The question therefore arises, what is the true Ledger Cinchona? Dr. Trimen says that the seed from which his plant was raised came from the late Mr. McIvor, and that there can be no doubt it was obtained from trees which originated from Mr. Ledger's seed. Mr. Howard states that his figures were drawn from trees grown in Java from Ledger's seed. His description of *Ledgeriana* is not so full as Dr. Trimen's, and the points which Dr. Trimen mentions as characteristic of the tree do not appear in Mr. Howard's statements. The features mentioned by Dr. Trimen as characteristic are as follows:—Leaves always having the broadest part at or about the middle, flowers drooping or divaricate, flower-buds not at all or very slightly widened at the end and never abruptly enlarged there, corolla somewhat inflated in the middle. The unexpanded leaves and the buds and young soft shoots have a bronzed or olive-orange tint, by which in a field of Calisaya, the plants of *Ledgeriana* may often be picked out at first sight. We have here, therefore, definite characters by which two excellent botanists as well as the planters in Ceylon distinguish a distinct form or variety or species, whichever it may be, for it can only be proved to be a distinct species by it coming true from seed. Dr. Trimen admits (*Journ. Bot.*, 1881, p. 322) that we have at present little direct evidence to show that the plant does come true from seed. He also remarks that the progeny which comes from any sowing of *C. Calisaya* seed are certainly less like one another than some are like *C. Ledgeriana*; moreover, seed from the latter has not hitherto been found to come very true, even the progeny of the original seed from Bolivia showing a good deal of variation. The theory that this is due in some measure to "cross-fertilization" might explain the undoubted improvement in the trueness of the seed from a tree grown in proximity to other species, after isolation. This has been conspicuously shown in the case of *C. Ledgeriana* in Sikkim, the seedlings from which, since Mr. Gammie uprooted nearly all the neighbouring trees, now come remarkably true, whereas before that was done the sporting was so great that Dr. King would not propagate by seed at all. The results have been even more marked in Java.

According to statements now forwarded to us by Mr. T. N. Christie, there can be little doubt that the plant figured by Dr. Trimen is recognized in Ceylon by the planters, as well as by Mr. Moens, as the "true *Ledgeriana*." Some flowers and leaves marked A and B received from Mr. T. N. Christie correspond closely with Dr. Trimen's figures in the *Journal of Botany*. The flowers are small and drooping and the buds not swollen abruptly below the apices, these being the features pointed out by Dr. Trimen as most characteristic of this plant.

The samples of bark corresponding to these specimens give the following results on analysis:—

Quinine	7·50	8·32
Quinidine	—	—
Cinchonidine	·19	1·12
Cinchonine	·18	·20
Amorphous	·60	·60
	8·47	10·24

The amount of cinchonidine in one of these samples is certainly not in favour of its being the produce of a true *Ledgeriana* plant. Mr. Christie says, "The plant which Dr. Trimen figured was one "of those raised from McIvor's "seed by me, and planted on Mahanilu by Mr. Agar, and "its descent from Ledger's original seed is undoubted. "Other plants exactly similar in blossom, raised from the "same pinch of seed, have given over 12, 13, and 14 per "cent sulphate of quinine, and the very trees which Mr. "Howard called in to help him, the Yarrow Ledgers, have "the same blossom and came out of the same nursery bed "as the Ledger figured by Dr. Trimen. Before the least "doubt had been thrown upon his figured type, Dr. Trimen "selected a tree here for specimens, as being botanically a "typical Ledger, and his selection was well borne out when "on the following day the analysis of that very tree arrived "from England, and showed 11·29 per cent quinine sulphate." The specimens sent by Dr. Trimen to the Museum of the Pharmaceutical Society are considered by some not to be typical *Ledgeriana*, but more probably hybrids of *officinalis* and *Calisaya*. Concerning the satiny gloss and hairy margin of the leaves, which Mr. Howard appears to have put forward as characteristic of the true *Ledgeriana*, Mr. T. N. Christie remarks, "The veriest tyro in cinchona cultivation "could have told Mr. Howard that these characteristics "are common to all *Ledgerianas* and all the *Calisayas* when "young, and that there is not a sign of either in the mature "foliage." It is difficult to understand this remark, for Mr. Howard must certainly have cultivated seed of Calisaya and would scarcely have pointed out the satiny gloss and hairy margin of the leaves as characteristic of the *Ledgeriana* if it occurred in other Calisayas, and it certainly was not present in all the Bolivian Calisayas exhibited by Mr. Howard and Mr. T. Christy at the meeting of the Linnean Society. Mr. Christie also points out that while Mr. Howard is said to claim "on Mr. Moens' own authority" that his plants alone are authentic, he repudiates Mr. Moens' identification of Dr. Trimen's plant.

Mr. T. N. Christie claims that he, "having lived for "years besides mature *Ledgeriana* which have given the "highest analyses we have yet heard of, may presume to think "that he knows a *Ledgeriana* when he sees it, and that "Dr. Trimen, who has seen the Ceylon and Indian plant-"ations and many mature analysed *Ledgerianas*, knows "*C. Ledgeriana*, and that the latter has figured it; and that "Mr. Howard, with the knowledge of hot-house plants and "dried specimens, does not know and has not figured *C.* "*Ledgeriana*." In support of this claim he refers to Kew Gardens 'Report,' 1880, p. 12, where it is stated that some plants grown from seed were forwarded by Mr. Howard to Kew, and through Kew to Mr. J. A. Campbell, of Lindula, Ceylon; and three others from the same authentic strain, to Jamaica. Concerning those received by Mr. Campbell, that gentleman writes to Mr. Christie, "No one who knows a "*Ledgeriana* tree of pure type would think of calling the "trees I have (raised from cuttings received from Mr. "Howard) *Ledgerianas*. Two of them are very shrubby in "their growth and with hard shiny leaves. The other is a "Calisaya of the broad-leaved variety very much like what "I believe is called in Java, *Calisaya Anglica*. I have also "another plant that Mr. Howard gave me, which I under-"stood him to say had been raised from *Ledgeriana* seed, "received from Java. This is the best, so far as appearance "goes, but I should not call it a *Ledgeriana*."

It is not surprising that Mr. Howard should refer Dr. Trimen's *C. Ledgeriana* to *C. micrantha*, since in the 'Quinology of the East Indian Plantations,' p. 84, Mr. Howard remarks:—"By placing my plate of the B-form of *Ledgeriana* "beside that of *C. micrantha* in 'Nueva Quinologia,' the "reader will be struck with a certain kind of analogy and "general resemblance." In a previous note on p. 5, he says: —"It is specially remarked by G. M. van Gorkom that "about three thousand plants raised from seed from British "India present quite a peculiar character, which partly be-"longs to the *Calisaya micrantha*," and adds, "I assisted at "the purchase of the bag of seeds (collected by Lechler*) "for British India, to which no doubt this refers, and having "some growing freely side by side with the *C. micrantha*, "brought by Pritchett from Huanuco, can quite confirm "their resemblance. The plants are, I think, those of the "*C. micrantha* (Bolivian variety) Weddell." According to these remarks it would appear that Mr. Howard considered the plants raised from Ledger's seed to strongly resemble *C. micrantha*, and his reference of Dr. Trimen's *Ledgeriana* to *C. micrantha* is therefore easily understood.

Mr. Howard's plates of *C. Ledgeriana* do not seem to belong to one distinct form, such as is recognized by Dr. Trimen and the Ceylon planters, since one variety has the flowers light-red, and another has scrobicules much more numerous than in the two others, and Dr. Weddell himself seems to have thought this, as indicated by his remarks ('East Indian Quinology,' p. 85):—"I think you are quite "right in considering your two Java plants as constituting "a distinct variety of *C. Calisaya*, but whether one of the "two forms you have had pictured is worthy or not of being "ranked as a sub-variety of the other could hardly be "affirmed without comparing a considerable number of "specimens."

Mr. Howard doubtless has a right to claim, not only on account of his special acquaintance with the subject, but also as a botanist, that a cinchona, not corresponding with his published description and plates, should not be called by the name he has adopted. In this case, if Dr. Trimen's plant be distinct from what Mr. Howard has described, then the name of *C. Ledgeriana*, Moens, for the tree distinguished by the Ceylon planters as Ledger Cinchona is, to say the least, confusing, and the awkwardness would be best avoided by the adoption of a different name for Dr. Trimen's plant. Mr. Howard seems to have recognized the likeness of his own *Ledgerianas* to *C. micrantha* when they first came into his hands, and now attributes the same likeness to Dr. Trimen's plant. Moreover, it is understood that Mr. Howard, in selecting his types from a number of specimens, was partly guided by their large yield of quinine. The analysis of Dr. Trimen's plant showed it to be equally rich in quinine, and the specimens now sent by Dr. Trimen show the same result. In any case, the question whether Dr. Trimen's *Ledgeriana* and Mr. Howard's *C. Calisaya*, var. *Ledgeriana*, are indentical or not obviously requires further elucidation.

We must, however, admit that we do not understand the botanical part of the subject sufficiently to offer any opinion upon the point at issue or even to say with certainty what that point is. But at the same time the subject is of such importance, and has gained such an amount of public notice, that we think it desirable to place before our readers, so far as we can, a statement of what has been said upon it, without, however, accepting any responsibility for supporting either view.—*Pharmaceutical Journal.*

* Corrected to "Ledger" on p. 84.

COFFEE SENT TO EUROPE IN PARCHMENT SKIN.

TO THE EDITOR OF THE "INDIAN MERCURY."

In your number of 27th of April 1883, Mr. P. Zeper of the Preanger in Java, (see page 121, Vol. III, *T. A.*) has devoted a word to my articled ublished in No. 61 of the *Indian Mercury*, about the results of coffee-peeling in Netherland. Nay, the esteemed writer declares emphatically that he feels obliged to refute my arguments.

The civil manner in which Mr. Z. gives his views cannot but meet with acknowledgement from me, as I am also thankful for his practical hints and experiences.

However, for the present, I may safely refrain from offering a reply to Mr. Z.'s observations, for those who will take the trouble to compare our two papers, it will become obvious that Mr. Z. has not apprehended the drift of my writing, and has even made me pronounce judgments or assertions, which I myself now learn for the first time.

To one dictum, Mr. Z. must allow me to demur. It is where he says: "It speaks of itself that though a European government-official be willing to give himself ever so much trouble to master the details of laying out, planting, preparing, etc, he can seldom succeed under such circumstances."

All this indeed is not very flattering for the officials of our government; but if Mr. Z. has a right to suppose that the official reports and knowledge do not *always* deserve unconditional confidence, we on our side, warn against prejudice and partiality, nor desire to deem all so-called private reports and knowledge infallible. Only, be it observed, the diligent and sensible official, who really wishes to master the subject, will not confine himself to informations gained from the native chiefs. He looks with his own eyes and endeavours besides, wherever he can, to be enlightened by the practical experience and knowledge of European industrials.

So at least I understood my duty as an official, and Mr. Z. might have ascertained this by reference to our mutual —alas! too soon departed friend, his old neighbour, the quondam manager of Parakansalak. Could it be my intention to retort to a reproach with an accusation, I could adduce many instances of private enterprisers in Java not being always ready and willing to help embarrassed officials to see their way.

But now the subject,

In 1882-83 there were transported to Netherland from Java 181,005 bags of coffee in the parchment against 150,000 in 1881-82, which would again confirm what I have before endeavoured to prove, that the results of peeling in this country do not in general, or as yet, deter them in Java from sending coffee in the parchment.

If we see this still budding industry flourish at home, we have above all an eye and heart for a plentiful and profitable produce and a cordial co-operation of all concerned, whether producers, traders, or industrials. Mr. Zeper may believe me, for I myself have laboured as a private individual for eleven years in Java, and that quite of my own free will because I conceived an abhorrence of all control—that I am perfectly aware, from experience, as well as my body can be, of what great difficulties and cares free industry has constanly to struggle with in India. Besides, I numbered in Java too many good and intimate friends among practical men, not to have learnt from them also that most of them, with all their endless cares and disappointments, are really not to be envied by a single official.

I have ever deplored, and still deplore, that Government does not evince through its officials, more sympathy for the fostering of private industry, for it is this that must make India flourish, that can consolidate her position for the future, and so render the Mother-Country a gainer. Free industry demands no protection, but appreciation, and this loses its eloquence in vexatious intermeddling, in indifference to the honest producer, and in a sometimes unexampled laxity in settling business.

In addition to what I have already given, I must offer one more piece of advice to the coffee-planters who send their products to Europe for peeling. The peelers ought to be timely forewarned of what must be their endeavours. In that case they will be found better prepared. And now one thing more in conclusion. It is very true that the peelers are paid for their work, and not for the quality of the product delivered; but Mr. Zeper is too good a man of business in every respect, not to be aware that the peelers have their own interest to consult, in delivering a good article.—VAN GORKOM.

THEORY OF MANURES.

BY DR. DANIEL MARCH.

If water is chemically combined with any of the soil constituents, it cannot be absorbed by plants until its affinity for the retaining body is overcome. Mechanically likewise, water may be retained, and this sometimes so strongly that plant roots cannot obtain a sufficient supply to produce a healthful growth. Also if the water is in too great a quantity or not sfficiently united to the earth, its superabundance will injure the fibres of the roots, hence the conditional presence of water is an important point in considering the nutriment of plants, and does often determine the ascendency of health or disease. In other words, water may exist in a soil in two states, viz., united by chemical attraction, or simply held by the power of cohesion. Hence if water is chemically combined with a constituent of a soil or manure, it cannot be absorbed by a plant until decomposition of the retaining body is effected; but what is retained by contact (mechanically) is always in a condition to be absorbed by the rootlet fibres, and in the mechanical analysis of the soils this is termed the power of retention. In the analysis of soils, the mechanical analysis is of as much importance as the chemical; as the drainage power, power of retention and absorbing power are set forth and according to the prevalence of one of these over the other the value of the soil is increased or decreased in its relation to the withstanding of droughts and likewise the over retaining of stagnant water to the injury of the roots. Not many of the mineral or earthly constituents of the soil contain chemically combined water, yet the saline compounds existing in soils and manures may be united to water both by chemical and mechanical affinity. With very rare exceptions does such influence the relation of soil and water to each other, the quantity of saline compounds being so very minute; but when such rise above a certain percentage, the soil through excess of saline compounds actually becomes barren; barrenness may also arise through the exhaustion of plant food below a certain percentage, and this can only be prevented by the use of manures. This brings us to consider three important points—

1st. That plants derive all their mineral constituents and most if not all the nitrogen from the soil.

