently was dependent on the state of the atmosphere.

By means of an experiment, which we need not describe in detail, but the object of which was to expose the foliage alternately to dry and saturated atmospheres, the other conditions being uniform, and the roots in all cases plunged in water, it was found that the plants whose foliage was exposed to a saturated atmosphere became yellow. The yellow plants were then placed in a dry atmosphere, and the green ones in a saturated atmosphere, thus reversing the previous experiment. The result was that the yellow leaves became green, and the green ones yellow. A repetition of the experiments in both directions produced the same results. Thus atmospheric conditions alone sufficed to bring about these changes, the roots remaining in all cases under the same conditions. These results were tested in various ways, but the same conclusions were always arrived at—viz., that the yellow state of the leaves was the result of diminished transpiration, due to the more or less complete saturation of the atmosphere with moisture.

In other cases an unhealthy condition is brought about not by diminished, but by excessive transpiration. For instance, if a plant be grown under an almost constantly clouded sky, the atmosphere and soil alike charged with moisture, and then these conditions be suddenly altered, so that the leaves become exposed to a burning sun, then evaporation becomes excessive and the leaves wither. By removing a certain number of the leaves, and thus reducing the amount of evaporation, the ill-effects were checked. By observing what happened under given conditions, and by noting the result of reversing and alternating those conditions, it was shown conclusively that the unhealthy conditions were due in the one case to defective, in the other to excessive, transpiration. The gardener has the advantage over the farmer in this particular, that he can to a large extent regulate matters and prevent either extreme. For this nothing more than careful observation and tact, born of experience, are required.—*Gardeners' Chronicle.*

SAP IN TEA.

A question of the utmost importance to those interested in our tea gardens is beginning to crop up, which, though occasionally pooh-poohed, will have to be answered some day, and perhaps at no distant date. The question is whether, as the plants grow older and the old stems in consequence become tough and gnarled, the sap does not, in penetrating the tissues, lose a great deal more of its vigor than when rising through the stems of the new plants; and, in consequence, is there any soundness in the assertion that the teas from our old gardens show a marked deterioration in strength and flavor as compared with the produce of young plantations? So large is the capital now sunk in tea, that no subject connected with the business is too trivial to be discussed. The matter under present consideration can be easily set at rest by chemical analysis. Let, for instance, the constituents of some fresh leaves from two or three indigenous and ordinary class of hybrid bushes, each about two years old, be carefully investigated, and let the result form the standard of excellence: it will be easy then to deduce a formula by which any planter may from time to time ascertain whether or not any deterioration is perceptible in his plant. It is of little use seeking to slove the problem by testing manufactured leaf, as even if one uniform system of manipulation were pursued in the tea districts, atmospheric exigencies, begotten by the different sites on which the tea houses are built, would alone lead to confusion.

But, by whatever process, should a deterioration be established beyond doubt, we should have then the question to consider, first—whether such deterioration is due to the old wood and knots formed by pruning, retarding the distribution of the sap and cousequent loss of the plant's vigor, or whether the virgin constituents of the soil have been exhausted. In either case science must be resorted to. Were not our tea planters hounded on to get as much as possible off the gardens, there can be but little doubt that a periodical 'cutting back,' almost to the ground, of certain portions of the concern, in rotation, would be beneficial, inasmuch as it would result in having fresh, straight, bearing stems, springing direct from the roots with no knots in them to retard the circulation of the sap. We cannot help thinking however that an immense amount of mischief is done by the severe 'cutting back' of young plantations. No doubt the first effect, where the soil is rich and the growth of the plant vigorous, is a prolific yield, but it is at the expense of future crops, and the formation of knots and contortions which must retard the distribution of the sap. The subject of pruning has not received that amount of attention, when considered from the sap distribution point of view, that its importance demands. Our planters' efforts in the trimming line appear to have been directed too much towards obtaining the largest possible yielding area, without ensuring that the distribution of sap should be equal over that area. It has been in this way that, in a bush say of five years old, while we may have a large quantity of leaf, only a very small proportion is contributed by fresh wood springingdirect from the natural reservoir, the root. Hence, we are of opinion that a considerable differeuce in the strength of the usual properties that form the constituents of the flush will be found. Assuming our opinion to be correct, it is manifest that in a garden of, say twenty years old, the proportion of leaf taken from fresh bearing wood must bear but a small proportion to that taken from stems full of knots and old pruning obstructions. And herein lies perhaps the reason of the falling-off in strength and flavor of teas from what were once known as favorite gardens. We do not dogmatically assert this as the only reason: we express merely an opinion based on many years' experience, with a view of directing attention to the matter. The remedy will strike any professional man, but the difficulty will be to get proprietors and managing agents to give their assent. Great care and attention will be required in carrying it out. The old, and all gnarled stems, must be thoroughly excised down to the ground, and all growth emanating from the old stem, systematically cut away and discouraged, the object to be kept in view being to evolve fresh upright growth direct from the roots. The crop meantime would be considerably diminished, but it would possess uniform strength. The question as to exhaustion of soil requires the assistance of the analyst. A sample of soil, similar to that on which the garden is formed, should be taken from some uncleared portion of the grant, and compared with a sample taken from near the roots of a five-year plant. We have little doubt in our own mind but that considerable loss in valuable constituents will be discovered. For not only will evaporation have thrown off the more volatile elements, but the organic ones must be more or less absorbed by the plants: and it would indeed be a wonder if even the best soil should be found little affected by the demand made on it. If this latter experiment is carried out, we venture to assert that impoverishment will be found to be very considerable. The analyst however would be able to tell us what particular constituents had been exhausted, and, as they must all exist in the neighbourhood, there is no reason to doubt but that many gardens that are now referred to as "old and worn out" could at a small outlay be made to resume their old pristine position. During the period that new growth is being trained from the roots it would be better if no leaf were taken from that portion of the plantation under treatment, as the difficulty in preventing 'pluckers' from cropping the new shoots would be insurmountable. But the interval might be profitably occupied in returning to the soil those properties that the researches of the analyst would indicate had been taken from it. Instead therefore of going to the expense of large extensions, the renovation of certain plots in rotation are recommended, and the *jhuming* system, which some proprietors have of late years adopted, should be discontinued. In a future issue we may draw attention to the value of lime-stone as a powerful renovator for use on exhausted gardens, but the completion of the Soormah Valley Railway would place sea-weed and other marine manures within reach of the planting community, so that the gardens, or such portions of them as have been thrown up during the past three years, may be again brought into bearing with reasonable hopes of profitable result.—*Indian Agriculturist.*

NEW FRENCH SUGAR MACHINERY.

The Queensland Sugar Company, of the Johnstone River, commenced their first crushing on 14th January, and as this company are working with the only complete French plant in the colony, and it is specially provided with some labour-saving appliances, a detailed account will no doubt prove of interest to those engaged in this industry.

The manufacturers of the sugar plant are the Fives Lille Company, Paris, and the portable railway is manufactured by Decauville Company, also of Paris. The cane comes from the field cut in 3 ft. lengths, stacked on cane trucks, each containing an average of about 1 ton weight of cane, and travels on a 24-inch gauge railway arriving alongside the cane carrier. The trucks as emptied pass along an endless circular line of railway back to the field to be refilled. The cane is first operated on by defibreur, this and the cane-carrier being worked by engine No. 1. Whilst at this stage it may be well to point out what advantages the manufacturers claim for this new piece of machinery as against double rollers. They state that, by opening up the cane as it does, it enables the mill to do one-third more work and gives 12 per cent more juice without the necessity of increased evaporating plant or increased fuel and steam to evaporate, as in the case of double crushing. The defibreur further helps the rollers to such an extent that megass is better prepared for the new patent Godillot furnaces referred to later on. Another advantage represented is that the defibreur costs less than a second set of rollers.

The cane from the defibreur passes along a second cane-carrier to the mill rollers, which are worked by the powerful engine No. 2, 30-horse power. The top roller in this mill differs from any other in the colony, having a new patent shape of grooves 4 in. apart, running the whole length of the rollers, and these give the cane an additional grip as it passes through. The megass passing from the rollers shows most effective crushing, and is a decided improvement on what one is accustomed to see on other plantations.

The megass is conveyed by steam-travelling basketed trucks, of which two travelling on a short length of railway are worked by four kanakas, who simply tilt the wet megass into new patent Godillot furnaces for burning wet megass. These require special mention, as so far they are doing their work admirably, and furnish all the fuel necessary for working the mill; and owing to the immense labour saved by them, must be in general use ere long. Whilst at the furnaces, it might be well to mention that the boilers, which are tubular, differ from any others in the colony, inasmuch as each tubular boiler has underneath two tubeless smaller boilers or steam generators, which help to preserve the tubes of the boilers and get up steam quickly. Each boiler is provided with an alarm signal in the event of the water running too low, and another alarm when too much water is in the boiler. These boilers so far are giving every satisfaction. The juice from the rollers passes through the usual strainers into an underground tank, and is pumped up to a tank at the top of the building, from whence it passes to copper clarifiers underneath, of which there are four (the improved Fives Lille circular jacketed). The juice is here limed, and when clarified is left off underneath by two taps into shoots; one for dirty thick juice into a receiver, then into mont juice No. 1 to filter presses, clean juice from which goes to mont juice No. 2, and is blown up into juice tank at the top of the building, and goes with fresh juice to the clarifiers. Clean juice from the clarifiers passes along a shoot to blanket strainers, thence to charcoal filters, the supply in which is regulated by a floating ball which opens and shuts automatically as juice is required. The juice is filtered through this charcoal, and runs into a filtered juice tank on the ground floor. It is then drawn up by an aspirator into a triple effet (which can be worked together or singly), and when evaporation is completed passes by the mont juice to the syrup receiver alongside the clarifiers on the top floor. From this tank it passes through the syrup charcoal filter into the syrup receiver tank No. 1, on the ground floor; thence to syrup receiving tank No. 2, on the same floor under the vacuum-pan, where it is aspirated into the vacuum-pan and boiled to grain. From the vacuum-pan it passes to coolers, thence to the sugar-mill, and from this it is conveyed by buckets suspended from an overhead railway to the centrifugals, of which there are five of Coll's system and conical driving, and garnished with Lisbermon's patent copper tissue. The work of feeding the centrifugals is done by one man, who simply tilts the contents of the suspended bucket into the centrifugals.

The dry sugar passes to a large sugar store above, whilst molasses from the centrifugals passes along a shoot to a small receiving tank, and is pumped up to the tanks alongside the vacuum-pan, and is reboilled for seconds and so on for thirds.

The arrangement of plant for all purposes is perfect. The building, which is all iron (including columns), is 180 ft. long by 80 ft. wide, and is so arranged that spaces are left for additional plant to increase the present operations by one-third when required.

On the ground floor, which is all concrete and cement, there are in all seven engines, namely, one for cane-carrier and defibreur, second for defibrated cane-carrier, mill, rollers, and megass carrier, third for triple effet apparatus and pump, fourth for vacuum pan and pump, fifth for vertical and centrifugal pumps in well, sixth for centrifugals, seventh for pumping water into boilers.

On the second floor there is an arrangement in connection with steam worth attention. The direct steam from boilers is used in each apparatus requiring direct steam, and afterwards is sent as exhaust steam into a receiver, from which it is used for evaporating the juice or syrup. All the water from the condensation of exhaust steam is sent into a receiver alongside the boiler, to be returned into the boiler as hot water.

Exhaust steam being a mixture of steam and hot water, two special apparatus are provided for separating the two; the former passsng to the exhaust steam-receiver, the latter into the hot water receiver, thence into the boiler, all this meaning great saving of fuel.

The present is only a test crushing for about a fortnight, and though cane is standing at a density of 9°B., this no longer can be expected, as the rainy season is near at hand. The crushing of 1884 will commence about the end of May next, and the company having bought up all the selectors' cane on the river, expect with this and their own to turn out about 900 tons of sugar. Provision has been made for this estate to have under cane by early in July next 927 acres, all to be available for the season of 1885. The site of the Queensland Sugar Company's mill adjoins that of the Mourilyan Company's, and with the gauge of their railway the same, so that it has its outlet for produce either by way of Mourilyan Harbour on one side, or by the river to Geraldton, one mile and a quarter distant, on the other side.

This district of Johnstone and Mourilyan is making progress, as in evidenced by the fact that now four steamers a week are kept regularly going between Townsville and its ports.

The Mourilyan railway motor is now running three and a-half miles out from Mourilyan Harbour, all work on the line being most substantially done, and Mr. Bashford expects that he will soon be able to run the motor right through to the Mourilyan Company's Estate, thereby connecting Mourilyan Harbour with the South Johnstone River, a distance of six and three-quarter miles.—*Queenslander.*

A NEW GARDEN AT BARODA.

The Baroda (India) Public Garden is situated between the ancient city of that name and the British camp. It consists of about 100 acres of good alluvial soil, and is traversed by the Vishwamtri river its whole length, by many winding and graceful curves in a most picturesque manner, and its banks being studded with Hindoo temples adds much to the beauty of the scene, and says much for the good and enlightened taste of his Highness the young Gaekwar and his able late Prime Minister, Sir J. Madav Rao, in selecting such an admirable site for a garden. The garden was formally thrown open, and presented by his Highness to his subjects in perpetuity, in January, 1879. The main entrance is on the city side, and is adorned by massive and handsome cast-iron gates and finely-curved stone pillars, each surmounted by an ornamental lamp.

On entering there is a flower-garden on either side, which is always kept gay with flowering plants. If your visit be in the monsoon months, splendid Balsams, Zinnias, Cockscombs, Marigolds, &c., meet your gaze in all the brilliant colours of the rainbow; if in the cold weather, Nasturtiums, Phlox Drummondi, Petunias, Stocks, Verbenas, &c.; and if in the very hot weather of summer, Portulaccas, Sunflower, Calliopsis, &c., keep a continual succession of flowers, with an evergreen turf kept so by constant watering. Passing on over a fine stone bridge which crosses a small tributary of the Vishwamtri, you perceive the Gaekwar's pavilion, or pleasure-house, which alone is kept for his Highness's private use. On your right and left are extensive undulating lawns with magnificent specimen trees of Tamarindus indica and Maguifera indica; in front of the pavilion is a very large circular flower garden all on turf: it is divided into a very neat plan of eight large diamond beds, twenty-four smaller angular beds, and one large circular bed in the centre, which is intended for a fountain hereafter. Taking the road to your right brings you to a large plant-house in the shape of a cross, earch arm 100 feet long by 50 wide, with a handsome stone tank, 30 feet in diameter, with rocky scenery for fountains, their sides clothed with Ferns, Caladiums, and other moisture-loving plants, with fine jets of water playing from among the rocks in delightfully cool sprays. The other parts of the house is filled with the luxuriant vegetation of more moist climes, such as Palms, Crotons, Dracænas, Anthuriums, Dieffenbachias, Marantas, &c.; it is in such places you see the Eucharis in its full glory, with its dark pea-green foliage and snow-white flowers.

Leaving the plant-house by the opposite door from that which we entered, we pass on to the west through lofty clumps of Bamboo and finely-kept lawns, studded here and there with a nice standard Rose, or a stately Fourcroya, rearing its flower-stem some 20 to 30 feet high. A little further on we come to a small irregular lake with a small island and a pigeon-cot on it; we have now a straight avenue of Guatteria longifolia, and on either side a rosery, planted mostly with standards of the Noisette and Tea sections, which appear to thrive much better than the hybrid perpetuals. They are also all grown on the Rose Edouard as a stock, which renders them much hardier. At the end of this rosery stands a little ornamental hexagonal summer-house to all appearance, but it is the Superintendent's office, and about 50 yards further west stands a pretty little aviary, the dome of which is surmounted by a spread eagle. About 50 yards further on we come to the end of this avenue; when we turn sharp to our right before us is another avenue, but this time of Poinciana regia, on a slightly raised piece of ground. To the right of this avenue there is a fine band-stand, where music is freely discoursed once a week to all who like to come and hear it; over the band-stand climbs many a handsome creeper, prominent among which is the Bougainvillea glabra, Quis-qualis indica, Dalbergia scandens, &c.; round the band-stand is a portion set apart for pedestrians only, where horses and cariages are excluded: ornamental stone and cast iron seats are plentifully placed for the use of the public under the shade of fine clumps of Bamboos, and the magnificent Teak tree (Tectona grandis). Leaving the band-stand and following the Poinciana avenue for 200 yards, we come to the North or Camp Gate, where there is another lawn and fine flower garden, gay at all seasons with flowering plants; on either side are fine shrubberies to divide the three carriage drives that here meet, and then branch out through the garden. We will leave the gate on our left, and follow the drive that leads east through a fine grove of Babool trees (Acacia arabica), which when in flower scent the air for a long way with their sweet aroma. Having traversed about 100 yards, having on our left a tropical jungle which has been assisted by art to shut out the camp from view, we come to the River Vishwamtri: the carriage drive now follows its natural winding, and curves for nearly two miles through shrubberies of tropical luxuriance, past artificial mounds with winding paths to their tops, where fine views of the garden and surrounding country are obtained, the sides of which are planted with succulent plants and large stones for rocks. In a hollow of the bank is a fine clump of Arundo donax, with the variegated form in the foreground: to the right between us and the band-stand are three bowers, each 75 feet long, covered with twelve different varieties of creepers each, affording a cool and grateful shade from the mid-day sun. Passing on through groves of Cocoanut and Orange trees, we come out on a pretty little marble summer-house such as any Orientals indulge in, of beautiful and chaste carved workmanship. Still following the river we come to a large iron bridge which spans it, 200 feet long, with very handsome stone cupolas at each end This bridge connects the garden proper with the zoological part, which is still in its infancy. At the east end of this portion stands a pretty little cottage covered with creepers, at one end of which is the Antigonon leptopus, covering over 1,000 square feet of the roof. To the south of the Superintendent's house are the quarters for all the under-gardeners, of whom there are about forty, the rest of the labour required being supplied daily by about a hundred prison "hands," and who look the most contented of labourers.

We will now return over the bridge and resume our walk along the river bank. On our right is a maze, with dense hedges of Juga dulcis, from which you hear the hum of voices as the people in their holiday attire try to thread its intricate paths. Past this we come to three fine lawn tennis courts, where morning and evening, parties enjoy themselves. Divided by a shrubbery of Neriums from the lawn tennis courts is the general nursery, which has been a scene of activity for the last four years. When we remember that most of all the plants in this large garden have been raised from seeds and planted out into their permanent sites, we can fancy there has been work, but the climate has assisted also; everything grows with tropical luxuriance and rapidity.

As we pass round the nursery we observe a large square tank elevated some 25 feet above ground level, and naturally ask, What is this? Without this there could be no garden. Through this and a lower masonry tank passes the water for the whole garden. Two engines and two pumps works twelve hours every day all through the dry weather (that is, for eight months of the year), each throwing over 6,000 gallons per hour. The tanks are connected with the underground system of piping, which supplies the whole garden, and there is no part more than 300 feet from a standpipe. The water is distributed over the ground by means of canvas hose from these standpipes. The greater portion of all this has been done under the present Superintendent's directions. Some four years ago a few carriage drives and a few footpaths were all that could be seen of this now splendid garden. The present incumbent, J. M. Henry, is one of our northern gardeners who, after being through many of our good gardens at home, was sent out as a young man from Kew to the Madras Agri-Horticultural Society. After serving his contract time with the above Society he travelled a great part of India, and finally settled down under the enlightened and good government of one of India's most promising young rulers.—HORTUS.—*Gardeners' Chronicle.*

VEGETABLE PRODUCTS OF SMYRNA.

In a very elaborate report on the trade and commerce of Smyrna for the years 1877 to 1881, the British Consul has given some very interesting details on the products of the country. The following abstracts under their respective heads will, no doubt, prove acceptable to our readers. Thus we are informed that dried fruits are the most important of the many exports of Smyrna, employing a vast amount of labour, and giving an adequate return for the outlay of capital. Foremost among them are

RAISINS.—Those growing in the district of Smyrna are of four descriptions—black, red, Sultanas, and Currants. The black, which are exported chiefly to France, are used exclusively for wine making, and for the distilling of spirit. The red and Sultanas are for the table and fetch a much higher price than the black. Currants are shipped in insgnificant quantities, but are necessarily included in the general export.

The exportation of this fruit has increased greatly during the last few years. The ordinary crop some years since did not exceed 25,000 tons, but the cultivation having been extended to meet the demand the export in 1877 and 1878 advanced to 28,500 tons each year, and for the three following years it averaged 48,600 tons, and in value nearly £1,000,000 sterling. The production of black Raisins especially has been largely developed since 1877. In that year France consumed little more than 7,000 tons of this species of fruit; in 1879 her consumption rose to nearly 20,000 tons, and it advanced in 1880 and 1881 to an average of 25,500 tons. As the demand from France—in consequence of the ravages of the Phylloxera in her own vineyards, and a succession of bad vintages—still continues, and appears likely to increase year by year, the cultivation of the vine in the district of Smyrna is extending, even in a ratio disproportionate, it may be, to the future demand, and there is some danger lest the supply should overrun the demand, and the profits go to the consumers rather than to the producers.

Smyrna Raisins are of four qualities. The best are grown on the peninsula of Carabournon, at the entrance to the Gulf of Smyrna; the second quality at Vourlah, within the Gulf, and at Phokes, just outside it; the third at Chesmé, on the coast, opposite Scio; the fourth, called Yerli, in the neighbourhood of Smyrna, and inland. Between the value of the first and last qualities there is a difference of from 50 to 60 per cent. Currants are grown only at Phokes.

VALONEA.—This well-known tanning material is composed of the acorn cups of Quercus Ægilops, and the quantity exported is said to have fluctuated much of late years. The crop begins to reach Smyrna at the end of September, and continues to arrive until the August following. Each year's export, therefore, comprises the crop of the preceding year. It is necessary to dry the cups for some months before shipment in order to avoid fermentation, which would greatly diminish the value. Shipment is made from December to August. England takes at least two-thirds of the entire export, and chiefly of the middling qualities, while Austria will have none but the finest, and Italy is content with the refuse. Venice, however, demands the best. The Valonea Oak grows wild all along the west coast of Asia Minor from the Dardanelles to Adalia, and for about 200 miles inland. There are three different growths—first, that of Nazli, Davas, and Ghiunda; second, that of Aidia, Demirjik, Borlo, Budrum, and the Dardanelles; and third, that of Ushak. The quality of the Valonea depends on its being thick and heavy and of a light ash colour.

MADDER ROOTS (RUBIA TINCTORUM).—Madder, or Alizari, was some years since one of the principal exports of Smyrna, the yearly shipment reaching 65,000 to 70,000 quintals; but it has now fallen almost entirely out of demand, being superseded by cochineal. The average annual export of five years was only 1,678 bales of about 800 lb. each. The root used to be largely cultivated in Asia Minor for its red dye—the *garance* of the French; but the cultivation has almost ceased, and the root is now dug up merely to make room for some more profitable crop, and is sold to cover the expense of its extraction. The average price of Smyrna during the five years has been 13s 6d to 14s per cwt. free on board, Germany, England, and the United States being the customers.

OPIUM (PAPAVER SOMNIFERUM).—The export of this, the most costly product of Smyrna, has varied considerably during the five years in question, for the crop depends entirely upon the season. The export of 1881 was the largest ever known in one year. Opium is grown in the valleys and plains of the interior, and also in the highlands, throughout a wide extent of country, from Kutaya and Balukhissar in the north to Islarta and Koniah in the south. Its quality varies in different localities, and depends on the quantity of morphine it contains. Thus the best that is grown at Balukhissar and Ushak, for it contains 11 to 11½ per cent of that principle; that from Akhissar and Kirkagatch contains from 8 to 10 per cent; that from Afium Karahissar from 7½ to 9 per cent; that from Koniah only from 7 to 8 per cent. The best customer for the opium of Smyrna is England, though but a small quantity is consumed at home, the greater portion being reshipped to the United States, Cuba, and British Guiana; indeed, the larger part of the export to America goes by way of Liverpool. A considerable quantity is also shipped, *via* Egypt, for China, Hongkong, Singapore, and Java. The average value of the opium exported from Smyrna during the five years in question was £517,300 a year.

POPPY SEED.—Notwithstanding the abundant opium crop of 1881, the export of Poppy seed has experienced no development, but has fallen off since 1877, when it reached 4,220 tons to 1,493 tons in 1879, to 836 tons in 1880, and to 283 tons in 1881. This is owing both to the extension of the cultivation and to an increased home consumption of the seed, the oil of which is largely consumed by the Turkish peasantry of Asia Minor. This oil is used in Europe to grease machinery, for which it is well adapted, as it does not readily congeal, and in the manufacture of soap. The seed is exported chiefly to France, Germany, Holland, and Italy; none to England or the United States.

TOBACCO AND TUMBEKI.—Though the cultivation of Tobacco has greatly extended of late years in the district of Smyrna, its exportation has not been affected to any material extent, as the foreign demand is limited. The greater portion of the crop exported is sent to Egypt and other parts of the Ottoman Empire. The principal foreign consumers are the Russians, after whom come the Germans. England takes but a trifling portion of the export. Anatolian tobacco is of three qualities; the best grown at Lighda, in the district of Eudemish and at Ayaslouk, near Ephesus, both in the valley of the Cayster; the second comes from Baindyr and Thyra, in the same valley; from Pergamos, in the Caicus valley; and from Denizli, in the Meander valley; the third from Magnesia, Cassaba, and other spots in the plain of the Hermus, although Magnesia also grows some of the finest quality. The export was very large in 1880, and it was valued at £310,400; but in the following year it fell off enormously, not reaching one-tenth of that sum in value. This decline was in part owing to the drought and locusts in that year, but also in great measure to the fact that the Russians, having begun to grow Tobacco in Circassia and in the Crimea, have raised the duties on foreign growths, and thus take a much smaller supply from Smyrna. The entire crop from Eudemish and Ayaslouk has hitherto gone to the Russian market. Tumbeki is a description of Tobacco grown in

Persia, and imported both through Trebizond and *via* Bushire, on the Persian Gulf. A large quantity is consumed in the district of Smyrna, but much is also re-exported to Egypt and other parts of Turkey. It is much stronger than ordinary Tobacco, and cannot be smoked in the usual way, therefore it is used exclusively for the *narghileh*.

OLIVE OIL (OLEA EUROPÆA).—The oil of Smyrna is rudely pressed and carelessly prepared, so that it is not suited for the table, but only for ordinary purposes, yet it finds a ready market in the North of France. England, however, is the largest consumer, followed by France, Germany, Holland, Italy, Austria, and Russia. It is exported in barrels, which contain on an average 5 cwt. or 63 imperial gallons. The export varies greatly according to the crop. In 1879 it reached 6,550 tons, valued at £261,440. The following year it fell to 310 tons, worth £11,184, but rose again in 1881 to 4,200 tons, and in value £135,336. Olive oil is of three qualities. The first comes from Airah and Adramyti, the second from Mitylene, which is inferior only on account of its greenish hue; the third quality from Aidin and Baindye. All three qualities are produced in the neighbourhood of Smyrna.

LIQUORICE ROOTS (GLYCYRRHIZA GLABRA).—This export, which is a natural product, and not the result of cultivation, is largely increasing year by year. The plant grows wild throughout vast districts of the interior, and the only cost is the labour of digging it up, drying and packing it, and transport to the coast for shipment. The entire export, with the exception of a small quantity sent to France, and an insignificant one to England, goes to the United States in the state of roots, where it is boiled down and converted into paste, the Liquorice of commerce. The roots are packed in bales by hydraulic pressure. Till recently the bales were of different sizes; now they are generally uniform in size, containing 10 or 11 cubic feet, or about a quarter of a ton by measurement, and weighing 280 lb. to 340 lb. This export advanced from 44,700 bales, valued at £53,608, in 1877, to 63,000 bales, worth £127,600, in 1881. The demand for the root in the United States was very heavy in 1880 and 1881.

LIQUORICE PASTE.—The principal exporters of Liquorice roots, Messrs. McAndrews & Forbes, have a large factory in New York, to which they send the roots they collect in Asia Minor to be converted into paste. In America the paste is used for preparing tobacco; the leaves are soaked in the melted paste to give them the flavour which chewers of that weed most relish. The paste is also used in the United States as a remedy for scorbutic affections. In England it serves to flavour porter. In France it is used to make syrups and drinks for the sick. The juice expressed from the root is also used in France to flavour wine. Previous to 1873 some 30,000 or 40,000 cases of paste were shipped annually from Smyrna to the United States, where a very small duty was imposed on it, but in that year the American Government put a duty of 10 cents per pound on it, while admitting the root free. The consequence is that no paste is now sent direct to the States, but the greater part goes to British America, where it either serves for local consumption, or is smuggled into the States. Though the export of the paste has fallen off greatly of late years, a considerable quantity is still manufactured in the Meander and Hermus valleys. The roots when dug up are left to dry throughout the summer, by which process they lose some 60 per cent of their weight, and are then ground to powder and boiled with water, and the liquor being poured into boxes to cool, becomes liquorice paste. It is in a mass, not in sticks, for it cannot be made to keep that form without some extraneous ingredient, although the superior and more valuable liquorice of Sicily and Calabria can be made into sticks, and is so exported into England. The Turkish liquorice is not so sweet as that of Spain or Sicily, but generally keeps better, and requires more sugar, which is the only ingredient mixed with the paste. Liquorice paste is shipped in cases weighing about 2 cwt. and worth from £3 to £4 each.—*Gardeners' Chronicle.*

THE SUGAR INDUSTRY IN JAVA.

TO THE EDITOR OF THE "QUEENSLANDER."

SIR,—During a recent visit to Java and the Straits Settlements, on my way to England, I had an opportunity of looking into the mode in which the sugar industry is carried on in those places; and, as their sugar is likely to enter year by year into keener competition with the sugar productions of Queensland, I have thought that a few notes I have made may be of some interest to some of my fellow-colonists.

On the night of the 28th August my two well-known companions, the Rev. J. Tenison-Woods and Mr. William Allan, were landed with myself from the mail steamer "Chyebassa" at Banjoewangie, the most eastern point of Java. A few days spent at Banjoewangie, amusing ourselves amongst the many beautiful scenes that abound there, sufficed to reassure the authorities that we had no designs upon the island, and were not an embassy from Queensland to annex Java; and on the 1st September we started overland in two little two-wheeled traps for Bizouki, which is about 100 miles from Bangoewangie. The journey took us two days, but the many interesting scenes that we passed through from dense jungle to highly-cultivated and irrigated lands, with a teeming population of happy contented people thronging the innumerable villages we came to at every turn, far more than compensated us for the discomforts of our cramped position. At Bizouki we reached the richest of the sugar-producing districts.

The whole of Java may fairly be described as consisting of a series of great smouldering volcanoes at distances varying up to 40 miles apart, from which vast masses of volcanic ash have been vomited, filling up the intermediate spaces and surrounding shallows with huge deposits of fine rich volcanic powder. It is on the low levels of this ash-bed, where it slopes into the sea, that sugar is produced. The deposits at an elevation of 1,000 ft. up to 5,000 ft. yield coffee and tea, whilst above that again, from the high declivities of Malang and Losarie up to 7,000 ft., the big cities on the coast get their supplies of European vegetables and fruit.

Under the laws in force in Java no agricultural land can be purchased. All the land under cultivation (except some in the west of Java alienated during the English occupation) is held by the Javanese in community, each village owing the land that it cultivates, and each villager having a right only (subject to modification according to the locality) to the produce off it for a period in most cases not exceeding three years at a time. With so slight a security therefore as the owners were able to give, it was impossible for capital to embark in sugar producing. The Government accordingly years ago made contracts with capitalists varying in their terms according to circumstances, but giving them a lease of land for a period of years, and guaranteeing them a stated proportion of the area in sugarcane each year. The Government, by a system of forced labour, placed about a third of this land in rotation in sugarcane each year, whilst the natives had the remainder of the land for their paddy or rice growing. The Government undertook to prepare the land and cultivate it, and the mill-owner had to cut and carry away the crops. The various terms of tax and land rent, &c., which included everything paid to the Government, varied according to contract, but they usually amounted to between 240 and 280 guelders to the bahu (equal to 1·7537 acre), or roughly in our measurements to about £12 an acre; although in some instances it was as low as 190 guelders.

The Government, anxious to give up this system of forced labour, passed an Act some years ago by which each year a proportion of the land becomes free from contract; so that in the year 1890 all the land will be absolutely in the hands of the natives, free for them to cultivate sugar or not, as they think proper. On most of the plantations about one-half of the land is now free, and the mill-owners are obliged to make such terms as they can with the villagers. It is seldom that a mill-owner can make any contract or arrangement with the headman of a village—he is consequently obliged to lease land from the various families that compose the village, but even then the land can only be let for the following crop. In addition to the rent which has to be paid to the native, and is likely to increase year by year, the planter has to pay 25 guelders or rupees per bahu as a land tax to the Government. A first ratoon crop is usually taken off the free land; the land then reverts to the native, who crops the land with paddy for two years, and by copious irrigation restores virtue to the soil. During this period the native pays the annual tax to the Government, but 12 guelders a bahu instead of 25 guelders. The planter obtains the labour to cultivate the free land from the villages around.

There seems to be little difference in the actual cost of the cane produced under the two systems. On the free land, where the planter has the direct control of the labour, more and better cane is grown, although the cost per acre may be greater. On the free land the plant cane on one estate cost at the rate of 300g. per bahu (£15 per acre), and first ratoons 200g. per bahu (£10 per acre); whilst on another it cost somewhat less. They were average rates.

Very much fear is entertained by the Dutch mill-owners that the Javanese will prefer to grow paddy, which takes less trouble and labour, and gives abundance, in which case the mills will be brought to a standstill. The Javanese and Malays are very independent, care little for money, and love idleness, but there seems, so far, to be little doubt that a higher rent and better wages will overcome difficulties.

One source of the expense of cane growing in Java is that, on the Government contract land, the mill-owner is not allowed to take off a ratoon crop, but is obliged as soon as the crop is off to hoe up and burn the cane roots, and hand over the land to the natives for two years of paddy crops. The Government further require that all the crops shall be off the contract lands by the end of September, after which the mill-owners are fined a guelder a bahu for standing cane; and after 1st October the crop is taken off at the mill-owner's expense and burned. This is to protect the native, who would otherwise loss the season for planting his paddy crop. On the free land the planter is allowed to take one ratoon crop, but no more. The expense attending this system of cultivation is, doubtless, very considerable, but it is probably more than compensated by the returns, as after every crop in the case of the contract lands, and every second at most on the free lands, the soil is thoroughly worked with the rice crop, and restored by the fine deposits of silt from the mountains which result from the irrigation. The high cultivation which the entire country is subjected to has almost eradicated weeds, and so completely provides for a restoration to the soil of its lost constituents that the lands which have been cropped for many years bear as much sugar now as when they were first planted.

There are various modes of cultivating the sugarcane in Java. In some places the plants are soaked in water, and made to sprout before planting out; in other places the canes are planted in deep furrows about 3½ ft. to 4 ft. from centre to centre, and 1 ft. apart, and they are then well irrigated. As the plants grow the earth is thrown in from the sides, and finally heaped up in rows, so that what was the furrow becomes the mound. The varieties used seemed for the most part to be dark, small, and hard, and exceedingly healthy, notwithstanding the very dry weather. The large fleshy canes, I heard, had not proved very successful.

I was somewhat surprised to find that as a rule the sugarcanes were not trashed, and, in reply to my inquiries, I was told that trashing had been given up, as it allowed the suns rays to penetrate too freely and dried the moisture out of the ground. The very light friable nature of the soil unfits it to retain moisture. The volanic soil of Java, a true volcanic ash, must not be confounded with the volcanic soils of Queensland, which are the debrites of much older volcanic rocks such as basalt, and are of a very different nature and quality.

The sugar mills I saw in the neighbourhood of Bizouki were those of "De Mass," managed by W. H. Stockevans, and "Bondonan" owned by Mr. T. Ettey, and managed by Mr. G. Witzeuratte. Half way between Bizouki and Probalengo, I also saw the "Phaeton" estate, which had the second largest mill in Java, and was managed by W. Anderson. On the whole the mills in Java, judging by the typical ones I had the opportunity of seeing, are not so complete, nor do they possess so many of the latest improvements or appliances, as the average of the mills in Queensland; still less are they able to compare with the great works of the Colonial Sugar Company, which are now approaching completion at Homebush and on the Herbert River.

A large proportion of the sugar made in Java is sent to England, for which market the mill-owners seem to find it preferable to prepare the sugar by the clay process. About four-fifths of the sugar made at the De Maas mill is treated in this manner, and at Bondonan and Phaeton a rather larger proportion. Almost all the machinery is English, the names of Walker, Thompson, Marlowe being most frequently met with. It is admitted by the Dutch that although the English is rather more expensive it is stronger and more reliable than the foreign. In no portion of Java is the cane crushed twice over; the planters seem to think that it does not pay, and even, as at Phaeton, where they have two sets of rollers, the second set is used only as a help or stand-by. The ampas or megasse is dried in the sun and used as fuel, as in Queensland.

The triple-effet has only recently been introduced into some of the larger mills, and, though steam and compressed air monte-jus are not unfrequently used, the low buildings do not enable the mill-owners to take full advantage of the system by allowing gravitation to do the work of transport. Filter-presses had been used at the Bondonan mill, but had been given up owing to the difficulty, it was said, in getting the natives to work them properly.

A rule is made in Java to measure and weigh everything through the various processes. I was consequently able to obtain reliable statistics which may be useful to those who may have an opportunity of comparing them with their own.

At the De Maas plantation, in the year 1881, an average on the whole crop of 100 tons of sugarcane produced about ten tons of sugar—*i.e.*, 857 pickuls cane produced 34,000 litres cane juice, equal 85·5 pickuls sugar and 6·35 pickuls of molasses sugar, called by the Dutch "stroop" (16 pickuls equal short ton of 2,000 lb.). 1,000 kilos of cane yielded 276 kilos of ampas or megasse, or 137 kilos when sun-dried ready for burning.

In 1881 the average yield of sugar was 3 tons 8 cwt. to the acre. In 1882, average 3 tons 1 cwt. to the acre.

The average quality of sugar was in 1881 No. 11 in Dutch numbering; in 1882 it was No. 12. The total yield of sugar was 1,985 tons.

At the Phaeton Estate an average of 3 tons 8 cwt. of sugar was produced to the acre, the same as at De Maas. The total yield was 3,500 tons obtained from 627 bahus.

The number of tanks required for the clay process is very great, owing to the time that the sugar has to remain in each tank. At Phaeton there were two large sheds devoted to this process in which there were 300 tanks, half cylinders in shape, 24 ft. by 3 ft. each. The labour, it is needless to say, is purely Eastern. The Javanese do all the work in the fields, and carting and carrying. The Madurese are almost exclusively used in the eastern parts of Java in the mills, but the sugar-boiling is usually entrusted to Chinamen.

Almost all the mills work night and day during the crushing season, in shifts of eight hours each. The men in the mills get 50 cents (10d.), and women 30 cents. (6d.); but the rate of wages for field labour is about 30 cents for men and 16 cents for women.

To give an idea of the quality of labour that finds employment on a large Dutch Mill, at Phaeton 600 men and women are employed at the mill; 800 are employed in cutting the cane and cultivating the field; 528 carts employed in carrying the cane to the mill with two bullocks and a man to each cart. These 1,920 men, women, and children are employed with 1,040 bullocks, apart from those engaged in ploughing up the new land, who are hired on the free land at the rate of two men and two bullocks to the bahu.

Such a system of high cultivation is only possible in a country where labour is plentiful and thoroughly reliable. The native population of nineteen and a-half millions provide an abundance of labour, but the facility with which they are able to obtain a livelihood, and the fact that they are all small but prosperous land-owners, make the price of labour rather higher than it is in British India or Ceylon.

The Dutch planters, from whom we at all times met the utmost cordiality and willingnes to do everything in their power to help and assist us, naturally expressed great interest in sugar-growing in Queensland. The prospect of a production of 40,000 tons this year, and perhaps 60,000 next year, alarmed them considerably; but when the political position was explained to them, and the resolution of the country to exclude Eastern labour all but a few kanakas, and determination to attempt the production of sugar with European labour, they expressed themselves as much amused, and their peace of mind was completely restored. I fear indeed their smile was not unmixed with a considerable amount of pity for the poor Britishers, who always think they can do what no one else ever could, and that they know better than anyone else what can be done.

The total production of Java is very great; in 1880 it was

238,000 tons, in 1881 256,000 tons, and in 1882 300,000 tons, and there seems to be no limit to the production. The increase would be more rapid but for the uncertainty as to the effect of abolishing forced labour.

The average per acre over the whole island seems to be over three tons, which is very much higher than in Queensland, but it must be borne in mind that a very large majority of the sugar is produced from plant crops, after previous irrigation, and that the fallow lands are not included.

I had an opportunity at a later date of seeing a large sugar plantation at Province Wellesley, opposite Penang Island. This large estate, known as the Prye Estate, belonging to Messrs. Brown, is remarkable, inasmuch as every acre of the land cultivated is reclaimed mangrove swamp. A low dyke was constructed on one side of the Pyre River, and along the sea frontage in the mangroves; as the mangroves were felled and land cleared deep canals were cut at intervals of 500 yards which served as drains. The rains soon purified the soil, but as the loam was barely 6 in. deep, overlying clay, it was heaped into ridges for planting (the reverse of the system in Java), the spaces between serving as drains. It is only the excessive manuring, however, that enables this country to carry the crops it does. Upon an area of about 1,500 acres about 400 tons a month of fish from the river are spread over the roots of the canes. In addition very large quantities of guano from certain bat caves in the China seas, lime, and other manures are put into the soil. The expenditure per annum for manure is about $30,000 or a little under £6,000.

Almost all the work is done by contract with Tamils and Chinamen. The canals are kept clean and in good order at one cent per foot per annum by Chinamen (less than ½d.), and with the use of water weirs and locks all draught stock are dispensed with. There are six bullocks on the whole estate, and of course no draught horses.

I had the opportunity during my travels of seeing a good deal of coffee, tea, and cinchona ground in Java, the Malay Peninsula, and Ceylon. Little need be said of the prospects of their cultivation in Northern Queensland, as their cultivation would be impracticable during the maintenance of our present labour policy for the coast. There can be no possible doubt, however, that very large areas in the North must be suited to tea growing; and in the neighbourhood of the eastern slopes of the Herberton ranges a good deal of country is probably highly suited to the cultivation of coffee, cinchona, and indiarubber, all of which yield a large profit successfully grown.

It may be interesting to some in Queensland to know that during the recent bad times in Ceylon the prospects of doing well in Queensland have been much discussed, but so far all have been deterred from going there by the labour question. During my stay in that island, a letter appeared in the *Ceylon Observer* of about the 27th November, from a former planter, now settled in New Zealand. He had visited Queensland, and described the soil and climate as excellently adapted to coffee and tea planting, but adviced his fellow-colonists to give up all idea of going to Queensland, as there was no prospect of getting suitable labour, and there was a certainity that before long the introduction of kanakas would be stopped by the Legislature. Most of these men, who are all practical agriculturists, and generally with some little means, are finding their way to the Malay Peninsula, the Dutch Settlements, and New Zealand.—I am, sir, &c., HENRY WELD-BLUNDELL.

NOTES ON THE REARING OF SILK-PRODUCING BOMBYCES IN 1883.

BY ALFRED WAILLY.

(Membre Lauréat de la Société Nationale d'Acclimatation de France).

General remarks.—By referring to my report on the rearings of 1882, which appeared in four numbers of the *Journal of the Society of Arts* (19th and 26th January, and 2nd and 23rd February, 1883), it will be seen that during the very mild winter of 1881-1882, a considerable number of moths emerged from cocoons of Indian wild silkworms. During the last winter only six moths emerged from the 1st to the 16th of January, 1883, after which no more emerged till May. As I have observed, and stated in previous reports, moths from tropical species are apt to emerge during the winter when the weather is mild, while moths of native or northern foreign countries seldom, if ever, emerge before the spring. This irregularity in the emergence of the moths of tropical species is one of the difficulties in the way of their reproduction and acclimatisation; it may take place at any reason, though the greater number emerge in the summer and autumn. Hence the necessity, to have a fair chance of success, of having a large number of live cocoons.

I bred, or attempted to breed, in 1883, about the same number of silk-producing bombyces as in previous years, such as *Attacus Pyri*, of Central Europe, *Attacus Cynthia* and *Antheræa Pernyi*, originally imported from North China; *Telea Polyphemus*, *Samia Cecropia*, *Samia Promethea*, *Saturnia Io* and *Actias Luna*, from the United States of North America; *Actias Selene* and *Antheraa Mylitta*, from India. *Attacus Atlas*, as will be seen further on, could not be attempted. I reared, besides the above-named species, a number of lepidoptera, which, as they have no connection at all with sericiculture, cannot find their place here. My notes on the rearings of 1883 being very numerous, covering some 28 pages of my note-book, I shall not reproduce them *in extenso*, as details on most species have already been given in previous reports. Although it is sometimes necessary to repeat former statements, I shall confine myself principally to new facts.

As yet, only a few of my European and American correspondents have sent reports of their success or failure in rearing the various species of silk-producers. Of British correspondents, Mr. John Ball, of Macclesfield, has obtained a very great success in 1882 and 1883 with *Antheræa Pernyi*, *Actias Luna*, and *Actias Selene*, and he wishes me to record it. With respect to the rearing of *A. Pernyi*, in 1882, Mr. Ball says he found this most valuable silkworm as easy to rear as any of the British lepidoptera, and quite hardy, and he succeeded in obtaining two broods during the year. The moths began to emerge from the 1st of May, and the first larvæ hatched on the 16th of the same month; the larvæ spun up from the 20th to the 24th of June. On the first of August a female moth emerged, and on the 3rd a male, from the pairing of which ova were obtained on the 4th, which hatched on the 16th of August. Larvæ formed their cocoons from the 1st to the 7th of October.

Of *Actias Luna*, reared in 1882, Mr. Ball says:—With the 24 ova you sent me I obtained 22 larvæ, four of which died in first stage. The other larvæ thrived splendidly; they had hatched on the 15th of June from ova laid on the 2nd of June. The larvæ spun up from the 13th to the 17th of July. From the 18th of August to the 22nd all the moths emerged from the cocoons, and all were fine perfect specimens. In 1882, Mr. Ball was equally successful with this species, the rearing having taken place about one month later.

With respect to *Actias Selene*, Mr. Ball says:—The larvæ from the ova you sent me on the 8th of July, hatched on the 15th of July, spinning up from the 18th to the 19th of August, and the moths emerged from the 21st to the 24th of September. Mr. Ball's rearing of *Selene* in 1882 was also a great success; it took place at the same period, the moths emerging from 21st to 25th of September, all splendid specimens. Both *Luna* and *Selene* were fed exclusively on walnut.

WILD SILKWORMS.

Of late years, wild silk culture has attracted much attention in various quarters, and there is no doubt that the rearing, on a large scale, commercial purposes of such silkworms as *Pernyi*, *Cynthia*, *Mylitta* (tussah), *Polyphemus*, *Cecropia*, and others, would be a very profitable enterprise, if these wild silkworms were bred in climates suitable both to the worms and the plants they feed upon. These two indispensable conditions could easily be found. *Attacus Cynthia* is not only acclimatised but naturalised in France, and it can be reared even in England, in the open air, with the greatest success. *A. Pernyi* (oak silkworm) can also be reared in the open air, and it is reared, on a large scale, in Guipuscoa, a north-eastern province of Spain, where two crops of cocoons are obtained every year. *Telea Polyphemus*, introduced by me in this province, thrived equally well, and became acclimatised. Some years ago I sent large quantities of *Cynthia* and *Pernyi* live cocoons to the United States of North America, and both species are now found wild in many parts. The acclimatisation of these wild silkworms is, therefore, an easy matter when a suitable country is chosen.

I lately received from Paris a letter dated 31st October, from a gentleman who, together with some of his friends, intend to entrust a rather considerable capital to one of my correspondents in French Guiana, for the purpose of cultivating on a large scale the *Attacus Aurota*, a wild South American silkworm common in Brazil, the Guianas, and other parts of South America. No doubt, if the project is carried out, the rearing of this species will be easy, and the quantity of cocoons obtained will be enormous, for this silkworm has six generations every year in French Guiana. But I was asked before anything was done respecting that enterprise to give advice, and state what would be the commercial value of the silk, which was a difficult question to answer.

Cocoons, as is well known, are of two sorts: the closed cocoons like those of *Pernyi*, *Yama-Maï*, *Mylitta*, *Polyphemus*, and others, and those cocoons which are naturally open at one end, such as those of *Cynthia*, *Atlas*, *Cecropia*, *Aurota*, &c. The *open* cocoons, and *Aurota* is one of them, remain exactly the same after the moth has emerged, as they were before, and no opinion on the quality of the silk can be formed till these cocoons have been carded. The *closed* cocoons, on the contrary, are cut open (or are apparently *cut*) by the moth when it emerges from it; then the threads can be pulled and the silk examined and appreciated to a very great extent. Such is not the case with the open cocoons, the silk of which cannot be pulled by hand.

For the last ten years my work has been the reproduction, rearing, and study of the various wild silkworms of China, Japan, India, and America, of which I could obtain live cocoons or ova. Many persons in Europe and America, through my exertions, have also been able to rear and study them. But this work has occupied all my leisure hours. I have had, therefore, no time left to study the quality of the silk of the various species. All I know is that the silk of *Pernyi Yama-Maï* and *Mylitta* is valuable, and, if well worked, is almost equal to that of the *Bombyx Mori*; the silk of *Polyphemus* seems equally fine. I had always thought, and I still think, that the silk of these species, with closed cocoons, is superior to the silk of those with open cocoons, and my opinion also was that reeled silk was of more value than carded; but from a letter lately received from Mr. T. Wardle, of Leek, a great authority on such a subject, I see that carded silk is as good as reeled silk, a very important fact to know, as it would make some of the open cocoons as valuable as the closed ones, if the thread obtained by carding were as fine as that obtained by reeling. In his letter of the 5th of November last, on the subject of sericiculture, Mr. T. Wardle says:—"Have you visited No. 71, New Bond-street, London, where all my Tussur (*Mylitta* or *Paphia* of India) developments are? My partner, Mr. Brough, would be glad to explain anything to you. I think, if anyone went to India to collect Tussur cocoons and any other wild silks, that it would pay, and I think any enterprise of that kind would receive some Government encouragement . . . . . . To cultivate any cocoons would be a good speculation, if they could be produced in sufficient quantity; because, if they cannot be reeled, they can be carded, and, of the two, there is more demand for carded yarn than reeled, and a carded yarn fetches more money than reeled one."

I twice visited Mr. Wardle's place in New Bond-street, and I examined with the greatest interest the splendid and various articles manufactured with the Tussur silk, and I would recommend all persons taking an interest on this subject to visit the place. A visit to Mr. Wardle's would show of what importance would be the cultivation, on a large scale, of the Tussur and other equally valuable wild silkworms in such countries as would be suitable to them.

The collecting of wild silk cocoons in the forests of India, or other parts, would be profitable to reproduce and rear the various species, but I do not think sufficient quantities of these cocoons could be collected in this way for manufacturing purposes, and for the latter, rearing in the open-air and on trees must be resorted to.

Worms reared in a state of domesticity in warm rooms, or in "*magnaneries*," as the mulberry silkworm, would be liable to the terrible contagious diseases which, for years, have attacked the latter, to such an extent, as to make the supply of mulberry silk very much smaller than it used to be. In France, some fifty years ago, one of the most terrible of these diseases (which fortunately has now, it is said, disappeared) was the "*muscardine*," a white vegetable parasite which was developed inside the worm or in the chrysalis. Whilst the *muscardine* preyed on the mulberry silkworms, the other epidemics has disappeared; but, from 1845, two other distinct diseases made their appearance one after the other. The first was the "*pébrine*" (pepper disease), a very ancient affection of the worms, which, when attached by it, are covered with black spots, and grow smaller and smaller till they die. Later on, a second, very distinct from the first, and a worse disease, made terrible ravages among the worms; this is the "*flacherie*." The *flacherie* is worse than the *pébrine*, because, after all the expense and the labour of rearing the worms, which eat and grow well, showing apparently no signs whatever of disease, they die within a few days before the spinning period; hence, a great loss and disappointment. The contagious diseases may co-exist, but when they are intense, it often happens that one excludes the other, according to the ordinary law of epidemics. These diseases, created by the overcrowding of worms in hot rooms, may also be the consequence of rearing from eggs containing the germ of disease, for, it must be remarked, that a certain number of diseased worms live and procreate in spite of that germ of disease in them. On the contrary, silkworms reared in the open-air, on trees, and in suitable climates, could not be attacked by these contagious diseases. Since the deficiency in the production of mulberry silk, the cultivation in India of the Tussur silkworm has been considered of the highest importance. As yet, it does not seem that the rearing of the Tussur worm has been attempted on a large scale, though, no doubt, it will be so before long.

Major G. Coussmaker published in 1873 a most useful and interesting pamphlet on "The Tussur Silkworm," and every year, in spite of the difficulties in his way, Major G. Coussmaker reared this valuable silkworm in a state of semi-domestication in the neighbourhood of Poona, with a success which increased every year, as may be seen by reading his annual reports. In his last report to the Secretary of the Bombay Government, dated Poona, 14th February, 1883, previous to his final departure for England, Major Coussmaker, however, says that he regrets he cannot recommend Government to continue these experiments in that part of India, owing to three causes, the principal one being that the climate there was an insurmountable obstacle.

On a visit I paid to Major G. Coussmaker last October, I had the pleasure to converse with him at length on the subject of sericiculture in India, and I have since read the manny letters which were sent to him on the subject by correspondents in various parts of India. A persual of these letters shows that that the rearing of the Tussur silkworm could be successfully carried out on a large scale, if assistance were given to an experienced sericiculturist.

From the knowledge acquired by the reading of numbers of reports and letters, I think that a warm, moist temperature, such as that of Ceylon, is the best for the Tussur and some other wild silkworms.

I have also examined Tussur cocoons sent from Calcutta, Madras, Ceylon, and Bombay, the last having been kindly brought for me by Major Coussmaker. Major Coussmaker complains in his last report of the small size of the Bombay cocoons, as compared with those of other parts of India. Now, those from Ceylon are quite as small, if not smaller, than the Bombay cocoons, but the silk of the Ceylon cocoons, in my opinion, is finer and softer; they are, for the most part of a yellowish white, and similar in shape and texture to the Japanese oak silkworm (*Yama-maï*) cocoons.

In January, 1883, I saw in the offices of the Société d'Acclimatation de France, in Paris, cocoons which had been sent when alive from Cochin-China. These cocoons seemed to me exactly like those of the Ceylon Tussur in size, shape, and colour; but the moths varied in their shades of colour, just as those of the Tussur found in various parts of India. The moths of the Ceylon species, on the contray, as far as I have observed, are all of the same colour, the male being dark reddish brown, the female bright yellow. An interesting article on the Cochin-China silkworm, which I saw in Paris, written by M. J. Fallou, may be read in the June number, 1883, of the "Bulletin," of the Société d'Acclimatation. The species was at first considered as being *Antheræa mylitta* (the Indian Tussur), but subsequently it was found to be *Antheræa Frithii* (Moore), a species described in the "Proceedings of the Zoological Society," 28th June, 1859.

By comparing the species which I have considered as the Ceylon *A. mylitta* with the other Indian *Mylitta*, an entomologist might be lead to give the Ceylon race a different name than *Mylitta* as the cocoon is more oval and somewhat different in other respects, and so are the moths to a certain extent.

But, it is not possible that these differences are due to a difference of climate, and that the Ceylon species and *A. Frithii* are only southern species or varieties of *A. mylitta*. At any rate, whether or not the Ceylon silkworm is the same species as the *A. mylitta* of the more northern parts of India, it seems evident that the moist and warm climate of Ceylon is very suitable to the rearing of that species of *Mylitta*. In all probability other species would succeed as well, and the introduction of the more northern *mylitta* into Ceylon would, in course of time, show whether it is the same as the Ceylon silkworm.

Coming now to the rearing of the *A. mylitta* and other wild silkworms in various parts, and on a large scale, the plan adopted by the Japanese for the rearing of their valuable oak silkworm, *Yama-Maï* and very probably also by the Chinese, who are expert sericulturists, might be followed. Many papers have been written on the culture of the Japanese *Yama-Maï*, two published as far back as 1864, one of which had been translated from the Japanese into Dutch, by Dr. Hoffman, and then from the Dutch into French, by M. F. Blekman, interpreter to the French Legation in Japan. According to the pamphlet translated from the Japanese, the plan adopted for the rearing of the *Yama-Maï* consisted of three different operations. I say "consisted," because the first and second systems of rearing may, perhaps, not be adopted at the present time. Now, let us see what these three systems of rearing the *Yama-Maï* are:—

1. On branches, *en baquets*, in tubs.
2. On branches, *à fleur de terre*, at a level with the ground.
3. On trees, *en libre nature*, in the open air.

A note following these three headings says:—The first mode is employed for the rearing of the worms till after the third moult; after that period the second and third modes becomes applicable.

The first mode of rearing is this: tubs, placed under a shed, are filled with water and covered with lids in which holes have been bored, four, five, or six, according to the size of the tubs. The oak branches which are to feed the worms are plunged through these holes into the water, taking care to plunge the stalks of the branches into the holes which are opposite to one another, using only half of them, and corking or stopping the holes which have not been used, till the foliage has been eaten by the worms, or has become too old or faded. Then fresh branches are introduced into the tubs through the holes left vacant for that purpose. The fresh branches being placed so as to touch the old ones, the worms quit the old branches to go to the fresh ones. If the space is too wide between some parts of the old branches and the new ones, the old branches are cut in small pieces, which are placed, or pinned, on the new branches. A tap is placed at the lower part of the tub, so that the water can be drawn out and renewed every other day, or every day, as the purity of the water is of the utmost importance. This plan of rearing may be adopted till the worms form their cocoons, when the rearings are on a small scale.—*Journal of the Society of Arts*

GUIDE TO METHODS OF INSECT LIFE.—By Eleanor A. Ormerod, F. R. Met. Soc., etc. (London: Simpkin, Marshall, and Co.).—Miss Ormerod, whose name is so well known amongst agriculturists at home and abroad, for whom she has done so much, is to be congratulated on her last new work, entitled "Guide to Methods of Insect Life." This handy and most useful little volume embodies the course of the lectures delivered by this gifted lady on behalf of the Institute of Agriculture in the Lecture Theatre of South Kensington Museum in December last. Miss Ormerod does not magnify her work, but with her usual modesty says in her preface, "I have undertaken the work with considerable uneasiness, as I know well that it requires far greater knowledge than I possess to carry it out fully, yet I have endeavoured by all means in my power to ensure accuracy." Miss Ormerod's skill as an entomologist, particularly in connection with farm and garden crops, and the additional fact of her holding the post of honorary consulting entomologist to the Royal Agricultural Society, is sufficient guarantee for the accuracy of her details. A special feature in the book is the absence as far as possible of technical or scientific terms, plain language being used where practicable, so that the book is as useful to unscientific as to scientific readers or students. Where technical terms are used an explanation is given. In the first lecture Miss Ormerod treats of eggs and caterpillars, and gives descriptions as well as illustrations of the various stages through which the insects pass. In the second lecture the chrysalis, perfect insect and the orders are treated of, and in the succeeding lectures the different insect pests which affect our crops are referred to and described, and the last lecture deals with, amongst other matters, prevention. Miss Ormerod is to be commended for the manner in which she has brought this all-important subject before the nation, especially that section which comprises the farmers and growers of crops, for she has made it intelligible to all. One of her concluding remarks is as follows:—"I wish to point out that power of prevention of insect attack does not lie in the mere knowledge which may enable us to tell the name of an insect, but in the knowledge of its habits, which will suggest to the practical agriculturist in many cases how to counteract these directly by measures of husbandry, or indirectly how, if we cannot get rid of the attackers, we may at least carry the crop through the attack."—*Land and Water.*

CINCHONA CULTIVATION MADE EASY.—*The Indian Agriculturist* has the following wounderful deliverance:—At the risk of being considered advocates for urging Government to enter into competition with private enterprise, we would earnestly counsel the planting of cinchona in all places where the climate indicates the probability of success. We do not advocate the establishment of a large farm, or anything extensive in the way of glass propagating houses, but recommend that all hill jails, at suitable elevations, should devote a small space in the compound for the propagation of seedling which can subsequently be planted out on the coppice principle, forming hereafter forests of the tree—these forests, of course, to be strictly reserved as Government property and to be barked, or not, according to the rates ruling in the market for quinine. In fact, if only on philanthropic grounds, we would urge on the authorities the propagation of this valuable febrifuge until they have such quantities at hand as to prevent proprietors placing prohibitive rates on the medicine, as has been invariably done when suffering humanity increases the demand. We know that the actual cost of barking and precipitating the sulphate is most trifling, and were not fictitious expenses added to those of actual manufacture, quinine could be placed on the market at a profit, if sold at twelve to fourteen annas per ounce, provided the plant were treated in the way indicated, and not as an expensive exotic. The price we have quoted would put the medicine within the reach of the poorest sufferer, and so lessen in a marked degree the miseries and mortality that arise from neglected splenetic diseases. Coppiced plantations of cinchona if planted within short distances of our hill stations, would need keeping in order for the first eighteen months only, and this could easily be accomplished by the jail prisoners. The plantations might then be left to nature, as the trees would by that time be umbrageous enough to keep the undergrowth from checking their progress, and the only precaution necessary for the preservation of the plantation would be the cleaning and watching of fire-paths during the dry season. Though many of the hybrids, such as *C. Officinalis*, may contain a greater proportion of alkaloids, they are more delicate to propagate than other varieties. We would therefore recommend the selection of the robuster *C. Succirubra*, despite its reputed liability to the attacks of canker-worm—which repute by-the-way rests, we believe, solely on the dictum of the late Mr. McIvor, of the Ootacamund Gardens. This gentleman's opinions however on the suitability of sites for cinchona cultivation must be received with some reserve, as he was (owing to the large interests he held in private planting ventures, in common with Sir William Denison and others) naturally much opposed to competition. In concluding our remarks on the subject, we are of opinion that the bark from these coppices should be utilised for making the pure sulphate, as although the cinchona febrifuge sold by Government is undoubtedly of use in mild cases of fever, it has frequently been found far from efficacious in the more malarious districts.

THE USE OF CHARCOAL as a medium in which to pack seeds to be sent to this country from abroad is very common indeed; in fact, a considerable number of scientific correspondents seem to pin their faith to charcoal as a packing agent to a remarkable extent. As far as our experience goes, its use is, however, decidedly objectionable, as, apart from its dirtiness, it absorbs the moisture from the seeds, and in many cases so thoroughly, that all germinating power is lost by the time the package arrives at its destination. All short-lived seeds seem to travel best in damp clay or moist earth. Packed firmly in damp clay, Siebold succeeded in introducing tea seeds from the Chinese tea countries to Java, and also the seeds of a large number of oaks, camellias, and other Japanese plants, from their native country to Holland. Seeds of tea, coffee, and a host of other plants which utterly fail to retain their germinative faculty during a lengthened sea voyage when packed either without any packing medium, or forwarded in charcoal, grow readily when treated in the manner adopted by Siebold. We are glad to see Mr. Prestoe condemning the use of charcoal in his last report on the Trinidad Botanic Garden.—*Gardeners' Chronicle.*

GUM SARCOCOLLA.—A new light on the source of Gum Sarcocolla, which is also known in Bombay as "Gujar," and in Arabia and Persia as "Anzeroot," is given by Dr. Dymock in his *Vegetable Materia Medica of Western India.* For a long time this substance has been doubtfully referred to a species of Penæa, belonging to the natural order Penæaceæ, but it has always been felt to have a very shaky position there, inasmuch as the species are all African. Dioscorides describes Sarcocolla as the tear of a Persian tree, that the gum resembles powdered frankincense, with a bitterish taste and a reddish colour. It is seldom seen in Europe at the present time, though it is still largely used in the East as a drug. "It is also used internally as an antirheumatic and anthelmintic, and the Egyptian women eat it on account of its fattening properties." It is imported into Bombay from the Persian port of Bushire in bags containing about 2 cwt. Dr. Dymock says the total quantity imported must be considerable, as from twelve to twenty bags may often be seen in a single wherehouse. From pods and other portions of the plant taken from bales of the gum, he is strongly of opinion that its source will prove to be one of the desert Leguminosæ, not far removed from Astragalus. From the entire absence of leaves in the bales it would seem "that the Sarcocolla is collected by beating the bushes after the leaves have fallen.—*Ibid.*

TONQUIN OR TONGA BEAN.—Mr. Prestoe, in his report on the Trinidad Botanic Gardens has some interesting notes on what he supposes to be a new species or form of Tonquin Bean from Venezuela. He says the high price ruling for Tonquin or Tonga beans in a prepared state has attracted much attention to it as a tree of some promise under cultivation, and in consequence inquiries have been made for supplies of plants. The roots of the large trees in the garden are said to be seriously affected at the roots by fungoid growths, all attempts to suppress which have hitherto proved only partially effective. On the subject of this Venezuelan plant, or "Sarapia," as it is called, Mr. Prestoe, says:—"It has long been known that there existed in Venezuela a much larger variety of Tonga Bean than that produced on the garden trees, and differing considerably from that described as Dipteryx odorata, inhabiting the British and Dutch Guianas; and steps being taken to obtain supplies of fresh seeds, several lots have been received in the form of entire fruits, which are uniformly of this larger and very superior variety. The fruit is usually twice as large again as the Demerara Tonga Bean and that figured by Aublet. The habit of the tree bearing this superior Bean resembles that of the Mango, having much less the character of a forest tree than that bearing the smaller leaves. The present high commercial value of the Sarapia," Mr. Prestoe says, "arises from a widespread and ever increasing appreciation of its use in Europe and America as a flavouring material in articles of immense consumption, such as tobacco, cigars, cacao, confectionery, &c., but more particularly the former; so that its consumption will rather increase than otherwise." This paragraph, though it mentions the Sarapia, we presume, alludes to the Tonquin Bean of commerce (D. odorata). It is suggested that as a plantation of these trees would partake more of the character of a forest than a plantation, such, for instance, as Cocoa, the only cultural requirement would be such clearing as to render easy the collecting of the fruits as they fall to the ground.—*Ibid.*

TAMARINDS: TAMARINDUS INDICA.—There are but few people to whom the flavour of preserved Tamarinds is not agreeable, but do those who frequently use Tamarinds know how they are prepared? They come into commerce both from the East and West Indies; the latter, it would seem, are simply the fruits, or, rather, pods from which the shell or epicarp has been removed, and the pulp, together with the strong fibrous framework upon which it is built, and the seeds are placed in alternate layers with powdered sugar in a cask or jar, over which boiling syrup is afterwards poured. In the East Indies it seems they are prepared by first removing the epicarp and seeds by hand, after which the pulpy portion is usually mixed with about 10 per cent of salt, and trodden into a mass with the naked feet. Of these Tamarinds several qualities are known in the market, the best being free of fibre and husk, and the worst containing both, together with the hard stone-like seeds, which are commonly eaten in the East Indies after being roasted and soaked to remove the outer skin, and then boiled or fried, when they are said to be tolerably palatable. West Indian Tamarinds are alone officinal in the British *Pharmacopœia:* while on the Continent those from the East Indies are alone employed. Besides the Tamarinds sent to Europe, they are also shipped in large quantities from Bombay to Persia and other northern countries.—*Ibid.*

SEXES OF NUTMEG TREES.—Any method by which the sex of seedling plants of the nutmeg may be determined with any approach to accuracy is a matter of no little moment to many who are interested in tropical agriculture. As the males, in excess of those required for purposes of fertilisation, are useless, much labour and time may be saved by following Mr. Prestoe's directions. In the last published Report on the Trinidad Garden, Mr. Prestoe says:—"The planting out of successional nutmeg trees has enabled me to determine the sexes in seedling plants under a foot high by character presented in the leaf form and venation, and with sufficient accuracy for all practical purposes; as also the proportion of male trees and female as usually raised from seeds." In order to distinguish the male and female seedlings, the form of the leaf and the direction of the veins must be observed, the female leaf being the most perfectly elliptical, with the straighter primary veins; the male leaf is broader towards the point than at the middle—that is, of obovate shape, and furnished with a point much longer than that of the female; the veins are curved-in towards the point much more roundly than in the female. Mr. Prestoe has proved by experiments conducted by himself—and the young trees now fruiting fully bear out the statement—that by carefully following the tests above given, the results will be correct eight or nine times out of ten.—*Ibid.*

KOKUM BUTTER.—The following interesting note on Garcinia indica is contained in Dr. Dymock's recently published *Vegetable Materia Medica of Western India.* It is of value because it corrects a statement often made in books, that it is used to adulterate "ghee," or liquid butter. Dr. Dymock states that the tree is common on the Western coast between Damaun and Goa. It grows wild upon the hills of the Concans, but is often seen in gardens close to the sea. It is in flower about Christmas, and ripens its fruit in April and May. The fruit is largely used all along the Western Coast as an acid ingredient in curries, and in a dry state as an article of commerce. The usual mode of preparing it is to remove the seeds and dry the pulp in the sun; it is then slightly salted, and is ready for market. In Goa the pulp is sometimes separated from the skin and made into large globular or elongated masses. An oil is extracted from the seeds by pounding and boiling them; it becomes solid on cooking, and is moulded by hand into the well-known egg-shaped balls, or concavo-convex cakes, known as Kokum butter. "The natives occasionally use it for cooking, but the statement that it is largely used in Goa to adulterate ghee (liquid butter) is incorrect. In the first place no ghee is made in Goa; the bulk of the inhabitants, who are Christians, obtain their ghee (lard) from the pigs which abound in that territory, and the Hindoos import theirs from Bombay. So few cattle are kept in Goa that it is difficult to obtain milk, and still more so butter."—*Ibid.*

PAPER BY MR. S. WEERAKODY UPON PADDY CULTIVATION.

The Secretary of the Ceylon Agricultural Association, Colombo.

Kurunegala.

Herewith I beg to forward an account of experiments made by me in a field cultivated with paddy during the last *maha* harvest, and shall thank you to lay the same before the Association for the information of those who are interested in the cultivation of our staple food.

These experiments were made with the following objects in view:—(1) To see whether sowing broadcast in the ordinary way or transplanting is the better mode of cultivation. (2) The effect of manure. (3) Whether the cultivation of fields by cooly labour for daily wages, instead of giving out the same to goyas for shares as it is generally done in this country, pays better.

The field in which the experiments were made is one *amunam* or two acres in extent. The soil is the common red coloured soil of this district composed of about equal parts of clay and coarse sand. There is a small stream of water which flows into the top bed of the field, and, although the water of this stream becomes less during the dry weather, it does not altogether fail, and this helps to introduce water into many of the beds whenever required, which is a great advantage. This field was bought by me late in the season, and, as all were busy with their cattle in other fields, I had no time to plough it, but was obliged to get it dug up with mammoties by coolies. Owing to the careless manner in which the field had been kept by its late owners, many of the ridges were out of order and the soil was so very hard that a great deal of trouble was experienced in turning it up. For this purpose 14 men were employed at 33 cents each per day. After this, water was logged in the plots for four days, in order that the upturned grass may rot. But, owing to the heavy rains that set in just then and the rush of water from a drain, five ridges broke up and a large quantity of the loose soil was washed away. To make these necessary repairs and to open up a large drain above the field to prevent the rushing in of superfluous water, and also to dig up the soil once more, 15 men were employed. After this water was logged for two days and when the grass was well-rotted the whole field was again thoroughly dug up, drained and bedded, for which 21 men were employed. The field was sown from the 12th to 14th November in the ordinary way with six bushels of *kottiyaran* paddy which takes three months to ripen. When the paddy plants were about four weeks old, some were rooted out from the place where they grew rather thickly and were transplanted in a different bed which had been reserved; and when the other plants which grew by sowing were about two months old, a bed was manured with the refuse of fish (*halmesso*). Three equal plots of these were carefully reaped, and the results were as follows:—The transplanted plot had double, and the manured plot a little more than treble the quantity of paddy that was found in the broadcasted plot which had no manure.

I shall now submit some observations on this cultivation.

SEASON.—As everything else, paddy-cultivation should be done at the proper season and there is no doubt that a great deal of success depends on its strict observance. Fields cultivated at the begining of the season give as a rule better crops than those that are cultivated later, and, if this practice were followed, the corn could be saved from many pests, such as flies which suck away the milk from the ears before they are hardened, and from enquiry I am convinced that these flies are more to be found in the latter part of the season. This practice will also enable the cultivators to grow various kinds of paddy of long duration which usually give better returns and also enable them to gather their crops in the early part of the reaping season and thus escape from a deal of inconvenience, such as rain which comes down in torrents just after the harvest.

PREPARATION OF THE SOIL.—This is the most important point that should be observed in paddy-cultivation, and it is also the only work that can be satisfactorily done by the cultivator if he wishes to do so. Just as a child gets sickly and continues to be so till the end of its life when at its infancy it gets no nourishing food and is not cared for in the proper manner, it is almost impossible to improve a paddy plant in its advanced state of growth if it is not treated properly when it is a seedling. Cultivators should therefore spare no pains on this head. The first thing that should be done is to loosen the soil. This is done in two ways: ploughing by means of our common plough, —and digging up the soil by mammoties. Of these two methods, ploughing is easier, but I am sorry to say that our present plough does not at all answer the purpose It only scratches the soil to a depth at the most of four inches, and even this is done by many of the cultivators in a perfunctory manner. Ploughing, even as it is done now should be carried on at least four times at intervals till all the weeds are uprooted and destroyed and the soil well disturbed.

Digging up the soil with mammoties is undoubtedly preferable, but it takes a longer time and entails a greater cost. It is my opinion, however, that it is a very good practice to dig up the soil well once after ploughing the land about three times, and this I consider indispensable till at least a superior plough is introduced.

The next matter of importance is the total destruction of all kinds of weeds. This can be done in two ways: first, rooting them up and allowing them to be dried in the sun; secondly by water-logging. This can better and quicker be done by both these methods combined. However this is not possible to be done in all fields owing to mud or want of water at the proper time; but unless grass and other weeds are somehow exterminated, they not only exhaust the substance of the soil, which should only go to nourish the paddy plants, but also choke them.

The preparation of the beds is also of great importance They should be narrowly made so that a man may reach his hand easily to the middle of each of them in order to root up any weeds that may be growing. The small surface drains should be made in a sloping manner so that the water may not be stagnant. Care should be taken not to sow any seed in these drains or allow any plants to grow on them, in order that the cultivator may walk in them freely, and also for the free circulation of light and air which are essentials to the healthy growth of plants.

PREPARATION OF SEED PADDY.—This is done in two ways, sprouting and without sprouting. The former is fit for muddy lands. And even in this point the opinions of cultivators are divided: some say that to sow the paddy when their roots are long is good, and others say it should be done as soon as the roots sprout out. This is a matter deserving of a trial. The second method of sowing the seed without sprouting is only done when the ground is dry. But I have invariably seen that fields sown in this way always give better returns than in the other way, and on enquiry I have ascertained from the cultivators that this success is due to the roots of the paddy going deeper into the ground in search of food.

TRANSPLANTING.—This practice is undoubtedly far superior to that of broadcasting, and it is hoped that it will be carried on extensively before long. This is not altogether unknown in this country. Many of the fields in the Kandy district are transplanted. But this is not carried on in a systematic way. At present transplanting is resorted to only for the purpose of filling up vacancies in places where the paddy when sown is either wasted away or rotted by too much of stagnant water, without laying any importance to the condition of the plants. I have often seen plants transplanted when they were very near putting on their ears, this is a bad practice and should always be avoided It will be found from the experiment under notice that the yield of the transplanted portion was double that of the broadcasted ones. I must, however, confess that even in this instance it has not been done as it ought, for the tranplanted plants were only rooted out from the plots where the plants growing rather thickly This undoubtedly had a deteriorating effect on the plants at the first stage of their growth. If transplanting is conducted strictly in the proper way, I have no doubt that it will give four times as much as broadcasting. A bed should be prepared well and the seed should be sown on it sparsely and the age for transplanting should be regulated according to the duration of the paddy-plants. For instance, the plants may be from four to six weeks in the nursery if the paddy takes six months to ripen the crop; five to four weeks if it is five months, and four to three weeks if it is four and three months. But transplanting answers better with paddy of long duration, and, if possible, it should not be done with plants of shorter duration than four months, nor with plants of any kind which have put out their lateral shoots, for the time left for their development is not sufficient. Transplanting checks to the greatest extent the growth of weeds, and it enables the plants to put a large number of stalk-blades and thus increase the number of ears. The only objection raised against this practice is the great trouble and length of time it entails than for broadcasting. But I have no hesitation in saying that the saving in seed (which is half of the quantity used for broadcasting) and the larger yield of the crop more than compensate for all this. It is a mistake, however, to suppose that every field is fit for this sort of cultivation. Transplanting answers well only on those fields which can be regularly irrigated by means of tanks or streams; but not in fields that are cultivated by rain water or the water-supply of which is precarious, for the plants require constant moisture till they are well established in the ground.

Manuring.—That the inferior quality and the small quantity of the produce of our fields is due to a great measure to constant cropping, and to bring them again to yield the quantities that they gave in former times could only be effected by manuring, is beyond dispute. But I think this is a matter which requires the most careful attention. There are many kinds of manures (mostly artificial) that stimulate plants to bear heavily, and only very few that improve the soil. And I have no doubt that if the former were used frequently, the lands will not only be more impoverished but they might give rise to disease. It will be seen from the experiment above referred to that notwithstanding the lateness of the application the plot manured with fish gave a little more than treble the quantity of the manured plot; this is due to the stimulating powers of phosphoric acid which this manure contains which is very useful for the development of the bodies of animals. The grain gathered from this plot had also a very good appearance: they were more plump, and, what is still better, there was hardly any chaff. But manures like these will never answer by themselves, as their effect is very transitory. They should always be used in small quantities with manures of long duration. Of all manures that are known by man, I do not think there is any superior to cattle manure, and if the cattle are fed with poonac so much the better. The leaves of trees and plants, such as the suriya, jak, karanda, keppettiya, lantana, castor oil, &c., are very good. They should be applied to the fields just after the second ploughing. These manures not only improve the crops but the soil as well, and, what is better, they are the only manures that can be cheaply and easily obtained by the cultivators.

Giving out Fields to Goyas for Cultivation for Shares.—This is a practice that is carried on in this country from time immemorial, and it has taken root so firmly in the minds of the people (and I regret to say even among the educated people) that it will take a long time to undo it. It is the opinion of many land-owners that the cultivation of fields by cooly labor does not pay, and therefore they say that the present system is preferable. I have however no hesitation in saying that this notion is a mistake, and many of them entertain it without giving the other even a single trial. Even under this practice, the land-owner is found to advance the seed paddy to entitle him to the half; and if this is seriously taken into consideration, it will be found that the owner is a great loser. The value of the paddy and straw of the experimented field above refered to, was R65 and the costs were as follow:—

14 men at 33 cents each	...	R4·66
15 do do	...	5·00
21 do do	...	7·00
Cost of paddy (6 bushels)	...	7·50
Do of manure (2 cwt.)	...	0·50
Do of sowing ...	...	1·00
Do of reaping ...	...	4·00
Do of threshing ...	...	1·00
	Total...	R30·16

I consider even this amount as excessive, and it is due to the disadvantages that I had in getting coolies to dig up the soil instead of ploughing, and the permanent improvements I had to make, such as putting up ridges and opening a drain. If not for these, the cost would have been less, and I have no doubt that the cost of an acre of land for cultivating paddy will not be more than R10 per each harvest. It will be seen, however, that, in spite of the greater cost I had to incur, it still gave me a profit of R34·84. From enquiry I made from the late owners of this field, I found that, at that season in former years, this field hardly gave such a good crop, when even at its best; and its average yield was about thirty bushels, which is twenty bushels less than what I got. And even taking for granted the quantity I got as its probable yield, even if goyas cultivated it, I would have got R32·50; and when R7·50, the value of the seed paddy is deducted from it, the balance would be only R25, thus making me a loser of R9·83. It will be contended by some that this profit is hardly sufficient to warrant a change of the present system. But as I have said before, if the lands are carefully cultivated, the cost will be less and the yield much greater. Besides, it is the only way open to cultivate the fields in the proper way and to induce even the cultivators to adopt new systems. It is therefore, I think, the duty of every landowner to adopt it or at least to give it a fair trial.

JACKSON'S NEW TEA DRIER.

The untiring energy Mr. Jackson has shown in the direction of inventing and perfecting machinery for use on tea gardens has once more been rewarded with what promises to be a great success. His last production is a new drier, in which that great drawback to most previous driers, the use of trays, has been successfully abolished. In a series of trials last week, before several gentlemen interested in Indian tea-properties, the success of the new drier was demonstrated past all doubt save one, and that one is merely that elder leaves, with which the trials were made (after being well rolled in an "Excelsior"), are not tea leaves. This difference alone left room for any uncertainty, and it will be acknowledged that considering the elder leaves, after being treated and well rolled like tea, were, in addition, saturated with water till it poured from them, the trial was a severe one, and that the probabilities are all in favour of the results being as satisfactory when tea is tried as they have proved in the case of saturated elder-leaves. The machine is fed at the top by the tea being thrown into a hopper, it falls on to an endless-band, consisting of metal plates, and is evenly distributed over the band by a patent "kicker." The band supported, and given motion to by rollers, carries the tea forward till it drops on to a lower and longer endless-band, which carries it back in the opposite direction till it again falls over the end on to a still lower and longer band, the process being repeated till the tea emerges at the bottom thoroughly dried. The saturated elder-leaves were discharged thoroughly dried and crisped in 15 minutes from being thrown into the hopper. A furnace underneath supplies the heat and a series of pipes distribute it, an exhaust fan at the top sucking up the heat and damp air, and thus ensuring a thorough current. By means of thermometers placed at different points and speed-pulleys, the speed and heat are both under perfect control. The name and price have not as yet been decided upon. The patentee has already formed his calculations as to the quantity of leaf the drier can turn out dried per hour, but until his estimates have been proved by trial with tea, he cautiously abstains from making his theoretical estimates public. The machine was tried at the magnificent works of the makers, Messrs. Marshall, Sons, and Co., of Gainsborough. This first machine is going out to Cinnemara, one of the Jorehaut Company's gardens, on trial. We would mention that the Messrs. Marshall received th visitors who attended the trial with the hospitality and courtesy for which they have earned a well-merited reputation, not even second to that they have established by their splendid success from the purely commercial standpoint.—*Home and Colonial Mail.* [We suppose an early specimen will be sent to Messrs. John Walker & Co. for exhibition in Colombo. —Ed.]

THE SUGAR INDUSTRY IN QUEENSLAND.

Under the title of "The Sugar Industry in Queensland," Mr. Henry Ling Roth, hon. Secretary of the Mackay Planters' and Farmers' Association, has published a pamphlet which possesses an interest as well for Fijian as for Queensland readers. The writer divides his subject under the following heads :—The origin of sugar growing in Queensland as a commercial industry : the depression and its causes ; the scarcity of labor, its causes, and the attempts of planters to obtain supplies ; false remedies suggested ; and, the only means to restore the industry.

Under his first head Mr. Roth reviews the inducements held out by the Government which led many people to turn their thoughts to Queensland as a sugar growing country. He claims as a natural consequence the rapid progress which quickly made sugar growing the third industry in the colony, and points to the fact that it is the only one which has induced to any extent a permanent settlement on the land. Success encouraged further enterprize, and it is noticed that during the late period of cheap money, many investors from the adjoining colonies, acting on the well grounded belief that Queensland would not commit a breach of faith, pledged as she is to the men who have given such prosperity to the community, have taken up and purchased lands and spent large sums of money in laying them out as sugar estates.

The subsequent depression is attributed to failing prices as the production in Queensland and Fiji, approaches in quantity to the Australian consumption, but more particularly to the difficulty of procuring an adequate colored labor supply, without which the industry cannot be made to pay. The causes of the labor difficulty are stated to be that in consequence of troubles in the Pacific, the High Commission now sitting, and French aggression in the New Hebrides, owners of vessels are indisposed to continue them in the traffic. Furthermore, the continued drain on the islands caused by the increasing requirements of Queensland, Fiji, Samoa, and Honolulu is fast exhausting this class of labor, and it is now rare for a labor vessel to return to port with her full complement. This failure, and the incompleteness of legislation for the introduction of Indian Coolies, led to a private introduction of mixed blacks from Ceylon. This turned out to be a mistake, as the men appeared to be mechanics, servants, gaol-birds, and other scum unfit for agricultural labor. The attempt to introduce a low class of mixed labor from Malta, through Mr. Commissioner de Cesari, failed from an economic point of view. The experiment of obtaining Chinese from the declining Palmer Goldfield was not more successful for the same reason, as wages ruled at twenty shillings per week and rations. The same difficulty has arisen in the case of laborers imported direct from Swatow, and the general conclusions is thus set fourth :—"The result of this scarcity of colored labor is well exemplified to the cost and loss of the colony. The crops for 1883 should be equal in value to £1,000,000, yet this value will not be attained by some £300,000 and planters will have suffered a loss chiefly because during last spring's favorable weather they had not the hands to keep down the weeds. Instead of getting one and a half tons of sugar to the acre all round, the return per acre will be about one ton or under, and one ton to the acre does not pay."

Under the head of "false remedies suggested" the writer deals with the propositions first, to introduce European laborers who by their numbers are to reduce wages and take the black man's place. This he demonstrates to be impolitic in conception, and impracticable of accomplishment. Second ; the destruction of large estates owned by absentees ; a proposition to which the writer objects as injudicious and unreasonble. Third, the settlement of small farmers on the land who shall grow their own cane ; which it is pointed out, would only shift the burden from the shoulder of the large planter to those of the small farmer without removing the labor difficulty. Thus having disposed of fallacious suggestions, Mr. Roth comes to his "only means to restore the industry," and devotes the rest of his pamphlet to demonstrating this to be the initiation of a well regulated system for the introduction of Indian agricultural laborers.—*Fiji Times.*

[The Fijian journalist then goes on to shew that Fiji, with practically sugar alone to depend on, is in equally bad case for labour. If the soil and climate of Ceylon were suitable, no doubt, we have advantages in regard to labour supply. We shall, however, need a large force of labourers for our tea. —Ed.]

Mr. Morris' recent visit to St. Helena promises to have important botanical results, and his report upon the island will be awaited with as much interest as has attended the publication of his valuable work on British Honduras ; but, apart from questions of agricultural and botanical research, one interesting discovery made by Mr. Morris in another direction has already been communicated to us. The learned Director of Public Gardens in Jamaica is necessarily a geologist as well as a botanist, and, during his visit to St. Helena, he traced the existence of large quantities of black oxide of manganese, or pyrosulite, samples of which he brought away with him. These have now been analysed by Professor Roscoe, F.R.S., of Owens College, Manchester, with the result that one sample of St. Helena manganese, soft, found in clay beds, yielded 35·41 per cent of manganese di-oxide ; while a second sample hard, found in clinker, yielded as much as 63·19 per cent of manganese di-oxide. As the value of manganese ore containing 70 per cent of manganese di-oxide is at the present time about £3 10s per ton, delivered at Liverpool or Garston, there is every probability that this discovery may be of much importance to the Island of St. Helena. Still more important, however, is the discovery, from the fact that it brought into prominence the almost forgotten fact that manganese ore is also to be found in Jamaica. Since an analysis of samples of this manganese ore, made by Dr. Lewis Hoffman for the Geological Survey of Jamaica, shows that it yields as much as 88·89, or practically 90, per cent of magnanese di-oxide, or more than double the percentage of the inferior sample from St. Helena and nearly one-third more than that of the better sample from the same locality, the owners of land yielding manganese ore have before them the opportunity of working their deposits on a commercial scale, and of enormously increasing the value of their property. An experimental shipment of the ore ought certainly to be made, under practical guidance, in order to test the question. The peroxide of manganese is used by potters and glassmakers as well as by bleachers, and is also available for disinfecting purposes, throwing off a large amount of oxygen when exposed to the air.—*Colonies and India.*

Correspondence.

To the Editor of the Ceylon Observer.

QUESTIONS REGARDING CINCHONAS, RUBBERS AND CARDAMOMS.

6th March 1884.

SIR,—I am in the habit of using decayed wood mixed with earth for my cinchona nursery and get better results than I would without so manuring. Yet I am told it is quite wrong to manure. What is your opinion about the matter ?

This monsoon, some twenty Ceará rubber trees (five months old) over seven feet high were transplanted into the estate, and grew well until end of last month, when they commenced to wither at the top. Would you advise stumping them ? Have any of your readers bleached their cardamoms this way ? Is so, I should like to know result. Fill clean cootie sacks with well-dried cardamoms and then place in cisterns with water over the sacks, and leave them so until thoroughly soaked, say half-an-hour ; then take them to the barbacue and spread very thinly on mats ; lift in the evening when dry. Do this three days, and then pick out any cardamoms that do not look nice, and give them (the red cardamoms) two more washings. A small basket holding (say) ¾ of a bushel is to be preferred to a cootie sack, as the cardamoms can then be agitated in the water, but, perhaps, the latter can be got easier in Ceylon.

In regard to boxes, I think the planks from a wild cinnamon tree will make good boxes.—Yours faithfully, LOONIE.

MR. JOHN HUGHES ON SUGAR SOILS.

Analytical Laboratory, 79, Mark Lane, London, E. C., 20th March 1884.

SIR,—I have been absent from London for a few weeks in order to visit the rice-lands of the south of Portugal, and during my absence several copies of the *Weekly Observer* have been awaiting my return. I see that some attention is being directed to the possibility of growing sugarcane profitably in Ceylon ; and this being so, perhaps the enclosed cutting from the *Sugarcane* of May 1882, containing some analyses of Spanish sugar soils made by myself, will be interesting to those of your readers who may contemplate the production of Ceylon sugar.—Yours faithfully, JOHN HUGHES.

SPANISH SUGAR SOILS.

BY JOHN HUGHES, F. C. S., Agricultural Analyst.

Although only distant some six or seven days by steamer from London *via* Gibraltar, very little is known in this country respecting the sugar industry which has existed for many years in the south of Spain on the flat land on the shores of the Mediterranean, which is well protected from cold north winds by the lofty mountain ranges of the Sierra Nevada ; and yet the carefully arranged system of irrigation, whereby the canes are supplied with water during the hot season, the well appointed central factories with their neat boiling houses and excellent machinery, are certainly worthy of a visit from our West India planters, who can spare time to do so, during their annual temporary absence from their own estates.

In the autumn of 1879 I was engaged to visit several sugar plantations in the neighbourhood of Motril, and had every opportunity of noticing the system adopted in the preparation of the land for replanting, as well as the local plan of reclaiming new land at the mouths of rivers. The particular object of my visit was to endeavour from personal inspection, aided by subsequent chemical analysis, to detect the cause of some parts of estates being so much better adapted for sugarcane than others were.

For this purpose I spent about a week with a large proprietor who was anxious to ascertain if there were any deficiency in the mineral composition of these inferior portions of the land, and if so, what kind of manure would be the most suitable for application in order to supply artificially those elements which were naturally deficient in the soil.

About a dozen samples of soil, representing respectively good and bad sugar-producing land, were personally selected and carefully packed in tin cases for transmission to London, where the analyses were duly made, and from which I have selected two type specimens, as I believe the results will be of general interest to the readers of the *Sugarcane.*

SUGAR SOILS FROM MOTRIL.

Analyses of the air-dried Samples.

	No. 1. Good soil.	No. 2. Bad soil.
Natural moisture (dried at 212° F.)...	1·410	1·810
* Organic matter and combined water	2·890	2·850
Oxide of iron...	5·618	5·150
Alumina	3·207	3·070
Lime	3·234	3·316
Magnesia	1·460	1·162
Potash	·428	·448
Soda	·171	·059
Phosporic acid...	·172	·198
Sulphuric acid...	·251	·061
Carbonic acid	2·541	2·606
Nitric acid	·026	·020
Chlorine	·021	·017
† Silica and insoluble silicates ...	78·571	79·233
	100,000	100.000
* Containing nitrogen	·101	·112
† Containing coarse sand ...	7·120	20·015

Separated by washing.

Looking simply at these analyses we are quite unable to detect any special deficiency in the chemical composition of the soil marked *bad* ; indeed, in the matter of phosphoric acid and organic nitrogen, as well as the proportion of potash, this soil is rather richer than the soil marked *good.* It is only when we come to examine further into the mechanical condition that we find a difference, namely, that while No. 1 has comparatively only a small quantity of coarse particle of soil readily separated by washing, No. 2, on the other hand, contains 20 per cent of soil in a rough, coarse state.

In fact, in one soil we have the silicates in a finely divided condition, readily available for assimilation, while in the other there is a large proportion of these silicates, which are practically of very little use to the growing canes. That silica in a form readily available for the strengthening the fibre of the cane, is eminently necessary, we can easily understand, and the late Dr. Stenhouse has clearly pointed out, in his full and interesting analyses of sugarcane, that from 16 to 50 parts out of every 100 parts of the ashes of the whole cane, consists of finely divided silica.

These soils then are relatively good and bad, in proportion as they contain a large or small quantity of the finely divided silt brought down by the rivers during flood times years ago, for there can be no doubt that the finely grained soil is better adapted to sugarcane than the coarser quality.

As regards the improvement of soil No. 2, I suggested that previous to replanting, the land should be well dug over, and the soil frequently turned and exposed to the action of the air as much as possible, in the same manner as I saw gangs of men employed in preparing land recently gained from the neighbouring river. Much time and labour is spent in thoroughly mixing the accumulated silt so as to get a nice finely divided soil, before planting canes for the first time.

As regards any manure, I need hardly remark, that, looking at the small quantity of nitrogen apparent in the analyses, both soils would be likely to respond liberally to a dressing of 5 cwt. per acre of good sugarcane manure, rich in organic nitrogenous matter and ammonia salts.

In conclusion, I would only say that I have endeavoured in this short paper to draw attention to the great importance of not relying entirely on the chemical analysis of a soil, but that we should also consider the mechanical and physical condition of the same, as well as the nature and composition of the crop which is proposed to be grown on such soil, before we report upon the quality of the land, or on the kind of manure which is likely to be most beneficial as a fertilizer.

79, Mark Lane, London, E. C.,
Jan. 27th, 1882.

THE WALLABA TREE: EFFECT OF THE MOON ON SAP; HORSES AND GOATS IN CEYLON; YAMS.

DEAR SIR,—Last two numbers of the *Tropical* are worth anyone's perusal for the information they contain: March *for general*—I was going to say information. "There is more than was dreamed of in your philosophy, Horatio": that I found out in reading some articles in last number of the monthly aforesaid. By-the-bye the negroes have it, that the wallaba tree, used for *shingles*, should only be cut in the dark moon, and say it is *full of sap* when the moon is filling; they also say, some esculents grow more in the light and bright moonshine, than under the receding rays of Luna: can this be true?

For reasons, I wish to know what the Government is doing with the island of Delft. Does it still produce hardy and fleet ponies as of yore, or a superior kind of goats,* or cows; also can any of your Jaffna friends favour you with the mode of cultivation of yams in the northern peninsula, as now carried on there?—Yours truly, E. J.

TEA ON ABBOTSFORD AND THE QUESTION OF MANURING.

Upper Abbotsford, 26th March 1884.

DEAR SIR,—As the statistics I gave of the yield of tea on this estate have created a good deal of interest, I think it may not be out of place if I answer publicly the questions I have received as to whether the fields in question have undergone any manuring. I may say at once that not an acre has been systematically manured. In 1878 some China bean was by way of experiment applied, with stalks of nilu, buried, to the tea surrounding the bungalow, about 3 acres in all. In Dec. 1882 and Feb. 1884, 5 acres (which include the above 3) had a basket of ravine stuff added to the buried prunings. In June 1882 and August 1883, 15 acres had ravine stuff added to the buried prunings, mixed with the small amount of manure that five cattle give. About 7 acres have had their prunings buried mixed with a basket of cinchona twig ashes. So that, out of the total of 110 acres, 27 have been (in a fashion) manured.

The following little sum will show that my hopes of getting between 500 and 600 lb. por acre this year are not without some foundation.

Tea made in 1884 to 21st March:—

Acres 110) 16856 lb.

Weeks 12) 153¼

$12\frac{3}{4} \times 52$ weeks for the year.
52

663 lb. made-tea per acre.

We are therefore, already making at the rate of 656 lb. per acre although 5 acres were pruned in February, and about 10 acres more since 1st March, and pruning still going on. And the 110 acres includes our thousands of seed-bearers, from which of course we get no leaf. During one week in February we made 3,000 lb., or at the rate of 1,418 lb. per acre. If anyone is sceptical of tea doing well in Ceylon after this, let him now speak or for ever hereafter hold his peace. —I am yours truly, A. M. FERGUSON, JR.

* I feel sure Angora or Cashmere goats would thrive well on Ceylonian hills and would eat the tender mana grass, only requiring to be fed once a day with boiled gram, &c.

FLORIDA ORANGES.—A correspondent writes from Yercaud, South India:—"Can you oblige me by putting me in the way of obtaining some seeds of the best Florida oranges? I fear if I went to an ordinary seedsman, the seed would not be reliable, but, as I see old Ceylon planters are writing to you from Florida, perhaps you may be able to help me." Perhaps some reader in Florida can supply our correspondent?

INDIAN SPECIES OF CYPERUS.—At the last meeting of the Linnean Society the Secretary read an abstract of an important contribution "On the Indian Species of Cyperus," by Mr. C. B. Clarke, with remarks on some others that specially illustrate the subdivisions of the genus. The author divides his memoir into three sections:—1. A descriptive account of each part of a Cyperus, viz., the culm, inflorescence, &c., comparing these successively in all the Indian species; 2, a discussion of some difficult species and disputed genera; 3, a systematic arrangement with descriptions of the Indian species, with short citations of some non-Indian species that more particularly illustrate the subdivisions and groups.—*Gardeners' Chronicle.*

BACTERIA AGAIN.—When seeds begin to grow and buds to sprout, one essential preliminary is the conversion of the insoluble and indigestible into the soluble and digestible. In the seed and in the bud starch is stored up, having been formed by the conjoint agency of solar light and the green matter of the leaves (chlorophyll), the previous season. This starch is insoluble, but through the agency of a nitrogenous ferment called diastase, secreted by the protoplasm of the cell, the insoluble starch becomes converted into soluble sugar or maltose. So much has been known for a considerable time as a general fact, though the subsidiary details have and still continue to tax the patience and ingenuity of chemists. A further complication is brought about, in some cases at least, by the agency of Bacteria. It appears that these minute germs secrete either diastate itself or something like it, by means of which they dissolve the starch and appropriate its carbon, setting free in so doing some oxygen, which is used up by the germinating seed or sprouting bud.—*Ibid.*

THE ALMOND.—What beautiful objects are the fine trees of Almonds so frequently met with in gardens near London! In early spring the Almond certainly rules supreme in British gardens. One of the forms has snow-white flowers, another—the one most commonly met with—rose-tinted or flesh-coloured blossoms. A weeping form, too, is an ornamental low-growing tree, of great value where the ordinary type would require to be cut back and cramped in order to confine it to a space which is sufficient for the weeping variety. What country, or countries, can claim the Almond as a true native? De Candolle, in his extremely interesting work, *L'Origine des Plantes Cultivées*, inclines to the belief that parts of Western Asia can claim this honour, and that in Sicily, Greece, Italy, France, and elsewhere, where the Almond occurs in an apparently wild state, it has become naturalised more or less recently. Hasselquist, the friend and pupil of Linnæus, in the interesting account of his *Travels to the East*, quaintly philosophises about the Almond. "Why," says he, "does the Almond tree, which hath white flowers, blossom on bare boughs? not for the same reason as the Hazel; perhaps the fruit, having a stone, requires a longer time to grow? They adorn the rising grounds, and according to Nature's order ought to afford much fruit, as they bloom at a time of the year when the sky is constantly serene, and it neither rains nor is there any kind of bad weather, which in many countries prevent a fine blossom from giving the wished-for fruit."—*Ibid.*

CONSTITUENTS OF SOILS.

[THE REASON WHY.]

What are phosphates? They are salts formed by a combination of phosphoric acid, with a substance or base, capable of uniting with an acid and forming a neutral salt. The phosphates of principal importance to agriculture are, the phosphates of lime, of magnesia, potash, soda, alumina, &c. Their composition may generally be illustrated by the phosphate of lime, the difference between it and the others depending upon the base, with which the phosphoric acid combines.

What is phosphate of lime? It is a salt formed by a combination of phosphoric acid, with lime as a base. Phosphoric acid consists of phosphorus and oxygen in a state of solution; and a phosphate is phosphoric acid in a state of combination, with a base, forming what is termed a salt. Phosphate of lime constitutes the base of bones of animals, and is therefore an important ingredient in vegetables employed as food. The bones of man, and of animals in general, have their origin from phosphate of lime, which is never absent from fertile land. The bone earth passes from the soil into hay, straw, and other kinds of food, which are afterwards consumed by animals. Eight pounds of bones contain as much phosphate of lime as one thousand pounds of hay, or of wheat-straw, and twenty pounds of bones, as much phosphoric acid as one thousand pounds of the grain of wheat or oats.

What are sulphates? Sulphates are salts formed by sulphuric acid in combination with any base, as sulphate of lime, sulphate of soda, sulphate of alumina, potash, gypsum, magnesia, &c. Sulphuric acid consists of sulphur and oxygen only, and is known as the oil of vitriol of commerce. In its pure state, it is an exceedingly sour and corrosive liquid, destroying both animal and vegetable structures; but combined with potash, soda, lime, magnesia, &c., it contributes in certain instances to the fertility of the soil. It is rarely met with in nature in an uncombined state.

Whence do plants obtain phosphate of lime? Phosphate of lime is found in natural soils, as are other phosphates, such as the phoshhate of alumina, ammonia, magnesia, &c. The phosphate of lime is added to soils by the decay of vegetable animal matter, and especially by bones and shells. When alkaline or earthly phosphates are wanting in the soil, or when they are not introduced in the form of manure, the seeds are not developed. We may draw this conclusion that the development of plants, and the amount of the constituents of the blood they contain, are directly proportionate to the quantity of phosphates supplied to and taken up by them. Phosphates, so necessary to the formation of the blood, and to all animal life, are no less essential to the existence and to the propagation of all vegetable beings.

Whence do plants obtain sulphates? As far as our present knowledge extends, they receive their sulphur from the sulphates dissolved in the water absorbed by their roots from the soil. The water of springs is entirely derived from the rain which falls upon the surface of the earth; the water, percolating through the earth, dissolves all soluble materials which it may meet in its course. The substances thus dissolved communicate to the water properties which are not possessed by pure water. Thus rain precipitates the ammonia suspended in the air, and presents it to the roots of plants; at the same time that it presents sulphur, in some combined form, which it has met with in percolating the earth.—*Leader.*

REPLANTING WOODLAND, AND CAUSES OF FAILURE.

Whatever diversity of opinion prevails among foresters as to practical management, nearly all are agreed as to the impolicy of replanting with the same description of trees, at any rate until a certain period has elapsed. There must be time for the soil to become sweetened, for fresh mineral food to be prepared, or for the destruction of enemies, insect and fungoid. Let us examine these various causes.

Unless the soil be so specially suitable, by the abundance of requisite food for a particular class of trees, it is only natural to conclude that after proving material for fifty or sixty years' growth there will be exhaustion, even though much of the supplies are returned as decayed leaves, branches, &c. This is what we gather from our experience as regards the influence of rotation, but it only explains one, and perhaps the least important, reason of the fact that immediate replanting with similar kinds of trees seldom results in equally vigorous growth.

A more potent reason for failure arises from the poisonous nature of the excreta, which, until sweetened by oxidation, are prejudicial to the young plants. Of course this applies in some degree to whatever kind of trees are planted, but is more especially injurious when like follows like. It is for this reason that all experienced foresters so strongly recommend that, before replanting, the land should be thoroughly drained; this advice we emphatically indorse. None but aquatic plants can flourish in a water-logged soil. The matrix under such conditions is saturated with acid properties, and it is only by the aeration of the soil, which follows the removal of water, that a healthy condition is induced, that acids are neutralised, and plant food gradually set free. It is, in short, as absolutely essential to the healthy growth of timber as of our crop and pastures, that the land should be thoroughly drained.

A third reason against replanting with similar material is the injury to be anticipated from insect and fungoid parasites. It is well known that the eggs of the beetles—such as Hylobius abietis, Hylurgus piniperda, the pine beetle, and Adelges laricis, the larch bug—are deposited underground on old roots, and the grubs live on dead wood It is therefore most important that all dead wood should be removed, and all decaying matter burnt, before replanting; also, if possible, that a period of three or four years should elapse between cutting down and replanting.

We have now to consider other causes of failure. It must be understood that, as a general rule, hards woods should be followed by larch and pines. Even if we plant a certain proportion of hard woods to remain for the permanent crop, these should be of a different nature. Thus, if the previous crop were oak, ash or sycamore will be suitable to follow. It is better that these should occupy different parts of the same wood than that they should be mixed; the latter kinds, being the hardier, are best adapted to the most exposed part of the land. For the same reason, the Scotch fir is useful as a shelter to the more delicate larch, which, notwithstanding heavy loss from disease of late years, is under favourable conditions, the most profitable of quick-growing woods, not only on account of intrinsic value, but because it is the best nursery for the permanent crop.

Opinions differ as to the reasons for the great mortality and in many cases total destruction, of young larch wood of late years. The causes are various—we may allude to some of the more prominent. Climate is an important element. The natural home of the larch is on the slopes of mountainous districts; it enjoys above everything a dry, porous soil, in which air has free access to the roots. Strong soils are not favourable, and stagnant water is fatal; and, even where drainage is good, low damp bottoms, subject to fogs, are injurious to healthy growth. It is well known that the severest frosts occur in low valleys, and a great deal of the mortality which has occured of late years has, we believe, been mainly due to severe frosts late in spring when the sap was up, and which destroyed the smaller cells. The comparative healthiness of larch on hill sides sheltered from the colder winds is proof of this. Indeed, so great has been the mortality in young larch plantations in flat countries, that it is a serious question whether, under such conditions, the growth of larch should not be discontinued for a time.

Failure may often be traced to want of care in the preparation of the young plants, and too immediate change of soil from the nursery ground to their permanent home. The seedlings are often grown under the forcing conditions of highly-manured soil, of free, open nature, in sheltered situations; and, if at once transferred to a soil of different character, where the circumstances are much less favouable the change is too sudden, and a severe check is experienced; necessary supplies of food are wanting, and the vitality of the plant is weakened, rendering it liable to fungoid attacks.

The management of the nursery is a matter which requires more attention than it often receives. Mr. Brown, in his work on Forestry, says that "in no case should one year seedling larch be more than 3 in. high, nor one year seedling, one year transplanted more than 10 in. high, nor three year old plants more than 20 in. high." It is undoubtedly an excellent plan to buy yearling seedlings once transplanted, and keep them in a nursery for two or three years where soil and climate are of similar character to those of the proposed plantation. It is neither necessary nor desirable to have the ground highly manured; a strip of arable land near the scene of our future operations, clean, and in ordinary condition, will answer the purpose, provided it is to a free working nature. It should be well ploughed 6 in. of 7 in. deep, and then inclosed with rabbit proof fencing. Previous to bedding out, the surface may be well harrowed, and weeds removed. Planting may be carried out during the winter, *i.e.*, from November to the end of March. We advise placing the plants in rows six inches apart, and the same distance in the rows. This admits of hoeing with a 4 in. hoe, and it is of great importance that all weeds be removed. An acre of land will hold over a hundred and seventy thousand plants. The trench may be made by inserting the spade six inches deep and working it backwards and forwards. Then the plants are placed carefully against one side of the opening, the rootlets being straightened out and firmly secured by trampling with the foot. If left slightly on an incline, they will soon recover an erect position. The next year they should be replanted on fresh ground, nine to twelve inches apart each way, and if reset a third time, at least a foot to each will be required. When replanted, care should be taken to sort them out according to size, so that the plants may have an equal chance of growth. Exactly similar arrangements should be carried out with other kinds of timber.—*Field.*

LAWNS.

Amongst the numerous things in a representative English garden that present themselves to those who hail from lands of sunnier skies than we are favoured with, there are none that attract greater attention than our green grass, which soil and climate alike favour. Respecting the latter, which we so often grumble at for its fickle behaviour, it is well to bear in mind that to its changefulness we owe the perpetual greenness of our lawns, the long spells of uninterrupted brightness in the sunnier climes we frequently are inclined to covet being fatal to the justly-prized verdure which is undoubtedly the first feature in a garden, as in its absence the brightest flowers are like pearls in an unworthy setting. Still, with the favourable conditions of alternate sun and shower, with the soil suited to the growth of grass, our lawns are still far from being in all cases what they should or would be, if their construction and after-treatment were not at fault.

Confining the question to the means requisite to secure good permanent grass, it is all but needless to add that in making a lawn, as in all other things connected with the construction of a garden, local circumstances necessarily influence the proceedings. A course that would be expedient to follow in one place would be wholly unsuited in another. Whether turfing or sowing be adopted, if a satisfactory lasting green sward is looked for, there must be a sufficient depth of soil, of fair quality, neither too dry nor too wet. In the southern counties, where the rainfall is so much less than in the north, when the subsoil is of a sandy or gravelly nature, unless there is sufficient fairly holding top soil the grass is sure to burn in dry summers. A depth of 15 inches is not more than needful to avoid this, and in making a lawn where a dry bottom such as abovenamed exists, and the surface-soil is insufficient, enough of a suitable description should be added to bring it up to the required depth; the cost incurred will in the end be found to have been well spent money. The patchy, unsightly appearance often seen in lawns, where the grass in places is poor and weedy, or burns in dry weather, is frequently traceable to faulty construction. Where inequalities of the surface have required removal, sufficient of the under-surface is frequently not removed to allow the needful depth of top soil, thus entailing the mischief named. The effects of this kind of defective work are oftenest seen where the subsoil is of a clayey nature, for although grass does not burn so readily on a cool bottom of this nature, still it must have enough depth of soil to sustain the roots and admit their descending low enough in search of the moisture required during spells of dry weather.

On the other hand, there is frequently too much moisture present in land that has to be converted to a lawn, and with some who happen to be engaged in such work, there is often a reluctance to drain, if it can be avoided, on account of the subsidence that not unusually takes place afterwards, the end of which is not seen the last of for years, but of which there is not the slightest reason to have misgivings if only sufficient care be taken to ram the material in properly as the work of filling the drains proceeds. In draining a lawn, as in the case of land for any other purpose, it is necessary to be guided by the nature of the soil, and also to bear in mind the particular purpose required. The deep, 5 or 6 feet drains that sometimes find advocates, filled up with solid earth, and that can only draw off the water slowly, are all but useless in a lawn where the land is at all of a retentive nature, and the object is to get quit of the water with the least delay, so as to make the surface fit to walk on in the least possible time after a heavy rainfall. With this intention, whatever depth the character of the land may require the drains to be, they should be filled up over the pipes with some kind of porous material to within a foot or 15 inches of the surface, or, in some cases nearer, so as to take the water off readily. The advantages in lawn draining, where trees are present, of filling in over the pipes with rubble, ballast, clinkers, or similar open material, are twofold, as in addition to its accelerating the passage of the water it enables the drains to act even if the roots, as they usually do, get into the pipes so as to choke them. In heavy retentive soil it is mistaken economy to underdo the work by placing the drains too far asunder; if 15 feet apart they will, as a matter of course, dry the ground so much quicker than if a greater distance intervene.

SOWING.—In the important question of turfing or sowing, here again local circumstances will in each individual case decide. Where a lawn of considerable size is being made, sowing effects a great saving in expense, beyond which it has many advantages, not the least of which is that where the requisite judgment is brought to bear in selecting a mixture such as best suited to the nature of the soil, the result will be more satisfactory than with turf, such as is procurable in most localities, for if the land has been properly prepared and effectually cleaned from weeds, there is a certainty of an immunity from weeds and coarse grasses, such as have usually more or less to be contended with where turf is used. The idea that there needs be much waiting in getting a good close surface when sowing is adopted is a mistake; providing enough good seed of the right kinds is used, and the work collectively is done as it should be, an exceptional surface will soon be the result. Again, where the nature of the land and the climate are such as to favour burning in dry summers, sowing has much to recommend it, as grasses which can be selected naturally strike deeper into the soil than are procurable in turf from cultivated land which is always sown with a view to pasturage, rather than with any intention of its being used for the purpose in question. But when sowing is determined on, care should be taken to give time for all the seeds of the worst kinds of weeds, such as Docks and Plantains, that are near enough the surface to admit of their vegetating, to make their appearance, and be destroyed. By this means future hand-weeding, which otherwise would be necessary, will be avoided. This is a matter of no slight importance, as the getting out of these and similar pests necessarily entails the disturbance of the young grass, which can ill afford to have its roots interfered with. As to the time of sowing, there is little to choose between the latter end of March and the latter part of September. Much depends on the unforeseen in regard to the weather; the rains usually looked for about these periods are requisite to get the seed to vegetate evenly.

The weight of seed required per acre necessarily depends on the character of the land in its needing a greater or less proportion of heavy or light seeded grasses. Where turfing is decided on the best will invariably be found the cheapest. A good clean article, free from weeds and coarse grasses, is cheaper at the top figure of its worth than weedy indifferent material is, if obtainable for nothing, as more than the first cost will have to be expended in after-weeding.

TURFING.—When possible turf should always be laid in autumn after the ground has been well moistened by the rains we generally get then, as when carried out at this season the roots have time to take hold before winter; next best time is in the winter—early enough to avoid the watering that usually has to be resorted to where the work is done in spring. When deferred to spring the ground should be well watered before the turf is laid, giving it a good soaking immediately after, and mulching the surface over with an inch of fine soil, which latter in itself is worth two or three waterings, by preventing evaporation and encouraging growth. The best course in the way of after-treatment is not to mow oftener through the ensuing summer than needful to prevent an untidy appearance, not to cut the grass too close, and to do the work with the scythe, dispensing for the first season with the mowing machine.

RENOVATING OLD LAWNS.—In the matter of old lawns, there are many to be met with that are not so good as they once were, and that cannot rightly be described as an ornament to the respective gardens in which they should play no inconspicuous part. The soil in a lawn that has to support the grass that is constantly close cut, in time becomes so poor and exhausted that it cannot keep the crop it is intended to sustain alive, which in dry seasons succumbs, and its place is taken up by weeds and daisies. This kind of exhaustion is well understood and usually provided against in the case of other things except lawns, which are often subjected to this impoverishing process for scores of years without the thought of ever giving them assistance, whereas if an inch or two of fresh loam, free from the seeds of weeds, with a couple of hundredweight of fresh lime added to each cartload, were applied occasionally in the shape of a top-dressing, the condition in question would be avoided. Many old lawns are reduced to such a state by the neglect described that they are beyond recovery except by digging over and subjecting the soil to a thorough cleaning and re-sowing—an operation that need not be costly providing the right course is adopted.

As to the way in which lawns have been disfigured by making croquet or lawn tennis spaces on them, since these games have come into fashion, all that can be said is that where the ground slopes naturally, so that for the games in question one of these dead level deformities has to be made, as they often are, in a prominent position, the effect is so far hideous as to completely destroy the natural appearance, which is the greatest charm in any garden.—*Gardeners' Chronicle.*

PREPARATION OF TAPIOCA.

BY JAMES COLLINS.

The tapioca plant (*Manihot utillissima*, Pohl), a euphorbiaceous plant, is too well known to need a description here. The late Dr. Seemann informed me that he had heard from Chinese that the peculiar lumpy from in which we receive tapioca was owing to the action of a peculiar kind of wood used in the preparation of the starch. In the case of India-rubber, in a certain part of South America, the addition of the juice of *Calonyction speciosum*, brings about the more speedy coalescence of the particles of rubber, and salt water or lime juice is used in the East for the preparation of India-rubber and guttapercha. In India too, the capsules of *Puneeria coagulans* are used in the making of cheese instead of rennet, and thus the product does not interfere with the religious observances of certain castes. The common wood sorrel of the country, *Oxalis acetosella*, acts also as rennet, and in Jersey the leaves of the ash are used to prepare curdled milk and cheeses.

In the case of tapioca, however, I told Dr. Seemann that I believed the agglomeration and alteration was owing to the starch being partially changed into dextrine. This I have since proved to be the case. Whilst in the East I endeavoured to clear up the matter. In the case of gambier, I only saw part of its preparation in Malacca, where I was on sick leave. It was near a gambier plantation, and I saw two or three Chinese coolies just boiling down in the open air, the freshly gathered plant in a large copper, or "quallie," over an improvised fireplace. Their stirring apparatus consisted of two or three different kinds of wood, and a long-handled iron shovel, somewhat of the same shape as that used by bakers. The latter seemed to be most prized. Either from reticence or because the coolies understood but little Malay, I could not ascertain whether any particular wood was used or prized. In the case of the preparation of sago, although whilst in Singapore I purposely rode and drove several miles out in to the country on various occasions, I never saw the whole of the process of preparing granulated sago, yet what I did see left me no grounds to believe that any particular wood was used, and I was assured by European planters and native operators that various woods were used, but none for any particular quality, and iron stirrers were much preferred.

As to tapioca, whilst in Malacca, I saw the whole process, from tithe fresh root stock to the finished product in the process of packing for market. I ascertained that there were two or three large tapioca plantations some miles upcountry, and a friend kindly offered to make arrangements for my visiting them. We visited two or three plantations, but as they were all conducted on the same principle, it will suffice to describe the largest and best. It belonged to a wealthy Chinese, and the factory was well and substantially built of stone and brick. The first thing we noticed was a large hoizontal engine with a European engineer in charge. We were soon ushered into the presence of the owner, and received with that courtly ceremony for which the well educated Celestial is remarkable. Refreshments were quickly served, consisting of tea, tiger's milk, *i.e.*, cocoa-nut milk with a dash of brandy, various fruits, cigars, &c., and had to learn, if we did not know before, that an Eastern must not be hurried. At last we proceeded to the manufactory. Here above our heads, and in every direction, were driving bands, steamers of water flowing in every direction, glowing fires, and a hive of Chinese—a loin cloth, and that of the scantiest dimensions, alone saving them from being quite naked.

Taking our station at the far end, we saw droves of Chinese arriving from the fields with baskets slung on poles filled with the fresh tapioca root stocks. These were at once taken by others to large tubs, fed with a constant stream of water, and the root stocks cleansed from adhering mud, and then passed on to the "paring" table. Here the dark outer coat was peeled off, just as one might peel a turnip, and all discoloured or bad parts removed. Next, the cleaned root stocks were passed on to a machine furnished with knives, and sliced, then passed on to a pulping machine. After being thus treated, the pulp was removed in cane baskets to the strainers. These strainers were large wooden frames, with calico bottoms, and were fed from the pulp baskets. Above these strainers were tanks giving off a powerful stream of water impinging on the pulp, and the strainers had a motion communicated to them by a shaft exactly like that given by hand in sifting. As the starch became washed out, it was received into inclined troughs, and allowed, whilst in suspension, to run into settling "vats." Here, after well stirring, the starch was allowed to settle, and the water drawn off, and fresh being pumped in till the starch became clean and white. In this part of the building, which was on a lower plane than the rest, the smell of hydrocyanic acid was by no means faint. When the starch had undergone this washing, and had been strained, whilst still moist, it was removed to the drying department.

The machinery we have mentioned occupied the central line of the building, and on either side, next the wall, was the drying apparatus. On the one side tapioca flour was prepared, and on the other the granular form of it. The flour was prepared by spreading the wet starch on a long iron table or slab, heated slightly by fires placed underneath, and constantly stirred and turned over with iron shovels to prevent agglutination, and ensure equal drying. The granulation was performed as follows:—There were a long range of quallies, or small iron shallow pans, slightly tilted forward on ledges of brickwork, and heated with a wood fire. Each operator had a qualie and fire to himself. Taking up a quantity of damp starch, he stirred it round and round with his iron shovel, and the heat being greater than in the former case, as it became stirred about, became agglutinated together in small masses, and became coated with dextrine. We could not but admire the dexterity with which it was done; how well the open fires were managed, so that no more heat than was necessary was communicated. The "bullet" tapioca we also saw made; it is done by pressing the starch through perforated plates and "cooking" in "quallies." No wood was used in stirring, and when I asked why, I was told that only those who could not afford iron used wood.—*Journal of the Society of Arts.*

A CHEAP RAIN-GAUGE.

Mr. J. W. F. Stockton, in the San Francisco *Scientific Press*, describes the following simple and inexpensive rain-gauge:—

Let the tinsmith make a funnel with a small, say one-quarter inch, opening at bottom, and having a two-inch band soldered round the top to prevent the rain that falls within it splashing out again. The upper edge of this band must measure an exact eight inches in diameter. Take a good large bottle (an ordinary wine-bottle will serve; but, in localities where the rainfall is heavy, something larger is preferable): into this bottle measure three fluid ounces and a half, and mark the bottle at the water-level; so on till the bottle is filled, marking the water-level of each added measure of three ounces and a half.

Each of these graduations shows one-eighth inch of rainfall. For convenient reference, the graduations may be marked on a strip of paper, and gummed outside the bottle.

TEA IN WESTERN CHINA.

In our last issue we noticed at some length a very interesting Parliamentary paper giving an account of a journey made by Mr. Hosie through the provinces of Ssu-chuang Yunnan, and Kuei-chou. In the account of his journey Mr. Hosie incidentally gives a few details regarding the tea production and the western tea trade with Thibet. It was hoped by the pioneers of the Assam route towards China that this trade with Thibet might some day benefit Assam planters. Possibly when these have found the necessity for turning to fresh markets they may yet be tempted to look over their garden wall, after having exhausted the further corners of the earth. Mr. Hosie tells us that of the tea-growing districts within the prefecture of Ya-chou, Jung-ching Hsien ranks first; Ya-an Hsien, second; and T'ien-ch'üan-chou, third; Chiung-Chou produces least. Within the district of Ming-shan only the Meng-shan hills produce tea, and that exclusively for use in the imperial palace. This tea is brought to Ya-an Hsien for transmission to Peking. The best tea is picked by hand in the "second moon;" the coarse tea is picked—or rather cut, for a knife is used for the purpose—in the "third moon," when leaves and twigs are indiscriminately collected. The great tea trade is with Ta-chien-lu and Thibet.—*Home and Colonial Mail.*

PRACTICAL RECIPES.

GILDING LEATHER.—The leather is first moistened with a sponge, then stretched, and tacked on a board. When dry, it receives a coat of thick isinglass-solution, then one of white of egg that has been beaten, and allowed to settle. Upon this is laid lightly with a brush sheets of silver-foil, which are then pressed down with a wad of cotton-wool. When this is dry, it is painted over with yellow leather-varnish, which gives it a beautiful golden appearance. A varnish for bronze boots and slippers is made by dissolving aniline red in shellac or other varnish.

BOTTLE-GLUE.—A good bottle-glue, insoluble in water, and particularly suitable for sealing bottles containing volatile liquids, such as chloroform, ether, alcohol, &c., may be prepared by soaking glue or gelatine in water, dissolving it in glycerine, then adding tannin (about two ounces for every pound of glue), and heating the mixture on a water-bath until perfectly homogeneous, and as free from excess of water as possible. It may be coloured, if desired. When wanted for use it is melted and applied to the mouth of the bottles.

To POLISH EBONY.—To put a high polish on ebony, that will be durable, give the work two coats of fine copal-varnish, and when this is dry rub it down smooth with fine pumice-stone; put on a third coat of the same, and rub down with rotten-stone; clean, and put on a flowing coat of best spirit copal-varnish, and, when this has become quite dry, polish with chamois-skin and the palm of the hand.—*Popular Science News.*

HOW DRAINAGE HELPS.

Experiment has shown that for the best welfare of crops a soil should not be more than from one-tenth to one-third full of water; that is to say, most of the larger spaces between the solid particles are empty of anything except air. This healthy condition sometimes comes about of itself, when an open subsoil lets the surplus water run away freely from the surface; but usually artificial drainage is necessary to secure it. One of the most marked good effects of this under drainage, whether natural or artificial, is the improvement in the temperature of the soil. If this surplus water cannot pass off below in due time, it must be evaporated into the air, at the inevitable cost of a great quantity of heat which would otherwise have served to warm the soil; a wet soil, like a wet person coming out of a bath, is cold. The less heat a soil must lose in this way the greater will be its reserve stock, useful not only for the production of crops but also for their protection against cold. The sun's rays do not warm the air as they pass through it; they warm the soil and the rocks; these then throw out or radiate this absorbed heat into the air and warm it. The lateness of a frost in any locality depends therefore not a little on the reserve supply of heat in the soil; and this again depends largely on the freedom of the soil from surplus water during the heated season; a well drained and properly dry soil will not only give a larger and better crop than an undrained and wet soil, but its crops will not suffer the harm from early frosts that may ruin the harvest of undrained fields.—*New York Tribune.*

HOME-GROWN TEA.