2nd. That the constant removal by crops of such minerals results is more or less exhaustion of the soil.

3rd. The immediately available plant food in good soil is generally less than 0·5 per cent of the whole.

We may therefore conclude that if in any soil, the plant-food is lowered by croping below the half per cent, exhaustion must follow, and the aim of manuring is to restore to the soil the plant food which has been taken off by the crops, or by the animals grazing on it, or it may be only requisite to increase the amount of nutriment naturally in poor soils. It is often a matter of wonder to many how the soils originally obtained their constituents, but before the studies of geology, mineralogy and petrology, such amazement must give place to admiration of providence in providing such means for soil formation. The hard and apparently unimpregnable granite was first of all attacked by a microscopic like lichen or moss, this in its turn died, and was washed off by the rains into creeks and crevices, and became soil for another crop, again and again this growth repeated for ages, was deep enough for plants of a larger growth. The felspar of the granite, and also its mica gave us our potash and soda, and these combining with the chloric and sulphuric vapours evolved from the then active volcanoes everywhere on the face of the earth gave us our potassium and sodium sulphates and chlorides. In the same manner originated our lime and magnesia salts from such decompositions and recombinations, each trifling layer upon layer acquiring fresh life giving properties, the water in all probability dissolving large quantities by percolation, and this becoming evaporated gave us our salt beds. Hence the frequent occurrence of calcium sulphate (gypsum) with large and small deposits of sodium chloride (common salt.) In water weakly impregnated with saline compounds aquatic plants would grow and absorb the potash, more especially upon the edge of such aqueous basins and on the drying up or receding of these waters, would also decompose into soil. And as nature extracted such from the hardest of rocks in these unknown days, so do we extract them from the soil by vegetable growth, but at a much more rapid rate than can be replaced by nature, hence the need of replacing by manure is shown. Live stock does not manure land—such an idea is a vulgar fallacy—they do not put more back than they take away; it is upon this point that successful agriculture must hang—or in other words upon such foundation must it be laid. You cannot continue taking off crops unless you put more mineral matter back into the soil than what your crops have removed. But plants require more than pure mineral food, or mineral substance *per se* the nitrogen must also be supplied. The amount of this substance must to a certain extent be regulated by the nature of the crop, it may be presented to the roots as nitrates of potash, soda or ammonia or as sulphate or chloride of ammonium, or it may be in the shape of animal or vegetable matter containing nitrogen so as to decompose in the soil.—*Sugar Planter.*

MR. MOENS AND THE PRODUCTION OF CINCHONA BARK.

Mr. Von Winning, of Bandong, Java, brother-in-law of Mr. Moens, writes to us about a mistake in a note on page 69 of No. 1, vol. III., of the *Tropical Agriculturist*, in which Mr. Moens is said to have stated in his great work that in 12 or 15 years Java would supply the world with cinchona bark. What Mr. Moens really wrote, it appears, was that in 12 or 15 years, *India* would so increase its production that exports from the forests of South America should be impossible. The error, however, was not ours, but was made by the translator of the items from Java papers in the *Straits Times*, as will be seen from the extract on page 46 of the same number of the *T. A.*

FROM NEW ZEALAND THROUGH THE SOUTH SEA ISLANDS TO CENTRAL AMERICA.

(*By an ex Ceylon Planter.*)

According to promise, I must try and tell you something of my late wanderings but am quite at a loss to know where and how to begin. Queensland, Australia, has been written about and well exhausted by able writers, so that what I have to say will be old news. The same may be said of the Fiji and Samoan groups of islands. From the latter place I remember writing you, and am afraid of repeating what I have already communicated.

SAMOAN ISLANDS.

The Samoan group comprizes nine islands, varying in area from 700 to 2 square miles each. They contain a population of about 40,000, most of whom are distributed through the three principal islands, Tutuila, Opolu and Savaii. The men and women are very fine models and are credited with a perfect physique. A learned professor of America, in an exhaustive work on the human race, places the Samoan-speaking people first on the list for figure and general physical development. They can nearly all read and write, which has been brought about through the energy and perseverance of Dr. Turner and other veteran missionary representatives. Dr. Turner has spent fully 40 years of his life in Samoa, and has built a college at a place called Maloa to instruct the Samoan youth and teach him how to guard the moral welfare of his countrymen. I may here say that the language is spoken over a wide and scattered section of Polynesia. The groups are as follows:—The Society Islands, Marquesas Tahiti, Tongan, and Samoan Islands, besides the Maori of New Zealand. The language is very pretty and musical, which is greatly owing to the large number of vowels the words contain.

The language of a nation is truly considered an index to the character and manners of the people. In the case of the Samoans, the rule finds no exception. In their habits, they are polite and ceremonious. They never meet but they shake hands and say "How are you?" or part but say "Good bye." They have also words which have the full meaning of our "Thank you" and "If you please." All foreigners they call "Papalangies," which literally means "burst from heaven." This was the name they gave the first vessel they saw approaching their shores, and has since been corrupted to simply mean foreigner. They are very kind and very hospitable. Every village has a house built and set apart especially for the accommodation of travellers and is called the reception-house. I will, however, relate exactly what happened to me in an out-of-the-way village on the island of Savaii, which will give a good idea of all other receptions. The village was far removed from all communication with traders (except those who came regularly), and most of the younger ones had seen but few if any whites, or Papalangies; they rejoiced and stared accordingly. I had walked some 25 miles that day and was glad of the inviting shelter of the reception-house. My coolies and interpreter were equally pleased to have a sit down and smoke their "Soolooie" (a kind of cigarette made of tobacco and rolled in a dry banana leaf). Our arrival was soon noticed, and the cry quickly flew, and almost immediately the women came running with whatever cooked victuals were at hand, and placed them at our feet The food was conveyed on banana leaves and consisted, chiefly of breadfruit, taro, and fish, cooked in a rude way, but very palatable.

I passed the food to my coolies, as my stock of "civilized" provisions was not exhausted. By this time, the village chief, village orator and other dignitaries began to assemble followed by many others of low degree. Through the interpreter, the chief expressed himself very glad to see me (after shaking hands, which is always the first thing). In return he was informed that I was a great chief from England and had been in India, a country where the elephants run wild, etc., and that I had come to see the Samoan people and was glad to find them so kind and hospitable, etc. We all then sat down round the house. I may here explain that all the houses have one room only and are built perfectly round. There are no permanent sides; but a kind of venetian arrangement is let down on the windward side of the house whenever rain falls. The roof is very substantial and quite a work of art. Accordingly when we sat down we sat round the house and were facing each other. The ceremony of the kava-bowl was then gone through. The kava-stalk has a slight resemblance to a green bamboo of an inch or more in diameter. It is seldom used before it is three years old,and is dried first The bowl which was to contain the the beverage was placed in the centre of the room and two village maids were selected to prepare it. They sat down on each side of the bowl with their legs tucked under them like a tailor: in fact we were all seated in the same way, as it is thought extremely rude and bad-mannered to stretch ones' legs out towards the centre of the room. The maids were then handed small slices of kava, which they chewed into a pulp and then deposited in the bowl. After enough "pulp" had been produced it was mixed with water, at which time it resembles oatmeal and water. The next process in the order of preparation is to pass coconut fibres through the water in such a manner as to strain the oatmeal-like grains, which are thrown away. In this, practice has made them very expert, and it was very interesting to watch the cunning way the fibres were swept round. The preparation is then passed round, first to the chiefs and distinguished visitors; then to those of low degree. The chewers of the kava had the most beautiful teeth of any I ever saw. Their diet too is entirely vegetable if we except fish; and, being quite free of diseases, I half persuaded myself into thinking the kava bowl must be nice. The dignitaries thought so anyhow, to judge from the long and deep draughts they took with such evident relish. Accordingly I took mine with the best possible grace and sweetest smile:—thought of claret and champagne cups, and quaffed it to the dregs which delighted my friends more than it did me. In taste it resembles soap suds; but leaves a pleasant feeling behind. Almost immediately I was most ravenously hungry, and after a refreshing bath ate heartily.

I walked round most of Savaii; then returned again to the western end of Opolu in an open boat and walked thence over that island skirting the beach where all the villagers are located. Arrived at Apia harbour, I waited an opportunity of getting away which fortunately soon presented itself.

The trade with the Samoans is not very extensive. Their wauts are limited and means of purchase are limited also. The articles mostly used by them are handkerchiefs and cloths of loud design and brilliant colour; knives, axes, tobacco, rifles and ammunition. They are very proud of possessing the latter. To purchase these they cut out all the coconuts they have to spare and make copra which is given in exchange to the traders

The most of the business is done by two Germ n firms. Messrs. Godefroy & Co. and another, who have small trading stations scattered about over all the islands. Copra is brought to Apia, the centre. and goods sent in exchange through the medium of small schooners of 20 to 30 tons' burden.

There is a king, Maleatoa, whose authority is only nominal; judges too are appointed to administer the law among themselves but have no jurisdiction over foreigners. The Godefroys have several very fine plantations of coconuts and cotton. They however have expended money in a most reckless and extravagant manner. Their superintendents are men whose knowledge of matters relating to planting is only exceeded by one thing and that is a total ignorance of such matters. This may appear a sweeping assertion, but is nevertheless true. Shortly before I left the firm had taken into their employment an ex-planter from the Coorg district of Southern India, also a sugar-planter from the Fijis of considerable experience, who were working great reforms. Of coffee there are a few trees planted at an elevation of about 500 to 600 feet above sea-level and looked remarkably well. There was no leaf-disease or other pest that I noticed. The coffee planter had opened a nursery of some 600,000 seedlings, which were to be planted out and, I believe, will do very well indeed. The soil is a chocolate loam of great depth. Labour, however, is the great drawback. They have to get all their coolies from the Hebrides and Solomon Islands, which are a long way off and is also the recruiting ground for the Fiji and Queensland planters, so that Samoa is pretty well handicapped in this respect.

The land is all mountainous, but does not rise abruptly from the sea. Towards the beach it is planted with coconut groves, throughout which are innumerable villagers. Coral reefs circle all the islands, inside which the water is smooth and rarely ruffled by anything but a gentle breeze. To say they are inviting, enchanting and altogether charming does no more than express the feelings of all visitors. I was pleased and delighted beyond telling with my stay.

Darwin's sentence which you quote in your *Tropical Agriculturist* applies with equal truth here:—

"Every form, every shade, so completely surpasses in magnificence all that the European has ever beheld in his own country, that he knows not how to express his feelings." I am not good at high-falutin; accordingly, will content myself with a simple narration of facts.

On the 23rd of September I stepped aboard the good ship "Sheet Anchor" and waved a good-bye to Apia. We had to beat 50 miles to windward. where Manoa, Olasinga and Offoo are situated, calling at Tutuila on our way. But I will leave this for a future description.

Thence we visited the Gilbert group of islands, situated about 1,200 miles in a northwesterly direction. These islands are very interesting, and no one that I am aware of ever visited them before me, except some labour schooners and two American ladies. I shall, however, reserve these for a subsequent paper.

GUTTA PERCHA.

The *Java Bode* of the 21st July, after stating that the Netherlands Indian Government has directed the official stationed in Sumatra and Borneo to report on the present condition and productiveness of the gutta percha industry in those islands, and has instructed the manager of the State Botanical Gardens to plants several varieties of that tree by way of trial, says:—

"Of what great importance this gutta is to Netherlands India some idea may be formed when it is once known that the Malayan Peninsula is the only country beyond Netherlands India which furnishes a considerable supply of that article. Some further particulars of this description of gutta the districts wh re it abounds, the manner of procuring it, and how its production may be increased, will not be unwelcome, now that so much attention is directed to gutta percha and so much interest taken therein. Gutta percha is the coagulated milky juice of a tree called the Dichopsis Gutta, belonging to the Sapolaceæ family, one of the colossal forest giants in the woods of Sumatra and Borneo. The name for it is *Nyatu* in Borneo and *Balan* in Sumatra. In Borneo, especially many varieties of it are found, the milky mice of which is of more or less good quality. The juice, flowing from incisions made into the bark is collected by the natives, boiled, and then brought to market in the form of a tough leathery substance. In Borneo most of the Gutta percha is obtained by Dyaks, who in large parties of often a hundred men each, undertake expeditions for several months in the forests to collect this product. To obtain milky juice they simply fell the trees, then cut into the bark and catch the juice in earthen pots or large leaves. The boiling is effected in large cauldrons. The whole process is very rough, and the product thereby less refined than it would be by more effective or careful preparation. The whole method of collection is destructive in the extreme. Gutta-percha collecting is a wasteful and destructive industry on a large scale. Thousands of trees are yearly cut down, for it is estimated that to obtain one picul of gutta about one hundred trees have to be felled; hence the time is not far off when the stock of this useful and increasingly serviceable product will become exhausted. Experienced people say that gutta percha can be obtained by tapping the trees without killing them, and that they can be very easily cultivated and grow relatively rapidly, so that the milky juice becomes available within 10 years. Satisfactory and continued experiments in their cultivation have, however, not been made by us. It is very certain that the gutta percha tree will flourish in Borneo, Sumatra, Rhio, Banka, and Java, too, if only suitable land be selected and its cultivation not left wholly to the natives. Hence the establishment of experimental plantations, besides, in the chief towns of Netherlands India, will prove to be of inestimable advantage."—*Straits Times.*

RAINFALL AND TEA IN ASSAM AND CEYLON.—A planter writes to us:—"On seeing the table of rainfall in Monaragala published lately, I looked over my notes taken on a visit to Assam last year, and I find a table of the rainfall on a large tea garden of 1 200 acres in Nowgong, a copy of which I enclose, in case it should be worth inserting in your paper for the encouragement of Ceylon tea planters. Even Monaragala with its rich soil and hot climate ought to grow tea to pay." We quite agree with our correspondent that if tea grows well in Assam with a rainfall varying from 52·17 inches per annum to 77·72 there are few places even in the driest parts of Uva where the plant cannot be cultivated with success. The table is as follows:—

Rainfall on the Nowgong Garden, Assam from January 1875 to July 1882.

Year ..	1875	1876	1677	1878	1879	1880	1881	1882

THROUGH THE TEA DISTRICTS OF NORTH INDIA: No. V.