It is possible that planters in India and Ceylon have passed through recent vicissitudes only to encounter fresh obstacles at every turn? Is the home market to be closed to the fragrant herb from India just when its true value is becoming recognised, in order to make way for tea of home growth? This time it is not sloe leaves, but the dried leaves of *Chimonanthus fragrans*, which is the threatened rival. This is what the *English Mechanic* says:—"Our correspondent, 'Devonshire Squire,' in sending us a very fine sample of the dried leaves of *Chimonanthus fragrans*, says that he finds the tea made from them in the usual way has 'much the flavour of ordinary green tea—certainly less good than the best, but fully equal to much that is sold under that name. It also seems (but I may be wrong as to this) to impart a peculiar exhilaration to the nerves.' We can corroborate 'Devonshire Squire' as to the flavour, which is certainly superior to that of much of the coloured stuff sold as green tea (fine samples of which cost 4s. a pound), but we have not tried the effect on the nerves. There is a peculiar, but not unpleasant, bouquet with the Chimonanthus tea, and it is not impossible that if the leaves were dried by heat like China tea, it would be found as well worth cultivating as an economic plant as it certainly is as a flowering shrub. It is commonly known as the Japan allspice, and should be in all gardens where it can have the protection of a wall."

Until the editor of the *English Mechanic* tries the "effect on the nerves," Indian planters will remain in a state of anxiety. This gentleman, if he gives 4s. per pound for his tea, is not well served, and he will do well to avoid green tea in future.—*Home and Colonial Mail.*

THE CHICK-PEA.—"COFFEE PLANT."

The Chick-pea (*Cicer arietinum*), one of the oldest of cultivated plants, every now and then is sent us to know what it is, or by some one who has received it as the "coffee-plant," to know its value as a substitute for coffee. The Chick-pea was hardly known in this country until about twenty years ago, when some enterprising person advertised it as the "coffee-plant," and advised every one to grow his own coffee. The chick-pea is related to the common pea, and like that, is an annual. It grows about a foot and a half high, and is covered with fine hairs. The engraving of a small branch shows the shape of the leaves and the small pods, which contain one, or at most, two seeds. These are rather larger than common peas; they are so strongly wrinkled that they have been compared to ram's heads. This has given the plant its specific name, *arietinum*. The Chick-pea is cultivated in all warm countries. In India it is sold as a food for horses under the name of "gram." It is cultivated in Mexico, where a "garabanza," the Spanish name, it is esteemed as a luxury. We have eaten it there and found it a very coarse food, far inferior to the *frijoles*, or beans of the country. The reputation of the Chick-pea as a substitute for coffee has not yet died out, and we are often asked about it. There is no substitute for coffee. It is either coffee or no coffee. Still, for a warm-colored drink, Chick-pea is just as good as roasted rye, brown-bread crumbs, or parched Indian corn—and no better. Any starchy grain, when roasted, will give a colored infusion, but it is not coffee. As the Chick-pea belongs to a warm country, and its yield is small, it is not likely to gain a prominent place among our crops for "coffee" or other purpose.—*American Agriculturist.*

OLD CORKS UTILIZED.

That old bottles are used again and again is well known, and the gathering, cleaning, and selling of them gives employment to a good many people in the large cities both in this country and abroad. It is a less familiar fact, and a curious one withal, that old corks are made to do service a second time. The *Mineral-Water Trade Review* gives the following account of this branch of trade in New York:—

In a low wooden building in Mulberry Street old corks are made as "good as new." This is the only place in New York where they are dealt in. The dealer buys the corks by the barrel, and pays from one dollar to three dollars. His trade is mostly in champagne-corks. The best and cleanest of these he sorts, and sells to American champagne-makers. The bottom of the cork, where the first bottler's brand appears is shaved off, and the name of the second stamped on them. These corks were cut expressly for champagne-bottles, and, as they can be bought much more cheaply than any new ones, the bottlers purchase them. The old-cork dealer obtains twenty-five cents a dozen for them, and makes a handsome profit. The broken and dirty corks go through a peculiar process. They are first subjected to a sort of Turkish bath to clean them, and after they have dried are cut down. They are put in a machine and turned, while a sharp knife runs across them, and takes off a portion of them. They can be cut to any size, and, with the soiled surface removed, look as bright as when new. The corks cut down are purchased by root-beer and soda-water makers, who use smaller bottles. They can save a considerable amount by purchasing old corks, which, as it is easy to see, will do as well as new ones. The "old-cork man" is rushed with business. The champagne and root-beer and soda-water bottlers take all the corks he can furnish. He gets his supply at the hotels and elsewhere.—*Popular Science News.*

THE SWEET GUM TREE.

We trust that the recently awakened interest in forestry—the planting of trees to grow timber—will also call attention to the value of our native trees for ornamental purposes. If one who wishes to plant them to beautify his grounds consults a nursery catalogue, he finds that the greater share of the trees now offered are of foreign origin, while our most ornamental native trees are difficult to procure. Among the most desirable trees for ornamental purposes, is the Sweet Gum (*Liquidambar styraciflua*), and in New York and New Jersey, is often called Bilsted. This tree is found westward to Illinois, and southward to Texas and Mexico. It forms a large tree, sixty feet or more high, and two or three feet in diameter. The old trees have a deeply furrowed bark similar to that of some oaks. Its young branches are winged with wide longitudinal ridges of a corky growth. The leaves are rounded in their general outline, but deeply divided into five and sometimes seven pointed lobes, which give them a striking, star-like appearance; they are of a dark-green color and a firm texture. In autumn they assume a deep purplish red, and are so showy, that the tree is worth planting for the beauty of its autumn foliage. The flowers of the Sweet Gum are of two kinds, both very small. The staminate or male flowers are in small conical clusters which soon fall. The pistillate, or fertile flowers, are in globular clusters, which ripen into a spherical head, made up of beaked capsules which open to let out the small seeds. Both its generic name, *Liquidambar*, and its specific name, *styraciflua*, have reference to a quality only manifested in warm countries. In Louisiana and in Mexico it has exuded, when wounded, a sort of balsam like Styrax, which is deficient in the tree grown in the Northern States. As a timber tree, the Sweet Gum does not hold a high rank. Its wood is compact and fine-grained, it has a pleasing reddish color, and takes a fine polish. It is only of value for inside work, as it is very perishable when exposed. The tree cannot be recommended for economical planting, as we have so many better kinds, but as an ornamental tree, it is one of the finest, and in making a select collection of trees, this should not be overlooked.—*American Agriculturist.*

CURRY-POWDER.

We believe that a really good curry-powder (like Crosse and Blackwell's, for instance) is not only piquant and appetizing, but a wholesome aid to digestion. Of course it is easy to make a cheap imitation of the genuine condiment, which is "hot i' the mouth," but has no other merit. The fine flavor and aroma that a connoisseur recognizes in a good article depend upon a proper selection of materials, and the care with which they have been dried before being powdered. The famous curry-powder of good old Dr. Kitchener (whose name seems to have been prophetic of his culinary renown) is undoubtedly the best that has been made outside of India. A London exchange says of it:—

The flavor of this powder approximates to the Indian powder so exactly, that the best judges have pronounced it a perfect copy of the original *curry stuff*. The following remark was sent to the doctor by an East-Indian friend, "The ingredients which you have selected to form the curry-powder are the same as used in India, with this difference only, that some of them are in a raw green state, and are mashed together, and afterward dried, powdered, and sifted." The common fault of curry-powder is the too great proportion of *cayenne* to the milder aromatics (from which its agreeable flavor is derived), preventing a sufficient quantity of the curry-powder being used. Coriander-seed powder, 3 ounces; turmeric, 3 ounces; black pepper, 1 ounce; mustard, 1 ounce; ginger, 1 ounce; allspice, ½ ounce; lesser-cardamoms powder, ½ ounce; cumin-seed powder, ¼ ounce; to be thoroughly mixed together, and kept in a well-stoppered bottle. Those who prefer a hot curry will find the following give satisfactory results: coriander-seed powder, 1½ pounds; cumin-seed powder, ½ pound; turmeric, 1 pound; ginger-powder, 2 ounces; mustard, 1 ounce; fenugreek-powder, 1 ounce; cayenne, 1½ ounces; mix well, and keep in closed bottles.

Curry-powder is not only useful in the regular "curried" dishes that are duly catalogued in the cook-books, but it will be found a grateful addition to macaroni, whether plain or prepared with cheese. It is, perhaps, better to add it at table, rather than in cooking the dish, as it may not suit all tastes, and some persons like more of it than others do.

Macaroni, by the by, is a cheap and nutritious food that is not so generally known and appreciated as it should be, at least in many parts of New England; and the curry-powder will make it more acceptable to those who complain that it is comparatively flat and insipid.—*Popular Science News.*

CINCHONA, &c., IN INDIA.

From an official Statement of the Trade of British India that has just been issued it appears that the export trade in drugs of this dependency has doubled during the last five years, amounting in the year ending March 30, 1883, to about £130,000. As might be expected, the increase is due to the development in the trade in cinchona bark, which now represents about two-thirds of the total exports. During the last year the quantity of bark exported reached 641,608 lb., whilst seven years previously it only amounted to 72,452 lb. Madras contributed most largely to swell the exports, the cultivation of cinchona in that presidency being more extensively carried on in private estates than in Bengal, where the principal cinchona estates are the property of the Government, which reserves a large proportion of the bark produced for local alkaloid manufacture. Most of the bark hitherto exported has come to London, but the demand from Italy for Indian bark is increasing. The total outturn of cinchona bark from the Government plantations in India during the year 1882-3 was 527,199 lb. In Sikkim these plantations cover 2,294 acres and contain upwards of five million plants. The Nilgiri plantations cover 847 acres and contain about a million plants. The private plantations in Sikkim are estimated to extend over 331 acres and possess over six hundred thousand plants. In the Nilgiris cinchona is cultivated in combination with coffee on private estates, but no returns exist as to the extent. In Coorg also there are more than a thousand acres under cultivation, containing another million plants. The local manufacture of alkaloid, referred to above, appears to be affecting seriously the import of quinine from Europe into India, as last year it fell to 7,585 lb. from 10,615 lb. in the previous year. As matters now stand, it is officially stated in this report that imports of quinine on account of the Government have already practically ceased, and an opinion is expressed that in course of time quinine will be no longer imported into India, since that country will be able to supply all her own wants from the plantations of Darjeeling and the Nilgiris. We learn from this same report that lac dye, once an important item in Indian trade, is disappearing from the exports, under the influence of the competition of other dyes. Lac is exported chiefly as shellac, and to a smaller extent as button-lack. Stick-lack, which is the unmanufactured form of lac, is now hardly exported. Another dyeing material, safflower, the cultivation of which once constituted an industry of some importance in Bengal, has also been almost driven out of the field by the competitors that have been pitted against it by modern science. It would appear, however, that the chemical dyes are not everywhere to have all their own way, since the Government of Persia has issued a decree prohibiting the importation of aniline dyes into that country, on the ground that they have been found to exercise an injurious effect upon the textile industries. It is believed that if this prohibition be strictly enforced, Persian carpets will recover their former reputation in the European markets for durability of colour.—*Pharmaceutical Journal.*

GLAZED POTS FOR PLANTS.

The question whether glazed or unglazed pots are to be preferred for plants has lately been the subject of renewed discussion in the London *Garden*. On the whole, the weight of evidence and argument seems to be in favor of the glazed pots. One writer says:—

Thirty years ago, or more, Lindley wrote, that "experiment has settled the question, by showing that plants will grow in glass, in slate, in glazed earthenware, just as well as in soft-burned pots; and it is now admitted on all hands, that, if plants are ill grown, it is the fault of the gardener, and not that of the pot." The cottager was, however, the real original discoverer; for he grew his plants in pots glazed within and without, long before even Lindley wrote. One of the earliest examples I was familiar with was a fine fuchsia that grew in a black teapot for many a year. About forty years ago, Charles McIntosh put the whole of his camellias into slate tubs, which are as impervious to moisture as glazed earthenware; and I was familiar with these plants and tubs many years afterwards. The fact of the matter is, common flower-pots were not originally made of porous earthenware on account of the plants, but because they were cheaper made in that way when the labor of manufacture was greater than it is now. Cultivators only jumped to the conclusion that the porous pot was best, but for no good reason I have ever yet seen stated. The common flower-pot is, except when plunged in the ground up to the rim, the worst receptacle for a plant that could be devised, because it constantly exposes an active evaporating surface to the air; and an evaporating surface is always a chilly surface. How the roots of a plant are affected inside such a pot, any person may learn for himself by wearing a wet coat next his skin in the open air. In short, a plant in a porous pot upon any airy greenhouse stage may be said to be placed under about as adverse conditions as it well could be. A glazed pot is no better than a porous one while it remains moist on the outside; but then it soon dries, whereas the porous pot is always moist, and giving off moisture.

Another gardener of large experience writes as follows:—

All are familiar with the method of making water almost ice-cold in summer by placing it in a porous vessel, and exposing it to a draught. The roots of a plant in a porous pot are, when recently watered, under the same conditions as the above-mentioned water, and are made equally cold. It follows that plants are subjected to a serious check each time they are watered; this effect is sometimes avoided by plunging the pots. It is well known how much more freely plants grow when plunged. It is probable that the mischievous effects attributed to draughts do not result from their direct action on plants, but indirectly from the cold at the roots, produced by the rapid evaporation caused by such pots. Glazed pots would not only prevent surface evaporation, but render watering less frequently necessary, thereby saving labor, and preserving the fertilizing properties of the soil for a longer time.

In the moist air of greenhouses the evaporation from the surface of porous pots, and the consequent refrigeration of the roots, would be much less rapid than in the dry atmosphere of our furnace-heated houses. The porous pots might, therefore, do for the former when they would be decidely objectionable for the latter. For house-plants requiring a permanently moist soil, the glazed pots are clearly to be preferred, if not for all plants.—*Popular Science News.*

WEIGHT OF GRAIN AS A TEST OF MERIT.

The weight of a given measure (by capacity) of grain is almost universally accepted as a reliable test of quality and an infallible indication of the intrinsic value of the grain. Of course it is admitted as perfectly patent that a measured bushel of wheat that weighs 65 lb. is worth more for bread purposes than the same measure that weighs only 60 lb. This is to say simply that 65 lb. of wheat are worth more than 60 lb. of wheat. But the generally received notion is that 60 lb. of the heavier wheat are worth more than 60 lb. of the lighter wheat, either for bread or for seed. If the difference in weight is clearly attributed alone to the difference in the merchantable condition of the two samples, or the plumpness and soundness of the grain, we do not join issue. Sixty pounds of clear, plump, pure wheat are worth more than 60 lb. of a mixture of chaff, straw, and good, bad and indifferent grains of wheat. But it is insisted that of two samples of wheat, each of which presents the same plumpness and soundness of grain and the same freedom from all impurities, each being perfectly sound, clear and dry, the heavier sample is worth more than the lighter, and the conclusive test is the relative weights of a measured bushel of each. Now, upon what is this notion based? An intelligent upholder claims that the difference in weight is due to the more perfect development of the heavier wheat, or that its greater weight is due to a preponderance or greater proportion of the more valuable constituents of the grain. But this is a mere assertion—not sustained by any proof whatever. The expert miller when he buys wheat cares little what it weighs to the measured bushel so long as it is clean, plump grained, and of the desired color and brightness. He buys up the 60 lb. and finds no advantage in getting a smaller bulk of wheat for his money rather than a larger. But is it true that the difference in weight of two samples of wheat that are equally good in appearance is due to any real superiority of the sample that weighs the more to the measured bushel? We say not, but suggest that the difference in weight is generally, if not invariably, due to the difference in the sizes and shapes of the grains of wheat. A measured bushel of small grained wheat will outweigh a similar bulk of large grained wheat. This fact may not be very generally known, but it is certainly as true as the truth of mechanical principles. Take any material matter consisting of particles of uniform density and shape, and it is found the smaller the individual particles the heavier will be a given measured quantity of them. For instance, it has been remarked by close observers that 25 lb. of leaden buckshot require a larger bag to contain them than does the same weight of birdshot. The same principle holds good in the case of apples, oranges, Irish potatoes and other articles and substances that approximate uniformity in shape and size of separate specimens. The weight of a bushel of wheat of corn, as other similar products, is affected not only by the size of the grains or separate pieces, but also by the greater or less roundness of shape of these grains. A bushel of short, roundish grains of wheat will be heavier than a bushel of a long grained variety, although the average weight of individual grains may be equal. It is because a bushel measure will contain a greater number of the small, roundish grains. These two causes act together in the case of Indian corn as compared with wheat. This grain is rated at 56 lb. to the measured bushel, against 60 lb. of wheat, and the difference, we think, is owing entirely to the circumstance that the grains of corn are larger and of more irregular shape than those of the wheat. Indead, we believe that grains of corn are denser and of greater specific gravity than grains of wheat, and if both were of the same size and shape a bushel measure of corn would weigh more than the same measure of wheat. Now, a large grain of wheat contains a less percentage of bran and a corresponding greater percentage of flour. The thickness of peel being the same in each of two apples, the smaller specimen will contain the larger percentage of peel when compared with the whole apple. So it is with wheat or other grain. This is based on a well known geometrical principle that the solidity (or contents) of any round or nearly round body increases in a more rapid proportion than its surface. Large grained wheat, then, will yield a smaller percentage of bran, and therefore 60 lb. of large grained wheat will yield more flour than 60 lb. of small grained wheat. In regard to relative production per acre it is bald assertion to say that an acre will yield the same bulk of the same number of measured bushels of heavy wheat as of lighter wheat, and that, therefore, the heavier is the more prolific or productive. Nature deals by weight not by volume.—*Colonial Southern World.*

CONSTITUENTS OF SOILS.

What is silica? It is a substanee which occurs in nature more frequently and abundantly than any of the other earths. All hard stones which give out sparks when struck by steel; the enormous masses of granite, together with the vast accumulations of sand in deserts and in plains, are mainly composed of silica; and there are few stones that do not contain more or less of this substance. There is scarcely a single plant that does not contain it. Grasses, in particular, contain large quantities of it; and it forms the grass-like coating on the straw of wheat.

What is alumina? Alumina is the earth which, next to silica, is found most frequently, and in the greatest abundance, in our soils. Clay, into the composition of which alumina always enters, exists in a greater or less degree in every soil, and is also found in extensive strata beneath the surface of the earth. Moreover, alumina forms a constituent part of most stones, and in some it is the principal ingredient. A small quantity of it is found in the ashes of most vegetables. This earth is of great importance to the agriculturist, in order to enable him duly to appreciate the influence of clay upon his fields, and the improvement or deterioration of the soil which it occasions. Alumina appears to have a greater affinity for water than any of the other elementary earths. It has a very powerful affinity for the other earths, and in certain cases enters readily into combination with them. It has a very great tendency to unite with silica. It is in consequence of this affinity that silica is so often combined with alumina in forming the compound called clay. Lime also has a strong affinity for alumina, which explains the great fusibility of these earths when mixed. Alumina exercises only an indirect influence on vegetation, by its power of attracting and retaining water and ammonia. It is itself very rarely found in the ashes of plants.

What is potash? Potash is procured from the ashes of plants, by burning and other processes. The plants which yield the greatest proportion of potash are wormwood and fumitory. Refined potash is called pearlash, and is, in that state, an impure carbonate of potash, or potash with carbon. Wood ashes are certainly a valuable manure, and are peculiarly well adapted for gravelly soils and loams. This remark applies to the ashes of almost every description of vegetable land weeds, grasses, peat and sea weeds.

What is soda? Soda is obtained chiefly from two sources, the burning of marine vegetables, such as common sea weed, which furnishes the alkali called kelp; and the decomposition of salt. A material purpose which these earbonates (carbonate of potash and carbonate of soda) are supposed to serve is that of combining with and rendering soluble the vegetable matter of the soil, so as to bring it into a state in which it may be readily taken up by the roots. They may in this case be said to prepare the food of plants. This mode of action can be exercised in its fullest extent only where vegetable matter abounds in the soil. They are, therefore, most useful where vegetable matter is plentiful, and ought to be employed more sparingly and with some degree of caution where such organic matter is deficient. Another mode in which these substances act, more obscurely perhaps, though not less certainly, is by disposing the organic matters contained in the sap of the plant to form such new combinations as may be required for the production of the several parts of tho living vegetable.

What is lime? Lime is one of the most abundant substances in nature; it forms whole mountain chains, and together with other earths and metallic compounds constitutes a great number of minerals. It forms a constituent part of all vegetables; and in animals it forms the principal ingredient of shells and bones. In its chemical constitution, lime is composed of a peculiar metal called calcium and oxygen.

What is magnesia? Magnesia is an earth less abundant than lime. It is never met with pure, but always mixed with other earths, and combined with acids. Several minerals contain proportions of it; springs, rivers, the sea and salt water also contain it. The ashes of most vegetables contain it; it sometimes forms a very considerable constituent part of the layer of vegetable mould, and of that marl which is best adapted for the purpose of manure. The barn of flour contains a large quantity of ammoniacal phosphate of magnesia. This salt forms large crystalline concretions, often amounting to several pounds in weight, in the cæcum of horses belonging to millers; and when ammonia is mixed with beer, the same salt separates as a white precipitate. Liebig makes an important division of plants, according to their propositions of these organic substances. Thus: potash plants he defines to be those the ashes of which contain more than half their weight of soluble alkaline salts. Lime plants and silica plants are those in which lime and silica respectively predominate. The ingredients thus indicated are those which form the distinguishing characteristics of the plants which require an abundant supply of them for their growth. The potash plants include the beet, mangel-wurzel, turnip, maize, &c. The lime plants comprehend clover, beans, peas, tobacco, &c. The silica plants include wheat, oats, rye and barley. The potato belongs to the lime plants, as far as regards the ingredients of its leaves, but its tubers (which contain only traces of lime) belong to the class of potash plants.—From *Reason Why.*

CACTACEOUS PLANTS.

Grotesqueness of form or habit is rarely found in combination with floral beauty in the vegetable world, yet no family affords more remarkable examples of this union of widely divergent qualities than the great and peculiar Cactus order. In many large groups of plants we find numbers possessing handsome foliage, but having only insignificant flowers, and in many others also, when the flowers are more than usually attractive, the foliage appears chiefly to serve the purpose of a foil to their rich or bright colors, having in itself nothing of a specially striking nature. There seems to be something of Nature's economy in thus developing one particular quality at the expense of the others—a concentration of strength, which probably has a deeper meaning than we can perceive, for it is observable in the animal kingdom as well as amongst plants. The Cactus family is, however, an extraordinary exception, for whether flowering or not, the majority of the plants constituting it are distinguished by most striking characters. They do not possess beautifully colored or elegantly formed foliage to recommend them; on the contrary, true leaves are absent from nearly all, but in contrast to some of the most gorgeous flowers produced by plants, we see unwieldy masses of vegetable matter, spherical, cylindrical, or angular, armed with stout and formidable spines, and resembling what we might almost imagine to be the relics of a vegetation belonging to a period long prior to the development of the plant life familiar to us in the present age. Such would be the first impress on; but when the brilliantly colored rose, crimson purple or yellow blossoms were seen, the observer would be led to the conclusion that while the plant was advancing to so high a degree of floral beauty, one portion of its constitution must have been strangely stunted and altered by some external, long continued forces. There is an inconsistence of characters that must impress the least observant, and imparts an interest to the plants which increases with the knowledge we gain respecting them, for they are surrounded as it were by a degree of mystery that always adds a charm to nature. Cactaceous plants have, therefore, much to recommend them to lovers o the curious and the beautiful, but the majority also possess another very valuable character—*i.e.*, they are easily grown, so easily, in fact, that the cottager who can only devote a small space to them in his window may, and often does, grow many of them as successfully as the greatest magnate with all the most elaborate horticultural appliances at command. In the dry and heated atmosphere of a room, which is so trying to most plants, they are perfectly at home, and their demands upon the attention of their host are so slight that they may be left for weeks, nay months, without the smallest supply of water. It is not surprising, therefore, that many of the Cacti are favorites with dwellers in towns, and many a toiler has had his heart lightened by a sight of the lovely flowers produced by his window "cactus," or has felt the pleasure of exhibiting his vegetable curiosities to his friends. Amateurs, too, in many other grades of life, have found in the cultivation of these plants the satisfaction which is derived from the constant study of the wonderful phases of plant existence; and though it can never be expected that they will rise to a popularity approaching that of the rose, yet there is a steadily increasing demand for them.

The prominent general character of the plants comprised in the natural order Cactaceæ is the unusually large development of cellular tissue, to which circumstance they, in common with some others of different families, owe the popular and wide designation of "succulent plants." The stem is, with few exceptions, leafless, and varies in form from the globular Melocactus to the columnar Cereus, being generally unbranched, except in the Rhipsalises, Opuntias and slender growing Cereus. The surface is either marked with angular ridges from base to summit, upon which are arranged with great regularity a series of clusters of spines varying in size, color and number, or as in the Mamillarias the surface is broken into a number of small rounded projections or mamillæ, each crowned with a cluster of spines; these spines, in several of the genera furnish useful characters in distinguishing the species, size, color and number, being found constant in the majority of cases. They are exceedingly numerous, and specimens of moderate size of Cereus senilis have been found to have from 50,000 to 70,000. In fact, too, the Cacti have a wide range of variation, from some of the diminutive Mamillarias, a few inches in height, to the gigantic Cereus peruvianus, which is found in its native habitat upward of 50 feet tall, and the huge Echinocactus Visnaga, single specimens of which have been imported weighing as much as a ton. These plants contain comparatively little woody tissue except when they are very much advanced in age, the cellular tissue being very largely developed in the majority of the typical forms, the cells being large and mostly filled with a clear water-like fluid, but in others with milky, mucilaginous or slightly acrid juices. There is usually a quantity of crystals of oxalate of lime, which are readily seen if a stem is cut after being dried. Having no leaves, the function of respiration must be performed by the stem; but as this has to serve as a reservoir of nutriment generally exposed to a burning tropical heat, it is obviously of importance that the evaperation from the surface should be reduced to a minimum. As a means to this end we find that the stomata or breathing pores, which are so abundant on the leaves of most plants inhabitating temperate climates, are in the cacti comparatively few. To this, together with a peculiar structure of the walls of the cells forming the superficial layer, is due the remarkable heat and drought enduring character that enables it to live and thrive where most other vegetation would perish.

The flowers differ much in size and color, but they mostly agree in the large number of sepals, petals and stamens, both the former very frequently colored alike, and only distinguishable with great difficulty. The colors most abundant are shades of rose, crimson, purple and yellow, some being white and others greenish. Many flowers possess a powerful and most pleasing fragrance, but they are usually of extremely short duration, some lasting but a few hours during the evening or night. The fruit is of a fleshy substance, and in the case of several species, such as Cereus speciosissimus and Opuntia vulgaris, it is edible, and when well ripened of a very agreeable flavor, somewhat resembling that of the gooseberry, to which the Cacti are distantly related. North and South America are the principal homes of cactaceous plants, the greatest strength of the order being concentrated in Mexico, which contains nearly three-fourths of the entire number known. Brazil, Peru, Chili, Guiana, Colombia and some other districts in South America also contain representatives, but in relatively small numbers. In Mexico the vegetation assumes an extraordinary appearance owing to the prependerance of the Cerei and other members of the family, where in the several hot, dry, rocky regions which characterise this portion of the American continent, the Cacti flourish together with Agaves, Yuccas, Dasylirions, Beaucarneas, Echeverias, and similar plants of the Xerophyllons, or heat and drought loving type. In the Rocky Mountains some members of the family are found at great elevations, several having been observed as high as 10,000 feet. These being in a law temperature are practically hardy in a temperate climate, and form a group of additional interest to the cultivater.—*Journal of Horticulture.*

MUSHROOMS.

BY T. BENNETT.

The mushroom is a very scarce vegetable in our markets, except for a very short season, and it is a great pity for it is a great luxury.

Few people seem to have acquired a taste for it, perhaps from its scarcity, but I think the time is not far distant when a bottle of nice mushroom catsup will be considered a necessary condiment on every farmer's table. The prevaling opinion seems to be, that there is something very mysterious in growing them; and a great many people do not know how to distinguish between an edible mushroom and a poisonous toadstool.

I may be told they are a luxury that can be done very well without; to which I answer: So was tea in the time of our forefathers. But who would like to part with tea now? The mushroom only requires to become well known and its management properly understood, to be appreciated; and when it does, it will become almost a necessity, like many other blessings we now enjoy. Most good gardeners I believe grow them, but it is chiefly for private families.

When the farmers begin to grow them they will be found a profitable crop, their use will become general, and they will be found plenty in our markets. I do not wish to go over the ground already gone over so often by others, but to show in what I differ with them, what additions I have made (improvements, if you wish), and how easily they can be grown in abundance by any one who wishes to take a little trouble in the matter. There are many works, I believe, written on the subject, which I have not seen, but what is here given is the result of many years' practical experience.

In the first place 60° is about their mean temperature. It will readily be seen that they do not need a hot-bed in any of the summer months. A dry cellar, built of brick or stone, is best adapted to their growth in this climate, but an arched cellar built in a bank, with its end facing to the south, is peculiarly adapted to them. Little flat beds on cellar floors, made up of proper materials, will give abundant crops all summer and fall without artificial heat. A little light and a little air is necessary for wholesomeness' sake. In the next place, wood of any kind, especially pine, should never surround the beds when made on the ground; but the beds should be built up against the wall with a few bricks in front to keep the materials together. Common house slates, sunk in the beds, perpendicular to the wall and on their edges, about two feet apart, to half their depth, will obviate the necessity of watering in a great measure. These will be found dripping with water nearly at all times—by the wall, by the bricks, and by these slates, they will be found very often more plentiful than on other parts of the bed. But a successful crop bears all over the face of the bed in the greatest profusion. To have a successful crop, abundance of spawn is at all times needful. It is well known that mushroom spawn breeds, or originates in materials adapted to it; but many people will scarcely believe that a bed made up of proper materials, will, after five or six months, yield a plentiful crop without having been planted with spawn. However, it is not till after this spawn has bred plentifully in the bed, it begins to bear. It is not my intention to philosophize or go into elaborate details of what spawn is, but to enter at once into the practical part of the business. It is admitted by all that fresh maiden earth from under an old sod, or sods of an old pasture rotted well down, clean, and free from weeds, is the best kind of soil to earth over the beds with. Lime, old or new, is excellent in their compost, and oyster-shell lime by far the best of any. Old, dry, turfy peat, not that from a swamp, or in any way sour, is excellent in their compost.

There are different methods of originating mushroom spawn, but the droppings of horses highly fed, is considered the best or one of the best materials to work with. The droppings of horses out on grass will not do.

To originate spawn and have plenty at all seasons, let boxes of almost any convenient size be got ready and filled alternately with layers of dry horse droppings and red or yellow clay well dried. Old bricks pounded up fine are best. One inch of clay or brick dust, and three or four inches of the horse manure is about right; and when the boxes are full let them be well trodden down—the harder the better—and put in a warm place. Good, natural spawn will breed in these boxes in about four or five months; but if a few pounds of spawn bricks be bought at any seed store, broken up into small lumps and placed in the centre of these boxes, they will be full of good spawn in about one-half the time. After a few boxes of spawn have been generated in this way, it can be increased to any amount very soon by mixing some into other boxes of droppings, and in this case no earth need be put in the box.

It may be well to have a stock of spawn bricks on hand, for they will last many years if kept dry and in a warm place. I agree with the mode of making them, as recommended in the different garden books, but there is no need to impregnate them in the old way, but place them in a conical pile, or any convenient way, and between every layer of bricks put a layer of spawn from the boxes. Cover up well with straw in summer, or warm horse manure over the straw in winter, sufficient to throw a gentle heat into the pile, and after about four or five weeks the whole pile will be one solid mass of mushroom spawn. The place where mushrooms grow should be free from underdamp and noxious vapors. Straw covering is preferable to hay, as wet hay lying on the bed breeds noxious fungi, which would soon destroy the whole crop. To make a bed is a simple process when properly understood. Most people take too much pains, and this is the cause of many failures. But one thing is certain—they are greedy feeders, and must be well fed to have a good and lasting crop. Flat mushroom beds are recommended to be made of three or four-inch courses of dry horse droppings, with two-inch courses of earth between them; but these beds I found to soon run out and get too dry. Therefore, let about three inches of old, soft, unctuous manure be placed at the bottom of the bed in every case, with a small layer of earth underneath about half an inch thick, then one inch of earth on top and well trodden down. Then about three inches of droppings with a good coat of spawn from the boxes; then another layer of droppings, and all well trodden down and left for two or three weeks, or till the spawn has begun to run all through. Then, and not till then, must the last coat of earth be put on, which is best made up of three parts maiden earth and one part turfy peat, with a good sprinkling of oyster-shell lime through it, laid on two inches thick and well trodden down, afterwards smoothed very hard with the back of a spade. Then covered up with straw till a white mold covers the bed and mushrooms all over, like peas thickly scattered, when the straw may be taken off altogether. This is only one of about a dozen ways; but in all cases the old rich manure must be at the bottom. It must have been turned several times to sweeten and partly dry before it is used. These are a few of the principal points to be attended to.

There is one thing I wish particularly to mention to all who grow mushrooms, that is, to beware of salt. Dirty salt is often thrown out of horse and cattle mangers and gets mixed up with the manure. The smallest quantity of this will render a mushroom-bed unfruitful. This is the true key to the theory of throwing salt over grain crops in the spring of the year, which every farmer does, or ought to do, to keep down and kill rust, smut and mildew, and every other species of fungi. Besides, salt kills worms, grubs and numerous insects injurious to grain crops, and I believe is a good absorbent of moisture, as well as a good manure.—*Gardeners' Monthly and Horticulturist.*

FLIES AND BUGS.

SOME FACTS OF INTEREST CONNECTED WITH THE LIFE OF THE PLANT.

Plants do not absorb the nutrient substances which are adapted to them unless presented to them in a suitable form; they do not for example imbibe the *free nitrogen* of the atmosphere. Experiments have given on this point the following results:—

Free nitrogen of the atmosphere enters the plant through the stomata or breathing pores of the leaves, and also by the process of *osmose*; but this does not serve for nutrition. For the purpose of nutrition, this element must be presented to the roots of the plant in the form of nitric acid, or a salt of ammonia. [Whether non-parasitic plants absorb nitrogen also in the form of certain organic compounds is still undetermined.]

Sulphur. The only conceivable source of sulphur is the sulphuric acid of the sulphates present in the soil. It probably enters the plant only in the form of calcium sulphate, which is decomposed by oxalic acid formed in the plant itself, this being the source on the one hand of the calcium oxolate which so commonly occurs in plants [in the form of crystals or raphides] while on the other hand, the sulphuric acid gives up its sulphur in the production of protoplasm, and generally of albuminoids. It is evident that the remaining nutrient substances can only enter the plant by the process of diffusion; and in general, in the form of soluble salts. But their relations to the life of the plant are still obscure.

Iron.—Its increase is necessary for the production of chlorophyll or leaf-green. Plants grown in soil destitute of iron do not become green; but remain bleached until enabled to gain color by the addition of iron to the soil. The salts of iron so generally inert in soil afford the necessary supply of vegetation.

Phosphoric acid appears to stand in a certain relation to the production of albuminoids, so-called flesh-formers, or at least is invariably found in association with them; and in many seeds, there is a constant relationship between the weight of phosphoric acid and that of nitrogen contained in them.

Potassium probably has similar general relationships to starch, sugar and cellulose, so called fat-formers, and it is known that the amount of potassium in any part of a plant varies with the rapidity and energy of its growth. But in what form phosphoric acid and potassium enter the plant, and what their special functions are, is still unknown. In the case of buckwheat, it has been ascertained that food material destitute of potassium cannot be assimilated or transformed into organic substances, and that the chloride, and next to that, the nitrates, are the salts best adapted for the purpose.

Silica or silicic acid, which constitutes the greater part of the ash in many plants, as for instance the stems of cereals, cannot be considered a nutrient substance in the same sense, as those already described, since it has been proved by experiment, that it is not absolutely necessary to the growth of these plants; and its presence appears to be only a favorable condition to their development. Nothing more definite is known respecting it.

If plants are grown in *fluids*, which contain all the substances necessary for their life, it is found that these substances are not taken up in quantities dependent on the concentration of the fluid, nor on the proportion of the various substances contained in it; but that different species of plants, on the contrary, supply their needs from the same fluid in different ways. These phenomena depend on causes at present unknown, but as a consequence, we ascribe to plants "*a quantitative selective power.*" Since plants possess no *volition*, the term is an unfortunate one; but it seems necessary to retain it notwistanding its antiquity. Setting aside nitrogenous food-materials with reference to this peculiarity, different species take up in preference different nutrient substances, and, therefore, plants may be distinguished as *calcareous, alkaline, silicovs*, &c. The leguminous plants, for example, are specially dependent on lime; potatoes on potash; and all plants in which the seed is remarkably developed on phosphoric acid.

Now, if these substances are largely taken up in solution from the soil by plants, it follows *that the repeated cultivation of crops* withdraws from the soil immense quantities of substances, so that sooner or later the movement must arrive, when the produce will diminish, and at length altogether cease to be remunerative unless those constituents of the soil which the crops have withdrawn from it be replaced. The object of the agriculturist must therefore be, so to work his ground that the soil never becomes exhausted; but that he shall constantly obtain abundant crops, *and an adequate interest on his capital, the soil.*

There are two modes of securing this—(1) by a carefully selected succession of different crops; and (2) by manures. He must of course, in addition, depend (3) on a suitable mechanical working, loosening, and draining of the ground.

In consequence of the "*selective power" of plants*, a succession of a number of crops of alkaline plants causes the soil to become for a time—and at length when all the alkalies have been consumed—unproductive for plants of this description. But while the alkaline plant has the power of drawing an unusual proportion of alkalies from the soil, it leaves all the other nutrient substances comparatively undiminished. These substances, therefore, accumulate in the soil, the small consumption of them being outweighed by the decomposing influence of the atmosphere, which is constantly reducing to a soluble condition small quantities of soil; and thus rendering their constituents available for nutrition. The substances which are thus made available for the plant, *are retained by fertile soils;* and thus their solution by rain, &c., ensured, at least a sufficient time, for the whole of the soil to become saturated by them. It is therefore essential to good farming that the crop of the "alkaline plant" should be followed by one of another kind, say a "siliceous" or grass-plant, and thus a well chosen succession of different crops will remove from the soil one substance after another. This is known as a "*rotation of crops*," and the rotation must be continued, until the substances first withdrawn are restored in such proportion and distribution, that the same species of crop may again be grown.

In former times the influence of the atmosphere on the soil was utilized by cultivating only a portion of the soil, tpe rest being left untilled, or in naked fallow; but it is now admitted that this mode of agriculture is not economical. When agriculture is made to pay best, no considerable portion of land is left fallow, but the object is by a good rotation of crops to utilize as equally as possible, all the constituents of the soil. Even under the best system of agriculture however the soil must become gradually exhausted, and this exhaustion must be artificially counteracted. This purpose is effected by a scientific system of manuring, by which those substances are supplied to the soil of which it has most need. According to circumstances the most various *organic* and *inorganic* substances may be employed as manures. If, for example, there is a deficiency of nitrogenous substances, an addition of nitrates, guano and organic manure. The *physical changes* on the constitution of the soil, often so advantageous, or even indispensable to vegetation, caused by the rotation of crops, and by manuring, opens a field too wide to be entered in this connection. In Sicily and Asia Minor, once the "*granary of Rome*," in Compania and Spain, at one time so fruitful, in the valleys of the Potomac, Rappahannock and James rivers, we have the most sad and instructive examples of exhaustion of soils once fertile.

The nutrient substances taken up by plants are, however, by no means adapted in the raw state to take part in the construction of any vegetable structures: they must, on the contrary, undergo important transformations, and become changed into organic compounds, suitable for nutrition. [thus carbon must combine with oxygen and hydrogen to form cellulose, starch, sugar, &c., and C. H. O. N. S., and Phosphorus must combine in a way to form albumen], known as proximate elements. The process by which these simple elements are combined into proximate elements and tissue elements of the plant is called "*assimilation.*" It is not possible at present to follow step by step the process of assimilation. It seems to depend upon the following forces —(1) the evaporation of the water contained in the nutrient sap by transpiration, (2) the decomposition of carbon dioxide [CO_2] and the fixation of carbon; (3) the formation of albuminoids which are essential for the production of protoplasm and Chlorophyll, (4) the formation of the substances from which cellulose is produced, viz., starch, the different kinds of sugar, oil, and inuline. The chief source of the carbon required for building up the tissues of plants is the decomposition of the carbon dioxide [CO_2], contained in the atmosphere by the leaves. Only those *cells* which contain chlorophyll, and then only under the influence of *light*, have the power of decomposing the carbon dioxide which they take up, and of producing organic compounds out of its elements, and those of water, with elimination of an equal volume of oxygen.

Only living chlorophyll has the power of decomposing the carbon dioxide, and in general both sides of the leaf take part in the process, but with different energy. *Light and heat* are absolutely necessary for it. A small deficiency of heat may be compensated by more intense light, but there are limits which cannot be passed. Plants which do not contain chlorophyll have no power of decomposing carbon dioxide and hence of assimilating They must therefore obtain their nutriment from substances already assimilated, and hence grow either on, or in animals or other plants as parasites, and obtain their nutriment from them; or live [as saprophytes] on organic substances actually undergoing decomposition and absorb their organic constituents before they are completely decomposed, [*e.g.* mushrooms]. As I have said before the mode of formation of the albuminoids is still unknown.—JNO. R. PAGE.—*Southern Planter.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, March 22nd.

It is not more than a century since France had only one kind of meadow, the natural, and only one way for rearing stock, pasturage in summer and hay in winter. Thanks to the cultivation of artificial grasses and rotation of crops, the power of the land has been tripled. All abandoned lands become natural meadow, and will continue indefinitely so if not broken up. Artificial meadow is laid down for a fixed number of years, or one year even, and sown with selected seeds. A natural meadow demands less care and exacts less capital than artificial grass land, but the produce will be less. Certain grasses would die out as the mineral matters they preferred became less, and other species would in due course succeed. In laying lands down to meadow, not only the soil but the climate should be studied. A moderate temperature and a fair dose of humidity are requisite for the success of meadows. Where these conditions do not exist, lucern and sainfoin may succeed. As the condition of soil, climate and humidity vary, so will the grasses or flore; there are species suited for high, medium and low lands. For the higher, the grasses like a pure bracing air; aromatic plants will abound there, and so sheep and goats will thrive; for medium altitudes, the land will be less dry, and the plants more abundant; such pasture is excellent for horses; while the thirds, if not marshy, will suit black cattle. In marshy land the yield will be good, but the quality deficient. The best meadows are situated in valleys, below the arable soil; they will thus enjoy the drainage of such land, thereby acquiring food and humidity. Of course land lying on the borders of rivers and liable to be inundated must remain under grass.

In meadow lands the aim is to extirpate bad grasses, keep land clean, irrigate at the right season, and carry off all superabundant water. Ourches says that ordinary meadows contain forty-two specimens of forage plants; of these, seventeen are useful, the remainder worthless or injurious. On elevated pasturages there are thirty-eight species of grasses, of which only eight are useful; in low meadows twenty-five species, and but four useful. From experiments made in Bretagne, it results, that, in the case of natural meadows, there would be on high lands three-fourth's loss, and in low meadows six-seventh's, if cattle refused to consume all the grasses that were useless and injurious.

For natural meadows study the grasses peculiar to the locality. If the land be dirty, break up and crop it for a few years, and then lay down, sowing after corn suitable seeds—not the sweepings of hay lofts; caution ought to be used respecting the introduction of new varieties, chiefly because they are new, though they may be natural. Endeavour to have grasses that will come into flower at the same time. Not a few farmers allow the cattle to feed down the afterneath of the first crop: it is better to allow the land to get firm. In winter long manure is spread on the grass and scattered by a light harrow in spring. Mow the first crop of grass before coming into flower; roll frequently, but never let sheep feed thereon for two seasons, or they will bite the heart out of the young clovers; and as natural meadows have not only different species of grasses, but these species come more or less forward as the season is wet or dry, select accordingly.

Pasture lands are generally those of rather a poor character and not productive. However, in those districts celebrated for their grazing lands as Normandy, Nivernais and Hesbaye in Belgium, the lands are frequently turned into pasture, not fields into cultivation. The rich pasturages serve for the fattening of cattle, as in the valley of the Ouge and Calrados; others serve to keep cows and rear young stock as in the north of France, the Vosges and the Jura; elsewhere, the pasturage is for horses and mules as in Poiton, and the poorest lands support sheep, breed suiting locality. It is rarely wise to break up good pasture land giving fair returns; it is also a mistake to break up poor grass soils unless the farmer be prepared to apply rich manurings.

Lands when grazed produce more, many think, than when mown. The plants tiller better. The first inch of a blade of grass grows more rapidly than the first, and the second more than the third. The several short re-growths will in the aggregate surpass the total length of that when mown.

Never feed bare a field; give it rest and alternate the animals; divide the pasture land into sections, and graze accordingly; give stock to be fattened off the best bites, and do not torment them with such mixed company as horses and sheep. Indeed, the latter ought ever to be suspected, as they are very able in snatching up the tit-bits. For cart horses they are better rested when fed in the stable on soiling. It is now the custom to spread cracked coke on the sward for fat-stock; they pick it up with aridity, and it hastens them for the butcher.

A good pasturage ought not to be abused by being fed bare. It should be in harmony with the breed of cattle. The droppings or clots should be regularly spread out on the land. It is a good plan to only allow sheep to succeed after cattle; they and horses will eat the tufts and fairy rings that cattle dislike. On no account let pigs or geese on paddocks; their natural home is a special piece of marsh land.

It is difficult to know to what country belongs the honor of discovering artificial meadows. Italy claims it from Camille Tarello, whose work appeared in 1566. Hartlib does not appear to have treated on the subject before the seventeenth century. In any case it is only recently that the artificial meadow has been called into practical rotation use. Artificial meadows require good seed, good tilth and well-manured soil; they are generally sown in spring with a cereal crop, but if rye grass, which grows so rapidly, it is better to sow alone in autumn or after an early crop. The seed selected ought to be precocious, so as to come for the feeding or fattening of animals, when the natural pasturage may be late. Artificial grass land is the base of all ameliorating and progressive agriculture. It is most profitable when the grass, cut twice daily to avoid fermentation, is given to stock in the house. Some farmers adopt the pen system, and in Normandy, in the districts of Caen and Caux, the peg and rope plan is adopted. A cord eleven feet long is divided into equal parts, passed through oblique holes in a board 20 inches long and 4 wide; one end of the cord is attached to the sunken peg, the other to the horn or neck. The rope is thus never entangled nor the animals' legs caught; a sweep of 2½ feet or segment of sward is allowed. Thaer alleges cattle give more milk when thus fed, that if pastured at large or soiled.

For Italian rye grass, obtain the best seed; here it comes directly from Italy. The seeds are brushed in, covered to a good quarter of an inch and rolled. When clover is employed, three or four varieties are selected, as it is rather a fickle plant. A bushel of clover seed weighs 64 lb., and may contain from 16,000 to 54,000 seeds; a bushel of rye grass can vary from 15 to 30 lb., and one ounce of seed contains from 15,000 to 27,000 grains.

Ensilage in France is now confined to experiments as to dispensing with silas in masonry—all a matter of pounds, shillings and pence. The secret of ensilage resides in perfect compression of the mass and exclusion of the air. These secured, the green forage can be conserved under a shed or in the open air. The first attempts at ensilage failed, because efforts were made only to exclude the air. It was M. Goffart who demonstrated the necessity of heavy and continuous pressure at the same time. Some experiments made at the Agricultural Station of Münster demonstrate that maize is the best forage for ensilage; that the total loss can reach as high as 30 per cent. The proportion of fatty matters augment during fermentation, while those of a non-nitrogenous character diminish. The sugar, gum, dextrine and similar carbon solubles are decomposed and lost in the form of gas, but aromatics and organic acids are formed, which compensate the loss. Further, the maize is rendered more palatable and more easy of digestion.

The Cattle Show just held has been very successful, but it must never be viewed as other than a display of fat farm stock, a gathering for the butchers. For breeding cattle it would be ever best to exhibit these apart in a special annexe. The display of implements was especially fine, and the bringing together of cylinders for flour mills, instead of the old bun stoves, would alone pay the nation for the expense of the Show. There was something new in churns and in chaffing machines. The exhibition of farm-school requisites was a novelty. The prize ox was a Durham-Charolais, age 32 months 15 days, weight 18½ cwt.—the spine, though it had the curved line of beauty, was not so graceful as if perfectly straight. In sheep, the dishleys won: the three, aged 10 months and less fleeces, weighed 3¾ cwt.; in pigs, the Yorkshires carried off the blue ribbon: the prize, aged 12 months and 15 days, weight 5 cwt. 19 lb.

The scholastic part of the Show consisted of botanical collections on the part of masters and pupils of the primary schools where agriculture is taught. There were also exhibited and recompensed specimens of the geology and insectology of the locality and maps of the districts. Another feature, and which will come better into play next year, was the reports by teachers and pupils on local systems of culture, manners, customs, habits, wages, &c., of their region. A collection of such documents, handed over to an editor with the patience of a Benedictine, to "boil down" and classify, would be worth cart-loads of official Commissions' reports. Hitherto the Government has rather lent at all the Agricultural Shows, to reward the large agriculturists: so far excellent; for the future rewards will be made to suit the small farmers and their wants, as well as kitchen-gardens and laborers' well-kept homes.

Farmers and sugar-manufacturers are far from being reconciled on the subject of beet. The fabricants desire it to be plainly understood that their mills exist for manufacturing sugar and not for preparing pulp.

Arboriculture and the replanting of mountains are receiving marked attention. The phylloxera still holds its ground, advancing, not retreating; however, vineyards are being replanted with American stocks, and the foe shows no desire to come back. Those who can do so, intend trying the *summer* irrigation of the vines.

Weeds.—As early as the time of Alexander II. of Scotland, a man who let weeds go to seed on a farm was declared to be the king's enemy. In Denmark farmers are compelled to destroy all weeds on their premises. In France a man may prosecute his neighbor for damages who permits weeds to go to seed which may endanger neighboring lands.—*Leader.*

The Alfa Plant in Algeria.—It is satisfactory to learn that, despite the rising among the Arabs in the southern part of the province of Dran, in which the Alfa grass is so largely cultivated, the rapid increase in the production of that plant has not undergone any check. The Alfa grass is now one of the chief staples of agricultural wealth in Algeria, it being used, upon the one hand, in large quantities for paper making in England, while in the United States it is converted into a pulp and makes very good imitation china. For a long time the Alfa grass was unknown outside Algeria, where it was merely used for making ropes, sandals, hats, &c., but about twenty years ago its valuable properties began to get known, and upwards of a thousand tons were exported to England and Spain. Seven years later the total exports had risen to 12,369 tons, and since then they have reached just double that amount. Out of the 83,223 tons exported last year, nearly 70,000 tons came to England. Tho total value of the grass exported last year is estimated ta baout £450.000.—*Field.*

SUGAR AS A DRESSING FOR WOUNDS.

Dr. F. Fischer states in an English journal, that in the Strasbourg Hospital, where he is assistant in the surgical department, Professor Lücke has, since last May, used powdered cane-sugar as an antiseptic dressing to wounds. Hitherto it has been used in combination with naphthaline (equal parts) or with iodoform (one part to five of sugar). In cases of wounds united by suture, the mixture is put up in gauze, and applied to the part; where there is loss of skin, the sugar is sprinkled directly over the part. The sugar-dressing is fixed in place by some layers of gauze deprived of fat, over which a layer of guttapercha is applied, and the whole is secured by a bandage. The sugar-dressing may remain from eight to fourteen days, without the sugar dissolving. The secretion from the wound is equally distributed through the sugar, and it is only when the layer of sugar is too thick (more than about one-fifth of an inch), that lumps are formed. The wounds have a healthy appearance under the sugar, the dressings are not offensive. and bacteria cannot be found in them. Healthy granulations, with no tendency to bleed, are developed; and cicatrization proceeds rapidly. In wounds united by suture, healing by the first intention has always been observed.

Dr. Windelschmidt of Cologne says that he has used sugar alone as a dressing with good results. He finds, that, for small wounds and ulcers, powdered cane-sugar is not inferior to iodoform as a dressing; while iodoform is necessary in many cases, such as chancres and mammary abscesses. He calls attention to the fact that powdered sugar is a very old, popular remedy in cases of fungous granulations, ichorous eczema, and erysipelas of the face. Whether the action of the sugar is antiseptic is not certain: that it is aseptic is proved by its use in confectionery. In spite of his success, Dr. Windelschmidt has for several months desisted from the use of sugar as a dressing; partly because the patients found out the nature of the powder that was applied, and ceased to trust in it; partly because they treated themselves, and so passed from his observation. He thinks, however, that sugar, like iodoform and naphthaline, has its sphere of application; and joins with Dr. Fischer in recommending that it be more extensively tried.—*Popular Science News.*

TOILET PERFUMES.

SACHET-POWDERS.—The *Druggist's Circular* gives the following recipes:—

Violet Sachet-Powder.

Powdered orris-root	24 ounces.
Gum-benzoin	3 „
Tonka bean	4 drachms.
Oil of bitter almonds	6 drops.
Extract of cassia	6 drachms.

Musk Sachet-Powder.

Powdered orris-root	2 pounds.
Grain musk	30 grains.
Carbonate of ammonia...	10 „
Oil of rose	20 minims.

Lavender Sachet-Powder.

Lavender-flowers	8 ounces.
Dry thyme	4 drachms.
Dry mint	2 „
Cloves	2 „
Oil of lavender...	30 minims.
Tincture of ambergris...	1 drachm.

Patchouly Sachet-Powder.

Powdered orris-root	1 pound.
Patchouly-leaves	8 ounces.
Oil of rose	30 drops.
Oil of patchouly	60 „

EXTRACT OF WALLFLOWER.—The following is commended as a good preparation:—

Extract of orange-flower	1 pint.
Extract of vanilla	½ „
Spirit of rose	1 „
Extract of orris	½ „
Extract of cassia	½ „
Essential oil of almonds	5 drops.

This should be prepared for two or three weeks prior to putting up for sale.

EXTRACT OF HELIOTROPE.—The following is commended for this popular perfume:—

Spirituous extract of vanilla ...	½ pint.
Spirituous extract of French rose pomatum	¼ „
Spirituous extract of orange-flower...	2 ounces.
Spirituous extract of ambergris ...	1 ounce.
Essential oil of almonds	5 drops.

HISTORIC NOTES ON SUGAR.

Professor A. De Candolle, in his recent work, has some information on the subject of sugar which is interesting, and not to be found in works of reference. The Sanscrit name for sugar is *sarkara* or *sakkara*, whence come all the names by which it is known in European languages in Aryan origin, ancient Greek included. It would therefore appear that the Western World got its first knowledge of the article from the ancient Indian people speaking the Sanscrit tongue. But there is no word for sugar in ancient Hebrew, so that, presumably this knowledge had not progressed so far westward as the Euphrates at the time of the Jewish captivity in Babylon. When we get beyond India into Burmah, Cochin-China, &c., we find sugar known by a variety of names which in all probability, are most of them of still older date. In Telinga it is called *panchadara*, among the Burmese *kyam*, in Cochin-China *mia*, among the Chinese *kan* and *tche*, and by the Malays *aula*, the sugar cane being *tubu* or *tabu*. Contrary to the assertion made in most books of reference, the Chinese, it would seem, were not acquainted with the sugar cane in very remote times, but received it from the westward about two centuries before the Christian era. Dr. Bretschneider is very positive on this point. He states that he has been unable to find any mention of the sugar cane in the most ancient Chinese books (the Five Classics). The first notice of it occurs about 200 B. C., and the earliest description is given in a Chinese work written some six centuries later. It is stated that A. D. 286, the State of Funan, beyond the Ganges, paid tribute in sugar to the Emperor of China; and a Chinese Emperor who reigned from A. D. 627 to 650 sent a functionary into what now is Behar, to learn the art of making sugar. The sugarcane has never been found wild in India, but Loureiro ("Flore de Cochin-Chine") states that it grows wild abundantly in Cochin-China, and also, but less abundantly, in the adjoining parts of China —a statement which appears to have been very generally overlooked. From this and a variety of other arguments Professor Candolle infers that the sugar cane was originally a native of the region extending from the Cochin-China to Bengal, and that its cultivation probably began in Cochin-China, extending thence to India and from India to the westward. The Greeks and Romans had only a hearsay knowledge of the commodity. The Saracens in the Middle Ages carried the sugarcane into Egypt, Sicily, and the South of Spain, where it was largely grown until supplanted by the produce of the Spanish colonies in the New World. Don Henry carried it from Sicily to Maderia; from Maderia it was introduced into the Canaries in 1503; and thence into Brazil at the beginning of the sixteenth century. It was introduced into St. Domingo in 1520, and soon afterwards into Mexico; into Guadaloupe in 1644; into Martinique about 1650; and into Mauritius and Bourbon when the first French settlements were made there.—*Royal Gazette.*

EMULSIONS OF PETROLEUM AND THEIR VALUE AS INSECTICIDES.

BY C. V. RILEY, OF WASHINGTON, D. C.

The value of petroleum for the destruction of insects has long been recognized, and I have for years been endeavoring to solve the question of its safe and ready use for this purpose without injury to plants. This paper contains the results of extended experiments carried on under my direction by several of my assistants, and particularly by Prof. W. S. Barnard, Mr. Joseph Voyle, of Gainesville, Fla., Mr. Clifford Richardson, assistant chemist of the Department of Agriculture, and Mr. H. G. Hubbard, who has for over a year been devoting his time to practical tests in orange groves at Crescent City, Fla.

Passing over the ordinary methods of oil emulsions by phosphates, lactophosphates, and hypophosphites of lime, and various mucilaginous substances, experience shows that, for the ordinary practical purposes of the farmer and fruit grower, soap and milk are among the most available substances for the production of petroleum emulsions.

Ordinary bar soap scraped and rubbed into paste at the rate of twenty parts soap, ten parts water, thirty parts kerosene, and one part of fir balsam will make, when diluted with water, an emulsion stable enough for practical purposes, as the slight cream which in time rises to the surface, or the flakiness that often follows, is easily dissipated by a little shaking. Soap emulsions are, however, less satisfactory and efficient than those made with milk. Emulsions with milk may be made of varying strength, but one of the most satisfactory proportions is two parts of refined kerosene to one part of sour milk. This must be thoroughly churned (not merely shaken) until a butter is formed, which is thoroughly stable and will keep indefinitely in closed vessels, and may be diluted *ad libitum* with water when needed for use. The time required to bring the butter varies with the temperature, and both soap and milk emulsions are facilitated by heating the ingredients. Ordinary condensed milk may also be used by thoroughly stirring and beating it in an equal or varying quantity of kerosene.

The diluted emulsion, when prepared for use, should be finely sprayed upon the insects to be killed, its strength varying for different insects or plants, and its effect is enhanced when brought forcibly in contact with the insects.

Of mucilaginous substances, that obtained from the root of *Zamia integrifolia* (a plant quite common in parts of Florida, and from the stems of which the Florida arrowroot is obtained) has proved useful as an emulsifier.

These petroleum emulsions have been used with success by Dr. J. C. Neal, of Archer, Fla., against the cotton worm, without injury to the plant; but their chief value depends on their efficacy against the different scale insects which affect citrus plants. Experience so far shows that such plants do not suffer from its judicious use, but that it must be applied with much more care to most deciduous fruit trees in order not to injure them.—*Scientific American.*

FLORIDA, PER CONTRA.

Just at present, Florida is advertised as a sort of second paradise, though in reality in summer one is more forcibly reminded of a place celebrated for the peculiarity of its pavement, because the insects make it a place of torment, and some of the views really look something like the backgrounds of Gustave Dore's illustrations of Dante's Inferno. The whole present idea of Florida is to get up a boom. Fully three-quarters of the State is speculated. Land, dear at 5 dols. an acre, is sold at prices ranging up to 50 dols., and sometimes even higher. Hence the *couleur-de-rose* statements in the papers about products, which are either gross exaggerations or pure fabrications. Orange groves, for instance, take an immense time to really pay; lemons, besides taking time to bear, want a lot of knowledge as to proper time for picking; limes are too perishable ever to have a very active demand; citrons cannot pay unless there is a factory near for the peel; pomeloes and shaddocks do not seem to be in much demand; guavas are only useful for their jelly, and in America it would probably be found cheaper to buy up hoofs from some knacker's yard, and boil them down with some flavouring extract of tar. More money is lost than made on vegetables, as they require much skill, work, and fertilising; and to talk of them paying so much an acre is really almost as absurd as saying that frame cucumbers and melons pay so much an acre in England. Sugar is not much grown, neither is tobacco, and I doubt if labour could always be got to pick off the tobacco worm; cotton, of course, never pays well; cocoanuts only grow along the most malarious shores of the extreme south. As to Florida being tropical in vegetation, it would be equally reasonable to call London article; this year many oranges were frozen on the trees, and the thermometer went down to 21° at Leesburg, Sumter county, killing every plant that had any pretensions to being tropical, and cutting peas down to the ground.

In the winter of 1835 nearly every orange tree in the whole State was killed down to the ground. As to the soil, or rather sand, it wants fertilising abundantly and frequently, because it leeches readily, while everything wants manure In summer Florida swarms with insects, a kind of small fly rendering work impossible out of doors during the day, and in-doors can only be made bearable by darkness, since nothing can prevent them from entering the house. During the night the niggers love to yell, apparently just when one wants to go to sleep. The health of Florida is certainly not as good as it is said to be. Ague and malarial fevers are common, dysentery is frequent, and often fatal, while yellow fever seems always ready to break out, even in the interior, and everyone seems to lose flesh and energy.

Food is bad and dear, partly because so very little to eat can be raised in the State; consequently, canned goods are the chief means of subsistence, and the grocers make about 30 per cent profit. Furniture and clothing are equally dear, besides that they are utterly rotten and unsuited to the climate. Taking it altogether, Florida affords more openings to the speculator than the agriculturist.—PER DAMNA PER CÆDES.—*Field.*

THE QUININE MARKET.

Whatever may be the true history of the late unlamented quinine syndicate, it is certain that the trade and the public generally are to be congratulated on its untimely dissolution. When the manufacture of a staple of commerce is in a few hands there is always a temptation towards combination with a view of establishing an artificial rate of profit. On this occasion it is doubtful whether the ring had been completely formed, but certainly some negotiations had been entered into, and a good deal of money had been sunk in the effort to buy up a large proportion of the floating stock so as to pave the way for the standard price. It seems, likely, however, that the promoters of the scheme, who are understood to have been some of the foreign makers, had under-estimated the quantity of quinine held in second-hands both in Europe and America. Overproduction had been going on for some time, and at each fresh fall small speculators came in and stocked themselves. Agents for the syndicate, however, bought largely, both here and in New York, and in many quarters the permanence of the agreement was confidently asserted. In our own trade report, however, doubts as to this permanence were freely expressed, and the tumble came sooner than was anticipated. The bark growers and dealers naturally objected to an arrangement which would have checked consumption, and in the profits on which they would have had no share. It is possible that their discontent, which was not to be despised, had some influence, and it seems to be understood that the makers, even if they had all given their conditional adhesion to the plan, consented to it with varying degrees of cordiality. Whether the disagreement came about on principle or policy has not been proved, but it occurred coincidently with the attempt to unload some of the superfluous stock controlled by the syndicate. For some reason, which is more their own business than anyone else's, Messrs. Howards saw fit to strike at this moment, and they did so most effectively. By a sudden reduction of 1s 6d. per oz. just after an auction of 10,000 oz. of a foreign make had been announced, they no doubt reduced the proceeds of that auction by something between £500 and £1,000, and, of course, they shattered the combination at the same moment. The quinine put up sold at 5s to 5s 3d per oz., and afterwards, for a few weeks, large quantities of foreign were sold, and, to a great extent, stocked, at 5s and under. A somewhat stronger feeling has been growing since, and a legitimate advance had been established when the news came of the destruction of Messrs. Powers & Weightman's works, in Philadelphia, with a consequent sudden rise in the price of quinine. In this rise the hand of the speculator was very visible, and again Messrs. Howards seem to have checked an upward movement here by refusing to be influenced in their quotations by the news.

It is certainly not desirable, after such great efforts have been made to provide an abundant supply of cinchonas, that the advantage should be intercepted by some six or seven intermediaries; and though these cornerings may occasionally secure a fortune, they are universally recognised to be unhealthy excrescences on trade generally. —*Chemist and Druggist.*

SOME PERSIAN FRUITS.

BY W. G.

I have copied the enclosed notice of Persian fruits from a recent work on Persia,* by Mr. C. J. Wills, an English surgeon who spent some time in that country, and who has given an agreeable and instructive account of his sojourn. It occurs it me that you may like the extracts for the *Gardeners' Monthly*. Every one knows that many of our best fruits came originally from the East, but the fruits which Mr. Wills mentions have not to the best of my knowledge found their way to this country. We have a minister at the Persian court, but I am at a loss to know what he has to do. Why should he not collect roots, cuttings and seeds and send them to the Agricultural Bureau at Washington fot distribution?

Page 310: Persia has particularly fine quinces and pomegranates. The latter I have seen of four pounds weight. The Ispahan quinces are sent all over the country, packed in cotton as presents. They give forth a very strong and agreeable perfume which is much delighted in by the natives; and they are passed from hand to hand and savored like a sweet-scented flower. The Attar-beg pomegranates have no perceptible seed and their flavor is very delicious. Their variety is great—sweet, sour, or sour-sweet; they vary, too, from white to almost black in the pulp.

Page 163: These latter (apricots) grow in great perfection in Ispahan; they are seven known kinds, six of which are sweet, and one bitter. The most valued variety is the shukkenpara; it is excessively sweet and cloying. All grow to a great size, and so great is the plenty that the fruit in an ordinary season is sold for two pence-farthing the fourteen pounds or maund. The orchards where the apricot is grown are generally sown with clover; the trees are never thinned, but notwithstanding this, the finest apricots in the world are certainly produced in Ispahan.

Great quantities of dried fruit are exported from Ispahan, which is celebrated for its "keiri," or dried apricots; these are merely the fallen fruit which is either too much bruised for sale or has not found a market. They are simply placed in the sun, and become in a week dry, hard and semi-transparent, thus forming a very portable food; the stones are of course removed and the fruit becomes as hard as bone; an hour's soaking renders them fit to eat, or when stewed they are delicious, being so very sweet as to require no added sugar.

Small melons, called "gerwak" and "tellabi" now (May) make their appearance; these, though far superior to anything produced in England, are not much thought of. The big brown melon or "karbiza" of Gourg-ab which will keep good a year and attains an enormous size, some being seventy and eighty pounds in weight, is more highly prized; the flesh is white and tastes like a Jersey pear. They grow on a soft soil, are heavily manured with pigeon dung and freely irrigated until the plant flowers. Many choice varieties of melon abound, as the "Shah passand" or king's favorite, and others. The "Thridiwana" or water melons are of three kinds, the red fleshed, the yellow fleshed and the white fleshed; these run from three to twenty-eight pounds in weight as an ordinary size; there are long and round descriptions. The skin varies from pale green to almost black with green blotches; the latter are the best.—*Gardeners' Monthly and Horticulturist.*

* "The Land of the Lion and the Sun," by C. J. Wills.

THE SITUATION IN QUININE.

It is now a little more than a month since we had occasion to announce the collapse of the quinine syndicate which, though reported and believed to have been a bargain that would continue in force for a long time, we stated at the time the first announcement of its formation was made, could not be expected to last very long for reasons then given. The breaking up of this combination of manufacturers very naturally had a very depressing effect upon values, and the price has since been more or less steadily on the downward course. The operations in a speculative way have since been comparatively light, as few had sufficient confidence in the article to invest heavily even at the low prices at which supplies were offered. The price of German quinine dropped to $1·10 and some sales are reported to have been made at even lower figures, and it was believed in trade circles that the lowest point had not been reached. Interest in the article had begun to subside somewhat, and from an active speculative article there was every appearance that quinine would become one of the articles dealt in only in a legitimate manner and neglected entirely by speculative buyers, as was the case with opium after the memorable failure of the syndicate to control the markets of the world and bring about a boom in that drug.

This was the condition of affairs a week ago, but it appears the speculative fever was only slumbering, and required only a spark to kindle it into unwonted activity. The spark was supplied by the fire at the works of Powers & Weightman. No sooner was the announcement made in the papers that a fire was raging in these works, than the price of quinine went up five, ten, fifteen, and then twenty cents per ounce, and the speculative fever was in full possession of the operators, who by their exaggerated reports of the destruction of quinine, both finished and in process of manufacture, caused more excitement in the market than has been seen here in two years. Those who had quinine to sell asked exorbitant prices, and others, who were in a position to make contracts for future delivery of German, took advantage of the situation to realize prices that a week ago they would have thought impossible without another combination of manufacturers or a protective duty. But the fever was on, and buyers were more plentiful than sellers had been while the market had a downward tendency. Sales have been made of German in bulk at $1·50 and orders booked for later delivery at $1·45. All this has been done without either buyers or sellers knowing the exact state of the situation at Philadelphia, or whether the firm suffering by the conflagration would be able to supply quinine or not during the next three months, the operations being apparently on the assumption that they would not. When Power & Weightman announced that all their contracts were cancelled by reason of the fire, then the speculative fever was at its height, and no one seemed to inquire into the exact condition of supply and demand, the only object appeared to be to secure or engage a supply.

The reaction has not yet set in, but it will not be long before the speculative months will find they have singed their wings in this fire. Speculative crazes in quinine have heretofore been of frequent occurrence, and as a rule we have been able to point out their folly and have shown why and how they would result in loss to the operators confident of large profits on their investments, but we have encountered none in our experience for which there was less cause and which will likely show a more speedy reaction than the present. The Philadelphia house announce that not an ounce of their stock of quinine, manufactured or in process of manufacture, and not a pound of their supply of bark, had been destroyed, and the probability is that within a week they will deliver goods as heretofore. That their manufacturing facilities have become crippled is, of course, true but means will be taken to remedy this misfortune as speedily as possible. And when they again offer quinine for prompt delivery, what is to become of the foreign quinine so eagerly purchased at the higher prices? A little more prudence would prove profitable, but prudence is an unknown quantity with the average speculator in quinine.—*Independent Record.*

CHEMISTRY OF COTTON.

In November last, Professor Dabney, State Chemist of North Carolina, read an interesting paper in this city, before the Society of Arts, on the chemistry of cotton. We present below an extract from a report made by Mr. Swain the secretary. In future numbers of *Science News*, other portions of the paper will be presented. It will not only interest our patrons in the cotton-growing States; but all intelligent cultivators of the soil will read the statements and statistics with pleasure and profit.

Dr. Dabney prefaced his paper with the remark that a number of subjects in regard to the Southern States might be named which would interest the society equally as much as the one he had chosen. Within the last few years the phosphate industry the development of the high-grade phosphatic deposits near Charleston, S.C., and of the low-grade phosphates of North Carolina—had revolutionized the agriculture of the South. Then, again, the increased cultivation of upland rice (which in many parts of the South had almost supplanted the lowland rice, which was long the only species cultivated) was a recent development. Finally, the industrial botany of the South, where there are more plants of interest to the industrial chemist than in any other section of the country, might well merit attention in New England. The chemistry of the cotton-plant, however, offers many questions of interest to us in a section of the country where one of the products of the plant is made use of more than in any other.

The first point of interest is the exhaustion of the soil, which is the result of cotton-culture. The soil is the farmer's bank-account, and he must use it carefully, and draw only the interest: he must not take away from it any valuable constituents without replacing them. Man is a devastator of the soil, and is continually drawing on his capital; so that regions which were once favorable for the cultivation of certain plants become, in time, unable to support them, unless the valuable constituents of which the soil is robbed be returned to it. The speaker referred to the fact that the region of wheat-production has been gradually moving westward.

The exhaustion of the soil, due to the cultivation of various plants, may be seen from the following data in regard to the composition of those plants:—

100 bushels of wheat contain—
46 pounds phosphoric acid,
30 pounds potash,
125 pounds nitrogen.

100 bushels of corn contain—
33 pounds phosphoric acid,
20 pounds potash,
96 pounds nitrogen.

1,000 pounds of tobacco contain—
7 pounds phosphoric acid,
54 pounds potash.

The 480,000,000 bushels of wheat produced in this country in 1880 contain—
1,100,000 tons phosphoric acid,
720,000 tons potash,
2,800,000 tons nitrogen,

these quantities being ten times as great as those contained in *all* the manures used on *all* the crops in the United States in that year. What must be the result of this devastation of the soil? These valuable constituents must be replaced, or the soil will become unable to sustain the repeated draughts upon it. Now, in regard to the cotton-plant: one point of it, namely, the seed, has been thrown away until within a few years; but its value as a manure (containing, as it does, a large proportion of the valuable constituents of the soil) has within ten years been recognized, and it is now utilized very extensively as a fertilizer. By this means the valuable constituents of the soil are returned to it, and it suffers very little exhaustion. The cotton-lint contain very little potash, and does not impoverish the soil: it is a product obtained almost entirely from the atmosphere. Herein lies the cotton-producer's great advantage. By returning the seed to the soil, he can cultivate year after year, with no exhaustion of the soil, the most valuable product of the cotton-plant. The advantage that cotton has in this respect over such plants as corn, wheat, or tobacco, is evident when the figures are referred to, showing the relative amount of valuable constituents withdrawn from an acre of the soil by these different plants. Thus:—

1 bale of cotton (per acre) contains about
·6 pounds phosphoric acid,
2·1 pounds potash,
1·5 pounds lime;

30 bushels of wheat (per acre) contain about
15 pounds phosphoric acid,
10·5 pounds potash,
1 pound lime;

while tobacco is even more severe in its effects on the soil, producing some 1,500 pounds to the acre, and withdrwing about 130 pounds of lime, and nearly 100 pounds of potash and phosphoric acid.

Notwithstanding the fact that cotton impoverishes the soil comparatively little, fertilizers are extensively used in its culture. It was discovered, almost by accident, that blight and rust in the cotton-plant are due to the want of alkalies in the soil: the observation having been made that the salted mud from the creeks and bayous and arms of the sea, if put on the cotton-fields, was a cure for those diseases. Accordingly, fertilizers have been and are now imported in great quantities from Germany; and the phosphatic deposits in our own States, principally in the Carolinas, have been largely developed, mainly through the exertions of Dr. Ravenel of Charleston. This extensive use of fertilizers is also due to the fact that the cotton-seed is found to be valuable of itself, and is by no means universally returned to the soil; in which case other fertilizers would be scarcely necessary.

The cotton-seed is an egg-shaped seed containing a kernel within an outside woody hull, the former dropping out when the latter is cut in two. The kernel is the source of the well-known cotton-seed oil, and is mashed, rolled, strained, and pressed in hydraulic presses; the oil running off, and the cake or meal remaining. The latter contains more fat and more proteine than the cereals, but has less starch, and all the ingredients are mixed in less favorable proportions than in the latter; so that it is not as much used, and commands a lower price than it otherwise would. Cotton-seed meal should be used along with starchy matters, and when so used its value will be appreciated, and it will command a higher price than it does now.

The hull of the cotton-seed is woody, and seldom used for food, but is valuable as a composting material, being rich in fertilizing ingredients.—*Popular Science News.*

THE WEST INDIAN LIME.

The flowering and fruiting by the Earl of Ducie, F.R.S., of the Lime of the West Indies (Citrus medica var. acida), affords an opportunity of making better known a fruit which has been much misunderstood. I should premise that the word Lime is promiscuously applied to fruits very different to this, especially in British India, where the Sweet Limes of various forms are universally spoken of under that name, and that all these, together with the West Indian Lime, are varieties of the Citrus medica of Linnæus, which includes the Lemon, Citron, sweet and acid Limes of the East Indies, and the small globose-fruited plant here figured (*Cot. Mag.* t. 6,745). C. Medica is so closely allied to the C. aurantium, Linn., which includes the sweet Orange, the bitter or Seville Orange, the Bergamotte, &c., as to have been classed with it, as forms of one species, by several excellent authors, together with other fruits which do not concern us here.

The genus Citrus is essentially an Eastern one, and the forefathers of Oranges, Lemons, Citrons, and Limes are certainly Tropical Asiatic, and may be found (though whether always in their pristine condition as opposed to escapes from cultivation is not easy to determine) in the hot valleys of the Himalaya, of the mountainous districts of Eastern Bengal and of the Deccan.

From Tropical Asia they have, in their numerous cultivated forms, been transported into Africa, Australia, and the New World, where the Orange extends into the temperate zone, and the Lemons also, but with less power of enduring cold, whilst the small acid Lime seems confined to tropical or subtropical zones; hence, I do not find any plant exactly answering to the latter in the magnificent work of Risso and Poiteu, illustrating the South European Oranges and Lemons, whilst in the floras of the East and West Indies it is always included.

The first good account of it is by Rumph (*Hortus Amboinensis*, vol. ii., p. 107, t. 29), published in 1750. He describes it under the Latin name of Limonellus, *alias* Limontenius or thin-skinned Lemon, answering to the Malayan name of Limon Nipis (in Dutch, Liemis-Boom), as a spinous bush with small leaves much brighter than those of the other Lemons, small flowers with the odour of those of the Lime of Martinique, five petals, spherical, smooth, fruit the size of an Apricot, skin citron-coloured, extremely thin, pulp greenish-white, gratefully acid, having a delightful odour and taste. He adds that it is found in all the Oriental islands, but never in the woods, always near houses, implying that it is not indigenous. The only author who has definitely taken up Rumph's plant is Hasskarl, who, in his first *Catalogus Horti Bogoriensis*, published in 1844, has C. limonellus with two vars.—a pointed fruited and a rounded fruited; and in the second edition of the same work (1866) he publishes C. limonellus var. globosa from Amboyna. B. Hamilton had previously alluded to it in his *Commentary on Rumph's Hortus Amboinensis* (Wern. *Trans.*, vol. vi.); and the name C. limonellus, Ham., accompanies specimens of a plant collected by him in India, and distributed by Wallich (*Cat.*, n. 6,386), which is probably the same species. C. limonellus is also described by Miquel, who says that it is cultivated everywhere in the Dutch East Indies. Curiously enough, whilst Rumph describes the petals as five, he figures invariably four, and this and its other characters indicate his plant being the same as the Rungpore Lime of Bengal, the sixth variety of Roxburgh's C. acida, which includes the sweet and sour Limes (not the Lemon), characterised as a small bush, with a small pinkish flower, usually four petals, and a perfectly spherical fruit, having a thin skin of a lively yellow colour and pale acid juice.

Dr. King has had the kindness to send me copies of Roxburgh's drawings of the Limes cultivated by him in the Calcutta Botanical Garden, and they confirm this identification both as to flower and fruit. This plant is very well figured by Wight as C. limetta, Risso (*Icones*, t. 958), who says it is certainly wild in the Neilgherry Hills, forming a low, erect, thorny shrub, with a profusion of fragrant white fourmerous flowers. He adds, however, that the juice is "watery acid," sweetish, "or occasionally slightly bitter"—a variation not likely to occur in a native plant.

When preparing the *Forest Flora of Central and North-Western India*, Dr. Brandis asked me to help settle the synonymy of the genus Citrus, so that it should be in harmony with the *Flora of British India*, and after a long study we concluded that the various forms grouped themselves under three generally recognised species, of which two were indigenous to India, and one had been introduced. The native are C. medica (the Citron, Lemon, and Limes), and C. aurantium (the Oranges and the Bergamotte); the third, C. decumana, Willd., is assumed to have been derived from Polynesia, and is the Shaddock (Pumalo, Pomplemoes, sometimes called Forbidden Fruit). I think this arrangement holds good, except possibly in the case of the Bergamotte, which has the highly-scented skin of the Oranges, but its pale-coloured skin and sub-acid juice are those of the Limes. Turning to the West Indies, which is the great second home of the Lime, and the principal area of its cultivation, I find it described by the exact McFadyen as C. lima, McF., a thorny shrub with ovate leaves pentamerous white flowers, small nearly globose yellow fruit, with thin skin and an abundance of pure acid juice; it is naturalised in Jamaica, forming strong fences: all characters precisely accordant with Lord Ducie's plant. Grisebach unites with it C. spinosissima, Meyer, and refers both to a variety of C. aurantium, L., in which he is certainly mistaken. Brandis alludes to the West Indian Lime, following Grisebach as to its position and synonymy, but adds that the fruit is very much like the small acid Lime of India, and suggests the removing of it from under C. aurantium. The C. spinosissima of Meyer (printed by a *lapsus* "acidissima" in Brandis) is no doubt a sub-variety differing in its very small leaves, flowers, and fruit. Other authors refer the West Indian Lime to C. limetta, Risso, which is its nearest European representative, but which differs in its sweet juice. The last reference which I have to make is to a woodcut in the *Gardeners' Chronicle* (n. s., vol. v., p. 690, fig. 123) of what appears to be the fruit of this plant, under the name of "the Bijou Lemon," with unfortunately no history attached. With the exception of this woodcut, I know of no other published figure of the Lime than that here given. It is a favourite fruit in the West Indies and Southern United States, the acid being far more grateful than that of the Lemon; and it is hence universally used for flavouring soups, &c., and in the preparation of many alcoholic and acidulated drinks. In my younger days it was imported in vast quantities into the city of Glasgow, providing an indispensable material for the brewing of the famous Glasgow punch. That it is now so seldom seen comparatively is due to the declension of that social and family intercourse that once was so intimate between the great city and the Spanish main. It is still the principal source of critic acid, and is cultivated in the West Indies for its manufacture, especially in Montserrat and Dominica.

Earl Ducie, to whom I am indebted for the specimen figured, informs me that he purchased the plant, and is not aware of its origin; it fruited in January, 1883, and the flowering branch was sent in the following April. Both were very fragrant. Plants at Kew from the Montserrat estates of Messrs. Sturgess, presented by the firm, have smaller, more membranous, and darker green leaves; others from the same source, grown in Mr. Hanbury's garden on the Riviera, have ovate-lanceolate long-pointed leaves.—Sir J. D. HOOKER in the *Botanical Magazine*.

ALOES.

Like most other produce, the consumption of this article has largely increased during the past quarter of a century, and the following particulars may not be uninteresting to hundreds of your readers who daily have it under their notice, but have seldom, if ever, seen it as imported.

According to ancient history, this article of the materia medica was well known to our forefathers at least some 3,000 years ago, and, although it is only mentioned as a perfume, there is no reason to doubt that its virtues as a drug was also well known. It is worthy of notice that, whereas there are now several kinds of aloes imported, the only description which gives off that fine aromatic odour comes from the East, and is the sort which our ancestors were alone familiar with. Although now used in certain aromatic perfumes to a small extent, the principal portion is consumed in medicine.

In the present day it is recognised as one of our most important drugs for certain purposes, forming the bulk of many of the liver and antibilious pills, so extensively advertised, thereby being the partial means of building up more than one colossal fortune. The aloe plant may be seen at Kew and many other horticultural gardens in this country. In the Scilly Isles it flourishes, and when in bloom is one of the sights of the isles; but one has to travel to warmer climes to find the plant in full growth and in sufficient number to be of service as the source of our commercial supply.

There are three kinds of aloes known to commerce, viz., the East Indian, West Indian, and Cape, and these may be subdivided into seven distinct kinds, viz., the East Indian, Socotrine and Hepatic; Zanzibar Hepatic; West Indian, Barbados and Curaçoa; Cape, and Natal.

The greater portion of this drug is consigned direct to London, and thence distributed to all parts of the globe.

America obtains a few West Indian and Cape direct, but draws her supplies of East Indian and Zanzibar from London. The Continental requirements, with the exception of West Indian, are also obtained through the London market. Each country has its own idea as to the merits of the different sorts. Thus, the United Kingdom consumes East Indian, the finer sorts of West Indian, and but few Cape; whereas the Continent monopolises at least three-fifths of the supply of Cape, and only a small proportion of the finer descriptions. The United States, whilst taking a fair quantity of Cape, are also large buyers of fine East Indian Zanzibar.

I found it impossible to get at the exact quantity imported into London, as I was informed the records are returned as so many packages, but my informant kindly gave me an estimate which, I was assured, is not far wrong.

Last year about 4,500 packages of all kinds were imported, which was equal to about 350 tons, being about 25 per cent more than ten years previously.

The following particulars relate to the description, packages, &c.:—

East Indian (Socotrine) are brought over in old tin-lined spirit-cases, containing about 70 to 80 lb. each, the substance being about similar to putty, and when of good quality are of a light-brownish colour, with a fine aromatic flavour, and generally realise the highest price.

East Indian (Hepatic), usually imported in kegs of 100 to 150 lb. each, are much paler than the former kind, and almost liquid, being worth 5 to 15 per cent less than the former.

Zanzibar (Hepatic).—These come over in a most curious and original way, viz., in monkey-skins, and I was gratified by seeing several cases of these fine aloes also packed in saucers and plates of native make, and in tin plates, bowls, and baking-dishes of the cheapest Birmingham manufacture, which, I was told, was quite an exception, and may have been caused by the present troubles in the district from whence they came. The usual package—viz., the monkey-skin—when filled with aloes, is sent from the interior of Northern Central Africa down to the coast, and there packed into second-hand Manchester cases of various sizes.

The monkey-skins vary in size considerably. Amongst a very fine parcel I noticed a skin which could not have contained more than 2 lb. of aloes, in fact, its contents were by far less valuable than the little animal would have been, had it been sent alive to this country; whilst other skins contained some 30 to 40 lb., or even more. It was suggested to me by a gentleman I met at the warehouse, and who was showing me these skins, that it was a pity the natives could not find the means of making boxes; but in a country where the nail is yet unknown and the art of joinery a thing of the future, they no doubt do their best to supply the deficiency.

It has since been my pleasure to meet a gentleman who was for some time in Zanzibar, and the reason he gave for the natives using these skins was that monkeys are very plentiful, easily killed, and of such varying sizes as to suit both large and small collectors of the juice of this important plant. After all, the natives only imitate the Spaniards of a no distant date, who stored their wines in pig-skins after exactly the same fashion.

This description of aloes most resemble the socotrine; the colour, however, is paler, and the flavour, if anything, finer. This kind is practicably the only sort adulterated, if I may so use the term, as some of the skins are often filled with leaves, stones, dirt, and many other substances quite foreign to the aloe plant.

Cape are packed in large heavy cases, generally lined with sheepskins (which, no doubt, are plentiful in the colony), containing about 4 cwt. When of fine quality it is a hard bright, black (brownish tinted), glossy substance, with an offensive odour, and is generally known as the horse aloe. Its value (which, of course, varies according to supply) is about one-third that of the East Indian or Zanzibar. The production of this description is equal to the whole of the other sorts combined.

Cape (*Natal*).—The quantity of this kind collected is very limited, being only a few cases per annum. Like Cape, it possesses no flavour, but becomes a pale liver in colour by keeping, and, in consequence of its colour, realises about half as much again as the ordinary Cape.

West Indian (*Barbados*).—This is the most important kind, at least, so far as the English consumer is concerned. The quantity produced is large, say two-fifths of the whole, consisting both of fine and inferior qualities, the variation in values, I am told, being considerable, the fine bringing prices almost equivalent to East Indian, whilst common sometimes sell at less than Cape. They are packed in boxes of 60 to 100 lb., and in gourds of 10 to 15 lb. each, resembling Cape in substance, but in colour varying from a blackish brown to a pale mahogany, with an odour which is neither offensive nor aromatic, but quite peculiar to itself. There is also another distinguishing feature more noticeable in this aloe, viz., that it improves by keeping, and I was shown some boxes the contents of which were of a beautiful bright liver, and very valuable, but which, when imported some eighteen months previously, were quite a dark brown, and worth only about half their present value. I gathered that a regular trade is done by buying certain parcels when imported and storing them, but, as I am not a connoisseur of this commodity, I prefer to leave such selection to others more capable of judging, and wish them every success in their operations.

West Indian (*Curaçoa*).—These are identical with Barbados in description and quality, but the latter have always the preference when sold. It has been suggested that the true Babados is no longer cultivated, most of the plants having been destroyed, and what is now sold as Barbados is in reality the same plant cultivated in the sister isle of Curaçoa.

According to some authors, aloes are often found adulterated with various articles, chiefly resin, but from information I could gather such adulteration is unknown amongst the merchants who bring these goods to this country.

The natives of Africa (as I have before mentioned) in filling the monkey-skins are like the cunning Chinese, willing to get the price of aloes for a large stone or other refuse conveniently placed in the centre of the skin, but, except this trick, I could not learn of any adulteration being practised.

In concluding my remarks I would mention an aloe of the future which I have not yet been able to see, but of which I am promised a specimen at no distant date, viz., that procurable in Madagascar. The plant flourishes in abundance in this island, and the natives collect it in small quantities sufficient for their own consumption, as is noted by several European travellers who have written on the products of this island; but, as yet, it is not collected in sufficient quantity to form an article of export, although there is no reason to doubt that in a few years we may draw a considerable supply of this valuable medicine from this great semi-civilised island.—W. W.—*Chemist and Druggist.*

THE QUININE SITUATION.

The following article was contributed to the Philadelphia *Press* by Mr. A. H. Jones, of the firm of Powers & Weightman:—

As the recent fall in the price of sulphate of quinine has caused considerable comment in the newspapers, and as some of the statements made have not been quite clear, you may be disposed to give space to a communication bearing upon the present condition of the quinine industry in this country.

Prices for American sulphate of quinine varied very little during the year 1883, manufacturers' quotations having been $1.80 until January 5th, when the price was made $1.70 at which it remained steady until May 5th. On May 5th it was reduced to $1.60 On June 9th it advanced to $1.80, at which it continued until the close of the year.

As will be observed, the highest price was $1.80 and the lowest $1.60, including vials, the bulk price being 5 cents less. The difference between the two extremes for one year was but 20 cents.

January 1st, 1884, the quotation was $1.80, at which it remained until January 23rd, when it was made $1.60. A further reduction was made February 4th, to $1.40, at which figure it remains at the present writing.

There is nothing at all extraordinary about these alterations in prices, whether applied to this particular article or any other—whether in this country or abroad.

For example, in the month of January, 1884, Messrs. Howards, of London, quinine manufacturers, dropped their quotations in one day from 8 shillings to 6 shillings 6 pence per ounce, in vials, and referring to fluctuations that have occurred in years past, such variations as the following may serve to illustrate and confirm the statement that there is nothing remarkable in the recent changes in price, say, sulphate of quinine.

In 1857 sold as high as $2 and as low as $1.40.
In 1860 sold as high as $1.80 and as low as $1.20
In 1862 sold as high as $2.90 and as low as $2.25.
In 1864 sold as high as $3.75 and as low as $2.60.
In 1865 sold as high as $3.40 and as low as $2.20.
In 1877 sold as high as $4.50 and as low as $2.70.
In 1881 sold as high as $3.25 and as low as $1.90.

Altered conditions of supply and demand, variations in cost of crude material, etc., must act upon the price of this article, as upon all others, and in Europe and the United States alike.

Reference to quotations named in Europe for the year above cited will show precisely the same fluctuations as marked the condition of the market in this country. For example, Howards', of London, in May, 1877, 16 shillings 6 pence, while in November, 1881, 8 shillings per ounce in vials.

Present figures are regarded as low by those familiar with the business and the average value of the article, and they are so, in fact, but the cost of the crude materials, especially that of cinchona bark must be known before determining intelligently at any time whether sulphate of quinine quotations are high or low if reference is had to the cost of production

The removal of the duty from foreign sulphate of quinine, imported into the United States, cannot account for low prices ruling the world over at the present moment, nor can it have had any connection with very modest figures that have been occasionally named in years past in this country, when the article was dutiable.

The present value, as already stated, of American quinine is $1.40 per ounce, and foreign quinine comes free of duty. But foreign quinine was dutiable in 1857, and the American sold down to $1.40; so in 1858, when it touched $1.25, and in 1859, when it sold at $1.25, and in 1860, when it fell to $1. As far back as 1831 American quinine sold down to $1.35, and in 1837 to $1.40. These were low prices—for the most part lower than quotations named since the removal of the duty—but they were the natural result of the plentiful supply and low prices of cinchona bark, the principal crude material used in the manufacture of quinine.

On the other hand, we find that very high figures have been quoted in London, where there is no duty on the bark, none on the solvent, and where foreign quinine may enter free. For instance, in May, 1877:

Howards' in vials 16 shillings and 6 pence.

German, in tins, 14 shillings and 6 pence to 15 shillings and 6 pence.

Pelletier's, 15 shillings and 6 pence to 16 shillings.

The price, 16 shillings and 6 pence per ounce, equals about $4.12½ per ounce in London, and is nearly as high as the highest point the article has touched in this country in a period of fifty years. Against this quotation the low price of 6 shillings and 6 pence named in London for Howards', in February, 1876, will illustrate the great fluctuations to which quototions for this article are liable. The difference is equal to 10 shillings, or $2.50 per ounce in a little over one year, and this in the London market.

While, therefore, the removal of all protective duties has forced American manufacturers to struggle against unlimited foreign competition, and while it is true that the surplus product of a large number of European manufacturers has at times glutted this market, and been offered very low, and while American manufacturers have been compelled to follow these low figures named here and abroad for foreign quinine, yet, as a matter of fact, the low prices that have ruled during the past few years have been mainly due to the unusually large stocks of bark held in London and elsewhere, and to the cheapening of the bark, which resulted from excessive supplies. They can not be attributed but to a very slight degree, if at all, to the removal of a twenty per cent duty in the United States, because quinine is and has been cheap the world over.

But while present low prices can not be charged exclusively nor principally, to the removal of a twenty per cent duty—be caused equally low prices have ruled years ago, when quinine was dutiable—the facts, not to be controverted, are that the United States has become a sort of battle ground for foreign manufacturers; that their surplus has been sent to this country in large quantities; that the freeing of quinine stimulated and increased production abroad and curtailed it here; that this market has been handed over to foreigners, while we have not gained a single new outlet for our own product, and that our home manufacturers must either sell at about the prices named in England, France, Germany, Italy, and Holland, or go out of the business, and this without reference to the difference in cost of production.

That it cost more to make quinine here than abroad any one knows who is familiar with difference in wages, general expenses of doing business, cost of plant, charges for repairs, cost of crude material, taxes, etc.

The practical working of the removal of the duty on foreign sulphate of quinine has been to relinquish a great part of the market of the United States to foreigners—to the manufacturers of England, France, Germany, Italy, and Holland. These manufacturers supply to our people what under other circumstances would be furnished by American capital, skill, and labor. In return these countries do not take one ounce of American made quinine.

The vast increase in the importation of foreign quinine demonstrates the correctness of the assertion, as to this market having been largely relinquished to foreigners.

In 1877 we imported 75,804 ounces.
In 1878 we imported 17,549 ounces.
In 1879 we imported 228,348 ounces.
In 1880 we imported 416,998 ounces.
In 1881 we imported 408,851 ounces.
In 1882 we imported 794,495 ounces.
In 1883 we imported 1,055,764 ounces.

(For fiscal years ended June 30th, see Reports on Commerce and Navigation, Bureau of Statistics.)

As the importation of the foreign finished product has increased, so as the importation of the crude material for our manufactures' use diminished; so that while in 1879 we imported 6,389,378 pounds of cinchona bark, in 1883 there came in but 3,639,315 pounds. (See Reports on Commerce and Navigation.)

The diminished importation of bark results exclusively from the absence of ability to consume more largely in this country, on account of the large falling-off in the amount of quinine produced here, and not from any scarcity of the supply. In fact, the stock of bark in London is larger by over 30,000 packages than it ever was before. The shipments of cultivated bark from the East Indies to London have increased enormously. Perhaps these facts may be of interest.

"Under circumstances as favourable as those enjoyed by European manufacturers, it is quite possible that our American producers of quinine could compete successfully with foreigners—at least in this market, but matters now stand, it is a question how far and how long they will continue to battle for a share of the business, the disadvantages they labor under being so great as to largely draw upon their stock of pride and pluck, which may become exhausted, and then our people will be entirely in the hands of foreign makers."—*Independent Record.*

A LETTER FROM FLORIDA.

Near VOLUSIA, February 10, 1884.

Editor Southern Planter,—It occurs to me that a letter from this remarkable State, which of late years is attracting so much attention, might be acceptable to the readers of the *Planter*, for in Virginia, as in other States, there are many who are looking to Florida as a health resort, and as a profitable field for the cultivation of fruits and vegetables.

The traveller on the "Atlantic Coast Line," to reach Jacksonville, passes from the North Carolina line south a peculiar country—peculiar for its flatness, ponds, mostly without falls for drainage, and for its want of cultivation. The support of the country is drawn from its pine trees—yielding turpentine, resin and tar. From this source are being built up villages about the depots. An intelligent gentleman on the train, himself engaged in the manufacture of the products of the pine, informed me that the timber of the country was being rapidly cut and marketed, and at a period not remote the supply of turpentine, &c., would be exhausted, as the trees only bore one tapping or cutting in their life time. Now what is this country to depend on when these supplies are exhausted? It is time its inhabitants were thinking of this. Their only alternative is to go to work, clear some of their lands, cultivate them in such things as they find most profitable, and in something to rear and feed stock on, or to abandon their homes and villages. The soil evidently is not a good one, but may be suited for corn and oats, and particularly for ground peas, sweet potatoes and melons for market; then they may raise Bermuda grass, ever branching sorghum, or millomaize for stock. Now they have no stock but a few scrub cattle and razor-back hogs.

Many of your readers do not know that Florida is the largest of the United States east of the Mississippi, containing 60,000 square miles, while our dismembered Virginia contains 42,000 to 45,000 square miles (no one seems to know the exact number.) Florida was ceded to the United States in 1821 by Spain, and admitted as a State in 1845. It is only since the war that it has been known to the outside world or knew of an outside world. The St. John's River, on which there is much travelling in the Winter, is a noble stream, navigable to enterprise, 200 miles, and much further for very small boats. Its scenery is very attractive to the stranger, with its banks lined with the tree palm (cabbage palm) and other evergreens, in striking and pleasing contrast with the gray moss pendant eight or ten feet from numerous live oaks which line its banks.

After landing at Volusia I inspected a fine orange grove fronting on the river. The soil is very light, and filled with numerous sea-shells, which are found also filling the bank, of the river. The proprietor of the grove pointed out to me one tree, ten years old, which he said had yielded this year 3,000 oranges. There seems scarcely a limit to the production of the orange when properly cultivated and fertilized. Trees are found in Florida which have yielded 10,000 oranges, but this is very rare. A gentleman who has travelled in Mexico recently, told me he had seen there a tree which was said to have yielded 30,000 oranges one year. It was four times as large as any tree he had seen here.

After leaving Volusia by hired conveyance, we soon came on the pine lands of Florida, which constitute much the largest portion of the State. I was soon struck with mounds of white and yellow sand (which underlays the white), thrown up in quantity varying from a peck to more than a bushel. I soon enquired what this meant, and was told it was the work of the "gopher," resembling a terrapin, and of the "salamander," resembling a rat. I enquired why this dirt was thus thrown up. No one knew; but it is doubtless done to get the dirt out of the way of their subterranean passages, which are formed to procure roots and to furnish them homes. Our moles get rid of the dirt in their pass-ways by raising it above the surface. These mounds are very numerous, and form a novel sight. The gopher issues from his home in the Spring, and regales himself on the cultivated vegetables, particularly the peas, which are liberally sown (drilled) in the orange groves for fertilization. The salamander is very fierce, and bites severely, and among his other deviltries, amuses himself by chewing up the roots of the young orange and killing the trees.

My opportunities for observation in Florida have of course thus far been limited, but I have conversed with intelligent settlers, and consulted reliable publications, such as the Report of the Bureau of Immigration of Florida, and two publications, issued from the Department of Agriculture, Washington, the last by that intelligent and reliable gentleman, Mr. Wm. Sanders, Superintendent of the Public Grounds and Gardens of the Department, who was sent to Florida by Dr. Loring to examine the State and make report on it. With such opportunities I have come to the following conclusions:—That there is more opportunity to make the cultivation of land in Florida profitable than in any of the other of the United States; that the pine regions of Florida constitute the healthiest portion of the United States; and that the climate is unsurpassed in this country or in Europe. As regards the health, I am not certain that the river regions of the State might not be included in the above conclusion. I have not space to elaborate these points. The profits of orange growing in Florida are well established. The cost of making an orange grove in the pine region, independent of cost of land, is about $90 per acre. I mean by this clearing land, grubbing it enclosing with stake and rider fence, plowing, cost of trees and setting out. I speak from experience. The cost will be modified by cost of trees, which range from 30 cents to $1, according to age. Mine cost 75 cents. The fertilizing will depend on price paid for fertilizer. I think the "Ash Element," 400 pounds per acre, should be used along with peas, which furnish the ammonia, one year, and one-half peck cotton seed around the tree next year, and so on. The cost of the former in Richmond is $18 per ton; of cotton seed in this section 25 cents per bushel. The annual cost of plowing trees, hoeing sowing peas and mulching, will be about $15 per year. If the trees are well attended, budded trees, two years budded, and the trees budded on are four or five years old, they will begin to bear in three years from planting. Seedling trees (which are just as good, and some think more hardy and productive, but do not bear so soon), will begin to bear in eight years from the time of planting in the grove. There are at least two years in favor of budded trees from the time of transplanting to grove. It is calculated that trees ten or twelve years old, from time of planting in grove, will bear 1,000 oranges per year, selling on the tree in this section at one cent a piece. Near the landings and railroads, when boxed and delivered, they sell at three cents. When fifteen years old an orange tree well attended will bear 2,000 oranges. Seventy trees stand on a acre at 25×25 feet. The trees get at their prime at twenty-five years, and there is no telling how long they will continue to bear profitably if well cared for —we suppose until they are a hundred years old; this point is not yet settled in this country. In Italy there is said to be a tree 550 years old. No other oranges can compete with those of Florida, unless it be those of Cuba, and they have to bear a longer transportation. Oranges from Jacksonville reach New York by water in eighty hours, and rail in much less time. From Italy and Sicily it takes ten or twelve days by steamer, in which time many of them decay.

Besides oranges, many other things can be profitably raised in Florida, sugar, tobacco, Sea Island cotton, bananas, strawberries, pineapples, guavas, melons, cassava (for starch), and vegetables, particularly sweet-potatoes and tomatoes. A farmer in this neighbourhood told me he last year, from an acre and a half, sold $900 of strawberries and $300 of plants. Plants set out here in November bear a good crop in February, and bear for four months. The first shipments to New York bring $1·50 per quart, though from further south fine berries coming in early have brought $4 and $5 per quart. The range of production in Florida is much greater than in any other State. A writer enumerates more than sixty products, and yet a considerable number are omitted. Many of these, by proper cultivation, may be made very profitable. The pineapple is planted as close as cabbages, and 700 will stand an acre. They sell for ten cents a piece, and in South Florida are a certain crop. On the hammocks near St. John's river, in this county, four hogsheads of sugar have been made per acre, while the average yield in Louisiana per acre is only one hogshead. The seasons are long here, and the cane fully matures, forming seed before frost, which is not the case in Louisiana. Tobacco, cassava, Sea Island cotton, and other crops can be made profitable in this State. The beauty of agriculture here is that the Winter months are the best time for working the soil. Scarcely a day is lost at any season, and you may plow the land as soon after a rain as you can get a horse hitched up. In Jacksonville from 1874 to 1879, there was an average of thirty-seven rainy days in five months, viz., November, December, January, February, March, and these were only part rainy. (Signal office, U. S. A., Jacksonville).

As to the health of Florida, I have many statistics to prove it a very healthy country, but not space to quote them. Dr. Brinton, U. S. A., says: "All know how arduous is the campaigning in the *Everglades* of Florida, yet the yearly mortality from disease of the regular army there was twenty-six per 1,000 men; the mortality elsewhere was thirty-five per 1,000 men, while in Texas it arose to forty, and on the lower Mississippi to forty-five per 1,000. * * From my experience in hospitals and in private practice in and around New York, I am convinced that malarious diseases are more frequent there than in Florida." He then speaks of the mildness of cases of ague and bilious fever in Florida as compared with that prevailing in the Gulf States of the United States. There is almost no sickness here in the winter. A lady of Virginia, who has resided in this country for three years, tells me she has heard of but one case of pneumonia, and one of ague and fever in that time. I have enquired of different families in this neighbourhood and only one tells me that he has had ague and fever, and that was four years since, and has not subsequently heard of it. Statistics ("Florida: Its Climate, Productions, etc.," from U. S. Agricultural Department, 1882) prove "that the mean relative humidity of Cannes and Mentone during the cold months exceeds that of Jacksonville by nearly four per cent. * * The mean relative humidity of Duluth, Minnesota, for five years was 70·3; that of Jacksonville, 69·0." It must be remembered, moreover, that the pine regions of Florida have less humidity than Jacksonville. The climate of Florida is exceedingly *mild and uniform*. Dr. Wilson, U. S. A., Inspector of Camps and Hospitals, says: "Neither upon the south coast of France, nor anywhere under the bright Italian skies, can a Winter climate be found so equable, and so genial to the delicate nerves of most invalids as can be enjoyed in our sanitary stations in Florida." The mean temperature for the entire State, taken at eighteen stations during a term of years, is for Spring 71.°62, Summer 80.°51, Autumn 71.°62, Winter 70.°05 (Dr. Baldwin, of Jacksonville). It is well determined now that the thermometer rises higher in New York, Philadelphia, Boston, and Milwaukie than it ever does in any part of Florida. The thermometer in the latter rarely goes above 90° in Summer or below 30° in Winter. Mr. Spinner (of bank note fame), who spent a year in Florida, says: "I was more comfortable in regard to excessive heat than in any Summer spent in Washington, D. C., or at my home in Mohawk, N.Y." There are always cool breezes pervading all of Florida from the

Ocean and Gulf, Summer and Winter, and I am told by the lady from Virginia referred to, that the houses are never hot day or night in the hottest weather, except sometimes the nights are hot until 12 o'clock, then always cool. The average rainfall at Jacksonville for five years was 54·47 inches.—POLLARD.—*Southern Planter.*

UNCOMMON DRUGS.

The following notes were recently read at a meeting of the Chemistts' Assistants' Association by Mr. J. O. Braithwaite in a report on materia medica, samples of the various drugs named being submitted. The author explained that he had obtained his information in the laboratory of Messrs. Wright, Layman & Umney, and he expressed his obligations to them, and also to Mr. Holmes, the curator of the Pharmaceutical Society's museum, who had identified some of the samples. The first drug reported on was

SLICED JAMAICA JALAP.

This sample was grown in the Government Botanical Gardens as an experiment, to see if the yield of resin could be increased by careful cultivation. The first sample which reached this country was examined by Mr. Greenish, and reported on by him to the Pharmaceutical Conference in 1882. He found it to contain

	Per Cent.
Resin	9·89
Ether-soluble resin	1·21
Moisture	14·3

This second consignment has given me.—

	Per Cent.
Resin soluble in alcohol	12·6
Ether-soluble resin	1·0
Moisture	11·0

It will be thus seen that the second lot yields a trifle more alcohol-soluble resin, but that the ether-soluble portion—the jalapin of Mayer—is not so high.

Perhaps it will not be out of place for me to point out here the importance of thoroughly washing the resin with boiling water when making the official preparation or when assaying a sample of the drug, in order to get rid of the sugar. To determine when this has been effected, it is necessary to test a portion of the supernatant liquid with Fehling's solution. In many cases abundance of sugar will be found in the perfectly colourless washings, and if this precaution be not taken, as much as 5 or 6 per cent of sugar may be weighed as resin.

It has been stated that slicing the root increases the yield of resin, by allowing a more perfect oxidation of some of the secreted matter. You will notice that the sliced root has but little of that peculiar fruity odour which is found in the wild jalap; the powder, however, is fairly fragrant. The jalap resin obtained from this sample is of extremely good colour.

GAMBOGE IN TEARS.

The "gum" but seldom comes to this country in this form, but is generally met with in "pipes" or lumps. In tears it is quite free from adulteration, but it is not likely to be preferred to the other, on account of the large proportion of bark which is removed with each tear.

COQUILLA NUTS.

These hard nut-like seeds were recently offered as a "drug." It is difficult to imagine what medicinal virtue could be supposed to reside in them. They are the seeds of a species of palm, *Attalia funifera.* The testa is extremely hard and very thick. The nut is employed in turnery for making such small articles as door and tool handles, also for carving. As the name "funifera" implies, this palm also yields a valuable fibre of great strength, which is used to make ropes. The albuminous kernels of an allied species of *Attalia* are eaten in the countries where it grows. That of the specimen we have here is by no means unpalatable, abounding in a bland oil, and having an agreeable nutty flavour.

PHYSIC NUTS.

The next specimen was offered for sale as croton seed. It is the seed of the plant closely allied to the croton-oil plant, viz., *Jatropha curcas*, or *Curcas purgans*, the physic nut of the tropics. The genus *Jatropha* is closely allied to croton on one hand, and *Ricinus* on the other.

This *Jatropha* is largely grown in the tropics, where it is used as a purgative, the dose being from three to four seeds; an over-dose causes a burning sensation in the epigastrium and a determination of blood to the head, accompanied by violent purging. The negroes employ copious draughts of cold water to alleviate the effects. Dr. Christison found that 15 drops of the oil from this seed are equal in pugative action to 1 oz. of castor oil. Its therapeutic power is, therefore, intermediate between croton and castor oil. The utility of the plant is not limited to the medicinal action of its seeds. A decoction of the leaves is used in a similar manner to that of *Ricinus*, to excite secretion of the lacteal glands. The oil is also largely used as an illuminating agent and for dressing cloth. It has been proposed to use the juice of the plant as a marking ink for linen; when first applied to linen fabric it turns from dark brown to black, and the stain is almost indelible.

Another plant closely allied to this is the *Jatropha Manihot*, the source of our tapioca.

THE TRUE SOURCE OF SOCOTRINE ALOES.

This somewhat insignificant-looking fruit is, to me, of considerable interest. I rescued it from a steampan in which socotrine aloes was being boiled. Mr. Holmes has identified it as *immature fruit of Aloe Perryi.* Until recently the source of socotrine aloes was unknown; but Dr. Bayley Balfour has cleared up the matter, and proved that the species yielding the commercial article is new to science. He has called it *A. Perryi.* This new and interesting plant is now growing in the Economic House at Kew, side by side with *Aloe succotrina*, the species which was formerly supposed to yield the drug. The plant is, of course, a young one, but its characteristic points are already well marked, and distinguish it from *A. succotrina* at a glance. *Aloe Perryi* has thick fleshy *unspotted lanceolate* leaves, which spring directly from the level of the earth. *Aloe succotrina* has narrow rounded *ensiform* leaves, *slightly spotted.*

Considerable uncertainty exists in the popular mind as to the limit of the term aloe, and it is generally applied to any exotic endogen with thick or evergreen leaves. For instance, we frequently hear both the New Zealand flax and the American yuccas called aloes by the visitors to our Botanic Gardens. Many of you will doubtless remember the admirable *résumé* of the genus Aloinæ which Mr. Baker gave at one of the evening meeting about a year ago. He pointed out that the genus Aloe may be at once distinguished by having its stamens exserted, or equal in length to the perianth, which is gamophyllous; that the Yuccoidæ have never fleshy, but fibrous, leaves, and that the perianth is polyphyllous. The three other allied genera, Gasteria, Haworthia, and Apicra, have their stamens included.

COSTUS ROOT.

The next drug is a sample of genuine *Costus Root.* Although but little finds its way to this country it is a staple article of commerce of the East. Like most of the drugs sold in Oriental bazaars, the botanical source was long doubtful; it has been determined, however, that it is the root of a composite plant, *Aplotaxis auriculata.* It is cultivated in Kashmir, whence it is dirtributed over the whole of India and China. The quantity produced in one year exceeds two million pounds. The root is dug up when the sap begins to descend, and is carefully dried in the sun. It has a peculiar odour, with a warm aromatic taste. Although great curative properties are attributed to it in the East, it appears to be a simple carminative and stimulant. China absorbs the greater part of this root for use as incense. There, under the name of "pae bak," it is burned in enormous quantities in every "joss house," and in that abode of ritual, no ceremony, civil or religious, is complete without the smouldering *Costus.*

FALSIFIED DRUGS ON THE MARKET.

I have now to mention a few substitutions, and one or two cases of deliberate adulteration by the producers. The first is a specimen of bark which was offered for sale as cinchona, and failing to find a purchaser in the *rôle*, was afterwards put up as angustura. A glance will show that it is neither. It is, however, the bark of a tree closely allied to the cinchonas, viz., *Stenostomum acutatum*, the false quinine bark. Its chemical properties do not appear to have been investigated. I now call attention to two grossly sophisticated samples of "scammony gum." The first is soft of about the consistence of pill mass, but has the peculiar smell of scammony very markedly. It contains but 1 per cent of ether soluble resin, and is composed almost entirely of mucilaginous and extractive matter. It is probably an extract prepared from the root after the removal of the resin.

The second sample is much harder, breaks with a conchoidal fracture, and has little or no smell. This contains even less than the preceding, since ether dissolves only 0·6 per cent of resinous matter. It is partially soluble in cold water, entirely so in hot; the latter solution gelatinises on cooling. This sample of scammony consists of a mixture of mucilaginous matter and starch.

The next two samples of saffron are both sophisticated. In fact, the first consists entirely of the florets of the marigold carefully manipulated and dyed, so that the fraud might easily succeed upon a careless purchaser. The true nature of the imposture is at once made evident upon macerating the "saffron" in water. I have here some of these florets dried and mounted. They even show the characteristic forked stigma, and I have come across one or two tubulardisc florets as well. The sediment which fell, on standing, from this infusion was almost entirely composed of pollen grains of the shape peculiar to the composites. The dye used is said to be dinitrocresylate of sodium. It is possible that it may be used to heighten the colour of inferior saffron as well as to dye the florets or stamens of other plants. Since it is soluble in benzole, whereas polychroit, the colouring matter of saffron, is insoluble, its presence in a sample may be easily detected. If 10 grains are infused in 1 oz. of hot water for half an hour, then strained, and shaken with 2 or 3 drachms of benzole, the latter should separate out almost colourless on standing.

The other sample is genuine saffron, but it has undergone the process of "dressing" to increase its weight. The mineral matter used in this case is sulphate of lime. This fraud may be easily detected by the "infusion" method.

A small-leaved herb, looking somewhat like a dried heath, was imported from the Cape, and was offered as a new kind of buchu. It is closely allied to the Barosma, being the *Agathosma melaleucoides*. You will notice that it exhales a peculiar aromatic odour, which has earned for it the name "Agathosma" (sweet smelling), not that I consider that Barosma deserves its name, for freshly-imported buchu is far from "heavy" smelling. It appears that the Hottentot ladies are of this opinion. It is said that they rub themselves with the leaves of the plant, and that, excepting this fragrant odour, they wear little else. The genus Barosma is distinguished from Agathosma by the following characters. Leaves generally opposite, flat, and flowers axillary, whereas in Agathosma the leaves are rarely opposite, and the flowers never axillary. There are over one hundred species of Agathosma native to the Cape. The natives use them in infusions, as diuretics, and expectorants.

BLACKBOY GUM.

I have only one more specimen of vegetable drugs to bring before you. This is a sample of the gum resin of *Xanthorrea hastilis*, a plant of the natural order Liliaceæ. It is used as an application to wounds in Australia, where it is known as "Blackboy Gum." It somewhat resembles very yellow benzoin in appearance, and is said to contain cinnamic and benzoic acids. The inflorescence of the plant is curious, and deserves notice. It consists of a very long, closely-aggregated spike of perianths, so closely crowded together on a long primary axis that the arrangement looks like a huge bulrush.

TURTLE OIL.

I have one specimen from the animal kingdom. It is turtle oil, a product of various species of Chelonia. In the tropics it is largely used in wasting diseases where cod-liver oil is exhibited in this country. In some parts it is even preferred to cod-liver oil, and is said to be more easily digested. This sample was obtained from the Seychelles Islands, and is produced, I believe, by *Chelonia viridis*. It has a peculiar odour, and a taste something like rancid beef "dripping." I believe the oil is chiefly obtained from the female turtles which come on shore to deposit their eggs. They are either despatched by blows with a club, or are turned over on their backs, for when once in this position they cannot right themselves—hence the nautical expression of "turning turtle." As many as fifty turtles may thus be captured by two or three persons in a few hours. A large turtle will yield about 30 pints of oil, which is used as an article of food and as an illuminating agent, as well as for medicinal purposes. The flesh of the turtle is salted and dried in the same manner as we salt cod or dry herrings. In this state it is largely consumed by the natives, and exported to neighbouring countries.—*Chemist and Druggist.*

COCONUT GROWING IN FIJI.

SIR,—I am afraid your correspondent takes rather too rosy a view of coconut planting in Fiji. I have always understood labour to be the great difficulty in all planting operations. The greater part of the native labour employed in Fiji plantations is brought from the New Hebrides and Solomon islands, and the supply is nothing like equal to the demand. These imported natives are generally bespoke long before they arrive in Fiji, and many vexatious delays and expenses are attendant on their hire. There pay is, I think, £12 per annum; and I do not believe that anyone could make certain of being able to command the services of even ten natives for three years.

As regards Fijian labour, apart from the discouragement offered by the Government to Fijians to work for Europeans, natives as a rule will not work regularly in their own islands.

I know myself of one man who has quite 100 acres of nuts in full bearing; but I very much doubt his making anything approaching £2,000 a year, his difficulty being the impossibility of getting the labour to gather and prepare the copra. And I think that hitherto the number of really successful planters in Fiji could be counted on the fingers of one hand.

The usual price of yams is about 3s a cwt., and it is sometimes particularly hard to get an adequate supply for the labour, the planter or hirer being required by Government to supply each native labourer (imported) with a certain allowance, and I have frequently come across planters' boats, many miles away from their plantations, foraging for food.

The great future of Fiji probably lies in sugar and coffee, the former, of course, requiring large capital for the extensive plant and machinery required, an enormous amount of sugar land in Viti-Levu (the largest island) having been taken up and worked by Australian companies; and coffee has been very successfully tried in the higher islands.

For a man with small capital, fruit growing (*i.e.*, bananas and pines, the former especially) seems to hold out advantages. It is, however, desirable to be close to Levka or Suva, and so manage to hit off the arrival of the New Zealand or Sydney steamers with some degree of certainty. In some cases, however, the steamer is a few days late or perhaps put in quarantine, when the shipment becomes ripe, and of course comparatively valueless.

During a two years' cruise in Fiji waters, I have met and conversed with numbers of planters, all of whom are agreed that the difficulty of obtaining labour presents the greatest bar to success. A high official, who lately held an important position in the group, stated publicly that "Fiji is not a white man's country;" this to the initiated means a good deal.

I do not think a man with so small a capital as your correspondent mentions could afford to pay any one to look after his young plantation whilst he was in the colonies; and I think, to do any good in a small way, one must be on the spot.

As your correspondent says, planters' fare is not by any means varied, salt beef and an occasional fowl being the standing dish. Pigeons and ducks are in some parts plentiful, and fish can sometimes be obtained from the natives.

Some of the streams contain fish which afford sport with fly, grasshoppers, and minnow, the two latter baits being of course most successful. The fish, however, are scarcely worth eating.—G. E. R.—*Field.*

THE BUSY BEE.—The honey-bee has long been a type of the industrious worker; but there are few people who know how much labor the sweet hoard of the hive represents. Each head of clover contains about sixty distinct flower-tubes, each of which contains a portion of sugar not exceeding the five-hundredth part of a grain. Some apiarian enthusiast who has watched their movements concludes that the proboscis of the bee must therefore be inserted into five hundred clover-tubes before one grain of sugar can be obtained. There are seven thousand grains in a pound; and, as honey contains three-fourths of its weight of dry sugar, each pound of honey represents to and a half million clover-buds sucked by bees.—*Popular Science News.*

HOW TO USE HEN MANURE?—This question comes from several subscribers. The condition of the manure differs with the management of the poultry house. If the house is swept daily, and the space under the roosts is covered with earth to receive the droppings, no preparation will be needed. If, as usual, the manure is allowed to accumulate, and only occasionally removed, it comes out in solid masses or lumps. The lumps must be broken up by a pounder, and the manure sifted and mixed with dry peat, or dry woods-earth, or in the absence of these, dry soil may be used. Mixed one part to ten of muck, etc., it willbe useful upon farm and garden crops.—*American Agriculturist.*

TONQUIN BEAN.—In a report from Mr. Consul Mansfield, of Caracas, on the mining districts of Venezuela, he states that the *Dipterix odorata*, which yields the fragrant seed commonly known as the tonquin bean, abounds in the forests of the Caracas district, where the trees grow to a considerable size. The first crop of "beans" is yielded in the third year of the plant, the fruit bearing some resemblance to a small mango, and containing in its centre the "bean," which emits a powerful odour. A full crop is not yielded until two years later. The tree is said to grow in any climate in Venezuela, but to attain a greater perfection in warm temperate zones, alike removed from parching heat or the sharp mountain breezes. Last year's crop was a large one; Venezuela alone exporting five thousand quintals at an average price of 3½ francs per pound. It is estimated that the bean is used for curing and flavouring eight million quintals annually of tobacco exported from the United States. The vanilla also grows wild in many of the forests of Guayana. It may be remembered that a sample of Guayana vanilla was mentioned as having been shown at the Vienna exhibition last year.—*Pharmaceutical Journal.*

ARTIFICIAL EVOLUTION.—The London *Garden* says: "Every day brings before us some fresh evidence, same new development, of hybridism in the garden. Species-making is going on in our gardens as well as in nature, and so abundantly are hybrids appearing, that 'evolution made easy' would seem to be an appropriate motto for the hybridists of our own time. Hybridism as a means of evolving new phases of plant-beauty, new fruits, new food-plants, will remain to us or to posterity when every square mile of the world shall have been ransacked, and when new natural species shall have become old, or no more. Hybridism will then be the kaleidoscope through which all new and varied plant-beauty will appear. And not beauty alone; for by its magic agency, as taught us in Nature's own hornbook, old plants will be made more fit for new uses, old favorites of to-day become the new ones of to-morrow, and so will they serve the varied purposes and the unthought-of fashions of all time to come. Apart from present uses and practical appliances, hybridism and grafting in the garden will enable the biologist to verify or prove many, if not all, of his observations; in a word, apart from the present gain to our gardens, hybridism and cross-breeding will rank far higher in the botany of the future than they have already done in that of the past."

AFRICAN WOODS.—It is not too much to expect that one of the results of the forthcoming Forestry Exhibition at Edinburgh may be the development of the timber resources of some of our colonies. The subject is one of very wide interest, and there is room at the present time for an extension, not only in quantity but also in variety of our timber and ornamental wood supplies. Many apparently excellent woods are brought home by different travellers from time to time from various parts of the African continent, but their botanical sources are, for the most part, unknown, and they never come into actual use. The principal African wood indeed of acknowledged value at the present time, is the so-called African Oak or Teak (Oldfieldia africana), which is so useful for piles for wharve,s &c. This, however, is an example of a durable wood, useful for structural purposes, but not of an ornamental character. An example of a West African wood, both durable and ornamental, has recently been presented to the Kew Museum by Capt. Molony, C.M.G.; it is furnished by Chlorophora excelsa, Bth. and Hook. f., a tree belonging to the Moreæ section of Urticaceæ, growing at Yoruba, Upper Guinea, where it is known under the names of Roko, or Iroko wood. Notwithstanding its ornamental character, which, when polished, exhibits a combination of Satin and wavy Maple woods, it is noted for its great strength and durability for building purposes, as it resists the attacks of white ants—a great recommendation to any wood required for use in tropical countries.—*Gardeners' Chronicle.*

CLIMATE.—The following extracts, taken from the report of the Botanic Garden, Trinidad, will be of interest to cultivators as showing the comparative uniformity of conditions and the slight range under which tropical plants grow. The mean maximum temperature for the three years, 1880—1882, was 90°, the range being from 83° in January 1880, to 92° in April 1881. For the same period the mean minimum temperature was 61°.7, the range being from 60°.7 in February 1880 to 68°.4 in April, May 1881, and in September 1880. The extreme range between maximum and minimum for the three years was 38°.3 F. The mean temperature for twenty-one years is given as 77°.7, the highest being 79°.5 in May, the lowest 76° in January and February. The maximum humidity for twenty-one years is registered as ·885 in August 1880; the minimum in April 1869 as ·572—1.000 representing saturation. The average amount of rainfall for twenty years is 65·85 inches, the maximum being 85·2, the minimum 44. The average amount of cloudiness (ranging from 0 total clearness, to 10 total cloudiness), is given at 5·2 for the whole year, the range being from 4·5 as a monthly mean minimum in January to 6·4 in October. Where, as in countries like Trinidad, the range is so small, records of mean temperature are valuable, but for climates where the conditions are more variable and the extremes wide apart mean temperatures are misleading. A ready method of recording the relative duration of any given temperature or other meteorological phenomenon is still a desideratum.—*Gardeners' Chronicle.*

THE PEACH-TREE BORER.—The Borer is a wide-spread and destructive pest in the peach orchard. The mature insect is a moth, which appears from the middle of July to the last of August. The female deposits her eggs singly on the bark of the tree, near the surface of the soil. The young borers work downward into the roots, forming small winding channels. A full-grown borer is half an inch long, and is soft, pale yellow, and with strong black jaws. The borers make leathery cocoons out of castings or "sawdust," gum and silk, in which they remain in the inactive or pupa state, near the surface of the soil. If the earth is loose, the cocoons may be an inch or more below the surface. There are several remedies, and more preventive measures for this pest. The presence of the borer is known by the dust and exudation of gum, and when these are found, the burrow should be probed with a slip of whalebone, or a short wire, and the borer killed. Hot water is sometimes used, the earth around the base of the tree having been removed. The knife and probe used in late autumn or early spring, are the most effective means of reaching and killing the borer. Care should be taken not to cut the tree more than necessary. Among preventive measures, is the banking of the tree with earth for a foot or so. This mound with the earth firmly pressed around the tree, may be permanent, or better still, thrown up in spring, and leveled in autumn, after the season of egg-laying is passed. Ashes and cinders are sometimes heaped around the trees instead of mounds of earth. A covering of stout paper, a plastering of clay, or a wash of tobacco water may help to keep the egg-laying moth away from the trunk of the tree during the summer.—*American Agriculturist.*

REPORT ON THE GOVERNMENT CINCHONA CULTIVATION IN JAVA FOR 1880.

BY J. C. BERNELOT MOENS.

(*Translated for the "Tropical Agriculturist."*)

1.—*State of the Weather.*—As in 1879, the weather this year was very rainy, and there was no *bona-fide* dry monsoon. The plants developed favourably, but there were symptoms here and there, such as the leaves turning yellow, and a cessation in the growth, which must probably be attributed to too great dampness of the soil. The observations made at the establishments at Tjinjiroean and Kawah Tjiwi lei, of the rainfall there, were regularly continued, and the results published by the Director of the Meteorological Observatory at Batavia.

2.—*Increase.*—The total number of the plants in open ground at the end of December was 1,824,580. Of these 58,400 were Ledgeriana cuttings and grafts, and 439,670 Ledgeriana seed plants. There were 272,400 plants of this variety in the nursery beds, of which 8,300 were cuttings and grafts. The quantity of Ledgeriana seed was exceedingly small, owing to the rainy weather in 1879, which checked the blossoming. Nearly all that was collected had to be kept for the Government gardens, and the private demand was met as much as possible with seed of the best young Ledgeriana trees nearly six years old. Succirubra and officinalis seed could always be supplied on application. The grafting of Ledgeriana on succirubra stalks was continued after it had appeared that the grafted trees that had been planted out were growing well and fast. Special care was taken to procure grafts from the best trees that had been examined, and of these 1,000 were transferred to the open ground separate from the others; and the several numbers were carefully kept apart. As it would be a pity to dig up these costly plants, which have cost so much trouble to rear, at a later period when, after some years, they have developed so strongly as to be an obstruction to each other, it was decided to increase the distance of planting from 6 to 8 feet, and to put seedlings between the grafted plants, so that the little trees would eventually stand at equal distances of 4 feet. As soon as they begin to hinder each other, which will, probably, be the case after three or four years, the seed plants will be pulled up, and the bark collected. The grafts will remain at equal distances of eight feet, which will be sufficient for many years. The taking of cuttings and the layering of Ledgerianas were also continued. Officinalis was again only planted at Kendeng-Patoeha, and the number there increased to 43,000 plants. Succirubra was also planted in soil where Calisaya had formerly grown; and the number of this variety had augmented by 58,600. In harvesting fully 100,000 trees were pulled up, principally Calisayas and Hasskarlianas. In the course of the year, some tins containing cinchona fruit, which had been sent to Holland by Mr. Schuhkraft, the Dutch Consul at La Paz, were received here. The seed was on the whole in good condition, and some two thousand plants were procured from it. It is not possible yet to determine to which variety this cinchona belonged: the fruits resembled those of our so-called *Calisaya Javanica.*

3.—*Clearing and Upkeep.*—A fine space of ground of 27 bouws was cleared this year at Rioen-Goenoeng, which is intended exclusively for *Calisaya Ledgeriana.* The grounds at Tirtasari were being gradually prepared for planting according as room was required for the grafts and cuttings. The gardens at Tjibitoeng and Rioen-Goenoeng situated the lowest, that were planted with Calisaya, were cleared and made ready for *Cinchona succirubra.* The replanting with Ledgeriana of the grounds at Nagrak on which Hasskarliana had previously been grown is giving very good results. The little trees grow luxuriantly in most parts. The succirubra plants at Lembang, planted in soil where Calisaya formerly stood, have not progressed so favourably during the last year, as they did formerly. Especially in the perfectly flat parts of that establishment, it seems that the plants suffer from the continual exceptionally damp weather. A little more warm and dry weather in the ensuing east monsoon is very desirable for them. It appeared, however, that more careful attention was necessary in all these cases to ensure a good growth of the cinchona plants. These replanted pieces of ground have to be kept as clean as possible, whilst the trenching that was done and the burying of the weeds had also a favourable effect. The incessant damp weather during this year made it very difficult to keep the gardens clean, as the weeds continually shot up most abundantly. In normal years, when it does not rain much in July, August and September, the gardens do not require so much looking after at that time, and the labourers can be put to other work. In 1879 and 1880, however, this was not the case in any single month. The five and six year old Ledgeriana gardens at Nagrak, which were originally planted at 6 feet, now form, in many places, a perfectly dense plantation, among which there are no weeds growing. The trees are beginning to hinder each other in their growth, and it will be necessary to let in more air by propping up and careful thinning here and there. The measuring of the trees, which was commenced at Tjibeureum last year, was continued in the corresponding month of 1880. Unfortunately this very measured piece had this year to sustain a severe attack of Helopeltis, so that the growth was much less than it would otherwise have been. The average height was now 1·78 meter; the diameter of the top 1·07; the circumference of the stem 0·103 at 0·1 meter from the ground. The following was noted as maximum for these trees:—height 2·03; diameter of the top 1·9; circumference of stem 0·195 meter. The Ledgeriana cuttings and grafts planted at the same period at Tirtassari in November 1879 were also measured. The cuttings averaged 0·62 meter high; 0·37 diameter of top; and 0·04 meter circumference of stem at 0·1 meter from the ground. In the case of the grafts they were respectively 0·88; 0·60; 0·069. The greatest height of the grafts was 1·26; greatest diameter of top 0·9; and greatest circumference of stem 0·095; whilst with the most developed cuttings they were respectively 1·12; 0·6, and 0·06 meter. The grafts develop extraordinarily in breadth. The branches grow very strong, forming extremely handsome pyramidal little trees that soon shade the soil. It was sometimes necessary to cut off the side branches to prevent their growing out above the tops of the trees and pressing these down. On the whole the growth of these grafts has, up to the present, surpassed all expectation, and if it continues at the same rate, the plantation at Tirtasari will excel all the other cinchona gardens in appearance and not less in value. This year also the *Helopeltis Antonii* has more or less damaged many of the plantation. The fine new gardens at Tjibeureum especially suffered greatly from this insect, and also the new succirubra gardens at Rioen-Goenoeng and at Lembang. They also made their appearance in the cuttings and grafts at Tirtasari in the latter part of the year, but as they were immediately discovered they could be completely exterminated. Means were taken everywhere, by catching these insects, to prevent the evil as much as possible.

4.—*Cinchona Crop.*—The crop of 1880 was about 55,400 kilograms, of which about 53,000 kilograms were destined for export to Europe, and 2,440 kilograms for the medical service in Netherlands India. At the end of the year 41,860 kilograms were sent to Tjicao for export. The incessant rains made the drying very difficult, and the greatest exertions were necessary to collect and prepare the above quantity. A heated room for the artificial drying of the bark is urgently necessary; and at the commencement of 1881 a proposal will be made to build one at Nagrak, where there is a great want for one at present. The cattle plague breaking out in the vicinity of Bandong in May last, the transport by buffalo carts had to be immediately stopped. The conveyance of the bales of cinchona has since been carried on in carts drawn by horses, and as all the planters were compelled to send their produce in this manner, the cost of carriage rose by competition, and the transport was, moreover, very slow. No improvement can be looked for in this state of things before the completion of the railway from Buitenzorg to Bandong. The cinchona bark of 1879 was sold at Amsterdam on the 20th July. The following were the average prices per half kilogram obtained:—

C. Calisaya Ledgeriana	*f*7·573
„ „ Javanica	1·514
„ „ Schuhkraft	1·422
„ „ Anglica	1·367
„ officinalis	3·813
„ succirubra	2·169
„ Hasskarliana	1·455
„ Pahudiana	1·51

The avarage price realized for the whole was f2·166 per half kilogram. The highest price of the whole auction of 20th July 1880 was, as in 1879, paid for Ledgeriana bark cut in chips (scraped bark), for which f10·51 per half kilo was paid. The gross proceeds of this sale amounted to f201,559·23, netting f18,476·45½. The succirubra bark cut in chips realized a higher price than any other lot of succirubra: even more than the fine long quills that were sent. This result was contrary to expectation, for, although with barks intended for the preparation of quinine by manufacturers, the form in which they are offered for sale is totally immaterial, it was always taken for granted that the bark intended for pharmaceutical purposes—and the original succirubra is considered to belong to such—in the form of fine long tubes was what was required by the trade, and paid for the highest. The result is, at all events, satisfactory, as it removes the objection which existed against this sort of bark being cut in chips. It will now be necessary to determine—which can be done in 1881—the composition of the different barks after scraping: whether there is an analogous improvement, at has been observed in the renewing of whole strips of bark. It is remarkable that the long quills of succirubra that were packed in bales provided with cross strips of wood, and that arrived in Holland perfectly sound and unbroken, did not fetch a higher price than those sent without any protection in gunny bags, and of which the outer row of quills generally arrive more or less injured. And, further, that the broken quills of succirubra realized a much higher price (from 10 to 38 cents per ½ kilo) than the long ones. All this seems to show that the trade is beginning to care less for the form of these barks than was formerly the ease. A much better price was, however, paid for the long quills of the several sorts than for the short ones. Scraping was continued during 1880; but, in order to injure the trees as little as possible, the bark was only taken from two sides, whilst the other two sides were left untouched. And, if formerly mention was made of the trees suffering a little from this process, it was now found that no difference could be observed between the trees that were scraped and those that were not, although standing together. From the 60 Ledgeriana trees that were treated in this manner in 1878 for the first time, the new bark has been removed this year. In 1878, fifty kilos was obtained from these: now fifty-five kilos was cut from the stem. McIvor's method of stripping succirubra was continued, and use was made of the alang-alang to cover the trees. The Director of the Government Cinchona Gardens saw in Ceylon and at the Neilgherries that grasses, among them the *Imperatum Koenigii*, were pretty generally used with great success to cover the stripped trees. After this was reported to Java, a trial was immediately made here with this grass, which is so common near the cinchona gardens, and consequently so cheap. The renewed succirubra bark of the 1879 crop fetched a price nearly one-half in excess of the best original barks, notwithstanding its unsightly appearance. This difference in price was owing to the greater quantity of quinine it contained.

5.—*Staff; Materials; Expenses.*—The head overseer G. Scheen, who had been attached to the cinchona cultivation since 1862, was pensioned off at his request by Government resolution of 15th July 1880, No. 8. By the same resolution the oldest overseer first class, F. A. van Honk, was appointed in his stead, R. H. J. Frank was promoted first overseer, first class, and the overseer second class A. C. Hettfleisch von Ehrenhelm was made overseer first class. A. A. L. van Stauffenbell Lijmers was promoted from 3rd to 2nd class, and J. J. A. C. Zijmers was appointed overseer 3rd class by resolution of the Directer of the Interior of 24th July 1880, No. 486. The acting overseer 2nd class E. T. Veulemans was discharged at his own request in December. The native staff consisted on 31st December of one cinchona mantri, one carpenter, one storekeeper and postman, 13 mandoers, and 212 boedjangs. At the commencement of the year a sufficient number of laborers came in, but towards the middle of the year it was more difficult to procure them owing to the rice harvest and the erection of poggers (fences) for the prevention of the cattle plague taking away many hands. At some establishments situated near the pagger there was a panic among the hands in July, and all the laborers from Rantja Blang belonging to Kendeng-Patoeha fled and returned to their dessas (homes). The nursery sheds at Tjibitoeng were pulled down, the woodwork was quite rotten, and they were no longer required. This establishment now provides itself with succirubra plants from the plantations where the young seedlings are found by hundreds of thousands under the trees. The nursery sheds at Kawah-Tjiwidei were also pulled down, and were not rebuilt for the same reason. One of the nurseries at Rioen-Goenoeg will be repaired next year. The expenses of the undertaking amounted to:—

Salaries of European staff	f 287,257·00
Stationery	360·00
Travelling and halting expenses	1,484·04
Wages of native staff	20,863·95
Day laborers	12,086·77
Making and repairing agricultural implements...	1,090·85
Carriage, of and packing of cinchona	3,126·07
Do specie and materials	137·45
Books	127·75
Materials for repair of the nursery houses and sheds	1,228·21
Daily necessaries for the laboratory	57·10
Servants for the laboratory	180·00
	f 69,457·19

being f 3,897·19 more than was fixed by the budget of 1880. This surplus was caused by higher wages and carriage and by the necessity of a more careful cultivation, and consequently of more labor which had to be expended on the fields that were planted a second time.

6.—*Distribution of Cinchona.*—As the stock of seed from original Ledgeriana trees was very small, the great demand could not be met, or only partially so. Private planters, however, who wished it, were supplied with seed from the best offshoots of Ledgeriana. Succirubra and officinalis seed could be sent away in large quantities. Many private planters now apply themselves to taking cuttings from *C. Ledgeriana* using with great success the young shoots often found on the stems of the one and two year old plants. They only take cuttings from the most typical plants, and so obtain a very valuable material for the extension of their plantations.

7.—*Information regarding the Varieties of Cinchona Reared in Java.*—Of the trials made with artificial fertilization, and mentioned in last annual report, the following have succeeded:—*Micrantha* and *Calisaya Javanica; Micrantha and Calisaya Schuhkraft*; and *Succirubra* and *Calisaya Javanica*. The young fruit of the other crossings either fell off before maturity or were destroyed by the wind, by the breaking of the branches on which they were growing, or otherwise. The fertilization this year gave no results. Of the abovementioned three crossings the seeds were put to germinate, and a sufficient number of plants was procured to serve for study. They are yet too small to allow of much being said about them, but the effect of the cinchona varieties used for fructification can be clearly seen in the form of the leaves of many of the seedlings. The plants procured from the seed sent by Mr. Schuhkraft in 1877 are already commencing to flower, and they belong to the *C. Josephiana* (*C. Calisaya Schuhkraft*). Those procured from seed received from the same source this year are yet too small to allow of any opinion being given about them. A case containing a herbarium of the cinchona varieties reared in Java, with their barks, and an explanatory note, was sent to Mr. Schuhkraft. A better knowledge of those species will probably enable him to procure seed of the *C. Ledgeriana* from North Bolivia.

8.—*Chemical Analyses.*—Owing to the absence of the Director of the Government Cinchona Cultivation, the chemical analyses were suspended for five months. The stem and root wood, as also the leaves of the *C. Ledgeriana* dug up in 1879, the determining of the alkaloids of the several barks of which is mentioned in the annual report of 1876 under No. 1-21, were now examined to discover their alkaloids. A relatively large quantity of pure quinine was taken from the wood, but there were only slight traces of alkaloid in the leaves, the nature of which could not be ascertained more accurately. The particulars are noted under 9, 10, and 11. The analyses 2, 3, 5, 6, 7, and 8, are of young Ledgerianas obtained from seed. The bark No. 2 was procured by pruning—being from branches of different ages—mixed with stem bark of young trees that had been uprooted by storms. The details* under 3, 5, 6, and 7, are of private plantings of four and five year old trees, whilst

No. 8 is of large-leafed offshoots of *C. Ledgeriana*, the alkaloid properties of which point to a hybridization with *C. succirubra* as the habit does. The difference between original and two year old renewed barks of *C. officinalis* and *C. Calisaya Schuhkraft* is seen in the following review:—

On the whole the bark of *C. officinalis* may be said to be better after renewing, because it contains more quinine on an average than the original bark. The most remarkable feature in the forming of new bark is the great decrease, and generally the total disappearance, of the entire quantity ot cinchonidine which appeared in the old bark, whilst the quinidine increases. The increase of quinine in *C. Calisaya Schuhkraft* was so little, that it was decided not to apply the partial stripping to this variety. From the examination of renewed succirubra barks we learn that the nature of the covering produces little change in the nature of the alkaloids that appear in the renewed bark The bark (29-51) renewed under *indjoek* covering showed the same increase of quinine and decrease of cinchonidine as is seen in bark that had been renewed under moss. And the same peculiar change was observed even in renewed bark without covering (33). The renewed bark of a yonng Ledgeriana on the private plantation Djajagiri was also very luxuriant. In 1879 a strip of bark was cut off, which contained 5·88 per cent of quinine with a total of 7·44 per cent of alkaloids. At the expiration of nearly a year this tree was rooted up by a storm, and the renewed bark of eleven months old collected. This now gave on analysis (4) quinine 6·86, with a total of 8·79 per cent of alkaloids. The analyses of samples of bark from the crop showed little of importance. Mention is only made of the alkaloid found in officinalis bark taken from trees dug up at Tjinjiroen and which had been sickly for years; and of *C. Sancifolia* dug up at Rioen-Goenoeng, both because that variety grew badly there, and the room they took up could be more profitably used for succirubra. In accordance with Government resolution of 5th December 1879, No. 23, the Director of the Government Cinchona Cultivation left this on 19th August for Ceylon and British India, and returned on 31st December.

Bandong, 14th February 1881.

Appendix A showing the condition of the Government Cinchona plantations in Java in the years 1878, 1879, and 1880:—

REMARKS.—No. 1, original tree in flower; 2, branch bark of four and five year old Ledgeriana; 3, young stem bark and branch bark of do do; 4, renewed bark, 11 months old; 9, stem wood; 10, root wood; 11, leaves, 12, crop 1st quality; 13, crop dust; 14, crop root bark: 18, covered with moss one year; 19, to 24, renewed bark, two year old; 25, renewed bark, 32 months old; 26, renewed bark, 36 months old; 27, original bark same tree, cut off above renewed strips; 28, original bark same tree, three year old, covered with moss; 29, renewed bark, 22 months onderiod joek, uppermost part; 30, do do do middle part; 31, do do do lowermost; 32, original bark, same tree, cut off above renewed strip; 33, renewed, with covering, 24 months old; 32, original bark of same tree; 35, chips; 40, Koeripan is situated at about 400 ft. above the level of the sea; 41, renewed bark, 2 year old No. 1; 42, do do No. 2; 43, do do No. 3; 44, crop 1st quality; 45, do dust; 46, do root bark.

REPORT ON THE GOVERNMENT CINCHONA ENTERPRIZE IN JAVA FOR THE YEAR 1881.

BY J. C. BERNELOT MOENS.

(*Translated for the "Tropical Agriculturist."*)

1.—*Weather.*—For the first time for two years we had in 1881 once more a regular alternation of rain and drought. In the first quarter February was the driest month, in the second quarter the rains continued, so that on Kawah Tjiwidei in the three months 1,092, on Tjinjiroean 643, and on the Tangkoeban Prahoe 435 mm. rain fell. In the first days of July the drought began, and this lasted until the beginning of November, when the west monsoon set in in force. In January about 2,000 trees were destroyed by a storm on Nagrak; the other establishments did not suffer from it. During the dry monsoon night frost was again twice experienced. In the same gardens where, in 1877, plants were killed by it, flat, in some measure basin-shaped spots on the plantation at Tjibitoeng, the trees again suffered most. A 1½ year old group of *C. succirubra*, consisting of very well developed trees, was damaged the worst: they were frosted down to the ground; but there was enough of the lower part of the stem spared to allow of sprouts to be formed on it, which are now growing vigorously. The weather was on the whole very favourable for the growth of the trees, and the comparatively long drought was all on the side of the harvesting.

2.—*Increase.*—At the end of December the number of trees planted in the open had reached 2,036,450. Of this 73,000 are grafts and cuttings of *C. Ledgeriana* and 547,480 Ledgeriana seed-plants. In the nursery beds there were also 515,000 plants of this variety, of which 8,600 were cuttings and grafts. As in 1880, so in the past year, the quantity of Ledgeriana seed from the original trees was very small: the continuous rains of 1880 deprived the trees of the rest which is necessary in this variety for an abundant blossoming. In 1881 circumstances were much more favourable, so that a larger crop of seed may be reckoned on for 1882. As all the seed of the original trees was needed for the Government plantations, a number of analyses were made to ascertain which of the plantations of *C. Ledgeriana* descendants were richest in quinine, in order to furnish seed to private planters. As a result of this a plantation at Rioeng Goenoeng, consisting of descendants of mother-plant No. 4, was set apart for that purpose. Ten of the best trees of this garden gave 8·45 p. c. quinine, ten less good 6·39 p. c., so that it may be assumed that the seed supplied is obtained from trees with a medium yield of 7·4 p. c. quinine. The grafting of Ledgeriana on succirubra stems was continued. As the European nurseryman E. Veulemans had asked for his discharge at the end of the previous year, the grafting was continued by the native grafters trained by him. It appeared however that although these were suitable for the mechanical work, the whole care of the plants in the nursery boxes could not be entrusted to them, so that it is intended to obtain from the Netherlands a new nurseryman, acquainted with the method of grafting adopted here. The planting of *C. succirubra* on places which from one cause or another are not suited for *C. Ledgeriana* was continued steadily. Their number exceeded 147,300. *C. officinalis* is still confined solely to Kendeng Patoeha: the number of plants in the open now reaches 458,100, or 50,050 more than in 1880. In May another welcome lot of seed was received from the Netherlands Consul at La Paz, Heer Schuhkraft. From this have been obtained:—

- 5,500 plants of the finest Calisaya of Mapiri,
- 6,200 „ „ fine „ „
- 260 „ „ Calisaya of Inquisivi,
- 270 „ Cocola,
- 1,400 „ Zamba morada, and
- 3,700 „ Durazmillo.

Although the plants are still too small for us to be able to decide with certainty as to the varieties, it is evident that the first three belong to a variety closely related to *C. Ledgeriana*. *Cocola* is abandoned as an inferior variety: the seed is very peculiar and agrees only with that of the *C. cordifolia* of Venezula; the last two varieties must apparently be connected with *C. Josephiana*.

3.—*Extension and Upkeep.*—At Rioen Goenoeng, Kendeng Patoeha and Tirtasari the land opened in the previous year was cleared for plants. Of the land reserved for the lastnamed establishment 7 bouws besides were opened. The uprooting of fields of Calisaya was proceeded with on all the establishments, in order to utilize the ground thus gained for the planting, according to circumstances, of *C. succirubra* or *C. Ledgeriana*. The succirubra plantation at Lembang, of which it was said in the previous year's report that it did not appear a success, has been completely restored, by a steady thorough digging, kept up throughout the almost four months of continuous drought. All places planted a second time however require much care, effort and labor, to obtain for the trees standing there a satisfactory growth. Nevertheless, among them are included very vigorous gardens, where the trees show themselves grateful for the great trouble and are not inferior to those planted in virgin forest soil. The measurements begun in 1879 and 1880 were repeated in the same month of 1881. Although the plantation at Tjibeureum has recovered from the great damage which the *helopeltis* did there in 1879, the growth cannot yet be considered normal. The mean height was now 2·44, the diameter of the crown 1·42, the circumference of the stem 0·18 min. measured at 0·1 min. above the ground. The maximum found among these trees was: height 3·10, crown diameter 1·80, stem circumference 0·28 min. The grafts and cuttings at Tirtasari, which were planted in November 1879, and the length and girth of which were first determined in the same month of 1880, were now once more measured. The cuttings were on an average 1·32 min. high, had a crown diameter of 0·79 and a stem circumference of 0·09 min. at 0·1 min. above the ground. Among the grafts these were: 1·64, 1·28, and 0·13 min. The largest of these grafts was 2·19 min. high, had a crown diameter of 1·60 and a stem circumference of 0·18, whilst in the case of the most developed cuttings these were 1·80, 1·15 and 0·135 min. The grafts had increased so much in breadth that they had already begun to hinder each other in growth. although they were planted at a distance of 6 feet apart and were scarcely two years old yet. On this account, and because they showed too much tendency to grow shrubby, they were in October denuded of their lowest branches, in order to force them to grow more in length. The healthy appearance and the vigorous growth of these grafts hitherto leave nothing to be desired. The *helopeltis* steadily continues its ravages, and we are powerless to combat the little insect. The catching and killing was carried on in the young plantations, but the effect is very local, and those caught are speedily replaced from the millions that live on the high trees in the older plantations. At Nagrak a disease appeared in the officinalis plantations which apparently must be ascribed to the destruction caused by the location of a fungus in the bark. The tops of the plants are found to die off here and there, to about 3 to 6 feet from the ground, above a place on the stem where the bark is discolored and generally swollen. The portion of the stem below and the root are perfectly sound, so that the affection is a local one, and the explanation is very probably that it is caused by a fungus, which first obtains a nidus in the bark and then extends its ravages also to the wood, until the tissue is so altered and destroyed as to render impossible the nutrition of the portion of the stem situated above the diseased place. I caused all the diseased tops to be sawn off, and after the bark was gathered from them the wood to be burnt.

4.—*Harvesting of Bark.*—The crops of 1881 amounted to 82,697·5 kilograms, of which 81,043·5 kil. were sent to Europe, whilst 1,654 kil. were reserved for the medical service in N. India. Drying was rendered very difficult by the prevailing east monsoon. At Nagrak a drying-room has been erected, which was ready for use in November, and gave satisfaction. As the necessity for artificial drying is much felt, now that harvesting is carried on throughout the year, two of the other establishments will also be provided with similar drying-rooms. The transport of cinchona bales went on regularly and caused no trouble, though the price was somewhat high. An average of 3 49-100th cents per kilogram to Tjicao was paid. The bark harvested in 1880 was sold in Amsterdam on 12th July, at the following average prices per half kilogram:—

C. succirubra	*f*1·55[5]
„ Calisaya Javanica	1·32[5]
„ „ Schuhkraft	0·93[5]
„ Ledgeriana	5·86
„ Hasskarliana	0·92
„ officinalis	2·45
„ lancifolia	1·25
„ Pahudiana	0·95

or an average of *f*1·365 per half kilo. There was, at the time of the sale, a great decline in the prices of bark, so that the average price was consequently lower than that of 1880, though the composition of the lots was not materially different. The Ledgeriana bark cut in flakes fetched *f*6·94 to 7·48 per half kilogram. The two year old renewed Ledgeriana bark cut in flakes fetched, on the other hand, only *f*5·76 per half kilogram. The yield of quinine was lower than that of the original bark, and its separation was besides less easy, on account of the greater quantity of resinous and coloring matter. It has therefore now been resolved to leave the renewed bark of this variety until it is three years old before it is shaved off. Partial stripping has been carried on more and more largely, whilst the experiments with shaving have been continued on an extended scale. Although an opinion cannot yet be given with certainty as to the comparative value of these two methods, it is probable that in the case of *C. succirubra* partial stripping with a subsequent covering, and in those of *C. officinalis* and *C. Ledgeriana* shaving, is preferable. For covering, grasses are now exclusively employed: where alang-alang is easily procurable it has the preference, but other grasses also, found on the plantations, appear to be very good for use. The covering is bound fast with indjoek string, which is very durable and is used solely for this purpose, or with ratan. It is worthy of remark that for the first time the younger Ledgeriana plantations contributed to the harvest. At Tjinjiroean they were pruned, and at the same time trees of a very bad type, which proved evidently hybrids, were dug out. At Nagrak 13 bouws of 5 to 6 year old plants were pruned, which yielded an average of 700 kilograms per bouw: thinning out can, after this pruning, be deferred. At Tritasari it was necessary to prune the grafts, the oldest of which were just two years, and by this means about 150 kilos per bouw were obtained.

5.—*Staff and Expenses.*—Among the assistants there were the following changes in 1881:—J. J. A. Zijmers was promoted to overseer of the 2nd class, J. H. Heijnneman, who was formerly discharged on account of sickness, was again appointed overseer of the 2nd class, and O. Furst Bruininga acting overseer of the 3rd class. The fixed native staff consisted on 31st December of 1 cinchona mantri, 1 carpenter, 1 packhouse-mandoor and postman, 15 mandoors, and 221 boedjangs. The supply of labor was on the whole satisfactory. Wages, however, are slowly increasing. At Kawah-Tjiwidei the second nursery-house was also taken down. The materials were collected in order to build in 1882 a new, very large nursery-house at Tjinjiroean, of which there was need, on account of the extension which has been given to grafting under glass. The glass of the dismantled nursery-houses at Kawah-Tjiwidei will be utilized for that purpose. The expenses on account of the enterprise comprised:—

Salaries of European staff	*f*28,925·00
Correspondence	360·00
Travelling and halting expenses ...	2,720·32
Salaries of the fixed native staff ...	22,517·15
Wages of day laborers	11,408·11
Manufacture and repair of tools ...	588·52
Transport and packing of bark ...	5,603·86
Do. of money and materials ...	94·75
Materials of nursery-houses, drying furnaces and sheds	2,071·74
Requisites for the chemical laboratory	121·30
Servants for the laboratory	180·00
	*f*74,590·75

being *f*7,730·75 more than was estimated in the budget for 1881. This increased expenditure was chiefly due to the much larger harvest, the erection of a drying-room, and the rise in wages.

6.—*Distribution of Cinchona.*—It has already been stated above that the applications of private persons for seed from original Ledgeriana trees could not be met. Seed of descendants rich in quinine was however fully available, and was distributed in large quantities, as also succirubra and officinalis seed. Already several of the private growers are providing themselves with tree gardeners, in order to practice grafting on a large scale. The opening up of lots situated at considerable distances from the Government cinchona gardens has proved that the varieties of cinchona are already beginning to spread in the original forest

Many small trees were found there, which must have sprung from seed carried thither by the wind.

7.—*Information regarding Varieties of Cinchona grown in Java.*—The Calisaya plants raised from the seed received in 1872 from Mr. Schuhkraft gave a disappointing result on the determination of the yield of quinine. One of the thirteen trees is beginning to bud, so that a further investigation into this variety can be made. Plants of "hard Carthagena" were brought by the Director of the enterprize from British India, but they have all died. Plants of the hybrid raised in British Sikkim are however still living. 24 plants of *C. Pitayensis* (*C. Trianae*) have been obtained from seed received from Ootacamund. The hybridization experiments were carried on with success. Besides the plants already obtained of *micrantha* with *Calisaya Javanica micrantha* with *Calisaya Schuhkraft*, & *succirubra* with *Calisaya Javanica*, this year plants were got by the fertilizing of *C. Ledgeriana* with *C. succirubra*, *C. succirubra* with *C. officinalis*, *C. officinalis* with *C. succirubra*, and *C. Pahudiana* with *C. succirubra*. As a rule all these hybrids held the mean, as regards form of leaf, very clearly between those of the two parents. The hybrids in which *C. micrantha* is represented have generally a more or less marked purple tint on the under surface of the young leaves, just as is so strongly the case with *C. micrantha*. We have already spoken above of the seed received in the course of the year from Consul Schuhkraft.

8.—*Chemical Analyses.*—In the annexed statement B the principal results are recorded of the determinations of alkaloidal yield performed during 1881. Nos. 1 to 6 are analyses made with the view of ascertaining the value of the change which the bark of *C. succirubra* undergoes when it renews under covering after being shaved. It appears to correspond exactly with the alteration that takes place in the value of the alkaloids if the bark renews itself after being, according to McIvor's method, peeled off in strips, and these analyses confirmed the view already propounded by me, that the increase in the amount of quinine and the decrease in that of cinchonidine has no connection with the covering of the tree, but is a result of the process of renewing itself. This is also confirmed in the case of *C. officinalis* by analysis 20. On shaving the tree referred to under 5, the crown of the high stem was not looked at. But as the analysis showed a very abnormal yield of quinine the tree was more carefully examined, and it then appeared that it belonged to the officinaliform hybrids, which in leaf and blossom differ markedly from the true *C. succirubra*, and now and then this variety is met with in the cinchona plantations. Those mentioned under 18 and 19, which are found in the officinalis plantations at Kendeng Patocha, exhibit analogies with these. The value of the alkaloids also corresponds, but the yield of cinchonidine is extraordinarily high. Closely connected with these hybrids are Nos. 28 and 29. Known as *C. pubescens* in the British India Plantations, their value is to my mind generally estimated too high. Nevertheless, on account of a quinine-yield of 2 to 3 per cent. and forming besides a free quick-growing tree, it is worth the trouble of cultivation, and there is a great likelihood that on reproduction of its bark, after partial stripping, it will form considerably more quinine. The barks 13, 15, 16 and 31 were brought by me from British India, in order to see if there was much difference in the alkaloid-yield of the homonymous barks. The *C. succirubra* from Rungbee in British Sikkim, picked out by myself as a typical example, differs from ours in a lower cinchonidine and a higher cinchonine yield. This explains why the quinetum prepared there differs so greatly in composition from that prepared from the Javanese bark. The officinalis bark No. 15 was from trees which were no longer attended to, as the cultivation of this variety has been given up in British Sikkim. These and the abovementioned barks correspond moreover entirely with those of the same variety cultivated in Java. No. 30 is the bark of *C. pitayensis*, better named *C. Trianae*, which I have this year introduced into Java. It is worth cultivating, on account of its satisfactory yield of quinine and very high yield of quinidine. The 24 plants which we possess of this variety will be planted out at various elevations in order to find where they grow best. It is asserted that they thrive best at the height of 7,000 to 8,000 feet above the sea. The trees 33–35 described as *C. Calisaya* are three of the thirteen obtained in 1873 from Bolivian seed provided by Hr. Schuhkraft. As the appearance exhibited much agreement with Ledgeriana, the analysis was disappointing. The very high amount of cinchonidine, which appears to take the place of quinine, is very remarkable. At the end of the year, not one of these trees had yet blossomed, but one had begun to form buds. The analyses 36–43 are of already examined original Ledgeriana trees; the amount of alkaloid generally does not increase in certain years, as is seen from the following statement:—

Here and there a diminution has even taken place in the quinine and nearly always an increase of the cinchonine. Noteworthy is the increase in cinchonidine of No. 24, which in 1874 had only a very small quantity. The decrease in alkaloids may perhaps be the result of a superabundant formation of crust (rhytidoma), which contains much less alkaloid than the living bark. As this crust is pounded to powder with the bark for the analysis it naturally lowers the total amount of the various alkaloids. It may well be taken for granted that on the whole Ledgeriana bark is ripe in the 7th to 8th year, and that it does not increase in quinine after that age. The two year old Ledgeriana bark, renewed after shaving, No. 46, was not so good as the original, and made the crystalization of quinine sulphate difficult, on account of the great quantity of coloring matter. It was therefore resolved to leave the bark to become older by another year before it is shaved off for the second time. The analyses 48 to 69 served to check our practise in picking out various types in the plantations. The choosing according to external appearance seemed to be generally right. At Tjinjiroean the evident hybrids were removed from various plantations; 70-73 are specimens of the product thus obtained. At Tirtasari and Nagrak also young Ledgeriana plantations were pruned, on the first-named establishment five to six year old plants, raised from seed. The analyses 74-85 are of that product, and show therein a quinine-yield of from 1·5 to 3 per cent, whilst the prunings of the yet very young grafts contained already 1·38 per cent quinine. That no cinchonidine was found therein is important, as the fear might exist that the succirubra stock exercised influence on the Ledgeriana grafts, so that cinchonine formed in the latter. The further analyses of the harvest, which are collected in the statement under notice, yielded nothing of importance. In statement B, however, I have noticed those of *C. lancifolia*, because they show that these plants, obtained from seed of the original trees, however much often differing in exterior yet agree on the whole with the mother trees in the quality and quantity of the alkaloids.

Bandong, 1st February 1882.

Review of the alkaloid determinations performed during 1881.

REMARKS.—No. 1, original bark; 2, bark renewed after shaving, 2 years old, of the same tree; 3, original bark; 4, bark renewed after shaving, 2 years old, of the same tree; 5, officinaliform hybrid: original bark; 6, bark renewed after shaving, two years old, of the same tree; 7 to 10, sample of the harvest; 11 and 12, twig bark; 13, very typical, 13-year tree; 14, original bark cut in slivers; 15, sickly neglected trees; 16, renewed 4 year bark; 17, narrow-leaved variety (var. angustifolia); 18 and 19, very broad-leaved, succirubra-like hybrid; 20, 2 years bark, renewed, after shaving of the original; 21, do do after partial stripping; 22, loppings from trees that died at the top; 23, specimen of the harvest, 1st quality; 24, do do 2nd quality; 25 do do 3rd broken quill; 26, do do dust; 27, do do root; 28, original tree of McIvor; 29, descendants from seed of the foregoing, 8 years old; 30, ten year old tree; 31, 18 year old tree from seed from Peru; 33 to 35, 8 year old tree from seed from Bolivia (Mapiri); 36 to 43, original tree, serving for seed-bearing; 44 and 45, blossoming tree reserved for seed; 46, bark renewed after shaving, 2 year old; 47 and 48, original bark shaved off: harvest; 49, descendants of No. 9 five years old; 50, do No. 19 do do; 51, do No. 2 seven do; 52, do No. 4 five do, best type; 53, do No. 4 do do less good type; 54, do No. 3 seven do best type; 55, No. 3 do do middling type; 56, do No. 3 do do bad type; 57, do No. 40 do do best type; 58, do No. 40 do do middling type; 59, do No. 40 do do bad type; 60, do No. 12 do do best type; 61, do No. 12 do do middling type; 62, do No. 12 do do bad type; 63, do No. 12 do do best type; 64, do No. 12 do do middling type; 65, No. 12 do do bad type; 66, to 69, do. 13; 70 and 71, branch bark of 7 year old descendants; 72, stem and branch bark of Ledgeriana hybrids; 73, root bark of do; 74, twig bark of 2 year old grafts; 75 to 83, twig bark of 5 to 6 year old descendants; 84, stem and branch bark of do; 85, twig bark of 5 to 6 year old descendants.

GRAPE CULTIVATION IN CALIFORNIA.

The Californians have gone in for the cultivation of the grape with the same energy which they manage to infuse into every industry which they undertake. According to a recent writer in the English press, viticulture is now carried out in that much-favoured country with extraordinary activity. Very large districts are now planted with the grape vine, and the yield is enormous. It is calculated that within three years the vine will produce a wine making grape; in the fourth year there is a profit, which in the fifth year is sufficient to pay off all preliminary expenses, including the cost of the land. Some idea of the extent of cultivation may be gathered from the figures given. This year's crop of grapes will produce five hundred thousand gallons of wine and a hundred thousand of brandy. The labour is mostly that of the much-abused Chinaman, although a number of skilled experts from the wine districts of France and Germany are also employed. The process is simple enough, and is greatly aided by machinery which does the stemming and squeezing. After that the liquid is clarified by white of eggs, isinglass, or gelatine, filtered through charcoal, and drawn off into casks for shipment. Great quantities of these Californian wines are consumed in the States, and no pains are spared to make them popular. Cuttings of the best vines are imported and acclimatised. Just now experiments are being made with the Cochin China grape, one of the most prolific in the world, and no doubt we may yet see an American imitation of that rare and costly kind known as Imperial Tokay.—*Planter and Farmer.*

COCONUT CULTIVATION.

In the whole range of tropical products there is not one, perhaps, which shows such satisfactory results, *on paper*, as the coconut, that is to say, if the investor can afford to wait seven or eight years for the first return. It is easy enough to demonstrate, as a writer in the last week's *Field** does with regard to coconut planting in Fiji, that when the trees come into full bearing, the return upon the capital outlay is something enormous, or, at all events, it ought to be if every tree bore the number of nuts annually with which it is credited in the preliminary calculations, but whilst we call attention to the facts and figures set forth by the correspondent alluded to, we desire to preface them with a word of warning to those who may be inclined to think that they open up a new El Dorado to tropical planters. Let us not be understood, however, to question his statements as regards Fiji, because we have no personal knowledge of that colony, but very similar statements were put forward thirty or forty years ago respecting the coconut enterprize in Ceylon, with the result that a large amount of capital was invested in the creation of estates in the Batticaloa district on the east coast, and they turned out very disappointing ventures. The land was considered admirably adapted for the purpose, and a moderate price was paid for it, probably not more than £1 per acre, if as much, labor was cheap, and there was no extravagant expenditure in any department of the work, nevertheless it was found after ten or fifteen years that the properties gave no adequate return, for the simple reason that the trees did not bear as had been expected. The proprietors were, for the most part, non-resident, and their Ceylon agents having been requested to investigate the matter, discovered that the yield averaged only from two to ten nuts per tree per annum, instead of 25 to 40, which had been the estimate framed beforehand. They found, moreover, that an average yield of five nuts per tree about paid the expenses, these being very trifling, and of course those estates which gave ten nuts per tree left a small margin of profit, whilst those giving only two nuts per tree were a dead loss. No satisfactory explanation was forthcoming as to why the crop turned out so much less in all cases than had been anticipated, but there was the indisputable fact. The Sinhalese have a saying that the coconut tree will only bear, or, at all events, only bear well when it is within sound of the human voice, which practically means no doubt, that trees scattered about native huts, and, consequently, receiving constant attention and a certain amount of fertilizing matter, do better than those planted out in big estates, and it follows that calculations based upon the yield of the former are misleading when applied to the latter. In face of this experience of coconut planting in Ceylon, we cannot but recommend our readers to be cautious how they embark in the enterprise elsewhere.—*Planters' Gazette.*

* See page 772 of *T. A.*—ED.

THE SUPPLY OF TEA AND SUGAR.

The present condition of the two commodities which are so closely allied to the grocery trade is just now peculiarly interesting. Of the former there is, according to some of the prophets, a shortage in the supply, but we do not think that there is any fear of a tea famine, for reasons we gave in our last issue. We believe that the recent rise of 50 per cent in value is not justified by the situation. On the other hand the visible supply of sugar, according to the latest dates, is nearly 180,000 tons over that of last year. The consequence being that raw sugar is today as low as it was ever known.

The world's consumption of sugar, particularly Europe and the Northern hemisphere of this continent, has increased enormously and it was predicted some time ago that the supply would, in time, fail to keep pace with the demand. When these prophesies were made it was not expected that the consumption would increase to such dimensions in so short a time. Last year alone the consumption of sugar in the United States increased 80,000,000 tons and in Europe proportionately. But in spite of this great increase the stocks are augmenting.

The development of new sources of supply is the main cause of cheap and abundant sugar. In Europe beet sugar alone has increased from 1,860,947 tons in 1881-82 to 2,240,000 tons (estimated) in 1883-84. Not only has the cultivation of beets increased, but the yield of sugar through improved machinery has also added considerably to the result.

The development of the cane production too is also being pushed in every part of the globe where it is at all likely to be profitable. We learn that sugar is being cultivated to a profit in Northern Australia. This is to some extent a surprize, for it was always believed that the sugar cane could not be successfully cultivated excepting in the tropics. Of the recent experiment made by the sugar company of Sydney a writer says: "I have been informed that the return per acre in the Mackay district is 2½ tons and in the Burdekin district 3 tons. "It is found," says the same writer, "that capitalists from Victoria and New South Wales have secured all the best land, and that the sugar brings about $150 per ton for good refining. Laborers can earn from $2 to $2 25 per day, and a large supply of the raw material may be looked for from this quarter."

From Queensland we also have encouraging reports of the cultivation of the sugar cane. Even from the Fiji Islands we have the same story. These islands, which only a short time ago were little heard of except as the habitation of a race of cannibals, last year made their first export of sugar on a large scale. One cargo alone was estimated at over $90,000 in value. English capital is being employed and a great increase in the production is almost certain. Then the islands of Borneo and New Guinea, the two largest islands of the Oceanic group, have yet to be heard from. Therefore, a sugar famine, according to the present outlook, appears to amount to an impossibility.

A gratifying feature of the present condition of the trade is the satisfaction with which such old sugar producing countries as Java view the situation. A correspondent to the *India Mercury* says:—

"The sugar industry in Java runs no risk, as many manufacturers have feared for a long time. The production is importantly increasing, and to the constant improvements in culture and preparation, will be owing—I have not the least doubt about it—that it will be able to bear up aginst the sister-industry, which continues so vigorously to extend itself in Europe."

This compares very favorably with the ridiculous cries we hear from our Louisiana planters against free sugar.

The tea supply has not made such rapid strides as its companion, sugar; not because new fields of supply have not been forthcoming, but because the old sources, probably owing to the peculiarity of the Chinese, have not made much progress. India has unprecedentedly increased its production, its exports amounting last year to 60,000,000 pounds, almost as much as the total consumption of this country. Ceylon has made rapid strides both in the production and quality of tea in recent years. The Mariawatta tea estate has marketed its entire crop at an average of 35 cents per pound, which is, we understand, the highest price ever recorded for an entire crop. Java is also making progress, but not at the same pace as either of the former. Fiji may develop in a tea-producing country, for, according to the the *Australasian*, "a small quantity of tea grown and manufactured on Mr. James E. Mason's Alpha Estate, Taviuni, has been offered for sale by that gentleman's town agent, and its strength and purity of flavor are very highly spoken of by those who claim to be judges. The favorable result of the several experiments which have been made at various places on that island leave no doubt as to its capability for tea culture, and the industry promises encouraging returns for its more systematic prosecution." With the energy displayed in recent years by the nations in the East, our supply of tea, both in quality and quantity, is in a fair way of being vastly enlarged and improved.—*American Grocer.*

[We need scarcely tell our readers that the Mackay and Burdekin districts are both in Queensland, but we must add that the figures for yield are far too high.—ED.]

THE JOHORE RHEA COMPANY.

The preliminary arrangements for launching this company, the general outlines of which were sketched in our last, are making rapid progress in the hands of Messrs. George W. H. Brogden & Co., the London agents of the Lini Soie Syndicate, and we understand that in a few days subscriptions to the share capital will be publicly invited. On the 18th ult. a largely attended meeting was held at St. Michael's Hall, George Yard, in response to an invitation from the firm in order to hear what are the prospects of the enterprize, and to afford those interested in Rhea production and utilization an opportunity of putting questions upon any point connected with either branch of the subject. Various fabrics manufactured from Rhea, and used in conjunction with other materials, silk, wool, and cotton, were exhibited in the room. Mr. W. Leedham Crowe was voted to the chair, and stated that Messrs. Brogden & Co. were interested in England as the agents of two processes of treating Rhea fibre (the Favier and the Frémy-Urbain processes.) Mr. Watson was a successful planter who had been resident for some years in Johore, and possessed virgin lands there, which were considered of great value; and Johore was a country in which Rhea was indigenous. These facts formed the basis of a *pro forma* prospectus of the Johore Rhea Company. He believed there were two objects in calling the meeting; first, that those who attended might see the articles made from Rhea, or in combination with other products, and to ask Mr. Watson any question; and secondly, to see whether it would be possible to carry out the scheme of forming the company without going to the public. Mr. Casper afterwards addressed the meeting, and spoke of the enormous value of China grass, and of the various uses to which it can be applied. The article was no new thing, but its use had been limited, owing to the heavy cost hitherto of preparing it ready for the spinners. By the processes referred to, he stated that the present cost could be reduced by about one-half. Spinners would need no change of machinery or of their work people. The reason why capital was asked for was that the gentlemen so far concerned in the scheme (the Lini Soie Syndicate) had spent all their available capital in bringing the affair to its present state. They had now, he stated, works enabling them to produce anything which was, or could be made from China grass. As one proof of the superiority of Rhea fibre, he mentioned that some leading manufacturers of fire-hose had tested it against the ordinary material, and found that whereas the latter commenced to "weep" at a pressure of 100 lb, Rhea cloth would stand a presure of 600lb. Mr. Casper, having explained that the demand for Rhea fibre at a moderate price would be practically unlimited, proceeded to point out the advantages offered by Johore for the production of the plant, and the very favourable terms upon which the proposed company would acquire 21,000 acres of virgin land there from Mr. Watson. Estimates of the cost of planting and of annual up-keep had been prepared by several gentlemen of long experience in India and in Alegria, and these had been revised by Mr. Watson with his thorough knowledge of Johore with the following results:—

Cost of planting one acre of Rhea in Johore.

Clearing the land and burning the wood	Value of the wood.		
Levelling and straight lining ..	£1	5	0
Planting of 16,000 plants ..	1	5	0
Hoeing and weeding	1	0	0
Superintendence	1	2	6
Contingencies	0	12	6
Total cost ..	£5	5	0

Annual Expenditure per Acre

Rent of the land	£0	8	0
Harrowing and weeding	1	0	0
Cutting the stems	1	0	0
Carriage to the steam chest	0	5	0
Cost of drying and baling	0	1	3
Superintendence	1	0	10
Contingencies	0	9	2
Total cost ..	£4	4	3

Note.—As the head of each stem gives a cutting which will serve for planting up fresh land, the item for cutting the stems is reduced thereby.

In Algeria the cost of planting an acre was £12 9s 6d, and in India it was estimated at £7 10s 10d to £9 9s 2d, but in both these, provision was made for manuring and watering the land which would not be necessary in Johore. To all these, however, must be added £8 per acre the cost of the plants. There was no tropical product which could be so cheaply cultivated, and none that would give so large a return.

Explanations were given by Mr. Watson in reply to various questions addressed to him by those present, which confirmed the statements made as to the suitability of the soil and climate of Johore, the abundant supply of Chinese labour available, and the accessibility of the land selected. We need not go at length into the discussion which followed, but it was abundantly evident, from the views expressed by manufacturers present, that the value of Rhea for textile purposes is recognized, and that they will only be too glad to avail themselves of it, if it can be sold at a price to compete with flax. The chairman in conclusion expressed the opinion that the object of the meeting had been fully attained in the ventilation of the subject.

The Lini Soie Syndicate is convinced that in the Favier-Frémy patents, it has secured the best possible means of treating Rhea, and that through their use the cultivation of the plant will, in suitable localities, and where labour is cheap, prove highly remunerative. It will be observed that the Syndicate proposes to confine its attention exclusively to Rhea, and in this it is wise, because here it is working on the solid ground of repeated trials, and there is obviously abundant scope for its operations in this one product.—*Planters' Gazette.*

LIMESTONE A MANURE FOR TEA.

It seems now to be tolerably well accepted that the future of Indian tea depends, first, on better communications, to enable planters to place labour on their estates at but a tithe of the ruinous cost at present ruling; and secondly, on the throwing up of all unprofitable patches and the concentration of all energy on the high cultivation of those portions of the gardens which, from *jat* of plants and suitability of lay and site, promise remunerative returns. By the term 'high cultivation' we do not mean the ceaseless hoeing of steep inclines or even of flat lands, liable to submergence during the rains, but the application to tea planting of those principles of agricultural science that have proved so successful in Europe, America, and the Colonies. The tea planter of the future must combine within himself not only the qualifications that have hitherto been considered those of a good manager, tea-maker, and accountant, but he must also be a skilled agri-horticulturist, versed in the treatment of diseases incidental to the tea plant, the proper drainage of low land, and the application of manures, in the blending or proper admixture of which he will have to become an adept. Some time ago the *Indian Agriculturist* drew attention to the value of crude limestone as the basis of most of those fertilizing agents which have now become recognized as necessary stimulants to all lands that have been under cultivation for more than five years,—by which period the average of our tea plantations attain their maximum yield. That there are exceptions we know, but we are here concerned only with tea gardens as a whole.

In selecting sites for tea planting, no one who could get flat land would select *teelahs*. But though a large area of desirable plots exists, they are mostly in the hands of native or other proprietors, and thus many people in opening out fresh lands to supplement their present area are compelled to make use of *teelahs* more or less steep, and to counteract the drawbacks of such lands by a system of 'terracing.' Now, though this system is imperatively demanded to keep the plants in proper position on the hilsides almost all the surface soil is so much disturbed in the primary operation, that at the end of the rains but a very small proportion remains *in situ*. Theoretically, the only portion of the terraced land thoroughly deprived of the original vegetable deposit is the apex of the *teelah* so treated, the argument being that what surface soil is disturbed from above is retained on the lower terraces. But if we will but watch the effects of heavy rain on newly terraced land, it will be apparent that the surface soil, from the light nature of its composition, is carried so rapidly over the edges, as the terraces becomes soaked with water, that it is almost all washed down to the foot of the hill by the end of the first rainy season; and although the loss of it has no material effect on the tea plant for the first year or two, a few minutes reflection will tend to show that manuring, by means of renovating pits upon terraced *teelahs*, is absolutely necessary from the time the plant commences to yield, because the very process adopted for the benefit of the plant at the outset is such as, by depriving the soil of its most valuable constituents, to ensure the rapid deterioration of its yielding powers. Much indeed might be done were the surface soil from the upper terrace scraped together, and buried either in a trench running right round the inside of the terrace, or in pits dug behind the place subsequently to be occupied by the plant. But although this might eke out the yield, possibly for a couple of seasons, it must now be apparent to all who have had experience of *teelah* gardens that, without renovating aid artificially supplied, the yield must gradually fall off until it becomes no longer remunerative. To any one knowing the Sylhet and Cachar districts tolerably well, this can be ascertained beyond all question by referring to the statistical accounts of the annual yield of the numerous gardens in the agency of the firm publishing the quarterly reports alluded to. In the instance of one garden, the falling off has been so marked as to lead the shareholders to look upon the existence of the Company to be ensured only by large extensions yearly; whereas, had the money already sunk in such extensions been employed in the scientific application of manure to the older portion of the property, the average outturn would have been maintained, and the garden kept within the original area. Moreover, these extensions necessitate a much greater expense in the way of additional labour and supervizion than the careful nursing of the old garden would require. We think therefore that the efforts of our tea planters should be directed to the utilization of all such material for forming manures as can be collected within a reasonable distance of the factory, such for instance as cowdung, stable refuse, and *bheel* soil. But it is evident that these manures alone do not possess the requsite strength to compensate the plant for the severe strain put upon it, and so long as this demand is exacted, it appears to us quite evident that something more stimulating and nourishing is required. A close investigation into the merits of limestone has confirmed us in the opinion that the present yield of our *teelah* gardens would be largely increased were a regular system of manuring resorted to, and we trust soon to hear that the collection of a compost of all animal refuse, mixed with one-third its bulk of crushed limestone, is being carried out on all gardens where renovating pits can be dug without endangering the stability of the plant. That this would be a work of time we admit, but in the present state of the tea industry an increased yield as soon as possible is absolutely necessary, and the effects of manure, such as we recommend, would increase the outturn for quicker than large extensions even of the best *jat*, which latter must always remain for two or three years at least a dead weight on the finances of the factory. Some doubts have been expressed as to the safety of applying limestone to tea, but as that matter can at once be set at rest by a visit to easily accessible places, we need do no more than refer to it here. Terriah Ghat, at the foot of the ascents to Shillong via Cherra Poonji, is well worth a visit, if merely for the purpose of proving our arguments in favour of limestone. For here may be seen its effects on jack, areca, sago, plantain and *pan* (betel pepper vine), while, close by, the Khassias at Bolahgunge have recently discovered that the apparently infertile sand *churs* exposed during the cold weather, are so impregnated with the mineral as to yield heavy crops of *dhal*, potatoes, and yams. Those who are under the impression that limestone is inimical to tender vegetable life, may be surprized to learn that the most delicate of all the ground orchids, *Anæctochilus*, is found in the most flourishing condition in the clefts of limestone reefs. To such as would wish to see the effects of the mineral upon tea, we recommend a visit to the Sundai estate in the Jaintia Hills. It will thus be seen that limestone is suitable for enhancing the yield of fruit-bearing trees, not plants and pure vegetation, as demanded by our tea planters. Our object in advocating its use as the basis of a compost, is that it is procurable in limitless quantities and at a nominal price—recommendations that should have due weight with tea proprietors at the present juncture. —*Indian Agriculturist*.

DISEASE IN SILKWORMS.

We drew attention some time ago to the effect which the disease of the silkworms known as *La Pébrine* was supposed by some experts to have on the silk crop of this country. As was to be expected our articles greatly interested those who were engaged in silk manufacture in Europe. There has been much discussion of the statements we made public. Requests to be furnished with specimens of silkworms eggs have been received here, and attended to. European experts will soon be able to examine these eggs thoroughly, and test their condition by the process of M. Pasteur. The results of that gentleman's scientific investigations of Chinese silkworm eggs will be interesting and valuable. French and Italian sericulturists will no doubt give their attention to the matter. Manufacturers of silk goods in Europe, whose business is so deeply concerned in there being always a good crop of raw silk obtainable for export in China, are pretty certain to take measures to have the extent of the evil ascertained. We may therefore hope that something will be heard of the result of the scientific investigations before many months have passed. Since our articles appeared, several people engaged in the silk trade here have carefully considered the subject of them. The result is, as we are informed, that two opinions now receive support among the trade. One party sees evidence of the existence to a serious extent of *La Pébrine*, and others, while admitting that the disease has always prevailed to some extent in China, maintain that it has hitherto been successfully treated by the natives. As we stated before, their method is to subject the eggs to baths of salt and water and lime and water, by which means it is held that they succeed in preventing the weekly and consumptive eggs from hatching. These precautions are thought sufficient by the Chinese, and those among foreigners who do not consider that the decline in the supply of silk in late years is attributable to disease in the worms. Only a small proportion of sickly worms, they say, pass the bath tests and thus propagate the disease. That may be true, or nearly so, but the means adopted appear to us to be insufficient to irradicate a disease, which, as we know from its ravages and effects on the production of silk in Europe, can carry such wholesale destruction. As a contributor shows in the *Chinese Notes* we publish in another column, disease among the silkworms had almost destroyed the silk production of France and Italy. The discoveries of M. Pasteur, and their application as remedial measures have almost entirely restored the silk production of these countries to its former dimensions. The method now so successfully adopted in Europe is to examine all the seed with a microscope, and to separate from the healthy eggs all those which show symptoms of their containing the corpuscle which forms the elementary part of the disease. This, we understand, can be readily detected. A further protection against the increase of disease is to set aside certain places exclusively for the rearing of silkworms, the products of which are solely used for the grainage, or for breeding. This industry has of late years become a special business, and has attained such an extent that it has superseded the old system of setting aside a portion of the stock of each silk-rearer for reproduction. It is now quite customary for the Italian sericulturists to repair to well-known establishments in France, conducted on the system of M. Pasteur, for their supplies of eggs. This, no doubt, accounts to a large extent for the excellence and amount of the European silk crop in late years and also for the low prices at which cocoons can be sold in Italy. The risks of silk culture are very much diminished by this newly adopted system, for a rearer now is less exposed to loss from defective or diseased seed; from which causes he might formerly have seen half his crop destroyed. The adoption of similar scientific methods in China is scarcely to be hoped for; unless under the fear of a still further decline in revenue and trade. The memorials to the Throne of high officials in this province have shown that they fully recognize the critical condition of the silk industry. But they attribute the falling-off in the crops in recent years to climatical causes only, and Li Hungchang, to whom a representation on the subject was made by a connection of a foreign firm here, has merely commanded that his approval be notified. At the present time the mandarins have enough on their hands with foreign affairs, and will certainly not now trouble themselves about an inferior matter like the silk crop. But it is to be hoped that foreigners will continue to give their attention to the subject and bring it before the notice of the Chinese.

One gentleman here, whose opinion is entitled to the highest respect, has given us his views on the effect of disease on the crops. He does not attribute the diminution in the production of silk to disease, but to atmospheric causes, and says:—

In my opinion the last bad crop in China has been the result of most unfavourable atmospheric circumstances, and has not been caused by an increase of the disease by which the Chinese worms are to a certain extent affected. The best proof of the correctness of my assertion, is, I think, that the eggs of the same season sent to Italy have given there a most satisfactory result, as the worms have distinguished themselves by the greatest regularity in their moulting, and their beginning to spin cocoons three days earlier than the yellow race, which is considered the best now in Europe. The cocoons produced have turned out brilliantly in spinning. Further, this year's cocoons produced in China do not show a great falling-off in quality compared with other years; the proportions between best cocoons and inferior sorts have been the same, if properly bought, and even the outturn in spinning showed only a slight difference. The falling-off of the crop during the last four years, is I think, easily accounted for by the low prices which have been ruling. That the Chinese eggs are diseased is no secret, and has been known as long as Europeans have been in Shanghai, and it is likewise known, that the Chinese have till now successfully controlled this disease by their method, in giving the eggs a salt bath, by which the weak eggs are killed.

He gives also a quotation from the *Dictionnaire de Séricologie* of Dr. Luppi, a translation of which is:—

The presence of corpuscules (or minute germs in the blood of the silkworm which generate disease), indicates nothing good but it does not indicate anything that is at all irremediable—as their absence is not a guarantee that is not an absolute incontestible proof of an extremely bad crop.

These are the views, and the experience in egg and cocoon buying this season, of the manager of one of the filatures now working here. We give them in order that all opinions on this important subject may be made public. He admits the existence of disease; and the fact that certain shipments of eggs to Italy turned out well does not amount to much. Those who believe that the falling-off in the silk crop is mainly attributable to disease, hold their opinion just as strongly as our correspondent does his, but the question of the progress of disease in silk worms' eggs is too important to be settled by the outturn of a few shipments to Europe, or by observations made here unsupported by scientific investigation.—*North-China Herald.*

FIBRE PLANTS IN JAMAICA.

BY D. MORRIS, M.A., F.L.S., OF JAMAICA.

Great interest is being taken in the development of Fibre industries in Jamaica, and several important projects are on foot for utilising the large suppiles of pinguin, aloe, sansiviera, and other fibre plants with which the island abounds. One important factor in this revival of interest in fibre plants in Jamaica is the invention by a local engineer of a very portable and compact machine, for which it is claimed that it will clean and prepare all kinds of fibre in a most expeditious and economical manner.

Whether this machine will fully answer the expectation raised concerning it remains to be proved. The subject has, however, been taken up by the Government, and a special committee, consisting of Dr. Phillipo, Mr. Valentine Bell, C.E., Mr. D. Morris, M.A., F.L.S., and Mr. L. Mackinnon, has been appointed to test its capabilities upon local fibre plants, and report the results for the benefit of the community at large.

The information given from time to time in the columns of the *Planters' Gazette* respecting Rheea and Ramie fibre has stimulated attention also to this important fibre plant; and we are glad to learn that many cultivators have already begun to establish nurseries, and to grow the plant on a large scale.

In order to assist in the establishment of plantations of Rheea or Ramie, the Director of Public Gardens and Plantations has compiled some useful practical notes on the subject, from which we make the following extracts:—

The plant known as China Grass, Ramie or Rheea, belongs to the natural order Urticaceæ, and hence, strictly speaking, is not a grass but a species of nettle (without stinging hairs) closely resembling in appearance and habit of growth the common nettle of Europe. It is generally supposed that there are two species of Bœhmeria yielding fibre. That a native of China is known botanically as *Bœhmeria nivea*, the specific or trivial name being derived from the whitish appearance on the underside of the leaves. The local Chinese name for this plant is *Chû* or *Tchou-Ma* and the Malay *Ramie.*

The Rheea of Assam, at one time supposed to be different from the *Tchou-Ma* of China and the Ramie of Sumatra and the Malay peninsula, was named by Dr. Roxburgh *Bœhmeria* (*Urtica*) *tenacissima*, because he considered it to yield one of the strongest fibres he had ever met with.

Dr. Royle, however, expresses an opinion that "the proof is very complete of the identity of the plants from which these differently name fibres (*China Grass and Rheea*) are obtained." Hence we may look upon *Ramie, Rheea* and *Tchou-Ma*, as respectively the Malay, Assam and Chinese local names for one and the same plant, viz. that known botanically as *Bœhmeria nivea.* The plants with green underside to the leaves instead of white constitute, probably, only a variety of the typical species.

The genus *Bœhmeria* is very widely distributed throughout all parts of the world. In the West Indies and Jamaica there are three species of *Bœhmeria, viz., B. caudata*, a common, rank weed, 3 feet to 15 feet high, frequenting damp corners in the Blue Mountain districts; *B. cylindrica*, a small plant inhabiting similar localities with stem only 2 feet to 3 feet high; and *B. ramiflora*, with alternate leaves and stem 6 feet to 8 feet high. All these contain fibre more or less valuable, but neither can compete with that produced by the China Grass or Ramie plant, *B. nivea.*

As already pointed out in my Annual Report on the Public Gardens and Plantations for the year 1880, p. 22, the Ramie was cultivated by the late Mr. Nathaniel Wilson in 1857 at the Old Botanic Garden at Bath with great success, and Mr. Wilson drew particular attention to its capabilities as an industrial plant of great value.

Since that time the Ramie has been grown at the Castleton Gardens and elsewhere for experimental purposes, and the results of these experiments may be briefly summarised as follows:—

1.—The Ramie plant requires a rich, deep soil, plentifully supplied with water; and to produce good fibre it should be kept under careful cultivation and in a continuous and active state of growth.

2.—The Ramie plant is likely to thrive only in such portions of the island where, in addition to suitable soil, there is a plentiful and copious rainfall; or, failing this, where water can be regularly and largely supplied for purposes of irrigation.

The Bath and Plantain Garden River districts might grow Ramie without irrigation: as also portions of the Parishes of Portland, St. Mary's and Westmoreland.

Other portions of the island, where the soil is good, might grow Ramie by means of irrigation, and the plant would appear likely to lend itself easily to this treatment.

If proper appliances are found to prepare and clean the fibre expeditiously and economically, large Ramie plantations might be established on lands contiguous to the Rio Cobre Irrigation Works, and taking all the circumstances into consideration, probably the district will be found to offer the best localities for the economic culture of Ramie.

As shown in the treatment of the Ramie by the Chinese, it can be propagated either by seed or off-shoots.

Where seed is used, nursery beds carefully prepared, supplied with rich soil, and regularly watered, are essential. Care should be taken to mix the fine small seeds of the Ramie with soil and sow lightly on the surface of the ground. If the seeds are covered with soil they will probably not germinate.

The plants raised in these beds may afterwards be transplanted and put out at distances varying from $1\frac{1}{2}$ to 2 feet apart, according to the nature of the soil. The better the soil, the further apart the plants; and conversely, the poorer the soil the closer the plants.

Where off-shoots or suckers can be obtained they are to be preferred to seeds, as being more expeditious, and yielding better results, especially within the first year after planting. Where off-shoots or suckers cannot be obtained in sufficient numbers, young plants may be obtained by "layering" the taller stems, that is, bending them down (without breaking) close to the ground, and covering the joints with soil. From every ripe joint plants will be produced.

The burden of the treatment of Ramie, in all its stages, by the Chinese, is the plentiful use of manure and water.

Unless the soil is naturally rich and moist, the cultivators of Ramie must be prepared to supply their plants largely with manure and keep them in a "moist, vigorous, perpetual state of growth."

As regards the time when the stems should be cut, and the subsequent treatment, it may be mentioned, as noticed by Major Hannay, that the Raime is fit for cutting *when the stems become of a brown colour for about 6 inches upwards from the root.*

Care should be taken in cutting the ripe stems not to injure the young shoots springing from the root-stalk which are to form the succeeding crop of stems. It is beneficial to the roots after each crop is reaped to manure them heavily as well as to supply abundant moisture.

When once the Ramie plants are established, the stems are produced more abundantly with age and also grow much faster. Where too thick they should be carefully thinned, so as to promote the growth of large healthy stems.

The duration of life of a root of Ramie depends (as on the duration and yield of bananas and other similar plants) on the strength and character of the soil, the relative quantity of manure applied, the amount of moisture present, as well as on the general cultural treatment received by it.

There is no reason to doubt that where these favourable conditions exist, a plantation of Ramie will last for many years (ten or twelve at least), and prove very productive.

The portions of the plant which yield fibre are the cortical layers of the stem. The Chinese divide these layers as follows:—The outer green layer is generally coarse and hard, and only good for making common materials.

The second is a little more supple and fine; while the third, which is the best, is used for making extremely fine light articles.—*Indian Agriculturist.*

THE SUGAR INDUSTRY IN THE MADRAS PRESIDENCY

is fully discussed in a paper with which we have been favoured and some extracts from which will be interesting in view of the discussion on sugarcane cultivation in Ceylon:—

Particular kinds of cane cultivated; their suitability ot special soils; mode of selection by cultivators; possibility of introducing better kinds or better tillage.—The sugar-cane (*Saccharum Officinarum*) is indigenous to India, and has been cultivated from time immemorial. There are very numerous varieties of the cane quoted by the Distric Officers under local vernacular names, but Mr. Robertson, Agricultural Reporter to Government, states that many of these varieties cannot be distinguished, and that the distinguishing characteristics of other varieties arise from local conditions of soil and climate, and disappear when these conditions are absent. In popular parlance, the cane is divided into the three varieties mentioned at page 372 of Drury's Useful Plants of India—the red cane, which grows on dryer ground, the striped cane, which takes a richer soil, and the white cane, which succeeds in wet land unfavorable to the two other varieties. In the Madras Presidency, the cane is cultivated chiefly in the districts on the coast of the Bay of Benga, and some inland districts which have a comparatively dry climate, weile there is but little cane grown on the West Coast, where the climote is moist and resembles that of the Straits, the Mauritius and the West Indies. The cane in those colonies attains to a luxriant growth never equalled in this presidency, and at the recent exhibition at Madras, a sample of cane from Penang was far superior to the sample of cane from Bellary district which gained the second prize. Many attempts have been made to introduce into this presidency these larger varieties of cane. Otaheite and Bourbon canes along with the Minnesota Amber cane are now to be seen in the Godavari district, while at the Saidapet Experimental Farm successful trials have been made of the Chinese sugar-cane (*Sorghum Saccharatum*) and other sugar-producing sorghums. It has not yet been shown, however, that any of these foreign varieties will, in this climate, continue to produce more sugar than the country cane, and on this point the Board would quote the result of the experiment recorded in the Vizagapatam District Manual. It is there recorded that Messrs. Arbuthnot and Co., the renters of the Palkonda estate, brought a cane planter from the West Indies to teach an improved method of cultivation, spent large sums in the introduction of the Mauritius cane and placed the experiment under the personal supervision of Mr. John Young, now Chairman of the Oriental Bank, but the result showed that the native system of cultivation was more suited to the existing circumstances, and that the Mauritius cane was more precarious than the country varieties. It is not likely that any attempt to improve upon the tillage of the cane will ever be made more carefully or under conditions more favorable to success.

The first year for which statistics are available is 1852-53, when the area under cane was acres 38,403. It remained almost stationary until 1869-70, when it was acres 37,805, and then increased steadily till 1845-76, when it was acres 52,094. The famine years shew a great decrease, but in 1881-82, the area under cane in Government, Zemindari and Inam lands in this presidency was acres 72,382, the produce of acres 69,383 of which was manufactured into sugar and jaggery.

It is said that sugar or jaggery is manufactured from the produce of the following acreages:—

		acres.
Under sugar cane	..	69,383
Coconut palms	..	5,706
Palmyras	..	24,884
Date palms	..	1,575
Sago palms	..	19

so it is evident that the jaggery manufactured from the palmyra is the only considerable rival of the product of the cane.

It is not usual to cultivate the cane two years running upon the same land. In parts of Kurnool, Tinnevelly and South Canara, however, the stumps of the caneare left in the ground to sprout and yield a crop the following year, and in the Nandyal taluk of the Kurnool district, the cane is left in the ground for three years, and in the Cumbum taluk for as long as ten years, the yield diminishing each year. These instances of slovenly agriculture are, however, exceptional. The cultivator usually permits land which has borne some other crop to lie fallow for a year, and then prepares it for the cane by several ploughings, or by breaking it up with crowbars which disturbs it to a depth of nearly a foot, and by heavily manuring the soil with whatever manure he can obtain, the most common manure being that obtained by picketing his herds or folding his flocks upon the land. The land having been manured, ploughed and flooded, the cane is planted.

The cane in India never bears seed, although it flowers. It is always propagated by cuttings. The top of the cane is commonly used, but some cultivators leave a few canes growing in the fields from the previous year and cut them up into lengths of one or two joints. These tops or cuttings are planted horizontally in the wet soil about eighteen inches from each other in rows about four feet apart. Six days afterwards the field is again watered, and about the twentieth day four or six shoots sprout from each cutting. In Ganjam and Vizagapatam, some ryots plant the cuttings in nurseries and afterwards plant out the shoots in the fields.

After the shoots appear in the field, the ground is weeded and hoed, and when they are about a month old, chaff, weeds or some such manure is thrown around them. The soil is kept moist by occasional irrigation, and when about three months old the shoots ought to be a yard high.

After this stage, it often becomes necessary to give the canes support, and this is done by bamboos or by a sapling stuck into the ground in the middle of each group of canes, the leaves being tied round so as to bind the canes together. This process requires constant care until the cane, at ten months from planting, is ready for cutting. It is then from four to six feet in length and about an inch-and-a-half in diameter. In the Vizagapatam district, it has attained a diameter of four inches.

The rich alluvial soils near the mouths of rivers are best adapted to the cane, but it is useless to attempt to grow cane upon land which cannot be irrigated during ten months of the year. The black soil (regur) which suits sorghum does not suit sugar-cane, unless there is a considerable admixture of sand. It is remarkable that, although half the cane in the presidency is grown in the districts of Ganjam, Vizagapatam and Godavari, and although there is cane also grown in North Arcot, Nellore and Kurnool districts, there is not a single acre under that crop in the Kistna. The black soil is not suitable, and the channels in the Kistna delta do not carry a sufficiently continuous supply of water.

For the presidency generally, Mr. Wilson, would take the cost of production at R150 per acre, and estimates the outturn at 22½ tons of stripped cane, yielding 45 cwt. of jaggery, worth R250. This would give a profit of R100 an acre, but it must be remembered that the land lies fallow in the previous year, and this circumstance must be taken into account in any calculation of the profits.

At Aska, in Ganjam, Messrs. Minchin & Co., and in South Arcot Messrs. Parry & Co. and a native capitalist, have European machinery. At Aska, the cane is sliced and the juice is extracted by the action of hot water, which is afterwards evaporated, the process requiring a large expenditure of fuel. In South Arcot, the process is that usual in the colonies, the cane being crushed in a three-roller mill, and the juice defecated with lime and passed through filters before being boiled *in vacuo*, the molasses being driven off by centrifugal action. The sugar prepared by either process is much the same in appearance, the grain is small and white.

The ordinary process of manufacture of coarse jaggery does not differ from that in use in other parts of India. A wooden mill of two or three cylindrical upright rollers working into each other by endless screws at the top, the spirals being cut in opposite directions, is moved by a lever turned by bullocks. The canes, cut into pieces two or three feet long, after being soaked in water for a day, are passed between the rollers, and the juice flows down into a pit and thence by a channel into a tub or pot sunken in the earth. Near by is a boiler, and the crushed canes serve as fuel. The juice is poured into the boiler and a lump of lime is added. Sometimes gingelly-oil (sesamum) is also added. The juice is constantly stirred while boiling. To ascertain if it has arrived at the proper consistency, some is dropped into cold water, and if this solidifies, the boiling is poured into wooden vessels or bags and left to cool, when it becomes jaggery.

In North Arcot and Cuddapah, there is a rude process of refining the jaggery. The boiling is stopped before the stage of crystallization, and the juice is poured into pots with holes, through which the molasses drain for twenty days, leaving a crust of sugar, which is removed, boiled twice again and purified by means of milk and ghee. Sometimes when the crust of sugar is reboiled, thin slips of bamboo are left in the pot for forty days, and the syrup is allowed to drain off. The slips of bamboo are then found to be coated with sugarcandy.

The cultivation and manufacture of sugar is steadily increasing year by year in this presidency.

The profits are doubtless much greater than that derived from any other cultivation. They amount to at least R70 per acre, while the profit from indigo does not ordinarily exceed R50 per acre.

The local consumption is not affected by foreign competition, as only refined sugar is imported, but Messrs. Minchin & Co. state that, since the import duty of 5 per cent. was removed, they have been unable to compete in the Bombay market with Mauritius sugar. If means could be taken to render the surf on the Ganjam coast passable, or if Ganjam were connected by canal with other communications, Messrs. Minchin could undersell the Mauritius sugar at Bombay.

If the average production be taken at 45 cwt. per acre, the total jaggery produced in this presidency from cane would amount to about 150,000 tons. To this must be added the jaggery produced from 5,000 acres of coconut trees, probably 12,500 tons; the jaggery produced from about 25,000 acres of palmyra trees, probably 125,000 tons; and also that produced from about 1,500 acres of date and sago palms, probably 4,500 tons; giving a total estimate of 292,000 tons of saccharine matter for the whole presidency.

The imports from foreign countries are insignificant, seldom exceeding 2,000 cwt. per annum.

The exports have increased rapidly since the famine, and in 1882-83 reached a total of 1,246,964 cwt. valued at R75,68,940.

THE MILK IN THE COCONUT.—The coconut is a subject well deserving of the most sympathetic treatment at the gentle hands of grateful humanity. No other plant is useful to us in so many diverse and remarkable manners. The solid part of the nut supplies food almost alone to thousands of people daily, and the milk serves them for drink, thus acting as an efficient filter to the water absorbed by the roots in the most polluted or malarious regions. If you tap the flower stalk you get a sweet juice, which can be boiled down into the peculiar sugar called (in the charming dialect of commerce) jaggery; or it can be fermented into a very nasty spirit known as palm-wine, toddy, or arrack; or it can be mixed with bitter herbs and roots to make that delectable compound "native beer." Even as things stand at the present day Englishmen from morning to night never leave off being indebted to it. We wash with it as old brown Windsor or glycerine soap the moment we leave our beds. We walk across our passages on the mats made from its fibre. We sweep our rooms with its brushes, and wipe our feet on it as we enter our doors. As rope, it ties up our trunks and packages; in the hands of the housemaid it scrubs our floors, or else, woven into coarse cloth, it acts as a covering for bales and furniture sent by rail or steamboat. The confectioner undermines our digestion in early life with coconut candy; the cook tempts us later on with coconut cake; and Messrs. Huntley & Palmer cordially invite us to complete the ruin with coconut biscuits. We anoint our chapped hands with one of its preparations after washing; and grease the wheels of our carriages with another to make them run smoothly. Finally we use the oil to burn in our reading lamps, and light ourselves at last to bed with stearine candles. Altogether, an amateur census of a single small English cottage results in the startling discovery that it contains twenty-seven distinct articles which owe their origin in one way or another to the coconut palm.—*Cornhill Magazine.*

THE TEA PLANTING ENTERPRIZE AND TRADE OF JAPAN.

(*From our special correspondent.*)

Though I was unable to carry out my plan for a visit to the tea districts of Japan, and all my information had to be picked up in the coast towns: yet some compensation was afforded by the fact that among the "Oceanic"'s passengers were some of the merchants, buyers and inspectors most largely interested in Japan teas for the American and English markets—one gentleman especially being generally acknowledged to be the best authority on the subject by reason of his long experience and heavy transactions. He was most ready to afford information. He had made a large fortune in "tea" a good many years ago; retired to America, lost his fortune in mining; and was now once more selecting and buying teas. He pointed out that a visit to the districts would have been of little value at this season of the year, when all labour is suspended and the bushes are looking their worst. Nearly all, if not all, the tea exported from Japan passes through the ports of Yokohama and Kobe. In the country back from the latter beyond Osaka and Kioto, there are important tea districts, and the plant is cultivated at intervals throughout the island extending to Yedo (the capital), near to which is perhaps the oldest tea in the country. Some of the trees are reported to be 200 to 300 years old, but not much importance can be attached to this tradition, as the replacing of trees which give signs of decay by young plants from the nursery can be readily carried out. In the Yamashiro district, the people were long reputed to get their livelihood entirely by the planting, culture and gathering of tea; but in most districts we have rice cultivated in the valleys and low lands and tea on the sloping uplands and plateaux. Mr. ——— mentioned an important fact, that the tea districts reputed to yield the very best leaf in the estimation of himself and other experienced buyers was that at the highest elevation where tea was grown in Japan. He could not be sure of the height, but supposed it to be between 2,000 and 3,000 feet, which is considerable for a region above 30 degrees north latitude. Passing snowstorms and frost do not permanently, if at all, injure the tea-plant, coming as they do in the period of rest; but the cultivation is essentially a garden one, and each owner of a few acres pays special attention to his lot, at least in seasons when good prices prevail, using mats occasionally to cover his plants both from extreme cold and a too hot sun. Manuring is the most important operation in the cultivation with the Japanese, although in the interior where fertilizing material may be scarce and transport costly, a great extent is cropped without much being returned to the soil. But nearer the coast a large quantity of *fish* manure is carried and utilized specially for tea. Shoals of herring and other small fish are caught round the northern and eastern coasts mainly for manuring purposes and brought to points where a ready purchase is made. There is great variety in the mode of planting, but the prevailing system is to plant in rows at from 4 to 6 feet apart according to elevation. In some districts, the plants being raised from seed are put out 3 or 4 together, in raised mounds of earth, 3 or 4 feet apart, the intervals soon getting covered over, though the trees are not so strong or lasting. Three to four years are required to mature the plants for plucking, which is done mainly by the women and children. The first plucking, considered to yield by far the best leaf, takes place in the beginning of May, or sometimes before April closes; the second after a month's interval; the third, when inducement offers, during July. The Japanese make a fourth plucking, taking pretty well what is left on the trees for their own private use, that is of course when the foreign demand at a remunerative price is equal to the crop from three pickings. There can be no doubt, that in Japan as in China the export of tea can in any year be considerably increased to meet a brisk demand—though Japan after all cannot be counted on for more than four or five millions additional to a good season's export. The buying of the leaf from the villagers or cottar-gardeners is done by Japanese middlemen, many of whom have central gardens and tea-houses of their own and who arrange beforehand sometimes to pluck as well as receive the leaf. These middlemen traverse the tea districts before the plucking season and make their arrangements. They give the tea the first course of preparation sufficient to carry it to the coast ports, or indeed to preserve its quality, when packed in earthenware jars for a prolonged period. The Japanese mode of preparation has been described as follows:—the tea leaf brought from the field in flat baskets is laid (in these) over a steaming apparatus for a few seconds, the steam permeating and wilting the leaves; the leaf can then be rolled easily before being thrown on paper pans over a slow charcoal fire kept up for several hours, while the rolling and stirring with the hands is constant. Next, the tea is sorted by the women and children, a small quantity being placed by each on a tray from which by the use of chopsticks the stems and coarse leaves are cleverly separated, the large and small leaf being also separated. The tea is then sifted to separate dust and broken leaves, and all is then ready for the market at the port of export. The finer teas are often packed in earthenware jars; but the larger portion is packed in chests of 75 lb. upwards, and occasionally the tea is transported in bales made of paper. (The Japanese have excelled from time immemorial as paper-makers.)

In the merchants' gardens, the different purchases are bulked according to quality; the whole refired and sifted losing from 5 to 10 per cent in moisture and dust; the firing is done in pans over separate furnaces attended by Japanese, so that some godowns have hundreds of these separate furnaces; but I learned that a good deal has been done, in Kobe especially, in applying labour-saving machinery; one gentleman especially, who has devoted a good deal of attention for years to the subject, having patented several machines which are working successfully in his tea-garden. Of the nature of the machinery I did not get a clear idea, though evidently rolling, drying and sifting were expedited and rendered more regular. We shall hear more about it by-and-bye, from Kobe direct. Of course nearly all the Japanese teas exported are "doctored": America only cares for green, that is artificially-colored, teas, although it may be that a small proportion of the tea sent is genuine green tea. Still it is acknowledged that the vast bulk has foreign substances added, before the half-chests are neatly made up in the style in which Japanese workmen excel. Many of the wooden cases which came down from the tea districts are utilized to make these halfchests, and as many as 500 men are employed in a godown in the busy season, the average day's wage for ten or more hours' labor being under tenpence.

At a tea exhibition held at Kobe towards the end of last year, I see it was stated that no less than 211 varieties of tea were sent from the Kioto district alone. From an account of the opening of this exhibition published by the Japanese Commissioners in pamphlet form I quote as follows:—

The number of exhibits and exhibitors is more than 4,480 and 3,810 respectively. Of the former, 786 are from the prefecture of Saitama, 535 from Shiga, and more than 300 from Osaka and Miye; while Tokiyo, Kiyoto, Kanagawa, Niigata, Chiba, Ibaraki, Gifu, Fukushima, Fukui, and Kumamoto—two cities and eight prefectures in all—exhibited less than 300 and more than 100. The exhibits from all other prefectures were less than 100 in number. In a special apartment, were exhibited several samples of teas from the Botanical Gardens and the Engineering Bureau of the Imperial Household Department; tables and books on the use of tea, as well as drawings of the tools employed in the tea plantations,—sent from the Commercial and Agricultural Bureau, the Industrial Sections of the various Prefectures, and by exhibitors from different localities.

The address delivered by His Excellency Shinagawa runs as follows:—

The origin of the growth of tea in our country can by no means be accurately ascertained, yet topographical investigation leads us to the conclusion that the staple has grown wild in the Empire from very remote periods. As to the method of its culture and production, we are also unable to obtain any precise knowledge. Referring to the old annals, however, we remark that when the Emperor Saga proceeded to Kanzaki in Shiga, Omi, in the spring of the 6th year of Kojin—about 970 years ago—and took up a temporary lodging at the temple called Bonshakuji, the Abbot Yeichiu, of the temple Sofukuji, prepared tea in person, and presented it to the Emperor and his younger brother. From these facts it may be inferred that the culture of tea as well as the method of preparing it for drinking purposes has had its origin in the knowledge acquired by Yeichiu when he travelled in China in the epoch of Yenriyaku. However, the use of tea was temporarily abandoned, until, in the reign of the Emperor Toba II. during the years of Bunji, the priest Yeisei, founder of the temple Kenninji, who had previously been dispatched to So, in China, to study Chinese literature, returned with tea seeds and founded a plantation on the mountain called Seburiyama, in the province of Chikuzen. His produce was known by the name of Iwakami tea. Later he presented some plants to Hoye Shonin, rector of the Toganowo temple, in the province of Yamashiro. This priest planted them in Uji, and thus the cultivation of tea has been in progress during more than 860 years. Therefore the reputation of the Uji tea is traceable to these facts.

The exportion of our tea to foreign countries is of recent date—after the opening of Nagasaki to foreign commerce. The quantity exported was then so insignificant as to be hardly worth recording. When Yokohama was opened to foreign trade in the 6th year of Ansei, some American merchants made purchases of tea, and this gave rise to extended exportation. Later on, the export of the staple increased year by year, to such an extent that one-fourth of the total value of our exports from the 1st year of Meiji to the 14th year (1868-1881) was contributed by tea.

I have heard that the American Government has lately prohibited the import of spurious teas. That America, our chief customer, has adopted such a measure, will serve to terrify cunning and fraudulent, and encourage upright dealers. Both our tea cultivators and manufacturers must work candidly, taking legitimate measures for packing and transportation, so that they may be enabled to compete with rivals of other countries and maintain the reputation which our teas earned from Heaven more than one thousand years ago. This is the reason why the Second Competitive Exhibition of tea is opened, and why I call the attention of producers to the facts that I have mentioned above."

As regards spurious and doctored teas, I do not suppose the Japanese are so much to blame as American retailers and middle-class dealers who will have something cheap and even trashy. The following outspoken remarks are from the report of an American Consul in Japan, written about six months ago, and with special reference to the Hiogo-Osaka districts of which Kobe is the first:—

The tea trade has gone from bad to worse, until it has now become unsatisfactory, both to the Japanese producer and the foreign exporter. Whether as a result of over-supply, or of such deterioration in the quality of the teas shipped as tends to check consumption, the prices to which tea has fallen in the United States are ruinously low, and if some improvement be not effected, this important commerce will be shunned by all who have anything to lose. Some movement is now taking place among the growers of tea here against the production of the inferior leaf which gives the exporter his excuse for colouring the article to conceal that inferiority, and probably a larger proportion than usual of pure uncoloured tea will this year be shipped to the United States. But this movement will fail of success unless tea-drinkers in the United States can somehow be awakened to the fact that bluish-grey and broken leaf is not the natural and proper form of this precious commodity, and that coloured teas are neither clean nor wholesome, whereas the natural leaf of Japan is both good and delicious. If the American demand could be redirected towards these sound and pure teas, it is probable that the use of the fine and fragrant leaf produced in Japan would so increase as to restore vitality to a trade now vitiated by manipulations which naturally disgust all who become aware of them, and are perhaps the principal cause of the paralysis now prevailing in the tea business.

Fortunately the attention of the American authorities has latterly been directed to this matter of spurious tea, and more than one confiscation has taken place at the port of New York, a fact which has also directed attention to the pure teas which India is ready to supply. It will be some time, however, before the American consumers are educated to the pitch of giving up the light green fusionless Japanese and Chinese teas in favour of the stronger teas of India and Ceylon. One curious fact told to me on the "Oceanic" is that Ceylon tea is being imported into Yokohama, and that the foreign residents have taken to it very readily—so that it is likely to become their drink—a high compliment this!

The rise in prices of tea in America desired above has been partly realized, and the satisfaction of some of our passengers on arriving at San Francisco was very marked in hearing of good sales for their teas at increased prices. One merchant interested in about a million lb. shipped in November and held on for the rise had a good many thousands of dollars of profit to count on; while his companion who, shipped in December, found that a "stupid" agent had sold all off, just *before* the rise! Such is the chance of trade.

Sixty per cent of the tea consumed in America is claimed to be distributed from the one port of New York, and the imports there for 1883, I see, are given as follows:—

		lb.
"Green" Teas	...	16,257,673
"Japan" Teas (? all green)		16,370,368
Black Teas	...	23,149,775
Indian Teas	...	580,746
Total lb.	...	56,358,562
Against in 1882 lb.		54,387,000
Increase in 1883 lb.		1,971,562

An act of Congress is now in operation prohibiting the import of "adulterated" teas, and it is said that, as a consequence, the importation last year showed a better average quality. The press are in favour of the law.

It is evident to me from the information now collected, that our Directory statistics of tea production and consumption in both China and Japan must be modified. The home consumption is not nearly so great as I estimated on the authority of a report by Consul Allan of Shanghai, who wrote that the quantity of tea drunk by the rest of the world was simply a trifle as compared with the consumption within China itself. While admitting that there were no more reliable reports than those made by China merchants as a rule, the old China residents already referred to pointed out that there were larger districts—nay provinces—in China, especially in the North-West, where the people were too poor to drink any tea at all, hot water being their beverage; while the larger proportion of those who do drink tea take so weak an infusion that a very little of the leaf goes a long, long way with them. The case is still stronger in regard to the Japanese, who are not on the whole such great tea drinkers as the Chinese. Certain it is that the exports far exceed the home consumption in Japan: indeed, the home tea being that got usually in a fourth plucking of the bushes, it is probable that the quantity retained by the Japanese is only equal to from ⅓ to ¼ of that shipped to America and Europe.

The following interesting reference to Japanese tea is from a recent report by Consul-General Van Buren of Yokohama:—

The Japanese green teas may be divided into these general classes—coloured, uncoloured, and basket fired. The leaf used for all these is from the same plant, differing only in quality, condition, &c. All teas used by foreigners are first fired by the natives in the places where grown. If a grade of coloured tea is to be made, this fired leaf (four or five pounds) is taken and put into iron pans or bowls, which are heated, sometimes up to a temperature of 212° F. The leaves are then rapidly stirred by hand against the smooth iron surfaces some twenty minutes. A teaspoonful of thoroughly pulverized soapstone (sapomte) and five grains or so of powdered Chinese indigo are placed in the pan and thoroughly rubbed into the leaf for about twenty minutes more, when one-half a teaspoonful of soapstone or gyspsum and pulverized tamarack bark (a species of larch) is added, and the stirring and rubbing is continued for twenty minutes more. It is then put into cold pans and simply cold rubbed against the iron surfaces until it has the required polish, which is arrived at in from forty minutes to an hour. This colouring process is considered beneficial to the leaf, tending to preserve its shape and flavour. There can be no doubt that the Japanese prepared teas are far superior in purity to the Chinese. In colouring Chinese teas various drugs are used that are deleterious to health, unless it be that the heat to which they are subjected renders them innocuous. Basket firing is done in bamboo baskets, shaped something like our hour-glasses, which are shaken over hot pans. The leaf is put into the upper lobe of the basket and worked into the lower, and so back and forth until finished. The loss of weight is about 3 per cent.

WHEAT FARMING IN DAKOTA, U. S.

(*From an old Ceylon man.*)

* * * I can't say very much in praise of last year's operations. Crop was a partial failure, and both our own place and the one I have charge of were worked at a loss. I had about 10½ bushels of wheat to the acre, and the other only 9½ bushels. That at 80 cents a bushel does not pay, seeing it costs about $8 an acre to cover expenses.

At one time in August I did not expect to have any crop at all. We had a regular scorching drought in July, and everything seemed burnt up. The wonder was that we ever had the crop at all. My brother's place it is about 30 miles off, and, although he got the scorching just the same, he had rain a week before me, and he showed an average of 17 bushels an acre and a return of 18 per cent on capital invested.

Wheat is the staple here. Miles and miles, nothing but wheat. I expect to put in 2,000 acres in our own place in the spring; 1,200 in another place; and nearly 800 acres on two other farms to be opened in the spring, that I had all ploughed ready in the fall. If we only had a good crop, it ought to make a very good showing.

Farming here is a simple matter compared with Scotland. In April and May sow the seed, and in August and September cut it; thrash it out of the stook, and send it off to market. I had two thrashing machines running for the two farms, and we had only three days during all the thrashing to stop for rain. In the fall the ground is all ploughed up again ready for spring sowing. After sowing, if there is any prairie-ground to be ploughed, it is done in June; then the time after is spent in haying. The men work in gangs, something like the coolies, and, when it is possible to do it, we have to task work.

In harvesting our machines cut and tie throwing it to one side, and ready to bind again. I had thirteen of these, cutting on an average 10 acres a day. Then we have our own elevator at the station—a 30,000-bushel one—so that we can do all the handling ourselves.

The winter is the most disagreeable season, it lasts so long. Snow fell middle of November, and we expect to have it till the middle of March. Then it begins to thaw and gradually moves off. I tell you it can freeze here. I dug a hole in June, and found the frost 5½ feet in the ground then. Indeed that is the secret of our success. The frost keeps coming out, and throwing up moisture to the young plants, so that they don't feel the want of rain. I have seen grain sown on a Friday, sprouted and showing above ground on the Sunday following, and the whole field green on the Monday.

We have had a pretty rough winter, lots of blizzards, and some very cold ones. Coming home from town ten days ago (10 miles), I had a bit of my nose frost-bitten twice. These things however are so common nothing is thought of it. A good rub with snow puts it all right again. It is much healthier than Canada.

The Northern Pacific Railway has now been completed through, and runs regularly to Portland, Oregon. There was a tremendous demonstration when the work was finished. The last spike was a gold one driven in by a silver hammer, and all the bigwigs of the State were present at the ceremony. It cost the R. R. Co. about three-quarters of a million of dollars.

THE COLONIZATION OF TAVOY.

(From the *Rangoon Gazette*, March 22nd.)

We think it will be a great pity if the local Government agrees to Mr. Sevestre's scheme for the rapid colonization of Tavoy. There is no doubt but that a company such as that proposed by Mr. Sevestre, with abundant capital, could develop the resources of the district much more rapidly than individual planters will do, but the rapid development of the district is not the only thing to be looked to. It is not a matter of supreme importance that Tavoy should be growing large quantities of tea, indigo, coffee and spices in five years' time, instead of fifty years hence; but it is a matter of supreme importance that the colonization should be carried on out lines which will not lead to future friction. If Mr. Sevestre merely proposed to start a company to take up planting in the Tavoy district on exactly the same terms as individual planters do, we would wish him every success; we would not even grudge him some exceptional privileges in the way of a slightly extended period of exemption from taxation, in consideration of the impetus he would be giving to planting in Tavoy. But, when he proposes practically to create an *imperium in imperio*, by demanding a charter on the lines of the British North Borneo Company, free of reservations as to mineral rights and forest conservancy, it is quite another matter. A company of this kind, with chartered rights and large capital, might in time become a terrible thorn in the side of the local administration. Not only might it give very serious trouble to the future rulers of this province, but the neighbourhood of such a formidable competitor in the same field might do considerable harm to the individual planters, or deter individual planters from coming forward at all. All big and successful companies are apt to develop an idea that that they should be able to monopolize any business they take in hand, and this idea often leads to their trying, with more or less success, to crush the smaller fry in the same line of business. Now, we submit that the real interests of the province will be much better served by a comparatively slow colonization by individuals than by Mr. Sevestre's company. Of course, if Mr. Sevestre gets up a company to take up some of the Tavoy waste lands, on much the same terms as Government offers them to individuals, no one can object. On the contrary, such a company would be welcome for the sake of the impetus it would give to a new industry in Burma. The company would still have the great initial advantage of large capital, but if this were the only exceptional advantage it started with, we should not be afraid of its ultimately crushing out the individuals who dared to compete with it. Planting is essentially an industry the success of which depends very much on close, constant and unremitting supervision, and on ecconomical management; and in all these points the individual planter is likely to excel, and thereby more than counterbalance, in the long run, the company's initial advantage of larger means.

Planting has been started in Tavoy, and if the present planters meet with a fair measure of success, there is no doubt that others will come forward, and that in time the suitable parts of the district will all be taken up. Meantime, there is no need to be in too great a hurry, or to pay an exorbitant price for hastening by a few years a result which is certain to come.

The transfer of part of the overflowing population of Behar to Burma, which seems to be the bait which has caught Sir Stuart Bayley, sounds, attractive, but is, we fear, illusory. In the first place, even the promoters of the scheme do not seem to be certain of effecting this transfer, as they talk of falling back on Chinese labour if Behar fails them; and in the second place, if these people from Behar are only to come with the planters, and to work on the plantations, their advent will not really cheapen labour in Burma generally at all.

BRITISH HONDURAS.*

[We are indebted to Mr. Morris for a copy of his well got up and interesting work on British Honduras, and, as it may be some time before we are able to read and notice it, we extract the following review from the *Planters' Gazette*.—ED.]

The reputation which Mr. D. Morris has acquired for energy and thoroughness in his work will be heightened by a perusal of the volume before us. In his modest preface the author speaks of it as merely an attempt to give some account of the resources of the colony, and to supply a few practical hints to those who are, or about to be, engaged in developing them; but the Government of British Honduras, by whom its publication has, we believe, been undertaken, rightly judged that the dissemination of such information as this work affords would be the best means of attracting European capital and enterprize, and accordingly, determined to issue it at the comparatively low price of 2/. It was towards the close of 1882 that Mr. Morris visited the colony at the request of the Governor, and he evidently made the most of the opportunity afforded him of seeing the country and of studying its capabilities and requirements. His object is to dispel the ignorance and prejudice now prevalent in England with regard to British Honduras, which has, he says, "afforded one of the most remarkable instances of British enterprize and energy.

"Once the home of buccaneers, afterwards, for more than a hundred and fifty years, a mere station for cutting mahogany and logwood, its fortunes have practically been in the hands of a few monopolists. These holding nearly all the land, have been content to get from it, in a lazy, desultory, and somewhat spasmodic manner, such timber and dyewoods as lay within reach of the principal rivers.

"Now, however, such supplies are becoming exhausted, and as the land monopoly has been broken by the enforced sale of extensive tracts of forests, the colony enters practically upon a new phase of existence."

We need hardly say that Mr. Morris by no means advocates measures that would permit the wholesale destruction of the forests. He has, in his official reports pointed out the evils arising from such a system, but he strongly urges that the time has come when the local Government might, with advantage, offer such facilities for the acquisition of land as will attract an intelligent race of planters, possessing the necessary capital and energy.

The soil is described as being generally rich and fertile, and the climate as admirably adapted for a great variety of tropical plants. To the question which of these will prove most suitable and remunerative Mr. Morris addresses himself with all his wanted ability and industry. To begin with, he indicates the growth of oranges and other tropical fruits intended for the American and Canadian markets as affording a very promising field for investment in Honduras as in Jamaica, where this newly-developed fruit trade is the means of circulating more than £150,000 annually amongst all classes of the community. The fact that many of these crops mature earlier than the old established products, such as sugar, coffee, and cocoa- recommends them especially to men of limited capital, and the returns from them are likely, moreover, to be highly satisfactory. Mr. Morris mentions the Mullin's River Valley in this connection, as being peculiarly suitable. Two small fruit companies and several private owners have already commenced operations there with bananas, cocounts, and cacao, and there is plenty of room for more. Oranges, limes, and lemons are in regular demand for the American market, and may be advantageously cultivated with bananas. "Oranges should be put out at about 20 feet apart. Plants may be conveniently raised from seed, in boxes or beds, raised some 4 or 5 feet above grounds, so as to be beyond reach of ants, rats, mice, and other noxious animals so common in tropical countries. The export of oranges from Jamaica chiefly to the United States during the year 1882, amounted to more than thirty millions, of the estimated value of £33,700. Mangoes are also mentioned as a promising product, only the local kinds are of inferior quality, and need to have better sorts from Jamaica or Martinique grafted on them. The Avocado pear, the Loqueat, the Mangosteen, the Akee, the Durian, the Star-apple, and the Cherimonger of Peru, and numerous other tropical and sub-tropical fruits are recommended by Mr. Morris for trial, as they would find a ready sale both for home use and export. Although Mr. Morris devotes considerable space and attention to what may be called the minor products, viz., those suitable for settlers and men of comparatively small means, requiring a quick return; he does not, by any means, limit the sphere of his observation or the country's capabilities to these. On the contrary, he declares that, provided the necessary capital and labour are forthcoming, there is nowhere in the world that the large tropical industries can do better. "South of Belize River, and extending for many miles on each side of such rivers as the Rio Grande and others, there are," he tells us, "extensive areas of fine land admirably suited for sugar-cane cultivation, where the *usine* system especially might be adopted with every prospect of success. Further inland, cacao plantations might cover hundreds of acres of fine undulating country; while the finest coffee should flourish on the slopes and higher lands of the Cockscomb country, and along the western frontier."

At the present moment the sugar industry of British Honduras does not appear to be in a very flourishing condition, but as much as that may be said of it throughou the West Indian colonies. Twelve large estates were starte

* By D. Morris, M.A., F.L.S., F.G.S., Director of Public Gardens and Plantations, Jamaica, E. Stanford, 35, Charing Cross.

involving an outlay of capital of £300,000. Only five are now in working order, and two of the largest of these are in the market. Nevertheless, Mr. Morris is of opinion that sugar can be easily produced there for about £10 per ton and at the rate of two tons to the acre.

"One planter," he says, "informed him," on actual experiment one acre of picked canes yielded four tons of drained sugar. No artificial manure is required, nor any drainage, beyond mere surface drains, and hardly any cultivation beyond a couple of ploughings to clean the canes. Canes ratoon for ten or twelver years without deterioration, and instances have been quoted to me g some cut for this year's crop that have been ratoonin- for twenty years. From all I have been able to gather on the subject I think it can be demonstrated that well managed estates in the colony have been able to pay theis way, and persons judsciously managing their own estate, have been able to make a good general living out of them- besides adding to a reserve fund, or reimbursing a fair portion of the purchase money, within a very short time, even under recent adverse circumstances affecting the sugar trade. Whether estates can be continued with the same results will of course depend upon the state of the market, and steps taken to counteract the operation of sugar bounties, without which it is considered by those most competent to judge it will be impossible to grow sugar to a profit in any British colony."

There would seem to be at present only one small coffee estate in the colony, and that necessarily of an experimental character. The following description of this attempt will be read with interest, and it will be noticed that in this as in all the more important industries, Mr. Morris speaks of a regular supply of labour from external sources as essential to success:—

"About 100 acres had been cleared and established in coffee under the shade of bananas, with corn as an intermediary crop. The coffee trees, about 30,000, were from one to two years old, planted out. Seed had been obtained from Martinique, Trinidad and Guatemala. As a whole, the plantation was in a promising state; in some cases the trees were overshaded by bananas, and consequently, the plants were weak and 'spindled.' There is no doubt, also that the ground had been somewhat impoverished by the large crop of corn (maize) which was then being taken off.

"Most of the trees about two years old were, however, bearing their first crop, and looked as if, even at this early age, some two or three hundredweights per acre would be yielded by them. The plantation was well laid out, with roads and intervals of 18 feet dividing the blocks. Naturally, being a pioneering effort, the best mode of procedure adapted to the district could not be obtained at once; and, again, the difficulty of obtaining labour had hampered the undertaking and increased the expenses.

"I left the plantation, however, with a favourable impression respecting the possibility of growing good coffee in British Honduras, and I have no doubt that if coolie labour could be obtained, the whole of this western district would soon be dotted over with prosperous plantations. The cost of clearing and cleaning land ready for planting is put down at £6 per acre; the labourers, at present, owing to the remoteness of the district, get from 42 to 50 cents per day."

TEA IN AUSTRALIA.

(*From a correspondent of the "Darjeeling News."*)

One subject I must try to treat of in detail and that is the little I have seen and learned regarding Indian Teas in the Colonies. On reaching Melbourne I found that a large public sale was soon to come off. This I made it a point to attend, after having the previous day examined (but without having the opportunity of testing in cup) samples of all the 78 lots or thereabouts to be offered. The sale I was very sorry to find passed very heavily, and the result has proved most unsatisfactory to the growers. Some of the Pekoe looked well, and showed extra "tip" for spring teas, but on the other hand many of the Pekoe Souchongs and Broken teas were uneven, mixed with red leaf, and not calculated to take the eye. The whole (nearly 4,000 packages, if I recollect rightly) were knocked down to the highest bidders. The highets price realized for any lot was 1s 7d some went as low as 6d and the majority passed at 10d to 11d, some Pekoes not turning the shilling. I question much whether the whole realized an average of over 10½d per lb. Having an introduction from a Melbourne firm to Messrs. Henty and Co. (Agents for the Calcutta Syndicate), I called several times and had talks about Indian Teas and their prospect in the Australian market. Henty & Co., are a very old and respectable firm, (and as far as teas are concerned) seem to give themselves exclusively to Indian Tea. This is doubtless an important consideration. The gentleman who attends to the Indian Tea business of the firm seems interested in its success. He is full of the subject; builds a good deal on analysis; and keeps the topic before the public by writing for the press. From him I learned that Australia had been flooded with Indian Teas this season, and on this account prices had been so very much worse than last year. Henry & Co. also complained bitterly about so many full chests being sent them instead of those of the dimensions enjoined by the Syndicate; and it was quite noticeable at the auction that the former sold pence per lb. lower than boxes or half-chests containing the same quality. Last time I called, I was informed that there had been a small sale that proved more satisfactory to sellers than the large one referred to, and I trust times will improve. At Sydney I had the pleasure of meeting with Mr. James Inglis (our friend "Tam's" brother) the representative of the interest there, and had an earnest consultation with him and his partner Mr. Brown, who has had experience of Indian Teas in the London market. They kindly showed me their premises, stock and some samples of "Darjeelings" along with others Mr. Brown expressed himself as most confident that Darjeeling teas with appearance, though without strength or body, are what is required for the Australian market. Regarding New Zealand Mr. Herrold had also the complaint of overstocked markets. He told me that after I left Melbourne there had been another large sale even less favourable to sellers than the one referred to; and that some Planters had persisted in sending Darjeeling teas to Auckland though desired not to do so, the warehouses were overstocked, and that just then they were simply unsaleable even at great sacrifice. But should all those consignments have to go at unremunerative prices; if the teas be retailed *unmixed and on their own merits*, it cannot fail to have the best possible results in the long run. As tea is the drink of the colonies, it is to be hoped that the Indian produce will in time monopolize the trade. Efforts to gain a footing everywhere and achieve this end do not seem wanting. The first thing that greeted my eye on reaching the Adelaide Railway Station was a large artistic "poster" Advertisement, say 6 ft. × 4 ft.. displaying an elephant loaded with tea boxes proclaiming "ask for the Calcutta Tea Association's Indian Tea 1s 3d. to 3s. per lb. ½ to 10 lb. boxes." These large bills I noticed in almost all the towns of Victoria as well as Melbourne, also in Sydney. Notices in shop windows about Indian Teas were to be seen frequently in Hobart "Indian Tea 2s 6d.;" and in Auckland a Toon chest of a well-known Darjeeling brand was displayed as large as life. In addition to writing up Indian Teas, Henty & Co. have inserted in the principal Melbourne papers long lists of shop-keepers throughout Australia and New Zealand *authorized* to sell Indian Teas. This and the condition that the principal Agents entrusted with the trade should not meddle with China Teas, seem points of vital importance. Mr. Inglis has also been rendering good service by utilizing his literary and oratorical powers in giving the Sydneyites public lectures on the subject of Indian Teas—its culture and manufacture. And I have heard it from those who were not aware I knew Mr. Inglis that he succeeded in making his topic interesting and instructive, and it is to be hoped great results, to himself as well as the cause may follow. A very hopeful sign is that the import of India Tea into the colonies has increased as follows:—

1879-1880	3,000 lb.
1880-1881	700,000 „
1881-1882	1,000,000 „
1882-1883 (9 months only) ...	2,300,000 „

Efforts must have not however be slackened as there still seems an indifference—with very many even a prejudice, against Indian Tea. The Australian colonies alone are said to consume 18,000,000 lb. of tea every year, averaging 6·61 lb. per head of the population. Great Britain coming next with 4·59 lb. But it is the opinion of those who should be able to judge best, that it is not prudent at present for us to go in for what forms the great bulk of the trade—that is, the supplying of the "Stations" as they buy what is called "ration tea" at 1s 2d to 1s 3d per lb. This I am not prepared to endorse. However, the population and requirements of the colonies are bound rapidly to increase; may Indian Tea gain a firm footing everywhere, and soon form the lion's share of the consumption.

A New Product for Mauritius.—The Government of Mauritius has applied to the Government of India, in the Revenue and Agricultural Department, for five bushels of seed wheat, of the best and hardiest varieties cultivated in this country. The Panjaub Government is supplying the wheat for shipment.—Calcutta *Englishman.*

The "Tropical Agriculturist"—We have been kindly favored with copies of this most interesting magazine published at Colombo, Ceylon, by A. M. & J. Ferguson. From this excellent Tropical Journal, we have published several articles on Coffee, Silk, and Tea Culture, of value to our readers. The Magazine is a 100 page work, and worthy extensive support.—*Californian Farmer*, January 17th.

Camphor in India.—In an article on camphor in the *Vegetable Materia Medica of Western India*, Dr. Dymock records a peculiar fact in connection with the resublimation of the article in India. The object of this resublimation, he says, is to get as much interstitial water as possible into the camphor cake. After describing the process, he says, "Camphor sublimed in this way is not stored, but distributed at once to the shopkeepers before it has time to lose weight by drying. It is sold at the same price as the crude article, the refiners' profit being derived from the introduction of the water."—*Gardeners' Chronicle.*

Coconut Oil *vs.* Kerosene.—The Boston *Advertiser* states that the kerosine oil has driven coconut oil wholly out of use in Zanzibar. Fifty thousand cases of kerosene were imported by American houses in that country in the year 1882. We may add that kerosene oil has almost driven coconut and lamp oils out of the Madras market—or if it has not, it has tended to keep prices down considerably. Kerosene oil is imported in thousands of gallons and is largely used by private persons and public companies, and especially by Municipalities. In the forty-seven municipalities in this presidency kerosene oil is now used for lighting lamps, while lamp oil was freely used before. Kerosene oil is extensively used in Indian homes.—*Madras Standard.*

The Ground Nut Trade.—The ground nut trade between Pondicherry and France is in full swing and has been so since the month of February. The South Indian Railway Company has been running special trains with nuts from Punrooty to Pondicherry every day since the past nine weeks and will probably continue to do so for two or three months longer. The ground nut trade is the most important in the chief town of the French Settlements in India. Three ships are loading nuts in the Pondicherry roads, and more are expected. The European and Native merchants are fully engaged in this trade for ta least six months in the year and to facilitate shipment of nuts, the South India Railway has laid down a railway railway line from the Pondicherry Railway station to the pier, so that the bags are shipped off as fast as they come in from the interior. Coolies find ample employment during the present season and the price of labor is high. The European merchants in the port have entered heart and soul into the enterprize and it is surprizing how the South Arcot district can produce such an immense quantity of nuts.—*Madras Standard.*

Tomatoes a Cure for Apple Blight.—The following letter appears in the *Australasian*:—Sir,—Severl articles have appeared in your columns lately on the subject of "apple blight." Within the last few years I have witnessed a remedy which was tried accidentally, and which proved successful, in the garden of a gentleman in Geelong. When the garden in question was taken, two Pearmain apple trees were completely white with blight. When digging up some tomato plants, after the tomatoes had been gathered, the plants were placed temporarily in the lowest fork of one of these apple trees, which happened to be near, and before the next apple season came round the blight had quite disappeared from this tree. The other trees were tried in the same way in order to have it proved whether the tomato plants were or were not responsible for the cure, and the same effect was caused. I may add that although the trees were so badly attacked by blight at first, the apples were always beautiful eating apples.—I am, Sir, &c., Young Australian, Windsor, March 11.—*Adelaide Observer.*

Wheat growing and the question of soil in India are thus dealt with in a valuable paper issued by the Government of India:—

The broad result of this inquiry may be thus stated. The area under wheat in British India is about twenty million acres, and the yield between 5½ and 6 million tons. The area in native territory would give an additional 6,000,000 acres, yielding about 1¼ million tons. Of this 6¾ million tons or 135 million cwt., the quantity available for export to Europe must be a matter of the vaguest conjecture. It is known, however, that 15 million cwts. were exported for the twelve months ending 31st December 1882, and this has been followed by an export of 22⅔ millions during the twelve months ending 31st December 1883. It is perhaps not unreasonable to suppose that when the railway system is more developed, one-fourth, possibly more, of the total outturn of 6¾ million tons will in good years be available for Europe. The country has other food-stuffs to fall back on if to export its wheat pays, and should the external demand materially raise the price of wheat compared with other food-grains, the poorer classes are prompt to contract their consumption of the dearer article. It is, however, to be noticed that in spite of the large export to Europe and of the partial failure of last autumn's monsoon, the price of wheat is slightly lower now than it was two years ago. The contraction of the export to 3½ million cwt., for the three months ending 31st December 1883, has been due not to any rise in price in India, but to the low prices ruling in Europe. Wheat is still selling at 22½ seers the rupee, or (allowing for exchange) about 18s 6d the quarter * at Jubbulpore—a price which gave a good margin for profit to the exporter when the London rate was 4·s. the uarter, but not when, as now, the London rate has fallen to 40s for the best English wheats, and to 33—36s for Indian wheats. The alleged deterioration of the soil is the last point to which the Secretary of State has invited attention. The replies are, on the whole, encouraging. Frequent mention, it is true, is made of the popular belief that the soil has ceased to bear the rich crops which one rewarded the ploughman's toil. But the cases are exceptional in which this belief appears to embody a truth. Overcropping will of course exhaust any soil, and the rapid extensions of canals has undoubtedly encouraged the more improvident and poorer cultivators to overcrop. Irrigation always tends at the outset to outturn the manure supply, and this is one of the chief drawbacks to the many benefits derived by the country from canals. In the Narbada valley a falling off in the exuberant yield of the virgin soils has also been reported by careful observers. But when once the first riches of the land has been exhausted, a permanent, though lower, standard of outturn appears to be reached. The phenomenon is common to all newly-opened countries, and is not a matter which need excite either concern or astonishment.

* The quarter is taken at 496 lb. and the bushel at 62 lb. or 31 seers.

Correspondence.

To the Editor of the Ceylon Observer.

CITRONELLA GRASS AS PAPER MATERIAL.

24th January 1884.

DEAR SIR,—In reply to Mr. Whitaker's letter in your supplement of 19th instant, I believe a very suitable fibrous material for the manufacture of paper is available in Ceylon in considerable quantities in the shape of essential oil grasses, from which the oil has been extracted.

I have seen citronella grass in a manure heap 16 years old, so full of fibre that a mamoty could not cut it, and resembling coir more than grass.

Straw is used for making paper in large quantities at home, and is sold at from £3 to £5 per ton, I believe. The knotty stems in straw are a great drawback to its use, as they take so much longer to dissolve than the rest of the straw, that they retard the process of manufacture considerably.

Citronella grass, like esparto, could be supplied entirely free from those knotty stems, and would thus possess one great advantage over straw.

In extracting oil from grass, it is boiled or subjected to steam under pressure, and, as boiling under steam pressure of the raw material is one of the first operations in paper manufacture, grass which has once been treated in this way would, I believe, be very much more easily treated the second time than other raw material not previously boiled.

Citronella and lemongrass estates are all in the lowcountry and have all got good roads to them and in them, as the grass requires to be cut and carted to a central point at the distillery, and at present the grass I have referred to is a waste material, as on account of its fibrous nature it will not rot like straw in manure; so I think that a lower price than "£8 10s to £6" would pay a good profit on baling and shipping charges.

So far as I can make out from your "Directory," there are at present about 3,500 tons of this material available yearly for export, or, better still, for the manufacture of good paper in Ceylon.

Trusting you will give this space in your journal, I am, yours faithfully, D. W. F. L.

[We greatly regret that this interesting letter should have been delayed.—ED.]

ALL ABOUT TAVOY.

The Model Duko Estate,

Tavoy, British Burma, 12th Feb. 1884.

DEAR SIR,—Tavoy, the headquarter town of the district of the same name in the Tenasserim division, on the Tavoy river, is about 35 miles from its mouth. It is laid out in straight streets, and the houses are built mostly of sawn timber and shingled or thatched with dhanee leaves. To the east and west are ranges of hills running nearly north and south. Its extreme length is about 150 miles, its breadth at the widest part is about 50 miles, and its area 7,200 square miles. Its general aspect is that of a long sea-coast tract, hilly and densely wooded, enclosed by mountains on three sides and open to the west towards the sea.

The mouths of the Tavoy river afford excellent anchorage for ships and steamers, they are safe in all weathers under the lee of the island which shelters the coast.

There are three mountain ranges, viz., the main chain on the extreme east the "Nwa-hla-bo" in the centre, and a third intervening between the Nwa-hla-bo and the sea-coast. The main chain, with a general N.N.W. and S.S.E. direction, rises here occasionally to a height of 5,000 feet, and, throwing off numerous densely-wooded spurs, offers an almost impassable barrier, across which, into Siam, there are but three routes.

The northern is by the Hlan-dong, at the source of the "May-nam-naw-ey" in lat. 14° 26′ 53″ N. long. 98° 32′ E., a Siamese river, from Tavoy to Kan-boo-ree *via* Met-ta. From Tavoy to Bangkok there is no telegraph established; the "local Government" are now opening up a good road, and are now pushing on the work.

I have been on as far as the Hlan-dong pass. I was accompanied by Captains Schwolky and Watson. We had a very interesting trip. We went along the line of telegraph and joined the new road here and there. The new road is well traced, and more in Ceylon style than I have yet seen. The head of the department here, Mr. Bayley, is pressing on this work in person, and has done the work in thorough workmanlike style. The first station we came to is named Taltia, and now carts can go this length already: a good gravel road in good weather no doubt, but this road will be improved upon and metalled in due course, when once coolies are imported to Tavoy district. *Labour* is wanted in a country like this, the population being small for the great tracts of jungle-land available for all the different products, and such rich soil in those valleys and dales, as would make some Ceylon men's teeth water and wish for more *rupees*. The next station we reached is named Pagang-oya. There is a small pagoda here but the great curiosity here are the "sacred fishes." The river at Pagang-oya is almost chained in by rocks something like the *Linn o' Dee*. It reminded me of the linn o' bonnie Dee, near Marr Lodge, where I have wandered in my time. I was much struck with this great curiosity: a thing, which, if one was merely reading about it, would rather disgust you, as you would naturally put it down in your mind that it was lies or a draw of the long bow to give colour, but such is a fact. Those fishes come out to the call of the Burmese, who feed them and look upon them as sacred spirits, and, before they throw in the rice into the water, they call out "La-la-la," which means "come." You can see the great and many fishes of three different species swimming towards you and jumping about playfully, and, when the rice is thrown in, such a swarm of fishes of all sizes from that of a full-grown salmon to the tiny trout. Yes, the Burmese play with them, and put their hands upon them, and catch them playfully with loops of twine or jungle-cord, and they allow themselves to be patted like your little pet dog—no one would believe this until seen.

Mr. Dalgreen, the blasting man, rather astonished them about Christmas, and gave them a charge of his thunder and lightning, and, of course, killed hundreds—about four cooly-loads. He himself told me that they (the Burmese) came to him and threatened him at first that the fishes were spirits, and that his body would turn putrid, and that he would be covered all over with sores. Dalgreen said he had a good feed upon them, and found no ill-effect; the only thing was they were very tough, the large ones. They saw that the thunder-and-lightning-man had no fear, and then they came to him and pleaded with him not to kill their sacred fishes, as they were their pets, the *pets* of their forefathers, and that they believed them to be sacred and belonged to the *nats*, the good *nats*, "spirits."

Mr. Dalgreen brought up some rice in a Ceylon paper, and we went to the great pond of the river. "Now," says he, "call," and we called, and, sure enough, there they came in a great shoal and ate the rice and jumped and played, and tore the *newspaper*, the *old Observer*, to pieces. There is something new for *Barnum*, if he could secure those playful Burmese fishes.

We proceeded on to the Hlan-dong pass. This pass is rather steep, and has got a beautiful waterfall, much resembling *Devon waterfall*, and the soils in the valleys are a great depth and a rich chocolate colour. Now we gaze from the great pass towards Siam. We see the great Nwa-hla-bo mountain—almost you would think you could shake hands with his battlements. There is another large mountain towards the south, but I do not know its name. I think it must be "Mai-bhoora" pass, and perhaps may claim that name. The route is irregular and hilly, and great dales; great mighty trees, a great number of old Ceylon friends—*na, mora, wild bread-fruit, kina, jak, wanarani, malaboda, dun,* lots on the edges,—*sapu* in fact, nearly all the Ceylon timbers and a great many more than I know as yet. I found the wild "Yerba Mate" tree near the river-edge and lots of wild tea in the ridges, a few rubbers, fig variety, and loaded with figs on the stem rich in milk, a thick creamy milk; lots of sapanwood also near the river and tidal creeks nearer Tavoy; several gamboges of the mangosteen variety. We reached the foot of the range in three marches from Tavoy town, and computed the distance to be about 20 or 22 miles, perhaps may be a little more or less—cannot guarantee distance well in the jungle; in a thick, dense wooden jungle, such as Burma is.

The chief rivers are the Tenasserim and Tavoy: the former is remarkable for its two sources, the one rising in the north and flowing south to the Karing village of *Met-ta*, where it is joined by the latter, which takes its source about 80 miles due south of the source of the first and flows north; after uniting, they flow due eastward, then turn south and shortly enter the Mergui district. The Tavoy river has its source in the *Ma Ulwi* spur, and, flowing southward through a narrow valley and fed by numerous mountain torrents, falls into the sea at Tavoy Point about 40 miles below the town of Tavoy; it is navigable for about 32 miles above the town of Tavoy by boats not drawing more than three or four feet of water. The low hills east of the town of Tavoy and those at Shenny-dha-wai above and at Pan-daw and Ka-neh-bha-ree below, are all formed of alluvium composed chiefly of gravel with small boulders of sandstone, conglomerate and quartz; this is again covered with soil of the same material decayed and oxidized. The plains are composed of a stiff clay occasionally highly ferruginous. The soil near Tavoy will require to be well worked up, and from my own experience I know there is great strength and all the qualities that tea, cacao, cardamom, rubber and Yerba Mate and Liberian coffee require, and no doubt "old King Coffee" will flourish nicely in a proper situation. I have great faith in good old Coffea Arabica yet, and time will prove this. Ceylon men, be *kind* to your coffee; in proper aspects and suitable soils do not despair, Providence never means to ruin you, no, never, only to enlighten you and teach you never to trust to one, but to many, and enlighten you in your several arts and callings; but be kind to the plant that gives you the name of a rollicking "coffee planter."

By the bye, my report called down wrath on my poor old head from several of the officials. Now you all know well that I never backbite a man, but will tell anyone sharp to his face, should I have occasion to, and make no ceremony about it, and the report stands as I found it; but with the very best intentions to all officials—and I must say the whole of them have been most kind and obliging to me and *all* deserve my best and warm thanks for the, assistance they have given me, for their great information, and they have dragged me here and there to places of interest that I will write to you about later on.—I remain, yours most respectfully,

JAMES D. WATSON.

The Model Duke Estate,
Tavoy, British Burmh, 15th March 1884.

DEAR SIR,—You will confer a favour on me if you will publish the enclosed copy of a letter from the local Government to me, authorizing me to select land *near Tavoy*. This will save me a great deal of time, and will explain itself to all concerned,

British Burmah, Land Rev. and Agr. Depart., No. 374-38 R. (Revenue.)

From D. Mackenzie Smeaton, Esq., M. A. B., C. S., Secretary to the Chief Commiosioner.

To the Commissioner, Tenasserim Division, Moulmein.
Dated Rangoon, 13th Feb. 1884.

Sir,—In reply to an enquiry made by the Deputy Commissioner of Tavoy direct to this office as to whether it is the intention of Government to let Mr. J. D. Watson of Tavoy take up land in that district for other intending planters, I am directed to inform you that the Chief Commissioner has never forbidden such a course; on the contrary, parties who have applied to the local Government have been told that they could make selections of land through qualified agents.

2.—I am to explain that the Chief Commissioner desires to encourage the utilization to some extent of the hilly waste lands in the Tavoy and Mergui districts, and, having this aim in view, he sees no reason why Mr. Watson should not act for others, provided the Deputy Commissioner is made fully aware by application direct from the principals concerned that they have empowered Mr. Watson fully, and that Mr. Watson holds documentary certificates of agency, and provided the fees are paid in advance. But seeing that the tract in which Mr. Watson now desires to make selections is very different from Nat-ya-doung, in a more popular tract, and close to the people of the country and their cultivation and nearer Tavoy, the Chief Commissioner cannot allow the same rules, as to area at any rate, to apply to grants of such lands, nor can the Deputy Commissioner be permitted to make any grants outside of the Nat-ya-doung range, without a reference to you and the explicit sanction of the local Government in each case.

3.—I am to ask that Mr. Watson may be called upon to give a list of persons for whom he is authorized to select and take up lands, showing acres sought and locality.