(*By a Ceylon Planter.*)

TEA-PLANTING IN DARJILING COMPARED WITH THE HILLY-DISTRICTS OF CEYLON—ABSENCE OF DRAINS AND ROAD-TRACERS—PRESENCE OF WEEDS, GOOD BUILDINGS AND CHEAP GOOD LABOUR IN DARJILING.—PLUCKING LEAF—SIGNPOSTS—MACHINERY AND MOTIVE POWER.

Darjiling.

The lay of land in the Darjiling hill-district and the style of plant and of cultivation, is utterly different to that of Assam, and affords a more valuable basis for comparison with the Ceylon hill country. The soil at the top of the hills is mostly a very stiff clay, similar in appearance to much that we have in some parts of Ceylon, and exceedingly rich and fertile. Lower down, towards the valleys, the soil becomes quite different and consists generally of a rich black micaceous loam which is very free and porous. So stiff is the soil in parts near the ridges that it is almost impossible to walk along the roads without frequent falls, and ponies travel best if rough-shod.

Generally speaking the estates are as steep as any planted land we have in Ceylon, but the style of cultivation is different to ours. In most cases, the hillside at the commencement is formed into small level terraces, and a row of plants put along each; frequently, however, the land is lined in the usual way, up and down hill, is not drained, and yet the wash is trifling in the most heavy showers. The secret in this case is the tenacity of the soil and the fact that hoeing is only done once or twice early in the season, to open it up, and that, after that the weeds are only kept down by being cut with sickles.

On terraced land, hoeing can be done more freely, but even here the weeds are generally cut and not dug over the faces of the terraces being carefully treated. Our system of draining does not appear to have been tried: it would I think, be a success in stiff land, but in many places there is no tenacious subsoil to cut down into and slips would be the only result of any attempt at draining. Tea is, however, generally opened on land which has been previously cultivated and abandoned by natives, and is consequently, full of weed seed. To attempt to eradicate the weeds, during their rapid growth in the rains would be most expensive, if not impracticable, and, hence, wash is to a great extent prevented by the thick matting of weeds which cover the ground and hold the soil together. In consequence of this system of cultivation, the appearance of the estates is not pleasing to the eye, the bushes being in many cases almost hidden by the growth of jungle. Strange to say, in spite of the numerous zigzag roads that have to be cut to open up the gardens, a road-tracer is unknown in the district, and consequently, the gradients are very uneven and the roads generally steep and bad.

The buildings here are of a very different character to those in Assam, being *pakka* as a rule, and more like what we are accustomed to in Ceylon. There is a great dearth of machinery in the district many large gardens having rolling machines only and are still firing over stoves. Labour is very cheap, and where a manager is popular with his coolies very plentiful. The labourers are all hillmen, Nepaulese, Lepchas (the inhabitants of British Sikkim) and Booteas. They are all under sirdars, who receive their pay for them, and are recruited without any expense to the garden, small advances recoverable from the coolies' pay being alone given. The rate of pay varies from R3 to R5·50 a month, and hence Darjiling has the great advantage of plentiful and cheap labour.

There is one drawback, however. It is the custom in many localities to give up a large portion of the waste land belonging to the estate to the coolies for the cultivation of Indian corn. In some valleys, hundreds of acres of fine land are seen cultivated in this way, and the loss to the gardens is not apparent in any system of accounts, but none the less real and serious, must be very great. At the present time land fit for tea cannot be obtained in the neighbourhood of Darjiling by any means, and hence the waste of good soil in the way just mentioned is the more deplorable.

Continuous crops of native produce are taken off the same soil by the coolies in hundreds of acres of land, without the payment of any rent or the application of any manure; and the loss by exhaustion, wash and introduction of weeds, must be enormous. Not only this, but in a good (grain) year, the manager has frequently great difficulty in inducing his well-fed coolies to work at all, for they have no inducement to. As regards transport, the district is well served by the railway to its centre, though there are general complaints of delay in the transport of goods, which is excusable in view of the difficulties under which the line has been worked of late.

The hill labourers are very well accustomed to carry very heavy loads uphill, and it is wonderful to see the weight they can take up to the station. A maund-chest, weighing perhaps 130 lb. gross, is nothing to them, and I saw one man carrying a chest and a half, which cannot have been less than 170 or 180 lb.

The method of carrying is that which is, I believe, common to all hillmen a strap is passed round the bottom of the load and over the forehead, which, with the back, supports the entire weight. The weight is thus distributed over the whole of the upper part of the body in a way which enables enormous loads to be carried up steep hills which could not be taken for any distance on the flat by the method in vogue amongst Tamils. In appearance, as in character, the Lepchas, Nepaulese and Booteas are very different to the Bengalis. When well treated, they are a most cheerful, willing race, and make capital garden coolies. There is no labour law affecting them in Darjiling, and the vexatious returns and espionage which prevail in Assam are here unknown. With no agreement, the coolies, if mismanaged are given to leaving in a body, without any notice,—but this is a very rare occurrence, their extensive plantations of Indian corn and other grain acting as a powerful inducement to them to settle in one spot. The British frontier being so very close it says much for their honesty that cases of robbery and bolting are rare in the extreme, although it is the usual thing to send a few coolies and a sirdar alone to the station for cash, which they might easily make off with, if so inclined, with very small risk to themselves. The type of countenance of the Lepchas Bhooteas is decidedly Mongolian. The men are very ugly, though many of them have pleasing faces; a few of the women are nice-looking, but they are the exception. The latter have a custom of wearing their savings in rupees strung together and fastened round the neck, which would appear to offer opportunities for robbery though such rarely if ever occurs. The Nepaulese are by far the handsomest race of three. They come from Independent territory to the gardens, and take full advantage of the concessions which Government make to native settlers here as elsewhere.

Both in Assam and in Darjiling, the use of "cooty-sacks" for plucking leaf is unknown. In the former district, the leaf is collected in baskets slung to the waist, and is weighed in twice a day; in the latter, the baskets are supported on the back by forehead straps, and the leaf thrown into them over the shoulder, weighing-in being generally done once a day only. Baskets are, undoubtedly, very awkward things to carry, especially amongst closely planted tea, and, when due care is exercised, that the leaf is not pressed down and allowed to heat in any way, the employment of bags is, I think, best, especially with coolies who are accustomed to pick coffee "cherry" in this way. As we all know, sour tea is the result when leaf is allowed to heat in the field, and, in using bags for its collection, the greatest care must be exercisde that this does not occur and the *pressing down* of leaf be prevented.

There is one small matter in which Darjiling is ahead of us and of Assam, and in which we might well take a lesson. The road to every garden is indicated where it leaves the main road, by a sign-post giving the name of the estate. The great convenience of this system and the saving of the vexatious loss of time which sometimes occurs through losing one's way, should be tried to be appreciated. A stranger travelling from the station has only to be put on the right road to start with, and he can scarcely fail to find his way with ease and without the loss of time which "a cooly to show the road" means.

The coolies' lines are invariably situated high up in the hill side and never, by any chance near the bottom of ravines. In spite of the elevation, it appears that fever hangs about persistently whenever there is the bed of a stream, and stagnant air. The same cause makes it desirable to have the factory in the hill-side, otherwise the distance between it and the bungalow and lines would be a great drawback. The difficulty and expense of choosing and clearing sites for buildings, with which we are familiar in some ports of Ceylon, is therefore reproduced in Darjiling; but the most serious difficulty is that the supply of water-power can seldom be taken advantage of from the distance at which it is situated. The streams here have very little water in them during the dry season, at which time they are not required; our chief difficulty in Ceylon is that the dry season is the time when water-power is most necessary, and the minimum amount available during the dry months has to form the basis of our calculation in erecting tea machinery. The small extent to which water is used as a motive power in a hilly district like Darjiling is indeed striking. In some cases, turbines are being used successfully, and there are a few water-wheels, but steam-engines alone are employed in the large majority of factories. At one garden, I saw the most perfect piece of motive machinery I have seen in India: a very fine 30 feet water-wheel, perfectly erected, with no very large head of water, was employed driving the several rolling, sifting and firing machines of a large factory, and it did so with perfect ease, at a trifling cost compared with that of working the engine previously used. In another garden where a turbine was employed, great difficulty was caused in the entrance into the machine during rainy weather of sand and grit, too small to be collected in the boxes. The most ingenious transmission of power is at a garden in the neighbourhood where a turbine at the river drives machinery in a factory some distance up the hill by a succession of driving belts and pulleys. There must be great loss of power by this system, and the wear-and-tear of belting would be considerable. As I have mentioned above, the factories are all permanent solid structures, and the limited area of the sites necessitates the utilization of all space inside them. Withering space is generally provided in an upper floor, and hastened by the heat from the stoves and firing machines below, where all machinery, &c. are situated. The remark about untidiness and want of cleanliness which applied to Assam factories would be out of place here, the Darjiling buildings being, as a rule, kept clean and tidy, though not, I think, to the same extent as is frequently seen in Ceylon. T. C. OWEN

THE CEYLON TEA ENTERPRIZE AND ADVERSE CRITICISM.

The local "Times" in an editorial article specially mentioned that specimens of Ceylon tea would be shown at the Calcutta Exhibition, "With the double purpose of making known the excellent quality of the article to the thousands of visitors from many parts of the world who will be there present, and secondly and chiefly to make known to capitalists who will be met with in the exhibition in large numbers, especially from Australia, the capabilities of this island for the production of the article and the admirable returns that may be obtained by investments in this enterprise." We suppose the "Times" editor, in his capacity of "Representative of the Planters' Association," will attract the special attention of capitalists to a letter which encourages the capitalists, whom to attract to Ceylon will be avowedly the main function of the "Representative of the Association," after the fashion following:—

"Although a deal of writing on this product has appeared during the last twelve months, both in your own and in your contemporary's columns, there is still a great dearth of general and practical knowledge of the subject. What else we have seen published with authority may be termed the big gooseberry and monster cabbage portion of the subject: the 700 lb., the 730 lb., the 805 lb.

"I confess I would be better satisfied were writers [including the 'Representative,' of course] seemingly more anxious to spread accurate information and to give intending tea-planters a better average and a more unexaggerated idea of the prospects before them: in short had a few of the cases of short returns and low prices also appeared—heralded or endorsed by the editorial paragraphs, so liberally bestowed upon the monster cabbages.

"To diffuse fair, as distinguished from inflated, information, is doubtless to be accused by your contemporary as deliberately attempting to 'defile your own nest;' but at the risk of this, may I not ask if the figures in the report of the Ceylon Company are not as worthy of a place in the literature of tea as those bushes of gigantic girth in Dimbula?

"So far as I can read these figures correctly, I learn from them that from 1,000 odd acres of tea, over 3 years old, the average yield for the last year was 135lb per acre. Now the estates of that Company are not confined to any one district, elevation, or soil, nor is their tea all planted in old coffee land. On the contrary, we find it in Colonna korale, in Rakwane, Yellaoya, in new land in Ambegamuwa, in new and old land in Koladeniya near Nawalapitiya, in fresh patana soil on Sogama in Pussellawa, in new and old soil in Rambodda, and on 'Hope' in Upper Hewahette.

"So far as I can see and hear, the product seems to be put out anywhere and everywhere, and looked upon as the renovator of all soils, however worn-out and indebted. 'Plucky' is the usual epithet applied to our planters when their doings in new products are noticed, but surely our experience with cinchona, Liberian coffee, and rubber, points at this stage of our history to caution as a more valuable attribute than pluck, unless, indeed, when that quality is also well tempered with discretion.

"For instance, I saw lately in the weekly 'Overland' a dose of confidence carefully prepared for exhibition among English readers, to the effect that the activity of tea planters was beyond the power of words to describe. Among others, a vision of one especial district was brought before the eye, and a panorama exhibiting stalwart young Englishmen driving gangs of coolies at a lightning-pace over fields and fields of dead coffee and cinchona, rose before me. At every three feet a tea plant seemed to be dropped, and I tried to conjure a succeeding series of glowing pictures. But, throwing my matter-of-fact recollection back some nine years, two other periods of activity, equally exciting and hope-inspiring, forced themselves on my mind. The first was this district being rushed into coffee, although the experience of thirty years had proved that coffee only succeeded in its almost sheltered corners. The next, an indiscriminate planting of cinchona in a soil and climate which, *prima facie* at least, seemed inimical to its growth, and where, if it succeeded, it must have been a surprise to even the most sanguine.

"A new and more certain era is dawning upon us with the introduction of tea, but, unless we are careful, the very men who are now loudest in the inflationist shriek of 'Forward' will be the very first to turn on us with their present reproach in regard to coffee and cinchona, namely, that we went too fast.

"To start a discussion on tea, I would beg to ask some of those whose experience in India or Ceylon entitle them to speak with authority: 1st. Whether there is really so much difference in jâts as seed-vendors would have us to believe?

"2nd. Whether wages in Assam and other tea districts in India are as high as with us, or whether it be true that—labour once secured—the average pay there is only from 15 to 20 c. per diem.

"3rd. Whether in districts devoid of firewood even for the use of the coolies, say, twenty miles from a railway, firing with imported fuel can be done so as to leave a profit from old soils, which unmanured would certainly not give more than 300 lb. per acre?

"4th. Whether tea from coffee-exhausted soils is likely to have as good a flavour and liquid as tea from fresh soils?"

If the "Representative" will only attract the attention of capitalists to the above encouraging deliverances, we should think that the capitalists will be particularly careful to fight shy of the country and the product described by "Once Bit, Twice Shy." Capitalists will naturally say:—"When you are quite certain that tea will be a success in Ceylon, then ask us to invest capital in the enterprize. But, if your own favourite correspondent is to be relied on, tea is not only not an assured success but is likely to fail just as coffee and everything else has failed." Under the guise of anxiety for information, the letter of 'Once Bit, Twice Shy,' is obviously a warning to capitalists *not* to invest in tea cultivation in Ceylon. Not only is there no humus left in the soil, but even the wages of labour are higher than in Assam. Do you see any verdancy in our eyes that you ask us to carry our capital to such an utterly washed-out country? No thank you, Mr. Representative. Charm never so wisely with your *couleur de rose* catalogue, the deaf adders [of figures] will refuse to hear."

PROGRESS IN "NEW CEYLON."