4.—I am to add that the Chief Commissioner is only anxious indeed to encourage *bonâ fide* planters, but, now that the scene is changed from Nat-ya-doung to the vicinity of Tavoy, the same liberty of choice cannot be allowed, as it is the first duty of the Government to guard the rights of the people of the country.—I have, etc. etc.,

(Signed) G. C. KYNOCH, for Secretary

Revenue Department, No. 471-300.
Dated Moulmein, 18th Feb. 1884.

Copy forwarded to the Deputy Commissioner, Tavoy, for information and guidance.

(Signed) C. H. WHELDON, 2nd Assistant,
for Commissioner, T. D.

Memo. No. 1,042.
Dated Tavoy, 3rd March 1884.

Copy forwarded to Mr. J. D. Watson, for information and with a request that he will send in a list of persons for whom he is authorized to act, as called in *para* 3 of this letter.—(Signed) C. J. DRAKE, Deputy Commissioner, Tavoy.

I notice that Ceylon men are in a fix about germinating nutmegs: it 's all bosh about them being boiled.

The tip is this. Make up a bed near your bungalow about four feet wide; to one bushel of cow-dung, one of your best soil, you can get leaf mould if possible; add half-a-bushel charcoal pounded to a fine powder; equal parts any quantity of course according to the extent of your nursery; mix well together and put on to your bed four inches deep; put a stick on each side, and on the ends a little lopping over to prevent wash, then put a rough railing round about six feet high, and near enough to keep out hares. Then put in your nutmegs just as you get them, put them in an angle, say about 50, the thick end down. Cover only about ¾, the thick end covered, so that you only see the half of the back and end of the nut. This is best to be done in the rains, the first of the rains. Have a basket full of good soil near the same as your compost, and every morning, if any earth is washed off or your nuts exposed, sprinkle on a little earth yourselves, *but don't allow coolies near them, and do not handle the nuts after you put them down*, and I will guarantee you a success.

Captain Butler gave me this hint, and he had great success at Mergui. They grow slow at first, and require a deep and free subsoil near water or in a swampy sort of ground, but the subsoil must be free—when they strike a horizontal *pan* they die off sharp.

Henaratgoda Williams sent me a nice selection of seeds: Maragogipe coffee, yellow palest variety, silver wattles, black wattles, cardamoms, Bubosla croton oil seed, Ceará rubber, divi-divi, Liberian coffee. I put this in at once and shall report success. I am now busy felling; will finish about the 20th instant about 40 or 50 acres. One must do everything themselves here, and be daily on the spot now until I train in those "Nappie eaters." Have got two wells dug and a good set of lines up, and 38 Burmese and 5 Tamils at work. They make one dance a jig sometimes, but I must learn to bottle up and bear these things.—I remain, dear sir, yours faithfully,

JAMES D. WATSON.

CEYLON COFFEE ESTATES AS GRAZING FARMS: AN OPINION FROM CHILE.

Edinburgh, 2nd April 1884.

DEAR SIR,—Annexed is an extract from a private letter from Chile, South America, giving an opinion not unworthy of consideration; to me it seems a sensible view of our "situation," in Ceylon, but liable to the reasonable objections that, so long as any hope exist of profits in prospect from "next year," proprietors will continue to hold on as long as they can.

Besides, the purchase of stock and planting of grass &c. requires a large outlay of cash; also, many of our estates are too steep and rocky to be temporarily converted into cattle-farms. Likewise, both proprietors and those who hold bonds over coffee lands would object to give up any *prospects* of annual profits from properties in favour of heirs and successors in future generations.

These objections could be met by certain of the most hopeless fields of exhausted coffee being turned grass fields for the support of cattle, without giving up the cultivation of the whole.—Yours truly,

P. D. MILLIE.

"—— the discussions in the Ceylon papers are amusing to a cool, far away outsider. It is evident that a great deal that they say at meetings, and write in the papers, is but self-delusion. Here, large tracts of wheat lands are exhausted, and I doubt if anything but weeds would thrive on them. Coffee has proved itself to be an exhausting growth; all trees or plants which are kept undergrowth and weeds must be so, as whatever they yield in fruit or leaves is removed. Jungle growth fertilizes itself by the leaves, and rotten *débris* of ages.

"Keep the jungle quite clean below, and you would soon see how even scrub would in ten or twenty years, grow feebly where nature sows her seeds and reaps her fruits for consumption on the premises—nothing is lost. No doubt, heavy manuring will give you crops of anything for a time, perhaps occasionally for ever, but *people won't make fortunes out of land that requires it*.

"It strikes me in regard to unproductive coffee estates, that they might be made to support their owners by turning them into grazing farms, sowing all available land with good fodder grasses, and breeding cattle to fatten and export: after a certain time, the land would become restored and fertilized, and might *again* yield heavy crops of coffee to posterity.

"There are doubtless numerous 'new products' available, but to expect *debilitated soils* to yield *them* in a paying manner, is like putting new wine into old bottles."

T. J. W MILLIE.

[To Ceylon planters the opinion from Chile will be amusing. There is no export of cattle from Ceylon, only a large import from India, and cattle establishments have generally been given up as costing far more than they returned. The local market for meat is limited, and it will not pay to keep cattle for manure, as imported grain and cultivated guinea grass at high altitudes are very costly.—ED.]

CROPS AND SEASONS.

SIR,—To revive the question of crops and seasons, anyone who takes the trouble to carefully compare pages 374*a* and 405 of your new Directory will find that with hardly a single exception a good coffee crop follows a late burst of the monsoon and a bad one an early burst. In the period 1865 to 1871 the average date of burst of monsoon was May 29th, the average crop 956,420 cwt. In 1872 the monsoon burst on May 1st. and crop fell to 723,152 cwt. In 1858 and 1862 monsoon came early, and in each year the crops were far under the average. In fact, all through the 31 years in which the burst of the monsoon has been recorded there is a striking connexion between early monsoons and short crops, late monsoons and better crops. Let us hope this year for a late monsoon.—Yours faithfully,

W.

TEA MACHINERY.

10th April 1884.

DEAR SIR,—I have been very much interested by the communication in your last issue about the American "Dehydraters." Can you oblige me by letting me have a circular of Mr. Hollingsworth's? I am writing to the Planters' Stores and Agency Company, Calcutta, for the pamphlet referred to by him. As the writer calls himself special agent for Ceylon also, I think he should lose no time to have a representative here with full authority. Ceylon is not a little, out-of-the-way village that it should write to Calcutta or Assam. Mr. Hollinsworth should get a "Ceylon Directory" for 1884 and read the *Observer* to know the strides we are making.—Yours truly,

AGRICOLA.

P. S.—The Fairfield Ironworks Company should not advertize that they have rolling machinery on view and put planters to the expense of going down to Colombo till they really have them on view. I was one of the disappointed.

LEAF-DISEASE, NEW PRODUCTS, ETC.

No. II.

DEAR SIR,—In continuation of my remarks on the above subject,* I may be permitted to add, that, besides the trees and plants of the aloe, mudur, *Calotropis gigantea*, the pine, and several varieties of the *hibiscus* family, I may mention that fibres for cordage may also be obtained from the plantain trees, from the fleshy spathe-like covering of the entire trees, but the cordage is not strong nor durable. An attempt was, I think, made sometime ago by Dr. Ondaatje, Colonial Surgeon at present of Galle, to make paper from the plantain fibres, but without success. Besides all others, the epidermis which lines the spathes of the leaves of varieties of the palms, besides the coconut and palmyra, will make fine and strong cordage: for instance the lining of the spathes of the arecanut tree (*Acacia catechu*) of all others would be the best; then there is the Tucum, *Astrocaryum Tucum*, and Tucuma, A. *vulgare*. It appears that from the latter such strong materials are obtained that even hammocks are made out of it, which are sold at £3 each; or, if ornamented with feathery border, for twice that sum; besides cordage for bow-strings, fishing nets, &c, all that requires

* See page 487.—ED.

strength and durability in the materials of which they are made. The silky lining of the spathes of the abovementioned palms may be made into paper of very superior quality: it may be worked by moderate efforts and made into such articles as papyrus, or the kind of olas or leaves which the Sinhalese make for writing purposes from the leaves of the talipot palms. Members of the tucum, or tucuma family are very common: they grow in marshy and saline soil, they grow in several parts of the Kandyan districts; the feathery foliage used for decorations of pandals, at churches and at feasts is obtained from one of the varieties of the *Astrocaryum Tucum.* I am not sure whether the natives know the useful qualities of the spathes of those trees, but the fruit, which much resembles an arecanut, contains starch, and is cooked and eaten. In its raw state the starch or the kernel of the fruit is said to produce giddiness; the same effect occurs by eating tender arecanuts, or the flower of it. The tree is known as the *bandu gaha* by the Sinhalese, and *bandu* by the Tamils.

From the circumstance of the areca being an established article of trade, and largely used by the betel-chewers, it is not likely that the owners would allow speculators to make an attempt to utilize its spathes, for the early destruction of them may affect the vigour of its leaf and stalk, but, as the spathes are very soon cast off, as the leaves mature, the cast-off ones may be experimented upon if picked up before they get dry. SILEX.

CEYLON NUTMEG SEEDS.

DEAR SIR,—Referring to a letter in one of your issues of your paper signed "Anti-Humbug," permit me to say that I am afraid your correspondent is not correct in the conclusions he has drawn. My experience is quite otherwise, and for the benefit of your readers allow me to give it to them. First of all, it is, I think, impossible to get *fresh nutmeg seeds* in Colombo to any *considerable extent* except from Elie House, which is in the occupation of Capt. Bayley. The seed must be planted within a week from the date of plucking, to ensure their growth, as otherwise it loses its germinating power. A nutmeg, the kernel of which you can hear rattling inside, is not fit for planting. This is the way I got to work, and I can assure you I have been very successful, nearly 9-10ths of what I put down having germinated. No sooner do I pick a few from my trees than I remove the mace, fill a(gigantic)bamboo pot (which I have ready cut and prepared, with two or three holes drilled below) with fine earth nearly 2-3rds full; place the nutmeg perpendicularly right in the centre, with the germinating side upwards, and cover the same with about half-an-inch of earth; place it under shade, watering it twice a day in dry weather. Within six weeks the seed germinated and in two-and-half months I had plants with four leaves. Mr. Robt. Lamont, of Theobroma estate, to whom I supplied over 200 seeds, told me only last week that nearly all I gave him have germinated. Latterly I found that the seeds I thought fresh were not so, as, owing to the great heat at present, the seeds rapidly grew lighter, and I am afraid lost their germinating power and were unfit for planting. I have therefore fixed upon the idea of keeping them in a finger-cup with water; this method, I think, will preserve them longer. The great difficulty I find is to get "gigantic bamboo" in Colombo: I tried the experiment of putting the seeds in wicker-baskets, but white ants commenced attacking the baskets, and besides they don't bear removal so easily as "bamboo pots." Thirty seeds that I first put down I cracked slightly with a light hammer: these germinated sooner, but, learning that the plants so raised would be delicate, I stopped this process. I have nearly 300 in bamboos in nursery, and in two or three months hope to have as many thousands, with which I shall be glad to supply any of your readers at a moderate price. The idea of the seed being boiled you have properly characterized as absurd, the fact being, that, though the seeds must have been fresh when sent, by the time the same were put down, they must have lost their germinating power. Your own correspondent "W. B. L." is well informed on this subject, and I am certain can give you a more elaborate account than I can. As I mentioned before, I do not believe anyone in Colombo can supply *fresh nutmeg seeds*, say within four days of the plucking, *to any considerable extent*, Capt. Bayley excepting, and probably the tenants of Hill House, Mutwal.—Yours faithfully, D.

INDIA:—CROP AND WEATHER REPORT.

FOR THE WEEK ENDING THE 16TH APRIL 1884.

GENERAL REMARKS.—Heavy rain continues to fall in Assam. Slight showers have also occurred in parts of Bengal, Madras, Mysore, Upper Sind, Hyderabad, the Punjab, the North-West Provinces, and the Central Provinces.

The standing crops in the Madras Presidency and Mysore are generally in fair condition, but the paddy crop in Malabar is in need of rain. The rabi harvest has been completed in several districts of the Bombay Presidency, and is approaching completion in others. Locusts are reported to be numerous in Kanara. Water continues scarce in parts of Dharwar. Some damage has been done by hail to standing crops in Hyderabad. In Central India and Rajputana harvesting and threshing are going on, and prospects appear fair. In the Punjab prospects remain unchanged; in the south-eastern districts, where harvesting has commenced, there will be a short yield; elsewhere the crops promise well. In the Ferozepore district the crops have been partially injured by a hailstorm In the North-Western Provinces and Oudh the rabi harvest is nearly over, and a fair out-turn has been obtained in most districts. Water and fodder for cattle are scarce in some localities, and hot westerly winds continue to prevail. In the Central Provinces the rabi grains have come into market, but the exports of wheat are small.

In Bengal most crops have been cut. and rain is needed everywhere for the cultivation of early paddy. In Assam the prospects are good, and paddy sowings are in progress. Rain is, however, needed in Gauhati. In Burma there are no crops on the ground.

Smallpox, cholera, and fever are prevalent, especially in the Southern Presidencies, Bengal, and Burma. Cholera is severe in parts of the Moorshedabad and Pubna districts.

The price of paddy is rising in some districts of Burma and in Durbhunga in Bengal; elsewhere prices appear to be generally stationary, with local fluctuations.

MADRAS.—General prospects good.

BRITISH BURMA.—Some cholera in Pegu, Arakan, and Irrawady Divisions; smallpox still prevalent, but severity of epidemic greatly decreased. Cattle healthy except in Hanthawaddy and Tharrawaddy. Price of paddy in parts slightly rising.

ASSAM (GAUHATI, April 16th).—Weather dry and hot, but mornings cool. Smallpox still reported from Shastra Parbetta. Rain wanted. Sowing of the aus in progress. Cholera on the decline.

THE *Quinologist*, one of the numerous American technical journals, has been discontinued, to allow the editor (Dr. R. V. Mattison) to engage more actively in a business career which "the demands of an active constituency of customers and the exigencies of the situation in regard to the manufacture and sale of the alkaloids of the cinchona bark have rendered of the highest importance."—*Pharmaceutical Journal.*

ROYAL BOTANIC GARDENS.

REPORT OF THE DIRECTOR FOR THE YEAR 1883.

CONTENTS.

I.—Condition of the Gardens.
1.—Péradeniya Garden.
2.—Hakgala Garden.
3.—Henaratgoda Garden.
4.—Anurádhapura Garden.
II.—Interchange of Plants and Seeds.
III.—Additions to the Collections.
1.—Péradeniya and Henaratgoda Gardens.
2.—Hakgala Garden.
IV.—Economic Plants.
V.—Herbarium and Library.
VI.—Receipts from Sale of Plants, &c.
VII.—Expenditure.

I.—CONDITION OF THE GARDENS.

1.—*Péradeniya Garden.*

EVERY effort, compatible with the economy which the funds at my disposal compel, has been made during the year to maintain this large garden in a condition of efficiency and beauty.

Roads and Paths.—Several of the carriage roads, including the continuation of the main Central Drive and the Bat Drive, have been remade, and that so thoroughly, that little more work upon them will be needed for many years. The long outer or River Drive will require attention during the coming year. A new footpath, crossing a picturesque elevation, has been made from the site of the old nurseries into the Bat Drive; this has brought forward several interesting trees not previously easily to be examined by visitors. The opening of new paths greatly facilitates proper attention to all parts of the garden, and while it necessitates the removal of useless and unsightly vegetation affords fresh situations for planting out new kinds.

Buildings.—The "Assistant Director's" bungalow, which is adjacent to the new south garden, has been put into thorough repair, the old out-houses and stables cleared away and new ones built, the approach from the high road diverted, the garden levelled and improved, and the whole surrounded by a substantial wooden fence separating it from the Botanic Garden proper with which it communicates by a footpath only. I purpose making this bungalow my dwelling-house, retaining, however, my office at the present "Director's" bungalow—in proximity to the library and herbarium—where I also intend to form a museum for timber and other vegetable products.

A new and substantial tiled cattle-shed has been built in a retired portion of the garden, and the old erection of bamboo and mána grass destroyed. This has been effected from the ordinary vote for the gardens.

The glass-roofed plant-house was completed early in the year by the erection of the interior staging. The glass has been coloured green, and side screens hung between the pillars. The orchids and other rare plants contained in it are now getting well established, and the house promises to succeed completely.

The repairs of the Gardner Memorial were completed in February, and as a sufficient sum still remained, I expended it on a small brass commemoration tablet (executed in Colombo) which has been fixed in its place. It bears the following inscription:—

GEORGIUS GARDNER, SOC. LINN. SOC.,
HORUM HORTORUM AB ANNO 1843 AD 1849 CUSTOS,
REI HERBARIÆ PERITUS, VIARUM STRENUUS,
FLORES HERBAS ARBORES UTRIUSQUE ORBIS
DILIGENTISSIME SCRUTATUS EST.

CUI UT IN MEMORIAM HABEATUR
HOC CENOTAPHIUM POSUERUNT
AMICI TABROBANENSES,
A.D. 1855.

OBIIT IN URBE NUWARA ELIYA
A.D. VI. ID. MART. AN O 1849. ÆTAT 37.

Repairs to the principal plant-shed have been sanctioned for the coming year. The remainder of the buildings are in good order.

Lawns.—The meadow-mower, referred to in my last report, has proved a great success, and will quickly pay for its cost by labour saved. It is worked easily and rapidly by a pair of bullocks, the pole having been lengthened sufficiently to allow the driver to walk behind and guide the bullocks in the usual native manner. Another man occupies the seat, and is concerned only to manage the machine, elevate or depress the knives, &c. The improvement in the condition of the grass is already very conspicuous, and will steadily increase.

By the liberality of Mr. F. D. Mitchell, of Colombo, another great desideratum of the garden has been supplied. A large iron cylinder, 5¼ feet wide and 5 feet in diameter, weighing one and a quarter ton, which he presented, will be fitted up as a garden roller as soon as the necessary expense can be afforded. It is to be feared, however, that the old bullocks we possess will scarcely be equal to the draught of so heavy a weight.

It may be of interest to note the constituents of the lawns in the garden for comparison with those of other tropical countries; it should be remembered that they are entirely natural and self-made. Of true grasses, the most important and abundant are *Panicum sanguinale, P. cimicinum* and *P. ovalifolium, Setaria glauca, Andropogon pertusus, Ischæmum ciliare (Spodiopogon obliquivalvis), Chrysopogon acicularis, Anthistiria tremula, Sporobolus diander, Eragrostis pilosa, E. plumosa.* Less abundant factors of the turf are *Panicum colonum, Paspalum scrobiculatum, Stenotaphrum complanatum, Eragrostis Brownii, Eleusine indica, Panicum repens, Anthistiria arguens and Imperata arundinacea,* the last four coarse and objectionable species on lawns. Under the trees the principal turf-grasses are *Panicum trigonum and P. uncinatum, Oplismenus compositus, Apluda aristata,* and especially *Paspalum conjugatum.* The last named admirable species is the only one not native here; it appears to have been accidentally introduced less than 20 years ago, and is now the prominent grass in the garden, rapidly occupying the ground with its creeping stems, especially under shade, but also freely in the open, and seeding copiously. It is said to be native to South America (and we have a specimen in the herbarium from Guiana) but it grows also in the Malay Islands and elsewhere in the East, but may be in all cases introduced there. Besides the grasses there are many other plants in the turf, the principal of which are:—*Desmodium triphyllum* (an excellent turf-plant for dry places), *Vernonia cinerea, Emilia sonchifolia, Hydrocotyle asiatica, Justicia procumbens, Ipomœa tridentata, Oxalis corniculata, Commelina bengalensis, Aneilema nudiflorum, Fimbristylis monostachya, F. diphylla, Kyllinga monocephala, &c.;* whilst in the damper shady places *Sida humilis, Hydrocotyle javanica* and *Impatiens flaccida* are prominent plants.

Propagation and Planting.—A large number of additions to the systematic portions of the garden have been put out in their places, and many duplicates planted in other parts, in the arboretum, beds, rockeries, or fernery. A list of the species new to the collections is given in section III.

The water-course leading to the well at the plant-sheds has been bricked over throughout, so that the water now arrives in a clear condition.

Labels.—The writing of most of the zinc labels has required renewal. I am now using painted blocks of teak and palu wood, which are, I think, more lasting as labels than the zinc ones. I find white lettering on a black ground to be more easily read (though the labels themselves are less conspicuous) than the contrary arrangement hitherto followed.

Rainfall.—A rain-gauge having been supplied by the Public Works Department at the end of June, Mr. Clark has registered the fall for the latter half of the year, which was as follows:—

	Rainfall.	Rainy Days.
July ...	7·12 ...	18
August ...	9·26 ...	20
September ...	4·24 ...	11
October ...	9·77 ...	21
November ...	8·82 ...	19
December ...	7·90 ...	10
Total ...	47·11	99

The heaviest fall in any one day occurred on 18th December, the amount registered being 2·62 inches.

Guide-Book to the Gardens.—The want of some assistance in finding plants of interest in the gardens having become a pressing one, I drew up a short descriptive itinerary in a small Hand-guide of 32 pages. This, accompanied by a lithographed plan, was printed and issued in November, and is sold at the garden gate and at Colombo for 12½ cents. It is the first attempt to give any information to the public on the contents of this Government garden, and has met with full appreciation. I am now occupied in compiling, as accurately and completely as I can, a Classified Catalogue of the plants now growing here. There are, however, a considerable number of foreign trees which have never flowered, and many of these are as yet undetermined; but to endeavour to attain absolute completeness in the list before publication would be to indefinitely postpone it.

2.—*Hakgala Garden.*

Considerable progress has been made in the directions pointed out in my last year's report, and the garden has made great progress in every way. The principal works of the year have been the commencement of the extension of the carriage drive and the erection of the propagating house. As, however, the vote for labour is insufficient to do more than allow of the ordinary work of the place, the former of these undertakings has been mainly carried out by coolies from Péradeniya. I have made an effort to spare labour from the larger gardens to the amount of Rs. 500, and shall endeavour to do the same in 1884, but, of course, Péradeniya suffers to a corresponding extent.

Details as to the propagating house are given below. The votes for this necessary part of the hill garden amounted to Rs. 1,850; the actual cost has somewhat exceeded that sum, the surplus having been met by savings on the vote for the meadow-mower. Messrs. Boyd have supplied us with a first-rate building, the benefits of which would have been experienced five months sooner had it not been for the annoying delay caused by the overcarriage of two cases as far as Sydney. The furnace, damper, and other ironwork were made by a native blacksmith at Péradeniya.

The hope expressed last year that the water-course would give no further trouble has not been realized; indeed, the future of the supply to the garden gives me some concern. A serious breaking away of a further portion of the channel occurred in July, and this has not yet been repaired. Hence there has been no regular supply of water for nearly half the year, the garden having been dependent upon a little rivulet coming down from the mountain forest. This begins to fail after about a week's drought, and has on several occasions run very short, necessitating extra labour in carrying water from elsewhere. The delay in the matter, which was at once reported to Government, has been caused by the necessity for considering whether it might not be in the long run a saving of expense to abandon the old course, which is badly traced and constantly liable to damage, and either construct a new one in a different line, or form a reservoir in the garden capable of containing sufficient water to last through any period of dry weather likely to occur. I have recommended the latter plan, and the subject is still under consideration.*

A complete set of meteorological instruments was, in answer to my repeated requests, received from the Surveyor-General at the end of June, and on 1st July the Superintendent commenced his observations. The records at this remarkably situated station cannot fail to be of exceptional interest and value.

I am glad to report most favourably of the continued zealous activity of Mr. Nock who takes an earnest interest in his work. I trust that the repairs in his bungalow may be carried out without further delay. It is also much to be wished that some accommodation were provided for the Director on his visits to Hakgala.

From a very full report on the condition and progress of the garden for the past year, which the Superintendent has sent in, I extract the following details:—

"*Buildings.*—No repairs or painting having been done to the Superintendent's bungalow during the year, the plaster in many places has continued to crack and fall off, and the walls and woodwork are now in a very untidy state. The store-room, out-buildings, and foreman's quarters also require whitewashing.

"A new span-roofed shed for the carpenter to work in and for the storage of lumber has been built, and also a large potting shed for storing soil and manure, and for general use in connection with potting work.

* The breakaway has since been temporarily repaired by Mr. Nock, who has also put in a new sluice, with a small vote taken over from the Public Works Department. [*Note added.*]

"*New Propagating House.*—I am glad to be able to state that this building is now nearly completed. The roof, eaves, partitions and doors (made by Messrs. Boyd and Sons, of Glasgow) arrived in Colombo in the middle of May, but unfortunately two cases containing the main ribs of the roof were not landed, and we had to wait for them until the ship returned again to Colombo in October. The house is span-roofed, 36 feet in length, 15 feet in width, and 9 feet 6 inches high. There is a glass partition in the middle which divides the house into two equal parts. A shelf, two feet wide and 3 feet from the ground, runs all round the sides of the house. A bed, 4 feet 6 inches wide, occupies the centre, and a path, 2 feet 3 inches wide, runs round.

"The heating apparatus for the propagating bed is a flue which runs from a stoke-hole (7 feet by 7 feet) built at the S.S.E. corner underneath the path, into the centre of the bed, along which it passes and comes out underneath the shelf into a chimney at the W.N.W. corner. The size of the flue is 12 inches by 14 inches, and the length from mouth at stoke-hole to chimney 44 feet.

"The framework of the house is of the best teakwood. The top roof sashes on either side of the ridge are made to open for ventilation by means of iron rods with lever and gearing. Every alternate upright sash in the side is made to open with quadrants. The eaves have moulded cast-iron gutters The ridge is supported by iron tie rods. The roof is strengthened by iron bars, several between the principal rafters, and supporting the intermediate astragals. All the glass is good 21 oz. sheet. The sides of the propagating hot-beds in the centre of the house are built of brick to a height of 3 feet above the paths and are filled to a convenient level, first with rubble over the flue, and then sand above that for plunging the pots in.

"The partition in the middle of the house will enable us to so regulate the air that we can have one part hotter than the other whenever it is desired. The inside has received three coats of paint, and the fitting up of the shelves, &c., is finished with the exception of one on the right hand side of the second division. All that remains to be done of the outside work is the completion of the building of the chimney, the glazing of 36 panes in the roof, the painting of the roof, and the shingling of stoke-hole roof. The first division of the house has been in use for the last month, and the young plants placed in it have already showed a very marked improvement.

"This house supplies a much felt want, and in it we shall now be able to raise almost any kind of plants either by seeds or cuttings.

"*Carriage drive and paths.*—In the early part of the year the old carriage drive, for a distance of 394 yards, was broken up and remade under a layer of rough sand well stamped in on the top. Four hundred and eighty-eight running yards of turf, 12 inches wide, have been laid down as an edging to each side of the drive. There still remains about 300 yards of this work to be done to complete the edging of old drive.

"A temporary path, 112 yards long, has been made leading from the place where the new drive ends to the lower summer arbour.

"*Extension of carriage drive.*—The new loop to the carriage drive has been made for a distance of 150 yards. The fall for this distance is at the rate of 1 in 12, which will continue for about three chains further, and then a much easier gradient will be taken for the greater part of the curve back to the old drive near the entrance-gate. Near the beginning a large cutting, two chains in length, fifteen feet wide, and an average depth of eight feet, had to be made, and this, with the sloping of the sides to an angle of 45°, proved rather a heavy piece of work for us. However, all the soil got out from this was required to fill up a gully, a little further on, that we had to cross.

"A large quantity of rock which was in the way had to be blasted. This came in very handy for making the foundation and for metalling Seven hundred and fifty bushels of large stones, varying in size from two to three inches in diameter, were first laid along for the foundation, and on this was placed 740 bushels of metal of the size used on the public roads, and then 500 bushels of gravelly soil as a binding material was laid on, and over the whole a good sprinkling of river sand. It was then well watered and rammed at three different times.

"*Fernery.*—The condition of the fernery has been maintained, and it continues to be much appreciated by visitors. The roots of the jungle trees have, however, again encroached there and filled many of the beds, so that it will be necessary during the coming year to again renew the soil.

"A new path, 36 yards long, has been made at the lower end of the fernery through the jungle into the main drive, thus affording an outlet to persons visiting the fernery without going back over the same ground. A rock bed has been made at the fernery end of this path, and 200 plants of foreign species of ferns have been planted in it. A quantity of native orchids have been brought in from the jungle during the year and fastened on the trees, and the greater part of them are now growing freely.

"*Nurseries.*—A strong close fence, 120 yards in length, has been made on the S.E. and W. side of the nursery. A centre path has been made, 6 feet wide and 100 yards long, and nursery beds, 3 feet wide, at right angles with it on each side.

"*Borders and Shrubberies.*—The unsightly hollow near entrance to fernery has been filled up and a new path edged with turf made through it to correspond with the one leading from the fernery ; and borders made on each side of this have been planted with showy plants in lines to form a ribbon border.

A great deal of work has been done in the shrubberies in the way of thinning out trees and manuring and planting up. The soil here is generally very poor, and it is found necessary to give every plant a liberal supply of manure, and to make good holes for them. Eight thousand five hundred and eighty-two ornamental shrubs and garden plants have been planted out in the borders and shrubberies during the year.

"A small plot of land near the herbaceous ground was prepared for monocotyledonous plants, and specimen plants of most of the species growing in the garden have been planted in it.

"*Flower Garden.*—The steep sloping path leading across the flower garden has been altered by building a flight of steps at the lower end, and raising the path so that it now runs on a level with the garden. Two small turf banks have also been made and the top borders filled up level with the path.

"*Visitors.*—The number of visitors during the year was 460, being an increase of 90 over that of the previous year.

"*Weather.*—The weather during the year has been generally much finer than in the last, there being much less rain and wind ; though the number of days on which rain fell was only 9 short of last year—226 this year against 235 last—as follows:—

	1882.	1883.		1882.	1883.
January ...	10 ...	22	July ...	31 ...	22
February ...	16 ...	11	August ...	31 ...	25
March ...	6 ...	8	September ...	27 ...	14
April ...	12 ...	18	October ...	27 ...	22
May ...	15 ...	18	November ...	20 ...	24
June ...	18 ...	23	December ...	22 ...	19
				Total—235	Total—226

"The total rainfall from 1st July to the end of the year was 47·06 inches, as given below:—

	Inches.
July ...	11·96
August ...	7·96
September ...	3·27
October ...	6·80
November ...	9·24
December ..	7·83
	Total—47·06

"The greatest fall in any 24 hours was 4·85 inches from 12th to 13th July. The mean daily rainfall for the six months was ·26 inches nearly.

"High wind began on the 9th of May, but after blowing with great force for a few days it became light, and we had but little more until the 27th when it became very strong again and continued with few intervals to blow with great force until the beginning of September. On several occasions during this time the force was at the rate of over 30 miles an hour.

"The full records of weather observations are published in the monthly tables of the Surveyor-General, and it is only necessary here to give an outline of the barometrical and thermometrical readings for the six months:—

Barometric Pressure. ("5,400 ft.")	Mean.	Range.	Temperature of Air.	Mean.	Range.
July ..	24·500 ...	·218	July ...	61·8 ...	19·0
August ...	24·476 ...	·192	August ...	61·8 ...	19·5
September ...	24·542 ...	·170	September ...	62·6 ...	18·5
October ...	24·516 ...	·192	October ...	60·9 ..	17·0
November ...	24·506 ...	·190	November ...	60·2 ...	16·5
December ...	24·570 ...	·213	December ...	60·4 ...	20·5
The six months	24·518 ...	·292	The six months	61·3 ..	27·0

Highest reading 17th December, 24·666
Lowest „ 13th July, 24·374

Maximum temperature of air, 4th July, 74·0
Minimum „ 4th Dec., 47·0

"The mean amount of cloud for the six months was 8, the cloudiest month being November."

3.—*Henaratgoda Garden.*

The condition of this garden is excellent, and there is little calling for improvement The trespass of cattle has always been a trouble here, surrounded as the garden is by villages ; a living hedge of prickly bamboo has been planted in a part of the boundary specially liable to their incursions. The plant-shed has been enlarged and fitted with staging, and the well cleaned out and thoroughly repaired.

A heavy gale of wind on the night of June 11th blew down over twenty large trees, and pid some temporary damage to cacao and rubber trees.

Numerous plants have been sent to this branch from Péradeniya as likely to find here a more suitable climate. For example, *Nectandra Rodiæi* (Greenheart), *Galactodendron* (Cow tree) *Dichopsis* sp. (Gutta Taban Putih), *Hevea Spruceana* (a new India rubber), *ierardia dulcis*, (Rambeh), *Bertholletia excelsa* (Brazil nut), many palms, &c. Such plants do extremely well in this thoroughly tropical spot. On the other hand, the climate proved quite unsuitable for Senna and Peruvian cotton.

The very large distribution of Cacao pods and Liberian coffee seedlings to natives is referred to elsewhere. As projected last year, an avenue of about 200 shade trees (*P. Saman*) has been planted along the road from the railway station. They have all done well and some are nearly ten feet high.

The intelligent Muhandiram in charge continues to perform his duties in a very satisfactory manner. Besides being a skilful cultivator, he is very obliging and useful to visitors of all classes, many of whom, as there is no rest-house near the garden, have of necessity to spend there several hours between the trains. I have to report that the little house he occupies greatly needs painting, white-washing, &c.; he has lived in it since the establishment of the garden seven years ago, and it has never had anything spent upon it by Government.

4.—*Anurádhapura Garden.*

This new branch of the Department is as yet in process of formation only, but good progress has been made. It is the successor of the small garden at Toluwila, formerly under the Government Agent, the abandonment of which was rendered necessary by floods.

I selected the present excellent site in March, in concert with the Acting (since confirmed) Government Agent, Mr. Fisher. It is a piece of reserved Crown land lying close to the town immediately to the south of the Puttalam road and the Mirisawetiya dágoba, and easily accessible. In area it is a little over 16 acres, of which about 12 only will be opened as a garden. Paddy lots bound it on two sides, and there is an abundant and constant supply of water, the sluice to the fields passing down the centre whilst the longest boundary is formed by the channel connecting the tanks Tissawewa and Basawakulam ; there is also a small pond (ancient pokuna?) in the garden.

Most of the land has now been cleared of forest growth (chiefly wira trees), the finer trees being left, but a belt of two or three acres on the east side has been retained; a good driving road round the garden is nearly finished, a fence has been made, a house for the conductor erected, nurseries laid out, and the general plan of the garden sketched out on the ground. Such plants as could be removed from the old ground at Toluwila have been brought into the new garden, and in the planting season, November and December, five cartloads of plants and cuttings suitable for or worthy of a trial in the climate were sent from Péradeniya, a distance of 94 miles.

This progress could not have been made in nine months had I not had the use of a force of prisoners from the jail, some help from the Provincial vote, and especially the efficient and vigorous oversight of the Government Agent and his Assistant, to whom my thanks are due. My vote for the garden (Rs. 1,000) will do little more than pay the wages of the conductor and four coolies, who will find the upkeep of the garden fully sufficient to occupy their time.

The conductor, Sayaneris de Silva, deserves credit for the steady and persevering way in which he has stuck to his work in spite of several attacks of fever, and has started the planting of the new ground. I hope and fully expect that this experimental garden will play an important part in helping on the reviving prosperity of the North-Central Province, and will be the means of introducing the culture of plants of utility and beauty—especially from Southern India—into the northern parts of the Island.

A small beginning has been made in experiments with Tinnevelly senna and Peruvian cotton.

Proposed Garden at Badulla.—I am desirous of extending the operations of this Department by the formation of a small branch in the Uva District, the most convenient situation being probably in or near Badulla. Residents in that part of the Colony have frequently complained of the inconvenience and loss attendant on having to send coolies to Péradeniya, a distance of 80 miles, across the hills for plants. I recommended this addition to Government at the end of 1880 (see letter No. 65 to Colonial Secretary), and then suggested that the Badulla garden might be conveniently placed under the ordinary supervision of the Superintendent of Hakgala ; and this arrangement I would still support.

I am averse to frittering away money by the opening of numerous branch gardens, and the foundation of one at Badulla would complete the number of those which are really needed by the Colony. A suitable piece of Crown land could doubtless be found, and the annual cost of maintenance would be about Rs. 1,500.

II.—Interchange of Plants and Seeds.

The usual mutual exchanges have been carried on with the British and Foreign Botanical Establishments with which we have relations. During the past year we have received Wardian cases of plants from the gardens at Kew (4 cases), Calcutta (4 cases), Madras, Ootacamund, Singapore (2 cases), Buitenzorg, Brisbane (2 cases).

Boxes and packets of seeds have been received here from the following Botanic Gardens :— Kew, Dublin, Calcutta, Madras, Ootacamund, Hongkong, Mauritius, Natal, Brisbane, Jamaica, Demerara, and St. Petersburg. Also from the Colonial Secretary, Fiji; H.B.M.'s Resident, Perak; the Superintendent of Port Blair, Andamans; the Conservators of Forests, Moulmein and Nellore; and the Superintendent of Government Farms, Saidapet. I have also to thank Sir F. von Muller (Melbourne), and Messrs. L. B. von Donop (N. Borneo), H. Purvis (Hawaii), and T. Christy (London), for seeds, as well as Messrs. Veitch, Messrs. Barr and Sugden, and Mr. Roberts, of Melbourne.

We have despatched from the gardens Wardian cases of rare plants to the establishments at Kew (4 cases), Calcutta (2 cases), Singapore, Moulmein, and Brisbane, to Mr. T. J. Ferguson (Calicut) on behalf of Madras Government (2 cases), and to Mr. J. Costeker (Philippine Islands), for the Manila garden.

My thanks are due to the Agents of the P. & O. and B. I. S. N. Companies for free freight of cases addressed to or from these gardens and other similar establishments.

Packets of seeds have been sent out to the Botanic Gardens at Kew, Madras, Singapore, Hongkong, Manilla, Buitenzorg, Melbourne, Sydney, Adelaide, Jamaica, Demerara and Rio ; to the Hon. J. B. Thurston, Colonial Secretary, Fiji ; Sir H. Low, H. B. M.'s Resident, Perak ; Sir J. Kirk, H. B. M.'s Consul-General, Zanzibar ; the Conservator of Forests, Assam, &c.

As usual, plants, seeds and cuttings have been supplied to Government officials in Ceylon, free of charge—to the Government Agents of Kandy, Kurunégala, Ratnapura and Mátalé ; for the grounds of the Colombo Museum, a large collection ; for the Police Barracks, Kandy, &c.

I have to acknowledge with thanks plants and seeds from the following residents in the Colony:—Sir J. Douglas, K.C.M.G., Hon. B. L. Burnside, Hon. A. L. de Alwis, Hon. J. F. Dickson, C.M.G., Mrs. Baker, and Messrs. D. Blyth, W. D. Bosanquet, P. Braine, J. Cotton, W. I. Cotton, W. Ferguson, F.L.S., T. Gibson, A. Herfft, T. C. Huxley, A. R. Lewis, F. C. Loos, Rev. G. W. R. Mackenzie, C. A. Murray, C.C.S., H. Nevill, C.C.S., J. V. H. Owen, H. S. Saunders, S. M. Kay Shuttleworth, A. Whyte, E. Woodhouse, J. H. Wright, Messrs. Lee, Hedges & Co., and the Ceylon Company, Limited.

III.—Additions to the Collections.

These lists, in continuation of those in my former reports, contain the principal exotic species added to the gardens during the year. Only those are entered which seem to be satisfactorily established here.

During my visit to Southern India I visited the garden of the Agri-Horticultural Society at Madras and the Government Garden at Ootacamund, and made out lists of our desiderata which they contained. Many of these I have since had the pleasure of receiving and planting in Péradeniya and Hakgala gardens.

I.—Péradeniya and Henaratgoḍa Gardens.

DICOTYLEDONS.

Bocagea (*Oxandra*) *virgata*, (Rich.) Lance-wood. Jamaica, Cuba. (Kew.)
Oncoba spinosa, Forsk. Trop. Africa, Arabia. Fruit edible. (Kew.)
Marcgraavia umbellata, L. W. Indies, Venezuela. (Kew.)
Sterculia rupestris, Benth. (*Delabechea*, Lindl.) Bottle-tree. Queensland. (Brisbane.)

Cola acuminata, R. Br.* Cola-nut. W. Trop. Africa. (Kew and Jamaica.)
Reevesia thyrsoidea, Lindl. China. (Kew.)
Impatiens Sultani, Hook. f. A very pretty Balsam; figured in Bot. Mag. t. 6643. Zanzibar. (Kew.)
Balsamodendron Roxburghii, Arn. Assam? Said to be one of the the sources of the resin called Indian Bdellium. (Madras.)
Vitis Martinellii. A tuberous-rooted vine. (See Gard. Chron., 1882, 1, 438). Cochin China. (Hongkong.)
Paullinia pinnata, L. Trop. America, W. Trop. Africa. (Calcutta.)
Diploglottis Cunninghamii, Hk. f. Queensland. (Brisbane)
Harpullia pendula, Planch. Tulip-wood, Queensland. (Brisbane.)
Cupania pendula. (Kew.)
Sclerocarya caffra, Sond. Natal. (Madras.)
Erythrina speciosa, Andr. Coral Bean. Trop. America, W. Indies. (Madras.)
Lonchocarpus sp. Yoruba Indigo. (See Journ. Linn. Soc. xx., p. 404.) W. Trop. Africa. (Kew.)
Camoensia maxima, Welw. W. Trop. Africa. A magnificent climber, the flowers surpassing those of *Amherstia*. Figured in Trans. Linn. Soc. xxv., t. 36. (Kew.)
Peltophorum Linnæi, Benth. (*Cæsalpinia brasiliensis*, L.) Brasiletto-wood. (Jamaica.)
Cæsalpinia ferrea, Mart. Brazil. (J. V. H. Owen.)
Cassia acutifolia, Del. "True Mecca Senna." E. Trop. Africa. (Kew.)
C. angustifolia, Vahl. (*C. lanceolata*, W. & A.) Tinnevelly Senna. S. Arabia, S. Africa, Sinde; cult. in S. India. (Madras.)
Bauhinia Hookeri, F. M. Queensland. (Brisbane.)
B. Richardiana, DC. Cayenne. (Madras.)
Copaifera sp. Venezuela. (Lee, Hedges & Co.)
Quillaia Saponaria, Mol. Chili. Bark used as soap. (Kew.)
Terminalia melanocarpa, F. M. Queensland. (Madras.)
Eugenia Ugni, Mol. Chili. Bears an edible fruit. (Kew.)
Phyllagathis rotundifolia, Bl. Malacca, Sumatra. (Buitenzorg.)
P. gymnantha, Korth. Borneo. (Buitenzorg.)
Cuphea eminens, Hort. (Calcutta.)
Hodgsonia heteroclita, Hk. f. and Th. Assam, Burmah, &c. (Calcutta.)
Aralia spinulosa, Hort. (Calcutta.)
Brassaia actinophylla, Endl. Queensland. (Madras.)
Panax elegans, F. M. E. Australia. (Brisbane.)
P. obtusum, Bl. Java. (Calcutta.)
P. plumosum, Hort. (Calcutta.)
P. tricochleatum, Miq. Sumatra. (Calcutta.)
Sarcocephalus esculentus, Afz. Sierra Leone Peach. W. Trop. Africa. (Kew.)
Pogonopus (Howardia) caracasensis, (Wedd.) Venezuela, Panama. Figured in Bot. Mag., t. 5110. (Kew.)
Ixora alba, Roxb. China? (Madras.)
I. Pilgrimi, Hort. (Kew.)
I. sp. With yellow flowers. (Calcutta.)
Pavetta natalensis, Sond. Natal. (Natal.)
Hamiltonia suaveolens, Roxb. India. (Calcutta.)
Eupatorium paniculatum, Hort. Madr. (non Schrad.) (Madras.)
Ardisia, sp. Sikkim (Calcutta.)
Allamanda Hendersonii, Hort. (Kew.)
Chilocarpus, sp. Gutta Singret. Perak. (Sir H. Low.)
Rauwolfia canescens, L. W. Indies. (Madras.)
Kopsia fruticosa, A. DC. Burmah, Java. (Madras.)
Dipladenia boliviensis, Hook. Bolivia. Figured in Bot. Mag., t. 5783. (Kew.)
Cryptostegia madagascariensis, Boj. Madagascar. E. Trop Africa. (Kew.)
Gelsemium nitidum, Mich. False yellow jasmine. Mexico and S. United States. A powerful nervine sedative. Figured in Medicinal Plants, t. 181. (Kew.)
Ipomœa Horsfalliæ, Hook. Malaya? (Madras.)
I. carnea, Jacq. Trop. S. America. (Madras.)
Buttonia natalensis, McKen. Natal. Figured in Hook. Ic. Plant t. 1080. (Natal.)
Episcia (Centrosolenia) bullata, Lém. E. Peru. Figured in Ill. Hort., t. 607. (Calcutta.)

---

* The trees in the garden hitherto passing under the name of "Cola-nut" are not *Cola acuminata*.

E. (*Centr.*) *erythropus*, Hk. f. New Grenada. Figured in Bot. Mag., t. 6219. (Kew.)
Bignonia purpurea, Lodd. Trop. S. America? Figured in Bot. Mag., t. 5800. (Kew.)
Jacaranda brasiliana, Pers. Brazil. (Buitenzorg.)
Thunbergia Harrisii, Hk. Burmah. Figured in Bot. Mag., t. 4998; scarcely differs from *T. laurifolia.* (Kew.)
Ruellia rosea, Hort. (Calcutta.)
Aphelandra Chamissoniana, Nees. S. Brazil. Figured in Bot. Mag., t. 6627. (Kew.)
Geissomeria aurantiaca, (Lindl.) Trop. America. (Calcutta.)
Clerodendron fallax, Lindl., var. *albiflorum.* Java. (Buitenzorg.)
C. Minahassæ, T. and B. Celebes. (Buitenzorg.)
C. speciosum, Hort. (Hybr. *Thomsonæ* and *splendens.* Figured in Ill. Hort., t. 593. (Madras.)
Gomphostemma sp. (Calcutta.)
Seguiera floribunda, Benth. Brazil. (Kew.)
Antigonum insigne, Mast. Ecuador. (Calcutta.)
Nepenthes Ampullaria, Jack. Malay Peninsula. (Singapore.)
Eusideroxylon Zwageri, T. and B. Balian, Sarawak Iron-wood. Borneo. (Sir H. Low, 1882.)
Stenocarpus sinuatus, Endl. Queensland. (Brisbane.)
Baccaurea (*Pierardia*) *dulcis*, Müll. arg. Rambeh. Yields an edible fruit. Sumatra, cultivated in Malay Peninsula. (Singapore.)
Antidesma Dallachyana, Baill. Queensland. (Brisbane.)
Hevea Spruceana, Müll. arg. Hatie. Affords India-rubber. British Guiana, Brazil. (Kew.)
Aeurites vernicia, Hassk. Varnish tree. Japan, Cochin China. (Kew.)
Croton Eleuteria, J. J. Benn. The source of Cascarilla bark. Figured in Medicinal Plants, t. 238. Bahamas. (Kew.)
Boehmeria pulchella, Hort. (Calcutta.)
Ficus diversifolia, Bl. Java. (Calcutta.)
Cecropia peltata, L. Trop. America. (Kew.)
Callitris robusta, var. *microcarpa*, Benth. (*Frenela columellaris*, F. M.) Queensland. (Brisbane.)
Pinus Merkusii, Jungh. Burmah. (Major Seaton.)
Cycas pectinata, Griff. India and Burmah. (Calcutta.)
Macrozamia Peroffskiana, Miq., var. (*Catakidozamia Macleayi*, Hort.) Queensland. (Brisbane.)

MONOCOTYLEDONS.

Dendrobium Cambridgeanum, Lindl. Assam. (Calcutta.)
D. moschatum, Wall. Burmah. (Calcutta.)
Cymbidium Mastersii, Griff. N. India. (Id.)
Pholidota sp. (Id.)
Phalænopsis sumatrana, Korth. Sumatra. (Singapore.)
P. violacea. (Singapore.)
Cypripedium javanicum, Reinw. Java. Figured in Fl. de Serres, t. 703. (Buitenzorg.)
Kæmpferia Gilbertii. (Calcutta.)
Maranta setosa, A. Dietr. Brazil. (Id.)
Hæmanthus Katharinæ, Baker. Cape. (Natal.)
Vellozia (*Xerophyta*) *elegans*, Oliv. Natal. Figured in Bot. Mag, t. 5803. (Kew.)
Dioscorea Anæctochilus, Hort. (Kew.)
Dichorisandra Aubletiana, R. and S. Trop. America. (Kew.)

Palms.

Hydriastele Wendlandiana, H. Wendl. Queensland. (Brisbane.)
Hedyscepe Canterburyana, W. and D. Howe's Island. (Brisbane.)
Actinorhytis Calapparia, W. and D. Malay Archipelago. (Buitenzorg.)
Ptychosperma filifera, Wendl. Fiji. (Roberts, 1882.)
Howea Belmoriana, Becc. Howe's Island. (Id.)
H. Forsteriana, Becc. Howe's Island. (Id.)
Heterospathe elata, Scheff. Amboyna. (Buitenzorg.)
Hyophorbe amaricaulis, Mart. Mauritius. (Mauritius.)
Caryota, sp. Queensland. (Kew.)
Orania philippinensis. (Buitenzorg.)
Washingtonia filifera, S. Wats. California. (Kew.)
Pritchardia, sp. Sandwich Is. (H. Purvis.)
Licuala horrida, Bl. (? *L. spinosa*, var.) Java. (Kew, 1882.)
Calamus, sp. Perak. (Sir H. Low.)

Diplothemium caudescens, Mart. Brazil. (Kew, 1882.)
D. maritimum, Mart. Brazil. (Brisbane.)
Maximiliana, sp. "Palma Vino." (Kew, 1882.)

Pandanus Leram, Jones. Bread-fruit or Millore. Nicobar Is. (The late F. A. de Roepstorff.)
P. microcarpus, Kurz. (non Balf. f.) Java. (Buitenzorg.)
Colocasia violacea, Hort. (? *C. antiquorum*, var.) (Madras.)
Alocasia gigantea, Hort. (Madras.)
A. zebrina, C. Koch and Veitch. Philippine Is. (Id.)
Aglaonema commutatum, Schott. S. America. Figured in Bot. Mag. t. 5,500. (Buitenzorg.)
A. pictum, Kunth. Burmah, Sumatra. (Id.)
Dieffenbachia eburnea, Hort. (Kew.)
Panicum Brownii, R. & S. (*P. leucophlœum*, H. B. K.) Queensland, Trop. Africa and America. (Saidapet.)
Coix exaltata, Jacq. China. (Kew.)
C. sp. "Ma-yu'en." Cochin-China. (Id.)

FERNS, &c.

Pteris ludens, Wall. (*Doryopteris*, J. Sm.) Burmah, Philippines. (Calcutta.)
Asplenium Belangeri, Kunze. Malay Peninsula. (Calcutta.)
Selaginella lœvigata, Spring. Java. (Madras.)
S. Galeottii, aurea, paradoxa, &c. (Calcutta.)

2.—HAKGALA.

DICOTYLEDONS.

Clematis Meyeniana, Walp., var. *crenata*. China. (Hongkong.)
C. microphylla, DC. Australia. (S. Petersburg.)
Aquilegia atropurpurea, Willd. Cent. Asia. (Dublin.)
A. Whitmaniana. (Dublin.)
Berberis Leschenaultii, Wall. Nilgiris. (Ooty.)

Osmanthus aquifolium, (S. and Z.) Japan. (Ooty.)
Mandevillea suaveolens, Lindl. Temp. S. America. (Ooty.)
Cantua dependens, Pers. Peru. (Ooty.)
Ipomœa chrysorhiza, (Forst.) "Kumara" or New Zealand yam ; a variety of *I. Batatas* suitable for temperate climates. (Kew.)
Datura (Brugmansia) sanguinea, R. and P. Peru. (Ooty.)
Veronica speciosa, Cunn. N. Zealand. (Ooty.)
Jacobinia (Libonia) floribunda, (C. Koch.) Brazil. (Ooty.)
Salvia Columbariœ, Benth. Gives "Chia seeds." U. States. (Kew.)
Morus alba, L. White Mulberry. N. India. Cult. in S. Europe for Silkworms. (P. Braine.)
Ficus macrophylla, Desf. E. Australia.
F. stipulata, Thunb. China. (Ooty.)
Salix babylonica, L. Weeping willow. Persia and Caucasus. (Kew and Ooty.)
Buxus sempervirens, L. Box. Europe. (Ooty.)
Pinus Kasya, Royle. Khasia, Burmah. (Major Seaton.)

MONOCOTYLEDONS.

Dendrobrium moschatum, Wall. Burmah.
Cypripedium Drurii, Bedd. Travancore. (Ooty.)
Musa Ensete, Gmel. Abyssinia. (Kew and Jamaica.)
Iris Kaempferi, Sieb. Japan. (Mrs. Baker.)
Tigridia Pavonia, Pers. Mexico. (Mrs. Baker.)
Watsonia densiflora, Baker. Natal. (Ooty.)
Morœa Robinsoniana, F. M. Lord Howe's Island.
Clivia (*Imantophyllum*) *miniatum*, Hook. Cape. (Natal.)
Hœmanthus natalensis, Pappe, Natal. (Id.)
Buphane toxicaria, Herb. Poison Bulb. S. Africa.
Zephyranthes Atamasco, Herb. Virginia. (H. Nevill.)
Brunsvigia Josephinœ, Ker. Cape. (Natal.)
Cyrtanthus Mackenii, Hk. f. Cape. (Id.)
Bomarea oligantha. (Ooty.)
Agapanthus umbellatus, L'Her. Cape. (Ooty and Rev. G. Mackenzie.)
Lilium auratum, Lindl. Japan. (A. Whyte.)
L. speciosum. Thunb. Japan, cult. (Id.)
L. longiflorum, Thunb. China, Japan. (Id.)
L. tigrinum, Gawl. Tiger Lily. China. (Mrs. Mackenzie.)
Scilla Kraussii, Baker. Natal. (Natal.)
Hyacinthus candicans, Baker. Cape. (A. Whyte.)
Albuca fastigiata, Dry. ? Cape. (H. Nevill.)
Bowiea volubilis, Harv. S. Africa. (Natal.)
Livistona chinensis, R. Br. S. China. (H. Kong.)
L. oliviformis. Mart. Java.
Jubœa spectabilis, H. B. K. Temp. S. America. (Kew.)
Sabal Palmetto, Lodd. S. United States.
Richardia albo-maculata, Hk. Cape. (H. Nevill.)
Phalaris paradoxa, L. S. Europe. (Kew.)
Cornucopiœ cucullatum, L. Asia Minor.
Calamagrostis varia, P. de B. Europe.
Briza media, L. Europe.

Alopecurus pratensis, L. Fox-tail, Europe.
Poa palustris, L. (*fertilis*, Host.) Europe.
P. pratensis, L. Meadow Grass. Europe.
Festuca elatior, L. Tall Fescue. Europe.
F. geniculata. Willd. Mediterranean.
Lamarckia aurea, Moench. Mediterranean. A beautiful grass.
Dactylis glomerata, L. Cocksfoot. Europe.
D. "*undulistachys*."
Lolium multiflorum, Lam. (*italicum*, A. Br.) Italian Rye-grass. S. Europe.
Bromus longiflorus, Willd.
B. (*Ceratochloa*) *unioloides*, Willd.
And many other Grasses, all from Kew.
Also several Florists' flowers of the genera *Fuchsia, Begonia, Gaillardia, Calceolaria, Coleus, &c.*

FERNS.

Platycerium grande, J. Sm. N. Australia, Phippines, Singapore. (Brisbane.)
Alsophila latebrosa, Hk. India, Malaya. (Ooty.)
Anemia Wightiana, Gardn. Nilgiris (Ooty.)
And 62 packets of Fern spores from Kew, and 18 from Jamaica, from which a large number of plants have been raised.

IV.—ECONOMIC PLANTS.

Coffee.—The transition period of the planting revolution which has been in progress here for the last few years may be now considered nearly over, and the new conditions to be in a fair way to full establishment. Coffee, which was estimated only three years ago to cover 252,000 acres, now occupies little over 178,000, acres ;* and, what is more striking as evidence of the change, very much more than half of this is being grown along with cinchona, tea or cacao, a condition generally preliminary only to a complete substitution of the old by the newer and more promising crop.

The export for the past commercial year (ending with September, 1883), 260,000 cwt., is the lowest for 40 years, and is considerably less than half that of the previous one.

This tremendous falling off in crops is, with a due allowance for a series of bad seasons, the result of leaf-disease. On estates, no doubt this has operated indirectly as well as directly by rendering it impossible to afford a liberal cultivation, but the terrible direct effects of continued attacks of the pest are strikingly seen in the condition of so-called "native" coffee, the export of which has dwindled to 14,422 cwt., little over one-third of that of last year.

The complete extinction of "native" Arabian coffee would under present conditions be no great loss, and as regards *Hemeleia* even a direct benefit; and the same may be said of that on many old and ill-tended estates. There is indeed reason to hope that when coffee becomes one crop out of several, and its cultivation, instead of occupying vast sheets of country to the exclusion of all other vegetation, becomes restricted to localities and estates where it is known to respond to good treatment, attacks of leaf-disease will be less severe and less frequent. We may hope that the fungus will then take its place with the many other more or less similar pests which afflict cultivated plants and which, though always present, vary in mildness or severity in accordance with climatic conditions (weather) from season to season. It is to be earnestly desired that every encouragement be given to keeping up a liberal cultivation of coffee where possible.

The papers and specimens relating to "grub" obtained by the Planters' Association were forwarded to me, and I transmitted them early in July, through the Director of Kew, to Mr. MacLachlan, F.R.S. I regret that I have not yet received any report on them from him.

The area, 4,651 acres, given as under *Liberian Coffee*, shows that the cultivation of this species is slowly increasing. It appears to be allowed that its yield is, as a rule, better than that of Arabian coffee, in spite of severe attacks of leaf-disease. A large distribution has been made to native cultivators, principally through the Government Agents. From Henaratgoda garden over 40,000 seedling plants have been given out, and a smaller quantity from Péradeniya.

Tea.—Though the progress in this cultivation was astonishingly rapid in 1882, the past year has seen a far greater extension. Ceylon exported in the commercial year (1882-3) over a

* I take the estimates and other figures throughout this part of my report from the series carefully prepared for Ferguson's Directory for 1883-4.

million and a-half pounds (1,522,882), and in the three closing months of 1883 probably not less than 150,000 lbs. more. The acreage under tea is estimated at 32,000, but on 20,000 acres of this the plants are not yet three years old. A very large proportion is, however, old coffee land, and about 5,000 estimated acres of tea are mixed with coffee or cinchona.

The prospects of tea-growing are, on the whole, very favourable, and present experience is most encouraging. From the first, when the consumption was almost entirely local, an excellent character distinguished Ceylon tea; and its special qualities appear to be generally maintained and to be winning approbation in the home market. The fine series of samples (over 80 in number) which competed at the Colombo Agri-Horticultural Show in August, has been sent on by the Planters' Association to the Calcutta Exhibition, where they will be able to be compared with the picked teas of India.

It may be pretty confidently hoped that the lesson of leaf-disease has rendered it impossible that exclusive attention to one cultivation should ever again be the practice in Ceylon agriculture, but a warning in the case of tea is perhaps not quite unnecessary. In addition to the ordinary vicissitudes of all crops, it is wise to bear in mind that there is still some doubt as to the extent of the demand for such high class teas as those which Ceylon *must* produce. We are at present disappointed of a market in Australia for the reason that people there do not care to pay our price, being quite contented with an inferior and cheaper article. It is probable that the same is true of the great tea-drinking classes in England; they must have it cheap. It is predicted that in three years' time Ceylon is to throw 10,000,000 lbs. of Pekoe and Pekoe Souchong on the market, and it is perhaps possible: but it will be well to be prepared for the probability that this may have to be disposed of at the price of inferior qualities, to the benefit no doubt of the consumer but at the expense of the cultivator.

In some of the coffee districts where tea is being largely planted, some difficulty is felt as to the supply of fuel necessary for its manufacture. The reckless and ill-judged clearance of the whole of the jungle, as yet regretted principally as shelter from wind, will now be felt from another cause. As it is quite useless to attempt to bring back the old native trees to their much changed habitations, it will probably be necessary to plant and keep up fuel reserves. For this in the higher elevations nothing can be better than the quick-growing wattles, blackwood and eucalypts of Australia. In the lower districts (2,000—4,000 feet) there are many quick-growing native trees that would be found suitable; for example, "Malaboda" (*Myristica laurifolia*), which is recommended also for tea boxes, "Milla" (*Vitex altissima*), "Badula" (*Semecarpus Gardneri, &c.*) "Gedumba" (*Trema orientalis*), "Gúranda" (*Celtis cinnamomea*), "Nuga" (*Ficus laccifera, &c.*), "Kalaha" (*F. Wightiana*), "Walgona" (*F. callosa*), "Dawul kurundu" (*Litsœa zeylanica*), "Etamba" (*Mangifera zeylanica*). "Wá" (*Cassia siamea*) is an excellent tree for fuel at elevations below 2,000 feet. Several of these woods would also do for tea boxes, and, "Helamba" (*Anthocephalus Cadamba*), a common low-country tree, is also well spoken of for that purpose. It is of great importance to use only perfectly seasoned wood for boxes; if used green the juices may act on the lead lining, as happened in a case which has recently given rise to litigation.

Cinchona.—The export of bark from Ceylon for the last commercial year attained the extraordinary total of nearly seven million pounds (6,925,595 lbs.), and it is supposed that fully one and a-half million more have been exported in the three concluding months of 1883. This is a greater quantity than could have been expected, but it is to be feared that a large proportion has been very poor stuff, which, at the low prices prevailing, it can scarcely have been worth while to send home. To make it profitable to sell "twigs" at 2*d.*—6*d.* a lb., needs the existence of a local manufactory in operation. This, too, would be independent of all "rings" and combinations in Europe, such as that which during the past year has succeeded in lowering the price of bark and raising the cost of quinine. A local factory for extracting alkaloids on the spot, when it is established, will indeed be an equal benefit to the growers of cinchona and the consumers of the febrifuge alkaloids in the East; but at present it seems more likely to be set up in South India than in Ceylon.

It is estimated that there are probably 128 million cinchona trees in the Colony, of which not over 22 millions are more than two years old. What proportion of the remaining 106 millions is likely to grow up to maturity can only be guessed at, but it will probably not be a large one. Much less cinchona has been raised during this year, and it is a very doubtful if the large export of the past one will be maintained.

Much disappointment has been felt at the heavy mortality of seedlings and young trees now experienced. Planters allege that this is very much more serious than was formerly the case, and that it is now very difficult to establish new plantations, successive supplies dying out one after another. The experience of Mr. Nock at Hakgala is, so far as it goes, of a similar character. He reports as follows:—

"The plants in the specimen plot (see page 4 of last report) continuing to die off, I took up, in July, those of them that were alive, and after lime and sand had been mixed with the soil they were replanted and all vacancies supplied. But I regret to say that although some have improved since, hardly one has made satisfactory growth, and those of the Calisaya class have nearly all died.

"The grafted plants of *Ledgeriana* have scarcely grown an inch during the year, and the tallest is now only 18 inches high after being planted 16 months. Of our own seedling *Ledgeriana* there is hardly a plant left, and these are no bigger than when planted out Of eight fine strong healthy plants of "Class D., Yarrow," *Ledgeriana*, (kindly given to the garden by Mr. Tom Gibson, Mirialedda,) planted out in May, there are only two alive, and they are looking very badly. The "Jamaica hybrid," Java *cordifolia*, Nilgiri *magnifolia*, *succirubra*, and Jamaica "*Calisaya* No. 1," are looking fairly well, but have made but little growth. Nilgiri *pubescens* is unhealthy, and only three plants of *C. lancifolia* var. *discolor*, from Java, are alive, of which one is very healthy.

"A plant, from a cutting, of Hard Carthagena (*C. cordifolia* of Markham) is doing very well; it has only been planted out six months, and is now about one foot high, and very strong and healthy looking. The row of *C. pitayensis* has been supplied several times, but so far none of the plants have become established. The plants of "C. Verde," like the Ledgerianas, have nearly all died, but there is one plant that looks well and is now one foot high. Every attention has been paid to the plants in this plot, both in the preparation of the sites for each plant, in shading in hot sunny weather, and in watering when very dry, and I think that the continued foggy sunless weather we have here at times is the chief cause of their not thriving; the elevation will of course in a measure account for the deaths of *Ledgeriana*. During October and November the mean amount of cloud was 8·5 and 9·1, respectively, and it was a rare thing for the sun to be out for half an hour at a time."

The cause of this mortality has been assumed by some to lie in a "degeneration" of the cinchonas since their cultivation in Ceylon, each generation being supposed to be of inferior vitality to the last. I cannot see any clear evidence of this; the tendency to die at an early age is as marked in plants (under similar conditions) grown from seed fresh from South America or the W. Indies, as from Ceylon-grown. It appears to be rather in the climate and soil of Ceylon that the cause is to be sought. We have had a series of bad seasons. Much of our shallow soil and cold subsoil, and many of our wet, windy and exposed hillsides are very unsuitable for cinchona as a permanent cultivation; in well-protected localities with a deep soil and good drainage, it is probable that it grows as well as it ever did in Ceylon. For it must be remembered that the mortality was always very great both here and in South India; in 1872 my predecessor called special attention to it, and Mr. McIvor in the Nilgiris allowed that his losses were never less than 30 per cent. in planted-out seedlings. But when cinchona was thought little of, a heavy mortality passed almost unnoticed here; now the case is altered.

A good deal of discussion has taken place during the year on the botanical questions which underlie cinchona cultivation, especially as to the correct names of the sorts grown in the East. Early in May, Mr. J. E. Howard (whose recent death, on 22nd November, is a great loss to quinology) read a paper at the Linnæan Society of London, calling in question the right of the cinchona grown here as *C. Ledgeriana*, which I had figured and fully described in the "Journal of Botany" for November, 1881,* under that appellation, to bear the name. This paper was not published till September, but in the interval he had supported his views by two other communications to other perodicals. I have fully replied on the whole question in a letter to the "Pharmaceutical Journal,"† which has also appeared in the "Observer" newspaper for 26th November, and have, I believe, shown conclusively that my late friend's doubts on the subject were grounded on a series of misapprehensions. With regard to this same species I have also had to refute, in two short communications to the "Journal of Botany," the assertions of Dr. O. Kuntze, who maintains it to be a hybrid between *C. Calisaya* and *C. micrantha*.

A more extensive contribution to the botany of cultivated cinchonas is contained in a

* See my report for that year, page 4.

† The publication of this was delayed till 19th January, 1884. [*Note added.*]

report* upon the Government plantations in the Nilgiris, which I had the honour of offering to the Government of Madras, after a visit made in May at the invitation of that Government and with the kind sanction of His Excellency the Governor of this Colony. The most interesting question here dealt with is the nature of the cinchonas known in the Nilgiris as "magnifolia" and "pubescens." In my report for 1881, page 5, I have referred to these kinds of cinchona, and there proposed the name *robusta* for them, expressing the opinion that their local hybrid origin, as maintained by McIvor and generally accepted in Ceylon, was more probable than the correctness of Mr. Cross's statements as to their identity with the "Pata de Gallinazo" of Chimborazo—*i.e.*, *C. erythrantha*. Against this view it had been urged that the trees existed in the oldest plots at Naduvatam, planted in 1862 before any cinchona had flowered in India. A careful examination of these and of the reports of the plantations has confirmed the original opinion, and I have shown that these trees were almost certainly planted by McIvor as supplies in 1866-7 and as hybrid seedlings. I was also able to name the puzzling corky-barked species called "*crispa*" by Cross (who collected it in the Samora Mountains east of Loxa in 1861), "*lucumæfolia*" by Markham, and "*decurrentifolia*" by Howard. It proves to be *C. Humboltiana*, Lamb., a species botanically allied to *C. carabayensis (C. Pahudiana)*, and not likely to prove of value. Attention was also called to another corky-barked cinchona, a form of *C. officinalis*, to *C. lancifolia*, of which a few trees still remain, and to the valuable *C. pitayensis*. A good deal of synonymy has been cleared up, and it is to be hoped that the nomenclature now given, the result of much trouble and research, may be generally accepted in S. India and Ceylon, where at all events uniformity ought to prevail. The practical suggestions made in the report as to the principles which should regulate the future management of the plantations—including the appointment of a Quinologist to work with the Superintendent in a system of experimental cultivation based on selection by analysis – are under the consideration of the Secretary of State.

It is still too soon to speak with any certainty as to the species to which the "*Verde*" and "*Morada*" cinchonas ought to be referred. The leaves of the young plants, for which I am indebted to Mr. J. V. H. Owen and other gentlemen, are very handsome; they present considerable variety, but are usually thin in texture, remarkably "velvety" in appearance above, have a strong vinous or coppery-crimson tint beneath, and are generally finely ciliate on the margin. I am informed that the plants are doing well, and hope during the coming year to arrive at some conclusion as to their nature.

Cacao.—The position of this product is very satisfactory and improving, the export in the last commercial year (3,588 cwts.) having actually trebled that of the year before. Of the estimated acreage (9,896 acres) over a half is growing along with coffee (mainly Liberian), and much is not in full bearing. The efforts of the last two or three years to induce a native cultivation have lately been more vigorously pushed; and, encouraged by the Government officials, the natives seem at last to be more favourably disposed towards it. The garden at Henaratgoda has played the important part in this attempt to supplant in suitable districts the nearly valueless native coffee by a profitable substitute. As many as 8,400 pods have been distributed from that garden during the year, and about 1,400 from Péradeniya, being together equivalent to over 250,000 seeds. In the Dumbara district of the Central Province, the site of the oldest and best cacao estates, the native cultivation is especially promising, and in the Kurunégala and Negombo Districts cultivators are even *purchasing* seed. No useful plant is more suited for the village garden than this, if only the cultivators will take the trouble to protect and look after the young plants for the first year or two; when once established little further attention is required.

In last year's report (pp. 11, 12) I made some remarks upon the pale and yellow-fruited varieties in cultivation. With regard to the value of these, as compared with the old red sort, Mr. Jardine, of Udapolla estate, has kindly given me the following information. His statistics show that the number of pods required to give one pound of dry seed is, of the pale varieties, $11\frac{1}{2}$, and of the ordinary red, 22—*i.e.*, 1,288 and 2,464 respectively to the cwt. If we reckon the pale-fruited trees to be 170 (16 by 16) to the acre, and the red-fruited ones 300 (12 by 12), it appears that to produce one cwt. per acre would require only $7\frac{1}{2}$ pods per tree of the former against $8\frac{1}{4}$ of the latter. Thus, if the market value of the product were the same, there would be an advantage on the side of the pale kinds, which are also of more rapid growth, attain a much larger size, and are quite as prolific as the red, if not more so. It appears, however, that the flatness of the

* Printed with G. O. No. 1,189, 26th September, 1883.

seed and the dark colour of its interior, already noticed as characteristic of these sorts, are not so favoured in the home market as the rounder shape and pale interior of our ordinary red kind. Whether this estimate has any foundation in actual quality or is a mere trade fancy in a particular market, cannot be said; there are, however, several distinct varieties among the pale-fruited kinds, and it would be well if the produce of each could be separately cured and the markets tested with each.

The varieties received from Trinidad in 1881 are being allowed to fruit this season, and pods have ripened already on trees of "Cundeamar," "Cayenne," and "Forastero." Though these have all been red-podded, yet in each of them the interior of the seed is more or less deeply violet-purple (like our pale varieties), and none as yet examined present the yellowish-white section of the seeds of our ordinary "Ceylon" cacao.

Specimens have been sent to me from a few estates of young pods and tender shoots in a dried-up, shrivelled or drooping condition. This "blight" has been considered due to a fungus, but on examination can be clearly seen to be the result of very numerous punctures of a sucking insect. This I have obtained, and it proves to be a species of *Helopeltis,* apparently identical with the *H. Antonii*, so destructive to cinchona in Java, and probably also with the *H. theivora*, the tea-bug or "mosquito blight" of the Assam tea gardens. This Hemipterous insect is armed with a very long sucking proboscis, and may be known very readily by the curious spike projecting upwards from the thorax and capped with a knob like a pin's head. It has not, I believe, been noticed in Ceylon until the present year, but may probably have previously existed, this group of insects being little studied. It is to be hoped that this mischievous little insect will keep within bounds.

*India Rubber.** *Ceara.*—A planted area of 977 acres is credited to this, but rubber has not yet appeared among our exports. Since it has been ascertained that the quality is excellent,† cultivators have been endeavouring to discover a means by which the milk can be obtained at a cost sufficiently low to give a return, but without, as yet, encouraging results. The removal of the outer separable bark, as practised in the experiments referred to in my last report, has been objected to on the ground that the bark formed in its stead is of a different character, very hard and inseparable from the green layer a second time. Instruments have therefore been devised for bleeding without such removal. A knife with two parallel blades, which took out a strip of bark, has been modified into one in which the very sharp cutting edges meet to form a V, the basal angle during use being at the cambium. Another invention avoids all cutting, being a double spur-like wheel with sharp but guarded points which puncture the bark without further injury. The milking (one can scarcely call it tapping) has also been practised on trees of various ages and at different intervals and seasons. While it is found that the yield of individual trees varies extremely,‡ none of the experimentors is satisfied that the small quantity obtainable by present methods is sufficient to make the cultivation profitable at the existing price of rubber. Mr. Wall, however, who states that hundreds of young trees have been bled *daily* with the "pricker" for some weeks, and that thus a cooly can collect about half a pound of dry rubber per diem, thinks that, if trees will bear this treatment for 240 days in the year, the cultivation would be remunerative. It appears evident that milking must be repeated at frequent intervals, and (as often already pointed out) the cultivation be conducted on a large scale. Much of the 35,000 acres in private hands in Ceylon at present growing nothing but *Lantana* and other weeds is suitable for this hardy plant, which costs nothing to cultivate, affords a substance of a value which is continually increasing, and awaits only the discovery of a process by which the latter can be cheaply and exhaustively extracted.

Castilloa Rubber.—From a single tree at Péradeniya a considerable crop of seedlings was raised. The fruits ripened at the end of May; they are little, white, pointed nuts, about half an inch long, covered by a bright orange pulp, and some 20 to 30 are crowded together on the fleshy flattened scaly receptacle, forming collectively what is called a compound fruit: about half of the fruits ripen and contain each a single seed. I have already expressed my opinion as to the

* The import of Caoutchouc into Great Britain during 1882 amounted to nearly twenty million pounds.

† I am informed that as much as 4*s.* a pound has been obtained for Ceylon Ceara rubber.

‡ This is to be expected; for it should be recollected that the "milk" in plants is quite distinct from their sap, and is contained in special channels. It has no nutritive function, but, like the alkaloids in cinchona, is rather of the nature of an excretion. Its removal, therefore, *per se*, inflicts little or no injury on the plant.

suitability of this tree for cultivation by a Forest Department as a source of prospective revenue; and as comparatively few of the plants were disposed of to private persons, I made an endeavour to get plantations of this valuable tree formed at Ratnapura and Kalutara. The plan was sanctioned by the Governor, and I gave the necessary instructions: but after three months' delay it was discovered that the trifling sum necessary could not be provided.

The growth of the largest *Castilloa* tree at Henaratgoda is, at a yard from the ground, $30\frac{1}{4}$ inches, an increase of $4\frac{1}{4}$ inches during the year.

Six of the seedlings of 1882 were sent in April to Mr. T. J. Ferguson (Messrs. Hinde & Co.) of Calicut, who has undertaken experiments on behalf of the Madras Government at Nilambur.*

Para Rubber.—A Wardian case with 27 rooted stumps of *Hevea brasiliensis* was sent to Calicut with the *Castilloa* plants.* There are some trees of this already at Nilambur, 33 having been sent to the Forest Officer there in 1879 from Ceylon.

Nine trees flowered at Henaratgoda in March, and the fruit ripened in August. About 260 seedling plants were raised, many of which have been disposed of to persons desirous to try the cultivation. Our largest tree is now 30 inches in circumference, an increase of $4\frac{1}{2}$ inches in the year.

Eighteen plants of another species of Hevea, *H. Spruceana*, were received from Kew in October. This is a native of British Guiana where it is generally known by its Arawack name "Hatie." It has been studied in its native forests by Mr. Jenman, who sent us a plant in 1881, which unfortunately died. Dr. Spruce also collected it on the Amazons. It is closely allied to *H. brasiliensis*, and grows under quite similar conditions. The specimen of the rubber sent home by Mr. Jenman for report appears to have been unfortunately mixed with some impurity which prevented its value being accurately ascertained. The plants have been put out mostly at Henaratgoda, and are doing well.

Some seeds of this species were also kindly sent to the garden by the Manager of the Ceylon Company, Limited, in July, but were quite dead. It is useless to attempt to import seeds of this description from any distance, as they loose their vitality in a few days.

Other Rubber Plants.—*Landolphia Petersiana*, one of the E. African rubbers, has flowered during the year, and *L. Kirkii* is now in bud at Henaratgoda. Two plants of *Tabernæmontana crassa* are now doing well. Among seeds received from Mr. L. Wray, of Perak, were some of "Gutta Singret" which appears from leaf specimens, also sent, to be a species of *Chilocarpus*, another climbing apocynaceous genus. Its rubber is not of a good quality, and is chiefly used for adulteration. A few plants were raised and are planted at Henaratgoda.

Gutta Percha.—A valuable series of dried herbarium specimens, of woods, and of the commercial products of the various gutta-producing trees of Perak has been sent by Mr. L. Wray, junior (collecting for Sir H. Low), which has enabled me to determine with more certainty the species we possess is a living state. He has also sent me a copy of a report to Sir H. Low on the gutta question, which contains some valuable additional matter to that collected at Kew and published in the report of that institution for 1881, pp. 38-47.

I am now satisfied that the identification of "Gutta Sundek" with *Payena* (*Ceratephorus*) *Leerii*, on which doubt had been thrown, is correct. Mr. Wray describes the tree as partial to swampy places near the coast even where the water is salt; the wood is hard and close-grained, and the fruit sweet and eaten by the Malays. There is an inferior variety with a thinner bark known by its longer leaves. Our plants at Henaratgoda have grown quickly; their rate of growth is much more rapid than the species of *Dichopsis*—the largest are over eight feet high; the tallest at Péradeniya is six feet two inches.

The young plants of "Gutta Taban putih" grow very slowly. The good dried specimens now sent show this to be distinct from *Dichopsis Gutta*, but I am not able to say to which species of *Dichopsis* they should be referred. This tree is found in the lower hills, 1,800 to 2,500 feet, and not in the plains; the gutta is a dirty white (whence the name, putih=white), coagulates slowly, and does not thoroughly soften even in boiling water. Mr. Wray also distinguishes a small-leaved variety with a longer fruit.

The specimens further confirm our previous knowledge that the best and most frequent sort of gutta percha of commerce, "Gutta Taban merah," is the produce of *Dichopsis Gutta*.

* Though the receipt of these was not acknowledged, I see that they arrived in very good order. Of the *Castilloa*, five have done remarkably well, and of the *Hevea* 25 are flourishing.

Our trees of this are now nine years old, but the tallest is but nine feet high. According to Mr. Wray, this tree attains 100 to 200 feet in height, with a clean straight trunk of four to five feet diameter, flanked at the base with large thin buttresses; the bark is one-third to half an inch thick, brown-red in colour, and flakes off; the leaves are much narrower on young plants than old ones, the flowers are white, and the seeds yield an oil solid at ordinary temperatures, but used for cooking. The gutta is at first white and cream-like but becomes pink and ultimately brownish-red ("merah"= red), and this colour is strongly imparted to the water in which it is washed. There is a variety of this species affording a paler gutta called "Gutta Taban sutra" ("sutra"= silk), which is found at a higher elevation (500 to 600 feet).

Other sapotaceous trees affording gutta, of which specimens have been sent by Mr. Wray, are "Gutta Taban simpoo," *Dichopsis Maingayi*, Clarke—the product of which is also sold as "gutta putih"—and "gutta garru," *Bassia Mottleyana*, De Vriese, which gives a white hard sort, only used for mixing with other kinds. He also sends examples of the curious substance called "Gutta Jelutong," used for adulterating gutta percha. It is obtained from a very lofty apocynaceous tree allied to our "Rukattana" (*Alstonia scholaris*),* and recently named *Dyera costulata* by Sir J. Hooker.

The yield of the gutta percha trees seems to be very small—less even than the rubber trees. Thus, from a tree of *D. Gutta*, thought to be over 100 years old, and over 100 feet high, Mr. Wray succeeded in extracting, by the ordinary native method of felling and ringing the trunk and branches, only 2 lb. 5 oz. of clean gutta. Of "Gutta Taban putih," a tree ten inches in diameter, gave 2 lb. 11 oz., and one of *Payena Leerii*, 2 feet 8 inches in circumference, only 6½ oz. Mr. Wray has satisfied himself that only about $\frac{1}{30}$th part of the gutta percha actually in the bark is extracted by this method, and he believes that by pounding and boiling the bark the whole could be obtained. As the question of the supply of gutta percha is becoming a pressing one, it is to be hoped that experiments on a large scale may confirm this opinion. To quote Sir J. Hooker (Kew Report, 1881, p. 38), "the time cannot be far distant when the natural sources of gutta percha will be definitely used up." In view of this contingency it behoves the Governments of those few British colonies—Ceylon being one—in which the trees will grow to lose no time in establishing plantations, which must in the future become a valuable source of revenue. But in this Colony neither in this case nor in the case of India rubber can anything be done until a proper forest conservancy in established.

Jalap.—Mr. Nock reports as to this drug:—"The plants have continued to grow most vigorously, and though very few tubers have been formed, the bed is now full of underground stems by which the plant can be largely propagated. The tubers, though few, have grown to a large size, one just taken up weighing fully 16 oz. This elevation (5,400 ft.) is, I fear, too low for jalap to be grown profitably; it is found to thrive best on the Nilgiris at an elevation of near 7,000 feet, and it is probable that the reason the plants make more leaf and less tubers here is because we are too low. They grow here, too, all the year round, whereas they should die down about April and take a few months' rest."

Taraxacum.—With regard to this Mr. Nock sends the following:—"I regret that I am unable to report anything very favourable of the plantation of this drug, for, from the soil being so poor, and the plants several times eaten down by elk, they have not made satisfactory growth. There are, however, a large quantity of fair-sized roots, which, if required, could be supplied to the Medical Department."

Senna.—The Customs returns show that in 1882 the value of this drug consumed in the Colony, wholly imported from India, was Rs. 1,212. There is no reason why this should not be grown in the Colony. Seed of Tinnevelly senna (a large variety of *Cassia angustifolia*, Vahl.) was received from Madras in April, and was tried at all the gardens. As was to be expected, the plants quickly "damped off" in Péradeniya and Henaratgoda, but succeeded perfectly at Anurádhapura, whence the conductor sent very good samples of the drug to the Agri-Horticultural Show at Colombo in August. Nothing is required for this cultivation beyond some irrigation, and no preparation beyond drying the leaves in the air; it is well suited for natives in the dry districts. Seeds of true Mecca senna (*C. acutifolia*, Vahl.) were obtained from Kew in February and March, and also did well in the northern garden.

Medicinal Rhubarb (Rheum palmatum and R. officinale.)—These inhabitants of cold high regions of Northern Asia can scarcely be expected to grow at Hakgala, but Mr. Nock has some

* This appears to yield a somewhat similar substance at Singapore called Gutta Pulci.

hopes of them. He writes:—"Beds were specially made for the young seedlings, but though the crowns look plump and healthy they have made little growth. The common garden rhubarb does so well that I think these may succeed if only kept going till used to the seasons."

Chamomile.—This has become thoroughly established at Hakgala and can be increased to any extent.

Breadfruit.—I am not aware of the precise date of the introduction of this commonly cultivated tree into Ceylon, but it appears to have been prior to the British occupation and possibly much before it. It is now said that the variety grown here is a "very inferior one," and a communication on the subject has been addressed to Government by the Agricultural Association. I had previously written to the Colonial Secretary of Fiji, requesting him to endeavour to send some of the kinds most highly esteemed there, and hope he may succeed in doing so. The late Dr. Seemann enumerates in his "Flora Vitiensis" thirteen kinds as known to him in cultivation in the group: he considered the tree to be truly wild there, and one of the forms, which bears seed, to be the probable source of all the rest; but the actual home of the tree is more probably Amboyna and adjacent islands.

Pasture Grasses.—A good many European pasture grasses have been experimented with at Hakgala, seed obtained for Kew being used. The following species promise to do well there:—*Lolium italicum* (Italian rye grass), *Dactylis glomerata* (Cocksfoot), *D.* "*undulistachys*," *Poa pratensis* (Meadow grass), *P. fertilis*, *Bromus (Ceratochloa) unioloides*, *Anthoxanthum odoratum* (Vernal grass).

In consequence of the very favourable account given in the report of the Saidapet Farm for 1881–82, I obtained from the Superintendent seeds of *Panicum Brownii.* These were sown in October at Péradeniya, and the grass has already flowered freely. Though a small grass, it appears able to hold its own and may form a good grazing turf. It is native to Queensland, Trop. Africa, and America.

Fibres.—Recent improvements in machinery have again turned the attention of planters to the prospects of success in the cultivation of plants affording fibre. It is native species that are particularly attracting attention, and to the list given last year (report, p. 15) may be added as more or less promising:—"Gas-dul" *(Debregeasia longifolia)*, which has been strongly recommended for cultivation in S. India under the name of "wild Rheea"; *Girardinia palmata* (the "Nilgiri nettle," which has no special Sinhalese name, but is called "Elephant Maousa" by planters; it stings badly); and "Dul" *(Anodendron paniculatum)*, a large climbing plant of the low-country. I understand that very satisfactory results are being given in S. India with our "Néyada" *(Sanseviera zeylanica)* treated when quite fresh-cut by Death and Elwood's machine.

Gamboge.—It is worth a note that a consignment of the Ceylon product exported in the natural tears has fetched £14. 5*s.* a cwt. in the home market. This is afforded only by *Garcinia Morella* (the "gokatu" or "kana goraka" of the Sinhalese); of which the tree *(G. Hanburii)*, giving the Siam gamboge of commerce, is probably a mere variety.

The principal *Resins* ("dummala") of Ceylon, as to which several inquiries have been addressed to me, are obtained from "Hal" *(Vateria acuminata)*, a good clear white dammar resin; "Hora" *(Dipterocarpus zeylanicus)*, "Dun" *(Doona zeylanica)*, "Na" *(Mesua ferrea)*, "Kekuna" *(Canarium zeylanicum)*, a fine white resin; and a resin, the origin of which is uncertain, called "Bin-dummala" from being dug out of the ground, generally during the cultivation of paddy land.

Eucalyptus trees.—The plantation at Hakgala is making good growth. All the 43 species planted out in August, 1882, are very healthy. Mr. Nock gives the height and girth of the different species, from which it appears that *E. robusta* (14 feet high, 8 inches girth) has grown most rapidly, *E. marginata* (Jarrah), *E. longifolia*, and *E. Gunnii* being not much behind. *E. alpina* is a pretty little shrubby kind, at present only 2 feet 8 inches high.

V.—Herbarium and Library.

Herbarium.—The arrangement of the cabinets containing the collections of dried plants has been completely altered and now affords increased accommodation and greater facility of consultation. They are arranged in projecting blocks between the windows on either side of the long building, and in each of the bays thus formed is placed a work-table. The building is divided into two unequal parts by a screen; in the inner portion is contained the Ceylon Herbarium in

36 cabinets, and the collection of drawings in two more; in the outer are the general (foreign) collections in 34 cabinets and in many bundles waiting proper accommodation.

To the former, additions have been made from many parts of the Island, especially from the Adam's Peak district and the country north of Kurunégala, both visited by me, and from the peninsula of Kalpitiya thoroughly explored by the plant collectors.

The rough arrangement of the general herbarium into genera in accordance with the "Genera Plantarum" of Bentham and Hooker (now happily completed) has been finished during the year, and the large accumulations of plants from many parts of the world have been gone through, sorted, and intercalated in their places. I have been very greatly assisted in this and in the herbarium work generally by Mr. W. de Alwis, the draftsman of the establishment.

Twelve additional cabinets have been added during the year.

The principal additions to the general herbarium have been:—219 species of exotic ferns, all additional to those in the herbarium, from G. Wall, Esq., F.L.S., and 71 species of plants from Perak collected by G. Wray, junior, from Sir H. Low, K.C.M.G.

The collection of drawings has been increased by 28, made during the year. With the object of the better preservation of this fine series of original illustrations of the Ceylon flora, I have had the whole mounted on cartridge paper uniform in size with the herbarium, and placed in covers.

Library.—The condition of the books is giving me some concern. The library is a pretty extensive one and well selected, containing many rare and some very valuable works; but from having been always kept on open shelves exposed to the alternate damp and desiccation of the seasons and the depredations of insects, many books are much damaged and have more or less fallen to pieces. From time to time I have had some of the most valuable or most used rebound, but it has never been possible to afford really solid and substantial binding for the large majority. To prevent further deterioration, it is necessary that the books be kept in locked glass-fronted cases, the best preservative in this climate, and I hope that provision for this not heavy expense may be made in the coming year.

The following additions have been made to the library during the year:—

Bentham and Hooker, Genera Plantarum, Vol. III., Part 2, 1883 (completing the work).
Rottböll, Desc. et Icon. nov. plant. illust. Lib. primum, 1773.
Retzius, Observationes Botanicæ, 1779-91.
Vahl, Symbolæ Botanicæ, 1790-94.
De Candolle, A., and others, Monographiæ Phanerogamarum, Vol. IV. & Vol. V., Part 1, 1883.
Elliot, Flora Andhrica, 1859.
Hooker, J. D., and others, Flora of British India, Parts 9 and 10, 1882-83. *(Presented.)*
Hasskarl, Cat. Plant in Hort. Bot. Bogoriensi cult. alter, 1844.
Howard, Quinology of the E. Indian Plantations, 1869-76.
Cross, Report of Mission to South America in 1877-78 [to collect Santa Fé and Carthagena barks], 1879. *(Presented.)*
Walker, C., Report of Government Cinchona Plantations [in Nilgiris], and Cinchona Committee's Report, 1878. *(Presented.)*
Trimen, Report [to Madras Government] on Government Cinchona Plantations, 1883. *(Presented.)*
Jenman, Report on some India Rubber and Gutta Percha Trees of British Guiana. [Hevea Spruceana and Mimusops Balata], 1882? *(Presented.)*
Acta Horti Bot. Petropolitani, Vol. VIII., Part 1 (in continuation). *(Presented.)*
Guilfoyle, Catalogue of Plants in the Melbourne Botanic Gardens, 1883. *(Presented.)*
Brandis, Suggestions for Forest Administration in the Madras Presidency, 1883. *(Presented.)*
Hutchins, D. E., Reports on Measurements of Growth of Australian Trees in the Nilgiris, 1883. *(Presented.)*
Grigg, Manual of the Nilgiri District, 1880. *(Presented.)*
Moore, F., Lepidoptera of Ceylon, Parts 6 and 7. *(Presented.)*
Baden-Powell, Manual of the Land Revenue System and Land Tenures of British India, 1882. *(Presented.)*

Also, in continuation, the following Periodical Publications for 1883:—

Botanical Magazine, Gardener's Chronicle, Indian Forester, Journal of Botany (presented), Pharmaceutical Journal (presented), Planters' Gazette (presented), Tropical Agriculturist.

There have also been received the usual annual and other Reports of Indian and Colonial Gardens, Forest Departments, &c., Catalogues, &c., and I am particularly indebted to the Government of Fort St. George for copies of all papers relating to botany, horticulture, agriculture, and forestry issued by the Government press of Madras.

VI.—Receipts from Sale of Plants, &c.

No less than 24 Wardian cases and 7 boxes have been supplied to private purchasers for transport to other countries at Péradeniya during the year, but in other respects there has been but little sale except of small packets of seeds at this garden. Especially has there been a great diminution in the demand for economic plants, the chief source of the garden revenue of late years. Hence the receipts at Péradeniya have fallen off; but both Hakgala and Henaratgoda show a considerable increase over those of last year.

The following has been paid to the Colonial Treasurer, being the proceeds during the year:—

		Rs.	cts.
From Péradeniya	...	1,988	32
Hakgala	...	503	13
Henaratgoda	...	597	91
Anurádhapura	...	15	1
	Total—Rs.	3,104	37

The number of purchasers was—

At Péradeniya	..	712
Hakgala	...	55
Henaratgoda	...	210
	Total—	977

VII.—Expenditure.

The following shows the total expenditure of the Department for the year, under heads:—

		Rs.	cts.	Rs.	cts.
Salaries ...	...	—		17,785	62
Gardeners' and Labourers' Wages:—					
Péradeniya ...	...	8,188	7		
Hakgala ...	...	2,999	90		
Henaratgoda ...	...	1,995	57		
Anurádhapura ...	...	996	4		
				14,179	58
Office Contingencies ...	...	—		2,599	83
Stationery ...	...	—		79	96
Travelling and Collecting	...	—		1,975	80
Special Votes:—					
Meadow Mower (Péradeniya)	...	500	0		
Propagating House (Hakgala)	...	1,850	0		
				2,350	0
Pavilion, Kandy ...	...	—		2,191	66
				Rs. 41,162	45

HENRY TRIMEN, M.B.,
Director.

Péradeniya, 1st January, 1884.

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, April 9th, 1884.)

IMPORTED FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White ...	Slightly softish to good hard bright ...	£7 a £8 10s
Yellow ...	Do. drossy & dark ditto...	£5 10s a £6
CINCHONA BARK—		
Crown	Medium to fine Quill ...	2s a 3s 6d
	Spoke shavings	6d a 3s 6d

THE CEYLON ROYAL BOTANIC GARDENS.

On pages 835-855 will be found Dr. Trimen's Report for 1883 on the Royal Botanic Gardens at Peradeniya and the subsidiary establishments at Hakgala, Henaratgoda and Anuradhapura. It will be seen that Dr. Trimen wishes to have one more garden at Badulla under the superintendence of Mr. Nock who has done such good work at Hakgala. This, the Director thinks, would suffice, but we should think Jaffna would put in a claim for some attention. The difficulty is to find the money, a difficulty which has prevented the formation of plantations of indiarubber-yielding plants at Ratnapura. The beautiful gardens at Peradeniya have been improved, and their botanical treasures largely increased; a glass-roofed plant-house (the glass coloured green) was completed, as was the Gardner Memorial, Dr. Trimen having placed on it an appropriate inscription. We suppose the Thwaites Memorial will be speedily added. We are glad to notice that attention is being paid to the labelling of the plants, and that Dr. Trimen hopes speedily to add to his valuable Guide Book to the Gardens as complete a list as is possible (classified) of the plants growing in the Gardens.

All visitors to Hakgala will bear out Dr. Trimen's statement, that, under Mr. Nock's able and zealous management, the Hakgala Gardens (below Nuwara Eliya) have made great progress in every way. Amongst the valuable additions are a new propagating-house; the carriage-drive has been extended, and the fernery, nurseries, borders and shrubberies and flower-gardens improved. Meteorological instruments having been supplied, we have the information, that, in the second half of the past year, the mean temperature at Hakgala (5,400 feet altitude) was 61·3; the maximum having been 74 on 4th July and the minimum 47 on 4th December. The mean amount of cloud was 8. The wet and cloudiness of Hakgala have militated and must ever militate against the success of cinchonas there, although Mr. Markham chose it as the site of the first experiment in Ceylon, on account of its resemblance to places in the true habitat of the plants in the Andean ranges. Well-deserved testimony is borne to the condition of the tropical garden at Henaratgoda and the attention of the Muhandiram in charge. Curiously enough, Tinnevelly senna and Peruvian cotton which failed here have succeeded at Anuradhapura, to which ancient city a garden is likely to be of great benefit, as well as to the country around; it is on the borders of the great tanks. Dr. Trimen's remarks on the decadence of the Arabian coffee under the influence of leaf-fungus and the rapid progress of tea and cacao, with the warnings held out will be specially interesting to planters. The remarks on cinchona, too, are interesting as showing the true causes of so many failures. Dr. Trimen does not hold the degeneracy theory. We notice with great regret that he seems to have identified "a sucking insect" which had done injury to shoots and pods of cacao with the "mosquito blight or *Helopeltis theivora* of the Indian tea plantations, more correctly named in Java (where it is most destructive to tea and cinchonas) as *Helopeltis Antonii*. Of all other pests, not even excepting red spider this is the one most to be dreaded by tea planters, and we trust the insect will never find out our young plantations. The only tea pest of consequence as yet is a minute moth which lays its eggs on the leaves, the grub sucking out the juices and causing the leaves to curl up and dry into tinder. It is not of much consequence, however, in comparison with the "green fly" or mosquito blight. There is much that is interesting about the trees which are the sources of indiarubber and gutta-percha. We may mention that the natives have done their best to kill a beautiful tree of *Alstonia scholaris* at "Blair Athol," Turret Road, Colombo, by taking pieces of the bark for medicine, just as they strip *Cassia fistula* trees. The breadfruit, pasture grasses, fibres, gamboge and the eucalypti are all noticed, and our readers will find much useful information in the report.

THE AMERICAN FRUIT DRIER AS A TEA ROASTER.

Apart from the question of its adaptation for tea roasting, it seems to us that it would be worth the while of some enterprising person to introduce the machine for the purpose of drying some of our Ceylon fruits, such as plantains, pineapples and mangoes. There is a peach-parer which, no doubt, would answer well for mangoes. The preparation of fruit for export in the United States, has assumed dimensions of great magnitude, and we think it probable that something in the same direction might be done here in Ceylon. At present we export only hard fruits, those of the coffee bush and of the coconut and areka palms. The use of the American drier or evaporator might enable us to grow and export a large surplus of soft fruits, such as mangoes, pineapples and plantains. The principles of the machine are thus described:—

We will, briefly as possible, state our claims of *Structural Superiority*, practically applied in an arrangement entirely new in the construction of fruit evaporators, by which separate currents of dry, heated air, *automatically created*, pass underneath and diagonally through the trays and then off over them, carrying the moisture out of the evaporator without coming in contact with the trays of fruit previously entered, and already in an advanced stage of completion.

We concentrate the greatest heat upon each tray or group when it first enters the machine, and each tray or group subsequently entered removes or shoves the previous one forward in a lower temperature.

These advantages are secured and continued throughout by reason of our *Inclined Evaporator Trunk*. No steaming, cooking, or retrograde process becomes possible.

Indeed, so perfect is the active circulation of dry, hot air over, under, and through each line of trays, that *any tray* taken from *any portion* of the trunk at *any time* after being in the evaporator ten minutes, (the fruit) will be found to be perfectly dry on the outside, to sight or touch, although the process of complete evaporation may be but one-fourth or one-half finished.

This condition of the fruit we guarantee our evaporator to maintain when full of fruit and working at its full capacity.

As a result, we secure maximum evaporating capacity per square foot of tray surface, and of fuel consumed, and entire freedom from burning or scorching, a bright color (characteristic) in the product, highest possible retention of flavor, development of sugar, and market value.

The peculiar shape of our evaporator was designed by Doctor Ryder, the inventor, in order to avoid the objectionable features and disadvantages incident to a perpendicular stack of trays, and to divert the currents of hot air and cause them to pass through and around a series of trays so placed as to secure continuous and rapid evaporation without motive power.

The Inclined Trunk answers the purpose admirably. The currents, self-created and continuous, strike the trays of fruit at a uniform upward angle with considerable velocity, quickly absorb all moisture, and then pass off out of the machine.

With it Doctor Ryder inaugurated the *rapid continuous evaporation of fruits, upon* the principle of *subjecting the fresh* *fruit to the direct and greatest heat first, moving the articles operated upon in the direction of the currents of heated air and into a lower temperature*; securing, by so simple a device, every advantage than can possibly be claimed for the most complete vertical evaporator with its costly blast or exhaust fans, engine, and manipulating machinery.

Without any of the disadvantages incident to a perpendicular stack of trays, (referred to on a foregoing page,) which cannot be used at all for evaporating such articles as grated cocoanut, finely cut sweet corn, starch, or any substance required to be spread on sheeting—which entirely obstructs the passage of hot air through the trays.

The same difficulty is experienced in drying small fruits and berries: if the fruit is spread unevenly upon the trays —and it is impossible to place the fruit so that there will not be some thin places—which will, by drying quickest, become still thinner, and then the hot air will rush through and dry too much, very often burning all thin spots, whilst those parts that are covered thickly no air can get through, and consequently will not be dried at all. In drying any fruit or vegetable made up of large and small, unripe and over-ripe, or irregularly cut, this difficulty will always be experienced. Whereas, in the Inclined Flue Evaporator, it matters not how much obstruction there is; even sheet-metal pans are used in evaporating semi-liquid and liquid substances, the divided currents of hot air passing between both over and under, the several lines of trays.

Of course, the process of passing the trays upwards through the flue from the hot air near the furnace into the cooler temperature further away, although best for soft fruits, may not be equally good for the preparation of fermented tea leaves, but no doubt any competent engineer could make the alterations necessary. The American Manufacturing Company, Waynesboro, Pennsylvania, assert:—

We know that our *Inclined Flue* for *simplicity, portability, small cost,* and *perfect work* stands unrivalled.

Regarding the perpendicular and steaming processes contrasted with their own, they say:—

The hot steam or vapour in the one cooks and bursts the cells, and the starch contained in them becomes acidified instead of changing to sugar, and the flavor of the fruit or aroma, which is an essential volatile oil, is dispelled, and the product is deficient in flavor and sweetness.

The consequent waste of fuel and time is also an important item that must be overcome in an appliance so differently adapted to economic requirements.

Our principle and *our arguments* are simply these: Subject all cut fruits and vegetables at once to *dry, hot currents of air.* Dry the surface quickly, which prevents discoloration, forms an artificial skin or cuticle, and seals the cells containing acid and starch, which yield glucose or fruit sugar; and then *keep it dry until finished*, without introducing any retrograde process. Discharge the hot steam or vapor at once, without bringing it in contact with trays previously entered. We have this principle demonstrated in Nature's laboratory, in the curing of the raisin, fig, and date, which are dried in their natural skins in a tropical climate, during the rainless season, by natural dry hot air in the sun. Though a crude and slow process, the development of glucose or grape sugar is almost perfect. Water in fruit is water and the medium of decay, and, to expose the cut surface to steam or vapor, retards evaporation and induces acetous fermentation and subsequent loss of sugar.

They add:—

In a few hours the juices, which heretofore formed and developed the fruit in the laboratory of nature, are quickly maturated, and the water simply evaporated, leaving a product exactly the same color as when fresh cut, without loss of pleasant or valuable propertie. The aroma, peculiar to each variety sealed against volatization, and easily recognized, soft and pliable, with crystals of sugar, perceptibly covering its surface, does not become harsh, dry, or brittle, and when placed in the rejuvenating bath of fresh water, returns to the original form, color, consistency, and size, defying an expert to distinguish the original slices from those evaporated, after being thus restored.

Evaporated fruit, once seen and tasted, can never after be confounded with ordinary dried fruit by any one.

Generally speaking, evaporated apples, with ordinary care in manufacture by our process, are as white as this paper, while the evaporated peach retains all the bright and beautiful blending of color found in the various red, yellow, and white varieties, with the most delicate pencilings of shade, and wonderful tissue of minute cells at stone perfectly preserved and intact.

They give figures to show what can be done with an evaporator by any industrious man, woman, well-grown boy or girl, and one of the great merits claimed for the machine is the few hands required to work even the largest sized. The various sizes are described, from No. 0 for the household to No. 5 which is only made to order. All the machines are furnished with trays of galvanized wire-cloth, and it may be a question if this substance would stand the heat of about 280° to which tea leaves in drying are subjected. Each machine has furnace, pipe and everything complete, and it is claimed for them that they can be easily and rapidly set up. No. 1 "burns coal or coke best, short wood will answer"; it can cure 6 to 8 bushels of apples per day of 15 hours, with a consumption of 50 lb. of coal. No. 2 is stated to be the favourite, adapted to burn wood, coal or coke; extreme height 6 feet; consumes about 80 lb. of coals per day. Either this or No. 3 would seem to be the machine to introduce here. Of No. 3, it is said:—

Size, 16 feet long, 42 inches wide; has 45 trays; capacity, 35 to 45 bushels of apples per day (of 24 hours.) Trays of galvanized wire-cloth, furnished with a durable, economical, and powerful furnace, adapted to burn wood, coal, or coke; pipe, and everything requisite, except the rear platform.

It can be set up and put in operation in a day. Shipped partial knock-down, to facilitate handling in transit. Extreme height, adjustable, 8 to 12 feet; weight, 1,600 pounds. Consumes about 200 pounds of coal per day.

NOTE.—We furnish, (when ordered), a furnace extension from $2\frac{1}{2}$ to 3 feet high, (price $5 extra,) useful and convenient when the furnace is to be placed in a cellar or basement of the evaporating building. This extension sets directly on top of the furnace, so as to raise the front end of trunk to a convenient height on the first or working floor.

NOTE 2.—Our furnaces for No. 3 evaporators are made with adjustable angle top plates, so that the fire door can be turned in front, or to the right or left hand as you stand in front of the evaporator, so as to suit different locations and convenience in the evaporating shed or building. This valuable feature answers equally well with or without the furnace extension.

Numerous patrons report the actual capacity of this evaporator in their hands from 50 to 60 bushels of apples per day. We adhere to our customary low rating, notwithstanding it would by many be classed as an 100 bushel machine. It is fast gaining in popularity by commercial evaporating companies, (worked in suits of four machines, right and left handed,) requiring but one platform hand to four machines.

This evaporator may be relied upon for quality of its product. 2nd. For capacity compared with its cost. 3rd. For economy in fuel. 4th. Simplicity and ease of management. 5th. For the facility with which the heat can all be concentrated by a cut-off in trunk, and the machine run at half its tray capacity without loss of heat or fuel. 6th. For the ease with which the trays (in groups of three) are carried forward in the upper flue by a geared cog-rack and pinion, operated by a crank outside of evaporating trunk. 7th. For its safety against fire. 8th. For its admirable adaptation and capacity to do more than has been claimed for it. 9th. For many special purposes it deservedly takes the highest rank, and is extensively used in the preparation of drugs, chemicals, dye-stuffs, pulp fabrics, coffee, tea, roots, herbs, animal and mineral substances, grain, peanuts, starch, yeast, fertilizers, etc.

Our readers will see that it is expressly stated that this machine is extensively used for the preparation, amongst numerous other articles, of coffee and tea to roast coffee, we suppose, and to refire damp tea Of No. 4 it is stated that "the evaporating flu consists of two separate and independent trunks, hot as to tray management and heat." The flues can be partially or wholly used. For Nos, 4 and 5, buildings are required, and the Company states :—

We have carefully drawn specifications of a cheap and suitable building for our large evaporators, showing plans, dimensions, and position of evaporator therein, ventilating it, etc., which we mail on application.

We copy the directions :—

HOW TO OPERATE THE AMERICAN.

The evaporators Nos. 0, 1 and 2 are shipped in two packages. After taking off the cribbing, set the furnace level, place the trunk upon it, and elevate rear end, with accompanying support, to the same angle as the furnace top, upon which it should fit closely. In making the first fire in heater increase the heat somewhat gradually on account of expansion and cement joints. Put your first trays of fruit, in groups of two or three as the case may be, *freshly pared or cut*, on the upper track immediately over, above, or beyond the furnace. All the trays are to be entered here. The second group of trays, when ready, takes their place by shoving the first entered forward or up the track, and so on consecutively until the upper line is full; then start the first inserted trays down the second or lower track, one after the other, as they reach the top, (No. 0 has but one track.) until the machine is full. If the trays are filled before any are completely dry, empty the contents of two or three trays in one; or, if any are done when the trays reach the top of first track, take the first off, or, if nearly done, put the contents of a couple trays in one at this stage. A little judgment and labor given at the time of changing from upper to lower track is well bestowed, and has much to do in determining your success with the evaporator, both as to quality and quantity produced. Proceed continuously in this manner. Full and minute directions accompany each evaporator. In No. 3 the trays are entered in groups of three.

Many of our patrons prefer, in evaporating apples, to put the fruit on the trays in single layers, others about a half inch thick; in either case close examination, slight stirring, or changing relative position of the trays in the group, or taking off finished fruit, or doubling up before returning down lower track, is labor *well directed*. This is a valuable feature in our Evaporator, *i. e.*, the opportunity to see and examine the fruit at this stage, and we wish to impress its importance.

Circulars with full instructions are furnished to "patrons." There is an immense number of certificates, from one of which we quote as follows :—

You gave the Evaporator the right name when you called it a household necessity. The black rot was destroying our potatoes, and to save them we evaporated them, and now they are safe with all the qualities of fresh potatoes. We have evaporated raspberries, blackberries, cherries, apples, peaches, pears, quinces, plums, grapes, potatoes, tomatoes, pumpkins, sweet corn, beans, and cabbage. No equal investment on the farm pays as well.

In regard to sweet-potatoes, it is stated that they should be parboiled and pared before being evaporated. The Company, with reference to invasions of their patent, state :—

We claim broadly by our letters patent—

1st. The inclined drying box, flue or flues.

2nd. The successive arrangement of the trays on tracks or ways.

3rd. The combination of the drying box, flue, or flues, with the heater or hot-air chamber.

They add that steam heat for the drier has been practically abandoned. Correspondents are answered thus :—

WILL IT PAY TO EVAPORATE PUMPKINS FOR MARKET ?

Generally speaking, no. Considerable trade is done in evaporated pumpkins, and then ground into meal. It makes a first-class custard or pie. The product is all right, but the trade is confined to those making it a special business.

Can a person of ordinary skill work an American successfully ?

Yes. The American is the simplest evaporator in the market. The currents of hot air are automatic self-regulating The trays are entered all at one place, and successively the whole process is simply a succession of trays going in and coming out, as simply as feeding a corn-sheller.

And now comes the important question of cost: prices in America and probable enhancement by the time land carriage, sea freight and charges for erection on an estate in Ceylon are defrayed. We copy the price list, adding to the dollars the rough equivalents in rupees :—

No. 0. American Evaporator—22 inches wide, 6 feet long, 2 lines (8) trays; capacity, 3 to 4 bushels of apples per day. Weight 200 pounds. Price $25. [About R55.]

No. 1. American Evaporator—23 inches wide, 6 feet long, 4 lines (14) trays; capacity, 6 to 8 bushels of apples per day. Weight 350 pounds. Price $50. [About R110.]

No. 2. American Evaporator—28 inches wide, 9½ feet long, 4 lines (22) trays; capacity, 10 to 15 bushels of apples per day. Weight, 500 pounds. Price, $75. [About R165.]

No. 3. American Evaporator—42 inches wide, 16 feet long, 6 lines (45) trays; capacity, 35 to 45 bushels of apples per day. Weight, 1,600 pounds. Price, $175. [About R370.]

No. 4. American Evaporator—7 feet wide, 18 feet long, 12 lines (102) trays; capacity, 90 to 110 bushels of apples per day. Weight, 2,000 pounds. Price, $350. [About R735.]

No. 5. American Evaporator—7 feet wide, 24 feet long, 12 lines (138) trays; capacity, 130 to 150 bushels of apples per day. Weight 3,000 pounds. Price. $450. [About R950.]

There are no duties, of course, and the progress of railway construction will lessen the cost of local carriage greatly. Perhaps, therefore, an addition of 50 per cent to the American prices might cover all expenses up to erection on estate. In that case,

No. 0	would cost	...	... R 82
,, 1	do	..	... 165
,, 2	do	...	... 247
,, 3	do	...	.. 555
,, 4	do	...	... 1,102
,, 5	do	...	... 1,425

In the cases of Nos. 4 and 5, special buildings would have to be erected, so that, at least, 25 per cent in each case would have to be added. To make the information complete, we repeat the circular of the "Tea Planter Agent," although he has not thought it worth his while to advertise—indeed, we heard recently of a "pawky chiel" interested in tea machinery who gave instructions that information about his machines should be sent to the *Ceylon Observer*, "but not by way of advertisement"!

This is what Mr. Victor M. Hollinsworth, late Divisional Manager, Doom-Dooma Tea Company of Assam, but now of Vineland, N. J., U. S., America, writes :—

Shortly after my arrival in the United States from Assam last year, my attention was attracted to the excellence of the *American Dehydrated* fruits so universally known in the East and most foreign countries. Further investigations fully decided my opinion as to the unqualified superiority of the machines here in use, as compared with any others I have seen, or heard of in the tea districts of India. In July, 1883 I addressed a letter to the Indian press upon this subject, as worthy of publicity, and consideration. Subsequent inquiries have shown me, that of all *Dehydrating machines* and *Dryers* in use in America, one class alone preeminently is fitted for use both in the "*Firing*" and "*Garbling*" of tea, as also for the drying of coffee, (either "*pulped*, or *unpulped*.") I have therefore accepted the appointment from the "*American Manufacturing Company*" as "*Special Agent in, and for the East Indies, and the Island of Ceylon*," and as such I now address you.

The reputation of the "*American Evaporator*" is its best recommendation, and its claims, are fully set forth, and explained in a concise pamphlet, which may be perused at, or obtained, if needed, from my Assam, Calcutta, or London Agents, (*the "Planter's Stores and Agency Co.*) in whose hands a telegraph code will be placed, which will enable tea, or coffee growers to order at once either in London, or direct from myself machines needed for use during the coming season, and a prompt order accompanied by draft, or London Agent's reference will insure as prompt despatch via Suez Canal, or as directed. The Evaporators are priced low as all sales are arranged as for *cash with order.* Remittances must be made in my own favor and name, or to my order, at ruling rates of exchange between India, London and America. My Banker in the United States is *The Merchants' National Bank*, of Philadelphia, (Pa.,) on whom drafts, or credits may be effected, or in London, at 1, Great Winchester Street, (*P. S. and A. Co.,*) if more convenient.

Any alterations required in the evaporators, other than as specified in the books, must be especially expressed clearly, and distinctly by letter, and all suggestions either from tea, coffee, or other planters will be thankfully accepted, and transmitted by me to the manufacturers, from whom they will command prompt attention. My own experience as a planter is based upon my position as manager in two of the largest, and best known London companies, and that experience permits me to recognize and appreciate the dominant attributes which will commend the "*American*" to the notice of all classes of planters, as *the dryer par excellence of the future.* In conclusion I briefly synopsize its value under the following heads, viz.:—

(1) Economy, in cost, labor, fuel and heat.

(2) Its simplicity, durability, and portability.

(3) Immunity from fire when used in "cutcha" buildings.

(4) Absence of lengthy smoke stacks, insures safety in cyclones, hurricanes or earthquakes.

(5) Preservation of aroma, strength, pungency, and color of outturn.

(6) Briskness of firing insured by direct action of heat, and combined avoidance of steaming, or soddening.

(7) Increased market value, and consequent profit.

(8) Freedom from scorching, or discoloration of "tips."

(9) Its adaptability for burning all kinds of fuel, viz: coal, coke, charcoal, bamboo, wood, or "Ekara."

(10) That its use is likely to reduce to a minimum, all such as brickmaking, lime, masons, carpenters and wood cutters' expenses, avoiding also the need of "chulas" or "dholes," and lessening the demand for "salonies," &c. The cost is such that the evaporator is placed within reach of the smallest gardens, in one, or other size, while large factories can likewise use them in sizes as needed, regulating their working according to the day's income of green leaf, or firing capacity required.

We have only finally to remark, that, if the dehydrating machines are not suited for the drying of tea without any such alterations, as Mr. Hollinsworth asks planters to suggest, his responsibility is a serious one, for he distinctly recommends the machines as specially and fully suited for tea-roasting. It would seem as if they either are or could be easily altered for the purpose. Who will try the experiment?

CHINESE AQUATIC VEGETABLES.

The following is a postscript to Dr. Macgowan's article on plants acclimatizable in the United States:—

Why not experiment with Chinese water plants? Those of the sub-tropical latitude would take kindly to rice regions and to marshy lands generally,—where waters do not freeze, or freeze but lightly. Among these valuable esculents in the water caltraps, (*Trapas bicornis, ling chiao*—buffalo-horn) sometimes called water chestnut, because of its flavour; it does not furnish much in the way of food, like the *Trapa hispinosa* of Cashmere, but it is valuable as a fruit, enduring the severe climate of Chihli and requiring no culture. The next in value is a tuber (*Ellocharis tuberosus*) water chestnut, although the water lily (*Nelumbium speciosum*) perhaps is more used for food (in some places people are veritable lathophagi); it appears to be the Egyptain bean of Pythagoras. It is rich in starch; its root-stock and seeds are alike edible; its arrowroot is much used by invalids; its leaves are used for wrapping paper, while its flowers are strikingly gorgeous and not without fragrance.

Another of the numerous water plants of the Chinese is the celery-like shoots of the *chiao-pai* (extending far north), and yet another is the *chin-tsai*, water celery, which is planted on bamboo rafts covered with mud, forming floating-gardens like those of ancient Mexico, and modern Kashgar. Let the plants be securely placed in Ward's cases, and an account of the mode of culture sent with the specimens. If any ornamental plants are sent, let me commend for the sunny south, or for conservatories, the *t'ieh-shu*, iron tree, the most beautiful of the *cycadacie.* Its name comes from its property of absorbing and assimilating iron; when it shows signs of decadence, nails are driven into its trunk, which gives it a new lease of life. The *tiao-lan* hanging epidendrum would be much prized; it flowers only when take from the ground and suspended from a ceiling. I omitted to state respecting the nut-oil tree, that it would prove easily cultivable in any port of our continent. —B.—*North-China Herald.*

THE PREPARATION OF CAMPHOR IN JAPAN.

The camphor-tree is much cultivated in Japan. It thrives best in the Southern part of that country, especially in the provinces of Tosa and Sikok, where, too, the most camphor is prepared. Dr. A. van Roretz, at Otayama, in Japan, says that the only tree that produces the camphor of the Japan and Formosa trade, is the *Laurus Camphorata*, called by the Japanese *tsunoki.* The camphor is gathered during the whole year, but the best season is in winter. When the camphor-seekers find a spot where many young camphor-trees grow, they settle down there, build a hut to live in and a furnace to prepare the raw camphor. When they have gained all that was to be gained, they take down the hut and depart to another region.

The method of obtaining the camphor is very simple. The workman selects a tree, and with a sharp instrument adapted for the purpose, he makes several regular incisions, by which he obtains slips or chips. These he carries to a furnace. These furnaces are generally built in the proximity of a running water and are of a very simple construction. A circular space is surrounded with bricks and covered with a kind of grating. On this grating is put a vesse in shape like a truncated cane at the base more or less 90 centimetres in diameter, at top more or less 45. A little above the bottom of this vessel is an opening which can be closed with clay. The whole of the upper part is surrounded with a covering of clay. In the upper plane of this truncated cone-shaped space an opening is practised in the clay-covering which can be closed with a plug. Near this upper plane, in the side of the cane, a bamboo tube is affixed, leading to a condenser. This condenser consists simply of a square box, divided into five compartments, while a stream of water flows from above upon it.

The process itself is as follows:—The cone-shaped vessel is filled with the chips, and, after closing the cover well with clay, a certain quantity of water is made to flow through the plug-hole in the cover. Then a fire is kindled under it and the vapour of the water, driven by the heat through the chips, carries camphor and camphor-oil with it into the condenser, in which the camphor is deposited. In 24 hours' time such a charge is completely worked off.

The deposited camphor is then freed from the oil by pressure, and the dry product—the camphor proper—is then sent to Osaka, the chief emporium of the camphor-trade. The camphor-oil is used by the lower classes to burn in lamps, notwithstanding the pungent odour and the fume, the products of the combustion. Camphor perfectly pure is never exported. The substance is subjected to further rectification in Europe by means of distillation. The remaining chips are dried on stages erected against the furnace, to be used as firewood.—*India Mercury.*

FLORIDA, PER CONTRA.

The statements made by your correspondent "Per damna, per caedas" (p. 802.—ED.), strongly inclines an impartial critic to believe either that he is only slightly acquainted with Florida, or else that he is so unaccustomed to travel in new and wild lands that he is unable to accurately judge of their merits, and grapple with the difficulties that are always met with in new countries. In reply to his remarks I may say that I have been travelling almost continually during the last five years, and lived in various remote countries, tropical and otherwise; and I have no hesitation in stating my opinion that Florida, at the present time, offers a better field than any other country for young men with small capital. I was employed during three months last year by an English company in Orange County, Florida, and my duties were arduous, being exposed to the sun and weather from sunrise to sunset during one of the hottest months of the year (September), tramping through swamps and marshes to make the necessary surveys, wet through for days and weeks running; but I enjoyed vigorous health throughout; neither am I aware of any case of sickness among the fifteen men at camp during the time I was there. I felt no inconvenience when working in the sun throughout the day, with no other protection than a black felt hat. On the other hand, the frosts of this year which are especially alluded to by your correspondent, did no injury of any consequence to young orange trees planted six weeks previously at our camp. The insects, which seem to have so powerfully disturbed your correspondent's equanimity, cannot be compared in number or in virulence to those usually met with in tropical and sub-tropical countries, and the house fly, which is such a pest in the Western States, is comparatively rare. The food of the country is extremely cheap, and can be most amply supplemented by fish and game of every variety, which abounds. My average cost of living per diem amounted to 15 cents, or about 8d. Hotels and the general social tone are far in advance of the fast and rough life that prevails in similar new districts in the west of America. From the tone of your correspondent's letter I imagine that he was induced by some of the land sharks that abound in Florida as elsewhere into buying bad land, and then, being inexperienced, found it impossible to make his venture pay. It is true that orange trees do take time to bear, but when bearing they give a splendid profit. In the meantime the land can be planted with speedily-growing crops—such as sweet potatoes—of the easiest culture. Cattle, pigs, and poultry rear themselves at no cost to the owner, and the general living expenses are so small that very little capital is needed to enable the settler to live until returns come in. It should be remembered that of the immigrants now settling in Florida in such numbers, at least nine out of every ten are Americans from the northern and central states—shrewd men, who are little likely to be taken in or impressed by exaggerated reports. If such men are convinced of the advantages of breaking up their homes and moving to Florida, as so many are now doing, Englishmen need not be afraid of following their example.—ONE WHO HAS WORKED IN FLORIDA.—*Field.*

THE SORONTIA PROCESS OF EXTRACTING SUGAR FROM BEET-ROOT MOLASSES.

A correspondent to the London *Times* says:—"The increase in the consumption of sugar in the United Kingdom during the last ten years is immense. In 1843 it was about 200,000 tons; in 1854 it was doubled, being equal to 400,000 tons; in 1874 it amounted to 850,000 tons; and in 1882 to 1,000,000 tons. Of these quantities, in 1870, 165,000 tons were beetroot sugar, and in 1882 over 400,000 tons beetroot sugar, the whole of which was imported from Germany, Holland, Belgium, and France. The value of the beetroot sugar imported into England is about £10,000,000 per annum. The manufacture of beetroot sugar is entirely neglected in this country, although it has been proved that sugar beets can be grown to advantage. When the cultivation of the sugar beet first assumed importance on the Continent (about 1850), an official inquiry was ordered by the then Lord Lieutenant of Ireland, Lord Clarendon, and the report was presented to Parliament in 1852. A series of trials were made in different parts of Ireland with sugar beets, the results of which may be summed up as follows:—78 per cent of the beets grown in Ireland, 75 per cent of those grown in England, and 70 per cent of those grown in Belgium, were rich enough to be worked. Notwithstanding this favourabe report, nothing was done, as no capitalists took up the idea. The West Indian sugar had then the command of the market, and those engaged in the trade saw no necessity for a change. Since then the sugar trade has been revolutionised. The Continental growers have improved the sugar beet, and, assisted by Government bounties, have ruined many of our largest refineries. An economical process has recently been discovered in Germany for the recovery of sugar from beetroot molasses, or any solution of sugar, by the use of sorontia, which is the alkaline earth of which strontium is the metallic basis. The process was secretly worked in Germany for some years until recently, when patents were taken out for its working by Dr. Scheibler, Professor of Chemistry at the Royal Agricultural College, Berlin, and Chemist of the Beetroot Sugar Institution. By use of this process very large profits are now being made in Germany, and refineries in different parts of the Continent (notably France and Russia) are adopting the process rapidly. A large deposit of sorontia has been proved to exist in this country. By the new process referred to, the prospect of beetroot cultivation and the manufacture of sugar therefrom in the United Kingdom is greatly enhanced. To produce one ton of beetroot sugar, one acre of land is required. The imports are 400,000 tons of beetroot sugar per annum. The crop of sugar beet can be taken every three years. If, therefore, 1,200,000 acres of suitable land could be brought under beet cultivation, the whole of the beetroot sugar consumed in the country could be produced at home. A large proportion, if not the whole of this land, could be obtained in Ireland. The advantages which may accure to Ireland from the establishment of the manufacture of sugar from beetroot, appears to be not only that it will create a new and extensive source of manufacturing employment, but that, as the material used can only be profitably obtained by means of improved agriculture, the manufactories of beet sugar should exercise a powerful influence on the agriculture of that country."

OSTRICH FARMING.

TO THE EDITOR OF THE "LEADER."

SIR,—Knowing the interest you take in all that relates to the progress of Victoria, I beg to enclose for insertion in your paper two letters. First, copy of letter sent to the Minister for Lands; and second, his reply thereto *re* ostrich farming. Ostrich farming has already been tried here on a small scale by the Acclimatisation Society, and the birds have been found to thrive well. In South Australia there are now somewhere about 300 ostriches, though the industry was only started three years ago. At the Cape so well does the business succeed that numbers of farmers have given up sheep altogether, and now devote their whole time and attention to the rearing of the ostrich. There is no reason, however, why the industry should be confined to the Cape Colony, and I desire to draw the attention of capitalists, squatters and mercantile men generally to the fact that the ostrich will thrive just as well here as there. You will perceive by the Minister of Lands' reply to my application for land for the purposes of ostrich farming that at present he has no power to grant it. What I want, Sir, is for you to use your influence to get a bill passed during the next session on somewhat similar lines to the act recently passed by the South Australian Parliament, giving power to the Minister of Lands to grant leases, with right of purchase, to applicants who desire to go in for ostrich farming.—Yours, &c., S. K. S

12th March.

The Minister for Lands, the Treasury, Melbourne.

Dear Sir,—Among the many industries which are successfully carried on in this colony, ostrich farming hitherto has been overlooked.

2. To give you some idea of the rise of this industry in South Africa, in the year 1865, 19 years ago, there were only 80 (eighty) tame ostriches in that colony; whilst in 1880, or 15 (fifteen) years afterwards, there were, according to statistics, 50,000 birds, and the exported feathers amounted to over £400,000.

3. Having had experience I have no doubt that there must now be at least 70,000 birds in the Cape Colony, and the export of feathers could not have been less than £600,000 during 1884.

4. There is no reason, however, why the Cape, which is a notoriously slow and backward colony, should monopolise

such a paying industry.

5. Having resided some years at the Cape and some two years here, I consider the climate of Victoria as being eminently suited for the successful rearing of the ostrich.

6. I therefore desire humbly to ask you to grant me the lease for 21 years of 10,000 acres in the salt bush country, for the purpose of rearing, breeding, buying and selling ostriches and ostrich feathers, the land to have a frontage or a permanent supply of good water.

7. And further, that a clause be inserted in the lease, granting me the right of purchasing the land at a price to be named.

8. Trusting you will see your way to granting me the land asked for, so that a new industry may be started in this colony under your *régime*.—I have the honor to be, Sir, your obedient servant, S. K. S.

Melbourne, 4th March 1884.

Sir,—In acknowledging receipt of your letter of the 1st instant, requesting that you may be granted a lease for 21 years of 10,000 acres of land in the salt bush country, for the purpose of rearing, breeding, buying and selling ostrich feathers, I am directed by the honorable the Minister of Lands to inform you that he has no power to comply with the request.—I have the honor to be, Sir, your most obedient servant, J. MORRAH, Secretary for Lands.

RICE CULTURE AND RICE CLEANING MACHINERY IN JAPAN.

Report by Mr. Jones, American Consul at Nagasaki:—

Modern agricultural implements have not found their way to the island of Kiu Shiu (Kew Shew). With the exception of an occasional garden hoe or rake, brought by some foreign resident from America or England, for use about his private grounds, one sees here nothing familiar in that line. The implements of agriculture of the country are of the most primitive character, and have been used right down the centuries from the earliest farmer. The farmer of Japan may be said to be hereditary. He never goes out of his vocation, but lives and dies upon the soil he tills, the same today he was two thousand years ago.

While this class of tillers of the soil are called farmers, in our meaning of the word there are no farms and no farmers in Japan, or at least in this part of it. Of the 150,000 square miles of surface of the whole country, two-thirds of it consist of mountain land, and much of this is rugged and precipitous. The valleys are small and the farms, so-called, are merely patches of ground, of a half acre or so. The country is laid out into innumerable gardens, not into farms, and in gardening the Japanese have little to learn. Even with their old-fashioned implements they produce results equal to the best in any part of the world. The mountain sides are terraced into garden plats, and are cultivated to their very summits, so that the general aspect of Japan in this respect is one of high cultivation and perpetual verdure.

The introduction here of simple hand implements of general and conspicuous use might be of advantage after a while to our manufacturers, when the Japanese become familiar with their use and have discovered their superiority over their own simple implements, but at present I would recommend only the consignment, as samples, as is were, of such things as hoes, rakes, spades, shovels, and the like. There is no room for expensive machinery, such as reapers, &c.

Improved and cheap rice cleaners and polishers might find a market. But it must be understood that with this people time is as yet of no object, and labour-saving machinery is of no consequence. The man supplies the place of the horse. Rice is the chief product of the soil of Japan, as it is the chief article of food of the people.

In gathering the rice the farmer uses an implement something like the old-fashioned reaping-hook, to cut the straw. The rice is separated from the straw by the women and children of the family striking it against wooden teeth, set in a row, of sufficient width apart to permit the straw to pass, but not the rice-heads. After the separation the straw is used for various purposes, such as making bags to hold the cleansed rice, thatching roofs, &c. They used it also as food for cattle and horses by cutting it up and mixing it with bran.

To clean the rice it is beaten with sticks and sifted, and then run through a mill to take off the husks. This mill is constructed of two bamboo baskets, without bottoms, resting one on the other, which are filled with bamboo splints about a foot long and burnt at one end, which are placed perpendicularly in the baskets and cemented solidly together by mortar. The bamboo ends act as the cuttings on a flour-mill stone; the basket, bamboo splints, and cement as the mill-stones. The upper basket is turned around by a handle fastened at one side, which is arranged as a kind of crank and worked by hand. The best rice in Japan is raised on this island, in the province of Hiogo, in the neighbourhood of Nagasaki.

The average price of rice in this market is \$2·40 to \$2·80 a picul of 133⅓ pounds. The rice crop of Nagasaki ken, or province, is about 762,266,153 koku per annum. A koku is 2½ piculs, and a picul is 133⅓ pounds. The value of the yearly crop is about 7,184,988 yensatsu. A yensatsu is a paper dollar, of fluctuating value compared with the silver dollar, generally about 60 per cent discount. The whole annual rice crop of Japan is about 31,604,730 koku, of the value of 305,744,158 yen. The yearly export of rice is about 6,827,076 catties (a catty is 1⅓ pounds), valued at about 210,861 yen.

An improvement on the original methods of the natives in cleaning rice has been introduced at Nagasaki by Messrs. G. W. Lake & Co., American merchants, residing and doing business in this city. They have erected a mill on an eligible site, by the bay, in the lower part of the foreign concession of Nagasaki, and have as much business in this way as their machinery can do. They have an 18-horse power portable engine and boiler, manufactured by the Erie City Works, Pennsylvania, as the motor for their rice-cleaning machines, of seventy-two stamps. There are in this vicinity, at this time, six other rice mills owned by Japanese, and constructed on about the same principle as the one described. Throughout the country where water power is to be had the natives use it. Much of the rice in the country is cleaned by manual labour, in a wooden mortar. Several bands of straw rope are placed in the centre of the mortar, which is filled with rice and pounded with a mallet. One man, by this process, will clean from one to two piculs of rice rice per day.

BABUL BARK AND PODS.

Mr. W. Wilson, Director of Revenue Settlement and Agriculture, has addressed the following circular letter to the Chamber of Commerce, Trades Associations and principal Merchants in the Madras Presidency:—

Sir.—"In forwarding for your information copy of a memorandum drawn up by Mr. J. S. Gamble, Conservator of Forests in the Northern Division of this Presidency, on on Babul Bark and Babul Pods, I have the honor to request that you will be good enough to give me any information that you may be able and are willing to afford regarding the commercial prospects of a trade in these articles with England and other contries. I have asked the Secretary to the Government of India in the Department of Revenue, Agriculture and Commerce to supply me with the information asked for by Mr. Gamble regarding the purchasers and mode of sale in London alluded to in a paper recently drawn up on this subject by Mr. Liotard of that Department, and the information when received will be communicated to you."

ACACIA ARABICA.

The Babul is not indigenous in the Madras Presidency unless possibly it may be considered to be wild on the black cotton lands of Bellary and Kurnool. Nor is it a 'Forest tree' properly speaking in this presidency, for it does not occur wild in any of our chief forest tracts. But it comes up plentifully, self sown, on old tank beds, on fallow lands, on black cotton soil, and on bunds and mounds and high lands among the rice fields of the Circars and Carnatic. Its real home is probably to be found in Sind and Guzerat, and in the first mentioned province it is the chief tree of the Indus bank forests, where it affords large supplies of fuel for the river steamers and the Railway. The wood and its uses are described at page 151 of the 'Manual of Indian timber,' to the information given in which I have nothing to add except that the Madras Railway refuse to take it as fuel, although other lines have no such prejudice. I understand

The refusal is due to the impression, right or wrong that the products of combustion injure the boilers of the engines.

In the re-afforestation of barren lands in suitable soils Babul is an extremely useful tree. It thrives well on the black cotton soil, which is more than can be said of most other trees, its usual companions being *Albizzia Lebbek*, *Balanities Ægyptiaca*, *Parkinsonia aculeata* (an introduction), the Tamarind, Margosa and Wood apple. Old tank beds in most Madras Districts quickly cover themselves with it and indeed wherever there is a patch of fallow alluvial land along the districts of the eastern coast and a few trees to give seed it springs up in abundance. Goats being largely fed on the pods, they are the principal agents in the distribution of the seed, and the value of the pods as an article of food for stock must not be forgotten in considering the possible effect of a large demand for them for tanning purposes. But the recent report on the value of both the pods and the bark for tanning are most valuable, and we shall bear them in mind in making future cuttings of Babul trees in the plantations and self sown Babul jungles of Bellary, Anantapur, Cuddapah and Kistna Districts. It would be useful if Mr. Liotard would inform us who are the purchasers in London who are likely to give £40 per ton for cleaned Babul pods and £12 to £14 per ton for bark (more than 50 per cent increase on the ordinary price of oak bark) and what is the usual method of sale. Are the tans sold like timber, tea, &c., at public sales, or are they merely consigned direct to the tanning firms? It would also be useful to know what prospect there is of firms in the presidency towns buying such tans as may be collected by Forest owners or managers.

At such rates as the above it is surprising that the tans have not long ago become regular articles of trade and that Babul planting has not been carried on similarly to and much more extensively than that of the Casuarina in such localities as Madras, where cost of carriage to the seaport is low.

Grown for the pods only and their yearly crop I expect the trees ought to be at least 30 feet apart, or 15 at first to be thinned out to thirty feet, to ensure a proper amount of air and sunlight for the full development of the fruit. This would give about 48 trees per acre, the yield of which can be calculated if the average yield of a tree is known. Grown for the bark it would probably be found most profitable to treat it in coppice and cut it over every 8 to 10 years. It would therefore require to be planted close say 10'×10' or still better propagated by broadcast sowing. The yield would probably be much the same as that of Oak bark, but actual experience only can tell what amount is likely to be realized per acre. The wood could at the time of cutting be also easily sold at good rates in any locality. away from the large forests, where Babul is grown. It will therefore be seen that different methods of planting must be adopted to secure the fruits and the bark, the former being an annual, the latter a periodical crop.

I should say that if only merchants can be found in our seaport towns to buy the Babul bark and pods, not to speak of other valuable tanning materials like the Tangedu or Avaram bark (*Cassia auriculata*) the barks of *Cassia Fistula*, *Acacia Leucophlœa*, *Terminalia tomentosa*, etc. and the myrabolams, there is not likely to be much questions of difficulty of supply. Our forest plantations and self sown scrub jungles alone could furnish a great deal of bark while a very large supply of pods would be given by the numerous village trees even if one-half of the produce is conceded to the goats.

INDIGENOUS SALT-PLANTS.

The following is a letter from Mr. J. Steavenson, Honorary Secretary, Agri-Horticultural Society, Madras, to the Director of Revenue Settlement and Agriculture, Madras, dated 8th February 1884:—

With reference to your memorandum, dated 22nd November 1883, No. 1622, communicating a letter from the Agricultural Reporter to Government, suggesting that it may be possible to find indigenous salt-plants that may be quite as effective as the foreign *Atriplex nummularia* in the reclamation of saline land and as useful for fodder, and inviting the co-operation and aid of the Agri-Horticultural Society. I have the honour to inform you that I fully concur with the Agricultural Reporter, I have, for many years, taken a special interest in the reclamation of waste land, though it was not with that view that I some years ago first wrote to Australia for seeds of "salt-bush," but in hopes of succeeding in introducing a good hotweather food for sheep. I have seen no saline land in this part of the country which could not be reclaimed, though whether its reclamation would always be profitable within a reasonable time is a more speculative question. Probably the worst class of such land I have seen is such as has been cultivated and has become barren from saline efflorescence. With such land I would deal by frequent breaking up of the crust with the plough, or better, the spade; by encouraging in every possible way the accumulation of vegetable deposits; by rigidly excluding all leaf consumers, such as fire, cattle and goats, and more especially women, who gather up every dry leaf and stalk for fuel; by growing seeds of, and planting the coarsest vegetation such as spear grass (Aristida setacea) wild crotons (Jatropha curcas and J. Glandulifera) and even prickly-pear; and, ultimately when coarse plants are established, by planting in their shelter deep-rooting trees which shed abundant leaves, such as banyans (Ficus of several species), portias (Thespetia populnea) Bassias. Woodias (Ordins woodea), coorkapilly (Inga dulcis), and many others. Doubtless these operations, before being effective, would occupy many years, but it is wonderful how soon a layer of vegetable mould accumulates when every leaf that falls remains upon the ground. Salt marshes, such as those near Ennore, I would treat differently. They usually overlie deposits of sand and shells and are caused by the standing of brackish water a mixture of the rain-water flowing from the higher land and the sea-water coming up the creeks with every rising tide. On the closing of the bars at the mouths of the creeks and the subsidence and evaporation of the standing water, the salt-marshes become green with coarse grasses, Cyperuses and rushes, one or two bulbous plants, and representatives of the orders Chenapodiaceæ, Mesembryaceæ, and others. These, in the early hot weather, the cattle greedily eat; but, judging from their universally starved appearance while on these plains, probably more for want of better food than from preference. That these lands are easily reclaimed is proved by the way in which the paddy fields and cocoanut topes creep down into them, even under the poverty-stricken management of the villagers. I would raise banks to exclude the flow from the "back-waters;" within the enclosure so formed throw the soil into ridges high enough to keep the crowns of the tree-roots above the level of standing water, and on the ridges plant trees, such as casuarinas, banyans, mangoes, Cassia florida, coorkapilly, &c. There are many trees and shurbs to be seen growing, for instance, on the banks of the Cooum and Adyar rivers, which have no objection to have their roots below the level of, and probably in, brackish water. Again, I would strictly preserve every leaf and self-sown weed, and few would believe, without actual observation, how short a time it would take to form a mellow soil above the level of salt water, which would naturally bear abundant crops of grasses and shrubs most useful as food for cattle. In this connection I would call attention to the wholesale destruction of indigenous shrubs which is going on round Madras. These shrubs are Nature's own reclaimers of waste-lands, and would, if the salt marshes above referred to were dried, and cattle excluded for a time, spontaneously, or sown by the winds and birds, take possession of them; but they are disappearing with giant strides. Within my recollection, acres, I may say square miles, of scrub-jungle, within a few miles of the town, have been cleared away. They are apparently grubbed up, in the hot weather when the cultivators are idle, for the sake of their roots, which are brought into Madras and largely used for fuel by the bakers and sweetmeat-makers. All such scrub jungle should, in my opinion, be strictly preserved on Government waste land as a nucleus for the formation of vegetable soil, a protection to seedling trees, and a source of much valuable hot-weather fodder.

The following is the Endorsement of the Director of Revenue Settlement on the above:—

The foregoing letter, for the suggestions in which the Director is very much obliged to the Honorary Secretary, will be submitted, through the Board of Revenue, for the information of Government, and be communicated to the Agricultural Reporter to Government, the Commissioner of Salt Revenue, the Forest Department and all Collectors. The reclamation of the saline tracts on the coast, in the manner indicated by Mr. Steavenson might, it is thought, be undertaken by the Forest Department, to which has been already entrusted the planting on the coast line of sand-binding creepers (G. O., No. 446, dated 16th April 1883. It is suggested that the attention of the Forest Department be specially directed to Mr. Steavenson's remarks, in paragraph 6 regarding the disappearance of scrub-jungle in the neighbourhood of Madras, and his suggestions as to the strict conservancy of such jungle on all Government waste "as a nucleus for the formation of vegetable soil, a protection to seedlings, and a source of much valuable hot-weather fodder.

The Government have ordered that the attention of the Conservators should be drawn to Mr. Steavenson's letter, and especially to his remarks about the denudation of Government waste lands about Madras.—*Madras Times.*

COCONUT GROWING IN FIJI.

Your correspondent "G. E. R." (p. 810.—ED.) evidently knows something of coconut growing in Fiji, but "a little knowledge is a dangerous thing." He is correct in stating that the employment of imported labourers from the New Hebrides and the Solomon Islands is yearly becoming more and more costly and vexatious to the planter; but he quite overlooks the fact that the labourers employed on coconut plantations are of quite a different character. These men and women come from the Gilbert group of islands, lying along the equator between longitude 172° E. and 177° E., and are known in Fiji as Line Islanders or Kai Tokalau, literally "people from windward." They are much better fitted for the work of a coconut plantation, or "copra" station, as some are designated, than are the men of Papuan race, and are themselves very distinctly of Malay type. It is not for coconut planters in Fiji a difficult matter to obtain their services, and their wages range from £3 to £5 per annum for a term of three years' indenture, the amount being regulated by the duration of their previous experience, if any, in Fiji. These people live largely on coconuts and fish (of their own catching), and are not dependent upon yams or taro for the maintenance of health, like the dark-skinned Melanesian further west. "G. E. R.'s" observations on fruit-growing in Fiji are just and to the point, and the rest of his letter presents a very fair view of the question raised by your former correspondent. I must disagree, however, with the statement that the fish are scarcely worth eating, and attribute his opinion either to too limited tasting on his part, or to want of skill on that of his cook. There is excellent sport to be had, either fly-fishing or spinning, both in sea and river, but the climate is very hard on a fellow's tackle. After a continuous residence of eight years in the colony, I can assure your readers that either of the fish enumerated below can be served up very simply as a most tasty dish; and though we have neither whitebait, salmon, nor trout, as "Coconuts" cunningly remarks, yet the little daniva is at certain times of year by no means to be despised as a substitute for the Blackwall dainty. Ika loa—a black mullet; mountain streams, trapped. Ika droka—a trout-like fish; mountain streams; fly. Ika-damu—a large, broad, red fish; river and sea; minnow. Saga—the king of Fijian fish; sea and river; fly or minnow. Kanace—sea mullet, netted. Salala—sea and estuaries; taken in fences and in nets. "Coconuts" is, I think, much too sanguine. He would certainly be unwise to make his headquarters anywhere but on his estate. And the estate would be seven years coming into bearing, and might even then or later on be entirely destroyed by blight. Such things have happened before on islands in the South Pacific; why not again? He would not do well to grow fruit, because the parts of the group which are best suited for that industry, on account of their proximity to the ports of entry, are the least adapted for coconuts for geographical reasons. The enterprise which has proved the best and most proper one to combine with coconut growing is cattle rearing. When the young palms are high enough to withhold their leaves from the cattle, the latter, by feeding upon the grass and bushes in the grove, prevent these from choking the growth of the palms, and at the same time manure the ground. And the same labourers who best suit the coconut work make the best drovers and butchers. As to Queensland bananas, they bear about the same relation to those grown in Fiji as a Barcelona nut does to a filbert, or a theatrical orange to a Chatsworth pine; and the Sydney, Melbourne, and Auckland people won't look at them. There are four large steamers monthly, whose principal return cargo is fresh bananas, sometimes carry as much as 10,000 bunches at a time; and I think the markets may some day get overstocked. Coffee has not proved a failure, as "Coconuts" asserts; for the experiment is even yet being carried on, and the prospects of this season's crop in Vitu Levu are, by the March mail, most encouraging. But, of course, sugar is the mainstay of the planting industry in Fiji, and a million and a quarter of money is already invested in it.—VUNUWAI, (London, March 24).

—— Surely your correspondent cannot have been lately in Fiji, or he would know that the export of bananas to the Australian and New Zealand colonies is anything but a case of "sending coals to Newcastle." The fact of Levuka shippers paying the high freight of 1s a bunch is, I think, sufficient proof of the estimation in which the Fiji fruit is held in the colonies. No one in Sydney would dream of buying Queensland bananas when Fijian, or even those from New Caledonia (which are decidedly inferior to the Fiji fruit), are procurable; in fact, I think comparatively very little Queensland fruit is imported. In Sydney, Fiji bananas average from 1s 6d to 2s 6d per dozen. All this is, however, wandering from the original subject, and taking up our editor's space. In the case of coconuts as well as in most others, "the proof of the pudding is in the eating," and, however favourable it may appear in theory, I have never heard of the man who has made even a moderate fortune at nut planting in Fiji even in the earlier days, when copra was worth a good deal more than it is at present, and the question of labour was not such a difficult one. I am quite aware of the extensive operations being carried out by the Colonial Sugar Company on the Ruva river. I think at present it has three large mills at work crushing cane, principally grown by planters in the vicinity; hence the punts and steam launches, which were of course used extensively in the first place for transporting the heavy machinery from the vessels at the mouth of the Ruva to the company's land. It must be remembered that this company has almost unlimited capital at its command, and could consequently tide over temporary reverses; it is close to Suva, at which port the imported labour is hired, and could, if necessary, import its own coolies from India, or even China, which would of course be impossible for a small capitalist. Coffee, I believe, has not hitherto found favour in the London markets. The same was at first the case with Indian teas; nevertheless, I believe the Fiji production will eventually prove a success: at all events, it is still being largely cultivated in Taviuni, and parts of Viti Levu and Vanua Levu. In conclusion, I have no doubt "Coconuts" would have no difficulty in buying land for his planting operations, the sellers of that commodity having hitherto been the most successful men in Fiji.—G. E. R.—*Field.*

PLANT CELLS.

From an early period in the history of Vegetable Anatomy—from the time that Grew and Malpighi demonstrated the varied internal cellular construction of plants—experiments to demonstrate the use of these varied structures have been made. And now, when this department of botany has taken a sudden bound onwards, and chemical reagents have come to the help of the microscope, it may be hoped that substantial progress may be made in this direction. The structure of plants, like their outward conformation, is partly an hereditary endowment from generation to generation, partly the result of progressive adaptation to certain conditions. So long as the power of adaptation or accommodation to circumstances remains, so long is there room and opportunity for variation as occasion may demand. On the other hand, it is conceivable that plants which have for a long series of ages become adapted or accustomed to one uniform set of conditions remain unaffected, do not vary when those conditions are altered, or, being unable to accommodate themselves to new circumstances, die out. On some such principles, probably, depends the fact that the gardener can grow certain plants without difficulty, while others defy all his efforts. But to descend from the region of speculation to that of practice, we may point out that the internal conformation of plants sometimes offers as good hints to the cultivator as to the conditions under which certain plants may be expected to thrive as the more easily observed external appearances do.

By way of illustration we may mention the presence in the leaves of certain plants of what are termed palissade-cells. These are oblong cells, arranged vertically, that is, at right angles to the surface of the leaf. Their form and direction may be indicated thus ||||||, the ordinary leaf-cells being more or less globular or branching, or, if elongated, then elongated horizontally in a direction parallel to the surfaces of the leaf. The term "palissade-cells," then, very well expresses the form and arrangement of a certain class of cells packed closely together, like the wooden rails of a park fencing. A very low power of the microscope is sufficient to allow these cells to be seen, and in some cases an ordinary pocket lens, if of tolerably high magnifying power, is sufficient to enable them to be seen. These palissade-cells are usually filled with "leaf-green," or chlorophyll.

We cannot here pursue the subject from the point of view of the anatomist or physiologist, it must suffice to point out the practical deductions which are insisted on by Stahl, Vesque, and other students of this particular structure. When a gardener, says M. Vesque, in substance, receives a new plant of imperfect or unknown history, he does not pay much heed to systems of classification, as a botanist would do, for they afford him little help. He judges by the external appearances of the plant what is likely to be the appropriate treatment, and so, for instance, he submits to the same general conditions Stapelias and Aloes, Agaves and Mesembryanthemums, and so forth—plants, in fact, whose "habits" and requirements are the same, whose adaptive characters, that is, are identical, although their more purely hereditary peculiarities are widely different. In the case of succulent plants, such as those just mentioned, the matter is easily determined; but in those cases where the exterior appearance gives no indication of the habit and requirements of the plant then a microscopic examination must be made, and this will enable the observer to say with something like certainty whether the plant naturally grows in the sun or the shade—whether its internal structure is such as to allow of free or of relatively little transpiration—whether it is likely to demand frequent and copious waterings, or whether it is capable of living long without any. We may give a few illustrations. If the palissade-cells are abundant and wel-marked, the probability is that the plant requires a proportionate amount of exposure to light; if, on the other hand, the palisades are scanty or not present, the inference is that the plant requires to be grown in the shade. Between these two extremes is a group of plants of variable and inconstant nature: such plants obviously are enabled by Nature to adapt themselves more or less successfully to different conditions.

In the case of moisture, the subject may be divided into the discussion of the arrangements for, in the first place, the supply of water; and, secondly, for its retention and storage. Indications as to the supply, great or little, may be gathered from the thickness of the cuticle, and the number and position of the pores or stomata.

As to the faculty of storage, that may be judged of from the nature of the epiderm or skin beneath the cuticle, the abundance of cellular tissue—that is, the succulence of the leaf, and other characters. The first set of characters supply hints as to the absolute quantity of water required; for instance, the thinness of cuticle and abundance of stomata would naturally suggest frequent and copious waterings; the second set of characters suggests the abundance and frequency of water, whether little and often, or a large quantity less often. Plants whose thick rinds indicate a relatively little amount of transpiration naturally require a hotter temperature and a fuller exposure to light than others.

A plant with small pores or stomata transpires less than one with large or with numerous pores. Hairs on the surface check transpiration, spongy construction of the leaf is also an indication of relatively little transpiration. Obviously, the more fleshy the plant the less need there is for watering frequently.

Hard woody cells, such as those which constitute the grit of a Pear, and which serve as a sort of skeleton to support the tissues, are taken by M. Vesque to indicate that the plant is exposed to bright sunlight and occasional drought, as Proteas, &c., or to occasional excessive losses of water, and indicate the necessity for copious watering at intervals, as in the case of succulent plants.

Pursuing his subject M. Vesque goes on to show how the epidermal cells, or those sub-adjacent to them, in some cases act as reservoirs for water; and how in the tissues of some leaves may be found other structures having a similar office, so that the thick rind, the deficiency of stomata, the dense hairs with which plants growing in dry places are provided, indicate the quantity of water which traverses the plant, while the reservoirs for water furnish indications as to the frequency of watering and the length of interval between the operations.

The intelligent observer, adds M. Vesque, will know how to avail himself of the indications presented to him, which will be varied and combined in a thousand different ways, but from which he will be enabled with accuracy and judgment to regulate the delicate operation of watering.

We have no doubt whatever that M. Vesque is on the right track, but we fear it will be long before our young gardeners will avail themselves of the help of the microscope rather than of the rough-and-ready measures that they are accustomed to practise. In any case it will be admitted that there are few operations in practical gardening which are carried out with less intelligent judgment than is watering, and any means which may serve to obviate this will be a boon to head gardeners.

Lastly, we may mention that we have put M. Vesque's notions to a partial test with reference to the leaves of Orchids, which present remarkably great variations of structure, and in some cases of great interest. We have examined one or two dozen species, with the general result of confirming M. Vesque's notions, or, at least, of satisfying ourselves that "there is something in them." On another occasion we may speak more fully on this point.—*Gardeners' Chronicle.*

PADDY CULTIVATION.

TO THE EDITOR OF THE "EXAMINER."

DEAR SIR,—In your issue of the 8th instant appea s the excellent paper of Mr. Weerackody on Paddy Cultivation, as read before the Agricultural Association. It is a sign of the times that intelligent interest is now being paid to the cultivation of this food product. If all landowners amongst the Sinhalese gentry took as intelligent an interest in paddy cultivation as Mr. Weerackody, and published the results of their experiments rice-growing will not be, as now, an industry that barely paid its way.

Mr. Weerackody seems to have had three objects in view in the experiments he undertook. The first two, to decide whether transplanting was better than sowing broadcast, and second the effect of manure, I am inclined to think, are sufficiently apparent to any intelligent observer to obviate the necessity of making experiments to determine. However, it is as well that they were decided by personal investigation. The third reason, to decide between the cost of cultivation on the share system by Goiyas and by hired labour—I confess was laudable, as it is an open question and one in which the decision is invariably given to the share system, by those who have tried both. Whatever influence Mr. Weerackody's figures and inferences may have had on others, they have not convinced me that it is cheaper to cultivate with hired labour, for I question his figures. To begin with, I believe Mr. Weerackody sowed his fields too thick, if he used, as he says, 6 bushels of paddy for two acres. My idea always was—I may be mistaken—that an acre represented two bushels sowing-extent. Even that is too much for fields with a rich soil, and the over-crowding of the plants acts injuriously on their crop-bearing powers. Then Mr. Weerackody does not tell us whether the three plots experimented on were of equal extent, and the soil nearly as possible the same. For, anyon e who carefully notices a paddy field will have found that the fertility, udging by the growth of the paddy, of any two adjoining plots is never the same. The remark that it is better to grow paddy early than late in the season, though not new, is true: but delay is not generally so much a matter of choice as a result of delay in rain and other unavoidable causes. That the turning up of the soil with mamoties gives better results and is better work than using the apology for ploughs in use amongst natives, is likewise my experience. That the extermination of weeds and grasses in fields is of vital importance no one will deny, but how to do it at a reasonable cost is the question. Mr. Weerackody suggests rooting them out and exposing them to the sun to be killed, and then turning water on the beds to rot them. Perhaps Mr. Weerackody in his next paper to the Association will give the cost of this interesting experiment, and leave his readers to judge whether the game is worth the candle. The worst and most difficult-to-be-killed weed is grass. After weeks of drying, one wetting seems to give it vitality. The usual method is to get it well under the soil in treating the soil and in the final preparation of the beds, and trust to fermentation to kill the roots. But they have a trick of growing with the paddy, and to a great extent choking it. I must confess it is news to me that to sow paddy without sprouting gives better results than after sprouting. I always thought that the former was adopted where sprouted paddy ran short. Why, may I ask, if sowing unsprouted paddy gave better results than sprouted paddy, the former is not generally adopted? Possibly owing to birds carrying away all the paddy before it sprouts and gets hold of the ground. The reason given by the Goiya in answer to Mr. Weerackody, if not convincing has the merit of novelty—the roots of the ungerminated paddy goes deeper in search of food. Transplanting is said to be preferable to broadcasting. It is a mistake to say that in the Kandyan country transplanting is to not systematically carried out, and is only resorted to to fill up vacant patches. All round Kandy, transplanting with very encouraging results can be seen. It is also a mistake to say that the seed bed should be sparsely sown. This will necessitate the seed bed being about half the size of your field. No evil results will follow if the seed bed is sown thickly, not very thickly, and the plants transplanted early. I have for my authority a paper on Rice cultivation in Japan. That manuring will increase crop does not need repeating, but the statement that stimulating artificial manures exhaust the soil is open to question. As far as my knowledge goes, only lime, which is not properly a manure, exhausts the soil by frequent applications, as it renders available inert gases, and these being constantly taken up by growing plants, the soil after a while becomes exhausted, till these constituents are again formed by different agencies. The *manure* applied was said to be fish; the *result* treble the quantity of crop gathered from the unmanured plot; the *reason* for this, the stimulating properties of Phosphoric Acid contained in the fish.

In placing cattle manure on the top of the list of manures, Mr. Weerackody will be glad to know that Liebig and all living chemists, with the exception perhaps of Ville, agree with him. But I believe in fields with rich soil, it will be found that cattle manure will have the effect of sending all the paddy plants into "leaf."

Now for Mr. Weerackody's figures. In spite of his finding his new purchase in a neglected state, and necessitating the putting up of ridges, and experiencing a great deal of trouble in digging up the soil, which was hard, it took him only 11 men to do the work. There surely must be some mistake, or the work must have been most carelessly done. Now, I pride myself on being able, owing to the training I had as a coffee planter, to exact from coolies a full day's work for a full day's wage. Under my personal supervision, and with my being at their backs for the better part of the day, it took me 25 coolies to turn up the soil of a field of 3 bushels sowing extent and composed mainly of sand. I will not question the correctness of the number of men employed in the same work the second time, as the digging, once done, the second round would not have been very difficult. But 21 men for the final operation of draining, dividing into beds and sowing seems excessive. It took me 8 men to mud the field twice over with buffaloes, and 7 men for the final operation which cost Mr. Weerackody 21 men. It strikes me Mr. Weerackody simply had a total of the men he employed and divided them at the different works when about to write his essay. Two cwt. of fish manure at 50 cents is decidedly cheap. I wish I can get as much phosphoric acid at the same figure; I would go in largely for manuring my field. There is a difference of only 4 cents between his cost of reaping and mine, but however did he manage to thresh his crop for Re 1? It took me on two successive occasions 11 men to thresh my crop, and their wages at 33 cents come to considerably more than Re 1. There are a few items Mr. Weerackody has omitted from his account. 1. The cost of transplanting. 2. The wages of a man to tend his field, either by fencing it or watching it against cattle trespass, and to turn water on and off his field. There is another slight omission—the quantity of paddy he reaped. Being told that the paddy and straw amounted in value to R66, does not enlighten us as to how many fold his field yielded.*

Now, my experience of the two systems—cultivating by paid labour and Goiyas—though not large may be useful. By the former system the return just balances the expenditure, valuing the paddy at Re 1 per bushel. I am not singular in my experience. A neighbour whose fields are extensive found it cost him about R200 to produce 200 bushels of paddy. By the Goiya system, after charging myself with the Government share, value of manure and seed paddy, I got two-thirds of the crop. So that my belief in the Goiya system is founded on reason and experience. This time the fields will be cultivated more intelligently and in a different manner, and I shall be glad to make the results public. I am at one with Mr. Weerackody when he says it is the duty of every landowner to adopt "new systems" as a means of educating the ignorant Goiyas.—Truly yours, B.

GLEANINGS IN THE SOUTH-WESTERN PROVINCES OF CHINA.

The interior of the enormous Chinese empire is still to the Western world so nearly a *terra incognita* as to render all fresh trustworthy information respecting it extremely acceptable. Such a contribution has just appeared in the form of a parliamentary paper containing an account of a four months' journey made in the early part of last year by Mr. Hosie, a consular agent, through a considerable portion of the important provinces of Se-chuen, Yun-nan and Kuei-chow in the south-west of China. It is principally in these provinces that, in defence of Imperial edicts, the cultivation of the poppy has been introduced and persevered in, until now it seems to be a tolerated industry, and home-grown opium has become in China a powerful competitor with the Indian drug. Scattered here and there among the observations made on this journey are several that appear to possess sufficient interest for the readers of this Journal to make them worth culling and binding together in a note. The starting-place was Chung-king, the great trade emporium of the province of Se-chuen, and the first objective point was Cheng-tu, its capital, lying about two hundred miles to the north-west. Along the road between these two towns the poppy was a frequent crop, more land being devoted to it in some districts than to anything else; indeed it is there cultivated to such an extent as to affect the price of corn and all other commodities. Nearing the capital the safflower was met with, but here, as in India, its cultivation is decreasing under the joint competition of opium and foreign dyes. Orange groves were also passed, and it was noticed that everywhere the skin of the orange was carefully collected and preserved, the epidermis and the white inner layer, when separated, both finding a place in Chinese medicine. Along this route and everywhere throughout the province there was an abundance of the Chinese "wood oil tree" (*Elæococca vernicia,*) a Euphorbiaceous plant, from the seeds of which an oil is expressed that is used by painters; the tree was also met with in the provinces of Yun-nan and Kuei-chow. Besides coal, a common fuel in this district is charcoal made from ferns, which are placed in a pit and allowed to smoulder, water being constantly sprinkled on the heap to prevent a blaze. A detour was made to visit the famous salt and fire wells at Tzu-liu-ching, where side by side with the

* Mr. Weerackoody says 50 bushels, and he sowed 6 bushels.—ED. Examiner.

sources of the brine are found the means for its evaporation. The fire wells would appear to be associated with petroleum deposits, and give forth an inflammable vapour which is conveyed through bamboo tubes lined with lime to the furnaces where it is burnt under the evaporating pans. The brine varies in quantity and quality; sometimes it is black and sometimes yellow, the latter yielding about half as much salt as the former. The black brine is obtained from a depth of at least two thousand feet and the yellow from seven or eight hundred feet. When the supply is good upwards of three hundred "buckets" of black brine and six or eight hundred of yellow may be obtained in a day. The "buckets" would appear to be large and the brine strong, since it is stated that a bucketful of black brine yields upon evaporation about twenty-four pounds of salt, worth from 6*d.* to 9*d.* The low price of the salt, however, does not save it from adulteration, since we are told that in the manufacture of granular salt bean flour is added to improve its colour.

After reaching the capital of Se-chuen the travellers turned south-west, passing through a fertile plain and reaching Ya-chou, which is considered to be the centre of a medicine-producing country. Here "huang-lien," or gentian, sells for more than its weight in silver, and "hou-po," the bark of the *Magnolia hypoleuca*, is valued at 15 to 30 taels (£4 8s. to £8 16*s.*) per catty (1⅓lb.), the product from the wild tree being most esteemed. It is curious, if not significant, that here and subsequently, next to tea, medicines and coffin boards formed the principal articles of trade. Brick tea is manufactured in Ya-chou, and is said to differ from the article made under the same name at Hankow in consisting of the entire leaf and twig loosely pressed together, whilst the Hankow brick-tea is tea-dust firmly compressed into actual brick shape. Still travelling south and bending towards the west of Yun-nan, the valley of Chien-chang, the great white wax insect egg-producing district, was reached. Wax is not produced here however, since, according to Mr. Hosie, the insects are not reared on the wax-tree, but on a tree called the "tung-chien," and are exported to the districts where the wax-tree is cultivated. If this observation be correct it will help to clear up some obscurity with reference to the origin of the Chinese white wax. The perseverance of the late Daniel Hanbury established it beyond reasonable doubt that one tree, at least, upon which the Chinese wax insect feeds is a species of ash (*Fraxinus chinensis*, Roxb.); but he mentioned in his first communication that the wax had also been attributed to a plant bearing the name "tung-tsing," variously spelt "tong-gin, "toung-thsing," etc., which has been referred to various species of *Ligustrum*. Mr. Hosie speaks very distinctly on the subject. He says:—"It has been hitherto a matter of surprise that the valley of Chien-chang should produce the insects and not the wax, and Chia-ting the wax and not the insects. The reason is perfectly simple however. In the prefecture of Chia-ting the wax tree is extensively grown; in the valley of Chien-chang it is not. On a small twig of the 'tung-ching' tree, which a dealer in wax insects has just given me, I find half a dozen round excrescences about the size of a pea, and innumerable smaller excrescences, like minute shellfish, clinging to the bark. On opening one of the brown glazed pea-shaped excrescences, thousands of minute whity-brown creatures, whose movements are all but imperceptible to the naked eye, are seen. In less than a month hence these excrescences will be collected, transported and suspended on the branches of the wax tree. At first they spread themselves on the upper side of the leaves during the night, but hide during the day from the sun under the leaves. After a time they spread over the branches and secrete the wax. A little wax is on the twig of the tung-tching tree which I hold in my hand."

Among the articles of medicine observed in Se-chuen province, Mr. Hosie mentions "China root," by which, however, he does not mean the rhizome of *Smilax China*, usually designated under that name, but the curious fungoid growth of a species of *Pachyma*,—resembling the "tuckahoo" or "Indian bread" of North America,—which is found on the roots of old fir-trees. Another medicinal substance, "tu-la," was met with after crossing the Yun-nan frontier, which is described as a "brown root-like substance, found underground in the hills." It has a bitter taste, resembling that of quinine, and is said to be efficacious as an antidote to opium and in the treatment of fever. This is not the only case in which a regret arises as to the limits of the traveller's scientific knowledge. In one place he vouches for having inspected a specimen of coarse dusting cloth, "manufactured from the fibrous roots of a coarse grass," the peculiarity of which is that "when it is dirty it is put in the fire, the dirt is consumed and the cloth is taken out clean and uninjured and ready for use." In Yun-nan poppy cultivation and opium collection were noticed almost everywhere, the purple and white-flowered varieties being grown in this province. This province also contributes armadillo skins for use as medicine in the more northerly parts of China. In the southern part of the province of Kuei-chou the proportion of land under poppy cultivation appeared to be still larger than in Se-chuen or Yun-nan, the poppy grown here being a white-flowered variety edged with pink, whilst further north the red and purple-flowered varieties become more common. Before concluding this notice mention may be made of a practice not devoid of a touch of humour. On several occasions Mr. Hosie's attention was attracted to travellers wearing official hats, which he was told indicated that they were candidates making their way northwards to attend the competitive examinations in Pekin. The statement appeared, however, inconsistent with the large quantity of luggage they carried, until the mystery was cleared up by the information that as examination candidates from the provinces travel with a pass exempting their luggage from all taxes *en route* to Pekin, such persons usually carry with them a good supply of opium and Ta-li marble, so that in the event of their being "plucked," they have some consolation in being able to return home with pockets better lined than when they set out, as the result of a little bit of smuggling.—*Pharmaceutical Journal.*

AGRICULTURAL ESSAYS.

The Committee of the Agricultural Exhibition held in Madras last February gave eight prizes for the best essays on various subjects connected with agriculture. The essays written by the prize-takers have only recently been published, with the report on the Exhibition. Dealing with them in the order in which they are printed, we find the essay by Mr. Thomas Clarke, of Teneasy, Tinnevelly, is "On the Management of Soils under Coffee, or Tea or Cinchona in this Presidency." For this Mr. Clarke received R150, and we are of opinion that the essay is cheap at the price. He refers to the advance made in scientific agriculture in other parts of the world, and points out that the cultivators of coffee have not reaped the full benefit of that advance, because working under conditions somewhat special they have not yet sufficiently tested theory by practice. The coffee planter is not possessed of the advantages secured by many other agriculturists, as the condition under which he works, to a great extent, forbids his utilising the experience accumulated in years of European agriculture. In order to remedy this state of affairs the planters should combine to ascertain, by careful experiment, the best method of applying to the cultivation of hill sides in a tropical climate the principles of scientific agriculture. A little assistance and direction from the Agricultural Department of the Government should be secured, if possible, and Mr. Clarke recommends the keeping up of an experimental field in each district, worked under a central authority, by which all results should be carefully collected and circulated. He advocates the use of artificial manures, and goes into statistics to point out the great waste of fertilizing material on a coffee estate apart from the loss in the crop taken away from the estate. He believes the great despoiler is wash, and to this cause he attributes most of the loss of the four most important elements in the production of crop. Here then, he argues, lies the whole secret of the progressive defertilization of coffee soils. "We have heard, and read, of the established principle in Europe of returning to the soil in manure the constituents removed in crop, and ignoring the different conditions, we have complacently imagined that by so doing here we were maintaining the fertility of our soil." He calculates that the waste by wash and leaf represent a loss in nitrogen alone on the coffee, tea, and cinchona plantations of this Presidency which it would take an annual expenditure of more than R28,70,000 to replace by manure. The prevention of this enormous waste should be, then, the first and most important part of any action for maintaining the fertility of land under coffee. This he contends may be accomplished by a combination of surface drains, terracing, wash-holes, and forking. He then endeavours to prove the economic value of such works by assuming what seems a maximum expenditure upon them, and balancing that against the value of the principal elements contained in any estimate of waste; "but only by actual experiments is it possible to demonstrate, first, that waste can be altogether prevented, and second, that it would pay to prevent it." As a measure of economy Mr. Clarke places weeding second only to draining. Then, as to manuring, he admits the great use of cattle manure, but points to the physical obstacle to its universal application on coffee estates in the cost involved in carrying it on coolies' heads to any distance up steep paths inaccessible to wheel traffic. Some planters forget or do not know the immense difference there is between various kinds of cattle manure; the food which the animals have been fed with is often ignored in estimating the value of manure. Mr. Clarke reproduces some figures published by the greatest authority on the subject, Sir John Lawes, who has shewn that the value of manure, from animals fed with cotton seed decoticated is worth £6-10s. per ton as compared with 4s. per ton the value of manure from animals fed with turnips. In summing up his valuable essay, the writer remarks:—

The time has come to coffee planting, as it must come to every industry, when the margin of profit allowed by the conditions of supply and demand no longer permits careless and wasteful cultivation. The planter of India has to contend with the effects of leaf-disease on his trees at the same time that over-production has reduced the price of coffee to a figure scarcely ever reached before, and he must meet the difficulty with all the resources that science can place at his disposal. No other country in the world offers the same advantages in cheap labor and suitable climate, so that if the time of depression acts as a spur to greater effort and stricter economy, we may well hope to see the industry emerge, strengthened and encouraged for a long and profitable career.

Major-General Morgan, of Ootacamund, contributed an easy on the same subject. It is brief and to the point. He says that the first thing to be done to maintain the fertility of the soil is to preserve it; in other words, to prevent the soil from being washed away. He differs from Mr. Clarke in his opinion as to terracing, and remarks that if thorough cultivation of the soil is to be carried out, terracing will not admit of it. He dismisses catchdrains as useless, and recommends shallow pits, he does not favour constant weeding—"absolutely nothing is gained by keeping the soil perfectly tree of weeds, for in wet weather you cannot kill the weeds, and in a fortnight they are as bad as ever. . . . After the monsoon sets in with violence, no mamotie should be allowed in the ground, but as soon as weeds flower they should be cut over with a grass knife and buried between the trees." As to manuring, General Morgan seems more inclined to use cattle manure than does Mr. Clarke. But he mentions ashes and poudrette, and points out the advantages to be derived by the use of latrines on the estate. In this connection we may mention for the benefit of Wynaad planters what he says of their operations:—

The sad state of Wynaad with regard to its coffee is a striking example of sterility produced by propagating from the same seed for thirty years. The trees had exhausted the soil and in turn became exhausted themselves, and from seed produced from such trees may be traced the principal cause of the ruin of coffee in Wynaad. I am aware that borer and leaf disease have mush to answer for, but the wretched stunted appearance of the trees is due to non-manuring and breeding in an in.

He recommends draining as a cure for some diseases of coffee and cinchona, and laments the wasted opportunities of many planters, who have not used the decomposed felspar which was to be found in the subsoil of their estates. His advice to pioneer planters is good:—

First secure a good climate, for torrents of rain at one time for months and dry winds for a long period are destructive to tea, coffee, and cinchona. Then see that your soil and aspect are good; the first should be a brown soil resting on a good yellow subsoil; the aspect should be north if possible. Having secured these, be careful that your seed is from strong healthy trees; this is a matter of vital importance, for the best soil treated in the most scientific manner cannot make weak trees strong, and the fault is put on the sail when it is due solely to weak trees. Assuming that the weeding, pruning, and ærating the soil are properly carried out, then apply the perfect manure and the results must be a success.

Three essays are given on the utilization of irrigation water, in view to obtaining the largest returns with the least injury to the soil and least waste of water. The first, which obtained the R200 prize. is by Mr. C. K. Subha Row, Deputy Superintendent, Madras Agricultural Department, and we are glad to find a native at the head of the essayists, for the subject is one which affects the native population far more than it does Europeans. Mr. Subha Row's essay is evidently the work of a man who has given much attention to the subject, and copious extracts from it ought to be quoted in the district *Gazettes*, and widely circulated among native agriculturists. The essentials of the system recommended are, briefly, thorough utilization of rain and promotion of the hygroscopic power of the soil; a large forest area to absorb heavy rains and secure perennial springs; storage of river and tank water; adoption of measures for checking the erosive action of rivers on their own beds, and for clearing canals and tanks of excessive silt and sand; distribution of water in measured quantities; proper application of water to the soil; selection of such crops as will, under given conditions of soil, climate, &c., produce the largest returns under the influence of irrigation; adoption of mechanical contrivances for lifting irrigation water; improvement of poor soils by the process of "warping," &c. The concluding remarks of the essayist are so valuable and outspoken that we have taken the liberty of quoting them in another column. Major Howard, R.E., of Meelut, N. W. Provinces, also contributes as essay on irrigation. First of all he describes the present method of distributing water from the canals of Northern India, and the successive steps by which that system has been developed from less perfect arrangements. Then he points out the injury which has, in some places, resulted from over-irrigation, and the measures that are being taken to remedy it. In conclusion he has alluded to the various means of preventing waste or water.

The best method of planting fuel plantations in India is a good subject for local essays, and those written by Mr. Rhodes Morgan, of Malabar, and Major-General Morgan are worthy the attention of European and native agriculturists and capitalists. The Government has spent R900 in obtaining these essays, and has had them printed in English. It now remains for it to do the most necessary part of the transaction, viz., to widely, but discriminately, distribute them throughout the Presidency.—*Madras Mail.*

CONSTITUENTS OF SOILS.

What are alkalis? Alkali is a general term. It includes all those substances which have an action like the ley of wood ashes, which is used for soap making. If this ley is boiled down dry it forms potash, as all know. Now lime, fresh slaked, has the alkaline properties of potash, but weaker, and so has the calcined magnesia of the shops, but in a less degree than lime. Here we have two substances, earthy in their look, having alkaline properties. They are called, therefore, alkaline earths. But what we understand chiefly by the term alkalis means potash, soda and ammonia. Potash is the alkali of land plants; soda is the alkali of sea plants; and ammonia is the alkali of animal substances. Potash and soda are fixed; that is, not easily raised in vapor by fire. Ammonia always exists as vapor, unless fixed by something else. Hence there is a distinction among alkalis which is easily remembered. This distinction is founded on the source from which they are procured, and upon their nature when heated. Potash is a vegetable alkali, derived from land plants; soda is a vegetable alkali, derived from sea plants; ammonia is an animal alkali, derived from animal substances. Potash and soda are fixed alkalis; ammonia is a volatile alkali. Potash makes soft soap, with grease, and soda forms hard soap. Ammonia forms neither hard nor soft; it makes, with oil, a kind of ointment, used to rub a sore throat with, under the name of volatile liniment. But though there be three alkalis, and two alkaline earths, it should on no account be forgotten that they all have common properties, called alkaline, and which will enable a person to understand their action without anything being said abou their chemistry. The property of alkalis to be especially borne in mind in connection with agriculture is their great tendency to combine with acids, and form, by that combination, what are called neutral salts.

What are acids? Acids constitute a numerous class of chemical bodies. They occur in all the kingdoms of nature. Phosphoric acid, found in bones, is of animal origin; citric (lemon) acid and oxalic (sorrel) acid are of vegetable origin; carbonic acid and sulphuric acid are very common in mineral bodies, and are produced by breathing, burning, decomposition, &c. As the word acid is, in common language, almost synonymous with sour, it might be supposed that the taste of a substance would determine whether it was included among the acids. The term has, however, been much extended by chemists beyond its original meaning, and includes bodies which are nearly, or quite, devoid of sourness, but are classed as acids because they agree with them in some other qualities. The acids are generally sour, but not universally. We have said that acids, as well as being found in the bodies of animals and plants, by living processes, are produced by burining, &c. Let us illustrate their production by burning, because this will, to a great extent, assist the explanation of the other operations. Take a lucifer match, and ignite it by friction; this sets the sulphur burning. Now, the gas arising from the burning consists of the sulphur and phosphorus united to the oxygen of the air. This compound forms two acids, sulphuric and phosphoric. Then the wood burns and its carbon, uniting also with oxygen from the air, forms carbonic acid. Thus no less than three acids, of peculiar, distinct and important properties, are formed while burning a lucifer match. The fact to be especially remembered with regard to acids is the converse of that with regard to alkalis. All acids unite or combine with the alkalis and alkaline earths, forming neutral salts; and acids also combine with the metals. Thus they are actively and constantly engaged in the vegetative processes, and possess great powers of combination.—*Leader.*

SUMATRA TOBACCO.

The Island of Sumatra is situated at the southern extreme of the Malaya Peninsula. Its productiveness, like most of the islands consisting of what is generally known as the "East Indies," is well known. However, its development as a tobacco-producing island is of recent date, and when it was first projected it was little expected that it would be imported into this country and enter successfully into competition with the domestic product. But as these importations are increasing a brief description of the mode of cultivation will not be considered out of place.

The principal owners of the plantations are Dutchmen, and the labor employed is Chinese coolies, brought to the island principally from the Malaya peninsula. The crop, according to one of these successful planters, is scarcely ever reared two years in succession on the same lands. The jungle is first cleared, and then the seed planted. After the first crop of tobacco is gathered, it is the next season used for rice, or something else, and tobacco is not planted again until the sixth or seventh year after the jungle is cleared. By adopting this method, a better result is obtained.

The drying-house is thus described by a recent visitor to the island:—

The interior is very much like a rick-yard, with tobacco stalks instead of hay-ricks, among which a perfect army of half-clad Chinese coolies, 400 strong, are hard at work sorting, ranging and stowing. So over-poweringly strong is the scent of the half-dried tobacco leaves that a smoker would have nothing to do but to take in an empty pipe with him and enjoy a good hard smoke gratis, merely by inhaling the air through it. But the Chinamen, whether habituated to it by long use, or fortified against it by the superior power of opium, breathe this perfumed atmosphere as easily as if it were the purest air of the sea. "That is how we measure the heat, you see," says our host calling our attention to the hollow bamboos thrust through the heart of each stack, with a stick inside it, which, when pulled out, is almost too hot to touch. "It must never be above or below a certain point, you know. Instead of stripping off the leaves at once, we hang up the whole plant to dry, and do not strip it till it is quite dried. The Sumatra tobacco, however, will not do for cigars. It is only used for what we call the 'deckblatt,' (cover leaf,) which covers the outside of the cigar." The coolies' quarters, which lie a little beyond the drying-shed, is exactly a reproduction of the drying-shed in the exterior of the building, but when we enter we might imagine ourselves in the midst of a military encampment. The tents are very fairly represented by two long lines of mosquito curtains, some blue and some white, while the avenue between them is straight and symmetrical enough to have pleased the eye of Wellington himself. Inside each curtain is, of course, the indispensible pipe, as well as one of those queerly painted boxes which one sees in every Chinese store from Penang to Shanghai. Right in the middle of the central avenue is a rude altar formed of two old pack'ng-cases—such as I saw last winter in a Dutch church far up the country in South Africa—decorated with "joss-sticks," colored paper and crabbed Chinese hieroglypics. But the most striking feature of the whole place is its spotless cleanliness, suggestive rather of a Dutch village in Zeeland or Overyssel than of a Dutch plantation in Sumatra. After our recent experiences of the "Chinese quarter" of Bankok and Singapore—not to mention our passing glimpse of Deli itself—it is somewhat of a novelty to find any place which is inhabited by several hundred Chinamen so clean that (as English housewives say) "you might eat your dinner off the floor." "I am always specially careful about that," said the host, "for you cannot expect men to be healthy if they don't keep themselves clean. It's one of my rules that this place shall always be kept in good order, and I hardly ever have any sickness among my men."—*American Grocer*

BEET ROOT SUGAR.—The profits in the manufacture of beet root sugar have been enormous. But there appears to be a change impending. According to *Sugar Cane*, a Frankfort paper admits that there are old established works which have been and are making their 100 per cent. Some of the new houses, however, do not clear more than 2 per cent, and things have a downward tendency at that.—*Planter and Farmer.*

IPSEA SPECIOSA.—A fine panful of this beautiful terrestrial Ceylon orchid, which has been in bloom for more than six weeks with Major Lendy, of Sunbury House, Sunbury-on-Thames, serves to remind us of its worth, and also to furnish us with the specimen from which our illustration was taken. The plant bears a dozen spikes of bright yellow flowers, with orange lines on the labellum. In habit it resembles a small Bletia. Many fail with this plant, but Major Lendy finds it very easy to grow if potted in about equal proportion of turfy loam and peat mixed with sand. His plants are placed in a light, airy part of the Cattleya-house, and are unsparingly watered while growing, and kept moist and cool while at rest.—*Gardeners' Chronicle.*

COFFEE TREE IN FRUIT AT KEW.—One of the most interesting plants now in the Palm-house at Kew—one at least which would probably attract a larger number of untravelled Englishmen than any other in that huge structure—is a fine healthy tree of Coffea arabica bearing hundreds of its large Cherry-like fruits. The plant in question is growing in the corner of a bed in the central transept, and the symmetrical habit, the dark glossy leaves, and the scarlet berries form a combination which cannot fail to please any one who has any perception of beauty in plants. When in flower the rich aromatic fragrance exhaled by the Jasmine-like flowers is very noticeable; indeed all that part of the Palm-house in which the plant is growing is suffused with the delicate and pleasing perfume. Little more than two centuries and a quarter have elapsed since Coffee was first used in Britain, and it has now become one of the most important household articles in many European countries. It is believed that Coffee was first used in Arabia about 1450, and in a century its use had spread to Egypt and other parts of the Turkish empire. For two centuries from its introduction into Arabia the use of Coffee seems to have been confined to the Mahommedan nations of Western Asia; and, considering its rapid spread and popularity among the European nations, it seems remarkable that it has not, like Tobacco, extended to the Hindus, the Hindu-Chinese, the Japanese, or the tribes of the Indian Archipelago, who no more use it than the Europeans do the Betel preparation.—*Gardeners' Chornicle.*

THE ASIATIC ELEPHANT IN FREEDOM AND CAPTIVITY.

BY G. P. SANDERSON,

Superintendent of Government Elephant-catching Operations in Bengal.

Whilst the popular interest felt in the elephant is, perhaps, greater than that attaching to any other wild animal, I think it may be safely said that regarding none, tame or wild, do more fallacious impressions exist.

The peculiar opportunities which have been afforded me during fifteen out of nearly twenty years spent in India, of observing the elephant in its wild and domesticated states—opportunities which it has been at once my duty as a public servant, and my delight as a sportsman, to make the most of—have induced me to believe that what I may be able to tell you tonight, regarding some of the most interesting features of the Asiatic elephant, may be acceptable to you, as being facts, and perhaps be of some small service to the cause of natural history. I will first commence with a few remarks on the elephant's intelligence.

The elephant's size and staid appearance, its gentleness, and the ease with which it performs various services with its trunk, have given rise to the exalted idea of its intellect that prevails among those not intimately acquainted with it. And its being but little known in Europe, whilst that is known of it justly makes it a favourite, leads to tales of its intelligence being not only welcomed with pleasure, but accepted without investigation. Many elephant stories are intended for the amusement of little folk; but in a sober inquiry into the mental capacity of the animal, they must not be accepted as facts.

The opinion is generally held by those who have had the best opportunities of observing the elephant, that the popular estimate of its intelligence is a greatly exaggerated one; that, instead of being an exceptionally wise animal, its sagacity is of a very mediocre description. The truth of this opinion no one who has lived amongst elephants can doubt. It is a significant fact that the natives of India never speak of the elephant as a peculiarly intelligent animal, and it does not figure in their ancient literature for its wisdom, as do the fox, the crow, and the monkey.

One of the strongest features in the domesticated elephant's character is its obedience. It may also be readily taught, as it has a large share of the ordinary cultivable intelligence common, in a greater or less degree, to all animals. But its reasoning faculties are undoubtedly far below those of the dog, and possibly of other animals; and it matters beyond the range of its daily experience it evinces no special discernment. Whilst fairly quick at comprehending anything sought to be taught to it, the elephant is decidedly wanting in originality. To begin with, the elephant displays less intelligence in its natural state than most wild animals.

Whole herds are driven into ill-concealed enclosures, which no other forest creatures could be got to enter; and though these enclosures are made immensely strong, and are generally capable of resisting the efforts of any single elephant, they would not for a moment withstand the combined attack of even two or three, much less of a whole herd. But elephants never thus combine to free themselves. I have frequently seen fifty or sixty crowded into a stockade only thirty yards in diameter, the palisades of which would have been of no more account than corn-stalks before the rush of three or four of them, but no such rush has been made. More significant still, I have, on several occasions, seen a single elephant in a herd, by a bold dash, burst through the palisade and effect its escape, but I never yet saw any other elephant follow, and the hunters have at once repaired the breach.

When a herd of wild elephants is secured within a stockade, or *kheddah*, the mahouts ride trained elephants amongst the wild ones without fear, though any one of the wild ones might, by a movement of its trunk, dislodge the men. This they never do. Single elephants are caught by being bound to trees by men under cover of a couple of tame elephants, the wild one being ignorant of what is going on until he finds himself secured. Escaped elephants are retaken without trouble; even experience does not bring them wisdom. Almost yearly, one or two tame elephants of the hunting establishment at Dacca are lost in the jungles by straying or other accident whilst engaged in the capture of their fellows. As an example, in December 1878, an elephant which had been captured three years, and partially trained to hunting, took fright at the fires and guns used in driving a herd and ran away. Her mahout fell off, and nothing more was seen of her until March last, when we re-captured her after four and a half years' absence, in a herd of twenty-one elephants, 100 miles from where she was lost. She had a calf at heel. When pricked with a spear and ordered to kneel, she did so promptly, and in three days she and another reclaimed runaway were employed in the capture of their fellows. While such facts testify to the docility of the elephant, they tell heavily against its intelligence.

Though possessed of a proboscis which is capable of guarding it against such dangers, the wild elephant readily falls into pits dug in its path; whilst its fellows flee in terror, making no effort to assist the fallen one, as they might easily do by kicking in the earth around the pit. It commonly happens that a young elephant falls into a pit, in which case the mother will remain until the hunters come, without doing anything to assist her offspring, not even feeding it by throwing in a few branches.

In its domesticated state one of the elephant's chief characteristics is, as before stated, its obedience; and it does many things at the slightest hint from its mahout which much impress the on-looker unacquainted with the craft of elephant-guidance. The driver's knees are placed behind an elephant's ears as he sits on it, and it is by means of a push, pressure, and other motions that his directions are communicated, as with the pressure of the leg with trained horses in a circus. It would be as reasonable, however, to credit performing dogs which spell out replies to questions with knowing what they are saying, as elephants with appreciating the objects to be gained by much which they do under the direction of their riders.

Then as to the stories regarding the elephant's reasoning powers, what an improbable one is that of the elephant and the tailor, wherein the animal on being pricked with a needle instead of being fed with sweetmeats as usual, is represented as having deliberately gone to a pond, filled its trunk with dirty water and returned and squirted it over the tailor and his work. This story accredits the elephant with appreciating the fact that throwing dirty water over his work would be the peculiar manner in which to annoy the tailor! How has he acquired the knowledge of the incongruity of the two things, dirty water and clean linen? He delights in water himself, and would, therefore, be unlikely to imagine it objectionable to another. If the elephant were possessed of the amount of discernment with which he is commonly credited, is it reasonable to suppose that he would, continue to labour for man instead of turning into the nearest jungle? We commonly use elephants to carry provisions for the hunting parties through the same forests wherein they were disporting themselves as wild animals less than a year ago. That they thus submit must be regarded as more creditable to their good dispositions than to their good sense.

All who have had to deal with elephants will agree that their good qualities cannot be exaggerated; that their vices are few, and only occur in exceptional animals; that they are neither treacherous nor retentive of an injury; and that they are obedient, gentle, and patient beyond all other domestic animals. But it is no traducement of the elephant to say that it is, in many things, a decidedly stupid animal.

Another matter upon which much misapprehension exists is the height to which elephants grow. We hear and read of Indian elephants 12, 15, even 20 feet high! As a matter of fact, 10 feet in males, and 8 feet 6 inches in females (vertical height at the shoulders, measured as a horse), is very rarely attained, and is not exceeded by one animal in 500. As bearing on this subject, I may quote the following from the "English Cyclopædia." The Mr. Corse referred to therein was a gentleman thoroughly conversant with the Indian elephant. A valuable paper of his on the subject was read before the Royal Society in 1799.

"During the war with Tippoo Sultan, of the 150 elephants under Captain Sandys, not one was 10 feet high, and only a few males 9½ feet high. Mr. Corse was very particular in ascertaining the height of the elephants used at Madras, and with the army under Marquis Cornwallis, where there were both Bengal and Ceylon elephants, and he was assured that those of Ceylon were neither higher nor superior to those of Bengal."

* * * * * * * * *

"The Madras elephants have been said to be from 17 to 20 feet high. Now let us see how dimensions shrink before the severity of measurement. Mr. Corse heard from several gentlemen who had been at Dacca that the Nabob there had an elephant 14 feet high. Mr. Corse was desirous to measure him, especially as he had seen the elephant frequently at a former time, and then supposed him to be 12 feet high. He accordingly went to Dacca. At first he sent for the mahout or driver, who, without hesitation, informed him that the elephant was from 12 to 14 cubits—that is from 15 to 18 feet high. Mr. Corse measured the elephant exactly, and was rather surprised to find that the animal did not exceed 10 feet in height."

In my own experience I have had some amusing instances of the difficulty of getting at absolute fact in this matter. I have for some years made a point of ascertaining the height of all the largest elephants I have heard of in India. Five years ago I inserted a request for information on this subject in all the chief newspapers of India. Accounts of 11 and 12 feet elephants poured in, but none stood the test of inquiry. To make it worth any one's while to establish such dimensions, I offered to give an order upon any gunmaker for the best double-barrelled rifle, and all accessories to any gentleman who could produce evidence of an elephant even 11 feet high. This was never done, and I only found one elephant above 10 feet. This magnificent elephant belongs to the Maharajah of Nahun-Sirmoor, in the Punjaub, and measures 10 feet 7½ inches in vertical height at the withers. I made a journey of 100 miles in a palanquin to measure him with my own hands. He is the only elephant over 10 feet in height that I have ever seen amongst many thousands, and he must be regarded as not less phenomenal than a human being of 8 feet.

In connection with this subject I may mention that twice round an elephant's fore-foot is his height, within an inch or two; more frequently it is exactly so. Out of many hundreds of elephants of all ages which I have measured, I have only once found the variation to be as much as five inches.

There is at present in the Indian Museum in Calcutta the skeleton of a male Indian elephant which Dr. Anderson, the Superintendent, informed me he thought must have stood about 11½ feet when alive. But this estimate is based entirely on the height of the skeleton as at present set up, which may be, and in my humble opinion is, too great. I unfortunately have not got my note-book, which contains the height of the skeleton with me in London. The elephant to which this skeleton belonged was shot whilst wild, and therefore could not have been measured when on the ground with any approach to accuracy. It was undoubtedly an exceptionally large animal, but was not over 10 feet, in my opinion, based upon the following consideration. There is now in the British Museum, in South Kensington, a skeleton which I lately brought to England of an elephant which died in June 1883, at Dacca. I measured this elephant most accurately before his death; his height was 9 ft. 10 in. at the shoulder. Now, his femur bone measures over all 3 ft. 11¾ in., and is only an inch shorter than that of the skeleton in the Indian Museum in Calcutta. This seems to me to be a reliable ground of comparison between the two, and to be fatal to the claim advanced for the Calcutta Museum elephant of being 20 inches taller than one with a femur bone only 1 inch shorter.

In June 1878 I measured the since famous African elephant, Jumbo. He was then 10 in. 5 ft. at the withers, and being about 17 years old, was still growing. I have been unable to ascertain his exact height, measured in the foregoing manner, when he left England for America in 1882. His height was then taken to the top of his back, with his fore and hind feet brought near together. This would tend to arch his back very considerably. He measured 11 ft. 6 in. in this way; but as his forefoot planted firmly on the ground measured 5 ft. 6 in., his height at withers was probably about 11 ft. According to Sir Samuel Baker who has seen large numbers of both Asiatic and African elephants in their native wilds, the Africans, male and female, average about one foot higher than the Asiatic. The case of Jumbo appears to confirm this to a great extent as regards male elephants; but I have never seen African females even as large as Asiatic females. Of course in captivity we do not see one African to 1,000 Asiatics (taking India into account), so the comparison is unfavourable to the Africans.

Much misapprehension prevails regarding the uses and powers of the elephant's trunk. This organ is chiefly used by the animal to procure its food, and to convey it and water to its mouth; also to warn it of danger by the senses of smell and touch. It is a delicate and sensitive organ, and is never used for rough work. In any dangerous situation the elephant at once guards it by curling it up. The idea that he can use it for any purpose from picking up a needle to dragging a piece of ordnance from a bog is, like many others connected with the elephant, founded entirely upon imagination. An elephant might manage the former feat, though I doubt it (I have never seen elephants raise coins and such small articles otherwise than by suction); the latter he would not attempt. Elephants engaged in such work as dragging timber invariably take the rope between their teeth; they never attempt to pull a heavy weight with the trunk. An elephant is powerful enough to extricate a cannon from a difficult situation, but he does it by pushing with his head or feet, or in harness, never by lifting or drawing with the trunk. Elephants do not push with the forehead or region above the eyes, but with the base of the trunk or snout about one foot below the eyes.

I may here mention that I have seen many instances of very severe injury to their trunks amongst wild elephants. These were evidently caused by the sharp edges of split bamboos whilst the animals were feeding. Some have had from a few inches to a foot of the member totally useless, merely hanging by a little muscle, both nostrils having been cut through.

The age to which the elephant lives is, as must ever be the case with denizens of the forest, uncertain. The general native opinion is that they attain 120 years in exceptional cases (they have been known to reach this age in captivity), but more usually to 80 years. Under the more favourable conditions of a natural life the elephant must attain a much grearer age than in captivity. I think it by no means improbable, looking to their peculiar dentition and other circumstances, that elephants live to 150 or 200 years, but this view is, of course, to a great extent a supposition.

One of the most remarkable facts in connection with wild elephants is the extreme rarity of any remains of dead ones being found in the jungles. This circumstance is so marked as to have given rise to the belief amongst some wild tribes that wild elephants never die; whilst others believe that there is a place, unseen by human eye, to which they retire to end their days. The latter belief is untenable, as there are no parts of the forests of India that are not well known to, and occasionally visited by, the wild tribes who inhabit them.

In my own wanderings for many years through elephant jungles I have only seen the remains of one female elephant that had died in giving birth to a calf, and of one elephant drowned in a mountain torrent. Not only have I never seen the remains of an elephant that had died a natural death, but I never met anyone amongst the jungle tribes or professional elephant hunters who had.

Sir Emerson Tennent says in his work on Ceylon:—"The natives generally assert that the body of a dead elephant is seldom or never to be discovered in the woods. And certain it is that frequenters of the forest with whom I have conversed, whether Europeans or Sinhalese, are consistent in their assurances that they have never found the remains of one elephant that had died a natural death. A European gentleman, who for 36 years without intermission had been living in the jungle, ascending to the summits of mountains in the prosecution of trigonometrical surveys, and penetrating the valleys in tracing roads and opening means of communication—one, too, who had made the habits of wild elephants a subject of constant observation and study—has often expressed to me his astonishment that, after seeing many thousands of living elephants in all possible situations, he had never yet found a single skeleton of a dead one, except those which had fallen by the rifle. The Singhalese have a superstition in relation to the close of life in the elephant; they believe that, on feeling the approach of dissolution, he repairs to a solitary valley, and here resigns himself to death."

This quotation from Sir Emerson Tennent shows the similarity of opinion between the natives of Ceylon and of India. But the belief of a universal sepulchre is untenable on many grounds. It may be believed that, in annually capturing large numbers of elephants, the hunters of the Dacca establishment penetrate the most retired parts of the jungles of Assam, Chittagong, and elsewhere; but though many men have grown grey in the service, I have not met one who has seen a dead elephant's remains, except at a time when an epidemic disease decimated the herds in Chittagong. Jungle fires seldom penetrate the large forests; thus their bones cannot be burned. Monsoon rains do not destroy them for some years, as is proved by the bones of elephants that have been shot, and which may be seen many years later. It may be thought that aged, weak elephants are sometimes unable to extricate themselves from morasses or the soft beds of rivers where they go to take their last drink, and that their remains are swallowed up therein. This possibly may occur occasionally, but there are many elephant jungles where no quicksands or bogs exist. In Mysore, for instance, a province where wild elephants abound, and which I know intimately, the jungle streams are small, and their beds are uniformly rocky. If elephants died in these, their bodies would be floated down through inhabited country where they could not escape observation. But this has never, to my knowledge, occurred. It is probable that the longevity of elephants may account to a great extent for their remains rarely being seen. If elephants live for 200 years, the annual deaths from natural causes would only amount to 5 per 1,000. This figure would, no doubt, be exceeded in reality, as elephants are liable to be killed by each other, and to die by various accidents. Though the number that die annually is thus, probably, much less than might be supposed, the mystery of what becomes of the remains of those that do die is still entirely unexplained.

Herds of elephants usually consist of from 30 to 50 individuals, but much larger numbers, even upwards of 100, are by no means uncommon. A herd is alway led by a female, never by a male. In localities where fodder is scarce, a large herd usually divides into parties of from 10 to 20. These remain at some little distance from each other, but all take part in any common movement, such as a march into another tract of forest. These separate parties are family groups, consisting of old elephants with their children and grand-children. It thus happens that, though the gregarious instincts of elephants prompt them to from large gatherings, if circumstances necessitate it a herd breaks up under several leaders. Cases frequently occur when they are being hunted; each party will then take measures for its individual safety. It cannot be said that a large herd has any supreme leader. Tuskers never interest themselves in the movement of their herds; they wander much alone, either to visit cultivation where the females, encumbered with young ones, hesitate to follow, or from a love of solitude. Single elephants found wandering in the forests are usually young males, animals debarred from much intimate association with the herds by stronger rivals; but they usually keep within a few miles of their companions. These wandering tuskers are only biding their time until they are able to meet all comers in a herd. The necessity for the females regulating the movements of a herd is evident, as they must accomodate the length and time of their marches, and the localities in which they rest and feed at different hours, to the requirements of their young ones.

Elephant calves usually stand exactly 36 in. at the shoulder when born, and weigh about 200 lb. They live entirely upon milk for five or six months, when they begin to eat tender grass. Their chief support, however, is still milk for some months. I have known three cases of elephants having two calves at a birth. It cannot be said that the female elephant evinces any special attachment to her offspring, whilst the belief that all the females of a herd show affection for each other's calves is certainly erroneous; were such the case it would preclude the belief in any marked love for her own young. During the catching of elephants many cases occur in which young ones, after losing their mothers by death or separation, are refused assistance by the other females, and are buffeted about as outcasts. When a calf is born, the mother and the herd usually remain in that place for two days. The calf is then capable of marching. Even at this tender age calves are no encumbrance to the herd's movement; the youngest climb hills, and cross rivers, assisted by their dams. In swimming, very young calves are supported by their mother's trunks, and are held in front of them. When they are a few months old, they scramble on to their mother's shoulders, and hold on with their forelegs, or they swim alone. Though a few calves are born at other seasons, the largest number make their appearance in September, October, and November.

The elephant is full grown, but is not fully mature, at about 25 years of age. At this period it may be compared to a human being of 18; and it does not attain its full strength and vigour before 35 years. Female elephants give birth to their first calf at from 13 to 16 years of age, when they are still palpably immature themselves. Only the male Indian elephant has tusks; the female is provided with short tushes, or downward prongs, in the upper jaw; they are seldom more than 4 in. in length. On the continent of India, *mucknas*, or male elephants without tusks, are decidedly rare. The absence of tusks appears to be a merely accidental circumstance. But in Ceylon male elephants with tusks are still more uncommon. Sir Samuel Baker says that not more than one in 300 is provided with them. It is difficult to imagine what can cause the vital difference of tusks and no tusks between the elephants of the continent and of Ceylon, as they are of the same species, and the climate and their food may be said to be identical. Elephants occasionally lose one, sometimes both tusks, in accidents in the jungle, and some have only one tusk from birth. The latter are known as *gunéshas*, and are reverenced by Hindoos if the tusk retained be the right hand one. Elephants never shed their tusks. Jerdon and others, following Mr. Corse, are undoubtedly in error in saying this occurs between the first and second years of the young elephant's existence or at any other time. The skulls of fœtal elephants exhibit milk tusks, but these never make their appearance; they are absorbed, and the tusk that cuts the gum is the permanent one. Nor are tusks lost by accident ever renewed.

The records of many hundreds of elephants, captured by the Dacca establishment, show that there are about 43 male elephants to 100 females; and one *muckna*, or tuskless male, in every 10 males.

Elephants are exceedingly inoffensive and retiring in their habits. They are very timid in their wild state, and withdraw at once from the intrusion of man. They usually drink after sunrise and before sunset. They prefer the water of the small tributary streams to that of the larger rivers of the jungles they are inhabiting; for what reason I have never been able to ascertain. Elephants seldom bathe after the sun is down, except in very warm weather. They swim remarkably well, as is proved by the fact that large numbers are annually sent across the tideway of the combined Ganges and Bramhapootra, between Dacca and Barrackpore, and they are sometimes six consecutive hours without touching bottom. I have seen an elephant swim a river 300 yards wide with his hind legs tied together. Elephants are sometimes drowned, apparently by being attacked with cramp or by a fit.

The only pace of the elephant is the walk, capable of being increased to a fast shuffle of about fifteen miles an hour for a very short distance. The elephant can neither, trot, canter, or gallop, nor can it make the smallest spring either in vertical height or in horizontal distance. A trench 8 ft. wide and 8 ft. deep is quite impassable to an elephant.

It has been satisfactorily settled that there is no such creature as a really white elephant, the so-called albinoes of the Kings of Burmah and Siam being merely elephants of a somewhat dirty cream colour, and in some cases even elephants with only an unusual amount of the flesh-coloured blotchings on the face, ears, and neck, common in some degree to all elephants. I need not advert here to Mr. Barnum's so-called white elephant further than to say that he is the commonest of common elephants, to be seen every day in India, and does not possess a single peculiarity of any description to justify the statements regarding his colour and special character, which preceded and even followed his arrival in England.

I will now pass to the modes of capturing and training the elephant. Elephants are not bred in captivity in India, as by the time the young ones would be of a useful age, 15 years, they would have cost more than would suffice to capture a number of mature wild ones. Elephants are, however, bred extensively in a semi-wild state in Burmah and in Siam, where fodder is very plentiful. With the exception of such elephants as come from Bürmah, almost every elephant seen in India has been wild at one time.

The following are the methods of taking wild elephants. For single elephants, pit-falls; running down and noosing from trained elephants' backs; or tying the animal's legs together under cover of trained females, usually called decoys. When a whole herd is the object of pursuit, a salt-lick, or sometimes a pool in the jungles, is surrounded by a stockade. Men are constantly on the watch, and the gate is closed when a herd has entered. But the most certain plan is that followed by Government, namely, the surrounding a herd, wherever found in the forest, by a large circle of men, and the building a stockade, into which it is driven. This method will be described further on. With regard to the other plans mentioned, the pit-fall is an old native method, and is now prohibited in British territory on account of its cruelty. It may be imagined that an immense majority of the elephants that fell into pits from 15 to 18 feet deep sustained permanent injury, if they were not killed outright, as often happened. The native hunters seldom took the trouble to put boughs into the pits to break the force of an elephant's fall. If an elephant was seen to be injured, it was left to die as it fell. I have known four elephants to fall into the same pit together, one only of which was got out alive.

The pits were arranged with great ingenuity by the hunters. Sometimes an uncovered one would be left in view, in avoiding which an elephant fell into a covered one alongside. Or several were dug in close proximity, in which others might be taken when fleeing in terror upon the fall of one of their number. Through the carelessness of the hunters, who only visited the pits occasionally, elephants were frequently starved to death before they were discovered.

The plan of enclosing elephants in salt-licks, or places to which elephants, in common with all wild elephants, resort at certain seasons to eat the earth impregnated with soda, used formerly to be much in vogue in Assam. It also led to much cruelty. Natives could seldom procure a sufficient number of tame elephants to deal with a large herd, should one be enclosed; and in former days scores of elephants died in enclosures from want of food during the delay that occurred in sending for tame elephants. Several of these salt-licks are perfect Golgothas to this day. Such reckless waste of elephant life has now, however, been put a stop to.

Running elephants down and noosing them from the backs of tame elephants is very rough and dangerous, but highly exciting, sport. It is far from an economical method of taking them, as the wear and tear of the tame elephants is very great. It is conducted as follows:—Three or four fast tame elephants are equipped with a rope each, at one end of which there is a noose, the other being secured round their bodies. On some, the noose is on the near side, on others, the off. Each elephant has three riders—the mahout on its neck to guide it; the nooser, kneeling on a small pad on its back, holding the noose in his hands; and a spare man seated behind, whose duty it is to hammer it unmercifully with a spiked mallet. This urges an elephant to a much greater pace than any use of the driver's goad will, though that inducement is by no means omitted.

Thus equipped, the elephants approach a herd of wild ones. Sometimes a musket is fired to terrify them, and the chase commences through or over everything, the men saving themselves from being swept off as best they can. Where the ground is favourable, the tame elephants endeavour to range up on opposite sides of a fleeing wild one, of moderate size and strength, when the nooses are cast, and generally encircle its neck. If this is effected the tame elephants are checked; but the choking of the wild one or fatal accidents to the tame ones or their riders by being pulled over, or dragged into ravines, or by being attacked by other elephants, are not unusual accompaniments to this rough work.

Hand-noosing is practised only in Ceylon, where several hunters on foot manage, with wonderful skill and activity, to noose the hind legs of an elephant when running away, and to secure the trailing ends of the ropes to trees as it passes.

The largest male elephants cannot be captured by the above plans; and from their habit of frequently absenting themselves from their companions, they are seldom caught with the herd by the stockade or kheddah plan. They are the most valuable beasts, and are easily caught in the following manner, or some modification of it. Four or five steady females, ridden by their mahouts, who partly conceal themselves with a dark-coloured blanket as they lie on their elephants' necks, are taken to the jungle where the solitary male is known to be, and are there allowed to graze like wild ones, and gradually to approach the male, if he does not take the initiative. Some wild males make off at once, probably scenting the riders, but many abandon themselves without reserve to the society of the females. These keep in constant attendance on the male, sometimes for two days and nights. When the male seems inclined to sleep soundly, usually soon after sunrise, the females stand close around him, and a couple of mahouts on foot tie his hind legs together, and bind him to a tree if one be near; or they withdraw the tame elephants, and after the male has tired himself out, by dragging his legs after him in his flight, he is fastened to some tree as he passes it. In a day or two cables are got round his neck, and he is marched off.

I may here say that the term decoy, often used in reference to elephants engaged in the capture of others, is entirely misleading, as they use no arts to divert the wild one's attention, as has been constantly asserted, but act entirely at the command of their riders. The statement that one elephant will assist in binding another, except in as far as it will hand up the end of a rope, or pull one when ordered to do so, is entirely incorrect.

The Government kheddah plan is the most certain and economical method of taking wild elephants. As many as 118 have been secured in one drive by this means. A Government hunting party consists of 370 men trained to the work. They are generally from Chittagong, the natives of that district being unrivalled in the craft. There is a large surplus labouring population in Chittagong, and there is no difficulty in raising one or two kheddah parties during December, January, and February, when there are no agricultural operations on hand. The men receive two and a half months' pay at R7 (or about 15s.) per mensem, and they also have free rations.

A kheddah party of 370 men having been collected, it marches to the hunting grounds, sometimes 200 miles distant, where a base camp is ready, and where the establishment of tame elephants, generally from 100 to 150, has been collected, together with the stores, tools, and ropes required for the operations. Muskets and rations having been delivered to the men, and religious ceremonies for success having been performed, the hunters enter the jungle. The trackers of the party have probably already marked down a herd, whereupon the hunters approach to within a mile, and then divide under two experienced leaders, one half filing off to the right, and the other to the left, their object being to enclose the herd in a large circle by meeting beyond it. A man is left at every 30 yards or so along the lines, according to the nature of the ground. The skill with which this movement is effected is very remarkable, as the ground is usually quite unknown to the hunters, and the difficulty of crossing streams and hills, of forcing their way through dense jungle where no path exists, and of gaining the point they are making for without a compass, is considerable.

The circle, when completed, is often five or six miles in circumference. A large one, with men posted fifty yards apart or so, is more efficient in keeping in a herd than a smaller one with men much closer. Unles plenty of room be allowed to the elephants, they are liable to break through the cordon of guards; but it is a maxim in elephant catching that, the circle having once been formed, a herd can only escape through accident or great carelessness. It usually takes three or four hours to surround elephants. In a couple of hours the hunters run up a thin fence of split bamboos round the enclosure, and clear a path for communication between each others posts. Their chief duty then is to see that the elephants do no break out of the circle. The animals seldom give trouble during the day; at night large fires are kept up, and shouts and shots are used to drive them back should they approach. The bamboo fencing serves to show the chief hunters, who patrol the circle at intervals, where the elephants have broken out should they escape, so that the particular men who are to blame can be detected. This investment of the elephants may have to be maintained for a week, sometimes for a month, if the elephants cannot be secured in the first attempts.

The elephants usually give some little trouble for the first two nights, but their conservative nature then seems to lead them to believe that there are set bounds to their wanderings; and unless fodder or water becomes scarce, they seldom try to force the guards. A small herd always gives more trouble than a large one. The former may only be a wandering party from some large body of elephants not far away; it then shows a strong desire to break through to join its companions. A small herd, too, probably has no calves with it, which is a great disadvantage, as it is then restless and quick in its movements. And a herd of a dozen elephants or so may be well in command of one courageous leader; whereas, in a large gathering, timid animals preponderate so greatly that a panic is easily established, and elephants that might otherwise behave boldly become infected with the general fear.

One or two of the males of a herd frequently pass in and out of the circle; and I have known several cases in which a portion of a herd has been absent when their companions were surrounded, and has been admitted by the guards by withdrawing at the point where it wished to pass in. Sometimes, but not often, men are killed at their posts by the elephants.

On the day following the investment of the herd, the construction of the kheddah, or small enclosure into which the elephants are to be driven, is commenced. It is situated on one of their chief paths (within the circle) and is constructed with the trunks of young trees, about 6 inches in diameter, and 12 ft. high, arranged in a circle of from 20 to 50 yards across. Inside, round the foot of the palisades, a trench 6 ft. wide and 4 ft. deep is dug, the earth from this being thrown up into a bank on the inner side. The trench and bank of loose earth usually deter elephants from attacking the stockade, or should they do so, prevent their employing their full force against it. The palisades are lashed together with canes, and are strongly supported by cross beams and forked supports behind, the whole structure being designed to support outward pressure only. Were elephants to pull the palisades inwards, they would yields at once, but they never use their trunks for this purpose. An entrance of 4 yards in width is left for the ingress of the herd, and a gate, studded inside with sharp spikes, is either slung from the trees overhead, or is made in two leaves, and is pushed to upon the entrance of the herd by men stationed behind it.

A stockade of 40 yards in diameter accommodates 100 elephants easily. To guide the elephants into it, two lines of strong palisades are run out from the gate along each side of the path by which the herd is to approach. These guiding wings diverge to perhaps 60 yards across at their commencement, which may be 100 yards or so from the gate. When the whole is completed, the new woodwork is hidden with leaves and branches. The stockade is usually completed in three or four days. The hunters consider Friday the most lucky day for driving, and they make extraordinary efforts to get the stockade ready by that day if possible. The work of the stockade is done by one-half the hunters being taken from the large circle from morning till evening daily, as a weak cordon of guards suffices to keep the elephants in during the day.

All being in readiness for driving, a number of men are taken from the original circle, and a smaller interior surround is formed by commencing at the guiding wings of the kheddah, and posting the men until the elephants are again closed. The original circle is, of course, still maintained, in case of the elephants breaking through the inner one. If the herd be in two or three detachments, as frequently happens, these are quietly driven together, and the whole are then moved forward towards the kheddah. Should they show an inclination to break to the right or left, the men deter them by striking their axes against the trees. When the elephants gain the funnel-shaped approach to the stockade, the men close in from behind, and from the sides, and urge them on with shots and shouts. If the herd suspects danger, and breaks back through the beaters, fatal accidents not uncommonly occur. Sometimes a herd declines altogether to go in the direction of the stockade, owing to their having the wind from that quarter. In such a case a new stockade may have to be constructed, and if that does not succeed, others also. In this way elephants are sometimes kept in a surround for a month.

Supposing the herd to have been got within the wings near the gate, a line of dry grass and bamboos arranged beforehand is fired, and their retreat is cut off. They then sometimes attack the guiding palisades, but men with spears and muskets receive them here. I have seen two cases in which the elephants forced the palisades, and killed men behind them. Tame elephants are used, if possible, to assist at this stage of driving, chiefly as a protection to the men on foot, who run behind them should any elephant turn and charge. There is much less danger of this occurring in dealing with large herds than with small ones, as should a single elephant charge out of a large herd, it is rarely supported, and it quickly rejoins its companions. But a determined leader of a handful of elephants is liable to be followed at once by the rest. When an elephant chases the men, they betake themselves to the shelter of tree trunks, bamboo clumps, or long grass, and it is astonishing how they frequently escape uninjured. I have known many cases of men standing against a tree, or hiding in tufts of long grass, within a couple of yards of elephants that were pausing in indecision, without being discovered, though the elephants were evidently aware of their close proximity, as they kicked up the ground in anger, and then made off. In such cases the slightest movement would have led to the hunters being instantly trampled to death. Men are frequently killed, of course, but they are almost always young hands who are learning. I saw one such make a narrow escape a few years ago; he ran from an elephant and climbed a tree; the elephant butted the trunk, and the man fell down, but his pursuer was so astonished at the sight that she fled at once.

Sometimes drives are conducted by torchlight, and these seldom fail, owing to the elephant's fear of fire. The scenes on these occasions are exciting beyond description. The elephants in rushing along tear down large branches of trees that are connected with the undergrowth by climbing-plants, and even sometimes upset dry trees bodily in their passage. The cries of the young, and the deep, thunder-like growls of the elders of the herd, the continued crashing of the jungle, and the shots and incessant cries of the men, form, with the unnatural light of the fires and of torches moving through the forest paths, a scene that cannot fade from the memory of anyone who has witnessed it.

When a herd has been driven into the stockade, the gate is closed and barricaded, and men with firebrands and spears repel any attacks upon it or the palisades. But the trench is usually sufficient to deter the elephants from crossing it. On the same or following day, ten or twelve tame elephants are admitted with a mahout and rope-tier upon each, and it is a very remarkable fact that the wild ones very rarely attempt to dislodge the riders, as they easily might. They naturally fail to comprehend anything so foreign to their experience as a man upon an elephant's back. I never knew a case, except one that happened to myself, of any rider being attacked by a wild elephant. The mahouts separate the wild elephants one by one from their companions, when their hind legs are tied by men who slip to the ground for the purpose. A rope is then secured round each captive's neck, and to its hind legs, and it is led out and picketed in the forest near.

If two well matched rival tuskers happen to be impounded in one stockade, they sometimes fight to the death, seemingly regardless of their novel position. If not well matched, the more powerful one bullies the weaker one incessantly. On one occasion, when a herd of forty-eight elephants had been impounded, a scene of this kind occurred, one elephant following and fighting with another almost continuously for two days and nights. The smaller elephant retaliated on others weaker than himself, and between them the pair killed four young elephants and a large *muckna*. They caused such commotion that the tame elephants could not be admitted. At last the larger tusker forced the smaller one across the trench, and against the palisades. The latter commenced to break his way out; and though muskets were fired into his face, and spears and digging tools made red-hot for the occasion, were applied to his trunk and head, the inducement behind was so strong that the counter efforts of the men were un-availing, and he made his way through the palisade, and went off into the jungle. This was at 2 a.m., and was a sufficiently exciting scene. No other elephants attempted to follow, and the gap was quickly repaired.

Amongst these forty-eight elephants was one that had escaped about twelve years ago. judging from the ages of her three calves. We first observed the fact of her being an escaped elephant by seeing old rope marks on her legs. When the tame elephants entered the stockade, two ranged alongside this one, and on being pricked with a spear, and told to kneel, she obeyed at once. She was ridden alone a few days afterwards.

The number of wild elephants that can be taken care of is, at the most, 50 per cent more than the tame ones. As each capture is concluded, the wild elephants are marched out of the jungle into open country, for if kept in the forest they continue to be excited by jungle sights and sounds, and to struggle for liberty, whilst flies are much more troublesome to their wounds in the jungle than in the plains. Each batch of new elephants requires a number of tame ones to be detached in charge of it; thus the hunting operations are limited by the number of the latter.

When a sufficient number of elephants has been taken, the hunters are dismissed, and all elephants under 7 ft. in height are sold to merchants who follow the kheddah parties for the purpose of purchasing such. Those above 7 ft. are retained for Government service, except some males and old females which are also disposed of. Not more than 30 per cent of the elephants captured are young and strong females, thoroughly suitable for Government service. The selected wild elephants are now divided into gangs of twenties, with a proportion of tame ones in charge. These escort the wild ones, bring their fodder, and lead them to water daily. The march from the jungle commences about the end of February, and the elephants reach the depôt at Dacca in May. They are then put into training, and by November are quite steady, and are drafted for military service.

New elephants are trained as follows:—They are first tied between two trees, and are rubbed down by a number of men with long bamboos, to an accompaniment of the most extravagant eulogies of the animal, sung and shouted at it at the top of their voices. The animal, of course, lashes out furiously at first; but in a few days it ceases to act on the offensive, or, as native say, "*Shurum lugta hai*," "It becomes ashamed of itself," and it then stands with its trunk curled up, shrinking from the men. Ropes are now tied round its body, and it is mounted at its picket for several days. It is then taken out for exercise, secured between two tame elephants. The ropes still remain round its body to enable the mahout to hold on should the elephant try to shake him off. A man precedes it with a spear to teach it to halt when ordered to do so; whilst as the tame elephants wheel to the right or left the mahout presses its neck with his knees, and taps it on the head with a small stick. to train it to turn in the required direction. To teach an elephant to kneel, it is taken into water five feet deep when the sun is hot, and upon being pricked on the back with a pointed stick it soon lies down, partly to avoid the pain, partly from inclination for a bath. By taking it into shallow water daily, it is soon taught to kneel even on land.

Elephants are taught to pick up anything from the ground by a rope. with a piece of wood attached, being dangled over their foreheads, near to the ground. The wood strikes against their trunk and forefeet. and to avoid the discomfort the elephant soon takes it in his trunk, and carries it. It eventually learns to do this without a rope being attached to the object.

I have only time to add a few facts regarding the financial results of elephant catching by the Government establishment at Dacca. Referring only to the official year ended 31st March, 1883, the expenditure upon the hunting establishment for twelve months was* £12,948, and the receipts by surplus elephants sold, and the value of those retained, £19,492, showing a profit of £6,544. Of this amount, £4,000 was surplus from the preceding year.

During the past five years the annual average number of elephants captured during our short working season, from December to February, has been 151. The greatest number in any single year was 252 in seven weeks in 1882, and 199 in a similar period in 1883. A ready sale is effected amongst the native landowners, and others who are fond of keeping elephants, of all those not required by Government.

The belief that wild elephants have decreased in India is not an uncommon one. and may have arisen from the fact of laws having been passed in late years for their protection. Also, from their undoubted decrease some years ago in Ceylon. But the case of that island is not analogous to that of the continent. In Ceylon, elephants have always been made a peculiar object of pursuit by large numbers of sportsmen, and by paid native hunters, whilst their range is not without its limits. To show the numbers that have been destroyed there, I may quote the official statistics between 1845 and 1859, which show that during those fifteen years rewards were paid for 5,194 elephants killed in, I believe, only a part of the island. Similar destruction has gone on for years, until rewards were abolished some years ago. But elephants are again becoming numerous, and are again allowed to be shot.

But on the Continent of India the number shot py European sportsmen has always been small, and it was only for a few years that natives were induced to turn their attention to killing them by a reward given for their destruction in the Madras Presidency. This was soon withdrawn, and the representations of humane officials having further led to the curtailment of the wasteful methods of trapping them practised by native hunters, the wild elephant now enjoys perfect immunity throughout the Western Ghats, and those boundless forests extending for hundreds of miles along the foot of the Himalayas into Burmah and Siam. The number annually caught by the Government hunting establishment at Dacca (the only one at present in India), and by licensed native hunters, is, comparatively speaking, very small; and there is no doubt that all the forest ground that can be legitimately allowed to the wild elephant is as fully occupied at present as is desirable. The elephant-catching records of the past fifty years attest the fact that there is no diminution in the numbers now obtained in Bengal, whilst in Southern India elephants have become so numerous of late years that they are annually appearing in places where they had never been heard of before.

In the Billigarungun Hills, an isolated range of 300 square miles on the borders of Mysore, wild elephants first made their appearance about the beginning of this century, having strayed from the forests at the foot of the Neilgherry range, across an intervening strip of some thirty miles of civilised country. Prior to that time the Sholagas, a wild tribe that inhabit the Billigarungun hills, but which has now dwindled down to a handful of savages, were a numerous people; traces of their former extensive cultivation, even of orange groves, gardens, and iron-smelting furnaces, still exist, together with lakes on the summit of the hills, for the convenience of the cattle which used to be driven thither from the neighbouring low country for pasturage during the hot weather. The Sholagas were almost destroyed by three successive visitations of small-pox, a disease which is always exceeding fatal amongst hill people in India; their lands relapsed into the densest forest; and wild elephants and bison now abound where probably not one was to be found a century ago. The case of these hills is an interesting instance of a large tract of country in India having relapsed into a wilderness in recent times.

To give an idea of the numbers of wild elephants in some forests, I may say that during the past five years, between 1878 and 1883, 1,066 wild elephants have been captured by the Dacca hunting establishment in a tract of country about fifty miles long by twenty miles broad, in the Garo-hills in Assam, whilst fully as many more were met with during the hunting operations. Of course these elephants do not confine themselves to that tract alone, but wander into other parts of the hills. There are immense tracts of forest in India similarly well-stocked with wild elephants.

I am sure it will be regarded as a matter for hearty congratulation by all, that so grand, interesting, useful, and harmless an animal as is the elephant is in no danger of becoming extinct in India. Though small portions of its haunts have been cleared for tea or coffee cultivation, the present forest area of the country will, probably, never be practically reduced, for reasons connected with the

* Taking the rupee at 2s. for convenience.

timber supply and climate; and as long as its haunts remain, the elephant must flourish under due regulations for its protection.

DISCUSSION.

Mr. A. D. Bartlett said he had had many years' experience of elephants, but only amongst those in captivity. He had had to do with probably the largest one ever seen in Europe, viz., Jumbo. When he came to the Zoological Gardens he was about four feet high, and weighed 700 lb; at first he was troublesome, but after a very short time became perfectly manageable, and grew very rapidly. This was to be attributed to his good living, and his constant bath in warm weather; in seventeen years he had grown from four feet to eleven feet in heigh. During the last few years of his stay he began to display, during a certain period of the year, a very troublesome disposition, and terrified every one who came near him, except his keeper, Scott, who had extraordinary control over him. Scott was a very curious man himself, and it was with the greatest difficulty he could be induced to allow another man to assist him in the management of the huge animal. But it was feared that on some occasion, if Scott fell ill, or were injured by the elephant, he would be entirely unmanageable, for no other man dared go near him in his house, though when out at exercise he was perfectly quiet. At night, however, he used to tear about, and almost shake the house down, and became such a source of trouble that the Council decided to part with him. He was glad to say that he had recently heard from Mr. Barnum that Jumbo had increased one ton in weight, and was the father of two little infants, and he believed it was Mr. Barnum's intention to send over here a female elephant which was expected to give birth to another descendant of Jumbo's in November next.

Admiral Ryder asked if Mr. Sanderson could give any information with regard to the worship of elephants in Siam.

Mr. Wedderburn Maxwell was very glad to hear that the cruel system of taking elephants in pits was condemned, and hoped it would be put an end to throughout India. Having lived in a district adjoining the scene of Mr. Sanderson's operations, he could confirm all he had said, and thanked him for the very graphic and accurate description he had given of the mode of capture.

Dr. Garson asked if some further information could be given as to the length and weight of the tusks.

Mr. Martin Wood said Mr. Sanderson had assured them that the number of elephants in India was not likely to decrease; but they all knew that in Africa the animal was being mercilessly destroyed, and he should like to ask if any means could be suggested by which the pitiless warfare against this noble beast could be checked.

Mr. Christy said this last point was of great importance. He frequently had inquiries from Africa whether it was possible to organise a body of retired officers, or others, who would go to Africa and assist the planters and Europeans there in devising some means of capturing and taming elephants. They had even gone so far as to authorise the purchase of some Indian elephants for the purpose, if necessary, but up to the present he had not heard of any practical measures being taken, though the matter had been much discussed in the *Field* and other papers.

Mr. Klenck was sorry to hear that there was so much sacrifice of human life in the capturing of elephants. He would also emphasise the remark of a speaker with regard to the cruelty of catching elephants in pitfalls.

Mr. Andrew Cassels thought most persons present were afraid to expose their ignorance on this subject, by making any remarks in the presence of two such authorities as the Chairman and Mr. Sanderson; but he must say that one of his illusions had been removed that evening, for up to then he had always looked upon the elephant as a very sagacious animal.

The Chairman said this was a subject on which he could talk for a long time, though he certainly could not claim to be an authority, and knew very little compared to Mr. Sanderson. As he had listened to the graphic description of the elephants rushing through the primeval forests in the sub-Himalayan districts, he could not help his thoughts reverting from those regions to the valley of the Thames in the time long past, when the very ground upon which they were then met was the *habitat* of elephants far larger than any of those whose dimensions Mr. Sanderson very rightly expressed such doubts about. Most people knew that the Thames valley was, at one time, the habitation of probably two species of elephants, whose remains were constantly dug up in the marshes. Only so recently as 1846, one of those enormous creatures, the *elephas primigenius*, which was by some supposed to be the ancestor of the modern elephant, was turned up in Siberia, by the action of the water, in a good state of preservation. He was 13 ft. in height and 15 ft. in length, with enormous tusks, and covered with a long coating of hair, with a thick matting of wool underneath, showing him to be adapted to a cold climate. The African and Indian elephants were the only remaining examples of a great race which had passed away, though the remains of eight or ten different forms were still occasionally found in certain parts of India, showing clearly marked resemblances to the present type. A question had been asked about the African elephant and its capabilities of domestication, and if anything could be done to stop its wholesale destruction. It would be very difficult to suggest anything in that direction; but he might say that, some years ago, the idea did occur to him and others that these animals might be caught and utilised, and he suggested then that Mr. Sanderson should be asked to go from India with a select number of men trained by himself in elephant catching, taking a certain number of elephants with them, and there set up an elephant catching establishment. Had that been done, he felt convinced that long ere this there would have been a number of useful working elephants in Africa. The African elephant was just as capable ot being tamed and trained as the Indian, though there were certain differences between them which might be of some practical importance. For instance, he did not know how a mahout could sit on the neck of an African elephant, on account of the immense size of its ears, but there might be other means of driving it. It was quite ascertained, however, that the African elephant was as docile, intelligent, and as capable ot doing good work as the Indian, and there was no reason why he should not be utilised in the same way. There was very little doubt that the elephants mentioned in the classic authors, as being employed in the Punic and other wars of Hannibal, and those slaughtered in the amphitheatres at Rome, were of the African species, as was shown by medals and drawings, though these were not always perhaps perfectly reliable in details, such as in the size of the ears and shape of the cranium. He hoped the suggestion made, some years ago, by Mr. Sclater and others, as well as by himself, would eventually bear fruit. Certainly such a scheme could be placed in no better hands than those of Mr. Sanderson, for there was no one living who knew more about elephants; and, if a mission of this kind were entrusted to him, within a few years he felt sure he would produce as good a stud of elephants in Africa as could be got in India. He did not know that he should agree with him in all he said, but where he did not, he should defer to his opinion. He confessed he put the animal's intelligence somewhat higher than Mr. Sanderson did, but perhaps this was because Mr. Sanderson had seen them more in the wild state, and might not have seen so much of their after training; but he had certainly seen from time to time instances of intelligence which went beyond what Mr. Sanderson had described. If the elephant fell short of the intelligence of the dog, it certainly came very near to it, and he could not call the elephant a stupid animal. He should have liked to know something more about the growth of the animal, and when it attained full maturity. He did not think this was yet known and appreciated in India, and he believed that if the *mukhna*, now in the Zoological Gardens, or his female companion, were presented to an ordinary mahout, he would put their ages considerably beyond 15 or 16, which was the undoubted age, because their birthdays were known. He had known them for many years, having come over in the same ship with them in 1876, when they were quite small; but they were now both over 8 ft., and in India such a sized elephant would generally be put down as 20 or 25. He had a certain amount of experience of these animals, from having kept them, known them well, and been known by them. The last elephant he had was a very good one, staunch, faithful, unintimidated in the presence of tigers or any other wild animal, and was about 30 years old, or possibly a little more, when he lost her, with other property, at the time of the mutiny. Several years afterwards, when he returned to India, he happened to go up into Oude, and in making a journey, part of it had to be accomplished on elephants. When he got out of his carriage to mount the elephant she recognised him immediately, before he recognised her, and he thought that certainly showed a greater amount of intelligence than could be expected from a stupid animal. Another important question was, how to tell the age of an elephant. By looking in his mouth you could tell approximately, but probably not within three or four years. Mr. Sanderson had mentioned an important fact, which was not yet generally acknowledged, that the tusks of an elephant, which did not represent canine teeth, but incisors, were not deciduous, but came once for all, and remained. Comparative anatomists said that these teeth had a deciduous from at first, that they grew for a year or a year and a-half, and were then shed and replaced by the permanent tusks. Mr. Sanderson said this was not so, and though this had yet to be verified, he (the Chairman) thought he might be right. That there was a deciduous tooth which was followed by the permanent one he had no doubt, but apparently it was not shed, but absorbed, which would explain the matter. If they looked into a large elephant's mouth they would see two enormous teeth, double teeth, but not generally more than two, and if they looked into the mouth of one of the elephants in the Gardens now, they would probably see in front of one the fragments of another double tooth. The fact was that the elephant had six molar teeth on each side in the lower jaw, three of which represented the deciduous, and three the permanent teeth; one grew behind the other, and pushed it forward. The first three were lost in the first nine years. At about the 20th to 25th year the fourth tooth was lost, and for the rest of its life the animal depended on the two last. Knowing this, you might, up to a certain period, estimate approximately the age. Again the mahouts said they could tell the age of an elephant partly by the general appearance, but what they depended most upon was a fold in the upper part of the ear; however he doubted if they were not frequently out some years. Then there were questions as to the kind and amount of food the animal required, and the best means of keeping it in health. It was laid down in the commissariat of India that, for an elephant at sea, there was required daily 150 lb. of hay, 20 lb. to 30 lb. of flour, a certain amount of rice, 4 oz. to 6 oz. of salt, and 30 or 40 pails of water. The amount consumed by Jumbo was a truss and a-half of hay, two of straw, 2 lb. of rice, 1 bushel of bran, 1 peck of oats, 7 lb. of biscuit, grass or green food as much as he could get, and 10 pails of water, so that an elephant was a costly animal to keep. Yet he remembered the time when you could keep one in India, including the mahout and grass cutter, for thirty or forty rupees a month. It would cost more than twice as much now. As to the value of elephants, their price was perfectly arbitrary and conventional. You might pay almost any sum for a good tusker or even a good *mukhna*, which was a male with very small tusks like those of a female. If they wanted to see fine specimens of well formed elephants, they could not do better than examine those in the Zoological Gardens, both of which had been carefully selected by men of extremely good judgment and knowledge of the animal. The larger, though the younger one, was a perfectly beautiful elephant, and was selected especially by the late Jung Bahadoor, who was a great lover of elephants; on the table was a picture of a very fine tusker which belonged to him, and was considered the finest in India. With regard to ivory and the size of tusks, he had copied some figures on the subject, stating that some African tusks weighed 100 lb. each, and one pair weighed 325 lb. It was also stated that the best ivory came from Siam, though why that should be better than the Indian he did not know, as it was the same species. The ivory of the mammoth was even yet exported in tons from Siberia, but whether after being exposed for so many centuries to the weather and water it was of as good quality as the modern ivory, he could not say. He concluded by proposing a vote of thanks to Mr. Sanderson, which was carried unanimously.

Mr. Sanderson, in reply, said he could not give any information about the alleged elephant worship in Siam, for he knew nothing about it. As to the use of pitfalls, he had intended to make it clear that the Government had prohibited them all over India, and though they were still in use in some of the native territories, yet even from these they had had inquiries as to the more advantageous method of catching elephants, and some of these native States had expressed their desire to abolish this barbarous system. With regard to the length of tusks, he had himself seen a pair from the Garrow hills, in Assam, obtained in 1879, which measured 8ft. 9 in. in length, and he had no doubt they were still in the possession of Lord Lytton, who was then Governor-General. They weighed 168 lb. Sir Victor Brooke, in the Mysore, shot an elephant, one of whose tusks was eight feet in length, and weighed 90 lb. As to discouraging the slaughter of African elephants, he feared that nothing short of giving up the use of ivory would bring it about; for as long as the native traders could sell the ivory they would destroy the elephants. With regard to the sacrifice of human life in elephant hunting, everything was done to prevent it; but it must be remembered that risk of life was unavoidable in fishing, and indeed in almost all industrial pursuits. Unless the elephant was left alone altogether, there must be some danger, but every possible precaution was taken to prevent loss of life. With regard to elephant catching in Africa, Sir, Joseph Fayrer communicated with him on the subject some four or five years ago, and submitted a plan to him. He then suggested that it would be well to send a few Indian elephants over first, to see if they would stand the tsetze fly, because some Indian buffaloes which Dr. Livingstone took there were killed within about ten days' march from the coast. Subsequently four elephants were shipped from Bombay, and landed at Zanzibar; they were under the care of Mr. Carter and another gentlemen; but unfortunately, after a few days, they quarrelled with the Indian attendants, who left, and he did not know how they got on. There were accounts sent that they were not at all affected by the fly, and did very well for some weeks or months; then one or two of them died, and subsequently the expedition was cut up. Mr. Carter and the other gentleman were killed, and what became of the elephants he did not know. As regards riding African elephants, he had three about 7 ft. high in the Dacca establishment for two years, with the object of testing them by the side of the Indian elephants, and they were found to be docile, but more stubborn. He had heard the same character of them from the keepers of menageries in England. The men set upon their shoulders, and put their feet behind the ears; if necessary, a pad could be arranged to be kept behind the elephant's ears, to take off the pressure on the rider's legs. It would be a very good thing if the African elephant could be subjugated, because one would carry as much load as thirty or forty porters, and half the difficulty of African exploration arose from having to take so many, the greater part of whom were carrying goods to be given to themselves and their fellows as wages. Three elephants would be sufficient for any expedition, and this would, no doubt, be the best means of opening up Central Africa. Unless, however, it was decided to settle in the country for some years, he did not see how elephant catching was to be established; the negroes were perfect savages, who regarded an elephant simply as so much meat; and so long as the African slave hunters had more profitable employment in their own line, they would not take to elephant catching. It would, therefore, require a permanent establishment. He had made many experiments on the quantity of food an elephant would consume, having kept as many as ten for a month on a stone platform, where everything they had was carefully weighed. They would eat from 650 to 800 lb. of green fodder in eighteen hours, and the rest of the time they had been out in the jungle getting it, during which time they got a picking also. With regard to their age, the sin of the ear was much relied on by the natives, but it was not always satisfactory, and required to be taken in conjunction with other things. As to the deciduous teeth, no doubt Sir Joseph Fayrer was perfectly accurate, and he was satisfied that they did not shed their tusks. He believed Mr. Corse originated the idea; whether any elephant ever did so he was not prepared to say, but to test the fact, he had, in a large number of instances, had a file mark put upon the tusk the moment it came through, but although he watched them carefully, and had never known a tusk drop, nor was the idea entertained by anyone in India who was connected with elephants. Mr. Tegetmeier, however, and other naturalists, judging from the skull, asserted that he was wrong, and that elephants had milk teeth. This was no doubt correct, but they were absorbed in the gum.—*Journal of the Society of Arts.*

Correspondence.

To the Editor of the Ceylon Observer.

NOTES FROM TAVOY.

The Model Duke Estate, Tavoy, British Burma,
24th March 1884.

DEAR SIR,—Moung-ma-gan is the Brighton of British Burma, and Tavoy, in the Tavoy district, on the sea-coast, about eight or nine miles direct west from Tavoy. A most lovely place it is, sheltered by an arm protecting the north-east and another arm protecting the south-west. Away at a distance is the Moscos Islands, which extend in a chain parallel to the sea-coast from lat. 14° 28' N. D. to lat. 13° 47' N., and are distant from it from three to five leagues, having a safe channel inside between them and the coast, with soundings mostly from 10 to 15 fathoms deepening generally nearer the islands. These islands are divided into three groups, called Hien-toesai, Moung-ma-gan and Loungloon respectively. These islands protect the lovely sea-beach at Moung-ma-gan, where there is a substantial Government bungalow built, and the two padres' bungalows. The background is interspersed with noble casuarina; it resembles the pine but is by far more elegant, a most remarkable tree growing 80 feet high and spreading out without a leaf of covering, but hanging in drooping bunches or floating out lightly upon the breeze like long skeins of deep green silk.

The distance from arm to arm from the south-west to the north-east, I would reckon, is about nine miles. The bungalows are built about the centre or a little nearer the south-west arm. Perhaps the curiosities are, on the N. E. side, the turtles and *hot* springs, on the S. W. side the temple of snakes or serpents. The bathing ground is perfection, so shallow that a child could scarcely drown, and the sand firm; when the tide goes back you could drive your trap nicely all along the beach.

You see the Burmese fishermen fishing with a net fixed on to two bamboos; it looks exactly like a *barrow* without a wheel, and they go driving along at a good trot. The other net I noticed them using was on the principle of a river-net in Ceylon, circular, with lead fixed on the outside. The fish is plentiful, and they know when and where to throw their net, and at times take out over two dozens at a cast. The fish from the sea is quite a treat; they are all carried over to the Tavoy market early in the mornings by women and sold in the market. Tavoy has got a splendid market-place, as good as Colombo nearly. The first time I was taken over to Moung-ma-gan by Dr. Dawson, I was so delighted with my trip, and, anxious to get back again, as I did not see the temple of snakes, we had not time, as we made the journey there and back in one day, but we bathed and rolled and tumbled in the water just like two boys; we were delighted with our trip, and, on the following week, Palmer, Deputy Conservator of Forests, asked me to accompany him and remain a night; I accepted his invitation, and back we went, bathed and went and inspected the "sacred temple" of serpents. Where art thou, O Father Colombo? This temple is a house not made by human hands. Let us examine it. Where are the windows and doors, to the *east?* No: direct west; but where are the serpents? Look into this door. Don't be afraid, they are hushed to deep sleep by the surging waves of the mighty deep blue sea; there they are entwined together, one of the greatest curiosities I have ever seen in my life-time.

In returning from the temple of serpents, we gathered a number of beautiful shells; saw a number of oyster shells and a few sponges washed on shore. To the right of the bungalow is the home of the turtles; they come out and deposit their eggs in the sand and are collected and sold in Tavoy. A Burmese has a monoply on them; they can be bought for R10, or even less sometimes. We slept at Moung-ma-gan at the bungalow and enjoyed ourselves and felt all the better for a dip of sea-water. I have not seen the hot springs as yet, but intend to explore them at another time when I have got more time in hand.

Someone asks how to germinate "teak seed." Keep the seed in a dark place, mixed with decayed leaves, and keep all *damp* but not wet; directly they germ, put them out in beds about 6 inches apart and about ¼ inch into the ground, throw a light-checkered shade over them and water sparingly. Teak will not grow well in a wet climate; it does not thrive well in Tavoy district.

27th March 1884.

Burned off my new clearing today; had a first-rate burn; had a narrow escape with my bungalow as the fires were all round. I had about eight men on the bungalow, the fire raged furious for a while, but the Burmese seemed to be in their element and sprinkled water here and there and waved green branches and saved my habitation, my Sheltie "ginger" scraped and snored, and my few Ramsamies worked hard. But Ramasami is a cute fellow: they took out all their boxes and chattels from the lines; this was more than their master did with his chattles.

Henaratgoda William's seeds have come up all right according to their instructions. Divi-divi up nicely, a beautiful feathery-looking plantie. Black wattle and silver wattle also up; also croton oil seed. Coffee and cardamoms have not had sufficient time yet according to their nature, but I have in here one pound of cardamom seeds, belonging to Captain Schwolky; they are Mysore variety and have come up like cabbage plants—could not be better. Schwolky found out the great secret how to germinate them himself.

People seem to have little knowledge of where Tavoy is; their geographical knowledge regarding British Burma is only limited: one man thinks it's awfully moist and unhealthy, and another wants to know if the land is anywhere near King Theebaw! The climate is similar to Ceylon and healthy for Europeans in the extreme; they all get fat, although I am one of the tough lean kind. The rainfall this year, 190 inches. The rain commences showery in April and May. In June the monsoon sets in, and breaks up in July the end off; then from July to middle of November nice showers; no rain from middle of November to middle of February; then a few nice showers only; also a few showers in March, a heavy dew at night, just the thing for the young planties. The blossom season same as in Ceylon: January, February and March, blossom in all the jungle, and also coffee and all fruit-bearing trees, durian, mangosteen, caju-nuts, etc., etc.; and as for "King Theebaw," he is farther away from me than old homie.

31st March 1884.

Cacao seed ought to be packed in dry straw, and put into a barrel, bored over with small holes and sent as "perishable goods" direct by B. I. dâk mail-steamers addressed *via* Calcutta, *not via Madras.* All seeds ought to be forwarded so, and the little extra charges in freight not taken into consideration. They are most *careless in Madras,* and good, "seeds," to the value of over R600, have been spoiled in their godowns through their carelessness; the seeds were simply rotten before they reached Tavoy two months on the journey, when it only takes 18 days *via* Calcutta.—I am, dear sir, yours faithfully,

JAMES D. WATSON.

AN ALLEGED CONQUEST OF LEAF-DISEASE.

Ootacamund, 10th April 1884.

DEAR SIR,—After over twenty years' experience in coffee, the latter part of which I have devoted to leaf-disease, I have been so fortunate as to work out a system of tillage which has nullified this pest on all climates, soils and elevations to be found in India.

It is by no means expensive, and I have full confidence that its results will make coffee pay well if it keeps up to £60 per ton.

You are aware that I am unable to protect a system of culture by patent. I shall therefore require Associations, Coffee Companies, joint and right proprietors and their legal representatives to enter into the following terms that they give me a gross one-fourth value of amount of coffee my system produces in the coming five years as over the average of the past five years ending crop of 1883-84 for the coming five years.

I think that I can give no better terms for the assurance that my system is not a swindle.

My address is left in your hands for parties to communicate, or to yours faithfully,

CRUX, OOTACAMUND.

[We give this letter without professing the slightest faith in the statement made. Even that most flatulent of blowers, Montelar, pretended that his system had been a success on his own estate, and invited inspection, knowing well, of course, that nobody was likely to accept his invitation. But this gentleman does not even challenge this test. If anyone wishes to communicate with "Crux," his name is at their disposal.—ED.]

CHICORY AND DISEASE.

155, Fenchurch St., London, E. C., April 10th, 1874.

DEAR SIR,—I have sent the particulars of some information that has lately come to my knowledge, to the medical profession through one of their journals. I can give you the outline of it, but I hope that medical men in England will endeavour to follow out the facts to see if they can be sustained generally.

A large consumer of chicory who has thoroughly studied the different qualities and the places that produced them became very fond of this addition to coffee, but he found that a disease known as "piles" attacked him, and he could not shake them off, even with the best medical advice. He was asked to think over what could have produced this in his mode of life, and quite by chance he happened to mention that he had lately taken more chicory than usual.

The medical man at once suggested that he had better discontinue the use of chicory for a short time to see if it had any effect.

The result was that he was very little inconvenienced. Being a large vendor of chicory, he endeavoured by experimenting upon himself to prove that it could not be chicory that produced these hæmorrhoids, but upon again returning to the use of chicory he found his malady to seriously increase.

The consequence is that he is now in excellent health, entirely free from these hæmorrhoids, and he has had to abandon drinking chicory.

Knowing that I take an immense interest in those subjects he laid the facts before me personally. If this is proved, it will be of immense importance to the coffee trade, for it is well-known that the mixtures sold here in the market at the present time as "French Coffee" contain the very lowest class of chicory, which has much more irritating proprieties than the chicory grown in Yorkshire. This my friend fully confirmed. I have also laid the facts before the Pharmaceutical Society. It won't effect people in the East, for they drink their coffee pure.—Yours faithfully,

THOS. CHRISTY.

[The moral of this curious letter seems to be that if persons wish to avoid a painful disease they had better not partake of chicory, and that if they will take chicory they had better choose the home-grown. The disease referred to (a natural counter-irritant), however, attacks people who are innocent of chicory drinking. —ED.]

RED AND WHITE CACAO.

Doloshage, 12th April 1884.

DEAR SIR,—Looking over the list of plants and seeds for sale at the Royal Botanical Gardens, I observe :—

Cacao.—Ordinary Ceylon red, pods R5·00 per 100.
Pale-fruited varieties, pods R12·00 per 100.

Apart from the one reason that the pale varieties are not so common as the red variety, it would be interesting to know if there are any other reasons for the one being so much more expensive than the other.

I have heard it said that the pale-fruited varieties are much hardier than the red, and it would be a very interesting addition to what we know on the subject, if those conversant with its peculiarities and and habits would be so good as to add to our knowledge by coming forward and mentioning in what points it is that they are hardier and better —whether by succeeding in poorer soil, requiring no or less shade, standing wind better, &c., &c., than the other. Also, of the different pale-fruited varieties, which one would be the best to grow.—I am, faithfully yours,

FELIX.

[When in Java we saw cacao suffering badly from black blight, and Dr. Treub, Director of the Buitenzorg Botanic Gardens, told us that the Government had at his instance, written for supplies of the white variety s being able to resist this blight.—ED..]

DISEASED CINCHONA LEAVES.

Ferndale, Balangoda, 15th April 1884.

DEAR SIR,—Can you tell me what is the matter with enclosed cinchona leaves? They come off a tree about eight feet high, and every leaf without exception is thus marked; it is planted in a succirubra field, and none of the surrounding ones show any of same peculiarity.—Yours faithfully,

HERBERT W. GUY.

[Our referee states :—"The leaves appear to be suffering from a disease arising from the condition of the tree, and not brought on by the attack of insects or of any fungoid pest." The soil had better be examined. —ED.]

PLANTING IN COORG.

SIR,—Mr. Anderson suggests (page 627, *Tropical Agriculturist*) that something might be done in the way of clearing wattie ravines by moonlight.

I would ask him and also "Aberdonensis" what sort of work could be got out of coolies cutting a large acreage by moonlight. Surely it is impracticable. In getting to fires, I have before now had to pass through clumps of watties with coolies, and I can vouch that the language used when a coolie stepped on the sharp stump of a wattie was very forcible. I opine, too, that, in cutting down the watties, the coolies would not be able to distinguish clearly cardamom plants close at hand and so some damage would be done.

I would suggest to "Aberdonensis" that he visit Coorg and especially the Bamboo, when, I think, he would find few estates without shade now, though perhaps the heavy pruning might get a few scathing remarks from his pen. But what no fellow can understand is that your worthy correspondent in a former letter as much as says Coorg coffee is the coffee, yet now in its very home he states we will hear of *Hemileia vastatrix* having broken out soon. Woe 's me, 't is a weary world, my masters.

Allow me to inform "Aberdonensis" to the best of my knowledge and belief nothing else is grown on Cannon's estate but Munzerabad coffee. The inference is plain, I fancy.—I remain, yours faithfully. LOONIE.

Query :—Did old Baba Boodeen carry his muddie (nursery ?) about with him. He had no doubt first class soil and manure to germinate his coffee, and, doubtless, the soil was mechanically free, having collected it on his journey to and from Mecca.

THE CULTIVATION OF PADDY.

DEAR SIR,—It is not that we have lost faith in coffee, nor that we have no hope in tea and other "new products," but for other and very good reasons we rejoice that the attention of Europeans—capitalists and working-men—has been directed to paddy cultivation as a remunerative investment. Climatic conditions and other physical causes which originally rendered Ceylon a rice-producing country remain unchanged: population only has shifted from what once were flourishing villages, or has entirely disappeared. Tanks innumerable abound in the vicinity of these villages, which is evidence of the fact that they were the means of irrigating the country all round. Breaches, originally small, have through ages of neglect become enormous, requiring heavy outlay for repair. But European capital will attract population from over-crowded centres, and European energy will effectuate the repair and restoration of tanks. Asiatics, born to be led, will follow in the wake of the Anglo-Saxon, born to lead, and Ceylon may once more become the granary of South India, instead of, as at present, depending on India for the "staff of life." The goya of the Sinhalese districts are as good handsat paddy cultivation as are the ryots in South India or the agricultural population of the north and east of Ceylon. A large proportion of this population have a natural aversion to cooly work, which is often mistaken for *apathy* or *love of ease*. Somehow they could not get over their prejudice, that it is degrading to work as a cooly. But they are not above working in the paddy field. It is on this account that *he* will be considered the real benefactor of the natives who could resuscitate paddy cultivation. There is not a native Sinhalese or Tamil, Moor, or Malay, but will engage himself and interest himself in it. Rice is not a luxury, but a necessary, sort of indispensible necessary to the native of Ceylon. If everything be dear, and only rice cheap, he will get on without grumbling, but if everything be cheap and only rice dear, it is a real calamity. It cannot be endured.

The present depression in trade and scarcity of money do not bear down so badly on the generality of Ceylonese, because providentially, there is such a plentiful supply of rice, as was scarcely known within the last 10 years or so. With the exception of a few places, local crops have kept up to the average, and imports continue uninterrupted. Burma and India pouring out their supplies without stint. But a failure—*one* season of failure—in India will result in famine in Ceylon: simply because even with the most plenteous outturn, local coops go for nothing in the total consumption.