We got on board the S. S. "Borneo" (commanded by Capt. Edwards, and owned by Messrs. Ross & Son), specially built for the trade between Singapore and North Borneo: with a draught of twelve feet and one hundred and eighty-four feet in length, she is well suited for the requirements of passengers as well as for cargo. After receiving on board a quantity of ammunition in the roads, we left Singapore at 10 a. m. on the 6th July for Elopura (beautiful city), having on board as passengers Messrs. Callaghan, Flint, C. Dent Young, and A. Hart Everett, Lieutenants Holme and Porter of the "Buffs," Hongkong, A. D. and Mrs. Henry, and Miss Keanghran. After four days' pleasant sailing we reached Labuan on the morning of the 10th, where we made a stay of two days; we met the S. S. "Royalist," owned by the enterprizing Messrs. Cowie Brothers, and left at 6 a. m. for Kudat; our company being augmented by His Excellency Governor Treacher of North Borneo and Mr. Lee's. We touched at Gaya in the afternoon, a small settlement on the north-west coast. Six months ago there was no habitation of any kind, now there is a steadily increasing and industrious population, with shops, houses, and gambier planted which says much for the country in so short a time. Leaving Gaya and the Kina Balu (or Chinese widow), the highest mountain in North Borneo, 13,698 feet above sea-level. As the sun was setting, we steamed slowly away for the north, and arrived at Kudat the seat of Government, at 7 a.m. on the 13th. The approach to the harbour is marked out with floating wooden beacons; the view of the town was very pretty. The moment the steamer touched the pier, we were met by most of the Government officers and Europeans stationed at this port. As we walked on the pier and through the custom-house, a substantial brick and mortar building faces the visitor it is composed of shops with houses above, and the Chinamen occupants seem to be doing a thriving business. During the afternoon several of our party indulged in a game of cricket, while others took to the more gentle game of lawn-tennis, and two enthusiastic sportsmen went pig shooting. We finished up our day's pleasure, with being entertained to dinner at Government House. All returned on board by the small hours in the morning very much pleased and delighted with their short stay at Kudat. We were off before sunrise; steaming along the beautiful coast; we reached Sandakan or Elopura at 11 p. m. on the 14th. It was too late to land, and we were kept awake by numerous visitors from the beautiful city. Few on board slept long that night, and we were all astir by early morning for landing. At 5 30 a. m., the steamer moored alongside a temporary wharf, built on piles with split bamboos laid across: they seemed to give beneath to the weight of the mass of natives congregated to witness the arrival of the steamer. Most of the native houses, at least the bazaar portion of the town, is built on a continuation of the wharf, and the Chinese and Moor shopkeepers seemed to be doing a brisk trade in fish and other sundry eatables for that early hour. All the land in and about Sandakan bay has been taken up some months back; felling and clearing is going ahead, sugar is growing very well, machinery for a sugar mill is expected to arrive shortly. Mr. J. C. Hesse has burnt off his special grant of land which he has obtained for the introduction of cinnamon and nutmegs; the call for land have been so great, that the Survey Department has and still is unable to cope with the strain put on it; contracts have been let to and taken up by private surveyors for blocking out, there are good openings for private surveyors; the prospectors for the Australian Company have, up to the present selected 52,000 acres for the cultivation of sugar on a large scale.—*Cor.*

THE SHAVING OF CINCHONA.

A planter writes to us:—"Enclosed is a cutting from the *Madras Mail* of the 18th August. If you think it would be of interest or use, would you kindly enter it in an early issue of your paper? As far as my experience goes, the views expressed by the writer are not correct. My original succirubra from trees 4 years old gave

Original Bark:—		per cent.
Crystallized Sulphate Quinine	...	1·[illegible]7
Total Alkaloids	... ...	6·11
Renewed from trees same age, &c.:—		
Crystallized Sulphate Quinine ...	...	2·75
Total Alkaloids	... ...	4·01

(Copy:) 3rd March 1883. ALEX. DIXON.

Whether the writer in the *Mail* means that the first shaving (viz. original) was better than the second shaving I cannot understand, or does he wish us to understand that the first renewed was richer than the second renewed? He may be right; but, by this time, surely several in the island could let us know, and if spokeshaving is a mistake the sooner we drop it the better.

"My trees are now ready to shave, but I shall let them stand on till March, but before I shave I will have an analysis taken. I really should like this matter cleared up. P. S.—The bark was richer in but shorter quinine or other alkaloids.'

The letter, we have already copied into the *Tropical Agriculturist* (see page 206).

The paper by Mr. David Howard which we published recently, throws light on the whole question, and is worthy of careful attention. But we are not equally impressed with the jeremiad of the Le Mair-Rivers-Hicks firm. We should receive the statement with a good many grains of salt. The truth seems to be that shaving, carefully conducted, is the best mode of harvesting cinchona bark.

THE MANUFACTURE AND SALE OF INDIAN TEA.

The following extracts from the London *Times*, are of interest, as showing in detail how the central factory system would work in regard to tea:—

"Undoubtedly the bulking of Indian tea inflicts a serious burden on the trade, not only through the expense, but the destruction of the chests and their contents. The time, moreover, required to prepare the tea for sampling keeps it for a week or ten days out of the market after arrival. The remedy for this state of things appears to be to take another leaf out of that great Chinese book from which Indian planters have already taken so many. Chinese tea comes to market so perfectly packed, that in a break of 600 chests you will find an absolute uniformity of weight, both of package, and contents, and of quality, so that no repacking is needed, and the whole can be sampled and sold the moment the steamer breaks bulk. The reason is that the Chinese carry on their tea business on true commercial principles, while the Indian planters are still in the wasteful stages of a half-developed industry, and have not yet learned the full advantage of the division of labour. The planter is, or tries to be, merchant, carpenter, and engineer as well, and one meets with persons holding shares in tea estates who harbour the delusion that they can not only send their tea to Calcutta for sale, but ship it to London, and, passing over the machinery of Mincing-lane, follow their lb. of tea into the consumer's pot. With such crude ideas of commerce, it is perhaps hardly to be wondered at that the Indian tea trade finds itself under some disadvantage. The number of gardens in India is, according to the planters 2,700 or 2,800, scattered over a wide area, and in very varied situations, and it would be absurd to look for uniformity or even reasonable similarity either in the product or the packages. The gardens are individually very small; yet every garden possesses a more or less elaborate plant, consisting of firing-houses, rolling machines, &c., and each has to keep up a staff of handicraftsmen to manage the machinery and to make the tea chests. The enterprise is thus severely handicapped at the outset, much as a small farmer would be who kept his own steam plough and reaping machine. The men and machines are necessarily half their time idle. The only true remedy for this is to organise a market on the Chinese method for the green leaves in the districts. Darjeeling is admirably situated for such a market, and there are several stations in Assam which would make most convenient depots for the purchase of tea. What is wanted is sufficiently strong companies or private capitalists to establish themselves at these centres, and set up all the necessary machinery for manufacturing and packing the leaf. The planters would then, like the Chinese, sell their basketfuls of leaves as they picked them from the bushes. They would be planters, and nothing more, and the better planters for being nothing more. The tea buyer, filling the functions of the hong in China, would collect the leaves in large storehouses, sort them out according to quality and kind, and manufacture the tea on a large scale, with the maximum of skill and the minimum of cost. The hong would pack the tea in large breaks of uniform quality, in chests of uniform size and weight, and such teas would never require to be bulked again, either in London docks or anywhere else. The advantages to the planter of such an organisation as this would be manifold. In the first place he would be relieved of the great load of financial anxiety, which he bears at present. He starts the season under a mass of debt to the Calcutta agents, which has gradually to be worked off during the producing season. These advances cost very dear, and the repayment cannot be made until the tea has been gathered, manufactured, packed, and sent down by a slow transport to the Calcutta market. Whereas, on the hong system, the planter would require very little advance at all, seeing he would need no machinery nor any expensive staff to work it, and he would receive his money as fast as he gathered his tea, instead of waiting two or three months for it, as at present. The chief difficulty in the way of this innovation would be the strenuous opposition of the Calcutta agents, who make good revenue out of the tea planters, not only in the way of interest on advances, but commission on sales of tea and on supply of stores and machinery. For once a tea concern is under the protection of a Calcutta house, it is an understood thing that it is nearly impossible to escape therefrom. The emancipation of the tea planters from this thraldom would fill them with new energy, and probably enlarge their intelligence."

To the Editor of "The Times"

Sir,—The interesting article on the manufacture and sale of Indian tea in your columns contains the very practical suggestion for the development of that important industry, that the Chinese system of tea-hongs should be established in the principal centres of cultivation. Having had exceptional opportunities of studying the whole Chinese economy of tea-growing, picking, sorting, firing, and packing, it is possible that my experience may be of some use to those who may wish to interest themselves in this subject. In the year 1861, when the Yangtsekiang had just been opened under Lord Elgin's Treaty, and the extensive tea-growing regions of Hupeh and Hunan, were made accessible by that great water-route, I was sent by my employers at the opening of the season to superintend the purchase and manufacture of the first pickings of the tea, under the impression, not always justified by experience, that the nearer one could approach the source of supply the cheaper one could buy. Europeans had begun to settle in Hankow, so soon to become a great inland-seaport, and there my modest expedition was equipped. After three days and nights of slow but comfortable travel in an empty tea junk, I landed at a point on the river 100 miles above Hankow, called Sz'ting, my most lively recollection of which is the unspeakable swarm of mosquitoes, which, however, entirely succumbed to the fumes of chemically-prepared touchwood. The journey thence to Yung Lantung was over a most interesting mountain track, the path consisting of steps cut out of precipitous wall of rock, round which the coolies, who carried the chairs in which we rode stepped like cats, gripping the rock with their toes, in places so narrow that their bodies could only pass when turned sideways. I doubt if I should have dared to walk on my own legs along such a track, and it was not without considerable trepidation that I allowed myself to be carried on the shoulders of other men who, far from sympathising with my nervousness, kept up a loud discussion with each other at the most critical turns as to how much money they would receive, and how they would spend it.

Yung Lan-tung is a town of tea-hongs, in a valley surrounded by tea plantations on the hill-sides. The first packing having been finished before my arrival, the sun-dried leaves were being brought in the hongs in baskets for sale. There is always enough free selling to make a market, but a large proportion of the crop is bespoken by the hong merchants, who make advances to the growers. A tea-hong is a large solid brick building on the typical Chinese plan, court within court, covering ground measuring 500 ft., by 200 it. The tea buying is carried on very rapidly. The buyer stands on a raised platform, the sellers in the large open court in front. Each seller hands up a sample of his leaf on a small wicker tray for inspection, when the buyer, without a moment's hesitation, fixed the price, writes it on a slip of paper, which is handed to the seller, who is equally prompt in accepting or rejecting the price offered, and there is no chaffering, time being too precious. If the price be accepted, the leaf is at once carried into the hong, weighed, and the money paid on the nail. There is always keen competition among the buying hongs, and the growers are thus secured a full market price. After the buying for the day is over, the qualities are sorted out, the leaves are slightly fired, and then packed away, as tightly as hay in a stack, in dark stalls in the interior of the hong, where the tea is left till fermentation commences. It is then put into the hands of the pickers, women and girls, each of whom receives one katty, from which they pick out the brown leaves and stalks. The leaf is then winnowed to throw the dust off. The fresh leaves which are left are gathered together and fired, which is the most important process of all, as the appearance, character, and flavour of all depend on the skill and care of the firing. The manager sits up all night watching his hundreds of baskets of tea slowly baking over charcoal fires. When done to a turn the charcoal pans are suddenly removed, and the tea allowed to cool. It is then ready to be packed into the familiar lead-lined chests, for shipment to England. A "chop," or one firing of Tea, varies from 600 to 800 chests. The chests are made to order, of uniform size and weight, and the tea is not weighed, but carefully measured into the chests. An impression used to prevail that the tea was all picked with chopsticks, but I found that it was only the samples which are made up for the sale of the tea that were put through this process of selection ; and much labour and sorrow it entails on both buyer and seller in the rejection of chops of tea for being inferior to sample. Not having visited the Indian Tea district myself, I should not like to say how much of the above-described Chinese practice might profitably be adopted by the Indian planters. But as in the course of my business, as a tea dealer, both Indian and Chinese tea pass daily through my hands I should judge from the practical results of the Indian, process that the Indian planter has little to learn from the Chinese in respect of the firing or manufacture of the leaf. There would seem, however, to be obvious advantages in separating the growing from the manufacturing and packing, carrying on the latter processes on a larger and more uniform scale, and at a very much less cost than is possible where each small garden has to keep up its own separate establishment.—I am, sir, yours truly,

JAMES INNES.

7 and 8, Idol-lane.

To the Editor of "The Times."

SIR,—Your correspondent's letter of the 24th instant, on Indian tea, will doubtless be copied by the newspapers of India, and read with considerable interest by tea planters, many of whom will at once admit the force of his arguments, that tend to show how the planter himself can, to a very great extent, put a stop to the inconvenience he now complains of—viz., the taring of the chest of tea by the Customs—and also, in small tea districts, the expense he incurs by manufacturing tea on his own plantation. As well might every farmer in England have a corn-mill on his farm as every planter have on his plantation a factory in which the "leaf," as the green leaves gathered from the tea bushes are technically termed, is manufactured into tea. It is not, however, my object to deal with so comprehensive a subject, which can be much better handled by the Indian, Tea Districts Association than by one planter, hailing from a very small tea district in India. I would, however, in passing, point out that it is not the green leaves, as stated by your correspondent, which are sorted out, but the manufactured tea, by the quicker process of sifting through cane sieves, of different-sized meshes, made for the various qualities of tea. I do not know, of course, what your correspondent's ideas of a small tea garden may be, but I have always been under the impression that in the important tea districts of India there were gardens of a very considerable area, and that in China the gardens individually bore no comparison to them, either in size or in appearance of being well cultivated and plucked. I do, however, wish to make my humble protest against the idea that owners of tea gardens should not ship their teas to London, and, "passing over the machinery of Mincing Lane, follow their lbs. of tea into the consumer's pot." Such ideas of commerce may, as your correspondent states, be crude, but when put into practice they often assume a very tangible form of profit to both the producer and consumer of the staple. Without in the least wishing to reflect upon the mode in which English tea brokers have fulfilled their duties as agents, the proprietors of the far-off gardens in the hill districts of India have undoubtedly found that, what with ther inability, by reason of distance, to closely watch the fluctuations of the tea market in England, and the heavy cost which the employment of intermediate agents entails, their produce is often sacrificed without benefit to themselves, as producers, or to the public, as consumers. The public, which is now fast becoming alive to the fact that Indian teas, pure and simple, especially those of the hill districts are much better than the majority of China teas, was for a long time allowed by interested parties to believe that the former were unfit for consumption in their pure state, and such has been the persistent misrepresentation which has accompanied and followed every honest attempt on the planters' part to introduce to the notice of the public in England an article second to none of the very best produce of China, that they have, in some instances, determined to establish agencie of their own for the sale of their produce. They find, what ever may be the cause, that under the system they have hitherto pursued their tea has not received that measure of support which their knowledge of its excellence and purity entitles them to believe is its due. The expenses incident to that system have been great, without any commensurate advantage, and they believe that those expenses re not always necessary, and, while they swallow up alls agitimate profit, they also increase the cost of their Teas le the public.—I am, sir, your obedient servant,

TEA PLANTER.