At present Ceylon imports not only her *food*, but her *labour* also from India, originally the coast cooly was a necessity, because the Sinhalese could not be had to do cooly work on coffee estates. But the cooly did not come alone; he brought in his train the petty pawnbroker, the wily usurer, the small tradesman and the boutique-keeper and a large nondescript class of adventurers from the South of India, who crowd every trade and calling and drain away the resources of the country in every possible way, leaving nothing to the home-loving, quiet-going Sinhalese nothing but absolute poverty.

It shall not be so if paddy cultivation is resuscitated. All the labour, the indigenous labour available in Ceylon could be turned into profitable account in paddy culture—profitable alike to the labourer and his employer—to the labourer because he can find a market for his labour, to the employer, because he can command skilled labour almost at his door. The coast cooly may be good for the coffee estates, but commend us to the Sinhalese goya for agricultural work. Not only could the Sinhalese do *more* work and *better* work, but he does it with greater thoroughness and in a more honest fashion.

Then we have a superabundant population in the north of the island, who will crowd to any part of the Island, if only for growing paddy. They are more rice-worshippers than Sivites. To them the paddy plant is an emblem of goodness, plenty and prosperity they almost adore it. Much of earthwork in tanks and paddy fields in the Vanni, Nuwarakalawiya and Batticaloa districts is usually done by sturdy workmen from the Island of Karativu in Jaffna, who in physique and in the quantity of work they could do, are as far above the coast cooly as the British navvy is above the ordinary day labourer. They move in gangs of forty and fifty in each, settle in the neighbourhood of agricultural villages, work throughout the season and return to their island homes with their earnings, thus they go on from year to year, a few stragglers only remaining behind, throughout the other islands as well as in the overpopulated villages of Vadamaratchi and a.likaman, there are hundreds of able bodied agricultural labourers who would flock to any place within a week's notice; and were there prospects of permanent occupation, many would make up their minds to settle in the neighbourhood, and Jaffna would be relieved and the entire island benefitted by this means.

Capital is what is wanted to push paddy cultivation on in the north and east. In Batticaloa the petty farmers or cultivators are yearly swamped by the big *podies* or rich land-owners. They are swallowed up in scores as minnows are by the whale. They cannot carry on cultivation in their small fields without some sort of capital. The *podi* lends this capital, often in the shape of paddy for what is known as *paddy-interest*, which is even more exorbitant than usury. Year by year the poor cultivator gets more and more into the *podi's* debt and finally his land is absorbed in the big podi's broad acres.

The European capitalist who invests in paddy cultivation will confer a blessing on large numbers of cultivators, who are in a state of semi-vassalage to the moneyed few in every village. These few prey upon the masses and under pretence of helping them, drain them of their vitality and finally dispossess them of their little *all*; when the seasons are not propitious, the money lenders are even more unmanageable than at other times; and it is no wonder that between the two, the petty cultivators soon enough terminates his agricultural speculation in a hopeless collapse. NEM. CON.

COTTON AT TRINCOMALEE.

Trincomalee, 25th April 1884.

DEAR SIR,—I noticed in one of your past issues a correspondent writing about cotton grown in the island. I send you by this day's post, in separate parcel, two pods from a tree I grew. It is about 6 feet high with branches 2, feet long. The seeds were given me by a friend, but not being particularly mentioned I did not bestow such care, which I should otherwise.

From [illegible] I noticed, it seems to grow very well here.—Yours faithfully, J. B. COLOMB.

[The cotton is a nice fine-stapled fibre, though not over-strong. It is probably Bourbon cotton. Cotton grows well enough in Ceylon: the difficulty is that the boles generally ripen in the monsoon rains to the injury of the cotton.—ED.]

THE TEA BUG: *HELOPELTIS ANTONII.*

Colombo, 2nd May 1884.

DEAR SIR,—I see you have in your last night's issue called attention to the existence of a possible enemy to tea in Ceylon, the *helopeltis*. On referring to Dr. Trimen's report I find that he supposes that the insect has not been noticed in Ceylon until the present year. This may cause alarm. It may there ore be reassuring to those interested in tea to know that the insect has been noticed before by cacao growers, and that it has confined its operations in Ceylon to the cacao alone so far. I noticed the insect first in 1882. But there are others who also know of its existence, with whom I discussed about it. Late in 1882 I visited an estate in Dumbara and observed some pods spotted over, which excited my curiosity. On cutting a pod, it was however found that the beans were not in the least injured or affected. I discovered however no such phenomenon as a spotted pod on my own plantation then—but did so afterwards. Early in the year 1883 I visited a plantation at Kadugannawa belonging to Mr. Ferdinandesz of the Botanic Gardens. The object of the visit was to gain information regarding the habit and growth of the pale varieties of cacao which were then in bearing there. I noticed that at the time of my visit the conductor of the estate was pulling the pods off the trees and burying them. On inquiry it turned up that he was engaged in a crusade against the mosquitoes or "bugs." The paler varieties appeared to me to be more affected than the red pods. The mosquito was pointed out to me, and I captured a few of them. I have not heard more about that campaign since; and whether or not extermination was the successful issue of it But I was then informed by the conductor, who seemed to have studied the habit of the insect, that it deposited its eggs in the pod; that the grub remained inside the pod, and in due course of time the winged enemy appeared on the surface. These immature mosquitoes with little growth of wing were also shown; to me as they luxuriated on the pod, living probably on the juices of the cacao.

On my way back to Kandy I remember meeting Mr. Russell Grant in the train, to whom, as one interested also in cacao, I mentioned the existence of what I then thought might prove a formidable enemy to cacao. He, however, told me that the insect was known to him and that it did no harm in any appreciable degree. Mr. Munton, a cacao-grower with whom also I discussed the matter afterwards, assured me that the insect was known and not dreaded by the cacao-growers of his acquaintance.

Shortly after, on going round my own plantation at Dumbara, I noticed some spotted pods in a dry situation of the garden. Mr. Alex. Whyte of Kandy accompanied me io that trip, and we captured a few *poochies* there; their ravages, however, have not told in a single pod with me from that time to this. It was noticed then, and I mentioned to several of my acquaintances interested in tea, that the mosquito bore a strong resemblance to a tea enemy shown in one of the plates in the "Tea Encyclopædia," and now Dr. Trimen seems to think so too. It is to be hoped, however, that the *Helopeltis Antonii* or *H. theivora* of Assam will confine itself to the low hot districts where it is now found and not extend its ravages from cacao to tea in higher altitudes, in quest of fresh fields and pastures now. It has not done so at least for the two years that I have known the interesting creature, and may not do so in the future. AGRICOLA.

PROPOSAL TO CUT DOWN NATIVE COFFEE.

Uva, May 4th 1884.

DEAR SIR,—I see by Dr. Trimen's last report that he would wish all native coffee done away with to save its being a nursery for *H. V.* A large proportion of the native coffee in the island is past the stage of being a nursery for *leaf disease*, and that still in *good heart*, if cut down and fresh suckers allowed to grow, would still give the owners a good return.—Yours truly, TRY.

[The same experiment might be tried with badly "shuck" plantation coffee.—ED.]

PINUS SINENSIS FOR TEA-BOXES.

The *Gazette* contains a correspondence on this subject. Writing to the Colonial Office (London) on 29th March, Mr. Thiselton Dyer states:—

Sir Joseph Hooker would remind you that *Pinus sinensis*, the wood of which is apparently largely used by the Chinese for the purpose, answers extremely well for plantations in Hongkong and on the neighbouring Chinese mainland, and it has been recently introduced by His Excellency Sir J. Pope Hennessy into Mauritius. It is worth consideration whether its experimental cultivation might not be attempted where suitable land is available in Ceylon.

Mr. Thiselton Dyer had written to the Foreign Office in Nov. 1883, as follows:—

I am desired by Sir Joseph Hooker to inform you that enquiries have been addressed to the Royal Gardens from Ceylon as to the nature of the wood used in China for marking the chests in which tea is imported into this country. It is a matter of considerable commercial importance, as in some cases Indian Tea has proved irretrievably damaged on its arrival in this country owing to the corrosive action of the wood on the ead lining of the chests. The tea has consequently been unprotected from damp, and has further been deteriorated by a flavour communicated by the wood.

Under these circumstances, Sir Joseph Hooker is of opinion that it would be well worth the trouble, if the Secretary of State should think fit to invite Her Majesty's Consuls in those parts of China from which tea is exported, to inquire into the matter and report, as far as they are able, as to the nature of the wood most generally in use. Perhaps the attention of Dr. Hance whose knowlege of Chinese botany is so extensive and accurate, might be particularly directed to the question.

The reply from the Foreign Office on 28th March 1884 was:—

With reference to the letter from this Department of the 5th of December last,* I am directed by Earl Granville to forward to you herewith, for the inspection and use of Sir Joseph Hooker, a sample of the wood that is said to be exclusively used at Foochowfoo for making the chests in which tea is exported thence to this country.

In forwarding this sample, Her Majesty's Consul at that port states that it is the common pinewood of China (*Pinus sinensis*), and is produced principally in Tingchowfoo, a prefecture of the province of Fuhkien in the north-western direction, several hundred miles to the north of Foochow, where timber of this description grows in great abundance and is brought down the Min river in rafts, like those seen on the Rhine.

Mr. Sinclair adds that this wood is also greatly used for coffins in preference to any other on account of its consistency and durability."

Now it *Pinus sinensis* can be grown in Mauritius it can doubtless be grown in Ceylon. But if it to compete with our suitable indigenous woods, it ought to grow readily and quickly. Perhaps Dr. Trimen can give some information about it? We have sought in vain for any notice of *Pinus sinensis* under that name. It does not seem to have been introduced into India?

ORANGE AND LIME TREES AMONGST COCONUTS.

SIR,—I shall feel greatly obliged for information whether it would be advisable to plant lime and orange in the spaces in a field of coconuts 25 feet by 25. I am aware that they grow pretty fairly in the shade but what I am anxious to know is whether they will produce enough fruit to cover expenses, and not interfere prejudicially with the coconut trees.—Yours truly, X Y Z.

THE CAJU TREE FOR TEA-CHESTS.

SIR,—Will you permit me to suggest to your reader interested in the important question of suitable planking for tea-chests, that possibly the caju tree might solve their difficulty. As there is no likelihood that the contents would exert any strain on the sides of the box, I am inclined to think that it will be found sufficiently durable for all purposes—as much so, certainly, as that used by the Chinese, and as light.—Yours truly, KAJJA.

CEYLON PRODUCTIONS 120 YEARS AGO.

6th May 1884.

DEAR SIR,—It may interest you to read what was said of the present chief products of Ceylon 120 years ago. I therefore send you a translation from J. C. Wolfs' book. In his introduction he says he was born at Meklenburg in 1730; he came to Ceylon in 1749 and was here till 1765. He wrote his account of Ceylon in German and it was translated into Dutch, but the name of the translator is not given. He was chiefly in Jaffna, and his title there sounds rather high in English. "Secretary of State and Justice at *Jafanapatnam*." His remarks on coffee are not of much value, but show that but little attention was paid to its cultivation in those days. What he says about sugarcane may be repeated now with equal correctness. Sugarcane will grow in Ceylon to great perfection as far as outward appearance is concerned, and excellent sugar can be made of it, but it cannot be produced here at rates that will enable the planters to compete with those of other countries. Every attempt to do this has failed most signally. Since C. E. Layard first started sugar planting, fully a quarter of a million sterling has been lost in the fruitless attempt to raise sugar in this island for exportation: and he would be a bold man that would try it again at his own cost.—Yours truly, CANNA.

[We are much obliged for the translation, but we have read Wolfs' book in English.—ED.]

The costly cinnamon grows here to perfection: no where else is it to be found of such excellent quality. This noble plant seems to thrive better in its wild state than under cultivation. The ravens (crows), which readily eat the red, sharp-tasting fruit of the cinnamon tree, are the best sowers of the seeds, for they swallow them whole, and distribute them all over in such a manner as causes them speedily to strike root and spring up. Shooting or otherwise killing crows is therefore forbidden under severe penalties. The Hollanders export yearly nine thousand bales of this cinnamon, each bale being 80 lb. net. They obtain this produce for almost nothing; a great deal more might be harvested if the bark would be renewed, but the branches from which it is peeled wither immediately. It is thus easy to conceive that the growth is very rapid seeing that the quantity yearly collected is so great. The growth of this plant is not the same everywhere, but varies according to the nature of the ground. When allowed to grow, it becomes a good sized tree; but the larger the tree, the worse the bark becomes, and that from large trees is only fit for the distillation of cinnamon oil. The assertion that cinnamon bushes cast a perfume for a considerable distance around is devoid of foundation, for I have frequently passed through woods of them without being able to discover the slightest odour. When the yearly delivery takes place, all the cinnamon peelers, who are called "chelassen"* assemble, and each of them receives the present of a piece of linen (cloth). On this occasion they act a comedy according to their fashion, which is not without a certain degree of entertainment.

Pepper grows here in some places pretty well, and has much resemblance to the *Solanum lignosum dulcamara* or *glycypicris* (the longer the better) or bitter sweet. The pepper-corns grow in bunches like grapes and are gathered when ripe; the natives steep them in a mixture of green pepper and vinegar, and use the preparation as a remedy for disorders of the stomach. Pepper does not thrive so well here as on the Malabar coast near Cochin and Venezuela, although the system of cultivation is the same as that followed in Ceylon.

Cardamoms will not thrive in Ceylon. It seems that the soil is not suited to this plant. Its cultivation requires a great amount of labour, and the labour bestowed on it is not remunerated. On the east coast of Java it succeeds better.

The coffee beans, on the contrary, answer better. They grow on a bush two together in a pod which opens of itself when the beans reach maturity. The inhabitants of Ceylon do not make the slightest use of this fruit.

Tea and fine spices are not found here. Efforts have been made to introduce them, but without success. The same may be said of sugar; it can be grown as a rarity well enough, but not in such quantities as are produced in the Batavian fields.

* Raynal (*Histoire des Etabl. des Indes, Tom.* I) says:—"The lowest class or caste are 'chalias,' who are employed in cutting cinnamon."

LEAF DISEASE—NEW PRODUCTS, &c.—No. III.

DEAR SIR,—In connection with my letter on the above subject which appears on page 833, I beg to submit the following facts:—That Indian Corn or Maize (*Zea Mays*) which is so well known to the natives, although its *many* uses are perhaps not, if cultivated largely will be a useful article of food and possibly for export also, and may be made an article of trade. Indian corn from its size certainly contains more starch. I have seen it pounded into grits and boiled, used as a good substitute for rice. Indeed, I was once mistaken, when in one of my journeys from Batticaloa to Kandy, I found I had run short of rice for the coolies, and the people in the mădam or inn, where I also halted (owing to continued rains for two days which delayed my journey), I saw in a pot belonging to others something which appeared to me to be some fine rice boiled, and felt annoyed that the people should have refused some to me when they had, and their protestation that it was not rice did not convince me, till I stooped down and peeped into the pot, took some and examined for myself and found it was Indian corn. Meal of equal quality and consistence as wheat flour can be obtained from Indian corn for bread and cakes, and Ceylon need not depend upon America for the much vaunted American corn flour. There is certainly a charm in foreign importations, and they are generally better prized than what is procured at home. When divested of its husk by pounding, Indian corn makes very good food for horses. It has been argued that Indian corn cultivation exhausts the soil. I suppose all cereals do. Even paddy is not sown in the same field till after ploughing and manuring again. Another important vegetable, which, although eaten in form of salad or in soups, is not largely cultivated, and is not thought to be good enough to be a good article to be considered staple food is Bandaki (*Hibiscus esculenta*). This plant, although not classed amongst the leguminous or Bean family, yet like beans it is also a pulse, but far better, inasmuch as Bandaki contains more albumen, which is the basis of all animal and vegetable organisms. It could be boiled and eaten in form of salad. The tender fruits, when boiled, squeezed and strained, yield a thick syrupy liquor, which, when mixed with sugar—some brandy and nutmeg added—makes very good jelly for invalids, does not however congeal easily, but by some efforts may be made to harden to the consistence of moss jelly. Invalids would prefer more liquid nourishment, and Bandaki jelly is easily taken. It is agreeable to the taste, the brandy and spices make it very palatable. Both of these vegetables can be easily cultivated, require little manuring, their growth does not depend upon the rains, they may be watered or irrigated morning and evening, they grow at all seasons of the year. They may be made to yield at least three crops in a year. The fibre of the Bandaki may be used for cordage. The wood and dry cast-off pods may be used for fuel. There are, I think, two varieties of the cultivated Bandaki, the short and stumpys and the long and slender, the latter contains more albumen and is preferable. SILEX.

EUCALYPTUS OIL.

TO THE EDITOR OF THE "PHARMACEUTICAL JOURNAL."

SIR,—In a recent issue of the Journal I noticed a paragraph under "The Month" in which it is stated that eucalyptus oil of the kind that has been in the market for some years is obtained from *Eucalyptus globulus*; this is an error, and one that I have endeavoured to get the wholesale trade at all events to give up.

Eucalyptus oil was first distilled by Dr. Bosisto, of Melbourne, some twenty years ago, from the *Eucalyptus amygdalina*, which is as distinct from *E. Globulus* as *M. Piperita* is from *M. sativa*, and is an entirely different oil from that obtained from the *E. Globulus*.

The success which Dr. Bosisto's oil has met with has induced people, having no knowledge of the different kinds of *Eucalyptus*, or gum-trees as they are called in Australia, to distil any oil from the leaves gathered indiscriminately from one or any of the forty or more *Eucalypti* growing in the Australia bush, and consequently have obtained an oil totally different from Dr. Bosisto's.

Some two years ago Dr. Bosisto distilled an oil from *E. dumosa*, or, as it is known in Australia, the mallee scrub. This oil differs slightly from the *amygdalina* in perfume, but Dr. Bosisto is of opinion that medicinally its properties are the same.

The *E. Globulus* is the tree that has a great power of absorbing moisture from the earth and passing it off by its leaves into the air, and has hence been largely planted in malarial districts. The introduction of this tree into Europe (at Rome, etc.) has doubtless been the source of the constant confusion as to the origin of Dr. Bosisto's well-known oil. —E. H. GRIMWADE, 82, Bishopsgate Street, E. C.

CONCERNING COCA.

Some years ago, we gave a detailed account of the famous South-American stimulant, coca, with the testimony of medical men in its favor, as well as some evidence of a contrary character from other authorities. Of its value in certain cases there can be no doubt, and it is safe to say that it is less dangerous when used freely than most drugs of its class; but it is improbable, on the face of it, that any such powerful tonic or stimulant can be habitually used without the direction or advice of a physician, and not produce harmful effects of some kind or other.

It is curious, by the by, that an agent which has been so much written about and advertised, of late years, should not have become more popular than coca has done, if we may believe Dr. H. D. Hicks, who contributes a paper on the subject to the *New York Medical Journal*. He says that "many druggists do not keep it in stock, saying that they have no call for it." His personal estimate of it is high, as will appear from the following extract from his article:—

I have used it both personally and in my practice, and find it of great service in the following conditions:—

To prevent and relieve fatigue.

In those cases of back-ache accompanied by high-colored urine with excessive amounts of urates and uric acid.

In short breathing, dependent upon weakness of the muscles of respiration.

Palpitation of the heart without valvular lesion, due to dilatation or to weakness of the heart-muscle.

It renews the vigor of the intellect, and relieves mental exhaustion, rendering the flow of thought more easy, and the reasoning power more vigorous.

It dissipates "the blues," leaving the mind calm. By its use the depression following an indulgence in alcoholic liquors is relieved.

It destroys the carving for alcohol, and in small doses is useful in sick-headache, and headache resulting from over-exertion. Its habitual use as a part of the daily diet conduces to mental clearness and activity, freedom from fatigue, and sound sleep.

I am using it in all cases in which the balance between nourishment and waste is not maintained, and find it a valuable assistance. In regard to the dose, I think that the one generally given on the bottles, viz., ʒ j-iv, is too much. I find just as good effects from ʒ ss for an adult.—*Popular Science News.*

TREE TOMATO.

This is the popular name of a fruit naturalised in Jamaica, and found in many old gardens of the Coffee districts of St. Andrews and Manchester. By the kindness of Sir Joseph Hooker it has been determined as Cyphomandra betacea, DC.,* a native of South America, including Peru and Chili, where also it is under cultivation. The plant (belonging to the natural order Solanaceæ) is of shrubby habit, about 5 or 6 feet high; the leaves are large (sometimes a foot long), broadly cordate, and softly pubescent, generally confined to the termination of the branches. The fragrant flowers appear as sub-axillary cymes, of a pale fleshy colour, with bright yellow stamens, followed by an obconical or ovate fruit, which at first of a greenish or purplish tint, gradually assumes a warm reddish colour as it approaches maturity. The bilocular fruit is of firm texture, about 2 inches or 2½ inches long, and about 2 inches in diameter. The pericarp is about ¼ inch in thickness, of a pale colour. It is not generally known, and seldom used in Jamaica, but it is without doubt a fruit that should be more largely cultivated, as it answers in every respect the purposes for which the ordinary Tomato is esteemed. On the mainland it is known as the Tomate de la Paz, here as the Tree Tomato, and sometimes, on account of its supposed beneficial action on the liver, as Vegetable Mercury. Plants are easily raised from seed, which come into bearing in about two years. It is a very prolific bearer, and the fruit is available during the winter months—November to March—when ordinary Tomatoes are not so easily obtained. If the fruit is allowed to fully ripen on the trees it may be eaten raw, and it has somewhat the flavour of Gooseberry. If the skin is removed and the fruit (without the seeds) stewed with sugar, it resembles Apricot, but with a slight sub-acid flavour which is very refreshing. In my own household it takes the place of Apple in Charlotte-aux-pommes, and it is preferred in this form to real Apples, especially such as grow in the Blue Mountains, or are imported from America. I notice the plant is under cultivation in the South of Europe, but I am not aware to what uses the fruit is there applied. Sir Joseph Hooker informs me that it is now in fruit in the Temperate-house at the Royal Gardens, Kew. As I have lately distributed seed of this Tree Tomato to numerous correspondents at Madeira, India, Ceylon, Hongkong, the Cape, and the Australian Colonies, the above remarks will no doubt prove of interest to them, no less than to other readers of the *Gardeners' Chronicle*, who may desire to secure a hardy perennial Tomato plant of more than ordinary merit. I may add the plant flourishes in Jamaica at elevations of 2,000—5,000 feet; the mean annual temperature of these districts ranging from 72°—63° Fahr.—D. MORRIS, Jamaica, March 25. [This fruit may occasionally be seen in Covent Garden Market under the erroneous name of Granadilla. It is we believe imported from the Azores.—ED.] *Gardeners' Chronicle.*

COLONIAL NOTES.

We have received the second part of *Field and Garden Crops of the North-Western Provinces and Oudh*, drawn up by Dr. Duthie, the Superintendent of the Saharunpur Botanic Garden, and Mr. J. B. Fuller, the Director of Agriculture of the Central Provinces. We have already spoken of the scope and purpose of this work, so that we need now only say that the present part contains figures and descriptions of numerous cereal grasses, pulses, and cucurbits. The drawings are faithful, and the descriptions contain, in addition to information condensed from well-known sources, the results of personal observation which will render the work useful as one of reference, not only to botanists and cultivators in India, but also to students of economic botany in this country.

Some few years ago we had occasion to figure a Melon-Cucumber, which excited some attention at the time, and was, we believe, received by some with something like

* *Pionandra betacea*, Miers in *Hook. Lond. Journ. of Bot.*, vol. 4, 1845, p. 358; *Solanum betaceum*, Cav. ic. 6, p. 15, n. 599, t. 524; *Ann. de Hist. Nat.*, i., p. 44, *Dun. Sol.*, 169, n. 70, syn. 7, n. 16; Andrews, *Botan. Rep.*, t. 511; *Solanum crassifolium*, Ortega, *Dec.* 9, p. 117; *Solanum obliquum*, Bertero, pl. exs. n. 1,125, in H. DC. nec. Ruiz et Pav.

incredulity. In plate 54 of the present publication, however, we find a fruit represented which might be taken for that of a Cucumber; it is, however, entered as Cucumis Melo var. utilissimus, and concerning which we extract the following notes:—"This is another of the extreme forms or varieties of the Melon, differing in the shape of the fruit and the uses to which it is applied. The fruit varies from short-oval or cylindrical to elongate, and is either straight or curved, like some varieties of Cucumber. Some specimens grown this year in the Saharunpur Garden measured over a yard in length. They also vary in colour from dark green to nearly white, usually changing to a bright orange colour when ripe. The seeds, like those of 'Phunt,' are rather smaller and more slender than true Melon seeds.

Roxburg, *Flora Indica*, *l.c.*, makes the following remarks on this plant:—'This appears to me to be by far the most useful species of Cucumis that I know. When little more than one-half grown they are oblong and a little downy; in this state they are pickled. When ripe they are about as large as an ostrich's egg, smooth and yellow. When cut they have much the flavour of the Melon, and will keep good for several months if carefully gathered without being bruised and hung up; they are also in this stage eaten raw, and much used in curries by the natives. The seeds, like those of other cucurbitaceous fruits, contain much farinaceous matter blended with a large portion of mild oil. The natives dry and grind them into a meal, which they employ as an article of diet; they also express a mild oil from them, which they use in food and to burn in their lamps. Experience as well as analogy prove these seeds to be highly nourishing, and well deserving of a more extensive culture than is bestowed on them at present.'"

It appears from these plates that cucumbers in India have sometimes egg-shaped fruits, while some Melons have long cylindrical fruits of the shape we at home associate with the Cucumber. It will be remembered that M. Naudin conclusively proved the specific identity of these forms by the experimental culture of every obtainable variety—a striking instance of the valuable results to be got from botanic gardens. We strongly commend the perusal of this work to the notice of those of our colonists whose lines may be cast under climatal conditions suitable for the growth of these Cucurbits, which are grown in certain parts of India on a scale which will excite the surprise of the reader.—*Gardeners' Chronicle.*

FUNGI ON PLANTS.

Sir J. B. Lawes, of Rothamsted, in the last number of the journal of the Royal Agricultural Society of England, says:—"I consider that plants are liable to be attacked by fungi, parasites, &c., in proportion as the soil is deficient in available mineral food. . . . It is quite possible that when the climate favors mildew it will prevail more or less, but that the extent to which it will prevail will greatly depend upon the relation between the mineral and organic matter in the soil, and I should be disposed to say that the greater the amount of available mineral matter (potash, lime, silica, phosphate) at the disposal of the plant, the greater would be its power of resistance. . . . We learn that in bad seasons the best crops are attacked with mildew, if that is the prevaling disease; but the power of resistance to disease is greatly affected by the condition of the soil. . . . Plants are very much like ourselves—their power to escape disease, and to struggle against it when attacked, depend very much upon their state of health." Dr. Voelcker says:—"I believe the soil has a great deal to do with mildew. . . . An excess of available nitrogenous food (be it nitrate of soda, ammonia salts, or organic matters which are readily decomposed in the soil), appears to have a decided tendency to cause mildew in wheat." The report on wheat mildew by Mr. Little, from which the above extracts are taken, concludes thus:—"It would appear that seasons are the chief cause of mildew, and that sudden changes of temperature and rain, accompanied with close still weather, are favorable to the spread of the disease. That low-lying rich soils are most subject to attack. That high farming and too generous manuring, particularly with nitrogenous manures, promote mildew. That early sowing is desirable. That while no description of wheat is proof against disease, red wheats are generally less injured by it than white wheats. . While I have been most anxious to prove that atmospheric conditions are not the sole governing cause of mildew, I must not be supposed to deny for one moment that a condition of humidity and saturation of the air is required to develop the disease. Again, I think that the exact influence of particular chemical constituents on the tissues of the plant is deserving of further inquiry." Mr. Little also says:—"Wheat mildew is caused by a parasitic fungus, known as Puccinia graminia, which attacks both oats and barley, as well as many of the natural grasses. This parasite lives within the cellular tissue of the plant, sapping its vitals, and converting to its own use the sap which should nourish and mature the grain. The presence of this fungus in the infected host plant is evidenced only by its fruit, or reproductive organs, which burst through the cuticle and appear in red or black patches on the leaves, straw, or chaff. The life history of this fungus is remarkable, as, according to the investigations of Mr. C. B. Plowright, M.R.C.S., a well known authority on British fungi, it has no less than five kinds of reproductive forms—Œcidium, Spermogonia, Uredo, Puccinia and Promycelium, Of these five forms three only —Œcidium, Uredo and Puccinia—come under the notice of the ordinary observer. . . . Starting then from this point—that is, with the blackened straw of the previous year—we find that in the spring the Teleuto spores are quickened into life, and from them are produced another kind of spores (Promycelium spores), which are said to be unable to retain life and bear fruit unless they can meet with a barberry-tree. Having settled upon a leaf of one of these shrubs, the spore bores into the interior, and there develops in Mycelium, which, in the course of about eight days, produces rusty patches on both the upper and under sides of the barberry leaf. From these spots of rust, two different kinds of spores are shed—Œcidium spores from the under, and Spermogonia from the upper side of the leaf. It is supposed by Mr. Plowright that they are of different sexes, the smaller spores, or Spermogonia, playing the part of the male. The Œcidium spores (perhaps fertilised by the Spermogonia) are distributed in the air in incalculable numbers, and those which fall on plants adapted to fulfil the office of host plants germinate under favorable atmospheric conditions—that is to say in damp weather—and throw out a germ tube, which enters the host plants through one of its stomata or breathing pores. Having effected an entrance, Mycelium is again developed in the tissue of the plant (wheat or grass), and the fungus has now obtained possession of a home in which it can complete its life cycle. In the course of ten or twelve days Uredo spores are produced on the outside of the leaf. These are distributed and germinate and reproduce their kind. The reproduction of Uredo is repeated generation after generation until the host plant approaches maturity, when the Mycelium throws out Teleuto spores and the life cycle is completed."—*Leader.*

CANKER IN APPLE TREES.

There are probably several diseased conditions of Apple trees known as canker. During the past two or three months I have been looking into this disease somewhat attentively, and I have come to the conclusion that the commonest and most serious form is due, as was pointed out by Goethe, to a sphæriaceous fungus, Nectria ditissima (Tul.).* The various members of Sphæriacei occur, as a rule, upon dead wood—not upon the living tissues of plants. There are, however, many important exceptions—such, for example, as the Valsa parmularia, described many years ago by Mr. Berkeley, upon living Oak twigs. More important, from an economic point of view, is the Sphæria morbosa of Schweinitz, the cause of black knot in Cherry and Plum trees in the United States; closely allied to which is Gibbera vaccinii upon living branches of Vaccinium Vitis-Idæa in our own country. The Dothideaceæ, too, occur, many of them, upon living leaves and branches, as the genus Phyllachora for example. Although there is nothing impossible in the notion that a Nectria may be

* *Nectria ditissima*, Tul., *Carp.*, iii., p. 73, t. 13, f. 1—4 (=N. coccinea of many authors).—Perithecia widely scattered or densely gregarious, globose-obtuse then papillate, naked blood red asci cylindrico-clavate, 82×8 mk.; sporidia ovate-oblong, uniseptate, 14×6—8 mk., hyaline. *Conidia tubercularia crassostipitata*, Fuckel, *Symb. Mycol.*, p. 180. Conidia ovate-oblong, continuous, $6—8 \times 3—4$ mk.

parasitic upon living branches, yet I must confess my first impression was, that the fungus found a suitable home upon Apple twigs which were already dead rather than that it was the cause of the death of the affected branches. It is well known that winter and spring are the seasons in which the Sphæriacei as a rule are found in the best condition of fructification. I have, therefore, closely examined cankered Apple trees during the past two months wherever I have had an opportunity of doing so, and in no single instance have I failed to find the Nectaria upon every tree examined. It is not implied that every cankered patch was found producing perithecia (spore cases); at the same time the majority of the cankers upon each tree were found bearing the fungus in abundance: and, further, it was not found upon any other part of the trees. The trees were not confined to one garden nor to one locality. The specimens which I submitted to the Scientific Committee recently were gathered from (1) Mr. J. Bird's nursery at Downham; (2) Mr. S. N. Marshall's garden at West Lynn; (3) Mr. J. T. Stevenson's garden at Cleuch Warton; (4) Mr. C. Peek's orchard at Tilney St. Lawrence; (5) Mr. G. B. Ffolke's garden at Wolferton; and (6) Mr. T. Piney's garden at King's Lynn. When the parasite gains an entry into the bark of a medium-sized branch, which it often does through a lateral twig having been broken or cut off, it at first causes the death of the bark and subadjacent wood to only a limited extent. The bark cracks concentrically; in the cracks and upon their edges the perithecia are most commonly found. It is obvious that a certain time must elapse between the period of infection and the time at which the mycelium or spawn can develope its perfect fruit. This probably takes some months, for it will be seen by inspecting the specimens themselves that the perithecia are most abundant in those cases in which this devitalised area has become surrounded by an enlarged and swollen margin of healthy bark. When the parasite attacks a small branch shoot of the last year it kills it outright for some inch or two downwards; especially is this the case when the end of the shoot has been cut off; but with the older and thicker branches attacked lower down the disease gradually but surely works its way through the branch, eventually cutting it quite through. In this case a callous above and below, as well as surrounding the canker generally, is observable. Thus the distal part of the branch becomes in course of time strangled by the fungus. It is useless to look for perithecia on those places in which the disease has only just made its appearance. As far as I can judge, the cankers made last autumn produce the perfect fungus in spring.

In the *Gardeners' Chronicle*, March 8, 1884, p. 312, Goethe's paper in the *Monatsschrift des Deutsche Garten* for 1880 is referred to, in which the author has shown that Nectria ditissima is capable of producing the disease on Apple, Beech, and Sycamore respectively. The remedy is to cut out the diseased parts and to seal the wounds thus made, which would otherwise remain as vulnerable points inviting the attack of the fungus-spores, by painting them over with warm coal-tar.

The injuries which branches receive by rubbing against one another may, of course, open the door to the fungus spores; but unless the latter be present, a true canker is not produced by this means.

At a recent meeting of the Scientific Committee a very curious form of canker on Hawthorn was exhibited, in which the disease resembled a honeycomb. Whether this was due to an insect or to another fungus, I cannot at present certainly say. It, however, bears some resemblance to the cicatrix of a wound caused by a fungus, Rœstelia lacerata. attacking a young twig last summer, and the presence of some brownish spores in the bottom of some of the cells seems to favour this view. There were also, however, found some spores very like those of a Fusisporium. By further observation I hope to clear this up. —CHARLES B. PLOWRIGHT, King's Lynn, April 7.—*Gardeners' Chronicle.*

ARBORICULTURE IN ALGERIA.—In connection with the subject of arboriculture in Algeria, it is stated that on December 31, 1882, the plantations of trees made in the three provinces consisted of 32,000,000 trees of all kinds, of which nearly half were fruit trees, and that this showed an increase of 335,759 over the previous year.—*Gardeners' Chronicle.*

VEGETABLE PRODUCTS OF SMYRNA.

SESAME (SESAMUM INDICUM).—This oleaginous seed is much cultivated in Asia Minor, chiefly in the valleys of the Meander, Cayster, and Hermus, also in the islands of Mitylene and Cos, and along the coasts of Caria, Lycia, Pamphylia, and Caramnia, but the produce of these coasts, that of Mersina excepted, is of a very inferior quality. Generally the Sesame of Asia Minor is exceptionally good. The cultivation is extending to meet an increasing demand; and the chief consumers are France and Italy then Holland and Russia. England and America take none. A considerable portion of the crop is consumed on the spot in the shape of oil. In France and Italy the cold-drawn oil of Sesame is used for salad and also for perfumes, as it keeps longer than Olive oil, and is free from offensive smells. In France it is also in request to make soap and to grease machinery. The seed alone is exported and in sacks containing about half an imperial quarter each, the price averaging from 35 fr. to 40 fr. the sack, or 19s. the quintal (124 lb.), free on board. At Smyrna and Scala Nuova the oil is badly made, yet it is extensively consumed either in the manufacture of the local sweet called "halva" or for cooking purposes.

GALL-NUTS (QUERCUS INFECTORIA).—The galls are formed by an insect (Cynips quercus folii) on the leaf of the native Oak, and are gathered when the insect is in the larva state. They are gathered chiefly at Magnesia, Alasheïr, Koular, Ushak, and Pergamus. In Europe they are prized not only for their tanning properties but also for the valuable black dye which they yield. The galls are exported in sacks containing from 80 to 100 okes each (220 to 280 lb.), and are worth on an average £4 to £6 5s. the sack. There are three qualities, distinguished by their colours—black, white, and green. The export is one of small value, never exceeding 3,000 sacks a year, valued at from £12,000 to £18,000. The largest share of it is taken by England and France. The export is sometimes largely increased by the crop from Mosul, shipped at Smyrna in transit for Europe.

YELLOWBERRIES are the fruits of a small shrub (Rhamnus infectorius) which grows freely in the neighbourhood of Kaiseria, Karahissar, Angora, and Chouem. Its fruit grows in clusters of berries not larger than Currants, and of a green colour; yet the juice expressed from them is a bright yellow, which is prized as a dye, and when mixed with indigo gives a most brilliant and durable green. The berries are picked when young, for they lose their colouring matter when fully ripe; the best qualities are in request in Switzerland, which they reach *viâ* France and Italy. The greater portion of the remainder is taken by England. The berries are exported in sacks, containing about 300 lb. each. In the first three years of the series their price was about 40s. per cwt., free on board. In 1881 the price rose to 50s., and has since made a considerable advance, the peculiar yellow of this dye having become fashionable in Europe. Some twenty or thirty years ago, before the dye was imitated by aniline, these berries used to fetch £15 or £16 per cwt.

GUMS.—The Gum Tragacanth of Smyrna is more in repute than that of Greece, Egypt, or Syria. It is the sap of certain shrubs. Species of Astragalus grow wild in the mountainous districts of Anatolia, chiefly at Karahissar, Isbarta, Kaiseria, Jalovatch, and in Caramania and the north of Syria. The best quality is sent to Europe and America for confectionery; the inferior qualities to England, France and Switzerland chiefly for dressing leather, and partly for giving substance to linen and calico. The other consumers of Smyrna gums are Austria, Holland, Italy and Spain. The export reached its climax in 1879, when its value was nearly £80,000. In 1880 and 1881 it fell to less than one-third of that sum. The best qualities are packed in cases, the inferior in sacks, in both instances weighing about 2½ quintals or 300 lb. The best quality is white, in thin flakes, and is worth from £14 to £18 per quintal; the second is a whity-brown from £8 10s. to £12 8s.; and the third is a dirty brown, and in thick flakes, fetching only from £6 to £8 per quintal.

GUM MASTIC is obtained from the bark of Pistacia lentiscus, an evergreen shrub which abounds in Chios. The bark is gashed in crosses, and the gum exudes in tears. What falls to the ground and becomes mixed with earth is used on the spot to make the spirit called "mastic," by flavouring alcohol with it; while the pure gum, carefully cleansed, is selected for exportation, chiefly for the manufacture of varnish. A large portion of the crop is consumed in Turkey and Egypt, where the women are in the habit of chewing this gum to sweeten their breath. The crop of Chios averages 4,500 to 5,000 quintals a year, but the portion of the crop exported does not exceed £1,600 to £2,000 yearly in value.

SCAMMONY.—This drug, a very powderful acid, much prized in some European pharmacopœis, is the juice of a creeping plant (Convolvulus scammouia), somewhat resembling the Jasmine, but bearing a pale blue flower. The juice is obtained by gashing the stem and catching the juice in a shell, which after two or three weeks is found to be white, resembling milk, which in time turns a greyish-black. This juice, when boiled to inspissation, forms a paste which is the scammony of commerce. It is very valuable, and consequently is frequently adulterated by the peasantry before it reaches Smyrna. The first quality or "lacryma" is worth at Smyrna about 25s. per pound, the second about 17s. It is packed in boxes of various sizes, lined with tin. The average value of this export for the five years in question did not reach £5,200. The demand for scammony has declined of late years. It was formerly worth £8 or more per oke ($2\frac{3}{4}$ lb.), now it never fetches more than £3 10s., the depreciation being owing to the shipment from Syria of the root itself, instead of the inspissated sap. England takes the larger half of this export; the rest is taken by France, Italy and Austria.—*Gardeners' Chronicle.*

SILK-CULTURE IN THE PUNJAB.

The Government of the Punjab, through Lieutenant-Colonel E. G. Wace, Commissioner of Settlements and Agriculture, Punjab, has collected a quantity of interesting information regarding silk culture in the province. Colonel Wace sent a Circular to the Commissioners of Gurdaspur, Kangra, Hoshiarpur, Umballa, Simla, Amritsar, Peshawar, Bannu, Mooltan, Lahore, and Ludhiana, asking for information on the progress of the industry in the various districts and also specimens of the ripe cocoons and eggs, as well as samples of the manufacture of Silk. The result of his enquiries is given below. Colonel Wace says:—

It will be seen from the report of Mr. Kennedy, Assistant Commissioner of Lahore, that sericulture is not practised in that district, but that the raw silk used in the manufacture is imported chiefly from Bokhara, Yarkand, Ladakh and Bombay, and that the industry gives employment to a large number of persons in Lahore. The silks manufactured are broadly known by the names of Darzai (plain) and Gulbadan (striped), but there are distinct varieties in these according to the degree of skein and texture. Purses, ribbons, waistbands, turbans, &c., are also manufactured. The silk trade is not now in the flourishing state it was formerly, having to contend with mixed fabrics of silk and cotton imported from England, which find favour with those, who, as Mr. Kennedy remarks, prefer cheapness and show to durability and intrinsic excellence. Mr. Kennedy has forwarded seven specimens of silks, which are detailed at the end of his letter, to which I have added their selling price at Lahore.

The Deputy Commissioner of Gurdaspur forwards a report on sericulture as practised in the Gurdaspur district, furnished by Mr. E. F. Keighley, agent for Messrs. Lister & Co.'s Filature at Madhopur; which contains information both as regards the domesticated and the wild silkworms. Mr. Keighley has very little hopes of the silk industry improving among the natives, owing to repeated failures among the cottagers in cocoon-rearing and disease among their silkworms. The people will insist on breeding their own eggs, which is in itself very precarious, and keeping them in the plains in the hot weather, instead of sending them to a cool *climate*. It seems the industry was first introduced into the district in 1854, and appeared to thrive till 1873-1874, when disease broke out amongst the stock and caused great havoc, so that now little or none of the old stock is left. In 1881 and 1882, Messrs. Lister & Co. imported and distributed eggs freely amongst the people. These at first were successful, and a fair crop of cocoons was obtained, but subsequently, owing to neglect and other causes, diseases broke out and the crops were a failure, a third distribution in 1883 has met with the same result, and Messrs. Lister & Co. have lost confidence in cottage cultivation; and in consequence started mulberry plantations of their own. At Madhopur, only the silk is taken of off the cocoon by the firm, the silk fabrics being manufactured at their mills in England. Mr. Keighley has kindly supplied specimens of the Bombyx Mori cocoon (*i.e.*, country and Japan) and also samples of the raw material, a list of which I have added. The Deputy Commissioner has also sent a small case containing cocoons, silk and eggs of native workers, of which he gives a list.

The Deputy Commissioner of Kangra has furnished no report on sericulture in his district, but has asked me to accept the report from Mr. Keighley as representing the subject for his district as well as for Gurdaspur.

In the Ludhiana district, the Deputy Commissioner states, an experiment in sericulture was started in 1854 but did not succeed, and that now raw silk is procured from Amritsar and Jullundur, into which districts it is imported from Bokhara and Kashmir. It is manufactured into Lungis, Turbans, Gulbadan (Pejjammas) &c., of which the Deputy Commissioner has sent a very complete collection. The exhibits are for sale, and their return is required if they are not sold. The silk industry is not of importance in this district, and is in the hands of four native firms. The chief demand is for turbans which are much sought after by native regiments.

Mr. Roe, the Deputy Commissioner of Hoshiarpur, represents, that in his district sericulture on a small scale is practised by only one native, who commenced it in the beginning of 1882. The venture, so far as it went, was profitable, but from some cause unknown, the worms and eggs died and the business is at present closed. Mr. Roe sends a specimen of manufactured reel silk obtained from the native who started the above undertaking. A full and interesting account of the rearing of Tasar worms and of the artificial propagation of Tasar cocoons is given in a memorandum and letter by a former Deputy Commissioner of the district, Mr. Coldstream, and published in the journal of the Agri-Horticultural Society of India, Volume VI, Part 4, New series. The Tasar cocoon is met with in its wild state extensively in the Hoshiarpur district. Much success attended Mr. Coldstream's efforts to bring the Tasar worm into a state of semi-domestication; but his experience goes to prove that the species will not fully domesticate. The worms he attempted to bring up by hand as in the case of the ordinary silkworm gradually died away. Whereas, those fed at large in the open air on the ber tree (Zizyphus Jujuba) throve and produced cocoons in abundance.

The report of the Deputy Commissioner of Amritsar is to the effect that sericulture is not carried on in his district, and that an attempt made by amateurs ended in failure. There are no wild silkworms in the district. The Deputy Commissioner has sent specimens of raw and manufactured silk to the exhibition, through the Punjab Committee of the Bengal Exhibition. His instructions were to send them to me, and I trust that no inconvenience will result from this miscarriage.

The Deputy Commissioner of Mooltan states that no silkworms are reared in his district, but that large quantities of raw silk are imported from Bokhara, and are manufactured. For a description of the manufacture, the Deputy Commissioner refers to that given in Powells' Punjab Manufactures, Volume II, beginning at page 57. I regret I have not been able to procure specimens of the fabrics manufactured in this district.

I am indebted to the Wazir of the Bahawalpur State for specimens of "Lungis and Sufis" and reel silk manufactured from the raw silk procured from Mooltan, which district imports it from Bokhara. It appears there are about 100 looms at work in this State.—*Civil and Military Gazette.*

THE INTERNATIONAL HEALTH EXHIBITION.—*The Fruits of all Countries* is the title of one of the handbooks now being written for the Health Exhibition authorities. The author is Mr. W. T. Thiselton Dyer, of Kew.—*Gardeners' Chronicle.*

THE GERMAN SOCIETY OF ANALYTICAL CHEMISTS offers two prizes, of about \$125 and \$75 respectively, for the best and second best treatises on cocoa and cocoa-manufactures, with especial reference to commercial and nutritive value.—*Popular Science News.*

ESSENTIAL OILS: THEIR DERIVATIONS, AND SOME OF THEIR USES.

BY WILLIAM A. WRENN.

When I last had the pleasure of addressing the Chemists' Assistant's Association it was upon the essential oils used in perfumery, and mostly from foreign sources. This time I have taken an allied subject, and, with your indulgence, will extend it over two papers, first treating those essential oils which can more strictly be called medicinal, and are obtained from plants cultivated in England. These English oils, for the most part, command high prices compared with foreign samples. But consideration of the labor, care, and patience of the English drug-farmers, the increasing value of land, the time occupied in carefully selecting the various shrubs, herbs or flowers before distillation, and the superior aroma and reliable quality of the oils should tend to increase their reputation and their right to the first rank in pharmacy. In a second paper I will notice these oils which are more or less aromatic—perhaps less—used in pharmacy, and will refer to some essential oils produced in the East Indies.

OL. ANETHI, obtained from *Anethum graveolens.*—There are two very distinct kinds of dill seeds in commerce, although both are regarded as coming from the same species of *Anethum.* The coasts of the Mediterranean, Crimea, Northern Asia Minor, and India furnish the largest supply. The East Indian seeds are called "Sewa seeds,"—and are nearly always so termed in drug-catalogues. Only a small quantity of dill seeds are grown in England. At Market Deeping rather more than ten acres were under cultivation this year, and about the same extent for some few years. The grower there has had the misfortune of utter failure of the crop twice in the last five years. About half the crop is reserved for sale as seed, and half for the distillation of the essential oil. The seeds are also grown in the neighbourhood of Beddington, in Surrey, and at Hitchen. The average yield of oil is 3·5 per cent; when freshly distilled it is almost water white, changing gradually to a deep straw color. When allowed to oxidize slowly by long contact with the air the original odor is completely lost and the oil can then be scarcely distinguished from that distilled from "caraway chaff."

Tho oil is distilled in England from the seeds, when scarcely ripe, about the end of August and in the month of September. The specific gravity I have found to vary considerably—from 842 to 858—and this can partly be explained. When the oil has been distilled from the same bulked sample I have noted a difference in the specific gravity. This led me to suppose that by distilling the varied temperatures a light and a heavy oil could be obtained. I therefore submitted some of the oil to distillation, and found that the first distillate was 6 per cent lighter than the after-product, the temperature being raised upon the removal of the first half. This experiment was made with oil obtained from Indian seeds. Some English oil, or oil distilled from English-grown seeds, was similarly treated, and this, too, gave different specific gravities in first and after distillates. The lighter oil had by far the superior odor, and I think this will explain the meaning of the term "extra strong," applied to certain brands of foreign essential oils.

Oil of Dill is not used to any very great extent, the distilled water in England and on the Continent and an infusion in India being the usual form of administration. It is practically unheard of in America.

Ol. Anthemidis, from *Anthemis nobilis.* Only a very small quantity of this oil is distilled either here or on the Continent. A very decided change takes place in the color of the freshly distilled oil, which is then of a very peculiar greenish-blue, and I think unique. This rapidly changes to deep straw color. In England the oil is distilled from the entire plant, and its color is as just described. The foreign oil is brownish-yellow in color, but whether it is distilled from the flowers or the entire herb I am not in a position to state. The oil is contained in largest quantity in the ligulate florets. Sq. gr., ·979 and ·983 in the two samples before me. The old oil is a little lighter, owing to a deposit which is thrown down in considerable quantity, similar to that deposited from oil of bergamot. The oil is an antidote in cases of poisoning by strychnine, acting as a preventive to tetanus and reflex excitability. Although tonic and stomachic properties are attributed to the infusion and extarct they are almost useless.

OL. CORIANDRI, from seeds of *Coriandrum sativum.*—The oil is ordered in the Pharmacopœia in one preparation only—syrup of senna—and the powdered seeds with nauseous preparations of senna and rhubarb, chiefly to conceal the flavor, and remedially as a carminative. The fruits yield only 5 per cent of essential oil, but a much larger percentage of fixed oil is stated to be obtained—about 13 per cent. Corianders are grown in the Eastern counties, and from those the limited quantity of oil required is distilled. From English distillers I have received the answer to my inquiries as to the quantity of oil distilled in 1882 and 1883, *none.* The foreign oil is chiefly in use, and of a very different aroma.

OLEUM CARUI, from the fruits of *Carum carui.*—This is distilled in England chiefly from foreign samples. It would be difficut to say the amount actually distilled from English-grown fruits, but the following facts will give an idea. The grower grows caraway on about 8 acres, and distills the whole, a second cultivates it on 10 acres, and distils about half his product, while a third, whose distillates of most essential oils are very extensive, grows none himself, but purchases a considerable quantity grown especially for him by his relatives and others in his immediate district. The yield of oil varies from 3 to 7 per cent; specific gravity, ·952 to 966. Almost colorless, or slightly tinged with yellow. It consists of two bodies—a thin oil, termed "carvol," and a camphor-like body, "carvene," which, according to Hanbury, can be obtained when treating the oil with alcoholic sulphide of ammonium. I have obtained some in a similar way, bergaptene, from oil of bergamot, by substituting hydrochloric acid for nitric acid. This substance *carvene* must not be confused with oil distilled from caraway-chaff, called "*oil of carven.*" It is very inferior oil; in point of fact, the smell of caraways is hardly perceptible, and it is used largely for scenting soaps and hair-oils. It is imported chiefly from Germany.

The oils of caraways and corianders do not improve by being kept more than a year; if this time be exceeded a disagreeable odor is observed, which is finally not much different from oleum pini sylvestris. The dose of the oil is two to five minims. It is added to cathartic pills, and used to allay the griping action of purgatives.

OLEUM MENTHÆ PIPERITÆ is obtained from *Mentha Peperita.*—I will chiefly confine myself to English cultivation. The produce of the United States is enormous, and considerable quantity is grown in France. The area under cultivation in England in 1883 was: Neighbourhood of Mitcham, about 250 acres; Cambridgeshire about 200 acres; Market Deeping and neighbourhood about 300 acres; Hitchin and neighbourhood, a few acres only. The herb is distilled in the months of August and September, when the flower buds are just opening.

The product varies very much according to the dry or wet state of the herbs; as a rule, from 2 per cent, and, in exceptional cases, as high as 9 per cent.

Specific gravities vary from ·845 to ·915. White needle-shaped crystals, called "peppermint camphor," and almost identical with menthol crystals, now so largely inquired after as a neuralgic remedy, can be obtained by submitting oil of peppermint to 20° or 25° of frost. They are entirely soluble in ether, alcohol, and bisulphide of carbon.

Peppermint is useful for the relief of nausea and flatulence, and is a grateful adjunct to medicines having objectionable tastes. Its use in confectionery far exceeds its application in pharmacy.

OLEUM PULEGII ANG is chiefly distilled in the Southern county, and OLEUM MENTHÆ SATIVÆ ANG. in Cambridgeshire. The former is cultivated more for the dried herb than for distilling. Neither, however, is largely cultivated in this country, supplies for the most part coming from France, Germany and America.

OLEUM RUTÆ, obtained from the evergreen shrub *Ruta graveolens.*—It is only cultivated to a very limited extent, Mitchan and its neighbourhood being, perhaps, the only source. The leaves require to be handled with care, or they will cause painful swellings. If bruised and applied to the skin, violent inflammation is produced, and if eaten, excoriation of the mouth and throat. The oil is of a light buff color, becoming a dark brown on keeping; the specific gravity varies from ·850 to ·910. The odor is very disagreeable. A weak solution of ammonia is the best means of removing it from the hands, and at the same time of all-ay ing the irritation. The dose of the oil is from 1 to 6 minims, and, of the powdered leaves, ½ to 1 drachm. Although enjoying in earlier days a reputation as an anti-spasmodic, anthelmintic, and stimulant, it has, from the uncertainty of its action, given place to more reliable remedies.

Oleum Sabbinas, distilled from the tops, leaves, and galbuli of *Juniparus sabina*, which is cultivated in England. It is grown largely on the Continent, and particularly in that latitude from the Pyrenees to the Caucasus. The product of oil is about ½ to 1½ per cent. The wood does not yield any oil. Specific gravity, ·895 to ·920. Samples have frequently been met with adulterated with turpentine, which may be detected by ascertaining the solubility in alcohol. By adding a noted quantity to a pure sample, and comparing the degree of solubility, the extent of adulteration can readily be proved.

Oleum absinthii, oleum rosmarini and oleum pulegii are distilled in small quantities. Yields of oils vary considerably.

I should like to mention again the subject of lavender cultivation. The main cause of the scarcity of lavender is the loss of plants occasioned by a disease which attacks them visibly in the summer and autumn, the first indication of which is a withering of the leaves, commencing on a small branch and extending throughout the whole plant.

On pulling a plant from the soil on the first appearance of disease, the pith in the small roots will be found discolored and sometimes almost black, indicating that the disease commences in the ground.

One grower writes, "When I commenced growing lavender in 1847, it had not appeared, and for more than twelve years I do not remember to have lost a single plant from this cause; now the complaint has extended throughout this country. We cannot now depend upon the plants lasting more than three years, the first year, even under most favorable circumstances, only paying expenses of cultivation let alone rent of the land.

There has been a marked decline in the number of acres under cultivation the last year. Mitcham and district, 25 to 30 acres; and at Hitchin, Messrs. Ransom & Perks, the two growers there about 65 acres; the outlying districts and every other source not bringing the total number of acres above 120.

In concluding I have to express my very best thanks to Mr. W. Ransom, of Hitchin; Mr. Holland of Market Deeping; Mr. Jones, Carshalton, Surrey, and other cultivators who have sent me statistics and very material information embodied in my paper.—*Chemist and Druggist.*

New Zealand Plants.—Mr. John F. Armstrong, of the Public Gardens, Christchurch, has published a useful list of timber trees, alimentary, fibre, fodder, medicinal, oil, and dye plants, plants for tanning and basket-work, for binding sand-drifts, and for making hedges suitable for cultivation in New Zealand.—*Gardeners' Chronicle.*

Kew Gardens.—The Royal Botanic Gardens at Kew received 53,000 visitors on Monday last, all respectable and orderly. Last Easter the number was only 38,000; the previous year it reached the high total of 56,600. With that exception so large a return as Monday's has not been reached on any Easter Monday, at least since 1878.—*Ibid.*

Propagating Euphorbia, Ficus, &c.—Most of those plants that exude gummy or milky juices are amongst those which are found rather difficult to root from cuttings, if the cuttings have not been exceptionally treated before being inserted in the cutting-pan or bed. It has been found by long practice that the rooting process takes effect sooner and with better results if the viscous juices are allowed to ooze out—a process that may take from twelve hours to four weeks, according to the species. As a rule the cuttings are best taken off just as growth has commenced, and therefore when the juices are rather abundant, still less so than during full growth. In the case of species with ligneous structure the cuttings may be of one, or two, or three years old wood, and should never be less than one year old. These cuttings, after being made fit for insertion, should be buried completely head downwards in a pot sufficiently large to contain them without bruising, and then be covered with some moderately moist soil or leaf-mould. They should remain till all sweating-out has ceased, when they should be taken out and washed clean with a soft sponge, when they can be inserted in the usual way. Cuttings so treated will be found to succeed in a shorter time than those not so handled, and there will be fewer losses in the cutting-pans.—*Ibid.*

Indiarubber in Para.—Reporting on the trade and commerce of Para, Mr. Consul Green says the chief article of export is indiarubber, and that this trade has increased so much of late years, owing to the high prices the article has been realising in the consuming markets, which has induced immigrants to apply themselves chiefly to its collection. "Should the demand continue for the article," Mr. Green says, "I see no reason why the yield should not go on increasing, as there are new fields being continually opened. From Peru now comes a class of rubber styled 'Caucho,' in slabs or sheets of about 4 inches thick and 2 to 3 feet long. It ranks a little higher in value than the coarse quality, *i.e.*, Sernamby, and I should estimate that 400 to 500 tons of this quality come to market every year." From a table showing the indiarubber crops from 1870 to 1882, it appears that in the former year 4,794 tons were produced, which steadily increased till 1881, when it showed 8,936 tons, rising in 1882 to 9,624 tons. The increase in value in the twelve years was about £1,749,011 13s. 4d.—*Ibid.*

The Annual Reports of the Royal Gardens, Kew, have of late years so largely developed in interest that they have become not only the formal record of work done in that establishment, and in the colonial gardens more or less closely connected with it, but constitute a sort of year book of economic botany. It is with regret, therefore, that we have only now received the report for the year 1882. Pressure of work, the ill-health and absence from duty of the Curator, whose duties thus devolved in a great measure on others, as well as other personal reasons of a similar regretable character, account for the delay —a delay, moreover, for which the officials are not wholly responsible, as, to make matters worse, nearly six months have elapsed since the report was sent in. * * Into the details of the colonial correspondence relating to economic botany we cannot now enter, as we may have occasion to make some extracts from them at a future time. We cannot, however, help adverting once again to the splendid service to humanity that Kew and those associated with it have been enabled to effect in the case of the Cinchona in India, Ceylon, Jamaica, and elsewhere, to which may now be added the introduction of the three most important sources of indiarubber into our Eastern dominions, where it has now been proved that they will yield products in no wise inferior to those yielded in the native countries of the trees in question. The commercial importance of this subject can under the existing demand for rubber hardly be over-estimated. The intimate relation between botanical science and practical utility is singularly borne out in the history of these two enterprises. Even the question of nomenclature, a dry enough subject, apt to be looked on by the profane as at the best laborious trifling, and to be slightly considered by the new biological school of botanists, is incidentally shown in the pages of the present report to be a point of first-class importance, to the full as necessary for the successful carrying out these great and beneficent schemes as any other department of botanical science. In quitting for the present the consideration of this report we must not omit to mention one of its most valuable features, which, like the traditional postscript to a lady's letter, occupies the appendix. This is a list of the Palms cultivated in the garden, amounting in all to 420 species. These have, so far as circumstances permitted, been identified by Sir Joseph Hooker, who here gives us a list of the names and localities of the species classified under the several tribes, sub-tribes, and genera, adopted by him in the last volume of the *Genera Plantarum.* In many cases the dimensions also are given, and references made to the illustrations of the plants in the "North Gallery." One more postcript devoted to figures. The number visiting the garden in 1882 was 1,244,167!—the largest number on any one day being over 95,000.—*Ibid.*

Purifying Water.—Water containing vegetable matter may be purified by dropping in a gallon of the water 2 or 3 drops of muriated tincture of iron. In the course of an hour or two the iron will carry all the organic matter to the bottom of the vessel, leaving the water pure and wholesome. This will not purify water that contains noxious gases, such as come from drains and cesspools.—*Rural Californian.*

THE PROPAGATION OF HOUSE PLANTS.

Nothing about plant culture is more fascinating than the multiplying of plants from cuttings. It is the making of a new plant, and one takes all the more interest in a plant thus produced. Florists, with their propagating benches, turn out plants by hundreds and thousands. Their propagating houses are regular plant factories, in which the raw material of cuttings is turned out as the finished product—the rooted plants. Several years ago we published a method by which the amateur could multiply his plants in all needed numbers, and with something like the certainty that attends the larger operations of the florist. The method alluded to is known as "the saucer system," and, as it will be new to a large number of our readers, we give it in brief. The out-fit needed is sharp sand—if from the sea shore, let it be thoroughly washed, to deprive it of all salt—and a saucer, soup-plate or other dish, that will hold an inch in depth of sand. Cuttings are made of the tender growth of house plants, an inch or two long, and set in the sand so closely together as to touch one another. The dish of sand containing the cuttings should be set in a sunny window fully exposed to the light, and the sand, from the beginning must be "sopping wet," and kept in the state of mud continuously. If the sand is allowed to get dry, most of the cuttings will be lost. Some cuttings will be rooted in a week, others in two or three weeks. As soon as roots are formed at the base, the cuttings should be potted off in rich, light soil. Shrubs that do not root readily from cuttings of the ripened stem, will often grow readily in the saucer if a tender shoot be taken.—*American Agriculturist.*

KEROSENE TO KILL INSECTS.—AN EMULSION.

Since the illuminating oil obtained from petroleum, known in this country as kerosene, and in England as paraffine oil, came into general use, it has been employed with variable success as an insecticide. That it would destroy insect life was long ago established; that it would also destroy plant life was sometimes demonstrated in a manner more convincing that pleasant. The oil in its concentrated form can be tolerated by but few plants. The first improvement in its use was to add a very small quantity to a bucket of water, enough to make but a mere film upon the surface: then diffuse it through the water by violent stirring, and apply before the oil and water had time to separate. This answered fairly well, but was troublesome. The next step was to divide the kerosene, not by dissolving it, but by diffusing it in the form of an emulsion. It is well known that oils may be suspended in water by means of gum, sugar, etc., and may be kept thus for some hours or even days. It has been discovered that milk, either fresh or soured, is a convenient medium to unite kerosene and water. Mix together kerosene and half as much milk, stirring them thoroughly to form a creamlike mixture. When the two are so completely united that no oil is visible, dilute the mixture with twelve times its bulk of water, adding the water gradually, and stirring thoroughly. This emulsion has been found especially useful in the treatment of the various scale insects, so difficult to destroy by ordinary insecticides, and is used for various other insect pests. For trees use a syringe or force pump, and for house-plants, often injured by scale insects, apply with a sponge or swab.—*American Agriculturist.*

RENDERING SHINGLES WEATHER AND FIRE PROOF.

Some of our eastern exchanges have of late contained articles on the use of crude petroleum on roofs to increase their durability. While there is no question of the preservative properties of petroleum when applied to wood of any kind, its use on the roofs of farm buildings is certainly dangerous because it increases the danger of fire from sparks from the chimney. A much better preparation of shingles is that used by some of the railroad companies whose depots are especially liably to take fire from sparks from the engine. The shingles in the bunch are boiled for a half hour in a solution of lime and salt, which penetrates every particle of the wood and renders them in a large measure fire proof, besides adding to their durability. In laying these shingles the roof boards are laid close together and covered with a thin layer of hydraulic cement and the shingles laid upon this, thus forming a fire-proof layer between the lime and salt saturated shingles and the roof boards. Any farmer the owner of a cauldron kettle could, at a small expense, give shingles which he proposed to use, this lime and salt saturation, though of course a large tank would do the work more cheaply and expeditiously. The use of cement between the shingles and roof boards is also an easy matter. It is mixed up thin in small quantities, as for plastering a cistern, and spread evenly with a trowel upon the roof boards about a half inch thick, keeping just ahead of the shingles so that the shingles will be partially imbedded in the cement before it becomes hard. With such a roof the entire shingles might burn off without the fire being communicated to the roof boards, though as a matter of fact it will be hard to start a fire on the lime and salt saturated shingles.—*Farmers' Review.*

GINGER BEER PLANT.

The Editor of the *Gardeners' Chronicle* has several times been requisitioned by correspondents (mostly anonymous) for a scientific description of the "Ginger Beer Plant." The correspondents wants to know its botanical name and native country. The writer of this note has also been tormented weekly, almost daily, on the same subject for two or three years. Every one has been asking him for the "regular Latin or Greek name" of the "Ginger Beer Plant." Benevolent old ladies, clergymen and officers of the Blue Ribbon Army, have called upon him, or written for a scientific explanation, hoping to make the "Ginger Beer Plant" a boon for the poor. One person wished to feed paupers with it; another hoped by it means to knock all the publicans on the head; a third to send it in barrels for the army in the Soudan. When such persons have been told it is merely a form of German yeast they have turned away disappointed and disgusted. Something more must evidently be done for this rum shrub, of which I have recently had applications for slips, rooted cuttings, and seeds.

The last letter sent to the *Gardeners' Chronicle* was to this effect:—"I cannot learn anything more about it than that it is an American plant. Cannot find out where it is procured—only how to make it. Empty the contents of the small bottle into the wine-bottle. Bruise about half an ounce of ginger, two table-spoonfuls of white sugar, put in a jug, pour boiling water over it, let it stand till nearly cold, then put the plant in the bottle of ginger, sugar, and water. Cork it tight, and when it begins to ferment the cork will fly out. The plant will grow if fed every day, and soon be enough for two bottles. It is best to empty it once a week into a pan and wash it with cold water, then put it in the bottle again."

To the unaided eye the Ginger Beer Plant looks like a lump of paste, and when placed under the microscope it is seen to consist of more than one of the Yeast fungi, in a mucilaginous medium. It belongs to the group of fungi termed Saccharomyces, of which there are many species, the one used for beer being S. cerevisiæ. Mr. Berkeley, Mr. Hoffmann, Mr. Huxley, and many other gentlemen, British and foreign, have written about yeast in its different forms and conditions.

The "Ginger Beer Plant" like all other yeast fungi, excites fermentation in sweet solutions and sets free carbonic acid gas. The carbonic acid gas formed in the process of fermentation at length causes the cork of the ginger beer bottle to fly out as a sign of maturity.

As all the correspondents insist on this "American plant" being a new species, I propose to humour them by calling it Zingibeerophora spumacephala!—W. G. SMITH. [Mr. Smith favours us with a Latin description which, to avoid possible perplexity, we omit.—ED.]—*Gardeners' Chronicle.*

NETTLE-FIBRE.

In the *Deutsche Allgemeine Polytechnische Zeitung*, Dr. J. Moeller gives a report of experiments on the histological character of the fibre of the common stinging-nettle, *Urtica dioica*, and its applicability to technological purposes.

The primary bast-bundles of the stem do not form a connected ring, and its fibres are mostly separated by intermediate parenchyma. The cortical parenchyma is not sclerenchymatous. At the base of the stem the fibres are mostly about 0·12 mm. in diameter; higher up they are thinner; but even at the summit they have a diameter of 0·04 mm. The thinnest fibres of the nettle are therefore as thick as the thickest of hemp. In consequence of their isolation they are seldom polygonal. At the commencement of the time of flowering the fibres in the upper portion of the stem only are completely thickened; those in the lower part have still large cavities. There are no pore-canals. Fibres were measured 22 mm. in length; they are very irregular in form. They consist of nearly pure cellulose; their behaviour with cuoxam is characteristic. They swell with extraordinary rapidity from without inwards; a sharply differentiated internal layer resists the action for some minutes; but this is also at length dissolved; and in addition to a small quantity of contents of the fibres a delicate network remains, the primary membranes of the parenchyma cells which surrounded the fibres.

Fibres baked or treated with acids or alcohol show two peculiarities. They are very irregularly isolated, being either united into bands or disintegrated into separate fibres; there are no thin bundles, like those of combed flax or hemp. This peculiarity depends on the structure of the primary and on the want of secondary bast-fibre-bundles. The second peculiarity is their complete and nearly regular investment with parenchyma, in consequence of which they are rough and dull; resulting from the incomplete differentiation of the wall of the fibres and of that of the parenchyma-cells.

Both these peculiarities are very disadvantageous to the employment of the nettle-fibre as a technical product. The chemical means employed to separate the fibres completely from the surrounding parenchyma would affect injuriously the fineness of the fibre.

Attempts have been made to naturalize in Germany the North American *Laportea pustulata*; but similar disadvantages attend the structure of the fibre. In August the bast-fibres in the upper third of the stem are not yet developed; in the lower portion they are but imperfectly thickened. The cortex, bast and fibres, resemble those of *Urtica dioica*; but the fibres are considerably larger at the base of the stem, usually, 0·5 mm. in diameter, and more than 80 mm. long; in the middle part of the stem they have still a diameter of 0·1 mm. They consist of pure cellulose; they dissolve rapidly and completely in cuoxam, leaving behind a parenchymatous network and the protoplasmic contents of the fibres.—*Pharmaceutical Journal.*

SUBSOILING AND TILLAGE.

Prof. Sanborn, of the Missouri Agricultural College, has, the past Summer, been conducting experiments bearing upon the question whether subsoiling and frequent stirring of a cultivated soil tends to make land dryer or less dry during a continued drouth. He gives his experience in Bulletin No. 5, from which we condense the following extracts:—Two areas of similar land, side by side, of one-tenth acre in area, each, were plowed seven inches deep. No. 1 was subsoiled nine inches deep, or stirred sixteen inches deep in total. September 12, when the severe drouth had become very pronounced, I drove an inch gas pipe fifteen inches deep in four places on each plat; mixed the soil of each plat thoroughly, and tested for moisture. From 960 garins subsoiled plat, 97 grains of water were evaporated. From 960 grains of soil not subsoiled, but 80 grains of water were lost by evaporation, making a difference of much importance in the total moisture of an acre, and which was made evident in the total product of the two plats. The subsoiled plat yielded of corn at the rate of 70·1 bushels per acre, while on the unsubsoiled plat the yield was but 49·3 bushels, while the variation in the yield of stover was only the difference between 4,734 pounds and 4,022 pounds, the diminished grain yield on the unsubsoiled plat being undoubtedly due to a lack of moisture at the critical period in the growth of the crop when the ears were being filled out. To show the difference in another way it may be stated that on the subsoiled plat it required only 67·5 pounds of stover to yield a bushel of grain, while on the plat not subsoiled, it required 81·6 pounds of stover, or stalks, for a bushel.

The experiments in tillage were made upon bare soil, an area being stirred daily, to the depth of two inches from Aug. 10 to Sept. 7, during which period the drouth had become very severe. On another plat adjoining, the surface was stirred but once during the period named. At the expiration of the period, samples of soil were taken at half-past five o'clock in the morning, from both plats, dried and weighed, the scales showing that the upper six inches of soil contained most moisture from that portion which had been stirred daily. Prof. Sanborn, however, would have it understood that tillage, to conserve moisture, must be very shallow, say not over two inches in depth, the aim being to get a thin layer of dry surface soil, that will act as a non-conductor of moisture between the dry air above, and the moist surface below. "Hence, deep tillage of surface rooted crops, like corn, is an erroneous practice, founded in erroneous views. Plowing out corn involves too deep tillage in dry weather, but adds to the mischief by severing the roots of corn needed at such times. Our double shovel plows work too deeply. Our true policy in drouth for corn is frequent and shallow tillage." The Professor thinks that nearly all our cultivators are defective in that they run too deeply for the best results in dry weather.—*New England Farmer.*

A NEW DEPARTURE IN QUININE.

One of the natural results of pernicious tariff legislation is now brought forcibly before the people. A few years ago the cry of free quinine became a popular one and demagogues and tricksters urged that a duty on quinine was taxing our fever stricken poor. The result was that in deference to this clamor quinine was placed on the free list, although some of the crude materials used in its manufacture had to pay an import duty. The alkaloid could be produced cheaper in foreign countries by reason of cheaper labor and cheaper materials, and the natural result could be foreseen—either that the foreign article would take the place of that of domestic manufacture, or our manufacturers would be compelled to establish factories abroad. The first of these probable results was averted by reason of the superior excellence of the American manufacture, the foreign made quinine selling in this market for about ten per cent less than is realized for the domestic make. The effect of the removal of the duty in the other direction has been averted so long only because the manufacturers here had expensive plants which could not be allowed to remain idle. A change has, however, been precipitated by the recent destruction of Messrs. Powers & Weightman's quinine manufacture at Philadelphia. As it will take some months at least to rebuild their works at Philadelphia, this firm concluded at once to inaugurate a new departure, although they will push the erection of new works on the site of the buildings recently destroyed with as much haste as practicable.

Mr. Alexander Boehringer arrived in this country, on a contemplated trip through the country, a day or two after the fire in Philadelphia, and at once tendered the use of one of the factories in which he is interested, and Messrs. Powers & Weightman have made arrangements to operate the factory at Milan, the largest quinine manufactory in the world. To this end they have already shipped about 3,000 bales of bark to Genoa, and Dr. John F. Weightman, with his family, departed for Milan, where he will superintend the manufacture of quinine as he he has heretofore done at Philadelphia, employing the same processes that have produced such satisfactory results here; and, although the quinine will be made at Milan, it will practically be the same American quinine that has always been produced by this firm. This transfer of the manufacture to a foreign country at first caused some surprise in the trade, but there were none but acknowledged the wisdom of the course. What the outcome of this move on the part of the Philadelphia firm will be is not certain, altuough if it is proved that the article can be manufactured cheaper at Milan than at Philadelphia, it would be folly to expect that the firm will again manufacture quinine in this country as extensively as heretofore. Other manufacturers will watch this experiment with keen interest, and some are of the opinion that this is the beginning of the end of this industry in the United States, and that it received its death-blow in the unwise removal of the entire duty formerly levied on this article. During the present agitation of the traiff question, it would be well for the advocates of sweeping reductions, and of the pronounced free traders, to study these results, and possibly they may learn caution, if not wisdom, from the lesson here presented. There are many articles which will bear a material reduction in the duty now imposed, while others could stand very little or none, and other industries will, doubtless, have to be killed before the wiseacres at Washington will heed the advice, and profit by the practical experience of the merchants and manufacturers of this country.—*Independent Record.*

A CHAT ABOUT CEYLON FRUITS.

Many, and widely spread over the length and breadth of Ceylon, as are its indigenous, its introduced and acclimatised fruits—highly salutary, too, as they are acknowledged to be in the dietary, both of the European and the native inhabitants—it is remarkable that, owing to an almost total neglect of culture, even of the roughest kind, how poor in size and coarse in quality they are mostly found to be, and how very badly they compare with the same fruits grown in other tropical latitudes even less favourable to their habits and idiosyncracies. The Pine-apple of Ceylon, except we can manage to secure it from the botanical gardens near Kandy, or from some experienced cultivator, is as a rule a hard, skinny, tough, and sour production vastly below that same Ananas of the West Indies, the Bahamas, the "White Man's Grave" in Africa, and other places we have visited. The very "first chop" Mango, which the lowcountry Sinhalese or the Kandyan grower will bring to market, is, in one word, trash, as compared to the large yellow fleshy Bombay fruit overflowing with luscious juice, or even with the smaller but equally delectable "No. 11" of Jamaica, and when you find a Ceylon mango quite free from stringy fibre and without the smell and the taste of turpentine more or less strong, make a gustatory note of it —it is a *rara avis* of its kind. At Jaffna, in the Northern Province of the island we are dealing with, and there only from the garden of the late Mr. Dyke—an expert in horticulture—have we ever tasted Mangoes worthy of the name. The Pummelow, or Shaddock (Citrus decumana), that cannon-ball sort of an orange which now-a-days we so frequently see in the windows of our fruiterers' shops, when grown in the West Indies is a tender fleshy fruit, a regular *bonne bouche*, over-running with an abundant sub-acid refreshing juice, delicious to revel in when fevered. But if we happen to meet this same Brobdingnagian Orange in Colombo, Kandy, Trincomalee, or elsewhere in Serendib (the old name for Ceylon)—and meet it we are sure to do, for it is common enough—*cave*, for ninety-nine times out of every hundred it is a cannon-ball outside and a cannon-ball within, the pulp contained in its closely packed tough, leathery sections, being hard, bitter, and as dry as a bone. And *apropos* of the Orange itself, how seldom does the thirsty traveller get one as succulent, sweet, and refreshing as those grown in other of their well-known habitats, even though he, the traveller, tramp all over the island for the cooling fruit. The Ceylon Orange tree is a deception and a snare. It blossoms as sweetly, it bears as freely, its product is as enticing to the eye as any of its species anywhere, but barring the Mandarin and one other variety which now and again literally and metaphorically crop up, the ordinary native-grown fruit is an Orange by name only —*vox et prœterea nihil*. Better to call it the "sweet lime," and by which appellation indeed it is sometimes known.

Alas! that in our chat anent the fruits of "the spicy isle," where, according to Bishop Heber, "man alone is vile," we should still continue to disparage, but in truth the Tamarind and the Lime, the Guava—that emperor of fruits, for its tooth-some jelly, and "*dolce*" of the West Indies—the Cashew (Anacardium occidentale), who does not know the kernel of its roasted nut as an after-dinner wine flavourer? The Papaw (Carica papaya) and the Plantain—we are enumerating the commoner fruits found in almost every native's garden—are very much below par with those same flourishing wild around the hut of any West Indian or African negro.

Space is wanting for our specifying in what particular characteristics the differences between the fruits we have alluded to exist, but, nevertheless, our statement may be accepted as fact—"'Tis true, 'tis pity, and pity 'tis 'tis true."

And now, if we take a very rapid glance at two or three of the fruits which are less common, and upon which some horticultural pains have been bestowed, or they would not be there at all, we shall yet see that these, too, fall far short of the every-day quality of their kinds in other lands. The Avocado Pear (Persea gratissima), the Subaltern's Butter of the West, is here in the East a smaller, harder, less buttery, thicker-skinned, and more stony production. The Custard Apple (Anona reticulata) is the worst of its kind we have ever eaten or tried to eat in "all our walks abroad." The Anona squamosa (Sweetsop) and the A. muricata (Soursop) are wretched, sapless, "cottony" imitations of their saccharine and juicy fraternity in Jamaica. And as for the Grenadilla (Passiflora quadrangularis)—I had a vine of the plant growing in the compound (yard) of my quarters in a certain up-country station; I treated the sparse but yet white jelly-like contents of the soft green capsules as systematically as I had seen them treated and enjoyed them in other tropical climates, but I could never get rid of a sort of uncanny twang—spice, wine, and sugar the stuff as much as I pleased.

From the remarks I have made it can be quite understood that a dessert table in Ceylon spread with its fruits, decorated with its brilliant many-hued flowers, and adorned artistically with leaves and the ivory-like spray blossoms of the Coconut Palm, which latter the Sinhalese or Tamil never omits to use liberally, is, indeed, an attractive picture to look upon—very! but it is eye-taking to the guests, and that only, for save and except certain dainty dishes of fruits, to be spoken about, be included, the whole collection, from the aristocratic Pine to the plebeian Plantain will be left untouched. And why this? Because, as we said at starting, even the most rude, haphazard cultivation has been pertinaciously neglected. The tree once planted must take care of itself, to bear, or not to bear, as Heaven chooses. And this *laissez-aller* sort of unconcern is somewhat remarkable too—at least, among the natives, who are Buddhists in religion, for their sacred books tell them, and Gotama Buddha, their high priest in Ceylon, encouraged them to plant fruit trees in highways and byeways for the use of all itinerants—to plant unquestionably, say they—but never a word of tending they add.

Just now we wrote that if certain fruits happen to lie upon the dessert-table they were sure to find favour in the mouths of the epicurean guests. *Primus ante et inter omnes* will be the Mangosteen, that most delectable of all Eastern fruits, and which Sir Emerson Tennent lauds as in delicacy resembling "perfumed snow." Be certain if host or hostess has got for love or money Mangosteens they will be pounced upon and devoured. Some of our readers may not know this, the alpha of fructaceous edibles. It is the fruit of the Garcinia mangostana, natural order Guttiferæ, a native of Java, the Straits of Malacca, and the whole archipelago thereabouts, but introduced and cultivated sparsely—alas! sparsely—in Ceylon. It is about the size of a small Orange, purplish-black in colour when quite ripe—if any one has seen the Star Apple, Chrysophyllum Cainito of the West Indies he may form a very good idea of its appearance—and three-celled, each cell containing a seed thickly enveloped with a pure white pulp of exquisite odour, and a taste entirely its own. We have eaten a vast number of the fruits of the tropics and known not one which at all resembles it. Some say the Sapodilla—*credat Judæus.*

Another fruit which treads closely upon the heels of the Mangosteen is the Rambutan (Nephelium Lappaceum), of the Sapindaceæ or Soapwort tribe. It is about the size of a large Date, oblong or roundish in shape, grows in thick clusters on the tree, and consists of a seed stone, covered with a white pulpy substance within a fibro-elastic capsule, reddish-brown in colour, and from which many soft, long spiculæ or points spring. When this indiarubber-like capsule is bitten through, the seed has a great tendency to be forcibly ejected, and we have seen it thus catapulted into a neighbour's face.

If the eater can get over the highly offensive civet-like smell of the Durian (Durio zibethinus, nat. order Sterculiaceæ) —but it requires much nerve to do so—there is hardly a greater treat in Ceylon than this fruit. The real Durian is not indigenous to the island; it comes from the same localities as the Mangosteen, and was introduced by the Portuguese in the sixteenth century, but it has another and more odoriferous brother, the Sterculia fœtida, to which the name of Sinhalese Durian has been applied. And now that we think of it, the Mangosteen has a very near relation in the Goorka, found wild in the jungles, uneatable save by the not-over-particular native. The despised and rejected by Europeans, Jâk (Artocarpus integrifolia) is by no means as bad as it is made to be, bar again the effluvium of its ripe and freshly cut fruit, which is the largest of all the edible ones in the world, and is made up of an infinity of stones, around each of which is a toughish, straw-coloured substance, sweet almost to mawkishness, and overflowing with juice. The Eastern substitute for roasted Chestnuts are its seeds aforesaid.

Lastly, one little word of chat about the Coconut, not as we know it in this country, but as we gather it—young, unripe, from its Palm in one of the thick belts by the sea, where it flourishes so luxuriantly—nowhere better than in Ceylon. The white, soft, gelatinous pulp scraped gently with a spoon from the yet unsolidified inner lining of the shell and mixed with the sweet, turbid, and cool "milk" is as nectar, and not so intoxicating. Old wives say that it is unwholesome—*ne crede Teucros.*—H. L. C.—*Gardeners' Chronicle.*

SUPPLEMENTARY NOTE ON CERTAIN CHINESE PLANTS ACCLIMATISABLE IN THE UNITED STATES.

BY DR. MACGOWAN.

[Subjects of previous note:—square, black, edible and paper bamboos: coir-palm, bannian, plano-convex-turnip, mat-grass, glutinous and red rice, bitter orange; specimens of living plants and seeds being forwarded, with a plea for an experiment with the Yak, or "grunting ox," hosphogus (*Bos grunniens.*) These specimens are, or ought to be, under trial at some of the agricultural experiment stations recently founded in several states.]

In compliance with a request of Edmund Stevens, Esq., American Consul, Ningpo, concerning several plants and their adaptability to acclimatising in the United States, the following notes (with matter not strictly germane to the text) are respectfully submitted, being supplementary to others on the same subject already published; premising that besides the plants indicated by Consul Stevens, there are many more that merit attention which are left for discussion by other American observers in China.

1. "Ningpo varnish" the commercial name of the *Chin Ch'i, i.e.,* "golden varnish," is a compound article, the product of two trees that first require to be described.

The basis of Ningpo varnish is obtained from a tree which Dr. Bretschneider says has not been described [botanically]. It is a kind of Rhus, denominated *Augia Sinensis* by Loureiro, and has a wide range, extending from the inland mountains of Chehkiang to the extreme west of the empire; the provinces of Hupeh, Shensi, and Szechuan are the chief sources of supply. In old books, Shingking in Manchuria (N, Lat. 38, corresponding in soil and climate to New England), it is stated, produced the best article. Chinese botanists describe the *ch'i shu* (varnish tree) as resembling persimmon (*Diospyrus*) with flowers resembling *Sophora Japonica,* and leaves like *cedrela odorata,* and having white bark: it is from 18 to 24 feet in height; and is compared by some to the ash. It is directed to be planted in the spring by one authority, and in winter by another: it is easily transplanted, and then, apparently, takes care of itself. In some places the sap is drawn in spring, and in others in autumn. Trees that are not vigorous are left until they are found in a thriving condition. The spot selected for operation is smeared with nut-oil (presently to be described), and an incision over an inch in depth is then made by night into the alburnum, into which a bamboo tube, cut obliquely at the point, is inserted, when the varnish gradually oozes out in a viscid condition and is passed through a gauze sieve. At first, its colour is pale yellow; then it becomes reddish brown, and soon as black as ink [thus resembling the black varnish tree of Birma. *Melanorrhoea Usita.*] An emperor of the middle of the sixth century once asked a courier "What is the blackest thing in nature"? "Varnish," was the reply. Yet as found in the shops the viscid mass is brown; it becomes black only when spread out and dried. Blackness is a test of quality; when it is pale yellow, it is inferior, presenting a honey-comb appearance: the best article is obtained with difficulty. It is frequently adulterated. Test:—Scoop up a small portion. If it is stringy, slow to separate, and, breaking, at once retracts, it is pure. Daub some on a bit of bamboo; place it in the shade; if it dries quickly it is good. Fanned, the genuine article looks like a mirror; dipped up, it retracts like a hook; shaken, it presents an amber appearance; and beaten, it becomes frothy. It should be further tested by brushing it on bamboo; if adulterated with nut oil it dries slowly and is lacking in blackness. It imports to sign boards which adorn Chinese streets their jetty gloss, beautifully contrasting with their gilt lettering. When applied, a priming of soot of brassica oil is laid on the board, when it receives a coating of varnish, which when dry is rubbed smooth with glue, followed by a second coat.

A peculiarity of this article is its requiring a considerable degree of moisture to dry it. In damp weather, three days suffice; in dry weather, several weeks are required; a sudden fall of temperature in winter causes recently coated utensils to present a fractured, wrinkled surface. Ningpo cabinet-makers use small chambers specically constructed for the drying process by artificial moisture; they are plastered with mud—walls, floor, and door—which is well watered; in these dark damp receptacles varnished articles dry in a couple of days. The paradoxical statement that Chinese varnish requires damp weather for drying is explicable by the wood on which it is laid being then more absorbent than when dry. Most wooden utensils in common use are of a bright red colour from the mixture of vermilion with the varnish: for coarse purposes, a ferruginous clay is used, which imparts a dull red. New articles require to be washed for some times (after being used) and sun-dried; otherwise they are readily stained. When once thoroughly seasoned, the-vitrious like coating resists the action of vinegar, salt and the like, and boiling water. The wood of the varnish tree is yellow coloured; it possesses no economic value. The acridity of varnish-poison is too well known; its emanation inflames the cuticle of about one per cent of natives who are exposed; foreigners are more susceptible, Americans most of all; no number of attacks affords immunity to the susceptible. Dealers in varnish and varnished articles if removed for a time from its vapours are attacked as severely as the uninitiated, and are obliged to resort to prophylactic measures:—thrusting pine shavings into the nostrils, smearing themselves with nut-oil. The Chinese remedies for the painful inflammation are crabs' liver, and a decoction of pine shavings. I have found lead lotions the best application. With regard to acclimatising the varnish tree in the United States, I advise that plants or seeds be procured in the West, although Japan (which also furnishes it) would be more convenient. When alchemy was in vogue, varnish was an important ingredient in elixiris of immortality; it is now used as an anthilmintic and emenogogue. This varnish was in use in prehistoric times. Among the arts communicated by the Chinese to Indo-Scythian peoples, was the preparation of varnish, from trees that they found growing in Northern India (second century B.C.), which the natives did not know how to turn to account; teaching them sericulture at the same time, and the reduction of iron ore also; but it did not form a constituent of Ningpo, or golden, varnish until the Tang period (say eleven centuries ago) when the Ningpoese acquired the art of preparing it, by mixing it with nut-oil, which is next to be described.

Nut-oil, the "wood-oil" of commerce (a misnomer) is the product of the hill *t'ung-shu* and the green *t'ung-shu,* which have been designated *Eleaococca vermeosa;—Aleurites cordata-vernicia montana;* both kinds had better be designated "oil-nut trees." Were the Chinese to select a tree as a national emblem, the nut-oil tree would be unanimously chosen, having beauty, utility and universality to recommend it. Poets never weary descanting on it from an æsthetic point of view. "Its bark has the hue of the kingfisher, its leaves (bracts) are like flowers; its elegance rejoices the heart and gladdens the eyes." Williams styles it the national tree of China; among foreigners it is regarded as a fine umbrageous specimen of sylvan nature: nothing more.

The hill oil-nut tree is the chief source of supply of nut-oil—"wood-oil"; it is sometimes called the "tiger oil-nut tree," from the poisonous nature of its fruit, and sometimes the "jam oil-nut" because its nuts resembles poppy capsules. It is of slow growth and is not lofty. It blossoms in spring, its flowers being pale red, producing a large round nut, each carpel containing two or three white seeds, having a sweetish taste and causing emesis. As its name implies, it grows on hills.

The green oil-nut tree, following still Chinese accounts, is sometimes called "coffin nut-oil tree, because of its ancient uses, and sometimes the *wu* oil-nut: it is straight, with a pale green bark, having bracts which resemble the corolla of a flower; its wood is firm. It flowers late in May, they are in racemes, small and yellowish, carpeting the ground; truly it is a beautiful tree." It produces fruit about the size of peas in July and August, adherent to the margin of the bracts. Its leaves are the last to appear, and the first to become sear and yellow. Both species are similarly treated: planted early in February, the seeds being mixed with clay and sawdust: to be freely watered every day. When a foot high they are to be transplanted from the nursery. The nuts are plucked when green; if they are allowed to ripen they will be destitute of oil, and instead of being acrid and poisonous, are edible. A rude press, such as I have described as used in separating stearine and oleine from the seeds of the tallow tree (*stillingia [excœcaria] sebifera*) is employed to express the oil from these nuts. Sometimes oil is cold-drawn, and sometimes heat is employed. The refuse is used for manure. Tallow tree oil is used as an article of adulteration, and also the still more inferior oil obtained from beans; with those adulterations varnish takes a long time to dry, and is of little use. Spurious oil may be detected by scooping up a portion with a small bamboo loop; if genuine, the oil will adhere in a film across the loop like a parchment over a drumhead. It is in universal use, for houses and boats; it is invaluable for caulking, and is used also in making the best kind of mortar. A mixture of glutinous rice congee, nut-oil, lime and sand was used on the Wusung forts; lime is sometimes omitted. A great amount of pounding is required to render the compound perfect. Before using nut-oil for any purpose it requires protracted boiling. When used for forming "golden varnish," nothing is added; but when used as a pigment, a small quantity of silver dross is added in boiling to facilitate drying, and at the same time a little white lead to impart lustre.

When applied, the wood is first smeared with pig's blood for dark red, and red clay for common red, and an infusion of flowers for yellow. Oil-nut wood is employed for musical instruments; the trunk for lyres, and the branches for lutes (their sonorousness differing). A species that is valued for its timber (being impervious to attacks of insects) does not produce nuts.

Its relation to folk-lore may be worth noting in conclusion. Among their innumerable modes of weather-forecasting, the Chinese say that a leaf of this tree falls on the day and hour when the sun enters the 15th sec., 9th August; there is an odd leaflet terminating the pinnate whenever an intercalary month occurs; when the buds are very red, a draught will follow; when they are unusually white, it betokens a wet season.

After this tedious account of the constituents of Ningpo varnish the story of its preparation may be soon told. When the aricle is good, it is composed of equal parts of varnish proper and nut-oil; but both ingredients are commonly adulterated.

It is now in order to offer a a few remarks on other varnishes. An important varnish is obtained from a wild persimmon *Diaspyros kaki sp.* (the cultivated and properly cultivated fruit of China is very different from our styptic persimmon). Its sarocarp is left to decompose in tubs in its own juices, a little lime being added; in a fortnight, or so, it becomes a putrid fetid mass, which, when deprived of seeds, is an excellent varnish. Without it umbrella makers could not pursue their vocation; two coats of it are laid on the paper (a tough material, the bark of the paper mulberry, *Broussonetia Papyriferi*) and then nut-oil is applied to kittysols and umbrellas. This is the varnish that is used to line willow baskets in which bean-cake oil is stored and transported.

A varnish resembling that yielded by the persimmon is obtained from what appears to be an alga; its appearance is compared to the *Paeonia albiflora*. China does not appear to produce a lac insect; but an ant is found in Annam that secretes a varnish. When a spot is recognised as containing their nests, it is dug, and a bit of bark is stuck into the hole, when the ants emerge and secrete a varnish. I commend this entomological subject to French naturalists in Tongking for investigation.*

* Chü-feng in Ch'ing-hua (obsolete Sung name) is named as the habitat of the varnish ant.

Dr. Bretschneider in his paper "Early European Researches into the Flora of China," states that Vol. xxii., Philosophical Transactions, contains an account of the way of making Chinese varnishes sent by the Jesuits in China to the Grand Duke of Tuscany.

II.—*Yang-mei*, sometimes called tree strawberry, or arbutus *myric sapida morella rubra*, for which the region about Ningpo is celebrated, "producing the best fruit of the kind in the Empire," Hsiao-hsing the coterminous department being included in the famous yang-mei country. It is only the very best that foreigners care to eat; as commonly found it is too sour. It resembles mulberry.

Cultivation.—Macerate the seeds in night-soil from the time of collecting, in May, for a month; place them aside until March following; then plant. When a foot high, transplant, or three or four years later, when other trees are to be grafted on it, transplant on a hill with its surrounding earth. In January dig a semi-circular trench about it from four to five feet distant, where the ground is higher than the tree, and place night-soil and ashes therein. Mulberry grafted on the yang-mei produces fruit without sourness. When the tree suffers from insects drive liquorice pears (*Glycyriza*) into the affected part; it will act as an insecticide. Grafting fir on this tree is not named in the books, but is practised by the Ningpoese; hence the fruit has often a terebinthine flavor.

This grafting of yang-mei on fir, a matter so much at variance with horticultural canons on the art of grafting, invites digression. It has been authoritatively stated that grafting was introduced into China by Jesuit Missionaries. That is a mistake. If the art was communicated by missionaries at all, it was by Nestorians, for Su Tungpo, the great poet and statesman, and writer on agriculture as well, (1036—1101 A.D.) gives directions respecting the process. Perhaps it followed the introduction of the vine into China in the second century B.C., or its origin may be traced to colony or pre-Christian Jews who erected a magnificent temple in Ch'én-tu.

It is taught that growth by grafting can take place only among plants of the same family, or order. Chinese horticulturists teach nearly the same thing. The stock and shoot must be of the same nature, or must have a constitutional affinity, (an idea suggestive of a special classification). The grape furnishes another illustration. It is planted near a Zizyphus, which is perforated to receive a branch of the vine; when by its growth the branch fills the hole, the vessels of both inosadating, it is severed from its parent, and produces and improved grape. Persimmon is grafted on peach—a fact noted by D'Entrecalles (1741) and quoted by Bretschneider, who says he was unable to confirm it. Books, and common report also, say that the black date zizyphus (*Dyospyros Lotus*), is grafted on persimmon and persimmon on that plant. At Hangchow a peach is brought to market called "White William peach," which is said to be obtained by grafting one on the other. Chestnut is grafted on a species of oak. Wenchow pomelo cultivators are not content with grafting until the fifth generation is reached—that is, on an engrafted branch of last year another is engrafted this season, and so on annually until the fifth year. Chinese floriculturists are famed in their art, particularly in grafting. The *Oleafragrans* which flowers in Autumn, is in Spring made to bear Japonicas. By grafting Buddha's finger (*Citrus Chirocarpus*) on a peony (P. Moutan) its vitality and fragrance are greatly prolonged, although no union takes place. Much more might be said on this subject. Certes, if the Chinese did not originate grafting (I assume they did not) they have cultivated it with signal success.

The kernel of the berry is recommended in "malarial leg," or beriberi (a malady that elsewhere I have described as existing in China) and a decoction of the bark, or root is used in ulcers, and various cutaneous diseases; the ashes of the same are an antidote to arsenic: and is used also mixed with oil as an application to a scalded surface.

Annam produces a yang-mei, as large as a bowl from which a famous liquor is prepared.

III.—Lichi, the other article on which information is desired is a delicious tropical fruit (of which there are between thirty and forty kinds) but is found as high as 30° N. In Szechuan. The kind most lauded in the books is produced at Huian in Fuhkien 25° N.

It is found on level ground adjacent to hills, and thrives best at a distance from water, although moisture and heat are essential conditions to its vigorous growth; it would not succeed in arid portions of the South; but the hummocks and high prairie land of Florida might prove adapted to its culture. Chinamen who have partaken of its fruit will generally concur, an illustrious statesman and patriot Chang-chow-ling of the eighth century, who wrote a poem on Lichi, lauding it as incomparably the most luscious of fruits. Many attempts were made by the Emperor Wuti (140-87 B. C.) to introduce it from Annam into his garden at Chang-an. For successive years hundreds of plants were brought from that distant region (as if the cultivation had not then extended to China) all quickly dying; at last one survived, but for a single season only when further attempts were abandoned.

In its contour, the Lichi is compared to an official umbrella or canopy, its name is descriptive of the toughness of its stack funiculus "trebly strong," it resembles a large strawberry, its watery pulp is covered by a tenacious integument which is compared in books to lard; it encloses a hard seed. The leaves are compared to those of the orange, the seed to the *ligustrum lucidum? phyllodes placentaria?* In Kuangsi it grows on the hills, in Kuangtung on plains, at a distance from water, it is not easily cultivated, its roots tending to the surfaces, rendering it necessary to pile on earth and manure, it flowers in March or April, ripening in July or August. Requiring to be protected by a covering from cold for its first five years, it is remarkably sensitive when owing to frost which destroys it and to electricity; when there is much thunder, flowers and fruit are small; much rain is hurtful, and in a drought the tree bears no fruit; and exposed to mark emanations no fruit is produced; that drug causes the flowers to fall. When the fruit is cut from the tree, the operation must be completed at once, for birds and bats devour what remains;—those bipeds seemingly hold aloof until man has had the first cut.

Medical writers describe lichi as heating, but men have been known to eat a thousand a day. Su Tung-po allowed himself three hundred per diem, and so delicious were they that the poet declared they might reconcile one to eternal banishment;—the poet was in exile at Canton. As a medicine it is given to hasten small-pox pustules, and in the delirium of fever accompanied by thirst it tranquilises; it is used as a topical application in boils and tumors and in toothache. Alchemists had much faith in lichis. It is stated in the Genii Records that there were those who from having attained immortality from using its flowers and fruit were denominated "lichi genii." Ko Hung, the highest authority among Taoist philosophers lauded it as a "marrow tonic." Having attained the age of 81 that mystic joined the immortals (fourth century A.D.) becoming one of the genii; lichi then ceased to fortify his marrow.

Lichi has a history. It was first sent as a tribute (dried) to the Emperor Kao-tsu about 200 B. C. Later it was obtained from Annam (?) in a fresh state (they keep fresh for a week or ten days; the dried are preserved for about a year) at a frightful cost of human life. To reach Chang-an in good condition, relays of men were required to run at full speed bearing a load of lichi, each man's task being fixed at five *li* with a moment's rest half way, vast numbers succumbed to the toil from sunstroke by day, and from wild beasts and venomous serpents by night, and from malarial fevers.

The corvée was resumed in a farm somewhat about the middle of the eighth century. As one of the means employed to gratify Princess Wang a pony express was established to bring lichis from her birth place in Zzechuan;—at great sacrifice of human and equine life. The Princess was "transcendently beautiful—"une belle sauvage" however. Charmed by her talents and smitten by her beauty, the Emperor Hsuan Tsung made her chief lady of his harem, mollifying his son, whose wife she was, by another from the seraglio.

This Lichi Princess is of interest to us, not an account of her eventful history but from an ethnic point of view, being (remotely) related to us. [It is easy to discover the style of her beauty by examining the group photographed in De Lagnée's and Garnier's, "voyage de exploration en Indo-Chine;" the central figure is undoubtedly Aryan. Eight hundred years later, tree from which the fair Lichi Princess obtained fruit was cut down by order of a magistrate; it had ceased to bear fruit, the wood was made into combs.]

Through many weary ages cultivators of lichi suffered exactions from Imperial agents who were sent from local yamens to collect that fruit as tribute. In 1821 Taokuang signalised the commencement of his reign by abolishing the oppressive practice.

Of tardy growth the lichi is remarkable for its longevity. The citizen who succeeds in acclimatizing it will be a benefactor to posterity: it does not mature until it is fifty years old, but it will continue to bear fruit for four or five hundred years, say, far into the twenty-fourth century, and judging from the history of lichi tree that our fair kinswoman, Princess Yang found so toothsome, the timber may be utilised late in the twenty-eighth century, A.D.—*North-China Herald.*

THE COCHINEAL.—A report has been submitted to the Madras Government by the Inspector-General of Jails on the experiments made to rear the cochineal insect in the Central Jail at Coimbatore. The attempts were made by Mr. Grimes, Superintendent of the Central Jail, but the Government have ruled that another attempt be made during the next cool season. Dr. Bidie suggested that in the next attempt some of these insects be nurtured in sparse shade as ferns are grown in Madras. In addition to live insects, bearing mothers, it was suggested, should be procured, and as they are likely to stand the transit better, there is some probability of the experiment succeeding.—*Madras Standard.*

THE MANGROVE.—Until recently we have never heard the mangrove spoken of approvingly as a honey producing tree. But we live and learn. A writer in the *Florida Journal* speaks in very high terms of this much absued tree, as far as its use for the honey bee is concerned. He says it is valuable as being unaffected by droughts, and that the honey gathered from it "cannot be excelled in appearance, even by the white clover honey of Vermont." He thinks the mangrove the most valuable honey producing plant in Florida, which country he looks on as the best he has ever been in for honey. This being so, dwellers on our bays and rivers where there are thousands of acres of perennial mangrove swamps should take this hint and go in largely for bee-keeping.—*Planter and Farmer.*

SAW-DUST.—We frequently see notices of good results obtained from the application of saw-dust to the sail. In an horticultural journal a writer affirms that he is always able to strike cuttings better in saw-dust than in any other material. Recently a writer in an American agricultural journal has given the results of his experience of saw-dust in growing potatoes. In order to give it a trial he used about a quart of saw-dust for each hill of one plot of potatoes and none in another. The saw-dust hills yielded nearly twice as much as the others and the potatoes were larger and smoother. It would be very easy for farmers near Brisbane to take home a load of saw-dust from one of the saw-mills, where it could be obtained free, and give it a trial for various crops. We have an idea that in a dry time it would tend to retain moisture in the soil.—*Planter and Farmer.*

EUCALYPTUS OIL.—The demand for eucalyptus oil and eucalyptol, based on the reputation of the products obtained from the leaves of *Eucalyptus Globulus,* has brought into commerce oils obtained from other species, which are said not to possess the same medicinal properties. However this may be, as there is a difference in their money value, it may be useful to quote from Messrs. E. Merck's circular the characters in which an oil that appears to be known in the German market as "Oleum Eucalypti australe" differs from the genuine product from *E. globulus* leaves. The genuine oil has a weak dextro-rotatory action, forms a clear solution in 90 per cent alcohol in all proportions, does not puff when treated with iodine, turns yellowish in contact with sodium, and has a specific gravity of from 0·900 to 0·925, according as it is distilled from old or fresh leaves. The "australe" oil is strongly lævo-rotatory, only slightly soluble in 90 per cent alcohol, puffs with iodine, is coloured red on standing with sodium, and has a specific gravity not higher than 0·860 to 8·070. The characters for *E. Globulus oil* answer for eucalyptol. The "eucalyptol puriss," has a boiling point between 170° and 173° C., a specific gravity of 0·910 to 0·920 at 15° C., and is as clear as water.—*Pharmaceutical Journal.*

MR. HALLILEY'S PRO-WEED THEORY.

There is nothing like having the courage of one's convictions, and so Mr. Halliley takes occasion from his name being mentioned in the local "Times" emphatically to re-iterate his theory that leaf-disease and short crops are coeval with and the consequences of clean weeding insisted on in 1867. He goes much on the fact that coffee is a surface-feeder. But so are the vast majority of weeds, and, as two bodies cannot occupy the same point in space, Mr. Halliley might, concede, that if two surface feeders are left to feed on the same nutriment, they will either share it half-and-half, or one will go to the wall. On the doctrine of "the survival of the fittest" most people believe that the weeds (mainly indigenous) would have the best of it against the foreign coffee, but Mr. Halliley sticks to his theory that weeds, alive as well as dead, are good for coffee. The printer has done the advocate of vegetation in the wrong place considerable injustice; for instance, in the passage where "Ducandole the acknowledged authority on Arboriculture" is represented as stating that "there is a very great similarity between trees and man, as both man and trees in the first instance convert their food into the same substance, 'chye,' Mr. Halliley, of course, wrote "chyle," but the printer did not make him pen the truism:—"With a constant state of growth, there can be no stoppage of growth," which all will admit, even those who like ourselves believe that the perfection of all cultivation is to prevent weeds from competing with the cultivated product. As to the disposal of weeds, that is quite another question, and "mulching" with withered weeds might answer where heavy rains are not likely to sweep the covering downhill and into the ravines. Burying seems the better process; if with some lime, so much the better still. But, while Mr. Halliley insists that clean weeding brought on the development of the fungus, and that coffee would flourish best with a moderate surface-covering of weeds, it is unfortunate that all the scientists should be against him and should insist on the burning of weeds, leaves and prunings, so as not to afford a *nidus* to the spores of *Hemileia vastatrix*. "I was told," writes Mr. Halliley,

"by the former proprietor of Rathangodde that when that was a weedy estate it used to give good crops, and that all the manure it used to get was only round about the cattle-shed, so that it cannot be the weather or the season."

But when Rahatungoda was a weedy estate, was in the days of its youth when the soil enabled the coffee to grow and fruit well in spite of the weeds. Ceylon planters may have gone to excess in the matter of clean weeding; but that weeds any more than "thorns and thistles" are a good and not an evil to be as much as possible kept down and got rid of, few intelligent planters, we suspect, will admit. But in case anyone should like to try Mr. Halliley's system, here are its principles as stated by himself:—

Every book that treats on coffee tells us that coffee is a surface feeder, and any one who has had anything to do with coffee must have noticed that when coffee was vigorous, or becoming vigorous, it sent roots to the surface. Under the clean-weeding system as carried out these roots are destroyed and we have been trying to force our trees to became subsoil feeders—with what result we all knew to our cost. We cannot change the nature of a tree; all we can do is to assist nature, and, by assisting the nature of the coffee tree, we assist it to bear and be fruitful. The proper way to cultivate coffee is without doubt with a carpet of weeds, taking care to keep these weeds down as an intermediate and not allow them to grow up and become a substitute. In wet weather, those weeds will absorb any superabundance of moisture and thus prevent the coffee taking up too much, and thus causing the impoverishment of its sap; as when the sap of a tree becomes impoverished, as soon as there is a little bright sun-shine, mildew is the result. In weeding, the proper place to put the weeds is on the surface of the ground, round the stem of the tree. In wet weather, these weeds will rot and form food which the tree will take up by these roots that it sends to the surface. In dry weather, these weeds will shade the roots and keep them moist: that moisture will keep the tree in a constant state of growth.

And here is a transcendental passage for those who believe with Darwin in the evil effects of self-fertilization and the value of insects in aiding cross-fertilization:—

If we read the account of the creation, we find that the vegetable kingdom was created in the third period, and that bees were not created till the sixth period, so that can any one state that trees did not bear fruit for two whole periods, although they were created with their seed within themselves each to bring forth seed after its kind! so that what ails our coffee can only be the cultivation?

"Cultivation" in Mr. Halliley's estimation being the cherishing of a well-regulated carpet of weeds, while, in his opinion, it shows the hardy nature of the coffee-plant that it could so long have survived the deprivation of weeds to which it has been so recklessly subjected.—Q. E. D.

FROM CAROLINA TO FLORIDA.

Under this heading there is a letter in *The Times* from which we quote a portion, as Florida and its orange orchards are of some interest to us here in Ceylon:—

For 90 miles the railway goes south-westward from Savannah on an almost straight line, through the great pine belt of Southern Georgia, and then, making a right-angled bend, is an almost equally straight line for nearly the same distance south-eastward towards the coast. It traverses the edge of the famous Okefinokee swamp, a moist and mushy region of mystery and Indian legend, drained by the poetic Suwannee river, which has given the scene for a well-known negro melody. This streams flows into the Gulf, and on the eastern side this extensive swamp overflows into the winding St. Mary's river, leading to the Atlantic, which the railway crosses into Florida. More pine woods, much of it cut off for timber, and growing out of a sandy soil as level as a floor in which every depression and fissure is full of water, is then crossed; and the balsamic odours of these pines combined with the mildness of the climate, are the attractions that make Jacksonville such a popular health resort. The line finally comes out upon the broad St. John's river, and the train lands us at the Florida metropolis, which has grown from 1,000 people in 1850 to 7,000 in 1880, and probably, under the recent stimulus, to 18,000 now—a Northern city set upon Southern soil, 900 miles from New York, a distance that is traversed in about 30 hours by express trains now, and next season will probably, by increasing speed and making better arrangements, be run in 24 hours. Jacksonville has been built by Northern capital and is a watering place with fine hotels and a fashionable Northern society in the winter, when many thousands come here from the North, seeking gentler air and a balmy climate. The negro seen here is a somewhat different type from the listless "darkey" of the Carolinas and Georgia. Contact with the energetic men of the North has infused life into him, and the hotels, which are conducted by Northern landlords, are managed on an improved plan compared with those of the other Southern seaboard towns. Here, with the large influx of whites, the Irishman also reappears among the labouring class. The "craker" wanders into town in his dilapidated cart, plodding slowly with his mule or ox along the heavy sandy roads, and is astonished at the progress a few years has made. The streets show a Northern population, and here in our Southern journey we first experience the revival that has come from the investment of so much Northern and European capital in Florida. This process has already done much for the State, and will before long make a complete change in its character and position, as a large immigration is coming in, and in many respects this land of the orange and the alligator is looked upon as a new American agricultural El Dorado.

WARM OR COOL AIR IN WITHERING TEA.

In a letter to the *Indian Tea Gazette*, Col. Money advocates the use of Blackman's air propeller in connection with tea factories to aid the process of withering in rainy weather. His position is that leaf would wither better in an atmosphere cooler than that which prevails in factories owing to the fires. Now we have taken it for granted that one of the benefits of furnaces or driers in a factory was the extent to which they raised the temperature of the air. But Col. Money desiderates air *cooler* than that inside the tea-house and this cool air in motion. No doubt dry air would be an advantage, but what have tea experts to say to lowering the temperature of the air in order to expedite withering? The Colonel's formulæ are :—

"The agents necessary to wither well—are 1.—Light.* 2.—*Dry* air in motion. 3.—A *lower* temperature than is generally found in Tea factories in the hot weather and rains. If these agents are present *in the factory*, the leaf will wither well in a few hours ; no need to move it from place to place. Turning it occasionally would be the only necessity, and it would of course wither equally well in all parts of the factory !" All will agree in the benefits of abundant light and dry air ; but is any advantage to be gained by cooling the air ?

* Many do not realize its importance. Let such place leaf in two lots to wither, both in the same atmosphere as to temperature and motion of the air, but one lot in a lightened space, one in a dark space ; a single experiment will convince them. Or test the time necessary to wither by day and night.

CINCHONA ALKALOIDS AND CINCHONA FEBRIFUGE.

Below, will be found a number of most valuable analyses of cinchona barks of numerous varieties, by Dr. Paul, as also his analysis and opinion of a febrifuge prepared from red bark in Jamaica, by a process similar to that employed in British Sikkim, and by which about 30 per cent of the total alkaloids contained in the bark is lost. The febrifuge is excellent, but it could only be prepared and issued by a Government like that of India more anxious to benefit its subjects than to make profit. If ever we have a manufactory in Ceylon, it ought of course to be conducted on the principle of extracting practically all the alkaloids. Manufactories out of Europe have not been successful, however, and at present low rates of freight the best course, probably, for Ceylon growers of bark will be to send their produce to the London market.

CINCHONA FEBRIFUGE.

The following very interesting papers appear in the Ceylon Government *Gazette* :—

His Excellency the Governor has been pleased to direct that the following letter from the Director of the Royal Gardens, Kew, to the Secretary of State for the Colonies, on the subject of a Cinchona Febrifuge prepared in Jamaica, be published for general information.

By His Excellency's command,

G. T. M. O'BRIEN,
Acting Colonial Secretary.

Colonial Secretary's Office,
Colombo, 10th May, 1884,

No. 1.

ROYAL GARDENS, KEW, to COLONIAL OFFICE.

Royal Gardens, Kew, 26th March, 1884.

SIR,—I am desired by Sir Joseph Hooker to acknowledge the receipt of your letter of 22nd January, enclosing a copy of a despatch from the Government of Jamaica transmitting a copy of a correspondence on the subject of a Febrifuge prepared in Jamaica from red cinchona bark grown in the Colony.

Sir Joseph Hooker has carefully considered your request to have the sample of Febrifuge, to be deposited in the Museum of the Royal Gardens, examined by a competent chemist. After some enquiry it was decided to entrust the investigation to Dr. Paul, F. C. S., who is entirely occupied with this branch of commercial chemistry.

I am now to transmit a copy of the letter addressed to Dr. Paul and of his report, which Sir Joseph Hooker regards as very satisfactory. You will observe that Dr. Paul was prepared for the investigation by having already on his own account made a careful study of certain samples of Jamaica red bark presented by the Jamaica Government to the Museum of the Pharmaceutical Society.

The process used in Jamaica was that devised by Mr. C. H. Wood, late Government Quinologist, Bengal, and it is believed to be that which is now employed in India in the manufacture of Febrifuge for the Bengal Government. The defects of the process are, as pointed out by Dr. Paul, (1) that the alkaloids are only imperfectly extracted from the bark by treatment with dilute acids; (2) that a portion of the alkaloids is lost owing to their solubility, especially in the case of quinine, in a large volume of water. This loss is probably to some extent obviated by carrying on, as described by Mr. Bowrey, the weaker liquors containing alkaloids in making subsequent extractions of fresh bark.

I gather from Dr. Paul's report that he fixes the total result of extraction of alkaloids, as the process is worked in Jamaica, at about 70 per cent., though possibly much less.

It appears that in the process as worked in Sikkim there is a loss of about 50 per cent. This is not considered satisfactory by the India office, and the question having been referred to Kew, Professor Armstrong, F.R.S., is now engaged in reporting on the methods employed, with a view to ascertaining if the defects in their working can be remedied. Mr. Wood was himself of opinion that this process could be worked so as to extract 75 per cent. of the alkaloids, and Dr. De Vrij, the eminent Dutch Quinologist, who was consulted on the subject by the India Office, was of opinion that by some improvements in the manufacture directed to reduce the waste of alkaloids, something like 80 per cent. of the total amount might be extracted. Better results than this cannot be obtained apparently without having recourse to the methods employed in Europe, by which something like a total extraction is effected. But these are more costly and complicated, and it is doubtful whether they could be advantageously employed except by persons working on a large scale and controlled by large commercial interest.

It will be observed, however, that Mr. Bowrey's work does not fall far short of what Mr. Wood thought the possible maximum of his process.

The question whether the manufacture of Febrifuge in Jamaica will pay is one for the careful consideration of the local Government.

That Mr. Wood's process—and no better one for the end in view has at present been devised—involves a waste, is generally admitted. This waste does not occur in bark worked by more perfect processes in Europe. The advantages on the side of local manufacture are, diminished cost in packing, transport and freight, and the lessened risk of loss from market fluctuations in the price of bark. It is a financial question how far these may be set off against the loss of alkaloids when the matter has to be viewed as in Jamaica from a revenue point of view. In India, the question is different: the bark is comparatively inexpensive to grow, the object of Government is not to obtain revenue, but the philanthropic one of supplying to the population a cheap and effective medicine. It can therefore afford to be wasteful of the bark so long as it is not actually out of pocket by the whole operation. So far it has largely effected the primary object and more than reoccupied its expenditure.

With regard to Dr. Paul's remuneration, I am to say that gentleman has named a fee of fifty guineas as a proper one for the work done. Sir Joseph Hooker, looking at the importance of the question, and the carefulness of Dr. Paul's report, is of opinion that the charge is fair and reasonable, and I am to request that the Crown Agents be authorised to pay this sum to Dr. Paul.—I am &c., W. T. THISELTON DYER.

Edward Wingfield, Esq., Colonial Office.

Enclosure.

ROYAL GARDENS, KEW, to DR. PAUL.

Royal Gardens, Kew, 28th January, 1884.

SIR,—A request has been addressed to this Establishment by the Colonial Office on the part of the Government of Jamaica to obtain a report upon a sample of Cinchona Febrifuge manufactured by the Government Analytical Chemist in Jamaica from red bark grown in the Colony, and which has been deposited in the Museum of the Royal Gardens.

The Febrifuge has been made according to the directions given by Mr. C. H. Wood, late Government Quinologist, Bengal.

The report is desired to be directed to the "qualities and commercial value of the Febrifuge."

This, it is inferred, covers such questions as whether it has been properly prepared, and, if not, how its defects may be remedied.

It is also desirable to obtain an opinion as to whether, from the figures stated in the papers, the manufacture has been economically conducted.

Sir Joseph Hooker would be glad to know if you would undertake the investigation, and if so, what fee you would charge for the report and analysis.

I am, &c.,

W. T. THISLETON DYER.

Dr. Paul, 1, Victoria-street, Westminster, S.W.

No. 2.

DR. PAUL TO KEW GARDENS.

Analytical Laboratory,
1, Victoria-street, Westminster, S.W.,

W. T. THISELTON DYER, Esq.

London, 24th March, 1884.

SIR,—The sample of Cinchona Febrifuge received from you on the 6th ultimo, and labelled "Cinchona Febrifuge prepared in the Government Laboratory, Kingston, April 1883," gives the following results on analysis:—

Quinine ...	23·10=31·07	crystalized sulphates.
Qunidine ...	·42= 49	do.
Cinchonidine	39·30= 52·42	do.
Cinchonine ...	21·36=26·29	crystalized muriate.
Amorphous alkaloids ...	7·80	
Ash ...	1·49	
Water colouring material ...	6·53	
	100	

In reference to the desire of the Colonial Office for information as to the qualities and commercial value of the Febrifuge on behalf of the Government of Jamaica, I beg, in the first place, to point to the above data as showing that this sample of Febrifuge is of good quality, and that, as regards its composition, it compares very favourably with the material obtained from East Indian Succirubra bark, inasmuch as the amount of quinine is greater in the Jamaica product than in that obtained from East Indian bark. In estimating the Febrifuge value of such a material, the proportion of quinine it contains is the chief point to be considered though not the only one.

In the present instance it is such as to make the preparation equal to nearly one-third its weight of pure quinine sulphate, while the aggregate amount of other Cinchona alkaloids, associated with quinine and their relative proportions, are such as to make the Febrifuge of the greatest possible value, and to show that it has been well prepared from bark of good quality as regards its general contents of Febrifuge alkaloids.

Last May, when some specimens illustrating the character of the bark grown in Jamaica were presented to the Pharmaceutical Society by the Colonial Office, I had an opportunity of analysing the trunk bark of the Cinchona Succirubra, and found, as I then pointed out, that it was of very good quality. Taking the results of that analysis and comparing them with composition of the Jamaica Febrifuge,, the relative proportions of the several alkaloids are as follow in the two cases:—

	Alkaloids in the trunk bark of the Cinchona Succirubra.	Jamaica Febrifuge.
Quinine	24·39	23·10
Quinidine	1·51	·42
Cinchonidine	30·80	39·30
Cinchonine	29·30	21·36
Amorphous alkaloids..	5·98	7·80
Ash	—	1·49
Water, &c.	—	6·53
		100

The approximation in most instances is sufficiently close to justify the inference that the trunk bark operated upon by the Jamaica Government Chemist was of the same kind as that presented to the Pharmaceutical Society last year by the Colonial Office.

So far as the physical characters of the Jamaica Febrifuge are concerned, there is every reason to be satisfied with it since it has a good appearance, dissolves readily and completely in dilute acid as would be requisite when used in dispensing medicine, giving a solution free from objectionable colour or taste, except a very slight sulphuretted flavour that is probably due to the use of sulphuretted alkali in the preparation of the Febrifuge. This character, however, is one that would scarcely be noticed in most instances.

In order to estimate the commercial value of the Febrifuge, since it is not exactly a marketable commodity at present, perhaps the best basis to take as a standard for comparison is the value of the quinine sulphate equivalent to any given quantity of the Febrifuge. For example, one ounce of the Febrifuge in question is equal as regards its contents of quinine, to 136 grains of ordinary quinine sulphate, so that, taking the present market rate of the salt in London, one ounce of the Febrifuge would be intrinsically worth about two shillings on account of the quinine it contains, and independently of the further value attaching to the other alkaloids associated with it.

The quinidine and cinchonidine sulphates and the cinchonine muriate equivalent to one ounce of the Febrifuge would, in like manner, be worth respectively 1*s.* 4*d.*, 1*s.* 2*d.*, and 3*d.*, so that the aggregate value of the Febrifuger thus determined would be about 3*s.* 6*d.* per ounce.

But the determination of the value of this Febrifuge as a medicine involves medical opinion as to the relative efficacy of the alkaloids associated with quinine, and if the views expressed by the Commissions that reported on the subject to the Indian Government be taken as a guide, the value of a material possessing the composition above stated would not be very much less than that of quinine sulphate.

In accordance with your instructions I have considered the various general questions which you regarded as being covered by the requirements of the Jamaica Government, and will now proceed to report upon them so far as the data at my command will permit.

The remarks already made as to the composition and character of the Febrifuge will perhaps suffice as an answer to the question whether the Febrifuge has been properly prepared so far as the actual product is concerned.

It is more difficult, however, to arrive at a conclusion as to whether the manufacture has been economically conducted, since the papers I have received do not contain all the data requisite for that purpose.

According to the estimate mentioned by Mr. Bowrey in his report to the Colonial Secretary, dated 14th April, 1883, the bark operated upon by him appears to have been taken as containing 5·36 per cent of total alkaloids. The Febrifuge obtained amounting to 4·8 per cent contained some part that was not alkaloids, so that the amount of alkaloids actually obtained from the bark in the form of Febrifuge was 4·41 per cent instead of 5·36 per cent., the difference of 0·95 amounting to 17·7 per cent of the total alkaloid in the bark being due to loss in manufacture.

Considering the nature of the process by which the Febrifuge was prepared, such a result would be very good; but from the same point of view there is reason for regarding it as being too favourable, especially when it is remembered that an undefined portion of the alkaloids is stated to have been left in the weaker liquors of extraction, &c., and carried on to another operation.

According to my own experience in the working of the process, the loss of alkaloid in preparing Febrifuge is necessarily very much greater than that indicated by the data given in Mr. Bowrey's report, and as a consequence the yield of the Febrifuge bears a much smaller proportion to the actual amount of alkaloids in the bark. The results of a number of careful experiments on this subject enable me to speak with confidence on this point, and, judging from these results, I should be disposed to regard the loss of alkaloid as being at least 30 per cent. of the quantity present in the bark, and possibly much more.

It will suffice here to mention briefly that the loss of alkaloid in the manufacturing operation is mainly due to two conditions, viz., the imperfect extraction of alkaloids from the bark by treatment with dilute acid, and the solubility of the alkaloids, especially quinine in a large proportion of water.

If the comparison already made between the composition of the Febrifuge from Jamaica, and the relative proportions of the several alkaloids in the Jamaica succirubra bark analysed by me last year, and the close approximation of the figures affords any ground for the inference that the Febrifuge has been made from bark of the same kind and quantity, it will be worth notice that the total alkaloids found in the sample giving the results above referred to amounted to 7·70 per cent. as against the 5·36 per cent. take by Mr. Bowrey as the amount contained in the bark he operated upon. In working bark of such kind and contents I should expect the results of an operation on the large scale to be about the same as those obtained in the Kingston Laboratory, and in that case the loss would be more nearly that which I have above mentioned as being usual when working the said extraction process.—I am, &c., BERN. H. PAUL.

No. 3

NEW GARDENS TO COLONIAL OFFICE.

Royal Gardens, Kew, 31st March, 1884.

Sir,—In reference to my letter to Mr. Wingfield, of March 26th, on the subject of the cinchona Febrifuge prepared by the Government Chemist, Jamaica, from red bark grown in the Colony, I am desired by Sir Joseph Hooker to suggest that copies of the correspondence might be communicated to the Government of Ceylon as it would probably be useful to the Botanical Department of the Colony as a guide in the event of its being thought desirable to attempt in Ceylon any similar local manufacture of Febrifuge.