TEA-BULKING.

TO THE EDITOR OF THE "GLOBE."

SIR,—The article on "Tea-bulking" in your issue of July 12th, raises the question: Why should tea require to be bulked in London at all? As a matter of fact it is only Indian tea that is bulked in London. Chinese tea is bulked in China before the leaf is cured; and it would be well for the Indian planters if they would imitate the Chinese system of hongs, by which uniformity in the tea chests is secured, and the necessity for bulking in London consequently avoided. In India, at present, every small tea-planter is also a curer, a packer, and in many cases an exporter. He grows his tea in such small quantities that he often has to keep one "picking" till another is ready, and then sends them both together to London. This is one of the causes of the variation of quality in the tea which makes bulking necessary in London; as not only one "picking" of tea varies from another grown on the same plantation, but the tea of each small plantation varies from that of its neighbour. Another reason for the necessity of bulking Indian tea is the variation in the wood of the chests. Each planter has his chests made by the plantation-carpenter, of any wood, heavy or light, that comes to hand; therefore, the chests, like the tea, of one plantation, vary in weight from those of another, and even the chests from the same plantation vary from each other, being often made of perfectly different woods. The result of all this is that in the small "deals," as they are called, of tea which arrive in London from India, there are hardly two chests exactly alike and the buyers naturally demand that the whole shall be bulked and repacked. Even if the buyers did not require this, the Custom House would do so, other.

wise the "tare" (*i.e.*, the weight of the wooden case and lead which has to be deducted from the weight of the tea) could never be arrived at. In China there are, of course, the differences between the tea of one "picking" and that of another, but the various pickings are sold at once to one common manufactory called a "hong," where they are all mixed or bulked together, and then cured and packed in chests of uniform size and weight. The result is that a Chinese "chop" of tea, consisting of from 600 to 800 chests, runs with such regularity that "taring" a very few of them gives a trustworthy estimate of the contents of the rest, and buyers willingly accept a sample from any one chest as a specimen of the whole "chop." The Indian Tea Planters' Association lately petitioned Government to prevent the Custom House from turning out and weighing the contents of each separate package, pointing out the loss suffered by planters from this cause. Their petition would carry more weight if they would do something to secure uniformity in the packing of their teas. It is surprising to the onlooker that the Indian planter has never realised the fact, so patent to the practical Chinaman, of the immediate saving to his own pocket which would ensue from confining himself to one branch of the trade instead of attempting all. If he would be content with growing tea, and sell it when picked to the tea-curer, he would be able to dispense with the expensive tea-preparing machinery, and with the services of the engineer required to work it. The capital thus freed might be applied to increasing the size of his plantation, and he would be enabled to concentrate more attention on the cultivation of tea. These remarks do not, of course, apply to the few large joint-stock plantations in Assam, where the quantity of land under tea cultivation and the large subscribed capital makes a difference. The Assam Joint-Stock Tea Companies' teas are not bulked on arrival in England. I have been told that the opposition of Indian planters to each other would render impossible the combination that exists with such good effect in China. If this be so, it is unfortunate for India, who will assuredly find herself outstripped in the race by those countries where the advantages of co-operation and division of labour are understood. It is probable that Ceylon will soon set India a good example in this respect, in which case Ceylon must take the first place as a tea-producing country, her teas already ranking higher than most of those we receive from India.—I am, Sir, your obedient servant, James Innes. 33, Seething-lane, E. C., July 16.—[This is a repetition, somewhat modified, of the letter which previously appeared in the *Times*. Neither India nor Ceylon is likely to adopt from China, a system of hongs and tea preparation, which accounts for much of the weakness and inferiority of China tea. Tea planting would require to be much more advanced than it is in Ceylon to allow of hongs either in the tea districts or at Colombo. It is of importance, especially in a moist climate like that of Ceylon, that tea should be packed as well as manufactured on estates. But the time may come, when sales taking place at Colombo, the buying merchants can blend and bulk.—Ed.]

MR. C. S. ARMSTRONG ON THE TEA ENTERPRIZE IN CEYLON.

Mr. Armstrong's papers on tea culture, preparation, yield, cost, &c., which we publish on page 251 *et seq.*, cannot be read with more attention than it deserves. It embodies, mainly, the results of Mr. Armstrong's own experience, with trustworthy information added, on the important point of average yield per acre. The figures given justify the encouraging and sanguine tone of the whole paper. Mr. Armstrong—and we think he is perfectly justified in his calculations—regards as moderate averages :—

400 lb. per acre for estates from 2,500 to 6,000 feet above sea-level.

600 lb. per acre in the case estates below 2,500 feet altitude and down to sea-level.

On his own estate, Mr. Armstrong obtained from one field, the very high return of 1,200 lb. per acre. The elevation of this field was 5,500 feet, but soil and shelter were exceptionally good. Now, much of the soil at high elevations is excellent in quality; and where such soil, with its subsoil, may be too stiff for cinchonas to live in, tea with its powerful taproot is able to flourish. As Mr. Armstrong remarks, the tea plant is able to go much deeper for nutriment than even the coffee plant. It may not be out of place to state, from our own experience, that not only will tea succeed where cinchonas have failed, but that, after tea has been in the ground for a few years, the soil gets so opened up and drained of moisture that *C. officinalis* flourishes where formerly it refused to grow. Of course, the more shelter the better for tea, as for coffee, cinchona and other cultivated plants; but our experience is to the effect that few plants are more tolerant of wind than tea. We have never seen the staking process noticed by Mr. Armstrong resorted to in this culture, and our main experience is derived from tea cultivation running up from 5,000 to nearly 6,000 feet, where the monsoon winds can certainly make themselves felt. Their main effect when laden with the cold spray of the south west monsoon is to check vegetation and so produce the winter in June-July of which advantage is taken to prune the bushes. Our chief, we might almost say our sole losses have been occasioned by the poisonous roots of a particular jungle tree. Round the root stem of such a tree (a symplocos) we have lost from four to twelve plants, and to supply such vacancies, (unless it is deemed better to fill them up with cinchonas) there can be no doubt it will be well to have "stumps" ready, such as Mr. Armstrong suggests. We may here, again, repeat what we have frequently stated, that the best sites for tea nurseries are the flat swamps in which ravines often terminate, or which rather mark intervals in the downward progress of streams. Of course drainage is necessary, and this can be secured by digging between the beds and heaping the earth over them. If rotting timber, roots and rubbish are burnt and the ashes mixed with the earth in the beds, the progress of the seeds, under the influence mainly of moisture which reaches them by capillary attraction from below, is rapid. Watering is resorted to only in very dry weather. Mr. Armstrong's experience ought forever to shut the mouths of those who are so fond of decrying high altitudes. It must be remembered that 6,000 feet in Ceylon, within 7° of the equator, is not more than the equivalent of 3,500 to 4,000 feet on the sides of the Eastern Himalayas, in the Darjiling district, in 27° north, where most of the rain falls in four or five months of the year and where a marked winter exists from November to March each year. *Our* rainfall is well spread over the year, only acting as a wintering, when the cold of evaporation is produced by the winds of the southwest monsoon. Looking at the exceptional return obtained by Mr. Armstrong of 1,200 lb. per acre, from a field of 3 acres at 5,500 feet, it is quite possible that ultimately, the high estates will increase their average to 500 lb. against 700 lb. in the case of the low estates. But 400 and 600 are exceedingly good, and, if, while the soil of the high estates is better and more lasting than down below, the climate is undoubtedly more favourable to human health, it will be seen that advantages will be pretty equally balanced. On the low country estates, where the forcing climate will lead to large crops from the first, manuring will have to be resorted to at a correspondingly early period. Of course, there are facilities of river and road to be followed in due time by the railway. When the Uva Extension is completed, a large proportion of the high estates will also be enabled to use manure. The *necessity* in this case will come at a considerably later date; but, of course, the benefits of manuring even at the earliest stages of culture will be large. It may be well in future statistics to indicate whether the acreage yielding a certain return has been manured or merely kept clean and the prunings buried by means of forking. The latter process ought never to be neglected. As to weeds, or "jungle" as the Indian planters term extraneous growths, we hope we shall never in Ceylon adopt the Indian system. Our soil, although evidently firstrate for tea is not equal to the growth of tea and jungle. What Mr. Armstrong says about the value of machinery in not only saving labour and money but turning out superior tea, is most encouraging. The idea to which the old Indian planters naturally clung so tenaciously and so long, in favour of the detergent and general chemical effect of charcoal fumes on tea. as well as its property of giving strong heat without smoke, seems now relegated to the limbo of superstitions. Mr Armstrong's experience enables him to deliver the verdict that teas prepared in the Sirocco drier are brisker and better than those fired (too often burnt) over charcoal-stoves. Having recently seen a sifter added to a roller and drier previously in use on the estate in which we are interested, we can bear personal testimony to the comfort the machinery yields to the superintendents as well as the saving it secures to the proprietors. And a fact much in our favour in most parts of Ceylon is, that water is in the vast majority of cases available as the motive power for the machinery. In proportion to area cultivated, we must provide tea house accommodation and withering space, far in excess of what is common in India. But the cause, about a doubled average yield, is entirely in our favour, even after the extra cost of extra-covered room is counted.

The proper withering of the tea-leaf is an essential preliminary to good rolling, sufficient and not excessive fermentation, and drying which secures crispness without an approach to burning. The surface space which must be provided for the withering of 4 lb. of green leaf, the equivalent of 1 lb dry tea, looks enormous when stated in feet; but there can be no more false economy than the restriction of withering room. The great object is to get the tea leaf to deserve Theodore Hook's description of the voice of David Wilkie, as "soft and silky," although we believe 'satiny' would be a better word in the case of the tea leaves. Mr. Armstrong's advocacy of 50lb. half chests for the packing of our Ceylon teas will be respectfully considered. Of course, it will be important to adopt sizes of packages which will give a certain number for the space which merchants and shippers may finally decide on as the cubic ton. At present it is 50 feet, and the Ceylon Company (Limited), as we showed some time ago, make chests with reference to this measurement. The facts that a single cooly can carry a 50 lb.-half-chest and that this weight does not necessitate the looping of the package are important considerations. Of course the great question of all, regarding tea, is, "Will it pay?" and our readers will see that Mr. Armstrong, from his own experience and from figures supplied by other growers, makes out a very satisfactory case. As most of the figures are for hand-made tea, we must take into account the saving to be effected by the use of machinery. We must aim at the production of tea at from 8d to 10d per lb. for the average, so that an average selling price of 1s. and over will leave a good profit. The consumption of tea is, doubtless increasing, but its production has been and is being largely extended. With our large yield, our experienced and docile labour, our good means of communication and our general nearness to port of shipment, we ought to be able to hold our own amongst our numerous competitors as tea growers. But it will be observed that Mr. Armstrong is strong in the faith that not only can we grow tea and coffee advantageously on the same estate, but a variety of other products. While sanguine about the new staple product, Mr. Armstrong has by no means lost faith in old coffee. He believes in working estates containing 25 acres tea and 100 coffee, or *vice versa*, and wherever there is coffee which produced wood, although it does not ripen fruit, there, he insists tea can be well and profitably substituted. As long as we can remember we have editorially done our duty, by urging the planters to grow several products instead of one. Leaf-disease came at last to enforce the lesson. We can, however, quite understand and make much allowance for the devoting of exclusive attention to that which at one time paid so well. A few incidental points may be noticed. Mr. Armstrong is right in saying that the sooner tea seed is in the ground, after it is ripe, and gathered the better. We may add, from our own experience, that many of the seeds force themselves above ground in the process of germination and require to be carefully pushed down or to have fresh soil sprinkled over them. Our readers will notice that Mr. Armstrong considers holes of 9 inches sufficient for tea plants put in amongst coffee, while for stumps he advocated the orthodox 18 x 18. Mr. Armstrong also records much higher gatherings of green leaf than the usual average of 16lb.

TEA AND COFFEE CULTIVATION IN CEYLON.

(*From the Proceedings of the Dikoya Planters' Association*)

Friday, 31st August, 1883.

Mr. Armstrong's Paper on Tea.

The Chairman, in introducing Mr. Armstrong, said he was doubtless already wellknown to all present by the high reputation he had deservedly won for the "Rookwood" tea, which had for some time been the best known in Ceylon, and had lately been awarded the gold medal at the Agri-Horticultural Exhibition in Colombo. Mr. Armstrong had been tea-planting for the past 8 years, and few were better able to give them more reliable information as to the desirability or not of planting tea at these high altitudes. He would now ask Mr. Armstrong to read his promised paper :—

Mr. Chairman and Gentlemen, I have to thank you for inviting me to attend today, and am glad to give you my experience of the cultivation of Tea in Ceylon, and I trust that the facts and figures, I shall have the pleasure to lay before you, will imbue not only yourselves in this district, but all of us, who have hitherto doubted—and we are now very few—with courage, to turn any unremunerative coffee fields we may possess into paying fields of tea, and in thus doing, I would still advise good bearing patches, which are to be found in every estate, to be kept as coffee, even if only aggregating 50 acres. 200 acres of tea will allow of this being kept in a high state of cultivation, without any increase in the labor force, as there are often, times when one is glad to have some other product that would employ one's labor, or a portion of it, for a few days, to the advantage of the tea. And the return from small patches of coffee worked in this way, are almost nett profit; or on the other hand, 5 acres even of tea may be worked to advantage with coffee. Do not let us, therefore, run into the other extreme, but let us keep all the coffee we can, where elevation and soil are suitable, and cultivate it highly with the aid tea will give us. Let our endeavour be to have as many products as our situation or elevation will allow us to grow. Bad fields of coffee we may have, but bad coffee estates, as a whole, I deny. As, at a meeting like this, time will not permit me to enter thoroughly into every detail connected with tea, I have endeavoured to curtail my remarks as much as possible. The more so, as your knowledge of coffee planting will fill up any gaps. I consider our knowledge of coffee cultivation goes very far to aid us in that of tea, and, with our trained labor, most apt at picking up anything new, to aid us, we can place our tea in the market cheaper than any other tea-producing country in the world.