I am to say that Sir Joseph Hooker will himself transmit copies of the correspondence to the India Office for the information of the Governments of Bengal and Madras. —I am, &c., W. T. THISELTON DYER.

The Hon. R. H. MEADE, Colonial Office.

IMPORTANT ANALYSES OF CINCHONA BARK.

From the Government of Madras we have received a valuable paper, in the shape of a letter from Brigade-Surgeon G. Bidie, M. B., C.I.E., Superintendent, Government Central Museum, to the Secretary to Government, Revenue Department.

Dr. Bidie writes:—I have the honor to report to the Right Honorable the Governor in Council that the specimens of Cinchona bark, which together with the botanical specimens collected by me in 1882 * were presented to the Pharmaceutical Society, have lately been analysed by Dr. B. H. Paul, and the results published with remarks in the Journal of the Pharmaceutical Society.

2. As the bark specimens were all collected from typical trees, the analyses are of much interest, and as it is not probable that Dr. Paul's paper may otherwise reach Government, I take the liberty of forwarding a manuscript copy of it for their information.

ENCLOSURE.

Report on Analyses of Specimens of Cinchona Bark.

Forwarded from Madras, through Her Majesty's Secretary of State for India, to the Pharmaceutical Society.

BY BENJAMIN H. PAUL, PH.D.

* See G. O., Revenue Department. Nos 1381, 1381-A, of 8th December 1882.

Footnotes to Table of Report on Analyses.

(1.) This and two following samples are from *C. Condaminea*, how. variety.

(2.) These botanical specimens and also the bark were taken from coppice shoots.

(3.) The bark belonging to this specimen is renewed after the tree had been subjected to the Java shaving process. In this the outer cellular portion is shaved or pared off, the inner vascular layer being left intact.

(4.) Bark covered externally with a thick corky layer, very peculiar, of *officinalis* type but undetermined species.

(6.) Large leafed or *C. Uritusinga*, Pavon type.

(7.) This is the No. 2 variety, in the estate nomenclature, of the variety *C. angustifolia*, How.

(11.) This species was discovered by Hasskarl, cultivated on a large scale in Java and found to be worthless. From Java it was introduced into India, where its culture never went beyond the stage of an experiment.

(17.) This plant was said by Cross, on his recent visit to the Nilgiris, to be the *C. crispa* of which he sent seeds from the Loxa Mountains. That it came from Loxa there is no doubt, as the few specimens of it on the estate of Dodabetta are growing amongst the "crown" barks introduced from that region. It differs, however, very much from the *C. crispa* of Tafalla, which belongs to the *C. officinalis* group of Weddell. In general appearance it is more nearly allied to Weddell's section *Pahudianæ*. Its bark is also very peculiar, in fact unique.

(20.) This form of the *C. Calisaya* grows to a considerable size and has bright green shining leaves, some of which measure from 6 to 7 inches in length by 3½ to 4 inches in width. Flowers pink, very sweetly scented.

(21.) This plant approaches the *Boliviana* form of Weddell, but the *calisayas* are most variable.

(23.) This plant, according to Howard, is a hybrid between *C. calisaya* and *C. succirubra*. On the other hand, it is said to come perfectly true from seed. Mr. Surgeon-Major Bidie thinks it to be only a variety of *C. calisaya*.

(26.) This is not the *C. pubescens* of Vahl, but a plant which was considered to be a hybrid by the Superintendent of the Cinchona estates, the late Mr. McIvor. Mr. Cross regards it as the pubescent form of "Cuchicara," referred to by Dr. Spruce in the Parliamentary Blue Book of 1863, p. 116. Mr. McIvor stated that it is a hybrid between *Cinchona succirubra* and *Cinchona officinalis*.

(29.) *Pata de Gallinazo* of Cross.

When the valuable series of specimens of Madras Cinchona bark was presented to the Museum of the Pharmaceutical Society by the Indian Government through Dr. Bidie it appeared to be important that analyses should be made, in order hat the specimens might be rendered thereby more useful for reference and that the analyses might be available for comparison with others, which might be made subsequently on the plantations. Therefore having learnt from Mr. Holmes, the Curator of the Society's Museum, that portions could be spared from the Museum specimens without destroying their value for reference, I undertook to carry out the examination. Unfortunately, the small, ness of some of the samples precluded the possibility o- dividing them. Only eleven specimens, however, out of the forty-nine received, were too small to be dividedf The proceeding table gives the results obtained. The footnotes are taken from remarks written on the herbarium. specimens by Dr. Bidie. The Specimens, No. 39 to 43, marked, "India," are barks which were forwarded last year from Darjeeling by Dr. King.

These specimens of bark illustrate very well the influence of hybridization in making [?masking] the characteristic features of the bark of particular species of *cinchona*, and the difficulty of forming an opinion as to the source of samples as well as their value in regard to amount of alkaloid.

I learn from Mr. Holmes that a comparison of the samples of *C. officinalis* bark indicates that the only one which could be easily recognized is No. 4. In this sample the bark presents an extraordinary development of the suberous or corky layer, which is divided into angular pi eces about half an inch square, each piece exhibiting a stratified appearance. It is totally different from Nos. 17 and 18 in which the suberous layer, although very much developed, presents a rough granular appearance more like toasted bread-crumbs and is very friable. The cork *C. officinalis* also possesses more quinidine (0·45) than the other varieties, and a good percentage (4·08) of quinine. No. 4 is evidently the bark referred to by Dr. Trimen in his report "On the Nilgiri Plantations" as being the "Crispa" of McIver and Beddome, of which a vigorous propagation was going on by seed. If it can be shown, therefore, by further analyses on the plantations, that these percentages are tolerably constant, this variety would appear in every way to be specially suited for pharmacy.

On examination of the several specimens of renewed bark of *C. officinalis*, Mr. Holmes is of opinion that it would not be possible to recognize by physical characters bark rich in alkaloids from a poor one, and that, however valuable such bark may be to the quinine manufacturer it would not be expedient for pharmaceutical use unless a guarantee as to alkaloidal strength were supplied to the retail pharmacist. It is also of interest to note that in Nos. 2, 6, and 8 the smaller amount of quinine found by analysis is associated with an increased amount of cinchonidine. The fact that No. 2 was obtained from coppice shoots adds weight to the supposition that the age of the tree may have something to do with the yield of cinchonidine; while the fact that the renewed (No. 6) and the natural (No. 8) *Uritusinga* varieties yield less quinine than the *angustifolia* and *Condaminea* points to the latter as being the better varities, *i.e.*, so far at least as can be gathered from a limited number of analyses.

The bark of *C. Pahudiana* might easily be mistaken by an unpractised eye for that of *C. officinalis*, and it seems desirable that such an inferior bark should be eliminated from the plantations as speedily as possible, lest by cross-fertilization it should deteriorate the seed of more valuable species. The same remark applies to the corky barks, Nos. 17 and 18, which, although very different in appearance from *C. Pahudiana*, are produced by a tree which has on its young shoots and capsules the peculiar coarse hairiness of that species, although in a less degree, forming a feature by which it is easily distinguished. The specimens of the bark *C. anglica*, from the Nilgiris, are not easily recognizable by physical characters, and Mr. Holmes considers that they bear evidence of the hybridization of the plants with *C. succirubra*, particularly No. 23, which gives 1·90 of cinchonine. This, he thinks, is further confirmed by the large leaves, resembling in size, shape and veneration those of *C. succirubra*. The capsules also more nearly approach in size those of that species, being much larger than those of *C. calisaya*.

With respect to the barks from Darjeeling, No. 39 to 43, Mr. Holmes is of opinion that the samples, judging from their physical appearance, were evidently collected from several different varieties of each species, and therefore the analyses cannot reveal anything special concerning them.

Judging from its physical characters the Ledger bark, No. 42, is good typical *calisaya* bark, and does not at all resemble the thick bark with scattered warts which was recognized by Mr. Howard as Ledger bark, and of which samples presented by him exist in the Museum of the Society. Taken in conjunction with the analysis, the characters of the No. 42 bark indicate that it approaches most nearly to the *Boliviana* variety of *Calisaya*.

The Nilgiri *calisaya*, No. 21, appears to be identical with that of Darjeeling. The herbarium specimen of the latter is marked 2,000 feet, an elevation that is hardly high enough to develope the alkaloidal richness of the *calisaya* to its utmost degree.

In Dr. Trimen's recent report on the cinchonas of the Nilgiris, he lays great stress on the importance of analysis as a guide in the selection of plants for cultivation, and he expresses his conviction that, in the present state of our knowledge, selection based on analysis is the most promising direction for the improvement of the trees as alkaloid yielders. From this point of view, he recommends the isolation of trees with high analysis, together with other precautions to prevent cross-fertilization, care in collecting seed, analysis of a selection of the resulting plants, and destruction of all that do not reach the standard of their parent. It is by the continuation of this mode of procedure in the cinchona districts of the Madras Presidency that Dr. Trimen considers the interests of the great industry of cinchona-growing in India can alone be efficiently promoted.

The attempt to draw deductions from the figures of the analyses now published of a limited number of specimens must, of course, be regarded as subject to correction by results of further examinations of a larger series of similar botanical specimens and barks that may come under future notice; but it may be hoped that the facts brought out by analyses of these specimens may prove of some value to the pharmaceutical public and to the energetic directors of the plantations in India and elsewhere.

PEARL FISHING IN THE TORRES STRAITS

(By "The Vagabond" in the *Australasian.*)

With the exception of some parts of Otago, Torres Straits is the most inhospitable place I have visited in the world. During my enforced detentions at Thursday Island I much wished to examine the workings of the pearl fisheries. I should like to visit some of the "stations" and describe the strange phases of life thereon. I desire, above all, to give reliable information and statistics relating to this industry. So with the assistance of the Professor I issue a circular letter to the proprietors or managers of all the stations, asking for particulars which I consider would be interesting to the public, and hinting that it is my desire to inspect some of the stations, although the time at my disposal prohibits my visiting all. This may be said to be fishing for invitations; perhaps I mean it in that light. It is the same sort of letter which I had despatched from Townsville to all the sugar planters in the district, and to which, in most cases, I received full replies. I also received pressing requests to visit many of the plantations and see how the Kanaka labourers are treated. This, as I have stated, I take to be a proof that the managers and owners consider that they have nothing to conceal from the public. How is it in Torres Straits? I receive only one reply to my letters, and not one single individual amongst the pearl-fishing "bosses," whom I meet at the store or the hotel, has the courtesy to offer me a sail in his boat, or invite me to visit his station. I apply to officialdom for information, and it is not supplied to me. I have travelled in many lands, and never had such discourtesy shown to me as here. There must certainly be a reason for this. One pearl-fisher informs me that my advent and the letters I send have created quite a scare in the Straits. "A few of us held a meeting, and we decided that it should be generally understood that we would not answer your letters, and that you should be kept away from the stations and fishing grounds." "But why send me to Coventry in this way?" I ask, astonished. "Well you see, you have the reputation of writing strongly, and we don't want to be stirred up. Personally, I am very pleased to meet you. Let's have a drink." I decline this *solatium* to my injured feelings, and at once set to work to find out what there is to conceal in the working of the Torres Straits pearl-fisheries.

Melbourne capital and Melbourne interests are largely represented in the sugar districts of Northern Queensland. The pearl-fisheries in the Straits have been established by, and are essentially in the hands of Sydney firms. There is a great difference in the public opinion of Victoria and New South Wales. Outspoken journalism is not relished in the sister colony. But that can hardly account for the treatment I receive in the Straits. Little by little I find out what is the evil on the pearl-fishing stations which it is hoped to hide from the world. Standing at Burns, Philp & Co.'s store, talking to gentlemanly captains, who have just come ashore from the elegant yacht-like boats anchored in Port Kennedy, I see case after case of spirits carried down to their dingies. Extra preparations, perhaps, are now being made for the Christmas holidays, but all the year round the stores of a fishing station include an abnormal amount of liquor, which is supplied to the hands employed, divers and crews of the boats. I am told on good authority that the amount of drinking on many of the stations is something frightful. Many station stores are only private grog-shops. The crews of different boats buy cases of liquor from their employers, meet at some island, and have a day's debauchery, as regularly as some English artisans keep Saint Monday. Drink is the curse of the Straits, and an act ought to be passed prohibiting any strong liquor being supplied to the Malays and the islanders employed in pearl-fishing. It is bad enough to see Malays and Polynesians come to the hotels here and get bottles of grog, with which they retire into the bush to get drunk and quarrel amongst themselves, the knife occasionally being called into play, but on the lone islands in the Straits, supplied with cases from the station stores, I am informed that there are at times veritable scenes of Pandemonium. The loss to employers in this waste of time is of course very great, but the custom of supplying men with liquor for an occasional spree sprang up at the commencement of the pearl fisheries. Employers argue it is better to give the men liquor and let them have their saturnalia over on the station or some lone island, where, when it is over, they will set to work again, than to let them go to Thursday Island and spend their money at the pubs there, with the difficulty of getting them back to the scene of their labours. Liquor, it is said, these men will have. If one employer attempts to run his boats on Blue Ribbon principles, the men leave him for others where there is periodical grog and a spree. There is no doubt, that, to counterbalance the loss of time, a large profit is made out of the sale of grog to the men, and that many of them, by drinking up their wages, are kept from leaving. Some employers, I daresay, are heartily sick of the system. They should arouse public opinion and a bond should be signed by every owner and manager that no strong drink should be supplied to their hands.

Until 1878 the islands in Torres Straits formed an Alsatia for European "beach-combers," runaway sailors, discharged Polynesians, and Malays. They worked a little at bêche-de-mer fishing, and spent their earnings pricipally in grog, which was supplied to them from Cooktown and Thursday Island free of duty. The majority of the pearl-fishing stations thus also obtained liquor at a cheap rate, and so the evil, which is now the curse of the Straits, grew up. In 1877 Mr. Chester suggested that he should be appointed a deputy-commissioner for Western Polynesia, so as to exercise supervision over the beach-combers, and he was accordingly so appointed by Sir Arthur Gordon; but in 1878, on the proposal of Mr. John Douglas, then Premier of Queensland, the "maritime boundaries" of that colony were quietly "rectified" on the assumption that police authority might be exercised over doubtful characters in the Straits. The Queensland shores were then some 60 miles from New Guinea. Now Queensland's boundary comes to within four miles of the New Guinea coast. The boundary line runs northward outside the Great Barrier Reef to Brumble Bay; thence westward to Saibai and Talbot Islands, extending for half a degree within a few miles of the New Guinea shore; thence extending to 138 deg. long. east, and running south into the Gulf of Carpentaria. It will be thus seen that Queensland has possession of Torres Straits, the toll-bar between the east and the west, the Indian and Pacific Oceans, a highway of yearly increasing and important commerce. With this annexation the days of cheap grog in the Straits were ended. The measure, which Mr. John Douglas innocently or artfully described as one merely of moral expediency to provide for proper police surveillance of the Straits, has not only proved to be one of the greatest importance to the colony in giving it entire possession of the Straits, but has also added many thousands of pounds to the Queensland revenue. The 60 or 70 boats engaged in the bêche-de-mer trade, sailing out of Cooktown, cannot clear out with bonded spirits as formerly. The customs receipts at Thursday Island have been swelled to an amount which makes this a first-class port. The protection policy is so fully carried out that a schooner which sailed up from Sydney the other day was charged £7 10s *ad valorem* duty for the fixed pump on board connected with the diving-gear. This is as much part of the vessel as the sails and ropes. But the revenue of Thursday Island is principally derived from the duties on strong liquors, and the sooner there is a falling-off in this respect the greater will be the direct and indirect moral and material benefit to all concerned in Torres Straits.

Afar off I survey the stations in Torres Straits, but, "boycotted" as I am I cannot visit them. It makes me mad to see the boats come sailing in and out whilst I am detained on dry land. The only craft for hire belongs to Jasper, the Malay, and his charges are exorbitant. Mac should have a boat of his own for the benefit of visitors. There is one small station on Thursday Island itself which I am enabled to visit. This belongs to Captain Edward Parkyns, lineal descendant of the Saxons who found the body of Rufus the Red in the New Forest, a Winchester boy and grand old veteran. His hair and beard are silvered, but he is hale and hearty as men half his years. Not at all of the "Father William" type is this Hampshire skipper. He never led such a stupid, inane life. He receives me heartily, and answers all my questions. He has been a long time in the Straits, and knows the pearl-fisheries from their commencement; has now four boats, and 28 men employed. As usual on all the stations, the nationalities are mixed—all sorts of Malays and all sorts of Kanakas. The Loyalty Island boys are the best; those from Mare preferred. Rotomah boys were the best in the old days, but they cannot be got now.. Wages average £2 10s. a month, but the divers also get paid according to the take, and earn very large sums. Grog is the only thing which prevents boats being worked profitably. Each boat should get at least seven tons of shell a year to leave a margin over expenses. Price in Sydney over £130 to £140 a ton. Thus Captain Parkyns. The only gentleman who has the courtesy to reply to my letters is Mr. Pearson, the Manager for Captain Tucker, of Sydney, who owns Goode Island. This station is situated three miles from Thursday Island, north by west. There are five dwelling-houses on the island, and five large stores. A sea-wall runs in front of these. There is a wharf 350 feet long from the shore to deep water, and a patent boat-slip, which can take up a vessel of 30 tons. Two large paddocks for sheep are securely fenced. Thirty thousand coconuts have been planted on the island, and the planting is still going on at the rate of 250 a month. Seventeen boats and one tender are employed in connexion with this station. Once a fortnight the tender goes out to the boats fishing on the reefs and collects the shell: 140 men of various nationalties are employed. Mr. Pearson prefers the Malay and Manilla men. The take of pearl-shell per year is about 160 tons, value in Sydney about £140 a ton. Mr. Pearson says:—"Annexation will not affect us at all in the Straits. New Guinea natives will not work away from home, although I believe they will work well on their own coast. Some have been tried in the fisheries, but the experiment did not succeed."

When one reads of the improvements carried out by private enterprize on Goode Island, and sees that on Thursday Island absolutely nothing has been done for the public good, one is apt to query the benefit derived from the sway of the Queensland Government in Torres Straits. I have given one sample of a station, but on the surrounding islands the stores and habitations are, I am informed, all of a superior order. The storing, sorting, and packing of the pearl-shell is the principal work on a station, which otherwise acts as a warehouse for provisions and grog. At most of the stations, stone or wooden wharfs have been constructed, and in some instances tramways and slips have been built. It is estimated that 170 boats are employed in the pearl-shell fishery in the Straits. I am told "the vessels in use are propably the finest and best found and fitted of their kind afloat; they range from 10 to 30 tons capacity, are excellently built, carefully equipped, splendidly handled, and are a credit to the colonies." Sydney capital is mostly employed in the pearl-fishery. The tax paid to the Queensland Government for occupation of each station is £5 a year, £6 a year for each boat, and £1 a year for each diver. This, with the indirect contributions to the revenue through the consumption of spirits, &c., proves that the pearl-fishery pays its fair proportion of Queensland taxation. There is a difficulty now in obtaining good sites for stations. All the best islands are occupied, and on many there is a great want of water. Good anchorage and landing-places are required, and most of these are pre-empted. It is held to be essential that a station should be within easy distance of the fishing-grounds and of Thursday Island, so that the boats can be readily reached by tenders and the shell be despatched to the port. I think it possible that a small steamer visiting all the fishing-grounds would be an improvement on the present system.

There is no mistaking the importance of the pearl-fishing industry in Torres Straits. It gives employment to some 1,200 persons, and supports the commerce of Thursday Island. The bêche-de-mer boats, between 60 and 70 in number, mainly belong to Cooktown. The Chinese merchants there buy up this fish, and give a better price than can be obtained on consignments sent to Singapore. It is some years since the practice of diving for pearl-shell was abandoned. The resources of science have simplified the mode of operation. Diving-dresses and air-pumps are now employed, which means that increased capital has to be expended. The cost of working a pearl-fishing station now is double what it was ten years ago. There are more stations and more boats employed, yet the take of shell is no larger than it was years back. This means that some men made very large fortunes in the early days, and that some are losing money now, for with the present appliances there ought to be a large increase in the returns. I read that "the shell can now be traced from the shallow waters of the shores, where formerly it was only possible to recover it by swimmers, to the deep waters of the Straits. The bulk of the pearl shell is now recovered from 13 to 15 fathoms of water. The area of distribution has been found to be very extensive. Pearl-shell has been traced all along the New Guinea coast, across the Straits and the Arafura Sea, and eastward from New Guinea to New Britain and and the Solomon." There should be promise of a permanent and lucrative future for the trade; but all the old station-holders grumble. It is certain that now-a-days a great deal of capital has to be expended, and that the returns do no more than recompense the time and tact necessary in supervision. There are no rapid fortunes made as in the days when shell was worth £200 a ton and expenses were slight, naked divers fetching up the spoil from the deep, risking their lives at every plunge. Now the divers walk along the bottom in the latest dress, ugly enough to scare away all sharks and devil-fish.

They now, too, know the value of the pearls, and, should any choice ones be discovered in the shells, there is little chance of the owners of the boats getting them. But the old hands grumble principally I think, with the hope of keeping away competition. You may take up a good station on an island in the Straits, and in that respect have great advantages over your rivals, but the waters and reefs are free to all. Rival fishing boats can anchor side by side, and often do so, and when one strikes a new patch of good shell there is often considerable ingenuity displayed in endeavouring to deceive all other comers. The pearl-fishery now is certainly not the good thing it was to a few Sydney capitalists, but a great deal of money is now circulated amongst the many in Torres Straits, and the industry is not by any means played out.

Tea in America.—Says the *American Cultivator* :—"During last year nearly 12,000,000 pounds of tea less than the year before have been imported into this country. This was due to the act of Congress prohibiting the importation of spurious tea. It is estimated that there will be only half a crop of green teas this season, consequently prices are booming."

Croquettes of Rice.—Put half a pound of rice and a pint and a half of milk into a stewpan, and stir it over the fire until it boils ; then cover the stewpan, and let it simmer until quite tender, put the rind from a lemon into half a pound of sugar, then pound the sugar in a mortar; add to it the rice and the yolks of five well-beaten eggs ; again stir it over the fire until the eggs thicken, but do not let it boil. When cold, form it into small balls ; whisk four eggs well on a basin, dip each ball into the egg, and then into some bread-crumbs, smooth them with a knife, repeat the egg and crumbs, and put them into a wire basket made for the purpose, place it in a stewpan of boiling lard, and fry them lightly. When done, drain them from the fat on a very clean cloth, and fole them very high in the centre of a dish on a pilded napkin, sift powdered sugar over them and serve.—*American Grocer.*

Coffee Leaf-disease Virulent in Java.—It was inevitable that the fell fungus should run its destructive course, Java soil to the contrary, and now it seems but a question of time for coffee to be as great a failure in Java as it has turned out to be in Ceylon, The latest accounts are most serious, thus :—*Batavia*, 8th April.—From the Director of Inland Administration, information has been received that the coffee leaf disease is becoming more and more noticeable in East Java, chiefly in the provinces of Pasaruan, Probolinggo, and Bezukie, which hitherto had been exempt from this infliction. The coffee trees there abound in berries everywhere, but, owing to the disease, all the leaves have dropped off. In many estates the trees display nothing else but branches full of berries, which are still fresh looking and green, but partially have become black, and have dropped off. As the disease shows itself everywhere, in mid Java also, where it is widespred in the province of Bagelen, it is to be feared that the coffee yield will fall off in consequence more than ever. Meanwhile every possible means is being turned to account to keep up the vigour of the coffee trees, and ensure their recovery from the disease.—*Java Courant.*

Cheap Tea-roller.—The following is extracted from the London letter of the local "Times":—

I see that Mr. Kinmond, the patentee of some of the best known tea machinery, has paid a visit to Ceylon on his way home from Calcutta, and that during his stay on some of the gardens using his machinery he devised several important improvements in it. Messrs. Robey & Co. of Lincoln are the the makers of all his machinery, and I happen to know that he has written to them in the highest terms regarding the prospects of Ceylon as a tea-growing country. Considering that he is intimately acquainted with all the Indian districts and perfectly disinterested, this is testimony worth having. Messrs. Marshall, Sons & Co. of Gainsborough are the manufacturers of Jackson's "Dryers" and "Rollers," which were awarded gold medals at the Calcutta Exhibition, and at their works on Tuesday last I was shown a new hand-power rolling machine, just patented by Mr. Jackson, which, he thinks will be in great request in Ceylon for small tea gardens, or estates having comparatively a small quantity of tea planted out amongst the coffee—wherever, in short, the produce is not sufficient to keep one of the larger machines employed. It is constructed upon exactly the same principle as the larger machines, the tea passing from a hopper above between two tables, the upper and lower surfaces of which are made to move in opposite directions by two hand cranks fixed at the angles. It is calculated that this machine—the cost of which will not be more than from £20 to £25—will, when worked by two coolies, roll as much tea as twenty men in the same time, and do it far better besides. If this be so, I should say it is just the thing for a good many of the young estates in Ceylon, which either cannot afford, or do not need, more expensive plant; and then, later on, when these have outgrown these hand-machines there will doubtless be native tea gardens ready to take them over.

A hand-roller at £20, which we suppose will mean about R350 laid down in Ceylon, will certainly be a great boon to small tea planters, but we scarcely understand Mr. Jackson's movement in view of the fact that he had authorized his local agents, Messrs. John Walker & Co., to manufacture and sell a hand-roller at R600.—Since writing the above we have learned that the model hand-roller is to be sent to Messrs. John Walker & Co., who are to manufacture the machines for sale in the island.

Sugar Cultivation in Egypt.—Minieh is the capital of a large district, one of the handsomest towns on the Nile and the centre of the sugar-cane industry. The factories are in five number, with chimneys of 200 feet in height and machinery of the most perfect and powerful kind. In February the scene in such a neighbourhood is one of prosperity and animation. As far as the eye can reach the earth is covered with luxuriant cane, and the factories give employment to thousands of men, women, children, camels and donkeys. At "Roda," also, the sugar industry is flourishing, and all the property which formerly belonged to the Khedive and his family, is now mortgaged as security for the Eight Million Loan of the "Dairah Sanieh." It is an immense estate of 400,000 acres, managed or rather mismanaged by an English, a French, and an Egyptian director. Dual control is not enough, so triple control, involving no control at all, has been invented. The fertility of the soil and the nature of the climate are such that this year the proceeds of the sugar crop will suffice to pay the interest on the loan, viz., £400,000, and this in spite of neglect and bad management. Truly it may be said with Ezekiel : "Everything shall live where the river cometh." There are 19,334 acres of first year's cane under cultivation in this district, 9,666 acres second year's crop, to crush which there are six double factories, each with four mills, and two single factories. The juice extracted is placed in open pans heated by steam, then passed through filters of animal charcoal into receivers, where it is concentrated in vacuum to about 21 degrees Beaumé. It is a second time passed through animal charcoal, and crystalized in the vacuum pans, then put into flat cooling pans and allowed to granulate. Afterwards it is turbined, taken into the curing house, dried, and put into sacks ready for market. From the mollass which flows from the sugar, a second quality, or No. 2 sugar, is produced, and again a third quality, the last juice of all being passed into the distillery, and made into alcohol.—*Times of India.*

BEET *VERSUS* CANE SUGAR.

What with improved processes and government bounties, there seems danger of beet sugar driving the produce of the cane out of the market. We quote as follows:—Some interesting calculations in this week's *Journal des Fabricants de Sucre*, show that the present average cost of all Raw Sugars produced in Germany and exported, after allowing for the profit on the drawback, is 16s. per cwt. The same calculations show that the most advanced German factories produce Sugar at far less, and that they can make it at 11s. 3d. and 12s. 3d. per cwt. None of these figures appear to include the cost of transit to the coast and shipment, but adding 1s. for these items, the lowest cost of German Sugar free on board at present is 12s. 3d. or 13s. 3d. per cwt. This still leaves a very handsome profit on the present free-on-board quotations if the Sugar were being sold by the best manufacturers only, and not by intermediate speculators, who bought at far higher currencies. The factories which can manufacture at these rates are apparently few in number, if the average cost for all Germany be 16s. at the factory, or 17s. at the shipping port. At the same time it is the advanced factories which would export, while the backward ones would sell Sugar for home use, so that there is certainly no reason to suppose that the present free-on-board prices would not in another season, if the yield were as high as it has been in this one, be sufficiently remunerative, the bounty being considered. With the large number of fresh factories which will be at work during the next season in Germany, and which will doubtless be erected on the most advanced systems, there appears a prospect of quite as low, if not of even lower, prices next winter. Added to this, France is apparently about to give her Beet producers a considerable bounty, while France, and it is said Holland, are also taking steps to impose surtaxes on foreign Sugars, which will have the effect of driving increased supplies of German Beet to England. Under these circumstances the long-threatened crisis has come upon the producers of old-fashioned Cane Sugar in our West Indian and other colonies. Taking the first cost of that Sugar at 10s. at the plantation, and the cost of transport to the coast, shipping, freight, landing charges, and selling commissions here at 5s. to 6s., it appears likely that the prices current for Cane refining Sugars in some cases show an absolute loss to the producer. If the fall goes further, the consequences to the producers of old-fashioned Sugar are too serious to be contemplated, even by those who have for years past been pointing out over and over again the approach of the crisis now upon us. If West Indian proprietors had read the signs of the times, and had erected proper machinery, the present prices, though unpleasantly lower than before would still have been sufficiently remunerative. Even yet there is probably time to escape, if arrangements are made to adopt modern processes by the next season. But what hope is there of those who adhere to methods which sacrifice two-thirds of the 18 per cent of Sugar in the Cane, while their rivals extract the whole of the 12 per cent in the Beet, and actually get double as much fine Sugar out of the latter, as the West Indian Planter produces in common Sugar out of the Cane?—*Produce Markets' Review.*

THE FERTILISATION OF THE FIG.

The following, on the Fertilisation of the Fig, is from Dr. Hermann Müller's "Fertilisation of Flowers," recently published in an English translation by Messrs. Macmillan & Co.:—

"*Ficus carica, L.*—The latest researches confirm the fact, which Linnæus (416A) was aware of, that the so-called Caprificus, which bears inedible fruit, and the Fig-tree cultivated for the sake of its fruit from time immemorial, stand in the relation of male and female to one another. Fertilisation is effected by a wasp, Blastophaga grossorum, Gray. (Cynips psines, L., Chalcidæ). The hollow inflorescence which we call a Fig is very markedly proterogynous* in both the Fig-tree and the Caprificus. The greater part of its inner wall is covered with female flowers, which are mature when the "eye" (ostiolum) of the young Fig opens. Male flowers line a limited zone near the orifice, and are mature until the Fig is ripe. The Caprificus produces three crops of Figs annually, one crop beginning to flower as the previous one is ripe. Many varieties of the Fig-tree ripen two crops, some three, annually. In most cases each crop of Figs, whether of the Fig-tree or the Caprificus, brings only flowers of one sex to full maturity.

At Naples, the Caprificus ripens its three crops of inedible Figs in April, June, and August. The first crop are called Mamme, the second Profichi, and the third Mammoni. Each of these hatches a new generation of Fig wasps, but it is only the second which produces the pollen with which the Fig tree is cross-fertilised. Each crop produces female flowers in which the wasps undergo their development, but male flowers are usually quite wanting in the Mamme, few in number in the Mammoni, and only plentiful in the Profichi. The Fig-tree also produces three crops in the season, called Fiori di Fico, Pedagnuoli, and Cimaruoli.

The reproduction of the Fig wasp takes place in the following way:—The female wasps force their way with the loss of their wings into young Figs of the Caprificus, through the narrow ostiolum. They lay their eggs in the ovaries of the female flowers, between the nucleus and the integuments, placing one egg only in each. The wasp dies within the Fig to which it has entrusted its offspring. In consequence of the puncture which the wasp has made, the female flower enlarges after the manner of a gall, and in its ovary instead of its own embryo, the wasp embryo develops. While the Figs themselves are proterogynous, the wasps on the other hand are proterandrous.* The wingless males are the first to emberge; they gnaw their way into the ovaries in which the females lie, and impregnate them, and afterwards perish within the same Fig in which they were born. The winged females then escape by widening the passage made by the males. They leave the ripe Fig by way of the ostiolum, and enter a young Fig either of the same Caprificus, or of a neighbouring Fig-tree, to lay their eggs in its femalo flowers. The wasps which enter the young Caprificus Figs (either passing from Mamme to Profichi, or from Profichi to Mammoni, or from Mammoni to Mamme) produce a new progeny; those, on the other hand, which enter young Figs upon a Fig-tree (passing from Mamme to Fiori di Fico, or from Profichi to Pedagnuoli, or from Mammoni to Cimaruoli) leave no offspring, since in the cultivated Figs the female flowers are so constituted that the wasps are not able to lay their eggs in the right spot.

Of the three generations of wasps, only those which have developed within Profichi act as fertilising agents. In the Profichi, at the time when the wasps escape from the ovaries, the zone of male flowers near the ostiolum is covered with pollen, so the wasps leave these Figs laden with pollen. They carry this pollen partly to the stigmas of young Mammoni of Caprificus, which, however, rarely set a seed capable of germinating, and partly to the Pedagnuoli of the Fig-tree, which, after this cross-fertilisation, bears good seed plentifully.

While the fruit of the Caprificus, whose only use is to supply pollen, remains hard and withers on the tree, or falls off without becoming sweet, the fruit of the Fig-tree, when the seeds ripen, becomes sweet and juicy, and so attracts birds, which disseminate the seeds.

From the most ancient times, as long as the Fig-tree has been cultivated, its artificial fertilisation by means of the Caprificus, or so-called caprification, has been practised. This process consists in hanging ripe fruit of the Caprificus (Profichi) to the branches of the Fig-trees, whose Figs, (Pedagnuoli) are then in their female stage, with open ostiola. The wasps issuing from the former enter the latter, bringing the pollen of the Profichi with them.

Sycomorus antiquorum, Miq.—The Egyptian sycamore has for its fertilising agent a small wasp (Sycophaga sycomori, Hasselquist), which is closely related to the Fig wasp, and has a similar mode of life. The females do not leave the ripe fruit through the ostiolum, but through several holes which they make near it. Both females and males are wingless, and the males are distinguished by

* Proterogynous plants are those in which the pistil (or organ which develops the seeds) comes to maturity before the stamens (organs which develop the pollen necessary for fertilisation).

* Proterandrous plants are those in which the stamens come to maturity before the pistil.

having a pair of long appendages at the side of the abdomen, which are attached to the stigmata, and probably protect them from the brown, sticky pulp within the fruit.

Paul Mayer has investigated the wasps of numerous other old-world species of Figs, mostly from herbarium specimens. In some species of Ficus and Sycomorus he has found Blastophaga and Sycophaga together, but the whole number of species of wasps was very small. On the other hand, the Brazilian Figs, of which Fritz Muller examined ten species in his own neighbourhood (Blumenau, province of St. Catharina), possess an astonishing variety of wasps belonging to the same family of the Agaonidæ; some of these belong to the genus Blastophaga, some to the genus like Ichneumon. Many are adorned with metallic colours, which fact suggests a longer stay in the open air. In point of fact, most of the Figs which Fritz Muller studied flower only once a year, so that many of these wasps must, in order to lay their eggs, seek another tree of the same species which is just beginning to flower at the time when the Figs are ripe upon the tree where they themselves were developed. In the case of many species of these wasps, at least four migrations are necessary in the course of the year.

In these Figs, the only inflorescence from which the wasps issue bears only male flowers, and the young inflorescence, which they enter, bears only female flowers. Self-fertilisation is thus rendered impossible, and separate individuals are regularly crossed. The fruit becomes sweet, and in many cases gaily coloured, when the seeds ripen, and parrots, which feed on it, help to disseminate the seeds.—*Produce Markets' Review.*

NEW RESEARCHES ON THE APPLICATION OF SALICYLIC ACID IN THE MANUFACTURE OF CANE AND BEET SUGAR.

Some new and important investigations have been carried on in various parts of the world, during the last few years, with regard to the value of salicylic acid in the manufacture of sugar from the sugar cane or beet root, and we propose to say a few words about them here.

The first problem of importance that had to be solved was that relating to the *cause of the production of glucose* in solutions of sugar or in cane juice. It has been long suspected that some organic *acid* was the cause of this transformation, so deleterious to the sugar-boiler by the large amount of *molasses* which resulted from it, and that was the origin of the introduction of *lime* as a defecator. This lime not only collected the scum and precipitated tannin compounds, etc., but *neutralized any organic acid* which might be present.

Now, although it has been long shown by actual experiment in the laboratory that acids of all kinds boiled with solutions of cane sugar will convert it into glucose, it appears very probable, in fact certain, that *acids* present in the juice *are not the chief cause of conversion, if indeed they are, in this instance, a cause at all.* It is now some years since Dr. Phipson first hinted that *micro-organisms* might be the origin of the inversion of sugar in the boilers of the West Indian plantations, and that this cause, so detrimental to the interests of the sugar producers, might probably be done away with by a judicious use of salicylic acid. His conjectures have since been fully verified by the discovery of the inverting micro-organisms in the moist sugar of the West Indies, and in the unrefined product of the beet root. They have been detected and isolated; moreover, they have been cultivated in appropriate media, and their action on the cane sugar (saccharose) fully investigated.

As might have been anticipated, this action is found to depend, to a great extent, upon *temperature.* At a low temperature the microphytes of raw sugar solutions are more or less inactive; but at the high temperature which constantly prevails in our West Indian colonies they are in full play, and convert cane sugar very rapidly into glucose, that is, in plain language, *crystalline sugar* into *molasses.*

According to some recent researches by Professor Gayon on the sugars of Guadaloupe, Mauritius, and other places, it appears well proved that the production of glucose in raw sugars is increased by *heat* and *moisture.* What is known as 'fermentation temperature" is a very appropriate degree of warmth for rapidly promoting an increase of glucose; moisture is also a very favourable condition for its production. It is also found that when sugar is stored in large heaps, glucose increases from month to month, until it attains to very considerable amounts.

Let us mention as a curious fact, *en passant,* that one of the micro-organisms isolated from raw sugars is known to naturalists as *Mucor circinelloides,* and possesses the singular property of causing the transformation of glucose into carbonic acid and alcohol, but is not capable of affecting saccharose or crystalline cane sugar itself. When a mixture of cane sugar and glucose is submitted to the action of this peculiar kind of *mildew,* it acts upon the glucose and destroys it without converting any of the cane sugar.

Four or five distinct species of microphytes have been isolated from raw cane sugar besides the one just alluded to; it is only the purest refined sugar that is totally exempt from them; and it is now generally admitted that their presence is quite sufficient to account for the gradually increasing production of glucose in raw cane sugars and in cane juice. This has, in fact, been proved by a number of direct experiments, in which the inversion was found to increase with the abundance or activity of the *ferment* added to solutions of pure sugar. Much interesting information on this subject is contained in Professor Gayon's little pamphlet, *Recherches sur la Formation du Sucre réducteur,* published at Paris in 1881.

With regard to the application of *salicylic acid* to neutralise the effects of these microphytes in the sugar-vats, Dr. Phipson originally proposed a minute quantity (say 1 part for 10,000 parts of sugar) to be used along with the defecating lime, but to be added to the juice before the lime, in fact, the moment the juice left the mills. This instruction appears to have been misunderstood: the juice was allowed to be heated after the addition of the salicylic acid; and before the lime was added to neutralise the acid by forming *salicylate of lime,* a certain quantity of glucose was already formed. Professor Gayon proposes, on this account, to use *salicylate of soda* in place of salicylic acid, but it is questionable whether the salicylate of lime would not prove the more advantageous.

Experiments made in test-tubes, in which salicylic acid and solutions of cane sugar were heated to boiling point in the proportion of 1 of salicylic acid to 1,000 of cane sugar, produced a notable amount of glucose in the course of two hours, but this is ten times the amount of glucose originally proposed to be used. It is probable, however, that pure salicylic acid could not be advantageously employed, unless Dr. Phipson's proposition of neutralising it (immediately before heating) by the addition of lime was properly carried out.

Fortunately the saline compounds of salicylic acid are almost as powerfully disinfectant or anti-parasitic as the pure acid, and they have, moreover, the advantage of being very much more soluble in water and solutions of sugar. Professor Gayon's experiments place *salicylate of soda* at the very top of the list of the many antiseptics tried for *arresting the development of glucose* in solutions of cane sugar. It has been found that 2 parts of salicylate of soda for 10,000 parts of pure sugar are sufficient to check the production of glucose, and this check corresponded precisely with that of the development of the microphytes. Sugar solutions which gave one to two microphyte cells in the field of vision before the experiment, were left for a fortnight, one-half of the solution having received 2 parts of salicylate of soda for 10,000 parts of sugar, and the other half containing nothing but sugar and distilled water. At the end of the fortnight the latter showed 15. to 25 micaophyte cells per field, whilst the half containing nothing but sugar and distilled water. At the end of the fortnight the latter showed 15 to 25 microphyte cells per field, whilst the half treated with salicylate of soda gave one to two cells as before. The original sugar contained 2·89 of glucose, the solution in distilled water, after a fortnight, showed 6·98 per cent, and that containing salicylate of soda 3·00 per cent. This experiment speaks for itself, and its importance will be at once understood by all sugar makers.

Experiments with salicylate of lime have not yet been made, but it is possible the results may be still more advantageous, as a *lime* salt would be preferable to a *soda* or a *potash* salt, being less liable to prove injurious in the ulterior processes. But when we consider the extremely small amount of salicylic salt which it is necessary to use in order to ensure so desirable a result, namely, 2 parts in 10,000 parts of sugar, the latter consideration is of minor importance

In face of these new researches, we cannot recommend too strongly to all who are interested in the manufacture of cane sugar or beet sugar, that their attention should be at once directed to the great improvement in this manufacture which is likely to ensue by a clever application of salicylic acid, salicylate of soda, or salicylate of lime. The production of glucose or molasses will be practically got rid of without incurring either trouble or expense worth speaking of.

ALCOHOL FROM CHESTNUTS.

The *Moniteur du Produits Chêmiques* informs us that alcohol can be extracted from chestnuts, and that 100 litres of the latter will yield 8 litres of very good spirit. The chestnuts are first dried to develop the saccharine matter. They may be kept for a considerable time in the dry state. They are next decorticated, afterwards treated by water, and warmed until the sugar has been extracted. The solution thus obtained is called *tanade*. The chestnuts are then crushed, and with the *tanade* submitted to fermentation, after which the alcohol is obtained by distillation; the residue is stated to furnish a useful food for fattening cattle.

THE GINGER BEER PLANT.

This is a startling or a sparkling little novelty, some account of which has been going the round of the journals, and which promises to provide all thirsty souls with a ready-made and refreshing gingerade during the coming summer. We do not prognosticate that it is calculated to produce any great alarm, or that it will revolutionize the Ginger Beer Trade; but still, like the "Vinegar Plant" which was, some few years ago, hailed with so much delight by frugal housewives, there is something in it, and that something appears to be a little fungoid growth or plant, which was first discovered in Norfolk, and consists of a mass of irregular white grains resembling cooked tapioca, or, still more, half-dissolved gum tragacanth when crushed in the fingers. A writer in the *Queen* remarks "Would that I could introduce it with a high-sounding botanical name! but, alas! I fear that if it has one at all, it must be far down among the Cryptogamia, for to the higher order it certainly does not belong. Its origin, like that of many illustrious discoveries, is lost in obscurity. It has been cynically asserted that its ancestor was a fungoid growth in a barrel, but these evolution questions are very delicate, and we may dismiss the charge as "not proven." The process of ginger beer brewing from this mysterious substance is as follows:—Whatever vessel is used should be at least half-full of the grains. Fill to the top (a wide-mouthed pickle jar is best) with water that has boiled, and add several lumps of sugar—the quantity must be regulated by taste, as a hard-and-fast recipe is impossible. Once a week, on a fixed day, drop in a few pieces of root ginger, also at discretion. Every day, the water poured in twenty-four hours before must be carefully strained off through muslin, and bottled and corked securely. Some advise adding a little yeast, but if the grains in the jar are numerous enough to produce sufficient fermentation—*i.e.*, a decided froth—there is no need to add yeast. Replenish your jar with boiled water and sugar, and cover again with piece of linen or calico; on no account cork it. The liquid you bottle off is fit to drink in two days, and, to a not too critical palate, it forms a refreshing, mild gingerade, easily prepared, and certainly the cheapest of all possible drinks of the kind. Every week the exhausted pieces of ginger must be fished out. Avoid handling the grains. They increase rapidly and must be thinned out by pouring off when too numerous, forming new colonies and consequently a larger supply of gingerade.

AQUEOUS EXTRACT OF CINCHONA.

M. Lepage, Inspector of Pharmacies, mentions the fact that he has met with aqueous extract of cinchona almost devoid of alkaloid, due to the extract being made with cold instead of *boiling* water as ordered in the Codex. This has been done to render the extract completely soluble in water to meet the fancies of certain physicians. Aqueous extracts of belladonna and henbane have been in like manner substituted for the true alcoholic extracts, with the result that they contain hardly a trace of the alkaloid.—*Burgoyne's Monthly Export Prices Current.*

SAP IN TREES.

Why the sap ascends in trees is yet a mystery. All attempts to slove it by mechanical or chemical laws have failed. At one time we think we have it when some good man talks to us about what he calls "root pressure." Then, some other tells us about osmotic action, and we get learned disquisitions on the power of endosmose and exosmose. Again, another gives us an explanation of the manner in which starch is converted into sugar, and the tension which occurs during this change acting as a pump to pull up the sap. But the orchardist, with his every-day experience, always feels that the philosopher has left out something in the calculation, which he at least is not permitted to forget, namely, plant life—and though the man of science may ask him what he means by life, or to explain what he calls vital power, he can only say that he does not know, but he is sure there is a something which he may call this, though science has not been able to get near it. The orchardist knows that a half dead tree does not draw up sap as freely as one in vigorous health, nor does a half dead branch act as freely as one with full vital power. Now, a transplanted tree is in some sense a half dead tree, and the proof is, that in a dry time, or a hot time, or a cold time, or under any unfavourable circumstances, the chances are two to one in favor of an untransplanted tree getting through. The only reason that it is half dead is, that the sap does not ascend as freely as it ought to do. The leaves push slowly, and the growth is feeble, simply because the sap does not ascend as it should do. Now we must help the tree to do this if we would have the best success in transplanting. As a rule, the healthier parts of the tree, those parts near the ground, get disgusted with the attempt to pass sap through the sluggish cells above, and push out sprouts along the stem, or suckers from the roots, and these will soon manage to get all if left alone. It is therefore essential to the well being of any tree with a weakened top, that every sprout should be taken out as soon as it appears. This applies not only to trees with a weakened top from transplanting, but from grafting, budding, or any other horticultural operation. Watch all such trees, as soon as they leaf in spring, and take out every sprout from trunk or leading branches as soon as they appear.—*Gardeners' Monthly.*

NOTES ON POPULAR SCIENCE.

BY DR. J. E. TAYLOR, F.G.S., &C., EDITOR OF "SCIENCE GOSSIP," &C.

The construction of tea-preparing machinery appears to be assuming the proportions of a new industry amongst us. It has its head-quarters at Gainsborough, in Lincolnshire.

A French scientist, M. Duchatre, has just published an account of some experiments he has been making with seeds. Everybody is aware of the influence which direct sunlight has upon the growth and development of young plants. Well, M. Duchatre has been experimenting upon the sprouting and germination of seeds with *moonlight* instead of sunlight. He subjected the seedlings of lentils, vetches, &c., to its influence. When the seeds had sprouted he put them in a dark place, and kept them there for a time, so that their stalks grew slender and of a yellowish white. Afterwards, on three nights when there was clear moonlight, he exposed them to its influence for six hours each night. He found that the stalks at once became seleniotropic—that is, they turned towards and followed the moonlight, just as many plants, such as the sunflower, are heliotropic, or turn towards and follow the progress of the sun through the heavens. From the very first the stalks of the plants began to bend, so that they constantly presented themselves and their budding leaves towards the moon, as if they were the most fervid worshippers of Diana.

The Linnæan Society has been occupied in discussing the question of the potato plant. The weakening of the potato through repeatedly propagating it by tuber alone has laid it all the more open to the attacks of disease. I have repeatedly drawn attention to this important item, and I was pleased to find Mr. J. G. Baker, the celebrated economic botanist, of Kew Gardens, in a paper on potatoes, read before the above society, stating that the ordinary potato is grown as if its sole object were to produce tubers, to say nothing about the other artificial conditions as to climate and soil to which it is subjected. Under these conditions Mr. Baker said he was not surprised that the potato plant lost its vitality, as is indicated by the fact that after a time it ceased to produce flowers and seeds, and then readily becomes a prey to the potato disease. Mr. Baker thinks the vitality of the plant may be restored by cutting off the stems, which produce tubers, and saving only the roots which obtain nourishment for the plant.—*Australasian.*

EGYPTIAN GARDENS.

On leaving Alexandria to take the train for Cairo from the old station of Miniet-el-Basal (great market of Alexandria), 4 kilometres from the Place des Consuls, the road traverses a superb forest of Date Palms, which looks especially well in autumn when these trees are loaded with fruit. The Date Palms are cultivated in forests, and wave their fronds in the air, about 60 or 70 feet above the ground, and with their straight stems, 6 to 9 feet in circumference, produce an astonishing effect, especially upon those who see them for the first time when arriving from Europe, where we see but small specimens of these trees in greenhouses.

The station of Miniet-el-Basal (the Onion market) is now only used for merchandise. Another station has recently been constructed nearer the town with the framework of a conservatory the size of that of the Société d' Acclimatation of Paris, and even larger, and which was ordered by the late Saïd Pasha during his visit to Paris in 1860. This great conservatory, which remained for fifteen years in the warehouses of Alexandria, has at length been utilised, but covered with zinc instead of glass. From Alexandria to Cairo the journey by express train takes four hours and a half. At Kafr-zayat, a station situated half-way to Cairo, the train stops for 20 minutes; there is an abundantly provided buffet, and a European *table-d'-hôte.* At intervals on the journey the Arab children offer at every station little baskets (made of Juncus spinosus) filled with fruits, such as Mandarin and Blood Oranges in winter, Loquats in spring, Bananas and Figs in summer, and enormous Pomegranates in autumn, which the European travellers buy for one or two piastres. For the Arabs and the Fellahs there are Radishes and green Onions in winter, Chick-peas and Fenugreek in spring, Cucumbers and Water Melons in summer, and Dates in autumn.

The chief garden worth visiting at Cairo is the park of Ezbekieh, situated in the centre of the European quarter, and having an area of upwards of 85,000 square yards of an octagonal form, with four gates—north, south, east and west. This garden was reconstructed in 1871 and embanked 6 feet all round, especially in its circular part. In the centre is a great basin fed with water by a cascade, falling from a reservoir, constructed above a grotto, and hidden by a rustic kiosque. There is a concert of military music given here every afternoon during the promenade hours.

The lawns are formed of Zapania nodiflora. The most remarkable of the old trees of this garden were carefully preserved during the alterations, especially fine specimens of Tamarix arborea, Albizzia lebbex, Cassia fistula, &c. All the other plantations date from 1871, and are specimens taken from the old Khédivial nursery of Ghézireh, established by us in 1868, and which was closed in 1879, on the abdication of Khédive Ismail. After the alterations, the garden of Ezbekieh was thrown open to the public in 1871-72; but the Arabs or Fellahs, who frequented it in great numbers, put themselves so much at their ease there, that the custodians were obliged to put turnstiles at the gates, and charge a copper piastre (about a halfpenny) as an entrance fee to get rid of these objectionable visitors, who made their ablutions in public on the borders of the lake, occupied a whole seat, or two or three chairs, where they stretched themselves to rest, or busied themselves with the capture of sundry parasitic insects, in great numbers, throwing them right and left without killing them, following the Mussulman custom, but leaving them to be swept up by the European ladies with their long dresses.—G. DELCHEVALERIE, in *L'Illustration Horticole.*

INFLUENCE OF TREES ON CLIMATE.—The Los Angeles *Herald* thinks tree-planting has secured to that section of the state immunity from dry seasons.—*Australasian.*

ORANGE-GROWING IN SOUTH AUSTRALIA.

At a recent meeting at Adelaide of the Agricultural and Horticultural Society, a paper was read on the cultivation of the orange. The author of the paper was Mr. Joseph Curnow, of Orange-vale, near Montacute, who appears to have read a paper on fruit culture generally some five years ago. In the interim his experiences have led him to condemn the use of the lemon as a stock for oranges, many of those planted by him and thus worked having died. Trees worked by himself on seedling oranges have remained healthy, except a few which suffered from over-irrigation. That over-irrigation was the cause of their death is proved by the continuance in excellent health of a large number of trees planted at the same time, but which have had no artificial watering. Irrigation might be practised with safety on a gravelly, porous subsoil, but when the latter is retentive irrigation is sure to produce bad results. Mr. Curnow attached much importance to the practice of keeping the surface open and perfectly free from weeds. A loose surface never cracks to let in the sun. He would employ mulching on stiff soils, but not place it near the stem of the tree. The discussion on the paper elicited rather wide differences of opinion upon practical matters. Mr Crozier said:—"In the cultivation of the orange the principal thing to consider was the class of soil, the next was judicious watering, and the third pruning. He had heard of a system of cutting off the surface roots, which was said to be effectual, although opinions differed much upon that point, some contending that the tree drew most of its nourishment from the surface roots, while others argued that by cutting those fibrous growths the tree then sent its roots deeper down into the soil, and was strengthened thereby. The proper treatment of the branches of the orange tree in the matter of pruning had a great effect upon the health and vigorous growth of the tree; circulation of air and shading of the roots being points not to be lightly considered." Mr. W. Jones's "experience told him that every tree was the better for being planted near the surface, as nature did when she took it in hand. Our gum trees naturally planted grew better timber than if they were put in by hand. The great fault about planting lay in going too deep in the first instance. Orange-trees should be grown in shape as much like an umbrella as possible, so as to shade the roots, otherwise the ground cracked, and they suffered from the too direct rays of the sun. In Sydney the gardeners followed an excellent plan in laying down a flagstone some nine inches below the surface and planting the tree over it, so that the roots should spread out as much as possible and gather nourishment from a wider area. There was a great deal of forethought in that system, and the result showed how practical it was." The president was not quite clear about the cutting of the fibrous roots; a tree so dealt with undoubtedly sent its roots deeply into the ground, inducing a vigorous growth. Mr. Davenport presumed that the reason for cutting the surface roots was that the other roots would then have a tendency to strike out better. He referred to a similar system adopted in Corfu in growing vines. The general opinion was unquestionably in favour of the Seville as a stock for oranges. The selection of a proper site and soil was also recognised as a point of the first importance.—*Australasian.*

AGRICULTURE IN JAPAN.

Those who live by the cultivation of the soil in Japan occupy a higher rank in society than farmers or gardeners generally do in Europe or other countries. They rank next to the official and military class, and above the artisans and merchants. About four-fifths of the population till the soil, and some sections of the country have the appearance of gardens. The hills are often terraced with prodigious labour, and cultivated with great skill.

A correspondent of the San Francisco *Bulletin,* from whose letter we make a few extracts, states that in a journey of twenty miles, between Tokio and Yokohama, the following crops were seen in the fields, all yielding profitable returns:—Rice, beans (several varieties), millet (three varieties), Indian corn, broom corn, buckwheat, onions, endives, tomatoes, beets, radishes, turnips, parsnips, carrots, salsify, artichokes, dock, sweet potatoes, Irish potatoes, cabbages, cauliflower, spinach, egg plant, rhubarb, taro (upland variety), ginger root, cucumbers, squashes, gourds, horseradish, red peppers, sesame, sunflowers, edible sarsaparilla, edible bamboo, shiro (leaves used for colouring pickles), chestnuts, pomegranates, oranges, kumquat (the small orange used for preserves), pears, grapes, jujube fruit, persimmons, tobacco, cotton, hemp, tea-plants, mulberry tree (for feeding silkworms), and mushrooms. From the same, or contiguous soil, had been gathered already wheat, barley, rape seed (for making oil), peas, strawberries, water-melons, musk-melons, lettuce, appricots, peaches, plums, and fruit of the loquat tree. The pools of water were also filled with lotus (the root of which is eaten very largely), water chestnuts, the water taro, and watercresses.

Less than one-tenth of the land is under cultivation, and it is estimated that twice or three times the present population could subsist comfortably in Japan. Rice is the most important product, one of the names of the island meaning "the laud of the prosperous ears of rice for 1,500 autumns." Both swamp and upland rice are grown in many varieties. Rice lands are estimated at 3,922,000 acres, and dry fields at 3,511,000 acres, making a total of nearly $7\frac{1}{2}$ millions of acres under cultivation. The annual yield of the rice fields is calculated to be about 138,907,000 bushels, or about 35 2-5 bushels per acre. The annual yield of the dry fields is estimated to be 91,575,000 bushels of wheat, barley, &c., 32,175,000 bushels of beans and peas, and 32,175,000 bushels of millet. While the population has increased and the tillable surface is somewhat enlarged, the crop has changed but slightly in bulk during the past 250 years. This large production from land that has mostly been under a continuous state of cultivation for centuries is owing to the great care that has been exercised in cultivating and manuring the soil and the system of growing the plants in rows, which allows the production of two crops, whilst a short time of fallowness is given to one part of the field. This shows that the Japanese have studied and mastered to good purpose the true economy of land tillage in all its bearings.

Rotation of crops is diligently attended to, undergoing modification according to soil and climate. Rice is generally sown in beds thickly, and afterwards transplanted in tufts of eight or ten plants about 8 in. apart. Fertilisers of all kinds are used. Among these are shells, ashes, residue of oil cake, decomposed vegetable materials, seaweed, dried fish, bones, stable manure, and night soil. The last-named is the most common, and is everywhere carefully preserved. It is applied in a liquid state during the younger stages of the growing crops, being poured upon the grain by means of a ladle.

The implements in use are very crude and inefficient. A mattock or hoe is the usual tool for digging and preparing the land for seed, and both sexes help in the work. Cows and horses are sometimes used for ploughing, but the implement used is only a forked stick with an iron point attached. The farmers there are very conservative, and reject all mechanical improvements; nor do they attempt to grow new or improved varieties of fruit or grain, but keep on with the same that have been produced for many generations. The country is void of fences, the fields being divided by slight ridges of earth, which are hidden by growing crops, so that a whole district has the appearance of one large field.

Much of the fruit grown is eaten green and is as much relished in that state as when fully ripe. Peaches, plums, and persimmons are all used thus, and this perhaps accounts for the fact that little effort is put forth to introduce or grow finer varieties. The soil and climate are admirably adapted for fruit growing, and of the kinds grown persimmons, grapes, peaches, plums, and melons are the best. The apples are small and inferior, but very good quinces are found in some places. A striking feature of every Japanese farm is the cleanliness and order everywhere prevalent. Each man seems to take a pride in keeping his land in perfect order, and clear of everything in the way of weeds. Upon lands unsuitable for cultivation, pine and ash trees are planted, and after fifteen years of growth they are cut for firewood, and then set out with trees again. In spade husbandry, the Japanese have little to learn. In stock-rearing, fruit-growing, and producing hardier grains than rice, there is much room for improvement.

There is no good pasturage in the island and very few stock. It is estimated that the total number of horses and cattle is only about one million of each, or little more than two head to every one hundred people. Almost all the grain and other products are transported on the backs of horses and cattle. Sheep are very few, and do not thrive owing to the coarse and innutritious grasses of the country. Swine are common, and meat is slowly becoming the diet of the Japanese instead of fish and vegetables. Thus far religion has prevented the free use of meat, which has also been scarce and high priced. The land is virtually owned by the people, but theoretically it belongs to the Mikado. A land tax is the chief source of Government revenue, and agricultural products form the chief wealth of the country. It will be seen from the above that, while Japanese cultivators show a large amount of skill, industry, and perseverance in the practice of their art, they are nevertheless far behind the times, and could afford to take some lessons from those nations where labour-saving implements are employed to do the bulk of the work.—*Queenslander.*

IS AGRICULTURE A SCIENCE OR AN ART.

BY RUSTICUS.

Much that is said and written on this subject now, is ambiguous and misleading, I think. Are we to define agriculture an art, and not a science; strictly a science, or made up of both? This pertinent enquiry will arouse varying responses. Opinions will be coloured much by the degree of culture and learning of the respondents. I regard it as no easy problem. But its solution is rendered somewhat easier, in the present age, than it was centuries ago. When agriculture was almost entirely guess-work, "firing at random," so to speak, neither of the above mentioned definitions would obtain. With the steady advance of knowledge, growing out of research, experiment, discovery, greater precision of statement can be made. A distinguished scholar has recently laid down the dictum that agriculture is an art, not a science. Shall we wholly accept his teaching? A study of the terms, arts and science will aid us in our determination. But first let us bear in mind that they are synonymous now. An expression is strictly a synonym of another expression, when the two "so nearly approach each other, that in many or most cases, they can be used interchangably. Words may thus coincide in certain connections, and so be interchanged, when they cannot be interchanged in other connections."—(Webster.) One of the synonyms of *art* is *science*. Art, of necessity, runs into science; science, perforce, draws upon art. The word art is derived from the Latin *ars*, denoting skill in execution, taken from the Greek, *apeir*, conveying like meaning. It involves the idea of doing, of accomplishing. "The employment of means to accomplish some desired end: the application of knowledge or power to practical purposes (*Ibid*). Now, this meaning, unquestionably, is alike to a certain degree, the meaning of science, that is, operative science, science in practice. Purely theoretically, there is a wide difference in the terms. Science implies speculative principles. Science comes from the Latin *scire*, to know, *scientia*, knowledge. Science is a complement of cognitions, having, in point of form, the character of logical perfection, and in point of matter, the character of real truth."—(Sir Wm. Hamilton.) "The comprehension and understanding of truth or facts."—(Dryden.) "Specifically, science is knowledge duly arranged, and referred to general truths and principles on which it is founded, and from which it is derived. Science is literally knowledge, but more usually denotes a systematic and orderly arrangement of knowledge. Science inquires for the sake of knowledge, art for the sake of production."—(Webster.) "In science, *scimus ut sciamus* (we know that we may know), while in art, *scimus ut producamus* (we know that we may produce)."—(Karslake.) Does agriculture embrace in any sense the two? Beyond controversy. Science is either pure or applied. The former is purely speculative, apart from application; the latter is, speculative principles carried out in practice. The one is simply rules, principles, deductions; the latter, these in operation. We see, then, how science belongs to the domain of art; that is to say, science in its practical working is art. Agriculture is science in the sense of being "knowledge duly arranged, and referred to general truths and principles, on which it is founded: systematic and orderly arrangement of knowledge."

Agriculture is art in the sense of these principles, this knowledge being utilised. But is agriculture entirely a science? In other words, has it reached that point that it can be classed as one of the sciences; is it pure science? Assuredly not. But it certainly has progressed sufficiently to be rated as scientific. Its attainments in this are far greater than its deficiencies. Its problems are not all solved, it must be admitted. There are certain questions in agriculture that so far have baffled all investigations. Time may explain them. Perhaps we should rather call agriculture inchoate science. This much we may safely claim, I think clearly, there are many things it has firmly established, and upon which it can and does safely proceed. Analysis by its wondrous searching reveal facts which become truths, axioms; and upon the strength of which action can be logically based. Herein is agriculture science in the most rigid acceptation of the term. Its conquests are many and great. But little that is tentative belongs unto it. True, certain processes of growth and assimilation are yet a sealed book as to their comprehension.

Dr. I. R. Nichells very pertinently says:—"I have said that the new agriculture rests upon science and positive knowledge; but this remark must not be understood to mean that all the various departments of modern husbandry rest upon pure knowledge or demonstrated facts, for this position would plainly be indefensible; but I do say that the great fundamental principles are understood and established as clearly as those of most other branches of human knowledge. So far as the chemistry of plant structures and the forms of food they require are involved, our knowledge is positive; and also it is true that most of the details of practical farm industry are now so well understood that they may be said to be almost or quite removed from the regions of doubt. Clouds of uncertainty, the feeling that every step was governed by chance or blind caprice, belonged to the old agriculture; it certainly does not to the new."

Dr. J. B. Lawes uses the term, scientific agriculture, in his able writings. He speaks of "our advance in the path of scientific agriculture." Says Prof. McBryde: "Agriculture requires for the elucidation of the principles involved in its various practices, a very wide range of scientific inquiry." It is this scientific inquiry which has brought to light many truths bearing upon agriculture which now rest on the bed-rock of accuracy. The intelligent farmer, with all the accumulated data of plant life, food assimilation, weather influences, soil structure and soil treatment, can proceed confidently, and not be tossed about on the waves of uncertainty and mere caprice.

[We are not prepared to accept the proposition that applied science is synonymous with art. Nor can we admit that because we properly use the term "scientific agriculture," science and art are therefore one and the same thing; and notwithstanding the original "*ars*" of the Latin may have meant skill in execution, the modern "art" must have a broader significance. There are numerous artisans who are anything but "skilled" in their arts—mere bunglers in fact. In short, art, as we must understand it today, is simply the power of imitation—the ability to do something without any particular reason—while science is the power of reasoning on what we do, so that by the facts we gather from this experience we may do something or know something which we have never done or known before. By art we can make a right-angled triangle; by science derived from the triangle we can measure the height of a tree or a star. Thus, it is not difficult to see that in agriculture mere art and science are two distinct things. Scientific agriculture becomes agriculture aided by science.—ED.]—*Gardeners' Monthly.*

CONSTITUENTS OF SOILS.

What are salts? Salts are all combinations of acids with alkalies, or, as they are called, alkaline bases. In their properties salts differ as widely as possible; some are crystallisable, others not so; some are colorless, others of various colors; some excite taste, others are insipid; some are soluble, others insoluble; some are volatile, others fixed. The term salt is of wide and various application. But, in relation to the subject under consideration, the common salt, used as a seasoner and preserver of food, is a good example. This is the chloride of sodium, formed when chlorine and sodium, or hydrochloric acid and soda, come together. Sodium is a soft metal of a silver white color, and light enough to float upon water. In the metallic state it is not known to occur in nature, and, therefore, does not directly act upon vegetation. With chlorine it forms the chloride of sodium (common salt), and in this form it is more or less beneficial to vegetation. With oxygen it forms soda; with sulphur, the sulphuret of sodium; and these salts are likewise variously beneficial to plants. Saltpetre is a salt. It is potash united to aquafortis. These have united, and their characters are neutralised by each other, so that in saltpetre one will not perceive either potash or aquafortis. They have formed a neutral salt.

What are "carbonates," "chlorides," "nitrates," "silicates," &c., frequently named in agriculture? These are some of the salts formed by the mutual action of acids and alkalies, or, in some cases, metals, already described. Thus: the carbonates (carbonic acid) of lime, magnesia, potash, soda, iron, manganese. Chlorides (chloric acid) of potash, soda, lime, manganese, silver, zinc. Citrates (citric acid) of potash and lime. Humates (the humate acid of soils) of lime. Nitrates (nitric acid) of potash, soda, lime, ammonia, magnesia. Phosphates (acid of phosphorus) of alumina, lime, magnesia, potash, soda. Silicates (acid of silica) of potash, soda, lime, magnesia, alumina. Sulphates (sulphuric acid) of ammonia, potash, soda, lime, magnesia, alumina, iron, copper, manganese. Thus it will be seen that the same acid with another base forms a different kind of salt. Many of these acids, alkalies and salts form essential constituents of animal and vegetable bodies, soils and manures; and the changes and combinations which they undergo are intimately connected with the development of animal and vegetable life, and the growth of animal and vegetable forms.

What are bases? The term base implies the leading constituent of a compound. Thus, in the compound "carbonate of lime," the latter is the alkaline earthy base. Every one is acquainted with the general properties of that group of substances which bears the name of acids. The term base is perhaps not so universally understood. We designate compounds possessing the power of combining with acids and neutralising their acid properties by the word bases. A compound of an acid with a base is denominated a salt (this name has no reference to the taste). Now, in these compounds—in salts—one base may be made to replace another base, one acid another acid. Carbonic acid, water, ammonia and sulphates are necessary for the existence of plants, because they contain the elements of which their organs are formed. But other substances are requisite for the formation of certain organs destined for special functions peculiar to each family of plants. Most plants, perhaps all of them, contain organic acids of very different composition and properties, all of which are in combination with bases, such as potash, soda, lime or magnesia; plants containing free organic acids are few in number. The bases evidently regulate the formation of the acids, for the diminution of the one is followed by a decrease of the other; thus in the grape, for example, the quantity of acid contained in its juice is less when it is ripe than when unripe; and the bases, under the same circumstances, are found to vary in a similar manner. Such constituents exist in the smallest quantity in those parts of a plant in which the process of assimilation is most active, as in the mass of woody fibre; and their quantity is greatest in those organs whose office it is to prepare substances conveyed to them for assimilation by other parts. The leaves contain more inorganic matters than the stem.

It is most important to bear in mind that any one of the many alkaline bases may be substituted for another, the action of all being the same. The law that one base may be substituted for another is of the highest practical value. This will be perceived when it is considered that if a soil, containing originally all the elements essential to a crop, becomes exhausted of one, yet another may be substituted, which, combining with the organic acid of the plant, enables it to perform and perfect all its functions; potash, soda, magnesia, &c., may, in certain circumstances, supply the place of lime. When roots find their more appropriate base in sufficient quantity they will take up less of another. The base of all salts acts ever the same in agriculture. Peculiarity of action depends upon the acid of the salt. This is the great practical principle of agricultural chemistry. It opens veins, rich in results, more precious than mines of gold. It is not known in what form manganese and oxide of iron are contained in plants; but we are certain that potash, soda and magnesia can be extracted, by means of water, from all parts of their structure, in the form of salts and organic acids. The same is the case with lime in many instances. The existence of vegetable alkalies in combination with organic acids gives great weight to the opinion that alkaline bases in general are connected with the development of plants. The ashes of the tobacco plant, of the vine, of peas and of clover contain a large quantity of lime. Such plants do not flourish on soils devoid of lime. By the addition of salts of lime to such soils they become fitted for the growth of these plants; for we have every reason to believe that their development especially depends upon the presence of lime. The presence of magnesia is equally essential, there being many plants, such as the different varieties of beet and potatoes, from which it is never absent. The whole argument suggests that by the analysis of plants we may arrive at a knowledge of their peculiar wants, and by the chemical examination of soils and manures we may take care that those wants are supplied.

Whence do plants obtain their principal salt? It has been proved that with the evaporation of salt water salt becomes volatilised and dispersed. When sea storms occur the leaves of plants in the direction of the wind are covered with crystals of salt, even to a distance inland of from 20 to 30 miles. But it does not require a storm to cause the volatilisation of the salt, for the air hanging over the sea always contains this substance, and every breeze must carry it away. Now as thousands (millions) of tons of sea water annually evaporate into the atmosphere, a corresponding quantity of the salts dissolved in it—viz., common salt, chloride of potassium, magnesia, and the remaining constituents of sea water—will be conveyed by the wind to the land. By the continual evaporation of the sea its salts are spread over the whole surface of the earth; and being subsequently carried down by the rain furnish to vegetation those salts necessary to its existence. This is the origin of the salts found in the ashes of plants, in those cases where the soil could not have yielded it to them. By the foregoing explanations the substances to be found in plants—which is the same to be found in manures and soils on which plants grow—are reduced from things not known to things that are known. In this way persons may feel familiarised with them without a deep acquaintance with chemical science. And it will be seen that in a multitude of cases the practical cultivators of the soil may understand the principles of the science, although ignorant of the precise terms which represent and explain these principles. Thus the housewife proceeds in making bread on scientific principles, although she never saw a book on chemistry, or learned the meaning of a scientific term.

It what respects does nature present to man the example of preparing soils? By the gradual processes by which she herself prepares the surface of the earth, in certain instances, for the reception of the higher orders of plants. What is the common action of nature upon a bare rock which is protruded in any way? You first have some lichens growing over the surface of the rock. These plants have the power without the aid of anything from the soil except the mineral ingredients of attracting substances from the air. After generations of these have grown and died, mosses take their place, and grow upon the remains of a kind of mould which has been made by the decay of the lichens. After the moss has grown for some years you will find different kinds of natural grasses. These are succeeded by others, until at last you have upon what was originally a bare rock a soil formed naturally, in which trees can and do grow from seeds naturally sown in it. Take, for example, the lavas ejected from Vesuvius, Ætna and other volcanoes. These lavas, which have been molten and red hot, of course contain no vegetable matter. They have not been long cooled before the wild fig tree and other plants, sending their rootlets into the interstices, spring up and produce abundance of woody matter, which must evidently have been obtained from the air, as it did not exist in the soil. It is clear, then, that there is something in the air which these plants have the power of obtaining; and it is this which enables nature to clothe the surface of different rocks with plants of various kinds, so as to present, even when man does not come on the stage at all, a fine scene of foliage wherever moisture and water and other elements of vegetation, can be found.—*Leader.*

NOTES ON THE REARING OF SILK-PRODUCING BOMBYCES IN 1883.

BY ALFRED WAILLY,

(Membre Lauréat de la Société Nationale d'Acclimatation de France).

(*Continued from page 781*).

The second mode of rearing the *Yama-Maï* silkworm in Japan, which is resorted to after the third moulting of the worms, is the following:—Pits are dug one foot wide, and about one foot and a half deep. These pits are filled with bales of rice, which are well watered and covered with mats, through which oak branches are plunged to the bottom of the pits. The worms previously bred under cover are now reared in the open air, and uncovered up to the time of their transformation on the branches plunged in wet rice. The bales of rice receive every day a plentiful supply of water, which allows the foliage to keep fresh for a long time. When the branches are changed, the old ones are pulled out and placed on mats, in order that no sand or dust should touch the worms, for, if they swallowed any with their food, they would become sick and die. When the old branches have been removed, fresh ones are inserted in their places, and the old ones are then tied or otherwise fastened to the fresh branches.

This mode of rearing has not, as far as I know, been adopted anywhere in Europe or in India, and I do not think it ought to be adopted at all, as the third mode, that of rearing on trees, is by far the most simple and the best, especially when the worms are reared on a very large scale.

Third mode.—Rearing on trees in the open air. This last mode, like the second, is adopted after the worms have passed their third moult, that is, when they are in their fourth stage. The place chosen is a plantation in the plain in preference to one in the mountain, and the ground, twelve months beforehand, is cleared of all weeds, also of the useless shrubs and trees. The branches of the trees which are too long are cut down, so that all on which there are worms or cocoons should easily be reached.

Without going into further details respecting the mode of rearing in Japan, it is certain that if trees were planted in rows, and the branches cut or bent down so as to form a bush eight, nine or even ten feet high, immense quantities of silkworms could be reared in suitable climates by taking the two following and indispensable precautions:—1st, to keep the ground clear of all weeds which might harbour insects injurious to the worms; 2nd, to have, especially when the worms are large, men to watch the worms constantly, and keep the birds away, as these in a very short time might destroy the whole crop. The worms might be placed on the trees as soon as they are hatched, which would be a great saving of time and labour, and the rearing would have no other limit but that of the plantation. I will now pass to my notes on the rearings of last season.

Hybrid Roylei-Pernyi.—On referring to my articles on the rearings of silk-producers in 1881 and 1882, it will be seen that I obtained this remarkable hybrid in 1881 by the crossing of *Roylei*, the Himalaya oak silkworm, with *Pernyi*, a north China species. The new hybrid, contrary to what had taken place previously with other hybrids, was larger and superior in every respect to the parent species; its reproduction in 1882 from the cocoons obtained in 1881 was most wonderful—many hundreds of fertile eggs from a small number of moths. I then felt most certain that I had created a most valuable silkworm, easy to reproduce and rear. But in 1883, the third year of the existence of my hybrid, I was cruelly disappointed, for it disappeared entirely.

Degeneracy was certainly the principal, and perhaps the only cause of this failure. Now, was this degeneracy due to the fact that this new silkworm was a hybrid? I could not to a certainty declare that such was the cause, for the *Pernyi* silkworms reared at the same time, and under the same conditions as the hybrid, had degenerated to the same extent; so that it may be that the cause of degeneracy was due to the unfavourable conditions under which the larvæ were bred.

The few hybrid larvæ which I reared in London in 1882 on a small scale, in torrents of rain for the greater part of the time, could not be relied upon to produce strong healthy pupæ. On the other hand, the hybrid cocoons I had from one of my correspondents in Scotland, and those I obtained in Paris, at the Société d'Acclimatation, were the produce of larvæ reared in large numbers in warm rooms. My correspondent in Scotland, Mr. Turnbull, reared an immense quantity of the hybrid worms, together with *Pernyi* worms, in warm rooms, and it is a well-known fact that worms bred under these conditions often get the germ of disease in them; the *Pernyi* worms were affected just the same as the hybrid ones.

Another difficulty came in the way of the successful rearing for 1883. The hybrid moths in 1882, in consequence of warm weather, began to emerge in April, about three weeks before the usual time, so that two generations were obtained. Most of the moths emerged in the autumn, 1882, leaving but a small number of live cocoons for the year 1883, and these were very likely the weakest; at any rate, they were smaller than the cocoons obtained in 1881.

In 1883, the moths of the hybrid did not begin to emerge till June 2nd, considerably later than in 1882, when they commenced to emerge on April 23rd, and several of the cocoons died.

Tho moths, which kept on emerging till July, paired with the same facility as in 1882, but almost all the eggs were unfertile. Out of a small quantity of fertile ova, I obtained about eighty larvæ, in all appearance very healthy, which were placed on small oak trees in my garden. These oak, together with some other kind of trees, were under one large frame-work covered partly with wire, partly with fish-netting. I made use of all the old materials I had in London for economy's sake, and I had here, only one large frame instead of three smaller ones, as I had in 1882, in London. The hybrid larvæ grew rapidly, without showing any sign of disease, till they had reached for the most part the third stage, when one day I found the fish-netting, which must have been rotten, entirely torn from top to bottom on one side of the frame, and all the larvæ had disappeared, destroyed by birds, together with some other species. The tearing of the net had evidently been the work of cats, which I had frequently seen climbing up to the top of the frame. Fish-netting is, therefore, of little use. This fatal accident prevented a rearing and study which would have been very interesting and important to me, *i.e.*, the preservation of the hybrid, or, if the worms had the germ of disease in them, to watch and see how long they would live in such a state. As I have before mentioned, they looked remarkably strong and healthy.

After this disaster, the fish-netting was mended, and several yards of new wire-netting were added to the frame-work, after which the worms of the few other species in the trees were left unmolested by the sparrows and other birds.

Actias Selene—Of this species I had, in 1883, no cocoons imported from India, but only about twenty cocoons obtained from the rearings of 1882, and of these several died. The moths emerged as follows:—June the 4th, one male moth; on the 13th, one male; on the 17th, one male; on the 19th, one male and one female, which paired on the 21st, between 2 and 3-30 a.m. On the 22nd, one male; on the 23rd, one male; on the 25th, one male; on the 26th, one male; on the 27th, one female. On the 28th, I obtained the second pairing. On, the 28th, a third female moth emerged, which paired on the 29th of June. On the 4th of July, a female moth emerged; on the 14th, one male; and on the 7th of August, the last moth, a female, emerged. By referring to this list of births registered, it will be seen that the first three female moths, which alone had a chance, all paired, and this is the greatest success I ever obtained with this species with respect to pairings, but the same success did not attend the hatching of the larvæ.

The first female moth laid 255 eggs, which were very good, and began to hatch on the 6th of July. The second female, which was smaller, laid only 154; none of these I kept. The third female, which was the finest and largest, laid 303 eggs, but none of the eggs I had kept of this last brood hatched, and this I attribute to a sudden change of temperature at the moment tho larvæ should have hatched; but there may be some other cause unknown to me. Some of the larvæ of the first brood were reared in the house on walnut leaves, others on a pear-tree in the garden under the netting. The larvæ reared in the house reached their last stage in a very short time; on the contrary, those in the garden were very slow, and did not begin to spin before the 11th of October, when I had to bring into the house the few which were on the pear-tree in the garden.

Attacus Atlas.—With a large quantity of Ceylon and a few Himalaya *Atlas* cocoons, I had no better success in 1883 than in 1882. The moths emerged from the 11th of July to the 28th of September. As usual, a number of the cocoons died, while others kept alive for the following season (1884). Only ten Ceylon and four Himalaya *Atlas* moths emerged at intervals, never giving any chance of obtaining fertile ova.

Two of the Himalaya *Atlas* moths, one female emerged on the 4th of September, and one male on the 21st of the same month, were very perfect and extremely beautiful, both measuring over 10 inches in expanse of wings. These, with a wonderful aberration of the genus *Samia* or *Platysamia*, and a large number of other specimens of silk-producing Bombyces and other lepidotera were exhibited on the 3rd of October, 1883, at a meeting of the Entomological Society of London. Among these specimens was a series of about fifteen *Mylitta* moths, showing most of the various shades of colour, from the bright golden yellow to the darkest brown or grey. Reference will be made further on to the extraordinary specimen of the genus *Platysamia*, which I consider as an aberration of *Cecropia*. Besides these specimens, I exhibited some of the living larvæ of silk-producers, which were still to be found at that time on the trees in the garden, such as *Telea polyphemus* and *Hyperchiria io.*

Antheræa Mylitta or *Paphia.*—The notes I took on this species, the most important East Indian wild silkworm, cover six pages of my note-book. Therein is registered the birth of every moth, the pairings, &c., which it would be unnecessary to reproduce at length. The first *Mylitta* moth emerged on the 6th of June, the last on the 29th of October. I had a very large number of cocoons, some of which did not hatch, and are still alive, even after having hybernated twice. These cocoons came from four different parts—Calcutta, Madras, Ceylon, and Bombay. Those from Madras, only ten in number, had already hybernated during the winter 1881-82, and had remained in perfect condition. Two of these Madras cocoons still remain alive for the year 1884.

The first moth which emerged belonged to the Bombay race; then, from the 25th of June, Ceylon moths emerged, and the first pairing was obtained during the night of the 2nd and 3rd of July, and a second pairing of the same race took place on the 6th of July. The third pairing which took place during the night of the 9th of July, was by moths of the Bombay race; the fourth during the night of the 11th, and ended at 10-30 p.m. on the 12th of July, was a cross between a female of the Bombay and a male of the Ceylon race. The number of eggs obtained from these four pairings was:—78 by the first, 183 by the second, 135 by the third, and 128 by the fourth, a total of 524 eggs. Later on, two more pairings were obtained, one from the 6th to the 7th of August, between a male Ceylon and a female Bombay; the sixth and last took place in the night of the 19th and 20th of August, between two moths emerged from the cocoons sent to me from Calcutta. I lately heard that these cocoons sent from Calcutta had been collected in Assam. The number of pairings, six only, is very small, considering the large number of moths obtained from the cocoons, and undoubtedly shows that the temperature was not sufficiently high for this species. The eggs from the last two pairings in August were obtained much too late to be of any use in England for rearing; therefore I sent them to some American correspondents, but as yet I have not heard of the result. The eggs of the first pairing (Ceylon race), that of the 2nd and 3rd of July, began to hatch on the 25th of July; those of the third pairing (Bombay race), of the 9th of July, began to hatch on the 3rd of August; and the eggs of the fourth pairing, a cross between the Bombay and Ceylon race, which took place on the 11th and 12th of July, began to hatch on the 4th of August. The ova of the second pairing had all been distributed, together with some of the other three pairings, among European and American correspondents, and I shall be glad to hear of the result of their experiments. Though there were great differences in the shades of colours in the moths of the different races, all the larvæ were alike. The second stage of the larvæ took place on the 9th of August, fifteen days after they had hatched; the third stage commenced on the 24th of August, and the fourth on the 10th of

September. The larvæ could not be reared beyond that date, the weather not being warm enough. It may be that oak leaves are not a proper kind of food for *Mylitta* larvæ; although they have been reared on oak, they did not seem to thrive well on it. Major Coussmaker lately informed me that *Mylitta* larvæ feed well on rose branches, and these should be used in future, together with oak and horn-beam, so as to find out on which plants they will thrive best.

A description of the larvæ in its six stages has already appeared in one of my previous reports, that for the year 1879. The interesting pamphlet on "The Tussur (*Mylitta*) Silkworm," by Major G. Coussmaker, gives full particulars on the cocoon, moth, egg, larvæ and food-plants of this valuable wild silkworm. It was published in 1873 by E. and F. N. Spon.

As I have stated, the *Mylitta* larvæ I reared only up to the fourth stage. Many died at the different stages, but some whre sent in all their stages to Mr. F. Moore, of the Bethnal-green Museum, and these were beautifully drawn and coloured, together with larvæ of other species by Mr. Moore's son.

Attacus Cynthia or *Ailanthus Silkworm.*—This silkworm is the easiest to rear in the open air in England; next to it is *Antheræa Pernyi.* Moths of *Attacus Cynthia*, in 1883, commenced to emerge on the 3rd of June, and they continued emerging till the end of the same month. Thirty pairings were obtained, producing thousands of eggs and larvæ. Having had no Ailanthus trees bearing any foliage this year after their transplantation, I had to try the rearing of the worms on various trees. I placed the immense quantity of worms I obtained on rose-trees climbing against the house, on maples, on a mountain ash, on a common ash, on lilacs, and on laburnums—alone, those which had been placed on the laburnums thrived, but not near so well as they do on the Ailanthus tree, their natural food plant. A few larvæ, out of a large number, also thrived on the lilac trees and on the common ash. The thousands placed on the other trees disappeared in the first stage, and in all probability because the foliage did not suit them, as they could not have all been destroyed by the insects that prey upon them.

The sparrows, as usual, do not seem to have touched any of the *Cynthia* larvæ, which commenced to form their cocoons on the laburnum trees on the 3rd of August, and the last on the 27th of September.

North American Species.—Telea polyphemus.—Moths emerged from the 23rd of May to the 25th of June. Only three pairings were obtained, one on the 20th, and two on the 23rd of June. On the 25th, a female *Polyphemus* paired with a male *Cecropia*, but the eggs, as usual, were not fertile. The larvæ were very successfully reared in the open air, on the small trees in the garden, in spite of bad weather, during the last stage. The first cocoon was commenced on the 18th of September, and the last on the 7th of October.

Actias luna.—Of this species I had no cocoons, but eggs were sent to me from France, and from three American correspondents. Of the latter, some were sent from the State of Iowa, which hatched and died during the voyage; some sent from Illinois hatched on the 11th of June, the day of or after their arrival. Others I received from New York, which had hatched during the voyage, and died afterwards. On the 28th of July I again received from New York two boxes, which, on being opened swarmed with young larvæ in splendid condition; these larvæ were from the second brood of *Actias luna*, the species being double-brooded.

Want of time prevented me from rearing such a quantity of *luna* larvæ, especially on account of the difficulty I have to obtain walnut leaves, on which they seem to thrive better than on other kinds of foliage. I therefore only reared a small number in the house.

Eggs sent from America are placed, as I suggested a few years ago, in a muslin bag containing leaves of the food plant, and then the bag is inserted in a tin box hermetically closed, so that the leaves keep, and arrive as fresh as if they had just been cut off the tree, although some small portions may decay or rot. If the eggs are sent as soon as they have been laid, many of them have time to arrive in England in good condition, after a voyage not exceeding fifteen or sixteen days. If some or all of the larvæ hatch during the voyage, they feed at once, and grow during the two, three, or four days they may have to remain in the box. It takes about twelve days for the *luna* larvæ to hatch; some other eggs require more time, and therefore can be sent with better chance of success. The great risk which the eggs and larvæ have to run is this, that the droppings of the feeding larvæ, falling on the moist leaves, create at once a rot or a fungus which is often fatal to the larvæ, and also to the eggs which have not hatched. But a proportionate number of larvæ and eggs escape, and arrive in good condition, especially if there is sufficient room for them in the box. Certain species can only be sent in the egg state, and this method of sending is the only one that can be adopted, and we must be satisfied if only a few eggs or larvæ are saved.

Hyperchiria io.—Moths of this bright and beautiful little species, described in former reports, began to emerge on the 4th of June, and continued to emerge till the first of July. The moths pair readily, if they are in good condition, *i.e.*, if the wings are fully developed, especially in males. Fourteen pairings were obtained, which must have brought the number of fertile eggs to about 5,000 and even more. I bred a quantity of the larvæ very successfully in the house, under glasses. They are easy to rear, but live a long time before forming their thin cocoons. I also bred a number of them in the open air on *salix caprea*; they were larger, and grew quite as fast as those I had in the house.

Samia promethea.—Moths of this species emerged from the 25th of June to the 16th of July; twelve pairings were obtained. On the 1st of July a male *Cynthia* paired with a female *Promethea*, but the eggs laid did not hatch. The pairings of this species, which are short, are easy to obtain, and they generally take place between 6 and 8 o'clock in the evening. A small number of *Promethea* larvæ were placed on a small cherry-tree in the garden, but they were destroyed when in the first stage. As mentioned in previous reports, they feed also on lilac.

Platysamia Cecropia.—Of this, the largest North American silk producer, I received an immense quantity of cocoons from various States: Iowa, Illinois, Delaware, New York, &c. With the cocoons I had preserved I obtained 19 or 20 pairings. On the 25th of June, a male *Cecropia* paired with a female *Polyphemus*, the eggs being unfertile. I record these pairings to show that whenever the species are not closely allied, the eggs have invariably been unfertile. I have heard of fertile ova obtained by the crossing *Promethea* and *Cynthia*, but I never obtained such fertile ova, although I have had many pairings between these two species.

The *Cecropia* moths emerged from the 24th of May to the 23rd of July. Ova of *Cecropia*, sent to me from Iowa, all hatched on the day they arrived, and the larvæ thrived splendidly.

The thousands of larvæ which I obtained were, except a few, placed on all the apple, pear, and plum trees in the garden, and also on some currant bushes, but as soon as they had reached the second or third stage, they were all destroyed by the sparrows and other birds. Late in October I found a full grown *Cecropia* larvæ which had escaped the eye of the sparrows, on a currant bush. The weather being then very wet and cold, I brought it into the house, but it died while attempting to form its cocoon.

From one of the *Cecropia* cocoons, there emerged in June a most extraordinary specimen, remarkable alike for its size and the exquisite beauty of its various colours. As I have been asked weather the cocoon from which the moth emerged differed from the other *Cecropia* cocoons, I must state that I did not notice any difference in the cocoons, and there were about 100 in the cage. I was then so busy that I entirely neglected to examine the cocoons: in fact, I did not think of it, and I very much regret not to have examined the cocoons. Later on, the cocoons, together with *Cecropia* cocoons from other cages, were all thrown into a large box with cocoons of other species; and some were given or thrown away. However, had there been a difference, and especially a notable difference, between the cocoon which produced the wonderful specimen and the other cocoons, I should certainly have noticed it.

Up to the present time, I have not heard that any such specimen has ever been seen, and as I stated, I consider it as an extraordinary aberration of *Cecropia*. The specimen has been photographed, natural size, and I have coloured a few copies of it, so that persons wishing to see it may have a representation of it.

On taking the specimen to Mr. W. F. Kirby, at the British Museum, he wrote the following description of it for the Proceedings of the Entomological Society of London (1883).

ABNORMAL SPECIMEN OF THE GENUS SAMIA,

BY W. T. KIRBY.

"This remarkable specimen, which has puzzled every entomologist who has seen it, was bred by M. Alfred Wailly, from a cocoon received from some part of North America. It may be a hybrid between *S. Cecropia* and some other species, but if so, it is so different from all the other known species, that it is difficult to guess with what it could have been crossed. It is equally difficult to imagine that it is a new species. The specimen is a female, and equals the largest specimen of *S. Cecropia* in size, measuring 6¾ inches in expanse; and the wings are more rounded and less oblique than in *Cecropia*. The body resembles that of *Cecropia*, except that the abdomen is banded with yellowish grey and black. The base of the fore-wings is brown, thickly scaled with white towards the costa; below this is a brick-red blotch, longer and narrower than in *Cecropia*. Beyond this is a white space extending nearly from the base to one-third of the length of the wing on the inner margin, but curving up to the costa in a rather narrow stripe. This is followed by a large irregular black blotch, broad at the costa (where it is thickly dusted with grey), and the narrow end extending to beyond the middle of the wing. On this stands the large kidney-shaped central spot, which is surrounded with red, and divided by a reddish stripe at the outer end of the black blotch; it extends beyond it into a broad red white-dusted band, followed by a black one, so very thickly dusted with yellowish grey, that it appears of that colour. This is succeeded by a grey space, divided by a black line (much less indented than in *Cecropia*) into darker and lighter; above is a blue space; on the inside is a row of rather large black spots, the uppermost, and the fourth and fifth being the largest. Hind wings, white at the base, followed by a broad slate-coloured space, on the outer half of which stands a large oval white spot, slightly surrounded with red, the outer part being incomplete, and it rests on a white band, much broader than in *Cecropia*, followed by a broad red band, three or four times as broad as in *Cecropia*, but followed outside by similar markings, only paler. The under surface differs from *Cecropia*, chiefly in the much paler colour, and in the different position of the central spots."—*Journal of the Society of Arts.*

COCONUT CAKES.—One cup of grated coconut, one cup of sifted sugar, a little grated nutmeg; milk enough to mould the cakes. Shape into round balls, and brown slightly in a cool oven. They should be made small.—*American Grocer.*

THE AMOUNT OF VEGETABLE PRODUCE now annually imported into England is more than double that produced by the soil. To say nothing of the tropical or sub-tropical vegetable products—cork, dye-woods, oils, resins, gums; nothing of sugar, spices, Tea, Coffee, Cocoa; nothing of Cotton and grasses, of Hemp and Flax, of indigo, madder, and fruits—we import sawn or split timbers, staves and Mahogany to the value of £15,000,000 per annum, of which the one item that we could not ourselves produce, Mahogany stands for under £400,000. Our imports of timber not sawn and split down to 1868 (the last year in which they figure in the *Statistical Abstract*), stood steadily for some years at about £5,000,000 in value. We look in vain for any corresponding item among our exports.—*Builder.*

BEET *vs.* CANE-SUGAR.—It is estimated that a ton of sugar made in Russia from the sugar beet costs on an average £29 per ton, nearly as much as some of our best Queensland sugars realise in the local markets. One hundred pounds of beet gives at the most 9lb. of sugar, and the appliances in use for manipulating the roots and the juice are as nearly perfect as can be expected. The megass of beet as now treated on the Continent of Europe shows scarcely any remains of saccharine matter, and between it and the megass from the sugar-cane there is in this particular a remarkable difference. Without increasing the cost of manufacture very materially, it is probable that larger yields will be obtained from the sugar-cane at no very distant date, in which case the beet sugar industry is doomed.—*Queenslander.*

FORESTS AND RAINFALL.—It is not so many years ago since the Editor of this magazine stood almost alone in showing that there was no evidence worthy of being called scientific to show that trees had any influence on the increase of rainfall; and in many instances he was roundly abused and held up to public reprobation as an enemy of forestry, because he ventured to differ from what then seemed to be the rest of the world. In the light of this chapter from history, it is interesting just now to observe how nearly universally writers are showing up this meteorological absurdity, and how such papers receive editorial endorsement. Aside from personal feelings of satisfaction, we are glad that these errors are being removed, for no cause receives any permanent advantage but from absolute truth. We believe that forests can be planted profitably in many places where good judgment is brought to bear on the problem, though we still believe, as we have always taught, that forests are the effect and not the cause of climate.—*Gardeners' Monthly.*

IN GRAPE RAISING people seem to go to extremes in management. A few years ago the poor plant was in leading strings. It dared not make one free growth, but it was pinched and twisted into all sorts of ways. Now the "prune not at all" maxims are getting headway, and this is as bad, if not worse. First, grape growing was such a mystery it took a life time to study it, and the "old vigneron" was an awfully sublime sort of a personage. He is now among the unfrocked and unreverenced. But there is great art in good grape treatment; and yet this art is founded on a very few simple principles. For instance, leaves are necessary to healthy growth; but two leaves three inches wide are not of equal value to one leaf of six inches. To get these strong leaves, see that the number of sprouts be limited. If two buds push from one eye, pinch out the weakest whenever it appears. The other will be strengthened by this protective policy, and the laws of trade result in favor of larger and better leaves on the leaf that follows. Allow no one shoot to grow stronger than another. If there are indications of this, pinch off its top. While it stops to wonder what you mean by this summary conduct, the weaker fellows will profit to take what properly belongs to them. There is little more science in summer pruning than this; but it takes some experience, joined with common sense, to apply it. This, indeed, is where true art comes in.—*Gardeners' Monthly.*

TAR AND CANKER ON FRUIT TREES.—It is frequently asked if tar or pitch will so far injure the bark of a tree as to cause the death of the tree so acted on. I may say that, so far as I know, there is no record of a robust tree with sound mature bark having been killed by it, although doubtless its effects would be decidedly injurious if the application was made over the major portion of a tree's bark surface. When tar is placed over wounds caused by removing large limbs it acts beneficially in stopping up the pores of the wood, and thus preventing air and moisture acting on the tissues so as to cause decay in them. This protective effect can be made to last till the natural growth of the bark has covered the place, which will generally happen, if the tree has not approached maturity, in a few years, more or less, according to the rate of growth. With regard to the usefulness of tar in arresting attacks of canker in fruit and other trees, it has been found that in trees so affected, if the infected portions of the bark, and even the wood, be cut away till sound tissues are reached, and tar (coal) or pitch be well rubbed into the wounds thus made, it has a fatal action on the particular fungus, which is the cause of the disease called canker. Of course it will kill the germs of the fungus only where it touches, will retard the spread of the disease on the particular trees which are manipulated on, and will lessen the number of attacks on neighbouring trees. But the real remedy in the case of young trees, and those of a manageable size, is to lift them out of the soil, that by its nature predisposes the trees growing in it to the disease, and to plant them in more congenial soil. Shallow or surface planting over an impervious floor, and in the case of small trees occasional transplanting and root lifting—and enough manure to ensure vigorous growth and superior fruit—will be discovered to be the best treatment.—M.—*Gardeners' Chronicle.*

SMITH'S FIBRE MACHINES.

We insert on page 925 a letter from Messrs. Collyer & Co. of the General Fibre Company, the purport of which is that the reason why Dr. Forbes Watson did not put in an appearance at the Calcutta Exhibition was not due to any defect in Smith's Fibre Machines, which, "*when properly handled, not otherwise,*" are capable of dealing with 10 cwt. per hour of rhea or any other fibre-yielding plants. This, our readers will observe, is equal to 4 tons of raw material in a day of eight hours, or five tons in ten hours. The great point is that the machine should be "properly handled," and it seems unfortunate that in so many cases here and elsewhere it has been found impossible to handle it so as to get anything like satisfactory results. When those delays in regard to the formation of the General Fibre Company, which really prevented Dr. Forbes Watson from coming to Calcutta and showing what the machines when properly handled could do, are overcome, we suppose purchasers will be fully instructed how to get good and profitable results. Last mail, which brought us the letter from Messrs. Collyer & Co., brought us other communications on the same subject. Amongst them is a letter from a gentleman connected with the Company, who was for several years a planter in Ceylon. We place his letter below that of Messrs. Collyer & Co., and our readers will see how positive our correspondent is as to the good results obtained by means of the Smith or Death fibre machine. The specimen of rhea fibre sent looks very nice. Our readers will see, that, given the treatment of five tons per diem of raw material, the clean fibre will vary from 3 to 5 per cent; that is, from 3 cwt. to 5 cwt, the latter maximum quantity being one-fourth of a ton. In four days a machine would turn out at this rate a ton of fibre, worth in the market from £20 to £100, according to quality. The mail, however, has brought us a communication, which we insert, showing very poor results obtained in Ceylon from one of Smith's machines, which probably was not properly handled. No doubt Messrs. Collyer & Co. will show Mr. Campbell and others that far better results can be obtained when the machines are properly handled, and when such results are realized in Ceylon we shall be very happy to record them. We have abundance of fibre-yielding plants, and only good, cheap, profitable machinery is required to add an important industry to those already established in the colony. But the problem has not yet been here practically and satisfactorily solved.

THE PALMYRA PALM.

HOW IT WAS CREATED; ITS NATIVE COUNTRY; AND A LIST OF SOME OF ITS PRODUCTS.

From the *Tala Vilasam*, a Tamil poem, describing "in brief an account of one out of the 800 items of things connected with the palmyra-tree, which is emphatically the kalpa-tree of the earth," given in the appendix to a "Description of the Palmyra Palm of Ceylon," by William Ferguson, printed at the *Observer* Press in 1850 (thirty-four years ago), we extract the following notice of the miraculous way in which it was created:—"Parvathi (Sivan's consort) then said to Sivan, 'There is fault neither in Vishnu nor in Brahma,' and thus appeased his anger. Sivan upon this after meditating in his own mind, said to Brahma, 'Hear me tell you something to supply the wants of the people of the earth. Create the kalpa-tree upon the earth also.' At the direction of the crescent-moon-adorned Sivan, Brahma created in abundance palmyra trees in the three countries of Panathar, Panyoor, and Panangasdoor, and called palmyra trees by the names of Pootpady, Ponthy, Ponay and Talam." In this creation, the *Tala Vilasam* shews that the Hindu gods, Brahma, Siva, Vishnu and Sivan's consort, Parvathi, took each an active part—how many years before the Christian era we cannot state at present. Whether any one of the three countries in which the Oriental gods are said to have created the palmyra palm is identical with the land of the '*Shanars,*' of the modern Tinnevelly or the palmyra palm region of Southern India, we do not know, but the following facts stated by two living Englishmen may go some way to disturb the self-complacency of the Hindu gods named and those who believe in them.

In the 3rd vol. of the *Genera Plantarum* by Bentham and Hooker, they state that there is only one species of Borassus or palmyra palm, a native of AFRICA but widely cultivated in *India,* whilst in the Report of the Royal Gardens of Kew for 1882 by Sir Joseph Hooker, the facts of its origin are thus repeated on page 69:—"Native of Tropical Africa, cultivated in India."

Leaving the original habitat of this useful tree to be settled between the gods and the two authors of the *Genera Plantarum,* we proceed to notice the following list of some of its products.

Mr. J. Alexander of Udapussellawa, a gentleman of the planting community who takes a very deep interest in the agri- and horticultural products of our island, is taking with him from Ceylon for the grand Exhibition of Forest Products in Edinburgh, amongst other things, a very complete set of the products of the coconut palm prepared for him at the Hulstsdorp Mills by Messrs. Leechman, and of the palmyra palm from Jaffna prepared by Mr. Robert O. D. Asbury who received a silver medal from the last Agri-Horticultural Society Exhibition for his collection of the products of the palmyra palm.

From Mr. Asbury we have received a most excellent photograph showing about 100 out of 800 products of this wonderful tree, which remind us of the times of old, 1843-7, when we shot doves of various kinds amongst the palmyras and the wandura-like monkey once, and not a second time.

To us this photograph, showing us no less than 120 objects, conveys a very wonderful idea of the number of uses of the tree, and the ingenuity of the natives of Jaffna in manufacturing so many useful and ornamental products from it.

We now give the complete list of the 163 products of the palmyra palm given in a printed list by Mr. Asbury and beg to recommend him to anyone who may wish to procure a complete set of the products of the palmyra palm from Jaffna.

THE PALMYRA PALM.

(*Borassus Flabelliformis.*)

A list of some of the numerous uses this tree is put to in Jaffna, Ceylon: Prepared by Mr. Robert O. D. Asbury, Jaffna.

Group I. Wooden Utensils.—1 Plough; 2 Yoke; 3 Well-sweep; 4 Water-spout; 5 Door; 6 Gate; 7 Stand; 8 Manger; 9 Bedstead; 10 Ladder; 11 Pestle; 12 Walking-stick; 13 Thatching-needle; 14 Paper-weight; 15 Roof-timber; 16 Fruit-mallet.

Group II. Food Materials &c.—1 Fruit, ripe; 2 do. young; 3 do. juice, dried; 4 do. juice, spiced; 5 do. juice cakes; 6 Root, edible; 7 do. dried; 8 do. boiled, dried; 9 do. boiled, sliced; 10 Flour of root; 11 "Tapioca"; 12 Stone albumen; 13 Jaggery; 14 do. syrup; 15 do. candy; 1 Toddy; 17 do. sweet; 18 Vinegar; 19 Tender shoot.

Group III. Leaves. (Ola).—Raw:—1 Last but one shoot; 2 Leaf prepared for work; 3 Leaf of young tree; 4 do. for thatching; 5 do. for feeding cattle; 6 do. Ribs; 7 do. Refuse shreds. Manufactured.—(1) Mats—8 White, common; 9 do. braided; 10 do. small; 11 Coloured, braided; (2) Fans—12 Common; 13 Ornamental; 14 Ola book form; 15 Poorer kind; (3) Fisher's (Materials.)—16 Net appendage; 17 Fish basket; 18 Shrimp do. (4) Cases—19 For jaggery; 20 do. iluppa seed; 21 do. sacred ash; (6) Baskets for Domestic use—22 Paddy store; 23 Panattu store; 24 Basket of all work; 25 do. common; 26 do. for curry stuff; 27 Sieve, common; 28 do. with holder; 29 Separator, large; 30 do. small; 31 do. round; 32 Cone-cake basket; 33 Oil-press do; 34 Betel-nut satchel; 35 Clothes-basket; 36 Quart, (measure); 37 Fancy-work basket; 38 do. comn. do.; 39 do. screen; (7) Baskets (Bazaar use)—40 Sack, large; 41 do. small; 42 Purse-sack; (8) Baskets (Farm)—43 Grass basket; 44 Cooly cap; 45 Rain cap; 46 Water basket, garden; 47 do. kitchen well 48 do. field; 49 do common; 50 do. used as pail; 51 For plucking mango. (9) Miscellaneous.—52 Rice bowl; 53, Toddy bowl; 54 Conji bowl; 55 Umbrella; 56 Head screen, rain; 57 do. sun; 58 Dyed ola; 59 Fence; 60 Pillow; 61 Ear lobe filler; 62 Manure; 63 Manger-cote.

Group IV. Fibre, Ribs, &c.—Raw:—1 Just as peeled; 2 Prepared for rough work; 3 do. for rope work; 4 Black fibre. Manufactured. (1) Ropes.—5 For pair of cattle; 6 do. single, neck; 7 do single leg; 8 do. grazing cattle; 9 do. milch cow. (2) Ropes made of Ribs &c.:—10 Rib rope; 11 Po-swing; 12 Pot-stand; 13 Whisk.

Group V. School Things and Toys. (1) Books:—1 Purana book; 2 Alphabet book; 3 Pocket book; 4 Copy book. (2) Letters:—5 Common; 6 Under envelope; 7 Ticket. (3) Book buttons:—8 Ola button; 9 Rib button (4) Miscellaneous:—10 Boy's seat; 11 Book satchel; 12 Ola knife; 13 Style; 14 Style case; 15 Puncher. (5) Toys:—16 Elephant; 17 Jaggery elephant; 18 Rattle; 19 Parrot; 20 Wind-whirl; 21 Cart-wheel; 22 Spectacles; 23 Kite; 24 Rings; 25 Bracelet; 26 Necklace; 27 Fire-work.

Group VI. Toddy-drawer's Utensils:—1 Toddy jar; 2 Utensil case; 3 Foot-brace; 4 Spadix mallet; 5 Hip-rope; 6 Lime-case; 7 Spadix knife; 8 Breast plate; 9 Ankle plates; 10 Drip-pot.

Group VIII. Miscellaneous.—1 Leaf-stem, bottom; 2 do. sharp edge; 3 Skimmer; 4 Splint; 5 Pith; 6 Spadix, male tree; 7 do. female tree; 8 Stone; 9 Stone-coal; 10 Spathe-besom; 11 Imperfect stone; 12 Basket-knife; 13 Torch; 14 Sandal; 15 Door (poorer kind).

In the accompanying photograph over 120 of the 163 articles mentioned in this list are shown. Some writers mention 800 uses of the palmyra.

In a Guide to the Collections in the Colombo Museum by Mr. A. Haly, the Director, published in 1882 and sold for 25 cents, the following information is given on page 5 respecting the *palmyra palm*:—"The root of the palmyra palm is eaten dried or boiled, and the ripe fruit either raw or roasted; the fruit bud is given as food to cattle." Now, having a long experience, we do not believe that the *root* of this tree is ever eaten at all, raw or boiled, by man or beast. Who told Mr. Haly that the fruits are eaten raw or roasted? We never heard that the fruit-bud is given as food to cattle, and we do not believe in Mr. Haly's statement. This information in the Guide to the Colombo Museum reminds us of the story about the learned authors of the French Dictionary who went to Cuvier with their definition of a crab as "a small red fish which walks backwards." The naturalist's reply was: "Very good indeed, gentlemen, but allow me to remark that a crab is not a fish, does not walk backwards, and is not red until it is boiled."

Mr. William Ferguson's account of the palmyra palm has been so long out of print that we intend publishing a new edition of it, and with this object we shall feel grateful for any information not included in the original monograph. We should in this respect appeal in particular to our friends, the American Missionaries at Jaffna, who so willingly aided the author 34 years ago, and who are so familiar with this palm and its various uses. We regret that we are not in a position to spare a copy for their annotations.

TIMBER FOR TEA BOXES IN CHINA.

The *Ceylon Government Gazette* contains further Consular Reports on the timber used in different districts of China for tea boxes. Mr. J. P. Hughes, of Shanghai, stated:—

The tea chests made at Shanghai are comparatively very few in number, the great bulk of the tea being packed in chests made in the interior. The wood generally used in Shanghai is a sort of pine known as "Shanmu," probably the *Cunninghamia sinensis*. It is chiefly imported from the Province of Fokien, and is different from that used for the tea chests at some other parts in China. The wood is cut into suitable lengths and stored in a dry place for at least a year, and sometimes two years, before use. Green wood is rarely used, and when it is it invariably injures the tea, causing a distinct pine flavour known in the trade as "woodiness." I am informed that this flavour has never been found in Congou tea, but occasionally in the kind called Ping Suez. Tea is packed up-country generally in chests made of the wood of the "Fung" tree, by which name maple is generally understood, but it also applies to the Liquidambar. More precise information on the subject of country-packed tea will no doubt be supplied from Hankow and Kinkiang.

The storing of the wood in a dry place for at least a year, no doubt, deprives it of the objectionable turpentine odour, which itself is far less prominent in some pines than it is in others. But Consul Oxenham of Chinkiang reported:—

The result of enquiries shows that the willow tree most commonly furnishes the wood used in China for making tea chests. It is cheap and abundant, is easily sawn into boards, holds nails well (not splitting when they are driven in), and does not exercise any corrosive action on the lead lining of the chest. Pine wood, which is equally cheap, has been also tried, but is found to be unsuitable for the purpose: it does not hold the nails, splits easily, is liable to exude turpentine and injure the lining, and when new shrinks and cracks.

Other woods, such as the chesnut and Huai or locust tree (Styphonlobium), are also equally available for the purpose, but are generally too scarce and dear to be much used. In a few places, however, where such trees are abundant, they are occasionally used, but never for long, as they are valuable both for ornamental and edible purposes.

Now if by "willow," the ordinary willow is meant, we fear the information will be of little practical use to us here. But the "willow" in question may be a tree suitable for growth in Ceylon and we have no doubt Dr. Trimen will address himself to this subject. We cannot forget that Mr. D. Morris of Jamaica wrote of *Ficus Benjamina* as "the Ceylon willow." Consul Jamieson of Kinkiang reported:—

I am informed that the wood universally used in this district for the above purpose is that known by the natives as the *Fung* tree. The Fung appears to correspond to the genus "Liquidambar" of which there are several varieties. I am unable to say which is the more common in this neighbourhood, but all appear to be available for tea packing, the recommending feature being that this wood imparts no flavour to the tea. A large proportion of the best teas is exported from Kinkiang, the chests for which have all been manufactured locally for many years, and I have never heard complaints of any corrosive action on the lead lining.

Finally we have a report from Officiating-Consul Foster of Tamsuy, in favour of pine, thus:—

Seasoned common pine from the mainland portion of the Fokien Province is the wood most generally used within this Consular District for making the chests in which tea is exported to foreign countries.

Note that the pine is well-seasoned.

GRAM, RICE AND INDIAN CORN.

Dr. George Watt in his catalogue of Indian food stuffs and fodder says :—

Gram is a grain peculiar to India. It has lately been tried in Egypt and with some success, and experiments are being made on the banks of the lower Danube, but the results have never been published. It is a delicate plant and singularly susceptible to cloudy weather, which retards the formation of the grain, and if this weather continues over a particular period of fructification, it destroys the grain altogether, leaving the seed capsule perfectly empty. The seed and capsule in a green state is much coveted as an article of diet. The natives use it largely as a vegetable curry. The capsule has a very pleasant acid, like sorrel or the young leaves of the tamarind tree. The cultivated area in the 30 temporarily settled districts of the N. W. Provinces is stated to be 4,270,000 acres, but the plant is very largely grown throughout lower Bengal and Oudh, so the total area cannot be much under 10 millions of acres. It is a small bushy plant ranging from 15 to 18 inches high, and the yield is much less than that of wheat or barley, being 10 to 12 maunds an acre in irrigated lands, and 5 to 7 maunds an acre in dry lands. The total production of India must be upwards of 50 millions of cwts., out of which 313,000 cwt. were exported in 1882 and 1883, and the remainder consumed in the country. It is a very favourite article of food with both mankind and animals, and insects also, as there is no grain so early attacked and so quickly and completely destroyed by insects as gram.

Regarding rice :—

Dr. Watt puts the area under this cultivation at 60 millions of acres, and the average crop or yield at 20 maunds of paddy, which is about equal to 15 maunds of cleaned rice per acre. If we take the mean consumption of the rice-eating classes at one seer of rice per head per day, which is the usual allowance made in all such calculations, we find that the total production of this single article of food represents the consumption of 50 millions of the population, but exportation has to be allowed for, as according to the trade returns for 1882 and 1883, upwards of 31 millions of cwt. were exported that year, leaving a balance of nearly 621 millions of cwt. for home use. Rice is the principal food of the millions of Lower Bengal. Except in the immediate vicinity of large towns and bazaars, the land in Bengal is one unbroken sea of rice, very pretty to look at when green, and very suggestive of peace and plenty when ripe. There are said to be 5,000 different kinds, in many of which the distinctions are very marked, especially before it is husked, as there is great variety in the colour and shape of the grain of paddy, but the minor and finer distinctions are only distinguishable by an expert In times of great scarcity, such as the Orissa famine, rice has been imported from Burma, but the Uriyas could hardly be induced to eat it, even to keep themselves alive.

Maize or Indian corn is another of the staple articles of food, and no grain is grown over a larger extent of country than this is. A native of South America, and prefering the moist, rich soil of the prairies, it can nevertheless be grown in tropical climates, and far away up in the hills, 9,000 feet above the sea level. It flourishes from the warmest climates of the torrid zone to the colder climate of Canada, and its nutritive qualities rank next after wheat. The area under cultivation in the thirty temporarily settled districts is given at 718,000 acres, but this is a very small part of the total area sown. A correct return would be a very difficult statistic to obtain, because it is grown in such small patches. There is scarcely a homestead in Bihar and Orissa without a little spot, often not more than ten square yards, of Indian corn attached to it, and although not so general in Lower Bengal, it is nevertheless sufficiently so to aggregate a large breadth of country. Perhaps two millions of acres is not too much for the whole of India. The yield is about 14 maunds an acre in irrigated, and 10 maunds an acre in dry lands, but the soil must not be too dry, as the plant is 4 to 5 feet high, and requires a good deal of moisture in order to "cob" at all. It is a common article of daily food over the Northern, Central and Himalayan tracts of India, Bihar, Orissa, Nepaul, Santhalia and Chutia Nagpur.—*Calcutta Englishman*.

TEA IMPORTS AND CONSUMPTION.

The imports of tea, according to the Government returns during 1883, amounted to 74,799,919 pounds, against 71,409,511 pounds for the previous year, or an increase of 4,390,408 pounds. The imports for December were over one million pounds more than the corresponding period of 1882. While the imports were so much higher than the previous year, the value was only $15,346,009, against $17,270,464. The imports for January, however, show a remarkable shrinkage, amounting to $6,386,958, against $9,629,529 for the same time 1883.

The imports of tea since 1870 and the consumption per capita for the statistical year were :—

	Pounds.	Consumption per capita.
1870	40,812,189	1.06
1871	46,972,788	1.19
1872	34,224,494	0.84
1873*	106,423,570	2.55
1874	54,410,055	1.27
1875	64,758,079	1.47
1876	62,744,429	1.38
1877	58,941,178	1.26
1878	65,366,418	1.36
1879	60,182,463	1.22
1880	72,159,266	1.44
1881	81,494,796	1.59
1882	79,031,854	1.50
1883	70,771,225	1.31

* Duty free since July 1st, 1872.

It will be seen that the consumption of tea per capita rapidly advanced after the duty was removed. While it was only 0.94 pound in 1867 it rose to 1.59 in 1881. Since that date, however there has been a gradual shrinkage in the consumption, last year it amounting to only 1.31 pounds. The above years are calculated from July 1st to June 30th of each year.—*American Grocer*.

"KRAKATOA AND THE COFFEE PLANT."—A correspondent sends us an extract from a letter in the last number of *Knowledge* signed "F. R. C. S.," who, in connection with the recent discussion as regards the causes of the coloured sunsets, writes :—

"There is a curious circumstance bearing in the question of the dust (which is supposed to have caused the 'green sun' which I believe, has not been made known yet. Some of your readers may perhaps have heard of the extensive damage done to coffee in Ceylon and South India during the past six years by a fungus. For this disease the only remedy has been thought to be the application of sulphur; but to be effective, this must be universal, and it was impossible to arrange that the cure should be applied to a whole district simultaneously. Now, from a private letter from India, I hear, that, after the eruption in Java last year, the peculiar colour of the atmosphere and the greenish appearance of the sun were very marked for some months, and at the same time a decided improvement in the coffee was noticed. As to the disease, could this have been a universal application of sulphur vapour?"

On which we have to remark, that, in the first place, the volcanic vapour or dust is hold to have been projected very high into the atmosphere; in the second, that vapour of sulphur sufficent to affect the coffee fungus would be obvious to the senses of human beings in a very marked degree (which has not been the case); and, in the third place, it is unfortunate for a theory, which at first sight seems very plausible, that in Java, where the effects of the Krakatau eruption ought to be specially felt, coffee-leaf disease has recently assumed a condition of unexampled virulence. We suspect, therefore, that the decreased virulence of this fearful plague in India is merely coincident with the outbreak of Krakatau, and scarcely, if at all, due to the vapours or dust it shot into space. We have more hope in the theory of the influence of seasons and cycles. The vital force of *Hemileia vastatrix* may be wearing out and becoming exhausted by "efflux of time,"

THE KEW GARDENS REPORT FOR 1882.

The magnificent collections of plants, vegetable products, pictures, &c., at the Royal Gardens over which Sir Joseph Hooker so ably presides are becoming more and more attractive and are better appreciated as the people become better educated. The number of visitors in 1882 was enormously larger than on any previous occasion, having reached 1,244,167 or close on 1¼ million. On Whit Monday the admissions approximated to 100,000, the exact number being 95,300. As not merely enjoyment but education of the most valuable kind must result from visits to this grand institution, we can but hope it will increase in popularity year by year. It is a good sign that the amount of damage done to the plants last year was practically *nil.* The various offices scattered over the Gardens have been connected by telephone, and we are glad to observe that

The lessons given to the young gardeners in the evening twice a week through about nine months in the year by members of the staff (assisted in the cases of elementary physics and chemistry by Mr. J. F. Harris, B. Sc., F.C.S.), have been well attended, and continue to give satisfactory results.

Interesting details are given of the reformation of the Botanic Garden, the formation of a Rock Garden, a Wild Garden, &c. Kew is specially rich in palms, as the following quotation shows :—

The elaboration of the order *palmæ* for the *Genera Plantarum*, published by Mr. Bentham and myself, has led me to a critical examination of the species of palms in cultivation at Kew. This proves to be of somewhat unexpected richness, a fact which, however, need scarcely perhaps be matter of surprise, seeing that for many years past, in fact since the existence of the Gardens as a public establishment, no pains have been spared to obtain seeds of these attractive plants for the cultivation of which Kew possesses peculiar facilities from our numerous correspondents in all parts of the world.

In Appendix II. I have given a classified list of palms, 420 in number, at present cultivated in the Royal Gardens.

The compilation of an accurate catalogue of palms under cultivation is a matter of great difficulty; owing, partly to the impossibility of determining them till they flower, and partly to the practice that prevails in the nursery-trade of attaching provisional names to seedlings of palms which, though unrecognizable both as to genus and species when in that state, are as full-grown plants well known under older names.

The Kew collection of palms is the oldest of any note, it was eclipsed altogether between the years 1820 and 1845 by the famous collection of the brothers Loddiges at Hackney, which in the latter year contained upwards of 200 kinds, but which was dispersed shortly afterwards.

Now it has but two rivals, a European and Asiatic one, namely, the magnificent collection made chiefly by Herr Wendland in the Botanical Garden at Herrenhausen, Hanover; and the Palmetum of the unrivalled tropical gardens at Buitenzorg in Java. The Royal Botanical Garden at Calcutta would doubtless hold rank with these, were it not for the destructive cyclones which have on several occasions decimated its contents, and especially struck down its palms.

The reference made to the Buitenzorg Gardens is well-merited. We have specially a vivid recollection of a scarlet-stemmed palm, exceedingly beautiful in form as well as colour. Kew furnishes the classes at South Kensington and students of botany in connection with London University, with needful specimens. Many fine old trees were destroyed by the cyclone of October 1881, which are being replaced and the Pinetum is being made complete. After references to leguminous and other collections, it is stated that the collection in the Arboretum is now by far the richest that exists and is

annually exciting greater interest amongst planters, foresters, nurserymen, and especially amongst gentlemen desirous of rendering their parks and pleasure grounds instructive as well as ornamental.

The *Arracacha*, a substitute for the potato, has, it appears, succeeded well in the mountains of Jamaica, and Mr. Morris speaks highly of it. Cacao plants sent to Fiji from Kew, Java and Trinidad are flourishing. In quoting what is said about a new species of papaw, we may say that this fruit, so little in repute for desert in Ceylon, is a favourite in Queensland. As a remedy for indigestion, it is understood to be valuable.

CARICA CANDAMARCENSIS.—Of this species of papaw (the fruit of which first ripened at Kew in 1875, *see* Report, p. 4), a large number of plants have been raised from seeds produced in the Economic House at Kew. They were distributed during the year, the principal recipients being the Botanic Gardens of Calcutta, Ceylon, Fiji and Madras.

Information is given respecting cuprea and the true cinchonas, the hard Carthagena kind seeming to flourish in Jamaica. In Ceylon where the sugarcane is grown mainly for eating purposes, it seems to us that the elephant cane thus noticed would be valuable :—

Mr. Morris reports. December 31st, 1881:—"This cane which was introduced last year from the Royal Gardens, Kew, has been propagated with great success. It is now well established at the Hope plantation and is of a most promising character, more especially for moist districts. As showing what may be done in propagating plants of this character, it may be mentioned that this cane, of which only two small plants were received 12 months ago, is now being distributed amongst planters by thousands at a time. As it has been taken up by the most intelligent and enterprizing planters, its value as a cultivated cane in Jamaica will soon be known. For eating purposes it is already a favourite among the peasantry; and I have no doubt that its yield under cultivation will prove it to be, for certain districts, of a valuable character. A block established at the Hope in June last, in ordinary soil, had canes in Oct. 8 feet long, with joints 7 inches in length and with a circumference of 6 inches."

The *Eucalyptus citriodora* ought to be a favourite garden-plant in Ceylon. It is thus noticed :—

EUCALYPTUS CITRIODORA.—*Bengal.*—I quote from the proceedings of the Agri-Horticultural Society of India, January 5th, 1883:—"*Eucalyptus citriodora* has taken very kindly to Bengal, and being sweeter scented than *Aloysia citriodora* sweet-scented Verbena, besides growing to a good size, ought to make it a very popular plant, and one that no house should be without."

Jamaica.—Mr. Morris reports:—"One of the best trees for the plains here is *E. citriodora.* You can safely recommend this for warm climates. Its foliage, as its name denotes, is beautifully fragrant, the tree itself is fast growing and hardy."

Fodder plants including the Mesquit bean, salt bush-sheep bush and *Tagaste* are noticed. Respecting rubber trees, information is quoted from "the extremely useful publication, the *Tropical Agriculturist.*" and there are large quotations from Dr. Trimen's reports. The leaflessness of trees of *Manihot Glaziovii* in Natal "appeared to surprize Mr; Scott Blacklaw who called here a short time ago, he has gone, I believe, to the Transvaal." This accounts for our not receiving the promised letters from Brazil. Liberian coffee is doing well in Fiji (barring leaf-disease), Natal and Queensland; but Mr. Wood wrote from Natal :—

"The berries do not seem to ripen as they ought, and remain upon the trees so long, that the monkeys, with which the adjoining bush abounds, usually forestall us in gathering the fruit."

From Queensland Mr. Pink wrote :—

"I think there is no advantage in growing *Coffea Liberica* here at present, as the leaf disease is unknown, and *Coffea Arabica* does well, producing at the rate of 6 cwt. per acre. There are now in this colony a number of coffee plantors from Ceylon who are anxious to go into coffee growing here, and the Minister of Lands is about to have a quantity of suitable land reserved for that purpose. The small farmers are likewise just discovering that coffee pays better than corn and potatoes when there is a family of children to pick the berries. Several farmers have brought and sold to the merchants of Brisbane green coffee berries at the rate of 10d. per lb. this season. Consequently the demand for plants has become very great, but fortunately we have an equally large supply on hand to meet it, both of *Liberica* and *Arabica*."