My remarks today have more especial reference to the cultivation of tea in what may be termed our coffee zone in fact, to the practicability of tea taking the place, in some instances, of coffee, or of its being planted in forest land adjoining our coffee estates, and which we have thought too high for coffee.

Throughout this paper I refer to Assam-Hybrid tea only.

At what elevations will tea grow at, in Ceylon, to pay? From almost sea-level to over 6,000 ft. provided soil and aspect are suitable.

Soil.—Should be fairly good—the richer the better—deep and friable, loam well mixed with sand; a shallow quartzy soil is not good. Tea will not flush readily in this although it may grow to a fair sized bush. A sub soil, well mixed with sand, or grit, without showing a very good surface soil, will, although giving a slower growth at first, turn out a better paying soil, than one with a rich surface and clearly defined clayey subsoil without an admixture of sand; the more we pluck, the deeper the roots must go, and we must have room for them. The higher our elevation the richer should our soil be, to make up for climate.

Climate.—That that is best for coffee, will I believe, *for a permanency*, be found to be the best for tea. The beau ideal of a tea climate is Avisawella, Yatiyantota and the lower portions of Morawakorale, also portions of Ambagamuwa; but they have not our coffee zone subsoil, as a whole; and our zone will, I think, make up, in its deeper soil, for the want of extreme heat with moisture, which prevails in these districts, where, however, tea will rapidly make a fortune for its lucky proprietors.

The higher the elevation, the less rainfall is required, and *vice versa*, light showers alternating with sun, if we could order them so, would give us 1,000 lbs. an acre at 5,000 ft. elevation. At the higher elevations, continued rain at the height of the monsoon has the same effect in checking the flush, for the time being, as a long continuance of sun has in the lowcountry. Perhaps a good thing: for, with us the bush has no wintering, and the only rest that of a 10 lb plucking, instead of a 21 lb.

Site and Lay of Land.—Gently undulating land, for choice, is the best; but I have tea on steep land, doing as well as that on fairly flat undulating land. In fact, any land that is most suitable for coffee is most suitable for tea. In our new districts especially, we find our fields at the higher elevations making wood freely but even at the best of times not giving much fruit, where we have coffee making most wood, there will our tea do best. In my experience I have had poor thin coffee pointed out to me as being suitable, *only for tea*. I say no; if we are to expect tea to pay, we must not pick out our thinnest, weakest,—because washed coffee, as being the most suitable site, but our free-growing leafy coffee, that from either a bad aspect with good soil (and we often see this) or from too high an elevation, has always persistently run to wood which we call leaf, in tea, with such coffee there, need be no hesitation in at once planting it up with tea. Again we have coffee that in the good old days has borne heavily, but that has now ceased to bear (temporarily or not, is beyond human ken) if we except occasional patches. *If the soil has not suffered from wash* no matter what the coffee may have borne in the past, tea can take its place and flourish, as it has that in the soil to give it a start, and it can seek for nourishment far deeper than the coffee has ever reached. To sum up on this most important point, do not let us waste time and money on a coffee estate trying to grow tea, where we have found coffee will not make wood, though we may do so, where our coffee, although now bad, has been good, in point of crop, provided the soil has not suffered from wash. Ridges and washed faces will be more profitably planted with aloes which we may grow with other products with profit, or mana-grass to keep out the weeds, than with tea. These remarks do not apply to Lower Ambegamuwa Yakdessa, &c., where tea is *flourishing*, but where coffee would not exist but to our true coffee districts.

Land at 4,000 feet to 5,500 feet that has failed in cinchona, provided soil and climate are suitable, will grow good tea. I have now tea $3\frac{1}{2}$ years old on land that I planted up four times with cinchona (both officinalis and succirubra),—and that failed completely, although no expense was spared in the opening and planting of it,—doing as well as could be wished. Again, I have tea doing well on abandoned coffee land that was cleared and planted $7\frac{1}{2}$ years ago with cinchona—which died out at 3 to 4 years. Elevation, in both instances, 5,000 feet and over. I have tea also, doing well, in land that was under cinchona for ten years.

Although tea does well, remarkably well, up to 5,600 feet in my own experience—and I have had figures shown me,—proving that tea, at over 6,200 feet gave, at 4 × 4, 400 lb. per acre at 6 years old, it does not follow that all and any land, at these elevations will give the same results. The higher we go the better our soil must be. We must be rather dry than wet not absolutely without rain for any length of time; but this we need not fear near our mountain tops; and the more shelter from the monsoon winds do we require. I will treat further down of the yield per acre from tea at the lowest to the highest elevations, and will now enter on *seed, nurseries, opening and planting of tea, its cultivation, and manufacture.*

SEED.—The greatest care must be taken to ascertain the seed you obtain is from the highest class hybrid, as with a poor jat, neither care in the manufacture nor cultivation can make a good liquoring tea, or give a profitable yield. Making allowances for poor plants, accidents, bad plants, and the having ample plants over for supplies, I calculate on one maund of 82 lb. for 6 acres planted 4 × 4; a maund of locally grown gives from 27,000 to 33,000 seed according to the time that is allowed to elapse in weighing after husking; the sooner the seed is in the ground after gathering the better.

NURSERIES.—Choose the site as near a stream as possible, for the sake of water. Let the land be as flat as possible, make your beds 5 ft. × 20 ft. with 18-inch walks (which act as drains) between them. If you are going to plant out at six months from seed, sow your seed 2in. apart every way. I find a very useful little tool for this is one I made many years ago for pricking out cinchona—a flat board, with handle on the top and pegs—50—underneath, any required distance apart, press the board, the pegs being underneath, on to your prepared bed, and you have it marked out in fifties to the distances apart you wish to sow your seed. If you are going to plant them out at 1 to 2 years 4in. × 2in. or, if space will admit, 4in. × 4in. apart; sow $1\frac{1}{2}$ inches deep, if no shade. If your plants are to be forced to save a season, manure your beds, sow 2in. × 2in. apart and 1 inch deep, shade with flat tats of jungle stuff 18in. to 2 ft. above the bed and water freely twice a day. You may begin to remove the shade by degrees, as soon as the wood at the collar of the plant hardens. Unless it is necessary for you to save the season, do *not* manure, nor pick out too good soil, as plants grown in better soil, than it is intended to plant them out in, suffer a check from their first start in the clearing. Give your nurseries time; do not dig your beds more than 6in. to 9in. deep, or the tap root, always unmanageable, will run deeper than ever. Every tea garden must keep up a nursery for supplies, which is a work we have to attend to every year. Stumps are best for supplies, and should be at the least two years old; even up to four, a permanent nursery can be kept up in *poor* soil sown 3in. × 3in., and the strongest plants taken out for supplies.

LINING.—In fairly good soil, 4 feet × 4 feet is the best distance, in poorer soil 4 feet × by 3 feet, on weak soil, or exposed faces 3 feet × 3 feet. It is as well to have 4 feet between the lines, as each line is almost a thoroughfare, from the number of times the pluckers have to move along it, as well as weeding contractors, in the course of the year, and the proper growth of the laterals is in a great measure stopped, if the pluckers have to *force* their way through too much; and in any ordinary fair soil, at a nearer distance than 4 feet between the lines, no light or air can get at the soil or through the bushes themselves, and they become towards the middle of the season an entangled mass of unhealthy wood. Therefore although 4 × 4 does not suit the coffee lines in any way, if the tea is to be planted through it, to eventually the extraction of the coffee, (when tea is one year old,) it is better to spend a little more money in lining than to try and suit your lining to your coffee lined, presumably 6 feet × 6 feet.

HOLING.—If for plants at 6 months or 1 year from seed in coffee or in new land 9 in. × 9 in. will do well. If for stumps in coffee or new land 18 in. × 18 in. If seed or germinated seed is to be sown at stake, *in coffee*, loosen the soil with the ordinary fork; this is better than holing; as we are all aware, the coffee roots soon find their way into and fill a hole in which the good surface soil has been scraped, to in this case the detriment of the seed: the same holds good with regard to manuring a young seedling which I have heard advocated in coffee.

PLANTS AND PLANTING.—The best plants are those at 6 months from seed, as they do not suffer the same check that a 1-year old plant does, and equal it in growth at 12 months from planting out; have not such unmanageable tap roots, and stand sun better. Will do with shallower holes, cost less to plant, and have a better hold of the ground at 12 months. The best of all 2 to 4 years old stump-roots of which at this age are woody, will stand being broken, in fact cannot be raised from the nursery (which should be in poor soil) without breaking them. They should be stumped as with coffee at 6 inches, and have roots that will comfortably fit into an 18 inch hole, which they require. In fair soil a stump can be topped at 3 feet in a year, and regularly plucked at 18 months onwards, giving a fine spreading bush.

SEED IN SITU has its advocates. Its advantages are cheapness in sowing out, and the good hold it gets of the ground, an advantage in windy sites. Its disadvantages are, on any *large* scale, greater first-outlay in seed, as from two to three seeds are required at each stake, the liability of its being smothered (as a seed) by wash. Insect enemies, weeders (more especially among coffee) scraping off, unawares, the young shoot as it comes above ground, being trodden on by worker among coffee; many failures, therefore an extra cost in supplying, showing an uneven field; or again three seeds all coming up at one stake and the cost of removing two, but which of course come in useful for supplies. Also a great loss of growth for the first year in coffee by being shaded by it. If you have no insect enemies, notably the black grub, which nips off the young shoot just above the ground, and it is desired to sow in situ, germinate the seed first and then one seed will suffice at each stake, and, although great care must be taken in sowing, I have found that even if the root germ is broken or wounded it throws out a bunch of rootlets and no harm happens.

STAKING.—This is not generally thought necessary. However, I consider it *most important*; and wherever we have enough wind to have made it necessary to stake our coffee, it is there necessary to stake our tea, up to 2 years old certainly, and sometimes even up to 3 years of age—a stake driven straight through the middle of the bush without tying will do at 2 to 3 years; at 1 or 1½ years, it must be tied. Aloe tape is best for this.

TOPPING.—First topping should be done at from 15 months on aspects affected by the S. W. winds to 18 months—3 feet is the best height, or at lower elevations or on exposed ridges 2 ft. 6 in. to even 2 ft. In topping the coolie has a stick of the desired height which he should place in the middle of the bush; the only care necessary is, to see he does not gather up a bunch of branches in his hand, to cut at one operation, but cuts each singly as it grows; the result will be a perfectly flat surface across the centre of the bush, with many young laterals round the bush untouched, which will soon reach the level to which we have topped; when they and the topped part, begin to run up, all should be nipped back to the second leaf below the bud to keep as flat a surface as possible giving, say at 6 months later or at 2 years of age, a bush with a fairly flat surface which will have reached 3 feet 6 in. to 4 feet in height. This very slight plucking after topping must be carefully done, only plucking those shoots that show an inclination to climb, so to speak; the plucking, with the topping, is necessary to force the lower laterals up, and keep your bush down and so form *surface*, otherwise, the bush will grow up somewhat in the shape of a poplar, and surface be lost for years. This plucking comes in useful in teaching your labour plucking and manufacture, and will eventually pay its cost in increased diameter of bush, and, therefore, increased yield.

PRUNING.—This is a most important work, and in Ceylon must not be too severe, yearly; more especially, if your bushes are topped early. It should take place from June to August, in any part of Ceylon, perhaps July is the best month. There are 3 ways of pruning:—1st, with a flat surface; 2nd saucer shape, *i. e.* hollowing out the centre; and 3rd, hacking down the bush. This last is murder, so I will pass it by without further remark. Saucer shape pruning does well for a time, but inclines to too matted a growth in the centre of the bush, which leads to too heavy a pruning yearly, more costly, and bad eventually for the bush. I have no doubt myself that pruning with a flat surface is best, so I will only treat of this mode.

When our branches *after* topping have reached up to say 3ft 6in to 4ft, having been kept down to this by plucking at 2 to 2½ years of age according to whether the planting was done in the N. E. or S. W.. (I am referring to tea at from 3,000ft elevation upwards), they should be again cut to a level surface at 3ft 3in, or if topped lower, as explained above, 3in above the topping. Any thin whippy branches trailing on the ground should be cut off close to the stems with a clean cut; and this is all for this year. Next pruning season, when our bushes will be 3 to 3½ years old, they should be first topped to 3ft or 2ft 6in according to elevation of garden, with a flat surface, all cross wood (*i e.* branches growing *through* the bush) and all white barked whippy branches, wherever growing, should then be cut, off with a clean cut close to the main stem or branch, and all growth encouraged outwards and upwards. No laterals should be cut back, except those growing into the bush which, as I have said, are to be entirely removed, but every branch should be topped or nipped back whether it has reached up to the limit of growth allowed, viz., 3ft or 2ft 6in, or not, thus we have given our bushes their first real pruning, and have got them into shape, which, with very little pruning they will keep for 4 years. Our procedure yearly for 4 years is then as follows always keeping a flat surface:—1st year, our bush being 4 to 4½ years old, top at 3ft 3in; 2nd year, at 3ft 6in; 3rd year, at 3ft 9in; 4th year to between 3ft 6in and 3ft 9in; or if topped at 2ft 6in, rising 3in yearly, keeping as much *red* wood as we can and removing *each* year thin white barked whippy branches, and cutting out all crow's feet from the surface, caused by plucking, leaving not more than a single fork on each branch at the surface; 5th year, cut down to 3ft or 2ft 6in at lower elevations or just below the original cut, and proceed as before. Thus low topping and heavy pruning is best done every 5th year. At our higher elevations, say from 3,500ft upwards, we can top our bushes far higher than at the lower elevations, and so get increased surface; the flush does not run up from the bush in the same manner it does lower down our limit here, however, should be at the outside 3ft 9in.

Exceptions.—Some bushes sulk, either from overplucking or from bad wood, or from some other cause. These should have the knife applied freely either by being cut down to 18in or by removing, with the aid of the same, one or two of the main stems in the centre, cutting down the outer growth as well, to 2ft or 18 inches, the centre thus opened out will send up a new growth. These bushes should not be plucked till they are well up, say to 4ft, when they can be plucked and then topped with the knife to 3ft.

Plucking.—This again is a most important work and requires close supervision. As a rule, plucking can be begun at 30 to 40 days after light pruning, I am speaking of coffee zone teas, be it remembered, and should not be begun till the bud with opened leaf attached, and half the next leaf, can be plucked at one operation *leaving on* one or sometimes two fully formed leaves to carry on the young shoot. The shoulder of the half leaf plucked remains on, and protects the eye at its base which in its turn throws out a shoot. Shoots, according to elevation, will measure 6in to 9in long *before* the first plucking, after pruning, takes place. In after plucking, a good deal depends on the number of leaves on the shoot. If, with the bud and its partially opened leaf, we have four full leaves, then I should pluck at the second leaf down, (leaving on the shoulder of this leaf, which protects its bud, and will probably give red leaf if removed,) at one operation, and again half the 3rd leaf at another operation, leaving one fully formed young leaf on the shoot. Towards the end of the season, when the bushes are well up, I would act as above, only plucking at the 3rd leaf, leaving its shoulder on the stem, and thus removing at one operation a half leaf and the shoot consisting of two leaves and the bud. One simple rule in plucking is, to avoid having a bare shoot without a single leaf to help it on. As in most things a practical lesson is best in plucking. As for the number of days in which it is necessary to go round the garden, I learn at a low elevation, it is considered necessary, according to the time of year, to get round in 7 to 10, up to 12 days at the longest. At high elevations, I have found in my *best* months, I should get round in 10 to 12 days to keep pace with my flush and, again, in 15, to, in the very cold weather December to January, 20 days. I do not think any hard and fast rule should be laid down, at any elevation, as to time. It is for the manager to watch his flush, and wait on it, *just* long enough but no longer and not to rush violently round his estate in a given number of days, which *must* lead to over-plucking, which means a reduction in yield sooner or later, although perhaps higher prices, for the time being; the benefit of this is also in a way nullified by a smaller outturn.

My average runs this season, from in my worst month, 10 lb. up to 29 lb. of leaf per coolie, including children. Some of my best pluckers have brought in from 36 to 47 lb.; in ordinary months, I average from 20 to 26 lb. My plucking last season 1881-82 cost 5 3-5ths cents per lb. of tea. This season it will cost 6 cents. Leaf should be weighed in twice, daily, at midday and at knocking off time; it is best plucked into the ordinary cooty sack, and emptied into cane or bamboo baskets of the following dimensions, to avoid any chance of tight packing:—2 feet high, 18 inches across bottom, by 1 feet across top. Cane baskets cost me 62 cents each, bamboo 25 cents to 37 cents, but cane are the cheapest in the long run, and nearer the cane country than I am would probably run from 37 to 50 cents each. Leaf must not be pressed down in either cooty sack or basket. Each basket is best kept by its owner in the line he is working in, the cooty sack should be repeatedly emptied into it to avoid any risk of fermentation. As soon as weighing in begins, leaf should be removed without delay to the withering shelves. Both baskets and cooty sacks should be taken in after the last delivery, or the coolie may use them to carry bazaar stuffs which may taint the leaf, and in any case they get smoked in his lines. *Bangy* tips, *i.e.* a hardening of the bud and stoppage of growth, should always be plucked, if the single leaf of which it consists is soft, it can be utilized, if not, it should be thrown away. It is as well to take the opportunity of any small plucking to nip off all bangy, the next eye will then nearly always throw out a free running shoot.

Withering.—The most simple and best shelves for this are formed of a framework of reepers, covered with sacking,—6 feet long and 3 feet 4 inches wide, the reepers forming this should be 2½ inches wide by 1 inch thick; it takes 1½ sacks to cover this or Jute-Hessian forms a good cover. It is most convenient to have 12 of these shelves hanging at 6 inches one above the other. The reeper forming the front and back of the frame should project 1½ inches; these projections are rounded off, and at the back are let into holes cut in an upright post to fit them; in front, the projecting ends serve to hold up the shelves by fitting into knotted loops 6 inches apart in ropes, suspended from the roof. When it is desired to empty them, it is done by simply pulling out the ropes at each end, when the shelves hang flat down on their hinges, throwing their contents on the floor; the upper shelves are reached by the coolies who lay out the leaf to wither, by 3 legged stools 3 feet high. Leaf should be spread as thin as posssible and turned over once during withering—a shelf of above dimensions 6 feet × 3 feet 4 inches, holds very thinly spread 2 lb. of leaf, or at a pinch it will wither safely up to 4 lb., but not more. Say we put on 3 lb. in full plucking time, we require about 6 feet per lb. of leaf.

Leaf is properly withered, if, when held tight in the hand it does not crackle, and keeps the shape into which you have pressed it; properly withered leaf is best told by touch, which experience gives us after a time. Leaf to give a good make, that is twist and colour of infusion —copper colour—should be well withered, soft to the touch, not dry or crisp; underwithered leaf will not give a malty liquor, and the larger leaves (souchong) break in rolling, probably lessening the value of your broken pekoe, nor is the make so good as with well-withered leaf.

Rolling.—Rather overdo this than underroll; when leaf is properly rolled, it shows a good even twist, is very soft, and gummy to the touch, any liquor that exudes during the process of rolling should be mopped up by the leaf, now called *roll*. In hand-rolling it saves tip, if, when the rolling is half finished, the leaf is sifted through a No. 4, that which remains in the sieve is rolled separately, that which comes through *lightly* finished off. A man can take 2 lb. of withered leaf to roll at one time, and it takes him 20 minutes to finish it.

Fermentation.—After your leaf is sufficiently rolled, break up the roll well, so as to have no lumps in it and place it lightly in saucer-shaped baskets of bamboo, or cane 18 inches wide by 6 inches deep; these again to be placed inside a sack to ferment. Each basket holds about 12 lb. of roll—no actual time can be laid down for fermentation, as it all depends upon the day or time of year. In cold weather at 5,600 feet, I have waited for 6½ hours for it to ferment, although my house has been kept at 90°. Again, at low elevations, I have seen roll properly fermented in 20 minutes from rolling. As far as time is concerned, at high elevations in ordinary weather, I find it takes from 1½ to 3 hours. Machine-rolled ferments quicker than hand, an advantage in favor of machine. Roll is properly fermented when it shows at a *first* glance a bright new copper color. We must not in making this test, examine the roll too carefully as, if we do, we will find almost as many green as copper-colored leaves; the *first* glance on taking up a handful must decide us. As a rule, we should ferment up to our pekoe-souchong and let the rest take care of itself, if in doubt, underferment rather than overferment: overfermentation may cause the tea to be altogether sour, and in any case gives a dark-colored flat liquor, with dark dead-looking infusion.

For the first two or three rounds after pruning, our leaf will not give us a very bright infusion, and there is no use waiting on the fermentation to try and get it; all comes right as the wood matures.

Having arrived at a proper state of fermentation we should hand-roll lightly again, even if machinery is used. Coolies employed in the factory, firing, withering, &c., &c., are sufficient to do this. It is necessary, as it inclines the roll, opened more or less by fermentation, to take its twist again as it is being fired, and it also ensures the whole being thoroughly well separated, before being placed in the firing trays.

In Firing.—Over-charcoal the bottom of the tray which is covered with 24 to 26 brass mesh should be 21 inches from the fire grate which is again 9 inches above the level of the floor, or the stoves are from the level of the floor to the top 30 inches high, 3 feet wide, at the top inside measurement, sloping to 1 ft. 2 inches at the grate, which rests on ledges 1 inch wide, making below grate to floor level 1 ft. wide. It takes 40 minutes to complete the firing of each tray of roll, as thus:—

Each tray 3 feet square inside measurement will hold 5 lb. of roll, which when fired equals about 2 lb. of tea. The tray should be constantly removed from the stove, and the contents well turned (on no account should any turning or fingering be allowed when the tray is over the fire, as dust drops through, burns, and smokes the tea at once) after about 15 minutes drying, being constantly turned the while, the partially fired roll should be sifted through a No. 8 sieve; that, which remains in the sieve is again placed over the stoves, being as before constantly taken off and turned, and in 15 minutes is ready to be again sifted this time through a No. 6. It then takes 10 minutes to finish off, being constantly turned the while The siftings are left on the table till all teas are finished firing: these represent broken teas, broken pekoe, pekoe No. 2, and dust; and are finished off over the hot stoves by the expiring fires—this takes about 10 minutes. Experience alone can tell us when teas are properly fired, they should feel crisp to the touch, and when bent resume their shape. As each tray is fired off, the tea should be put into a bin, for the purpose, and exposed on the tables as little as possible.

Tasting.—The first thing the next morning as sorting begins, the "make" of the previous day or night should be infused and tasted carefully; we then know what to do with it, as we should keep our classes of different values (or grades) separately, and a good break may be spoiled by having one or two days inferior make mixed with it. Accidents sometimes happen also, such as overfermentation, if there is much night work, and this can only be detected by infusing the leaf; burning also. No tea should be packed away therefore (mixed with the bulk) till it is tasted and faults, if any, discovered, to be rectified in the future.

SORTING.—This is best done by women—one woman to every 100 lb. of tea. Red and large flat leaf is first picked out, and the tea is then passed through a No. 7 or 8 sieve, according to the size of leaf, *i. e.*, tea of any particular day, that which comes through is next put into a No. 10 or 12—the higher the elevation the smaller and more wiry the make—that that remains in the No. 7 or 8 must be *lightly* broken through by hand; and what still remains in (very little) is congou and black fannings; that broken through is broken tea and broken souchong, which is mixed after removing the dust and broken tea with the pekoe souchong pure, remaining in No. 10 or 12, and the mixture classed as pekoe souchong. We then have left to deal with, pekoe, broken pekoe. broken tea and dust, all of which has been passed through a No. 10 or 12—to extract as shown our pekoe souchong. This we *again place* in No. 10 or 12, *lightly* sifting it, to remove broken pekoe, broken tea and dust, leaving the pekoe in the sieve. We then with an ordinary rice winnower ("shologoo"), remove broken tea and dust from the broken pekoe, the broken pekoe remaing in the winnower; the broken tea and dust we then put into No. 24, passing the dust through. To separate tea dust from pekoe dust, we can use either muslin or the winnower again. We have now sorted our teas into the following classes:—1. Pekoe. 2. Pekoe souchong. 3. Congou (and fannings with large unrolled leaves). 4. Broken pekoe. 5. Broken tea, tea dust and pekoe dust. I do not count as a make nor yet fannings; the latter may, in most instances, unless the plucking has got ahead of you, be mixed, after breaking, with the broken tea. Fannings we break through a Reid's breaking machine, turning out a reddish make about twice the size of our broken tea, which, if poor in liquor, we ship separately as fannings; or, if showing a fair liquor and not too much red leaf, mix with our broken teas. Of congou, fannings, and the dust, we have a very, very small percentage each day. The numbers of sieves we require are as follows:—No. 4 for sifting green leaf in rolling by hand, to give more "tips." No. 5 useful sometimes, when plucking has got ahead of you; and Nos. 6, 7, 8, 10, 12 and 24.

PACKING.—As, according to the new rules, bulking on the gardens is now accepted in London and our tea saved from being all turned out, provided tares run pretty equal, I recommend each class of tea to be packed as soon as sufficient can be bulked to make 25 half chests of 50 lb. each. These should measure 15 × 16 × 16, and tare, on an average 18 lb. including lead, do not require hooping, and represent one cooly load. As soon as we have packed all our teas to complete that particular break or shipment, (which ought not to be under 5,000 lb. nett I think, and the more the better), we may add our dust, fannings, and congou which will only amount to a half chest or so of each. These teas will run from 5d. per lb. to 10½d. and are as well shipped, if a half chest can be made up with each break from which they have been made. I find a half chest takes 3½ lb. of lead and 1¼ oz. of solder—or cost of half chest with lead-lining, &c. ready packed cents 3·500 per lb. of tea. Whilst on this subject, I think it would be of great advantage to us all if we could arrange to use one uniform package, and no package can be more convenient for us than the half chest as above—the majority of us have to transport our chests to the main road on cooly's heads—this half chest represents just a full cooly load. Whereas a chest takes two coolies to carry it, has to be hooped—a costly work—and there is all the worry of rope which is constantly stolen, and poles, to carry it; therefore, the saving in draft in London (under ½-a-lb. of tea) and the slight difference in its favor in cost, in the first instance, is more than counter-balanced by the cost of hooping and transport, with the accessories of poles and rope. I trust, therefore, that those interested in tea in Ceylon, will from this year,—our first great start almost,—arrange to use one uniform package which shall be peculiar to Ceylon, and become known as the *Ceylon chest.* This for the bulk of our teas, but we may also pack occasional breaks in boxes; these should weigh under 28 lb. gross and thus save draft, say 10 to 15 lb. nett. Any especially fine make could be shipped in these, forming a small break, and will often fetch fancy prices. Brokers at home accept both half chests and boxes, so there is no innovation here. A coolie can pack carefully, 15,—shall I call them Ceylon-chests?—in a day.

I now come to yield and cost per lb. f. o. b. at Colombo.

YIELD.—In my own experience, at 4,700 to 5,600 lb. elevation, with fair soil, ordinarily featured land, as our hill country goes, fairly steep, I find the yield has been as follows, and I do not consider I am yet in full bearing:—

At 2½ to 3½ years old 165 lb. tea per acre.
3½ to 4½ „ 292 „ „ „
4½ to 5½ „ 262 } pruned heavily in July last season,—season ends in Sept.—to shape bushes which explains shortness of yield.
5½ to 6½ „ 450
6½ to 7½ „ year finishes end of Sept. 700 lb. per acre will be exceeded all round.

Bushes from the first have been under-plucked.

Again, I have yield given me at an elevation of 1,800 to 2,500 feet.

Average age 3 years 224 lb. per acre.
4 „ 380 lb. „
5 „ 315 lb. „

And please note, on this garden of over 200 acres in extent, there was a considerable loss of leaf, from allowing large areas to grow up during these three seasons, for seed, from which little if any leaf was plucked; had the full acreage been plucked, the average would have reached 100 lb. more per acre.

Again, I have given me figures of an estate, at an average of 2,500 feet elevation, 400 lb. per acre at 3½ to 4½ years old.

Another estate, at an average of 500 feet, gives for the first *six months* of this year, January to June, being in June 4 years old, 400 lb. per acre, the estimate to December is 600 lb. per acre; and will probably be exceeded. Again, an estate from 100 to 400 feet, showing an avarage age all round of 4 years, gives 430 lb. per acre. This estate is widely planted 5 × 6 and 5 × 5, and had it been 4 × 4 would have given a larger yield, as bushes do *not* cover the ground; but 430 lb. at 4 years is good enough, you will allow.