The great fear, we may say the absolute certainty, is that leaf-disease, which exists in Ceylon, in Mauritius and Fiji, will sooner or later affect coffee grown in Queensland.

Reference is made to the system initiated by Mr. Morris in Jamaica of instructing "cadets" in cinchona cultivation and natives as foremen of estates. Dr. King long ago laid down the principle, that, where forcing houses were necessary, cinchona cultivation had better be abandoned. Here in Ceylon cuttings of succirubra and officinalis were from the first grown in the open-air at Hakgala, but in Jamaica it appears that for many years elaborate and costly heating apparatus were in use by Mr. Nock, now doing such excellent work at Hakgala. Mr. Morris introduced the open-air system he had seen in Ceylon, and Mr. Nock loyally carried it out. The notice of Seychelles we quote in full :—

SEYCHELLES.—These interesting but little known islands appear to admit of a great variety of tropical cultures. I am indebted to Mr. C. Button, the Conservator of the Crown Lands and Forests, for the following notes upon the agriculture of the past year :—

The principal revenues of these islands are coconuts and coconut oil; the latter is manufactured on all the principal islands as well as in Mahé. Since the year 1880, three different diseases have seriously affected the trees, principally in the south part of Mahé, where several large forests have been destroyed in a very short time, and had it not been for the young coconut trees beginning to bear, the diminution of the production, which was actually about 25 per cent would have been more than 60 per cent.

Since the end of the year 1882, the diseases have nearly stopped their depredations, a very few trees only have died since; the production of this year will show a much larger quantity than that of last year, as all the old trees are recovering their vigour, and a great number of young coconut trees are coming into bearing.

Vanilla is now cultivated with success, in every locality in Mahé, and also on some of the islands, and everywhere I have met with some small plantations: a few proprietors, however, have lately planted on a scale averaging 12 or 15 acres each.

Cocoa was formerly cultivated with success at Mahé, and afterwards abandoned; but some new plantations have lately been made, and will, before long, add to the revenue of these islands.

Cloves, which were also formerly cultivated and planted in valleys where the soil was too rich, with a space of no more than five or six feet between them, grew with such rapidity that some trees attained a height of sixty feet, and the cloves could not be collected without cutting down branches, which, undoubtedly, is of great injury to the trees, and keeps them sometimes two years without bearing, until new branches have sprouted. If cloves were planted in poorer soil, and the trees stopped at a certain height, cloves could be collected without injuring the trees and their bearing would be much more productive every year.

A large portion of clove trees which existed formerly have been destroyed without any consideration whatever, for the purpose of making timbers for houses and also firewood. What remains actually amount to about 250 acres.

The cinnamon which grows here is said to be of an inferior quality. I sent some specimens twice to Europe, where it was not favourably reported upon; but its strength and aroma led me to think that its inferiority can only be due to the mode of preparation.

Liberian Coffee has also been cultivated since 1880; the first plants were sent from Kew and distributed among a few planters by Mr. C. S. Salmon, then Chief Civil Commissioner. They grew very rapidly, and those planted in proper soil, and entirely exposed to the sun, began to bear before two years old, while others in rich ground, and at a short distance from other trees, grew with more vigour, but only began to bear long after. It has been propagated in different localities, and everywhere seems to prefer an open situation where it bears abundantly. The quantity lately planted may amount to about 100 acres.

We also quote the portion about cacao :—

COCOA.—The notices in the Kew Report for 1881, pp. 27, 28, have brought me several interesting communications.

COLOMBIA.—Mr. R. B. White, of Medellin, has furnished me, January 13, 1883, with the following interesting particulars as to the conditions of its cultivation in the United States of Colombia :—

"*Soil.*—The cocoa tree exhausts the soil very rapidly. It requires a good, rich, and thick stratum of vegetable soil, which should overlie gravel or some open substratum. Stagnant moisture round the roots is prejudicial to cocoa At the same time it requires so much moisture that sloping ground does not suit it. In dry seasons and dry climates irrigation should be judiciously employed.

"*Disease.*—In Antioquia, United States of Colombia, South America, the cocoa plantations have been nearly ruined by a fungus which attacks the tree in a similar way as *Hemileia vastatrix* does the coffee. The leaves appear spotted, then turn brown, shrivel up, and finally the tree looks as if it had beeen scorched. If the tree is in flower, the buds fall off, but if it is already in fruit, the pods shrivel and wither and the beans become mouldy and dry up. Hundreds or perhaps thousands of acres of plantations have been destroyed by this plague. No remedy has been found. The planter's resource is to clear the ground, lime it well, and then replant from new and sound seed, taking great care afterwards to prune away and destroy every branch or tree in which the disease may appear. It is believed that the disease was first induced by careless and indiscriminate irrigation during a season when the air was more humid than usual.

"The cocoa is such a delicate tree that the growth of the finest mosses and lichens on its bark affects its health. At the proper season the stem and branches should be cleaned by wiping them with a rough cloth or sacking. Parasitic plants are very fond of the cocoa, and are, of course, fatal to it. They should be exterminated.

"*Shade.*—The reason why *Erythrina* is preferred as a shade tree for the cocoa, is because it abstracts from the soil different elements to those which the cocoa requires. In fact, it is used on the same principle as that on which alternative crops are employed. The Guanco or *Inga* is as moderate in its demands upon the soil as *Erythrina*, but it spreads too much in proportion to its height. *Erythrina* throws out its branches well above the cocoa trees. Bananas should only be employed for a couple of years after the cocoa is planted out. They exhaust the soil and harbour damp. In adopting a tree like *Manihot* for shade, the above considerations ought not to be lost sight of.

"*Climate.*—Although cocoa will grow in a hot and very damp climate like Guayaquil or the Atrato Valley, yet it is found in Colombia that it grows best where the temperature (mean) is 26° centigrade, and where the two dry and two wet seasons are well marked in the year. It is possible or probable too, that a dry season affords a better opportunity of preparing the bean for the market."

Mr. Jean Van Volxem, of Brussels, also sends me, January 27th, 1883, the following remarks as the result of his observations in New Grenada:—

"To judge properly of the quality of cocoa beans in comparison with those found already in trade, attention ought to be payed to the curing process in either case. For the British market the beans are separated as soon as possible from the husk and pulp; for the continental market a little fermentation is allowed, which spoils their appearance and takes away some of their bitterness, so that you cannot mix them with such a large quantity of flour or fecula, as it is your wont in England. But ho fermentation develops and improves greatly the tflavour."

JAMAICA.—Mr. Morris, the Director of Public Gardens and Plantations, Jamaica, has, at the request of the Governor, thrown into the form of a pamphlet, the substance of a lecture delivered under the auspices of the Institute of Jamaica at the Town Hall, Kingston, "with the view of affording information respecting the cultivation and preparation of cocoa, an industry which it is hoped will become an important one among the 'minor industries' of the island." The title of the pamphlet is, Cocoa: How to grow and how to cure it. Copies may be obtained in London of Messrs. Silver & Co. It has been reprinted in Fiji at the instance of the Hon. J. B. Thurston.

In the case of "cinchona robusta," Dr. Trimen's researches and the opinions of the Kew Gardens Staff are taken to have set the question at rest of its being a hybrid and not Mr. Cross's Pata de Gallinazo. We extract what is said about coffee disease in Mauritius:—

COFFEE-DISEASE.—In reference to the brief note in the Kew Report for 1881, p. 31, on the appearance of leaf disease in Mauritius, I now quote a fuller account from Mr. Horne's report for 1881:—"During the year the coffee leaf disease (*Hemileia vastatrix*) was found to be common in the Colony. When, or how, this pest arrived in Mauritius it is impossible to say. It was noticed first on some young coffee plants growing on Deux Bras estate, Grand Port district, then at the Vale, Grand Bay, next on some coffee plants growing at the edge of the forests at Combo estate, Savanne; and on close inspection of the few coffee trees growing at the Gardens, Pamplemousses, all the young leaves were found to be thickly covered with the yellow spots which this fungus causes. The fungus having been noticed within a period of about two weeks at points so widely apart as these gave grounds for supposing that it was spread over all the Colony wherever a coffee plant existed. The correctness of this supposition was soon verified by the letters which from time to time appeared in the newspapers."

"During the year it caused a loss of about 15,000 coffee plants at the Gardens. They were so intensely infected by the disease and weakened in growth, that there was no hope of their recovery, and they were therefore pulled up and burned."

In a notice of jalap cultivation in Jamaica we observe that slices of the roots were dried on "an American fruit-drier." The information obtained respecting the lacquer tree of Japan is noticed, and there is a paragraph respecting phylloxera which we quote:—

PHYLLOXERA.—M. Tisserand, the French Minister of Agriculture, in a report on the progress of the Phylloxera and of the measures for combatting it during the year 1882, which has been communicated to Kew by the Foreign Office, sums up the situation as follows:—Fifty departments have been attacked; 764,000 hectares of vines have been destroyed; 642,000 are more or less seriously injured. A million and a half of hectares (or about half the total area of vine cultivation in France) are still free from the pest, and the champagne district is untouched; the most important districts of Burgundy and the Gironde are infected, but the Phylloxera has been so far held in check.

There is an engraving and the following description of "the North Gallery":—

NORTH GALLERY.

The accompanying illustration, for the use of which I am indebted to the proprietors of the *Gardener's Chronicle* represents the exterior of the North Gallery after its completion. A porch, affording accommodation for an attendant to take charge of umbrellas, &c., was subsequently added at Miss North's expense.

The arrangement and hanging of the pictures was accomplished under Miss North's personal superintendence, and the gallery with its contents was handed over to my charge on behalf of the public on June 8th.

The collection of separate pictures amounts in number to 627.

The following are the principal regions of the earth's vegetation which we owe to Miss North's skilful pencil, vivid and accurate impressions:—Teneriffe, Brazil, Jamaica, United States, California, India, Ceylon, Singapore, Borneo, Java, Japan, Australia, New Zealand.

Before the gallery was opened to the public Miss North caused a descriptive catalogue to be prepared by Mr. W. Botting Hemsley, A. L. S. Of this an addition of 2,000 copies was printed at her own expense, and she has expressed a wish that the proceeds of the sale should be devoted to the improvement of the small library kept up for the use of the young gardeners and open to them in the evening. The official publication of subsequent editions of the catalogue has been taken over by the Stationery Office.

A very large collection of plants from Madagascar, the gift of the Rev. R. Baron, is specially noticed, as also the curious fact, that, with all its wealth of plant life, the island exports but little vegetable produce. We learn that

The Assistant Director has contributed a "Note on the origin of "Cassia Lignea" to the Linnean Society (Journal, vol. xx. pp. 19—24).

and that

Mr. Bentham, F. R. S., in conjunction with the Director, has nearly completed tho concluding part of the "Genera Plantarum."

The detailed list of palms has a general as well as a botanical interest.

THE CULTURE, HARVESTING AND DRYING OF CINCHONA.

The report on cinchona by the sub-committee of the Dimbula Planters' Association given below embodies some important results, based on evidence more or less reliable and unanimous. Although a few plants had reached Peradeniya previously, yet the cinchona enterprize, as far as Ceylon is concerned, was really commenced at Hakgala in 1865 with the establishment of propagating beds under the care of Mr. MacNicol. In answer to queries circulated by the Dimbula Planters' Association, preference is given to seed obtained from trees, the result of rooted cuttings from Hakgala. And yet we remember, that, in a specially wet season when much "dying off" occurred, planters were inclined to attribute the fatalities to the cuttings from Hakgala, which were said to be destitute of tap-roots. Others regarded this as an advantage, there being no tap-root to go down into the damp, stiff clay subsoil. As to kinds, preference is given to succirubra and hybrids from Hakgala, owing, no doubt, to the extent to which officinalis went off in the third to the fifth years of its existence; but it is a curious commentary on the advertisements calling attention to seed gathered from "trees which had never been shaved," that the conclusion arrived at in Dimbula is that "no difference appears to have been found between seed from shaved and unshaved trees." On general principles we should think preference ought to be given to seed from trees which had never been shaved and which had not flowered and seeded until they had reached the age of maturity, between seven and ten years. Plants put into holes (as contrasted with those dibbled into the soil by means of crowbars) have generally answered best, as might be anticipated, and yet there must be much to be said for dibbling in soil which has been loosened in the tillage of coffee.

But, again, it is curious to find nursery-grown and self-sown plants declared to be equally good. In both cases, but especially in that of self-sown plants, we should think that careful selection was important. At one time, we suspect, a good many small and weakly plants were put out into the field and never became good trees. "Very few have succeeded in making cinchona grow where it has died before," sounds something like a bull. We all know what is meant: that where an original planting of cinchona has died out, neither draining nor trenching nor any other ordinary expedient has been successful in inducing further plantings to grow. Planters, in their loss and disappointment, have felt inclined to exclaim

"Something ails it now, the place is curst."

Our own belief is that the fault in such cases generally lies with sour, damp, stiff subsoil, or subsoil which is damp and stiff without being sour. Could the planter afford not only to drain and trench his stiff soil, but to leave it fallow until well-aerated, sweetened and pulverized, success might probably crown his efforts. It must not be forgotten, however, that in the Andean habitat of the cinchonas, they are not found in uniform forests of any great extent, but only in patches often widely-separated. The cinchona is not a plant that will grow in any kind of soil, and experience in Ceylon seems to prove that not richness so much as freeness of soil is desiderated. The plant grows well frequently in gravelly soil. But experience gained on Abbotsford goes far to show, that, even where a first planting of cinchonas has died off, in from the third to the fifth year, and tea has been substituted, the draining and opening powers of the new plant with the strong tap-root so alters the character of the soil, that cinchona plants interspersed amongst the tea are likely to flourish. There has not been time enough yet, perhaps, to set the question at rest beyond doubt, but all the signs are encouraging. If the cinchonas are not planted too thickly, we should think they would benefit the tea by their shelter rather than harm it by what they extract from the soil. Of course, in such cases, lopping off the side branches up to a certain height is essential. But this lopping (two branches at a time best), with forking of the soil and the application of manure, are amongst the requisites of good culture "generally approved of as stimulating the trees," amongst the Dimbula planters. We should attribute much more than stimulation of growth to the application of "bulky manure," meaning chiefly cow-dung, which is highly ammoniacal. From the application of such manures, Broughton obtained greatly increased proportions of alkaloids in the bark, and there can be little doubt that much of the high character of Ceylon bark from the very first was due to the fact that the cinchona trees were grown amongst coffee and received a large portion of the benefit of the manure applied to the chief cultivation. As a general rule, the amount of alkaloids increases with age and elevation; but if trees at comparatively low elevations could be heavily manured with such substances as guano, there can be little doubt the disparity would be largely lessened. We do not think any reliable results have yet been published of the comparative alkaloidal richness of the bark of an appreciable number of trees grown in precisely the same favourable circumstances of soil, altitude and climate but half of them left to the influence of soil, climate and tillage, while the other half were heavily manured. Of the benefit of manure in regard to growth of tree and richness of bark, there can be no doubt, but, in these latter days especially, the question "Will it pay?" presents itself in this as in other cases.

There can be no doubt that premature flowering and seeding indicate that either the plants are faulty or that the conditions of soil or climate, or of both, are not conducive longevity. The instinct of reproduction is forced into preternatural activity by circumstances endangering health or life. We well recollect feeling alarm on this account early in the history of the enterprize, when officinalis plants at two years in the field broke out into blossom which was succeeded by fruit. And just in proportion to tendency to premature blossoming was the tendency to early dying off in this species. Succirubras, except in rare instances, took six or seven years to blossom, and we believe there are trees, or were in Uva, which had not blossomed in their seventeenth year. The superiority of the hybrid, cinchona robusta, to officinalis, its female parent, is shown, not only in its more vigorous growth, but in its later blossoming. There can be no doubt, that, where trees are not grown expressly for seed, the cutting away of the seed or blossom branches must be beneficial to the trees, much of whose strength must be thrown into such enormous crops of seed as some trees, especially officinalis, bear. There seems only a slight inclination to believe that trees from foreign seed (India or Java) are less liable to canker than those grown from local seed; but our readers will observe, that, in view of belief in the degeneracy of the plant, fresh introductions of seed from its native habitat are recommended. Such seed ought, of course, to be obtained from well-grown and specially healthy trees in the forests, and not from those grown on the plantations which have been established in Bolivia and other places. We cannot forget, however, that Ceylon cinchona seed was recently carried to America to be the origin of cinchona plantations! Generally, no treatment has been found efficacious in stopping "canker" when once it had set in; but baring the collar of the plant, as suggested by Mr. Nock, has been found useful as a preventive. There is a difference of opinion as to whether the shaving process does or does not increase the tendency to seed-bearing, but certainly it is natural to infer that anything which gives a shock to the vitality of the tree (provided the shock is not fatal) *would* increase the tendency. In harvesting, shaving was almost universally approved of: the process to be commenced at three years old, repeated twice again between 5½ and 6 years old, when the trees ought to be coppiced and three suckers allowed to grow up.

We have reason to believe that one of the gentlemen who signed the report has now altered his opinion in favour of shaving, preferring McIvor's stripping process. In that process, only strips of bark were taken, generally three, equal breadths being left on. The mistake in shaving seems to have been to have shaved all round, but this practice has, we believe, been abandoned. If the shaving process continued to answer and if covering (which is "almost generally approved of") could be dispensed with, it would be the simplest and cheapest mode of harvesting the bark; but besides the danger of baring the trees too much and the damage done by inclement seasons, it seems settled, that, while the alkaloids increase at the second or even in some cases the third shaving, they then seriously fall off. The bark increases between the shavings,—sometimes largely. It is curious that the Committee indicated no definite periods between shavings, but we suppose, if the first shaving took place in the third year, two more, at intervals of eight months would follow, which would bring the tree to its fifth year. Then, at some period from 5½ to 6 years old, the tree would be coppiced and the renewed bark on it harvested. It will be observed that the amount of sulphate of quinine in original succirubra bark is considerably in excess of that from officinalis (which surprises us) but that renewed officinalis bark is much richer than renewed red bark. The yield of succirubra bark (in shaving we, presume) said to be 1-5th to 1-3rd of a pound per tree. "Coppicing trees," meaning doubtless trees when coppiced, are said to give three times as much bark as one shaving of them. This we can well suppose, the quantity of bark, of course, depending on the interval between the last shaving, which ought not to be less than eight months or a year. Sun-drying of the bark is deemed preferable and yet the furnace-dried bark from the Nilgiris sold at high prices. The great point is, of course, so to dry the bark that it will not mould. The Committee believe that coppicing reinvigorates the tree and their final recommendation is to shave twice (once in the third year, once in the fourth ?) and then to coppice (at the end of the fifth year ?).

We have thus dealt with the main conclusions drawn by the Dimbula Committee from the answers received and their main recommendations, but some of the individual answers are worthy of consideration. One word from ourselves. It is far cheaper to bury or even burn the lopped branches from cinchona trees than to employ labour in barking them. Nothing but stout stem bark should be sent to market now, for nothing else will pay.

DIMBULA PLANTERS' ASSOCIATION.

REPORT OF SUB-COMMITTEE ON CINCHONA.

The plan pursued by the Sub-Committee appointed to enquire into the cultivation and harvesting of cinchona has been to send to various estates where a certain quantity of cinchona was growing a series of questions referring to all points connected with this subject, hoping in this way to bring together and compare the opinions and experiences of the different managers of estates: and thus to arrive at reliable data.

In an appendix attached to this report will be found an abstract of the answers sent by each estate to the questions given. A number has been given for the purpose of this report to each estate that has sent answers, and that number is used throughout wherever that estate is referred to.

The points on which questions have been asked have been 1, origin of trees, 2, planting, 3, cultivation, 4, harvesting, 5, coppicing, 6, curing.

The Sub-Committee have arrived at the following conclusions on the above points after going through the answers they have received.

1. With regard to *species and origin*, succirubra and hybrids have answered best chiefly from seed from Hakgala trees, that is trees growing on estates that was procured from Hakgala. The trees raised from Hakgala cuttings are highly spoken of by those that have them. No difference appears to have been found between seed from shaved and unshaved trees.

2. Plants put into holes have answered generally best, nursery and self-sown plants being equally good: very few have succeeded in making cinchona grow where it has died before.

3. In *cultivating*, lopping and forking are generally approved of as stimulating the trees, also bulky manure; a gradual lopping of two branches at a time is considered best.

Trees are generally considered to seed early because they are unhealthy or in unsuitable soil; and there appears to be no method in vogue that has stopped the flowering of the tree. Shaving is said by the majority not to increase the tendency to seed but by some excessive shaving is thought to have that effect. By nearly all cutting off the seed is said to strengthen the tree. By the majority no difference has been noticed between trees raised from foreign and local seed, but by some that have tried it they are considered to be less liable to canker. Canker is said by most to be caused by damp soil and by some by the degeneracy of the stock and successive generations have been found by nearly all to canker more than the original; by most managers no treatment has been found to stop canker; by some, baring the collar has been found to do good and by some forking.

4. *Harvesting.*—Shaving is almost universally approved of as the best means of harvesting and there is a good deal of evidence in favour of stopping shaving when the tree is five years old. Most have found commencing shaving at 3 years old the best, but some at 2 years and some at 4. Covering is universally approved of, grass being the best covering, while in dry weather the covering should be put on immediately after shaving, some recommending an interval between shaving and covering of two months. It appears that generally a part of the cellular bark is left on as well as the liber, and that it is thought best to leave the covering on till the next shave. The majority are of opinion that shaving checks the growth of the tree especially after 5 years old and in some cases it is said to kill the trees. In every case except one an increase of bark is reported between the shavings and in some cases as much as 50 per cent but generally speaking about 20 per cent.

From the answers received original succirubra appears to give 2½ per cent sulphate of quinine; officinalis about 1¾ per cent; renewed succirubra about 3¾; renewed officinalis at 5 years old covered 5¾ and in one case at 7 years old 7 per cent. The yield of succirubra is said to be from 1-5th to 1-3rd of a lb. per tree.

The best months for shaving are said to be March and April and September and October and the majority approve of dry weather for covering in. Most managers report that some trees have suffered from the bark rotting after shaving owing to this being done badly or in unfavourable weather; again there is an equal weight of evidence as to whether or not this rotting occurs when trees are not covered. The majority are of opinion that trees will renew bark well if shaved after 5½ years old, and again most managers say that 3 is the greatest number of times that they have found trees renew well after shaving.

5. Six years old is considered the best age to *coppice* trees and between March and May the favourite months, while it is considered best to leave 3 suckers. Very few stools are said not to throw out suckers after coppicing and from 5 to 7 years the best interval to leave between coppicing. Coppicing trees are said generally to give three times as much bark as one shaving of them.

6. *Curing.*—Drying in the sun is generally considered the best way of curing; artificial drying by those that have tried it has been found unsuccessful.

The Sub-Committee think it will not be out of place to offer a few remarks on cinchona generally that have been suggested by the information they have collected.

The stock generally appears without doubt to be degenerating, and it therefore behoves cinchona growers to import as far as lies in their power seed from the native habitat of the tree.

Canker which has so far proved incurable, undoubtedly is much more prevalent among the present stock than the original. Importation of fresh seed is looked upon by the Sub-Committee as the best remedy for it.

Shaving twice and then coppicing is in the opinion of the Sub-Committee the most profitable mode of harvesting the bark of the tree and the best means of prolonging the life of the stock; for by this treatment (namely coppicing) the system of the plant is reinvigorated.

G. A. Talbot, P. H. Maitland, Chas. R. Paterson. J. A. Campbell, J. K. Symonds, A. Cautlay, J. N. Martin, C. J. Scott, W. Smith, W. B. Jackson.

APPENDIX.

SECTION 1.—*Origin of Trees.*

Question 1. What species of Cinchona grow best on your estate? Were the trees raised from seed or cuttings?

Answer. 1. Approximate elevation 5,500 feet, Officinalis and hybrids from seed. 2. 4,550 feet, hybrids from seed and cuttings. 3. 4,500 feet, Succirubra and hydrids in the higher fields, Officinalis does well as also Calisaya and Ledger. 4. 4,850 feet, Hybrids. 5. 5,000 feet, Officinalis, all raised from seed. 6. 4,400 feet, Succirubra, Officinalis and Ledger. 7. 4,400 feet, Hybrid and Succirubra raised from seed. 8. 4,400 feet, Succirubra and hybrids from seed. 9. 4,300 feet, Succirubra from seed. 10. 4,500 feet, Hybrids, believed to be from cuttings. 11. 4,300 feet, Hybrids, the best being from Hakgala cuttings. 12. 4,700 feet, Hybrids from self-sown plants. 13. 4,700 feet, Succirubra and officinalis, succirubra from seed Officinalis from cuttings. 14. 4,450 feet, Hybrid and succirubra. Self-sown seedlings. 15. 4,750 feet, Succirubra and hybrid. Ledger had done well in all situations where tried. 16. 5,000 feet, Plants from seed unsatisfactory. 17. 4,600 to 6,000 feet, Officinalis and hybrids from 5,300 feet upwards and succirubra below that. 18. 4,300 feet, Succirubra cuttings. 19. 4,200 feet, Succirubra and hybrid from seed. 20. 2,300 to 4,300 feet, do., do. 21. 4,000 feet, Succirubra from seed and cuttings. 22. 4,200 feet, Succirubra from Hakgala cuttings.

Question 2. If from seed, where was the seed obtained and what was the age of the trees that yielded the seed?

Answer. 1. Seed from Hakgala trees. 2. Seed from Gallela, Muturatta. 3. Seed from India, Ceylon and Java, age of trees unknown. 4. Seed from Hakgala trees. 6. Abbotsford and Indian seed, Ledger from Java. 7. Ceylon seed. 8. Seed from India and Ceylon. 11. Seed from Ossington Estate, India. 12. Seed from trees from Hakgala, 8 to 10 years old. 13. Seed from India. 14. Seed from Tillicoultry, age 5 years. 15. Seed from Hakgala trees, 5 to 7 years. 16. Indian seed. 17. Seed from Nilgiris, Darjeeling and Java. 19. Seed from old Hakgala trees. 20. Seed from Hakgala trees. 21. Various.

Question 3. If from cutting give the origin of the stock?

Answer. 2. Hakgala cuttings. 4. Do. do. (Officinalis). 6. Little experience. 10. Hakgala cuttings. 11. Cuttings from Hakgala. 13. Hakgala cuttings. 15. Hakgala cuttings. 17. Cuttings from succirubra on estate. 18. Hakgala cuttings. 21. Various.

Question 4. Have you found any difference between seed from shaved and unshaved trees?

Answer. 1. No difference. 2. Prefers seed from unshaved trees. 4. No difference observed, 6. Do. do. 9. Do. do. 15. Do. do. 17. Do. 20. Do. do.

SECTION 2.—*Planting.*

Question 1. Have you found plants, stumps, or cuttings to answer best?

Answer. 10, 18, 22, 5, 3, 17, 14, 11, 7, 19, 8, 1, 9 and 20. Plants. 15. Plants from cuttings. 2. Plants from cuttings. 4. Plants, cutting in doubtful weather. 21. Plants and cuttings. 16. Stumps. 6. Nursery plants.

Question 2. Have you found holes, forking, or dibbling answer best? If holes, what size of hole do you prefer?

Answer. 3. Small holes. 5 and 17. Dibbling.. 7, 10, 14, 15, 4, 8, 18, 19, 20 and 22. Holes varying from 12 to 18 inches. 11. Holes, 15 in. 150 cooly. 12. Dibbling in S. W. monsoon. Holing in N.-E. 1, 13, and 21. Forking. 2. Holes and forking. 16. Forking and dibbling. 6. Depends on soil.

Question 3. Have you succeeded in growing cinchona the second time where it has been uprooted or died before?

Answer. 5, 6, 10, 11, 17, 18, 22, 7, 12, 15, 2, 19, 1 and 21. No. 3. Yes, when it has died another variety has grown. 20. No, where uprooted, grown fairly well.

Question 4. Do you prefer self-sown or nursery plants?

Answer. 5, 10, 17, 7, 15, 13, 8, 9, 1, 21, 16 Nursery plants. 22, 18, 14, 12, 4, 2, 20. Self-sown. 11, 19, 6. No preference. 3. Nursery of self-sown seedlings.

SECTION 3.—*Cultivation.*

Question 1. What mode of cultivation have you found best for stimulating the growth of tree other than manuring?

Answer. 3, 5, 10. Lopping lower branches. 17. Shaving. 11. Lopping, forking and cutting off seed. 11, 16, 20. Forking. 2. Lopping and forking. 9. Lopping, pruning and lopping. 6. Lopping and pruning. 1. Baring crown roots.

Question 2. What manure gives the best results?

Answer. 11, 14, 15. Cattle manure. 6 Fresh cattle manure, salts of ammonia, bones and coconut poonac. 2. Lime compost, coconut poonac and bones.

Question 3. What style of lopping do you find to answer best?

Answer. 4, 7, 20. Moderate lopping. 3. Gradual lopping beginning at one year, leaving ⅓ to ½. 10. Lop lightly between ages of 3 and 5. 18. Lopping two lower branches annually. 17. Lower branches. 11. Two branches twice a year. 5. Lopping half way up. 12. Low branches at 2½ years. 15. Lopping as required when in coffee. 8. Lopping ⅓ to ½. 2. Moderate lopping beginning at one to 2 years. 9. Pair of branches every 6 months. 1. Moderate and yearly 6. Undecided.

Question 4. Have you tried pruning the upper part of the tree, and if so was it successful?

Answer. 9. Yes; Yes. 6. Yes; Yes.

Question 5. Do your trees seed profusely, and, if so, at what age? Can you give any reason for their doing so?

Answer. 3. Officinalis seed at 3 years old owing to bad soil, seed, or climate. 18. Unhealthy trees at two years. Accounted for by plants being raised from seed from immature trees. 10. Officinalis have not seeded so much since shaving. 17. Seeding before 5 years, sign of sickness. 11. Succirubra seed at 5 years because they have come to maturity. 12. From pruning. 6. Yes, trees unhealthy. 15 Succirubra seed from 4 to 5 years, Ledger 4 to 6, officinalis 2 to 3. Degeneration of stock is the cause of early seeding. 19. Trees 7 years old have not seeded. 2. Seed from soil and climate being unsuitable. 9. Seed owing to a check in the flow of sap. 1. Increased by shaving. 16. Considers seeding a sure sign of death, officinalis seed more freely in coffee than in clearing.

Question 6. State any system of cultivation you have found effectual in preventing or checking seeding.

Answer. 10. Found cutting off blossom to fail. 14. Cutting off seed. 11. Lopping prevents seeding. 4. Cutting off blossom saves many trees.

Question 7. Do you consider that shaving causes trees to seed earlier than they otherwise would?

Answer. 3, 18, 5, 8, 1, 2. Yes. 16, 21, 9, 19, 12, 14. No. 10. With succirubra and hybrid. Yes. Not with officinalis. 6. Certainly not if carefully done. 11. Excessive shaving may cause succirubra to seed, not officinalis. 15. Do do 4. Light shaving doubtful, heavy shaving undoubtedly.

Question 8. How do you account for canker?

Answer. 3, 5, 2, 22, 14, 12, 16. Dampness. 18. Dampness and immature seed. 10. Do. and clay. 11. Degenerate plants and unsuitable soil. 7. Unsuitable soil. 15. Degenerate stock and unsuitable land. 4. Dampness and bad seed. 8. Unsuitability of soil and weak stock. 19. Wind. 20. Unsuitable land. 9. Damp substance against the stem. 1. Damp around roots and crown. 6. Excessive moisture and seed from cankered trees.

Question 9. Do you think the successive generations of cinchona are more liable to it than the original stock?

Answer. 22, 18, 5, 14, 11, 7, 12, 15, 13, 2, 20, 1, 16. Yes. 4, 17. No. 3, 10 No. Seasons to blame. 19. Yes, doubtful if cause is canker. 9, 6. Yes, owing to trees being cankered when seed was taken.

Question 10. Have you found any treatment that stops or checks it?

Answer. 3, 5, 10, 18, 22, 17, 13, 14, 15, 19, 4, 20, 21. No. 6, 9. Removing damp substance from collar of tree. 11. Forking checks it. 2. Forking. 7, 8. Baring roots and collar occasionally does good. 1. Baring roots. 16. Collar canker can be checked by baring roots.

Question 11. Have you had any experience in foreign seed and if so have you found the plants raised from it less liable to canker than those from local seed?

Answer. 1, 2, 3, 4, 5, 6, 7, 12, 22, 17, 21, 15, 20. No difference noticed. 9, 11, 13, 16. Less liable. 19. Foreign seed proved a failure.

Question 12. Have you found that cutting off the blossom and seed strengthens the tree or improves the analysis?

Answer. 2, 11, 14, 8, 9, 10, 20. Strengthens the tree. 3. Strengthens the tree and saves deaths. 18. Has improved the tree. 6. Strengthens the tree; should increase alkaloids. 1. Does not strengthen tree.

SECTION 4.—*Harvesting.*

Question 1. What method of harvesting do you consider best: shaving, coppicing, or any other system?

Answer. 1, 4, 6, 7, 9, 11, 14. Shaving. 2, 18, 19, 20. Shaving and coppicing. 17. Insufficient experience. 10. Shaving up to 5 years. 11. Shaving to 3 and 5 years and coppicing at 6. 15. Shaving to 3 and 5 years; after coppice. 3. Partial shaving. 8. Partial shaving every 6 months. 21 Shave once. 13. Coppicing.

Question 2. If shaving, state (*a*) at what age you commenced shaving, (*b*) what interval you allowed between each shaving?

Answer. 19. 3½ years; 10 to 12 months. 14. Every 6 months. 8. 5 years; 12 months. 10. Officinalis 2 years, Succirubra 3 years; every 6 months. 1. 4 years; 6 months. 12. 4 years. 18. 3 years; 12 months. 21. 7 years; 6 to 12 months. 5. 2 years; 6 months. 15. 3 years. 20. 4 years; 12 months. 11. Officinalis at 2½ years; Succirubra 3 to 4½ years; Officinalis 6 months; Succirubra 8 to 9 months. 16. 3 years; 6 months. 7. 6 years; 12 months. 4. Officinalis 4 years. Succirubra 3 to 4; 10 to 12 months. 9. 2½ to 6 years; 6 months. 3. 3 to 4 years; 6 at 8 months. 2. 3 years; 10 at 12 months.

Question 3. Whether you covered or not?

Answer 6. 14, 10, 12, 21, 15, 7, 9, 3, 2, 19, 20, 1, 4, 5, 18. Yes. 17. Uncertain. 11. Yes. Not necessary with Officinalis. 8 Partial covered.

Question 4. What material you covered with if any.

Answer. 6 10, 5. Patana grass. 12, 21, 7, 3, 1, mana grass. 17. 2, Various. 14, 18, Paddy straw and mana grass. 15, 9, 20. Grass. 11. Patana grass and straw. 8. Mauritius, mana and patana grass. 19. Dried mana. 4. Dried patana. 16. Paper and grass.

Question 5. Whether you covered immediately after shaving or not?

Anewer. 17, 12, 21, 3, 2, 19, 15. Immediately. 11, 7, 9, 3, Immediately in dry weather. 6. Immediately after until rot appeared. 14. A few weeks after. 10. In dry weather immediate. In wet after a period of 2 months. 8. Various. 1, 20, 4, 5, 16, 18. Immediately.

Question 6. Whether you shaved off the whole of the cellular bark leaving only the liber, or whether you left the liber with a part of cellular bark?

Answer. 6, 17, 10, 15, 7, 20, 4, 16. Left liber and part of cellular. 12, 11, 9, 3, 2, 8, 19, 1, 18. Left liber only. 21. The whole.

Question 7. Whether you kept on the covering until you next shave or whether you took it off some time before you shaved again?

Answer. 6, 14, 10, 21, 15, 11, 9, 3, 20, 8, 19, 4. Kept on till next shave. 12, 7. Taken off at beginning of S.-W. monsoon. 18, 16. Kept on for 3 or 4 months. 17, 2. Grass removed, other covering left. 1. Kept on except in case of rot.

Question 8. Whether you shaved all round the tree or left a strip; if so what proportion did you leave?

Answor. 10, 12, 21, 15, 11, 19, 8, 1, 4, 18, 5. All round. 6, 17, 7, 9, 16. All round, now leaving strip. 14. Left strip 1½ to 2 inches. 3. Left alternate strips. 2. Left ¾" strip. 20. Left 1" strip.

Question 9. Has shaving in your opinion checked the growth of the tree or has it killed any?

Answer. 6, 17, 15, 9, 19. No in both cases. 20, 4, 16, 1, 10. Checks growth. Kills none. 14, 21, 18, 5. Checks growth. Kills some. 12, 3. Checks growth: kills sickly trees. 11. Checks after 5 years. No deaths. 7. Does not check old trees 2. 2nd shaving checks growth. None killed. 8. Deep shaving checks growth and kills many.

Question 10. Do you get an increase in weight of bark at each shave off the same piece of the tree as shaved as the previous round? If so how much?

Anewer. 12, 2. No. 6. Yes, 20 at 25 per cent from healthy trees. 10. Yes, 7 at 18 per cent. 11. Yes, 12½ at 30 per cent. 7. Yes, 10 at 20 per cent. 9. Yes, 25 per cent. 3. Officinalis Yes. Succirubra No. 19. Yes. 1. Yes, 20 per cent. 20. Yes, 25 per cent. 4. Yes, 20 at 50 per cent. 18 Yes, slight increase. 5. Succirubra no. Officinalis 25 per cent.

Question 11. If possible give analysis of bark of each shave and the average quantity obtained per tree of different ages, stating the year and month when each was harvested?

Answer. 11. Officinalis 4½ years first renewal 5·35 per cent sulphate of quinine. Succirubra 4½ years second renewed 3·68 per cent sulphate of quinine. Shaved in January, 8 months renewal. 7. Original succirubra bark shaved in November, February and March gave 2·07 per cent sulphate of quinine. First renewal from same trees 4·05 per cent sulphate of quinine. 18. First shaving off 1,742 trees 6 years old shaved in May 1881 gave 704 lb. dry bark, sulphate quinine 2·76 per cent. Second shaving off 1,610 trees 7 years old shaved in May 1882 gave 516¼ lb. dry bark, sulphate quinine 4·42 per cent. Third shaving off 1,600 trees 7½ years old shaved in February 1883 gave 599¾ lb. dry bark, sulphate quinine 3·09 per cent.

Answer. 19. 1881, 1,700 lb. original shavings from succirubra trees rising 4 years 2·65 per cent. 1882. 2,589 lb. renewed, 5 years 3·71 per cent. 1883, 5,591 lb. renewed; first and second time 3·16 per cent. 1883, 2,399 lb. original shavings, 2·37 per cent. 1881, harvested in February, 1882 in April, 1883 March and April. In 1881, 7,361 trees yielded 1,700 lb. dry shavings. 1882, 6,725 trees yielded 2,589 lb. dry renewed shavings. 4. Officinalis natural 1·96 per cent. Second shaving (covered) 5·76 per cent. 3·20 per cent. Uncovered 3rd shaving (covered) 7·05 per cent. February and May.

Question 12. What time of the year do you consider the best for shaving so as to cause the least shock to the tree and what time of year do you get the best results by analysis?

Answer. 6. February, March, April, August and October. 17, 12. February to April. 14. March and April. 15. April and October. 11. 15th March to end April. 15th September to October. 3. Light shaving weather. 2. March. 19. March and April. 8. March, April, September and October. 1. April, May, September and October. 20. January to March. 18. May and June for analysis. 4. March, April. September and October.

Question 13. Whether you condsider your trees renew best if shaved in showery or sunny weather?

Answers. 6, 11, 9, 3, 1, 2, 18, 4. Showery. 10, 12, 17, 19. Sunny. 15. April weather. 14. Slightly showery. 7. Dry months. 8. Cloudy. 1. Showery and cloudy.

Question 14. Have your trees when covered rotted after shaving, and how do you account for it, and how can it be prevented?

Answer. 6. Yes, trees being unhealthy. Stimulated by cultivation. 17. Yes, from the rotting of covering. 14. Yes, from being covered with wet grass and shaving too close in monsoon. 10. Yes, by too deep shaving, (6) Covering lightly with mana in preference to patana. 12. Yes, by all round shaving. Might be prevented by partial shaving. 21. No. 15. No. (3) By covering in dry weather. 11. Yes. (2) Covering in wet weather. (3) Not covering in weather. 7. Yes. 3. Yes, from wet grass can be prevented by using waterproof covering. 2. Yes, can be prevented by using jute covering. 19. No, rot, covered in dry weather. 8. Yes, can be prevented by careful covering to prevent the bark getting wet. 1. Yes, can be checked by uncovering. 20. Yes, from covering in wet weather. 4. Yes, from shaving too deep and in wet weather. Prevention uncover! 18. Yes, principally in exposed places. 5. Yes, from wet. Prevention uncover! 16. Yes, when covered with grass, not so with paper. Succirubra more liable than officinalis. Caused by rotting grass. Prevention removal.

Question 15. And have they if uncovered?

Answer. 3, 7, 10, 12, 8, 5, 17, 18. Yes. 14, 21, 15, 9, 2, 1, 20, 4. No.

Question 16. Have you found trees renew well if shaved after 5½ years old?

Answer. 6, 21, 19, 1, 8, 9, 20, 4, 18. Yes. 10, 11, 12, 14. No. 17, 15. Yes, not so well as younger trees. 2. Yes, with hybrid and officinalis; doubtful with succirubra.

Question 17, What is the greatest number of times you have found trees renew well after shaving?

Answer. 9, 6. Six times. 10, 11. Four times. 3, 14, 15, 20, 4, 18, 5. Three times. 2, 7. Twice. 1. Seven times. 19. Three and then coppiced.

Question 18. Have you tried stripping on the McIvor principle, and if so has it answered? Please give the method of successive harvestings.

Answer. 6, 21, 11, 9, 1. Yes, unsuccessful. 17. Yes, expense of covering prohibitory. 20. Yes, unsuccessful after coppiced.

Question 19. Have you found an interval of 4, 6, 8 or 12 months between shavings give the best analysis of bark, and how have you found it increase when left each of periods?

Answer. 11. Three months' old officinalis after 5 months renewal gave no increase in alkaloid over original bark; 4 years' old officinalis after 8 months gave 5·35 per cent sulphate quinine; 4½ years' old succirubra after 8 months renewal gave 3·68 sulphate quinine. Eight months renewal of succirubra between ages of 3 and 5 has given 30 to 33 per cent increase in yield. 2. Would not shave oftener than every 10 months. 20. About 8 months gave the best *looking* bark. No analysis. 4. Officinalis 10 at 12 months. 19. Between 8 and 12 months is only what I have tried on a large scale. An experiment of bark renewed 23 months = 4·20 per cent; 9 months = 4·20 per cent. 18. In the second shaving at 12 months the analysis showed an increase, but the third shaving at 6 months a decrease of sulphate of quinine.

SECTION 5.—*Coppicing.*

Question 1. At what age do you prefer to coppice and in what month have you found the suckers to grow best after coppicing?

Answer. 12. At 4 years in October. 14. At 6 years in April and May. 21. At 7 years. 15. At 6 years in March and April. 11. At 6 years in February. 19. No experience except at 4 years. 20. At 6 at 10 years in April and May. 18. September and October. 1. At 5 to 6 years. 13. At 4 to 6 years. January and February. Analysis of succirubra, 3, 4, 5, and 6 years old coppiced in May, shows 2·33 per cent sulphate quinine; February, 2·21 sulphate quinine; 4 years January, 2·736 sulphate quinine; 6 years (not yet coppiced), 4·90 sulphate quinino.

Question 2. Whether you start a sucker previous to coppicing or not?

Answer. 14, 3. Yes if possible. 12, 8, 1. Yes. 11. Prefer to do so. 18. No preference.

Question 3. Have you any method of encouraging a sucker to start?

Answer. 14. Beating or bruising the stumps. 12. Manuring. 11. Wounding cambium. 8. Baring roots. 20. A cross cut.

Question 4. How many suckers do you allow to grow after coppicing?

Answer. 14. As many as possible. 21. Three. 15. One. 3. Two or three. 8. As many as possible, then thin out to 1 or 2. 13. Thin out after two months to four. 1, 11. Three. 20. Thin out after 6 months to 3 or 4. 18. Two.

Question 5. What proportion of coppiced trees do not throw out suckers? What do you consider the cause of this?

Answer. 14. 11, About 5 per cent. 6. All healthy trees. 15. Very small proportion. 3. A large proportion (6) suckers being pulled off when trees were younger. 13. Very few. 20. Very few healthy trees. 18. None.

Question 6. After coppicing what interval do you allow before coppicing again?

Answer. 1, 12, 21, Three years. 20. Five to seven years. 18. Six years.

Question 7. Do three suckers give a greater weight of bark than two and two more than one.

Answer. 1. Three suckers best. 20. Three more than two and two more than one. 15. Succirubra, one officinalis two or three.

Question 8. What in your experience is the proportion of bark obtained by coppicing as opposed to shaving (*a*) in one harvesting, (*b*) in a series of years?

Answer 14. Three times as much. 15. Sixteen times as much. 11. Three times as much (between 3 and 4½ years) 20. As 8 is to 2½. 4. As 4 is to 1. 18. As 6 is to 1·81. 6. 2 shaves—one coppice nearly.

SECTION 6.—*Curing.*

Question 1. Do you prefer to dry your bark in the sun immediately or slowly in the store?

Answer. 17, 22, 21, 11, 7, 13, 8, 20, 16, 5, 18. In the sun. 6, 15, 47. Gradually in the sun.

Answer. 10. Prefer slowly in the sun. 14. One day in store, next day in the sun. 12. In sun with matting over bark. 3. Slowly in sun. 1, 19. No preference.

Question 2. Have you tried artificial drying, and with what success? Kindly give cost of any operation you refer to in your answers?

Answer. 6. No difference by Mr. Moens' analysis. 14. Tried, prefers sun. 1, 4, 5. Tried, not successful. 16. Baring roots ½ cents per tree. 20. Shaving costs about 1 cent per lb. dry bark. Coppicing costs about 2 cents per lb. dry bark. Uprooting 2 cents, 4 cents. Thatching 7 at 8 years old trees about 2 cents per tree. 6. Shaving costs 4·4 cents per lb. dry bark. Grass covering 7 cents per lb. dry bark. Preparing, transport and shipping 4·7 cents per lb. dry bark. 11. Shaving costs 2 at 3 cents per lb. dry bark. 19. Shaving costs 1·16 cent per lb. dry bark. Grass and covering 3·5 cents per lb. dry bark. Branch bark 2 cents per lb. dry bark. 18. Shaving costs 16 cents per lb. dry bark. 15. Shaving 3 at 4 cents per lb. dry bark. Coppicing 2 cents per lb. dry bark.

THE DATE COFFEE COMPANY.

In the Queen's Bench Division, on the 8th ult. before Justices Denman, Manisty, and Watkin Williams, judgment was given in the case Bellairs *vs.* Tucker and others which had been tried at great length before Mr. Justice Lopes and a special jury (the trial taking eight days), and had then been argued at great length in this court before Justice Denman and Mr. Justice Manisty, who had taken time to consider their judgment, which was now delivered in favour of the defendants. It was an action against three persons —Tucker, Henley and Haymen—to recover by way of damages a sum of £95, which the plaintiff had been compelled to pay or become liable to pay, in respect of shares held by him in a Company called the French Date Coffee Company (Limited), which had been projected with 50,000 shares at £1 each, and a prospectus of which had been issued (as was alleged) by the defendants, and on the faith of which the plaintiff represented that he had applied for and accepted 95 shares in the Company. The facts, so far as they were material, and not in dispute, and as stated by the learned judge, who delivered a written judgment, were as follow: The plaintiff was a dealer in stocks and shares, who had formerly been on the Stock Exchange. The defendant Haymen was chairman of a Company called the "Date Coffee Company." The defendant Tocker was solicitor, and Henley consulting engineer to the same Company, the latter having obtained a patent for manufacturing from dates a substitute for coffee. That Company (an English Company) was registered in December 1879 with a capital of £50,000 in shares of £5, and its objects were to acquire and purchase or take licenses for use of that patented invention or other patents granted to Henley, and to form or assist in forming or developing any company for the same or cognate objects. That Company proceeded to issue shares and make arrangements for the sale of the material which it was to manufacture. The three defendants appear to have attended regularly at all the board meetings, Henley having been elected a director soon after the formation of the Company. At the first general meeting of the Company on the 1st of March, 1880, a resolution was passed authorizing the directors at once to purchase royalty from Henley for £30,000, which was done, and Henley was paid within a few months. In June, 1880, one Mare was sent to Kurrachee in India, there to superintend the manufacture of dates into the powder which was to be mixed with coffee, in order to produce the date coffee. He arrived there on the 25th of August, 1880, and from that time was in constant correspondence with the English Company through Haymen and the secretary as to the quantity of materials which it would be possible to manufacture, and as to the quality of the ovens and other apparatus required, and it appeared from his evidence that during the first 12 months, having only two ovens to work with, he sent over 10 tons of date-powder per month, which was as much as the machinery would produce; that in September 1881, having six ovens, the largest amount he turned out was 35 tons in a month, and that the largest amount he could have turned out was 40 tons or 480 tons a year, though it appeared that he was in his letters writing of the possibility of producing at a greater rate, but he did not appear to have contemplated at any time the possibility of turning out more than 20 tons weekly, even with six ovens, the largest number ordered, or apparently contemplated, at all events until a later period, though it appeared that tho directors were insisting upon production at the rate of 40 tons a week as soon as four more ovens were supplied, as they afterwards were, and they were in active correspondence with Mare at and after the date of the prospectus as to the best mode of carrying on the manufacture at Kurrachee on a large scale. It appeared, however, that in order to make a profit of £34,000 a year it would be necessary that about 30 tons a week should be manufactured, and the quantity actually manufactured in September, 1881 was 17 tons, and in October 20 tons. At the time of the publication of the prospectus, of which the plaintiff complained (that of the French company), a few tons only of the date powder manufactured at Kurrachee had reached England, and two cargoes were on their way, but the shares of the English company had been sold at a very considerable premium—£5 shares having been sold for as much as £17 and in December 1880 one Young, a Colonial broker, had proposed to take the whole of the company's produce, and had afterwards in February entered into a contract for it. These being the circumstances as to the position and prospects of the English company the circumstances leading to the publication of the prospectus of the French company and to the formation of that company in which the plaintiff had taken his shares, were as follow. One of the objects of the English company was to sell the patent rights of the company, among which was a French patent they had acquired from Henley, and there was a resolution to sell it for not less than £50,000, and also to divide the amount of the purchase-money among the shareholders as a bonus. In February, 1881, an agreement was entered into between the English company and one Talbot Haymen (a brother of the defendant Haymen), as a trustee for the French Company, whereby he was to purchase the French patent for that Company for £50,000, and the memorandum of Association of the French Company dated February 4th, 1881, stated as one of its objects the carrying out of this contract, and next day a Company was incorporated. The plaintiff had had no connexion with the English Company, and he had, he said, on the 1st of February 1881 seen a "proof" of the prospectus, and had applied for a hundred shares, and on the 7th he received a copy of the prospectus, and confirmed his application in a letter in which he stated that he read the prospectus, and his case was that he had made his application on the faith of the statements in the prospectus, in which, however, the only statements complained of as fraudulent were contained in the following paragraph relating to the English Company:—"From the success attending the Company formed for the working of Henley's English patent, when a duty of 2d ℔ lb is payable and the coffee sold at 1s ℔ lb, the directors feel justified in stating that they confidently believe the profits of this Company will be more than sufficient to pay dividends of at least 50 per cent. on the nominal capital, and will exceed those of the company working the English patent which, having been formed a little over 12 months, has entered into a contract which will yield the return by way of annual dividends, of a sum equal to the whole paid-up capital of the company of £34,000." The plaintiff's case was that these statements were fraudulent, and that he had taken his shares upon the faith of their truth. But he admitted that he saw the prospectus in a paper called the *Financier* of the 7th of February, and that paper contained a long report of an extraordinary general meeting of the English company, including a report of a speech of the defendant Haymen, in which he used language rather expressive of confidence in the future prospects of the company than stating as a fact that commercial profits had yet been made, and he spoke of profits "expected to be made," and that in the future great profits would be made. The plaintiff also admitted that he had tasted the material itself, and that he had faith in it as a product for ordinary commercial purposes and for ordinary consumption. And the copy of the *Financier* in which the prospectus appeared had also a leading article strongly in favour of the French company, and stating that the direction was "identical with that of the original and highly successful company." And, further, the plaintiff admitted that he had acted partly upon what had been said to him by a a person who had first shown him the prospectus. At the trial it was admitted on the part of the defendant Haymen that he was responsible for the publication of the prospectus, but it was denied on the part of the other two defendants. The learned judge, however, put it strongly to the jury that they were responsible for it, because they were so largely interested in the English company, being in fact, the holders of more than three-fourths of the whole of the shares. The mode in which the learned Judge dealt with the question of the prospectus was this —He read the passage relied upon to the jury, and said "If it could have been successfully contended that all that was mere confident expectation, I do not think this action could have been maintained, because a man is entitled to commend anything with which he is connected, so long as it is a matter of belief; but when he comes to statements of existing facts in respect of it, then if they are false to his knowledge, he becomes responsible to anybody who has been induced thereby to part with his money." And in conclusion, he left questions to the jury on which they found as follows:—(1) That the defendants were responsible for the contents and for the issuing of the prospectus; (2) that the statements in it relied on by the plaintiff were false; (3) that the defendants knew them to be false or were ignorant whether they were true or false, and made them recklessly; (4) that the plaintiff was misled by these false statements or some of them, and was materially influenced by them to part with his money; and so the verdict was entered for the plaintiff, and judgment given accordingly. This was an application for a new trial on the grounds of misdirection and that the verdict was against the evidence, and the case had been argued at great length before Mr. Justice Denman and Mr. Justice Manisty.

Mr. C. Russell, Q. C., and Mr. Channell for the plaintiff Sir H. Giffard, Q. C., Mr. Pollard, and Mr. M'Millan for the defendants.

The Court had taken time to consider their judgment, and that judgment was now delivered in favour of the defendants.—*Times of India*, May 3rd.

Vegetable Rennet.—A Kurrachee paper learns that the successful experiments on the farm of H. E. the Governor of Bombay with the Puneria berries (*Withania coagulans*) in producing a perfect curd for cheese-making, have induced an American firm of dairymen, Messrs. Burrell and Whiteman of Little Falls, New York, to address Sir James Fergusson on the subject, and accordingly a supply of about ten pounds of these berries has been procured from Sind and forwarded to them for experiment.

The Norwegian, Schubeler, mentions some striking peculiarities of plants in high latitudes. He says that seeds produced in these regions are much larger and weigh more than those grown in more temperate climates. The leaves, also, of most plants are larger in the north than those of the same species farther south. Flowers which are white in warmer climates, become colored when they blossom in the north. All these differences he ascribes to the continued light of long days.— 'Jaffna College Miscellany."

Vegetables and Fruit.—People need to be frequently reminded of the fact that if they make a practice of using a variety of vegetables and fruit as a part of their ordinary diet the doctor will not be needed to prescribe for them so frequently. Asparagus is a strong diuretic, and forms part of the cure for rheumatic patients at such health resorts as Aix-les-Bains. Parsley is also useful as a diuretic, and those requiring such aid should make free use of it. Carrots are understood by the peasants of Savoy to be a specific for jaundice, and, although they are thought to be hard of digestion, it is only the yellow core that is so. Onions are admitted to be rich in those alkaline elements which counteract the poison of rheumatic gout, and people who are of studious or sedentary habits should make a free use of them, gently stewed and served with other vegetables. The stalks of the cauliflower if properly cooked also serve a like purpose. Celery has acquired a great reputation as a remedy for rheumatism, and in many cases has proved beneficial. Watercress is prescribed by many medical men as helpful to the liver and lungs. Many other vegetables are useful, not only for their special medicinal properties, but as general regulators of the bowels and as correctives, and withal they contain valuable elements of nutrition which should commend them apart from every other consideration.—*Queenslander*.

Correspondence.

To the Editor of the Ceylon Observer.

PLANTING AND PLANTERS ON THE NILGIRIS.

Neilgherry Hills, April 26th, 1884.

DEAR SIR,—I should be glad to see planters avail themselves more frequently of the opportunity afforded in your columns of ventilating freely various mooted points concerning practical cultivation. For instance, would some experienced planter give his opinion and experience regarding pruning tea at high and low elevations? Suppose we started with the proposition that tea at an elevation of 6,000 feet requires severer pruning than tea at 3,000 feet, in order to force out a decent flush within a respectable period of time after pruning: how does experience support this theory?

Officialdom in India thinks it is high time to assert itself more fully and to bring planters especially into a due spirit of subjection and dependence. Owing to our modern land rules strictly reserving all jungle and swamp by our paternal Government, I was, a short time ago, reduced to the alternative of applying to the Forest Department to grant me permission to cut a few jungle posts. This permission was granted at the exorbitant charge of six annas per post. My arrangements were accordingly all made to cut and cart the said posts, when I received another intimation rescinding this permission. In my presumption I actually imagined that some reason would be adduced to explain this sudden inconsistency, just as if officialdom could ever stoop to a "reason why"! My only consolation was to behold a jungle cut down wholesale in order to afford fuel for Government purposes, although a few posts could not be spared to your humble servant.

The swamps being likewise reserved, we also are obliged to apply to officialdom for permission to cut a bundle of wattles. A local representative has hitherto been empowered to favour us with the required permit. But this evidently fostered too great a spirit of independence in us, for, on lately applying to the said local personage for a permit, I was informed that an application must be made in due form to the Forest Department for a small bundle of wattles wherewith to repair my cooly lines. This application I duly made, and am now comforting myself with the reflection, that, after my cooly lines have tumbled about the ears of my unfortunate coolies, a permission from high officialdom will be received with the aforesaid permission.

I trust, Mr. Editor, that you will, to the best of your ability, combat the prevalent hot-headed. radical idea that planters are prone to indulge in, namely that their convenience can have any possible weight with the solemn dignity of officialdom!

What a happy lot is ours with such a considerate and truly consistent Government.—Yours faithfully,

NOVICE.

RHEA FIBRE AND SMITH'S MACHINES.

141, Fenchurch Street, London, E. C., 1st May 1884.

SIR,—Our attention has been called to your issue of 4th April. Permit us to give a few facts bearing upon this subject.

1st.—Since 1862, nearly all the China grass imported to Europe has passed through our hands, and we have been consulted on most of the new machines and processes brought forward since that date.

2nd.—By special request we in conjunction with Dr. Forbes Watson investigated the theory and working at the Favier-Frémy process in Paris in October last.

3rd.—Our conclusions were unfavourable to its being worked successfully on a commercial scale.

4th.—Shortly afterwards we were called upon to examine Smith's machine, and the results of the experiments we made on imperfect material were so remarkable, we were convinced that we had found the machine that could extract the fibre *fit for market* in one operation.

5th.—The General Fibre Company was subsequently formed on our recommendation to secure the patent rights and to sell the machines, &c.

6th.—Unavoidable delays connected with the formation at the Company *alone* prevented Dr. Forbes Watson leaving in time for the Calcutta Exhibition.

7th.—Further experiments show that the machine is capable of extracting the fibre from nearly every plant, yielding fibre from either stalks or leaves.

8th.—It will treat about 10 cwt. of green leaves per hour, when properly handled at a very small cost.

9th.—A considerable number of machines have already been shipped and will shortly be at work in India, Africa and America, &c., and are confident the results will be satisfactory if *they are properly handled*, not otherwise.
—Yours truly,

COLLYER & Co.

(*From a former Ceylon Planter.*)

"I wrote you last about the end of December, I think, and have been intending to do so again for some time past, but until now have not been able. Though no longer a planter and not likely to return to Ceylon, I take still much interest in the colony and all that concerns it, and am always glad to have a look of your *Weekly Observer* and *Tropical Agriculturist*, giving as they do so much general and useful information. When I last wrote you, our Company, of which I am Secretary, was just starting. I sent you several papers referring to it, and also Dr. Forbes Watson's lecture on Rhea. Under separate cover I am today sending to you a copy of our prospectus and circulars referring to our machine—possibly you may have seen these before. Further matter is now in the press and will be sent you when completed. It was our intention when I last wrote you that Dr. Watson and Mr. Death should visit the Calcutta Exhibition to show our fibre-cleaning machine there. Most unfortunately it was found impossible to get the Company floated in time, owing to legal requirements, and the consequence was, that, by the time Dr. Watson and Mr. Death could have started, it was found to be too late for the Exhibition, and it was then decided that Mr. Death should go alone but that it would be better to put off his visit until next season, so likely he will leave this for India about September next. The delay was a most unfortunate one, not only in losing us a session, but people naturally think that our machine has proved a failure. Far from it! Every day we become more convinced of its success. Machines are now at work in various parts of India, and we have got home samples of fibre treated by the machine there. I shall send you samples of aloe and moorva which have been sent home. These are just as they left the machine without any after-process of bleaching, and finer samples one could not possibly wish. I also enclose a small specimen of rhea treated by the machine here in London. From advices lately received from India and Africa we learn that 5 tons of *green* leaves can be passed through the machine in a day of ten hours. Outturn of dry fibre must of course depend on the percentage of fibre in the plant operated on, which varies from 3 to 5 per cent.

I think I mentioned to you that it was after Dr. Watson and Mr. Collyer, our Managing Director, had gone thoroughly into the Favier-Frémy process, "weighed it in the balance and found it wanting," that they made their experiments with Death & Ellwood's machine with such excellent results; any one can see what must be the result of treating a plant with a strong solution of caustic soda. It is possible to do so without deteriorating the fibre as well as dissolving the bark? The Johore Rhea Company which you refer to in your weekly issue of April 4th has not, as far as I am aware, been floated, nor is it likely to be so. I wish the Lini-Soie syndicate (G. W. H. Brogden & Co.—Manager Edward Casper) could float it, as sooner or later they would be customers for our machine. But even allowing that the Favier-Frémy process is a success, it would never prove to the planter the boon that a simple machine like Death & Ellwood's will. The latter will extract the fibre from *every* known fibre-yielding plant (except coconut and bristles) in the condition most suited for the market here, whereas the Favier-Frémy can deal with rhea only. The waste by above machine, I may mention, is almost "nil."

(*From a Correspondent in London.*)

You ask in the *Ceylon Observer* which is just to hand, how it was that Dr. Forbes Watson did not go to Calcutta to test the Death & Ellwood or Smith patent fibre-cleaning machine.

The best answer to be found to such an enquiry is the report brought home from Ceylon by Mr. Arthur Campbell of the capacity of one of these machines.

It is reported that he worked to the very utmost, having the stems handed to him by natives, and the utmost quantity that could be turned out was the equivalent of 5 lb. of dry fibre per hour.

He naturally admits that no native would work the machine at its utmost speed nor would he exert himself as he and his partner did, for ten hours in the day; therefore it would be too much to calculate the outturn of one of these machines at 50 lb. of dry fibre a day. That would be 18s a day, supposing the fibre sold at £40 a ton here, from which would have to be deducted the cost of growing the fibre, bringing it to the machine, treating it, drying it baling it and sending it to England, and then having to pay the brokers charges and warehousing.

There is no doubt this machine turns out excellent stuff, but improvements will have to be made upon it to prevent the necessity of having to draw the fibre back with the hand and then turn it to put in the other end.

A similar report is sent over of the quantity that can be turned out of this machine in India, and also from Jamaica; so it shows that all the different people have been working their very utmost and calculating upon the result of *an hour's* work at *high pressure*.

We add to the above communications the following extract from the London letter of our morning contemporary :—

In a recent issue of the *Times of Ceylon*, I noticed an editorial commenting favourably on samples of various fibres prepared at the Beddegamma estate by one of the Death and Ellwood machines, chiefly aloe, plaintain, and pine-apple, but you went on to remark that, although the quality of the fibres was excellent, the practical utility of the machine depended upon the quantity it could turn out in a working day, and the cost of the labour and power employed. Now Mr. Campbell, by whom these trials were personally conducted, has just arrived in this country, and at first it looked as though his report was most damaging, if not fatal, to the machine, for he declared that, when worked by two Europeans doing their level best, and therefore twice as much at least as coolies in the ordinary way, the best yield was 5 lbs. of dry fibre per hour obtained from aloe leaves, whilst that from pine-apple leaves and plaintain stalks was much less. It needed no argument to demonstrate that, if this really was the utmost capacity of the machine it was practically worthless, but it is only fair to say that after an interview with the manufacturers, Mr. Campbell has greatly modified his views, being convinced that he could have done vastly better, if he had been in possession of proper instructions for working, and had been able to remedy certain defects in the machine, of which he is now conscious. Chief amongst these latter was the absence of a sufficient head of water to create the necessary pressure from the jet, which forms the cushion pressing the leaf or plant against the beaters, and also serving to clean the fibre from the gums and other extraneous matter adhering to it. Mr. Campbell admits that this was wanting, whereas it is an essential feature of the invention, and will make a considerable difference. Then, too, experience in other places has proved that, as those working the machine become accustomed to it, the outturn steadily increases, and the actual result obtained in one instance has been 113 lb. of rhea fibre in a day of 10 hours from stalks of inferior quality giving only 3 per cent of the gross weight, instead of 5 per cent, which is the ordinary yield; and of course there would be no more labour employed, and no more time occupied in obtaining the latter, than the former, if it were there. I think therefore that judgment must be suspended until the machine had been fairly tested under satisfactory conditions, and I have no doubt that a great effort will be made to do this at the exhibition to be held in the Agricultural Hall in August and September next, though it will obviously be no easy matter, owing to the difficulty of obtaining a sufficient quantity of fresh leaves and stalks. This is an exhibition of textile fabrics, and the machinery for manufacturing them, including also the raw materials, and I understand that the inventors of several of the processes and appliances for the treatment of fibrous plants intend to compete.

MR. ARMSTRONG ON MR. HALLILEY AND HIS WEED THEORY.

Rookwood, Deltota, 15th May 1884.

DEAR SIR,—May I ask you to be good enough to insert the following letter which I have written to the editor "Times of Ceylon," as you gave such prominence to Mr. Halliley's remark concerning my former estate, Rahatungoda, and weeds?—I am, yours faithfully, C. SPEARMAN ARMSTRONG.

15th May 1884.

The Editor the "Times of Ceylon," Colombo.

Dear Sir,—With reference to Mr. Halliley's remark anent Rahatungoda, in his letter appearing in your issue of the 10th instant, viz.: "I was told by the former proprietor of Rahatungoda, that when that was a weedy estate it used to give good crops," &c., I beg to inform him, I was the immediate former proprietor of that estate, and that I have known it for 19 years, and can say, during the time it gave GOOD crops, it was *not* a weedy estate. A friend, who has known the estate six years longer than I have, endorses what I have said.

Where weeds have been allowed to grow, coffee has, in every instance under my knowledge, succumbed to them. Had we not enough varieties in Ceylon already, I would recommend Mr. Halliley to import a new weed, to try his theory on.—I am, dear sir, yours faithfully,

C. SPEARMAN ARMSTRONG.

[We cannot help thinking that Mr. Halliley referred to a period anterior to Mr. Armstrong's connection with Rahatungoda.—ED.]

G. W. ON CEARÁ RUBBER TREES.

SIR,—Referring to an inquiry of one of your recent correspondents, I may say that I have nothing satisfactory to communicate further about Ceará. The collection was continued from trees of different ages and in different localities as long as I could afford to carry it on, but, except on rare occasions, the quantity collected did not pay for the labour of collecting.

The last method tried was to take advantage of those times when the trees yielded milk freely, and to take from them at such times as much as could be got, and to neglect them at all other times. But even this method has not hitherto succeeded in the all-important matter of a remunerative result. In fact, all that I have done leads me to the conclusion, that, except at some particular times, the quantity of milk procurable by any known means does not pay for the labour of extraction.

Having lately had to cut out some Ceará trees that were occupying ground required for other purposes, I had a few of them pricked all over before they were cut down and all the milk taken from them that could be got. But even this drastic treatment failed to yield a remunerative result.

During the late drought of the first three months of the year, a great many of the trees on several estates suffered very severely, and not a few have died. It was at first supposed that the leafless condition of the trees was natural, and indicated only a change of leaf; but when the new foliage began to appear only *partially*, and showed that many of the branches and some individual trees had entirely succumbed, it became pretty evident that, unless on rich soils, the Ceará will not stand with impunity such droughts as we have had this year!

The inferiority of some badly cured samples of rubber sent home for valuation has been ascribed by the brokers to their having been taken from trees that were too young, but this is clearly a mistake, because well-cured rubber from the same trees was valued at the highest prices. G. W.

FORMING TEA PLANTS.

DEAR SIR,—There seems great diversity of opinion as to the proper time or stage at which young tea should be first cut down to form the bushes. One experienced tea planter, in the course of a lecture which appeared in the *Observer* some time ago, mentioned, I think, that tea should be allowed to grow to a height of six feet before cutting down, and not a few cultivators seem to adopt this system as a sound one. As I consider the matter of great importance, I shall be glad if you will allow me space in the *Observer* for my own decided opinion and to invite discussion.

Anyone who has given attention to the habits and growth of the tea plant must have observed that the best sorts or greater proportion of them, if allowed their own way, would send up one, two or three stems as the case may be, and, so long as these are allowed to go on unchecked, few, if any, side-shoots will grow out from below when they are required to form the bush, and, even if a few grow, they would be weakly and useless so long as one or two stems are allowed to go ahead as leaders. Some of the objections to allowing the tree to grow to six feet are, there is the great waste why grow them to six feet, then cut off and throw away four feet of that? Would not this extra height have been better added to the width which would have been simple enough. Another objection is, they are much more apt to grow seed; but, possibly, the strongest objection is, the oppportunity is lost of forming equal, well-balanced, well-shaped trees from the beginning, instead of the spreading bush with the shoots regular and as nearly as possibly the same strength. The tree cut down after attaining a height of six feet is but two or three thick stumps with all its other shoots to grow and its breadth to make, is unequal and is more difficult to keep in shape ever after.

Tea-fields should be gone over with the knife when only ten or eleven months old. All plants that are only sending up two or three stems should be cut down to eight or nine inches to make them send out shoots all round. Any shoots running ahead of the rest, especially centre shoots, should be cut lower than the others. This will give an advantage to the outsides which they require in forming the bushes. A little attention in this way to form the young trees from the beginning will be required more than once before the final cutting down for flushing, but will amply repay the little cost. Some say it would be a check on young plants; such is not the case. let us have your own opinion. M.

[Our "own opinion," not being that of a practical tea planter, would not carry much weight, but it seems to us that our correspondent has much reason on his side; and we know, that, on the property in which we are personally interested, the superintendent tops plants at and under eighteen months in the field, and we believe he would never think of allowing a plant to attain a height of six feet unless it were grown for seed-bearing.—ED.]

TIMBER FOR TEA-BOXES: CAJUAL REMARKS.

15th May 1884.

DEAR SIR,—Referring to a letter in your columns suggesting the caju-tree as suitable timber for tea-boxes, a friend of mine remarked that the timber might do well enough but that it is not a very common tree in some districts—in fact, one only comes across it *caju*-ally!

Happy thought:—To send this to the *Observer* as my own joke.

"Kekuna" is a common tree, and could be cheaply sawn up; do you know of any objections to it on account of taint in the wood or other drawbacks? AJJAK.

[We do not know about the timber of the kekuna, but, apart from the value of the trees as oil-yielders, they enliven the scenery so much by their bright foliage that we should be sorry to see them cut down.—ED.]

CAJU TIMBER FOR TEA-BOXES.

Colombo, 21st May 1884.

DEAR SIR,—Referring to the letter on "Timber for Teaboxes: Cajual Remarks," permit me to inform "Ajjak" that the caju tree is not the rare thing he supposes it to be. They could be had in abundance in almost any village in the Western Province, where (and so I suppose in other coconut-growing districts). It is customary to grow a caju between every coconut plant for the sake of the shade. It is besides such a hardy and quick-growing tree, that, wherever care is not taken actually to root them out, it will be found that caju forests form themselves spontaneously.

I have not had the pleasure to see my first letter in print and am therefore unaware that any reply has been given in the way of footnote to the question I raised as to whether caju timber would be suitable for the purpose of packing tea, lead going on the sides of course. This question settled, I can promise "Ajjak" that he will find no lack of caju timber.

If required, I shall be glad to send you samples of caju planking, fresh as well as dry.—Yours truly, X. Y. Z.

[We should be glad to see a plank of the timber.—ED.]

INSECTS ON CACAO PLANTS.

Orangegrove Estate, Polgabawela, 21st May 1884.

DEAR SIR,—I send to your address some insects I found on my estate feeding on cacao plants. The branches are denuded of leaves and the tender bark at the tips of branches is stript off.

There were about ten to twelve on a tree, but on a few trees only.

I shall feel obliged to know what these are, and if cacao planters are aware of the inroads of these insects. —Yours faithfully, ED. D'SILVA.

[The box sent contains a number of active little insects marked on the back like castor oil seeds. Our entomological authority pronounces them to be weevils, but he does not know the name —ED.]

WEEDING AND COFFEE CROPS.

Deltota, 22nd May 1884.

SIR,—In reply to Mr. Halliley, I beg to inform him that I had charge of Rahatungoda from 1864 to 1869. The estate was *never* a clean one, but I tried to keep down the weeds by monthly weedings; during the time of my management (after the first year), the average crop was about 5,000 bushels of parchment.

Mr. E. H. Cameron took over charge from me; he did not continue the monthly weedings, and he did not get half the amount of crop.—Yours faithfully,

W. A. HOWIE.

MR. HALLILEY'S WEED MANIA.

Dear Sir,—I notice Mr. Howie's letter. * * * Perhaps Mr. Howie may not be aware that Mr. E. H. Cameron lived on Rabatungoda with his father, I believe previous to 1864. Is Mr. Howie writing against his own experience or does he not believe in his own conviction? Supposing a piece of land had been chenaed, part of it only a year previous and part twenty years before, which part would he chose to form a plantation? Undoubtedly that part with the twenty years' growth on it, because the decayed vegetable matter of twenty years must have improved the soil. If plants only returned to the soil what they had taken from it they could in no way improve the soil, but plants derive some of their component parts from the atmosphere, and it is what they derive from the atmosphere added to what they derive from the soil that improves the soil. So that if plants derive more of their component parts from the atmosphere what better plant can we cultivate among our coffee to regulate the moisture and to keep up a constant supply of food than the plant, that we have been told, contains the very essential food of the coffee-tree? Where weeds will not grow, coffee will not thrive. It is now acknowledged that the oidium—a similar disease to our leaf-disease—was through not allowing anything to grow in between the vines. There is no country in the world where coffee has been cultivated as it has been for some years past in Ceylon, and I think it must be acknowledged that it has proved a failure. Coffee thoroughly neglected will become diseased and coffee after giving a succession of good crops may become diseased through the weeds not being able to supply sufficient food* in proportion to what has been taken away.—Yours truly, G. F. HALLILEY.

[The subject has now been fully discussed, and Mr. Halliley must be "shut up" on the same principle that the inmate of the lunatic asylum was—"I believed the whole world to be mad; they believed me to be mad, and they being in the majority shut me up." Amongst the majority is Ed. *T. A.*]

THE NORTHERN TERRITORY.

Pearling.—The principal excitement here at present is in connection with the pearl-shell fishery. For years past a few pearl shells have been found at various times both in the harbour and along the coast. This gave rise to the hope that at some future time a payable bed would be found, no one imagining that beds of such a character could be found immediately at their doors, and the idea was further removed owing to the fact that on two previous occasions the harbour had been visited by vessels fully equipped with swimming divers, and who prospected Port Darwin waters without success. This prospecting must have been done in a careless manner, for upon the arrival of the pearling schooner "Sree Pas Sair" on February 16th last with a complement of sixty divers, they were immediately set to work in a systematic manner, and in a few days succeeded in obtaining about one-and-a-half tons of shell. After this the men could not be worked to advantage, owing to the increased depth of water shells were obtainable in, and the vessel was not provided with diving dresses. The success attending the "Sree Pas Sair" immediately awakened a keen local interest in diving matters, and a local Company, in which previously no great amount of interest was taken, completed arrangements, and set to work with two boats and diving dresses. A few days afterwards three more boats equipped in the same manner arrived from Thursday Island, since when these five boats have been steadily at work, and up to the present time have been very successful. Up to date, as near as I can ascertain, about twelve tons of shell have been obtained by these boats. The credit of pointing out that shell could be obtained so close at home certainly belongs to Lieutenant Chippendale, commander of the "Sree Pas Sair." This gentleman believes that large quantities of shell are obtainable near at hand, but that principally they will not be obtained by using diving dresses, the shells lying too deep for swimmers. On the 9th of last month a large deputation, representative of those having a considerable interest in the pearl-fishing, represented that the licence tax imposed by the Government upon pearling boats was excessive and liable to check of the growth of the industry. Up to that time no success of any importance had attended the boats, consequently the proprietors were not in the best of spirits, but in a very few days, when fortune began to dawn upon their efforts, a different spirit existed. I do not think that any one now considers the tax otherwise than fair. There is no doubt that in a very short time Port Darwin will have a very large fleet engaged in this industry and a large increase to our local population. Consequent upon this it will be absolutely necessary to have a larger Police Force stationed here. It is well-known, and one need not go further than Thursday Island to be aware of the fact, that a diving community are rather a troublesome lot to manage. If they are dealt with here strictly from the commencement a great deal of otherwise ultimate trouble would be avoided. On all pearling grounds it is well-known that the pearls found in the shells are purloined by the divers and surreptitiously sold. The losses to the owners of boats from this source is very considerable. The trouble in prosecuting lying in the fact that the pearls cannot be identified, I would suggest that, for the purpose of supervising this offence to as great an extent as possible, a law be enacted prohibiting any one from either buying or selling pearls within the limits of the Northern Territory without a licence, punishing any infringement with a heavy fine or imprisonment. Such a law would, I believe, be of great benefit in protecting those who invest money in pearl-fishing. There is also another matter to which I would direct your attention, viz., that of protecting the beds upon which the oysters are found from denudation. I am credibly informed that both in Western Australia and Torres Straits beds that were originally very prolific have been completely destroyed owing to the fact that they have been robbed of the young oysters even down to two inches in diameter, thus preventing any chance of recovery. I am not prepared to say what ought to be the least weight of the shells allowed to be taken from the water, but this might be ascertained from some one who knows more of the science of the subject than myself. What I wish to point out clearly is that pearl oyster-beds if honestly fished over recover themselves in from five to seven years, on a great length of coast such as the Northern Territory possessions, and along which it is only reasonable to suppose many beds will be found, and which if properly protected will be a never-ending source of revenue to the country, and afford occupation for a very large number of people. —*South Australian Register*, May 8th.

Leguminous Plant Fertilisers.—Sir J. B. Lawes, the great English scientific and practical farmer, reasons from experiments in this style:—To obtain maximum crops of grain the proper course to pursue is to precede them with a crop of leguminous plants, that is, peas, clover, vetches, &c., to which the minerals should be applied, and this enables these plants to make an unusual growth which renders them capable of storing up a large amount of ammonia—more than is necessary for the grain crop that follows—and the latter by this active stimulant is rendered capable of obtaining all the minerals required from the soil and the decaying vegetation for maximum crops.—*Leader.*

IN THE KAURI GUM FIELDS.*

Sombre, solemn, and grand are the kauri forests of Northern New Zealand. If you want beauty of mixed foliage, of wide-spreading, branching trees, all interlaced with knotted vines and tufts of rosy blossoms—forests where the golden sunlight steals in delicately-divided rays through the exquisite canopy of tall tree-ferns, to fall in radiant gleams on the carpet of all manner of silver-backed and other lovely ground-ferns—you will find these in perfection wherever the grievously "improving" hand of the settler has spared the primeval bush. Alas, that we should have to say, such precious visions of Eden are already few and far between—only to be found in the least frequented districts.

But the kauri forests are a thing altogether apart; and alas! indeed, of these also we must say that they are rapidly diminishing before the too busy axe of the lumberer. The kauri is the pine-tree of New Zealand, the sole representative of the coniferous family, and a very noble representative it is, though by no means answering to our ordinary notions of pine-trees, inasmuch as its foliage consists of leaves instead of needles; but it is tall and straight as a mast, and a very majestic mast, for these stately trees range from fifteen to fifty feet in girth, and attain a height of from a hundred to two hundred feet ere they commence throwing out the branches which form their crown of sombre green. This is a special industry peculiar to Northern New Zealand, and the precious gum is a semi-fossilized deposit which is found buried at a depth of five or six feet below the surface of the ground, on tracts of open land, where in bygone ages grew kauri forests which have long since disappeared. It is thought probable that these forests have been burnt, and that the exceeding heat liquefied the resin and caused it to flow more freely, for the digger is sometimes rewarded by finding a lump as big as his own body, though more frequently it lies buried in fragments from the size of an egg to that of a man's head.

The value of the gum varies with its colour, which is sometimes of a rich brown, sometimes bright amber, and occasionally almost like pale crystal. Sometimes it is clouded, sometimes quite clear, revealing flies and tiny beetles which perhaps for ages have been enshrined in its transparent depths. The clearest and most crystaline pieces fetch the highest prices, and are carved into ornaments hardly to be distinguished from amber, but very much more brittle. When these extra fine pieces have been selected, the rest is sold in the Auckland market at from £30 to £40 a ton, and is purchased by English and American manufacturers of varnish. The amount collected must be enourmous, as the value of the annual export from the colony ranges from £70,000 to £200,000. None is found in the Southern Isle, nor, indeed, to the south of latitude of 37° 30′, which is the southernmost limit of the kauri.

Whether the special qualities of the buried gum are due to old age, or to the possible action of fire, is unknown; but that which is obtained from the living tree is altogether worthless for the market, being soft and sticky,—in fact, simple resin. Large quantities in this condition are sometimes found about the roots of growing trees in the forest: but of this very little can be turned to account.

At one time as many as two thousand men made their living as professional gum-diggers, but in these more settled days other occupations are found to be more remunerative, and a comparatively small number now adopt this as their regular employment,—those who do so being for the most part the unsettled, roving members of the community. They are a mixed lot,—of very much the same stamp as an average colony of gold-diggers. Bohemians of every nation, European, American, Australian, all find their way to the gum fields. There men of all classes rub shoulders; and a white-handed "swell" lately, perhaps, an over-extravagant officer in Her Majesty's service, or an unworthy member of one of the universities, may deem himself fortunate should be chance to fall in with some sturdy navvy who will accept him as his pal.—*Pharmaceutical Journal.*

WELLS' "ROUGH ON CORNS."

* From *Lippincott's Monthly.* Reprinted from the *Oil, Paint and Drug Reporter*, March 26, 1884.

THE RED CROSS FRUIT-PRESERVING COMPANY.

One of the most interesting exhibits at the Intercolonial Exhibition is the trophy of the well-known Red Cross Preserving Company, the Crosse & Blackwell of Australia. Space has been allotted to the company close up to the main entrance, their exhibits being the first to catch the eye as the visitor comes through either of the entrances from the ante-room to the main hall. The brightly labelled tins containing the jams, jellies, and sauces made by the Red Cross Company are built up in pyramidal and other designs, and with similar business trophies claim attention for a minute as specimens of the tasteful arrangement of ordinary objects. Some of the exhibits, however, should receive more than passing notice from those interested in the development of colonial industries. These are tins of canned fruits made up after the American fashion, so fully described by Mr. T. K. Dow, the special correspondent for the *Australasian*, during his recent travels in the United States. Recognising the value of an industry that should, by reason of all natural conditions, become a standard pursuit in this country, the Red Cross Company have obtained the services of Mr. G. Ward, whose Californian experience in this particular trade has been obtained as superintendent of the firm of Sol Wangenheim & Co., of San Francisco and Sacramento River, and other firms, to the magnitude of whose operations reference was made by Mr. Dow in his American letters. The means of turning Mr. Ward's special knowledge to profitable account has been attained by the importation of a complete preserving plant, the machinery being of the most approved American patterns. The exhibits now shown are—outside any figure of speech—the first fruits of their labours, but operations were started too late in the year to permit of the company placing anything like a stock upon the colonial markets. As already stated, the industry is one altogether apart from the work of jam and jelly making, which constitutes the popular idea in the way of fruit preserving in this country. All except the larger fruits, which are cut into convenient sizes, are preserved in their natural state, and a clear syrup being used, they retain their colour and flavour in a remarkable degree. Nearly all the ordinary fruits may be successfully treated in this way, but the popular sorts in America—and taste here is apt to run in the same direction—are peaches, apricots, Bartlett pears, and golden drop plums, with other kinds in lesser quantities. Two of the most perfect of the colonial fruits are figs and muscatel grapes, the flavour of which seem to have been improved rather than otherwise by the addition of the syrup. Another useful phase of fruit-preserving is putting up the various thorned fruits so popular for pastry. The syrup for these is not sweetened, so that in preparing them for table different tastes may be studied, the manufacturers being able to retain the full flavour of the fruit by immersion in the prepared liquid. The tinning of green peas, beans, and asparagus for use in the interior or on shipboard is also a prominent feature in the company's operations, while that hybrid between a fruit and a vegetable—the popular tomato—has also received a large share of attention. The only preparation is peeling, after which it is hermetically enclosed in the tin and preserved in its own juice. All the fruits and small vegetables are put up in 2½ lb. and the tomatoes in 2 lb. tins, all running two dozen tins to the case. When finally placed on the market, each tin will be covered with a neat wrapper bearing a coloured representation of the fruit contained inside. Thus far the only difficulty has been to secure a supply of first-class fruit at profitable rates, and no doubt fruit-growing will extend rapidly with the prospect of a large demand to meet the requirements of this industry. In some parts of the Murray Valley alone peaches and grapes might be profitably grown in large quantities but for the difficulty of finding a market for large stocks. Outside any consideration of the prospective profits the Red Cross Company are likely to receive from their enterprise, they are certainly entitled to a great deal of credit for having taken the first important step in the way of establishing a great industry. Outside the especial feature in their trophy just described, the samples represent a stock of some 60,000 cases of jams and pickles turned out annually by the firm. Vinegar making has also become an important feature in their work, and under the superintendence of Mr. S. Capper, some 3,000 gallons per day will be manufactured.—*Australasian.*

THE ORIGIN OF GRAVELLY SOILS.

[THE GARDENER'S AND FARMER'S REASON WHY.]

Gravel is a description of sand, but consisting of larger particles of disintegrated rocks, distributed over the face of the earth, chiefly by the action of water. Gravel, having been dispersed by a more powerful agency than that which caused the distribution of sand, differs more widely in its qualities, because of its frequent admixture with various substances, organic remains in a fossil state, and especially clay, loam, flints, iron-stones, &c. Hence there are rich gravels, poor gravels, hungry gravels, sharp gravels. Sands will frequently be found to be the production of flat countries, gravels of the mountainous and rocky. The characteristic of gravelly soils is the quantity of loose stones which they contain. These stones will be found to consist of those varieties of rocks which the mountains of the country afford; and the nature of those rocks will frequently indicate the characters of the soil; thus, soils of which the stony matter is silicious are generally found to be barren, while those of which it is calcareous are found to be fertile.

How may gravelly soils be improved? By draining. if they are troubled with springs. which is frequently the case; by ploughing rather deep; by mixing them with large quantities of clay, chalk, marl, peat, or other earth; by frequent returns of grass crops; by repeated applications of manure; and by irrigation, more especially if the water be full of sediment and judiciously applied. The materials to be added to gravelly soils of a calcareous nature, to increaae their fertility, are clay and clay loam. A mixture of carbonate of lime or chalk with clay has also appeared beneficial to such soils. Chalk is particularly recommended for those kinds of gravelly soil which contiguity to springs is apt to render moist in the winter season. The application of chalk is stated as having a powerful effect, not only in counteracting the redundant moisture, but in correcting the tendency to become parched in the summer—an evil to which most gravels are in some degree liable, and which is often so injurious to the crop. The defect of vegetable and animal matters is to be supplied by means of dung from the farm, in its reduced state; and much benefit is derived from other animal matters, prepared in the form of composts, with good loamy mould, ashes, clay depositious of rivers and ponds, with other substances of a similar nature. The proper alternation of green vegetable and other crops also contributes greatly to improve the fertility of such lands.

What is the origin of clayey soils? Clay is a mixed natural earth, very widely distributed. It consists of a large proportion of alumina, united to silica, of various degrees of fineness, and frequently also a portion of carbonate of lime. The formation of clay deposits took place, according to geological theory, in consequence of the degradation and waste of certain portions of the globe, followed by a removal of the materials to localities of comparative tranquility. In the formation of clayey deposits both chemical and mechanical agencies were exerted. The mechanical agency operated in the disintegration of solid parts and the removal of the fragments, and the chemical agency operated in the uniting of alumina, silica, &c., into a compact earth. A clay soil is distinguished above every other for its tenacity. It is principally composed of particles of matter, many of them so small that when separated from each other they are imperceptible to the touch, and will easily float in water; yet these minute particles form a soil that is far more tenacious than any other species of earth. Clay always contains iron, in a higher or lower degree of oxidation; and it is probable that this metal constitutes an essential part of it.

How may clayey soils be improved? By a suitable admixture of other soils to ameliorate its texture, such as common sand, sea sand, and above all limestone gravel. Peat moss, which has for some time been dug up and exposed to the action of the atmosphere, may be used with advantage. It is likewise necessary, in the course of its cultivation, to enrich it with putrid and calcareous manures; and it may be much improved by having a considerable quantity of ashes mixed with its putrescent manures. Burning part of the clay, to be afterwards incorporated with the soil, to render it more friable, has likewise been attended, in some instances, with advantage, more especially if there is any marl in its composition.—*Leader.*

BOURNVILLE, THE "COCOA" TOWN.

(CADBURY'S MANUFACTORY, BIRMINGHAM.)

After describing the little colony of six hundred workers completely housed and kindly looked by the Messrs. Cadbury, and describing the Cocoa Plant and Pod, the roving correspondent whom we quote describes graphically the processes of preparation as follows:—

When the fruit is quite ripe it is gathered, generally, by being sliced from the boughs by a cutlass wielded by the arm of some stalwart negro; the pod being slit open and the nuts, with their creamy adjunct which holds them altogether, placed in casks, where they are pressed down by weights and left to ferment, so as to get rid of the pulp, and, as it is said, improve the flavour of the cocoa. After some little time has elapsed the nuts are then placed in wide open trays in the Boucan or drying-house, where they are exposed for some days to the sun, after which they are placed in bags and exported to England.

The first process the cocoa undergoes is to cleanse it from all impurities of dust, dirt, and such-like that accompanied it from the land of its birth. This is done by sifting it in a long cylinder fitted with variously graduated sieves. From these the nuts drop, automatically assorted to several sizes, into boxes below, cleansed from all superfluous substances, and ready for "cooking"—their second experience being to be roasted in revolving cylinders over bright coke fires. It is requisite for those who have charge of the cuisine to determine the precise period at which the nuts are sufficiently roasted, for very much depends upon this point. A miscalculation of time, of course, would tend to spoil the flavour of the nibs, not to speak of burning them and so ruin them altogether. In connection with this process, methods of treatment peculiar to the establishment are successively adopted. After being roasted, the nuts are placed in trays to cool, the fresh air speedily reduces the temperature of the cocoa beans, and they are then ready to be what is technically termed "broken down." The now crisp, roasted nuts are placed in a hopper, and afterwards raised by an elevator, and passed through a machine which gentle cracks them, disengaging the hard thin skin, which by this means can be separated from the nutritive portion of the nut—that is, the rich glossy kernel, known in the market as "cocoa nibs." The separation is effected by a winnowing machine. From the outlet of the cracking machine the husk and nut are carried to a point over the "winnower," and as the cracked nut falls into its allotted receptacle below, a powerful blast of cold air blows away the shelly parts into an upper division of the same receptacle. They are next taken to the grinding room, where a series of revolving mill-stones speedily resolve them into a thick brown fluid. From this liquid paste the oil is extracted, of which there is some 50 per cent in the nuts; and then the substance, without the admixture of a single foreign element, but pure as it came originally from the tree, with the exception of being deprived of its fat, having "done Banting," so to speak, is known as "Cadbury's Cocoa Essence," celebrated for its purity and nourishing properties all the world over, an essence which indeed has gained the little town on the banks of the Bourn its local habitation and name. The cocoa essence having been reduced to a very fine powder is then weighed and packed automatically in the well-known packages familiar to all cocoa consumers by an ingenious American machine which contrives to measure and put up some twenty thousand parcels of this theobromine —or "food of the gods," as Linnæus christened it—per diem.

The next article of Messrs. Cadbury's manufacture, and one almost as important as that of their cocoa essence, is the Mexican and other sweet chocolate for *bonbonnières* and other dainty uses too numerous to be specified. The pure cocoa is in the first place incorporated with the best white sugar in a machine called a *mélangeur* or mixer, where heavy granite rollers like millstones set on end, and a double-bladed knife acting as a screw propeller, thoroughly incorporate the substances into each other, after which it is flavoured with vanilla. The "Chocolate," as the material is now called, is then run into moulds, and cooled on stone slabs in a cellar, the temperature of which approaches more to the freezing point than any other part of the establishment I visited.

After seeing chocolate thus "put through its faces," in slang phrase, I was ushered into the cream moulding room where *bonbons* are manufactured apparently in quantities enough to fill all the *bonbonnières* of the juvenile world. The place seemed really more like a mill—that is, a flour mill—than a chocolate turn-out, for everything here—the floor, the ceiling, and all surroundings—was covered with a white efflorescent deposit, while pulverised particles of similar substance permeated the very air and every nook and cranny in the place. As for the girls working here, they were like so many pretty little milleresses, and seemed to perform their task of manufacturing those delicious chocolate creams, which some of us with a sweet tooth wot of, with a skilful expertness which constant practice in filling the tiny moulds could only teach. They manage to fill each mould with just sufficient of the cream and no more, thereby preventing waste of time, if not of materials. Hardly is this done than the "creams" solidify, and when cooled they are taken to another department and coated with chocolate, whereupon all that has to be done is to eat them!—*Public Opinion.*

CINCHONA BARK, BALSAM OF PERU, &c.

Some important facts have been assertained concerning the development of bark, which may probably throw some light upon the best mode of cultivating cinchona trees for the bark. A. Gehmacher finds that the growth of bark is influenced greatly by pressure, that the less the pressure the more numerous the cork cells become, and the greater the pressure the more they diminish. The bast fibres also increase considerably in number with diminution of pressure; when the pressure is very great very few bast fibres or none at all are formed. The bast fibres also increase in size with diminished pres-ure. *Apropos* of what has been remarked concerning the value of cinchona barks, Dr. de Vrij writes that at Amsterdam on February 29 last he observed that two lots of Ledgeriana bark containing 4·05 per cent of pure quinine were sold at 3*s.* 7*d.* per half kilogramme, whilst one lot of red bark containing 7·35 per cent of total alkaloids and only 1·18 per cent of pure quinine was sold at 3*s* 5*d.* per half kilogramme. The latter was, however, in long quills having a fine appearance. It is obvious, therefore, that price alone is no indication of alkaloidal contents. He also remarks that the presence of cinchonidine in many samples of commercial quinine is easily detected by the optical test recommended a few years ago by Professor A. C. Oudemans.

When balsam of Peru arrives at Acajutla and La Libertad, the ports on the "balsam coast" from which it is chiefly shipped, it is in a crude state, usually of a grey-green to a dirty yellow colour, and requires to be submitted to a process of purification before it is fit for exportation. Concerning this process a correspondent of Messrs. Gehe & Co. furnishes some interesting information. He states that a first clarification is effected by allowing the crude balsam to stand in a large iron vessel capable of holding six or seven hundred pounds during a week or a fortnight, by which time the heavier impurities sink to the bottom and the lighter ones float as a scum on the surface. The clear balsam, which has already attained its characteristic black-brown colour, is then drawn off through a tap fixed about four inches from the bottom of the vessel and run into a tinned iron boiler set over an open fire and boiled moderately for two or three hours. All scum is removed as it makes its appearance, and the boiling is continued as long as any continues to be formed. It can easily be understood that the physical properties of the balsam will differ according to the temperature to which it is submitted during this boiling, and it is alleged that the lower specific gravity observed in balsam of Peru during recent years is attributable to a modification it undergoes in this operation, and is quite consistent with the genuineness of a given sample.

Besides the foregoing the new quarterly report of Messrs. Gehe has several interesting notes. It is mentioned that whilst a few years since the price of quinidine (conquinine) was double that of cinchonidine, cinchonadine has lately found so much favour in the United States that its price has now become relatively higher than that of quinidine. This tendency has been favoured by the large quantities of cuprea bark that have been worked during the last few years, since in it quinine is accompanied only by quinidine and by no cinchonidine.—*Pharmaceutical Journal.*

HOW SHOULD TEA BE BREWED?

The above question to many may appear a very simple one. "Pour boiling water on to the crisp leaves in a scalded teapot, lay it aside in a warm corner for five minutes or so, and there you are!" But I beg to say, there I am not. Tea-making—or tea-brewing, or whatever else you may call it—is, in my humble opinion, a more important matter, entering into considerations entirely overlooked by the thousand-and-one tea-drinkers usually met round about.

To begin with the *water.* All agree that soft is preferable to hard water for obtaining the best infusion, whether of tea or of anything else. Good. But pure soft or hard water, not being in a general way obtainable, the happy medium naturally steps in, which, taking the country all round, is more or less the true state of affairs. The happy medium then shall constitute the water we will take.

Now for the *teapot.* What sort is the best? Here is another important matter. Those teapots which keep in the heat, must obviously be better than those that let it go. A rough black teapot is one of the best radiators of heat that could be invented. Hence black earthenware teapots should not be used. Glazed earthenware or porcelain are much better; but better still, are highly polished metal—particularly silver—teapots; for they radiate, or part with heat, much less than any other material. Herein, however, there is room for cavil, for two teapots, alike apparently in size, colour, and material, may differ widely in their tea-brewing properties.

To come to the *boiling-water.* In a general way this is simply poured upon the herb, and the teapot and contents allowed to stand in a warm place for five or ten minutes to brew. Now, as all those who profess to be well-up in tea-making, lay great stress on the proper temperature of the water; that we will next consider, as the most important question of the whole.

Water, under the ordinary pressure of the atmosphere, may be taken as boiling at 212 degrees. It is, therefore, of consequence that it should be kept up to the 212 degrees during the whole operation. But how often is it so kept? Very rarely. In a general way, the boiling water is poured from the kettle into the heated teapot, and the latter placed perhaps on the hob, perhaps on the bare table, or under a cosy. But how much has the infusion cooled during the process? A good deal. In the first place the water cools in its passage, short as it is, through the air from the kettle to the teapot; next (however well the teapot may have been heated), it is seldom kept as hot as boiling water; and, thirdly, it is often removed to a place where the temperature is still further lowered. By this method it will be seen that by the time the teapot is full, the temperature will have considerably fallen—perhaps 10, 15, or even as much as 20 degrees. To show how speedily the heat of boiling water declines, it is only necessary to remove the kettle from the fire for a few seconds and afterwards replace it, when its recovery will be by no means so sudden as might be expected. Radiation is directly at the bottom of this; for the instant the kettle is taken off the fire it parts with its heat at a double-quick rate, being facilitated in every way by its rough, black exterior.

All this may appear to many people like treating a common subject with a great amount of ceremony, but they must not forget one thing, that there are thirty millions of inhabitants in Great Britain, mostly tea-drinkers, and that fact is quite sufficient to justify a longer communication on the subject than this.

For many years it has always been a well-understood rule in the making of tea, that to obtain perfect infusion it was necessary that the water in the teapot *should absolutely reach the boiling-point,* or 212 degrees Fahrenheit. But in how many houses (particularly from the middle classes upwards) is that permitted? Perhaps not one in ten thousand.

Such being the case, there is an easy mode of getting over the difficulty. Take an ordinary metal teapot—that commonly known as block-tin will do very well—and make the tea in the ordinary way. Now place the pot on the fire (or what is much better, the gas-stove), and bring it right up to the boiling-plant; *but the* INSTANT *that is accomplished, turn off the gas,* leaving the pot on the hob or stove for a minute or two. It will now be found that the infusion is as thorough and complete as it is possible to make it.

It should be distinctly remembered that the tea must not be allowed to continue boiling. If it is, it will only advantage those who prefer it stewed—a luxury so exclusively the privilege of coffee-houses, that one might well abandon it at home if only for a change. Should a change be really wished, no better one could be devised than the following:—

AN EASY WAY OF SCENTING TEA.

One of the easiest and perhaps the best methods of giving to tea a highly-scented character—an odour as astonishing as it is simple, to those who have never tried it, and unquestionably a vast improvement—is to put into the teapot a leaf or two, according to taste of the herb erroneously called the Scented Verbena (*Aloysia citriodora*). The plant is common enough amongst nurserymen, and is readily procurable for a few pence. If not, an ordinary lemon will answer the purpose very well—equally so according to some people. Take, therefore, a little of the peel, about the size of a shilling, and put it into the teapot. Recollect that a very little of this goes a very long way. The secret is, to use only a minute portion, otherwise its origin will be readily detected; though for the matter of that, many people will prefer a decided smack of the lemon like the Russians, who hardly ever omit a generous squeeze into their glasses, from which they take the luscious beverage that Englishmen pine for but never get.—KEE POTTE.—*Practical Confectioner.*

CURE FOR BLIGHT.

TO THE EDITOR OF THE "DAILY TELEGRAPH."

SIR,—As it is one of the leading questions of the day among the agriculturists—"What remedy is there for blight in the vegetable kingdom?" and as agriculture is the most noble pursuit of man, and intelligent farmers a blessing to us, as well as being the most useful members of society, it cannot be out of place to make your numerous readers acquainted with the following remedy for blight.

To irrigate the land with liquid manures is the most scientific and proper manner to keep away blight and to nourish the plant. Liquid manures can be made in large quantities at small cost. Let the farmer procure a barrel of tar, and tar his water-tank inside, then fill it up with water, which will in a couple of days be tar-water. A hundred tons of liquid manure can thus be made with one barrel of the best stockholm tar (wood tar). The tar could also be made out of the Eucalyptus trees. The tar-water must not be made too strong, because tar has an irritating property as well as an antiseptic one. The object is to render and preserve the water in an antiseptic state, or non-putrid condition, and to influence the air in the vicinity of the plant. Charcoal and peat (which every farmer can make on his own land) put around the plants will also nourish the plant and keep away the blight. The farmer who does that will have the largest crops and least quantity of blight. He should top-dress his lands with suitable antiseptics when the plant is above ground before the blight commences. This should be particularly attended to by growers of hops, as it would contribute to prevent the fly.

Hop plantations should be freely manured with charcoal and peat, as an excess will not injure the plant, because it has no irritating properties, but is purely antiseptic, more so than any other substance in nature.

Botanists know that a root or acorn put in a glass with water will not grow unless the water is frequently changed, because the water would perish, but if a piece of charcoal were put in the water it would preserve it, and the acorn would not perish, but become a small oak. Again, the cook knows that should a joint of meat smell when put in the pot to boil if a piece of charcoal be put in the water the meat will become sweet. Again, the poulterer knows, or ought to know, that when he sends game a week's journey if he puts a piece or two of fine charcoal with it, it will preserve it sweet. The butcher knows, or ought to know, that should a joint smell if he rub fine charcoal on it it will turn it sweet. Florists and ladies who love beautiful flowers should always sprinkle charcoal on the soil, as it will create in the flowers the most delightful hues and brilliant colours. It is not only the vegetable life that is benefited by charcoal, but also the animal life, and if the farmers would give a dozen of cattle some charcoal in their food they would see that they would greatly increase in weight as compared with any dozen of cattle not supplied with charcoal. Racehorses are much benefited by the use of charcoal. A leading industry in all forests is the production of charcoal; and a few words as to the best way to make it may be useful. It may be made in mounds, caverns, or ovens. The best method adopted is that in mounds or meilers, and to this I may devote a few explanatory words, as not every one here may be conversant with the process. Simple as that process may appear, it is after all not performable without some skill, if coal of a superior quality is to be the result. The wood is closely packed around a central post in regular form, the pieces either all horizontally, or oftener the lower vertically. Only such wood should be used as is unfit for timber. It must, however, be of one sort only, or of such various sorts as require the same degree of heat for being converted into a perfect coal. It must be sound and almost air dry. A loamy sand-soil forms the best base for a mound, and this soil requires to be broken up, levelled and pressed, also dried by branchlets being burnt on the ground. The form of the mound or meiler is usually hemispherical, and support is given to this mound in the manner indicated, the outer support consisting of short logs of wood. The inner part of the cover is formed of sods of grass, branchlets, rushes, and similar substances. Over this is placed the outer portion of the cover, consisting of moist forest soil, particularly fresh humus. The united covering must permit the vapours of the glowing meiler to escape. Shelter against wind is absolutely requisite; the operation of burning coal can therefore be well performed only in still air. The ignition commences from an opening left purposely, either at the base, or, less frequently, at the summit of the structure, but either opening is closed again during the burning process. Caution is needed to prevent the expansive vapours and gases causing explosions during the glowing of the wood. To promote combustion at places where it may have been suppressed, holes are forced through the covering on the second or third day, particularly on the lee side. Over-great activity of fire is suppressed by water applied to the covering, or by adding to the thickness of the latter.

The specific gravity of charcoal stands generally in a precise proportion to the specific weight of the wood employed. Drier wood produces a heavier, moister wood a lighter coal. Slow combustion also renders the coal heavier than a more rapid burning process, because in the latter case more carbon is consumed for various volatile products formed from the wood. As a rule the quantity of coal obtained is about a quarter of the weight of wood employed. Good coal has a light metallic lustre, is firm, not friable, causing a clear sound when thrown on the ground. It must burn without flame or smoke.

The heating power of coal as compared to wood is ascertained to be as one hundred to fifty-five or sixty, so an equal volume of wood produces less heating effect than the same space of coal.

I thank you, sir, for giving space for the above, which must be of interest to many of your readers. I have the innumerable proofs of the good results following the use of the above-mentioned remedies for blight on the vegetable kingdom.—Yours, etc., HANS P. RASMUSSEN, B.C., Botanist, Launceston.

WHY DO SOILS DIFFER?

[GARDENER'S AND FARMER'S REASON WHY.]

The differences of soils are, to a very great extent, explained by the geological characteristics of the localities in which they exist. Any one who has observed the appearance of large rocky masses, the clefts and crevices they present, the bare surface of their smoother and harder parts; the growth of mosses and smaller plants on the more softened portions; the accumulations of gravel, smaller fragments of minerals, and fine mud, with their luxuriant vegetation at the foot of these rocks, and in the valleys of mountanious districts, must be aware of the importance of these ever continuing operations in nature. Thus, soils originate in the disintegration and decomposition of solid rocks in their immediate neighborhood, especially of those which occupy the eminences. But as rocks differ much in their composition, the soils which are formed on their degradation must necessarily present, in many cases, great differences equally with the rocks themselves. But, in other instances, the nature of the soils in a given locality partakes nothing of the character of the rocks in the immediate neighborhood, nor even of those upon which they rest. The first class of soils to which we have referred are those which may be said to arise from "mechanical causes." the others, the origin of which is more difficult of explanation, arise from "chemical causes," and in the production of others both these causes are combined. Among the mechanical causes which operate in the disintegration of rocks may be mentioned the action of winds, rains, streams of water, and the tendency of all bodies when moved in elevated situations to gravitate towards the centre of the earth.

Among the chemical causes are the action of the gases of the atmosphere upon mineral surfaces; the action of the sun's rays; and of the fermentive processes wherever accumulations of organic substances take place. To these causes may be added the action of living beings upon all classes of substances. All rocks, and indeed almost all mineral substances, have a greater or less tendeocy to combine with the oxygen of the atmosphere, especially when under favourable circumstances of heat and moisture, and probably also of electricity and light. Carbonic acid and water, also, are absorbed by rocks, in considerable quantity; and the effect of these combinations, whether chemical or mechanical, is to loosen the cohesion between the particles of stone, and induce a tendency to disintegration. This separation of the parts is very much accelerated by these sudden expansions and contractions which are occasioned by changes of temperature, and especially during frost, when the imbibed moisture is converted into ice. This slow and silent work of waste is unremittingly going on wherever rocks are exposed to the weather. No species of stone is exempt; and even granite, which in general is so little subject to change as to be proverbially a symbol of endurance, aud is selected for our bridges and other great works of architecture, under peculiar circumstances of constitution and exposure, is remarkably disposed to this process of crumbling. The granite of some parts of Finland is so liable to decomposition that masses of it may be cut down and shaped in the same manner as a hay rick. To devise an arraugement of soils at once comprehensive and distinct is no easy task. The distinctions ought to be simple and obvious, without regard to minute differences, which may be of no material importance. For practical purposes soils may be classed under the following general heads:—Sand, gravel, clay, chalk, peat, alluvial, marsh and loam, or that species of artificial soil into which the others are generally brought by the effects of manure, and of earthy applications in the course of cultivation.

What is the origin of sandy soils? Most sands, whether on the surface of the ground or in strata at a certain depth, whether forming the beds of rivers or the shores of the sea, are the fragments of disintegrated rocks, and are red, white, grey or black, according to the rocks from which they were derived. The grains of sand are, for the most part, composed of silica, and soils containing it are called silicious. Sand is probably formed for the most part of quartz, as it does not differ materially from that mineral in its chemical composition. Immense floods of water, the action of the atmosphere, and probably also that of fire and other agents, have reduced quartz to fragments, which have subsequently acquired a rounded form by rubbing against each other, in consequence of the motion communicated to them by air and water. River sand is deposited by the waters of springs and rivers. Pearl sand, having lain imprisoned in the earth, is larger than ordinary sand; it is frequently found below the surface, and is sometimes washed up, and deposited by springs of water. Moving sand—which is frequently heaped up in valleys by currents of air and water—is generally mixed with various heterogeneous matters, with which it becomes associated by shifting; it generally carries with it alumina, lime, &c.

How may sandy soils be improved? By a mixture of clay, marl, or warp (the sediment of navigable rivers,) sea ooze, sea shells, peat or vegetable earth. It frequently happens, that under the sand itself, or in its immediate neighborhood, the materials may be found which are requisite for its improvement. Even light sandy soils may be rendered retentive of moisture and manure, when mixed with the subsoil, or ameliorated by admixture with other soils. In the management of sandy soils three rules are to be observed:—1. Never to pick off any small stones that may be found in them, as they answer many valuable purposes; they shelter the young plant in bad weather; they preserve moisture, and prevent the crops ftom being burnt up by scorching heats; they hinder the evaporation of the enriching juices; and, by these means, greatly assist the progress of vegetation. 2. Frequently to renovate the streogth of such soils, by laying them down with grass seeds, and pasturing them for a few years, as they are apt to be exhausted by ploughing if corn crops are too frequently repeated. 3. When farm yard dung is applied to this description of soil, always to give it in a state of compost, with a view of adding to the tenacity of the soil, and of preventing the manure, from being dissipated in a dry season, or washed down by rain. Example of improvement:—The north and west of the country of Norfolk forms an immense sandy plain of 750,000 acres, where there is no obstacle to large property aod large farming, and where everything favors horse tillage, cultivation of roots, the use of machines—in one word, the four course rotation. By means of this system, steadily pursued for sixty years, these inferior lands, producing scarcely 5s. per acre in 1780, now return on an average 25s. per acre, or five times their former net production, and the gross production has risen in at least an equal proportion. A large part of the credit due to this wonderful transformation beloogs to an extensive proprietor in the county, Mr. Coke, who, in acknowledgment of his services to agriculture, was created Earl of Leicester. He died a few years ago, at an age not far short of 100. Mr. Coke had a large property in the west of the county, called Holkham, containing about 30,000 acres. This immense estate, which is now worth at least £1,200,000, was worth at most £300,000 ln 1776, when Mr. Coke inherited it. It was then in the occupation of a great number of small farmers, who paid their rents with difficulty, although these were very low; and ultimately a great many of them abandoned their farms altogether, because they could not make a living out of them. It was then that Mr. Coke decided upon farming a portion of these sandy wastes himself; the rest he put into very large farms, and, by offering leases of twenty-one years, held out an inducement to farmers of inteligence and capital to take them. The farm which Lord Leicester personally directed lies in the park belonging to the mansion. Its extent is 1,800 acres, 500 of which are permanent pasture; the rest is arable, laid out exactly for the four course rotation. The farm maintains 250 large cattle, 2,500 sheep, and 150 pigs.—*Leader.*

NOTES ON SOME MALAY TIMBER TREES.

BY JAMES COLLINS.

The subject of a regular and large supply of timber is a most important one, and a few notes on the question as regards the Straits Settlements will, it is hoped, be found of use. These will be but brief and preliminary, as the materials at command are too scanty at present to deal with the question otherwise. Johore, although an independent State, under the rule of his Highness the Maharajah of Johore, K.C.S.I., &c., is also included in the present note.

The extent of forests has been variously stated, but the following figures may be taken as an approximation:—

Singapore	20 to 30 square miles.
Malacca	160 to 170 ,,
Penang and Province Wellesley..	110 to 120 ,,
Johore and adjacent Islands ..	10,000 ,,

To this must be added Selangor, Perak, and the other native States of the Malayan Peninsula, some of which are more or less under British Government control.

The forests of the Straits Settlements, properly so called, are the sole property of the Government, as is the case also with those under the Maharajah's rule. They are, however, in all cases rapidly decreasing, and no means are taken to stop this. The system of working them is as follows:—A person wanting a tract of land applies to the land office, and pays tenths on the value of the timber cut. Forest rangers, and occasionally the police, have to see that none but those having this license or permit cut timber.

This land may be required for the timber on it, or for

EXPERIMENTS ON THE STIFFNESS OF SOME OF THE PRINCIPAL WOODS OF SINGAPORE, MALACCA, AND JOHORE.*

Name of Wood. I.	Average weight per cubic foot. II.	Deflection in inches. III.	Weight producing deflection in lb. IV.	Breaking weight in lb. V.	REMARKS. VI.
Krangee...	77	5/8	980	1,339	Very hard, close-grained, well adapted for beams of every description. White ants or other insects do not touch this timber. It is well adapted for piles for bridges in fresh or salt water; it is also used for junks' masts; stands well when sawn, ranks with Tampenis for durability. Fracture long, fibres tough, colour dark red.
Panaga	72	5-10th	688	1,310	Is a bright red wood, very hard and durable, well adapted for roofing timbers, joists, and timber work of bridges; is very cross-grained and difficult to work; can be obtained in any quantity to 9″ square. Fracture short.
Tumboosoo	67	5-10th	306	548	Is a capital wood for piles, or for any wood-work which is exposed to the action of fresh or salt water; is not attacked by worms or white ants. Fracture short.
Billian Wangy... ...	72	5-10th	473	1,038	Is a very hard, durable, and heavy wood, close-grained, fibre long, is not liable to be attacked by worms or white ants; beams of 50 ft. long and 18 in. square can be obtained. Very suitable for roofing timber, girders, joists, and timber bridges.
Billian Chingy... ...	60	5-10th	408	913	A hard, close-grained, fine-fibred wood, but very much inferior to Billian Wangy, of a brownish grey colour; readily attacked by insects and dry rot; is used for flooring joists.
Marbow, Murboo, or Marraboo	61	5-10th to 5/8	399 to 578	894 to 987	Is a durable wood, principally used for furniture, is readily worked, and takes polish well; it is also used for flooring beams, timber bridges, carriage bodies, and framing of vessels. Trees 4 ft. in diameter are sometimes obtained. It is not readily attacked by white ants, but is by worms. The colour is almost like English oak.
Johore Teak, or Ballow	73	5/8	737	1,210	Well adapted for permanent sleepers, beams, piles, ship-building, engineering, and general purposes where strength and durability are required. Piles which have been in the ground for 100 years have been found in a good state of preservation. It is one of the few woods which will really stand the climate of India. Colour dull grey.
Johore Cedar	40½	5/8	410	616	Well adapted for house-building purposes as in the manufacture of doors, windows, and flooring planks. Fracture short, timber open-grained, and is not liable to be worm-eaten.
Kruen	50	5/8	472	625⅓	Close-grained, tough fibres, and resembling yellow pine. Used for native boats, planks, &c. Contains a kind of dammar-like oleo-resin.
Darroo	61	7-10th	840	1,300	Is much used for beams of houses and door frames; is durable, if kept either wet or dry, but rots soon if exposed to sun and rain; colour white, close-grained, fracture long; has an agreeable smell.
Tampénis	67	7-10th +	802	1,599 +	Very hard, close-grained, red-coloured, long-fibred, and tough wood. Well adapted for beams of every description; white ants and other insects do not touch it. Used largely for bridge piles in fresh or salt water; considered one of the most lasting timbers; it warps if cut in planks.
Kulim, or Johore Iron-wood	73	5/8	766	1,141	Somewhat similar to Ballow (*vide ante*). Used for planking cargo boats; fracture short; makes superior beams and telegraph posts, as it lasts well in the ground.
Johore Rosewood, or Kayu Merah (two samples)	38	5/8	583	952	Resembles rosewood in appearance, and used largely in cabinet work and household furniture.
Samarau	42	5/8	326	532	Well adapted for doors, windows, moulding, and other house-building purposes; is close and even grained, dullred colour, short fracture, but liable to attacks of white ants.
Jolotong	29	5/8	280	732	Well adapted for patterns and mouldings, excellent for carving purposes, grain very close, scarcely any knots, colour whitish yellow, fracture short, but the wood is not very durable.
Seriah	47	5/8	438	737⅓	Of a dull red colour, close-grained, and largely used in house-building, for boxes, boards, &c.

* From the Tables of Dr. Maingay, Captain Mayne, R. E., Mr. W. D. Baylis, of the Public Works Department, Straits Settlements, and Mr. J. Meldrum, Manager of the Johore Steam Saw Mills. The billets of wood tried were 3′ × 1½″ × 1½″. The average three billets of each kind is given.

clearing for the cultivation of various products, and the forest supply of timber suffers most materially if the occupation of the land is not permanent but temporary. Thus a tract of land having been secured, the primeval forest is cut or burned down, and the timber left to rot. Between the fallen trunks, gambier, pepper, rice, tapioca or other products are raised, and after a few crops have been taken off, the ground becomes exhausted. To procure and clear a fresh spot is often cheaper than manuring the old soil, so the previous plantation is abandoned to white ants, secondary jungle—as a rule of lalang grass—low scrub, with here and there small and useless trees. This lalang grass (*Andropogan caricosus*), when once it gets possession of the ground, stifles everything else, and its long fibrous and tough roots resist all native efforts to eradicate it; even a prairie plough would possibly reclaim the land at too great a cost.* The pretty little sensitive plant (*Mimosa*) soon carpets the ground with its flaming yellow flowers, and it is most difficult to eradicate.

Singapore hardly cuts any timber at all for her own use, being chiefly supplied from Rio and the adjacent islands, and also from Johore. In Malacca a great quantity can be cut, but from want of roads or streams, it is very difficult to get timber from a greater distance than fifteen to twenty miles from the town. Penang and Province Wellesley cannot cut much timber, unless the risk of climatic disturbance be run. The Straits Settlements exports no timber to speak of; what little Tampinis and other hard woods which have been shipped occasionally to Ceylon and Mauritius, being chiefly from other islands.

With the territory of Johore, the case is different. Some years ago, H.H. the Maharajah erected extensive steam saw mills, and these mills, under the enlightened and able management of Mr. James Meldrum, have placed in the markets a large quantity of fine timber.

The following figures have been supplied me by Mr. Meldrum. Exports of timber from Johore, 1864-1874:—

	Loads.		Value.
To British India	15,000	...	$115,000
„ China	7,000	...	84,000
„ Mauritius	3,000	...	36,000
„ Java	2,700	...	27,000

Taking in "sundry places," about 40,000 loads of hard wood has been exported, principally in the form of logs or railway sleepers; the trade in the latter has fallen off, through the more general employment of iron cradles. About 60,000 loads of soft woods, in the form of logs, planks, boards, &c., have been exported. Of these soft woods, 25,000 loads were taken by Singapore, at a value of $270,000.

Mr. Meldrum states, as the result of about twenty-years' experience, that the Johore forests are diminishing rapidly, that the sea-shores, islands, and other easily attainable localities are cleared, and that a good supply cannot be hoped for, till the rivers are made more navigable, and good roads pushed into the interior.

As will be seen, no steps have been taken as to conservancy or cultivation, and this calls for immediate attention. As to how this is to be managed, need not be entered on here, but in parenthesis, we may state that following in the lines of the Indian Forest Conservancy, with a few modifications, would amply meet the case.

As to the climatic changes brought about by the clearance of forests in this part of the world, very little can be said. The late Dr. Randell, Principal Medical Officer, S.S., in his Annual Meteorological Abstract for 1873, has the following:—

"The only causes that appears to me to exist, or have existed, to which this great decrease of rainfall may be attributed, is the extensive clearing of forest on the mainland of Johore, contiguous to this island (Singapore), which has been effected principally during the period under notice; and I would suggest that the conservancy of portions of forests may be taken into the consideration of Government."

Certainly, many old inhabitants have informed me, that the heat is greater and the rainfall less in the Straits Settlements than it used to be. One thing, however, has done largely to mitigate and render less apparent the great destruction fo forests, and that is the enormous extent to which the cocoa-nut palm and other fruit trees are cultivated.—*Journal of the Society of Arts.*

* The lalang would, I believe, prove one of the best sand-binding plants. When coming through the Suez Canal, I could not help thinking that if this were planted along the banks, much dredging would be saved, and render the passage through much more endurable.

TO DESTROY SLUGS.—Take one ounce corrosive sublimate and dissolve it, in a close vessel, in a quart of boiling water. When thoroughly dissolved, add to it six gallons of cold water, and with a rose watering-pot apply it to the places infested. It will have still more effect if every ounce of sublimate is made into only four gallons of mixture and the ground gone over the day after with a second watering of pure water, which will carry the destructive power deeper into the ground. This plan not only destroys the perfect slug, but the eggs, larvæ and pupa of everything which it reaches.—*Australasian.*

KEROSENE EMULSION.—The following is Dr. Riley's formula, which has proved useful in practice:—Kerosene, 2 gallons=67 per cent; common soap or whale oil soap, ½ lb.=33 per cent; water 1 gallon. Dissolve the soap in boiling water, and add, while still boiling, the kerosene; churn or stir the mixture very thoroughly for five or ten minutes. The emulsion, when properly made, forms a thick cream, which adheres without oiliness to the surface of glass. When required for use, one part of the emulsion should be diluted with nine parts of water. The above formula gives 3 gallons of emulsion, and makes, when diluted, 30 gallons of wash.—*Leader.*

THE OLIVE BOOM IN CALIFORNIA.—For the last few weeks no little competition has been going on between large buyers of cuttings, and several local proprietors who have had olive trees available have been besieged by the agents or principals of future olive orchards. Load after load of the beautiful green branches have passed through town, some to the wharf to be shipped away, others to convenient places to be rooted and thence transported to neighbouring places. The Santa Ynez, judging by the olive branches intended for that place, will be a great producing country for fruit and oil in years to come, and the elaborate preparations being made at Sunoi, Alameda county, and the thousands of cuttings being shipped there would indicate that much may be expected of that place when time brings fruition. The main source of supply of the cuttings is several old places about town and near here. The prices range from eight to twelve dollars per thousand, with a lively demand.—*Santa Barbara Independent.*

CHARCOAL AS FOOD.—Whatever increases the power of laying on fat or promoting the rapid and healthy production of flesh must be food or an equivalent thereto. This pure charcoal does most effectually, as was recently proved in the East by taking the live weights of two lots of sheep and simply separating them by an ordinary net, the artificial food, corn and cake, being carefully weighed out to each lot alike daily, one pint of charcoal being added to one lot only. When reweighed, prior to selling to the butcher, the increase in weight was in favor of charcoal by 16½ per cent. Sanitation causes easy and rapid digestion, and assimilation only can account for these results, which charcoal alone can accomplish. The charcoal should be given mixed with food, except in urgent cases, when it may be mixed in water or thin gruel and given as a drench. The dose is one pint to every twenty-five head of sheep or lambs; one quarter pint per head for full grown cattle, horses or pigs; half the quantity for young cattle, and two teaspoonsful to one dessert spoonful for young calves, daily, when suffering from disease or in ill-condition. To keep in good health and fortify against disease the dose should be given two or three times a week, according to the class of food they are having and the state of the atmosphere. The best plan is to wet a quantity of bran, pollard or malt combings; mix the charcoal with it and then with the food you give them. For rapid and healthy fattening of cattle it should be used daily amongst their food. Charcoal for internal and medicinal purposes must be pure vegetable charcoal, free from all irritating and injurious foreign matter. Charcoal when coming into the user's possession must be perfectly dry and free from any ill smelling surroundings, such as the vapors of a stable, artificial manures, &c., or it will absorb them, and thus become septic and of no medicinal value. It is better kept in a closed bin or tin canister with a closely fitting cover.—*San Francisco Weekly Chronicle.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, May 8th, 1884.)

IMPORTED FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White ...	Slightly softish to good hard bright ...	£7 a £8 10s
Yellow ...	Do. drossy & dark ditto...	£5 10s a £6
CINCHONA BARK—		
Crown	Medium to fine Quill ...	2s a 3s 6d
	Spoke shavings	6d a 3s 6d
	Branch	3d a 8d
,, Red	Medium to good Quill ...	6d a 3s 6d
	Spoke shavings	5d a 2s 8d
	Branch	3d a 6d
,, Twig	... ...	2d a 3d