I have again many instances of estates, up to 3,000 feet, giving 400 to 600 per acre up to 5 years of age; and at 4,000 to 5,000 feet, from 300 to 420 lb. per acre.

We have all heard of Gallebodde and its 800 lbs. odd per acre; also of the older portion of Dunedin with its 730 lb. per acre; a portion of one of my fields 3 acres in extent has given me at 7½ years 1,200 lb. per acre at 5,500 ft. elevation, well sheltered with fine soil—an exceptional field, I will allow. These figures are fairly representative of tea in Ceylon at this date, and not *one* of the estates mentioned is in full bearing. What *will* the yield be when we are in full bearing, from 8 years of age upwards? We shall want lots of withering room, gentlemen, so be prepared in time.

Young as we are, and in the face of these yields at 6 years of age and upwards I feel perfectly safe in estimating an *average* yield of 400 lbs. per acre from tea in the coffee zone and above it, say from 2,500 to 5,700 ft. in sheltered situations and in saying 5,700 ft. I do not wish it to be understood I draw the limit even here, but the figures I have had given me above this elevation viz. at 6,300 ft. are only from a very small area under tea, which however gave at 6 years old 400lb per acre at 4 × 4. For lowcountry teas, that is teas at from 2,500 down to sea level, at 6 years old and upwards, I shall be very much surprised indeed if they do not show an *average* yield of 600 lb. per acre. These estimates gentlemen, may seem excessive, looking at the average yields from Assam and India generally, but compare our yield in this our very infancy with that in India and you will find we can even now show an average, from estates at 3½ years old up to 6 which will more than double theirs. Inclemency of weather does not affect us in the same way in which it does our Indian fathers, as we have 11 months in which we pluck. If one month is too wet we benefit all the more when the sun shines again, as we have lots of time ; if we have a spell of dry weather, on the other hand, this again is sure to be followed by rain, when we at once make up any loss.

Cost per lb. F. O. B.—I have to thank many friends for furnishing me with cost F. O. B. at Colombo and choose the following which are representative of all and may be relied on. In all cases, the tea was manufactured without the aid of machinery of any kind.

450 lb. per acre	cost 36 cts. F. O. B.	
700 ,, ,, ,,	30 cts. F. O. B.	Including cost of upkeep of young tea not in bearing.
400 ,, ,, ,,	40 cts. F. O. B.	
430 ,, ,, ,,	29 cts. F. O. B.	

If we take the average of the above 4 estates, we have say 495 lb. per acre, hand-made, costing 34 cents F. O. B. at Colombo ; London charges including freight are under 2½d ; but for all practical purposes let us say 2½d, the above teas at an average price of 1s 2½d, and this is not a high average, leaves us 1s nett, or at 1s 8d per rupee, 60 cents ; a profit of 26 cents per lb. at 495 lb. per acre, say R128·70 profit per acre.

Whilst I am on the subject of yield I trust we in Ceylon will talk of *lb.* per acre and not *maunds* ; our tea is sold by the lb. what then can we have to do with maunds?

With regard to plucking and manufacture I find its actual cost is as follows without machinery :—

Plucking (including baskets and cootie sacks)	cents 7·000
Withering, rolling, firing	cents 6.500
Sorting, refiring, packing (in half-chests) including lead solder and chests	cents 4·000
Total ...cents	17·500

The rest of the works depend upon circumstances, and in many instances can be done cheaper with regard to some of the items than I now show. Take for example a garden of 150 acres, bearing at 400 lb per acre.

	cents.
Supt. including Factory overseer at R20 per acre, cost per lb of tea	5·000
Weeding at 87 cents per acre R10·44 per acre per annum	2·610
An ordinary pruning at R6 per acre	1·500
Nurseries R225	·375
Supplying at R4·50 per acre	1·125
Roads and drains at R3 per acre	·750
Tools say R150	·250
Transport Tea from estate f.o.b.	2·200
General Transport	·400
House and tappal coolies, medicines, stationery, contingencies, and export duty and medical aid	1·540
Upkeep of buildings at R450 per annum	·750
Manuring 30 acres per annum at R100= R3,000	5·000
Total estate expenditure per lb.	21·500
Add cost of plucking and manufacture as above	17·500
Total cost 400 lb per acre f.o.b. at per lb tea *hand*-made	39 cents.

Value of 400 lb tea at 60 cents per lb *nett*	R240
Less cost as above at 39 cents per lb	156
Nett profit per acre	R84

Or if no manuring is done R104 per acre profit. Manure of course eventually pays for itself by *increased* yield.

I believe the above to be a liberal estimate, it is at all events, one higher than I should allow for the working of my own garden, which is in perfect order. R150 per acre for 400 lb tea is liberal enough, without machinery. I will now show my experience of the benefit machinery gives us.—On a coffee estate with *water wheel already erected* a Jackson's universal roller should be purchased, for even only 25 acres of tea, as I think the following figures will prove. I take 400 lb. of tea per diem as my standard as the following machinery works up to it, and this machinery is sufficient for a garden of 150 acres giving up to 500 lb per acre.

One Jackson's Universal Roller fixed ready for working	R1.200
One Davidson's Sirocco	1,300
To drive the roller a 16 to 18 feet water-wheel will do, or if no water power a 1½ H.P. engine costing say on estate	1,500
A second Sirocco is most useful and if means allow of it should be purchased, so I will add it, although not absolutely necessary	1,300
	5,300
Add a sorting machine at a cost of say	950
	R6,250

If the garden is to be increased in area it is better and cheaper to purchase at the first Jackson's larger roller called the "Excelsior" exactly the same as his "Universal" only working up to 8,000 lb. of leaf per diem, instead of 2,000 lb. and costing at the garden about R2,250. This with 4 Siroccos will work up to a 300 acre garden, and requires 6 H. P. to drive it.

Working, however, with our "Universal" at 400 lb. of leaf per diem, costs us as follows :—

	cent.
Plucking per lb tea.	7·00
Withering, Rolling 1,600 lb. leaf = 400 lb. tea at 5 *coolies*, say.	·41
Firing ditto at 3 coolies *including* firewood, say.	·25
Sorting *by hand*, refiring, packing in half chests, including chests, &c. &c.	3·50
Total cost of plucking, and manufacture by machinery	11·16

or a saving per lb. of tea of cents 6·34 as against hand-rolling and charcoal firing. I have not as yet worked a sorting machine, but I believe with two coolies to attend to it (driven by water or steam,) a Jackson's or Ansell's will sort into four classes at the rate of 400 lb. per hour. Let us for example, take 5 coolies per 1,000 lb. including the picking out of red leaf, its cost is exactly half that of hand-sorting or cents 0·165 as against cents 0·33 per lb. or say we have *a saving of* 6½ *cents per lb. of tea*, with all machinery complete. This at 400 lb per acre yield, represents a saving of R26 per acre or brings up profits as per former estimate to R100 per acre, or, if no manuring is done, on a young garden, to R130 per acre. From these figures you can work out the profits at any yield per acre; cost of manufacture is always the same, except when machinery is used, when the nearer we work up to its full power, the cheaper are we able to manufacture our teas, as there is then no loss in coolie labor at machinery; cost of the other works is increased or lessened in proportion as the yield is lower or higher. In further reference to machinery, in making any quantity of tea per diem the machine roller will turn out a better make than can be obtained by hand-rolling. One or two picked coolies might roll better ; but when we have from 20 to 80 coolies to attend to, machine rolled tea will carry off the palm. Sirocco-fired teas, as I have myself tested, are brisker and fuller than charcoal fired teas. I find my Sirocco @ 275° will fire off 100 lb. of roll per hour, equal to about 45 lb. of tea ; my "Universal" rolls the equivalent of 200 lb. of green (unwithered) leaf per hour or 150 lb. of withered leaf in 75 minutes, taking in 37 lb. at a fill, which it rolls in 20 minutes, and we have to allow 5 minutes for emptying and refilling. If on a coffee estate you have not sufficient power already erected to drive the "Excelsior" roller (6 H.P.) I can, for *fine* leaf recommend Kinmond's Centrifugal, one of which rollers I also have. This requires only the same power as the "Universal," but will roll off 5,000 lb. of green leaf per diem, instead of only 2,000; its cost is about R1,700 on the garden. It will not roll coarse leaf well, so with one of these rollers you must keep up with your flush, its great advantage is its cheapness as compared with the cross action for amount of work it does, with the small power it takes to work it, (2½ H. P.) and with good leaf, the large amount of tip it turns out, although, where it can be worked, I prefer the large cross action (Jackson's) "Excelsior". To compare labour required to make 400 lb. of tea by hand and charcoal, with the number of coolies required to make the same with the Universal and Sirocco, I find the following :—

By hand-withering 1,600 lb. leaf	2	coolies
Rolling do	40	
Firing and charcoal	16	
Total for 400 lb. tea	58	

By machine-withering 1,000 lb. leaf	2	coolies
Rolling do	3	
Firing &c.	3	
Total..	8	

Saving in labour at 400 lb. of tea 50 coolies. This really represents a saving of $7\frac{1}{2}$ cents per lb. or the roller saves 37 coolies and the Sirocco 13 coolies at 400 lb. tea. To aid in working the Sirocco, I make any labor not carrying in leaf, carry in a log of firewood every evening, which one coolie can cut up for the Sirocco.

The Factory should be roomy and have as much light as possible. All green leaf, whether withering, or being rolled should be shut off from the firing, sorting, packing and store-room, or it collects dust, etc. Even with a Sirocco, we should be provided with stoves, ready for charcoal firing, in case of accident. Cleanliness must prevail from rafter to floor. Our coffee stores, when too large for our crop as at present, can be at a small expense turned into a suitable factory, a portion being walled off for our coffee crop.

Land can be opened, not including purchase of course, at the following rates per acre for the first year:—Jungle R80, patana R50, and coffee R40 to R50. Coffee should be uprooted when tea is at 1 to $1\frac{1}{2}$ years old, unless it has on it sufficient crop to make it worth while leaving it. Tea at three years of age will prevent coffee giving sufficient crop to pay, and will eventually kill it out, so the two cannot be grown side by side. Coffee, when uprooted, may be stacked with advantage for firewood or charcoal. We can grow *among* our tea to advantage, according to elevation, taking care not to overcrowd it, C. officinalis, (best of all, as it gives no shade to speak of, and thrives better among tea than in the open), small-leafed Robusta and Ledger, the upkeep is nil, harvesting being the only expense after planting. We can grow *with* tea to a *large saving of expenditure* in both, coffee or cocoa according to elevation. And let us aim, with tea as our mainstay to grow all the products the elevation of our garden will allow of, with it. "*Experientia docet.*"

And now, Mr. Chairman and gentlemen, I must bring this somewhat lengthy paper to an end. I have endeavoured througout to be as concise as possible, and have, necessarily, not been able enter into many minor details and "dodges" known to the tea planter. I trust, however, I have forgotten nothing useful, and that the practical experiences of a "Ceylon-grown tea planter" may, however lamely put before you, be of some benefit to you. We have all of us suffered during the past few years, but I can assure you, gentlemen, that I for one feel the turning-point is now at hand, and that never since the first coffee estate was opened in Ceylon has there been such a future as is now before us: *lasting prosperity* in our many products, among which coffee shall not be the least.

C. Spearman Armstrong.

Rookwood, 24th Aug., 1883.

Mr. Shand, rising to propose a vote of thanks to Mr. Armstrong for his paper, said that, as many had come from a distance to hear Mr. Armstrong, and as he saw signs of homeward movement in the room, he would ask them before they went away to join him in passing a cordial vote of thanks to Mr. Armstrong for the instructive paper he had just read to them. Mr. Armstrong was a *pure* Ceylon tea-planter; he had never been in India, he had carried out for himself a profession, and the practical paper he had read to them today was the result of several years of incessant mental and physical application, which they must be glad to hear were crowned with success. Those who like himself, had visited Rookwood, had seen how, step by step, Mr. Armstrong had conquered those difficulties inseparable from pioneering, and those who had not visited Rookwood at all events knew Rookwood tea, to which gold medals and other honors had been deservedly awarded. Long might Mr. Armstrong move among them to contribute to their instruction as he had done today, and to his own substantial advantage, as his paper clearly proved he was doing.

The Chairman briefly seconded the vote of thanks, and the meeting endorsed it unanimously.

Coffee and other Products.

The Chairman next read Mr. Kelly's resolution:—"That this meeting is of opinion, that it is expedient to introduce new products to all portions of properties unsuitable to the remunerative cultivation of coffee, but deems it of the highest importance to give the most careful attention to the cultivation of all good coffee, having faith in its profitable cultivation."

Mr. Kelly in speaking to his resolution said that, so much having been said on the subject, he would not refer to his reason for bringing it forward. It had been before them in print for some days, and they had had ample time to consider it and vote according to their candid impressions. He had now been out just twelve months after an absence of some six years and he thought he was competent to express an opinion. Having been constantly asked his views of the future of coffee on his first arrival he was always most chary of then giving an opinion, though from what he heard on his first landing he confessed he was agreeably surprised when he got upcountry. He remembered that he was addressing the Dikoya Association and therefore his remarks were confined to Dikoya coffee. He had known, and been connected with the district for 20 years, and he found on his return twelve months ago fields of coffee all over the district looking quite as well as when he left it in 1875. He did not, nor did any sane man, for one moment deny the ravages of leaf-disease, especially in wind blown portions of the estates, but he did say that there was still a very large quantity of coffee on almost every estate, comprising in the aggregate a large area which would well repay care and cultivation and still pay well. It was, in his opinion absurd, and far too early days to say that coffee was done, but let him read them a few figures from the Chamber of Commerce report for August 22nd for the commercial year ending September. He added one-twelfth for the month of September. Here we had a probable

250,000 cwt. coffee	valued at R40	f.o.b....	R10,000,000
7,000,000 lb cinchona bark	,, 30 cts. ₩ lb...		2,100,000
1,400,000 lb tea	,, 50 ,, ...		700,000
15,000 tons coconut oil	,, R330 per ton		4,950,000
13,600 plumbago	,, 85 ,,		1,150,000
4,780 tons copperah	,, 150 ,,		717,000
1,117,000 lb. cinnamon	... @ 50 cts...		588,830
			R10,205,830

or in other words, this, the shortest crop ever exported from this island was valued at only R205,830 less than all the other principal articles of export put together. He was therefore a rash man who would declare our old friend dead. While urging the conserving of all good coffee, he heartily advocated bringing in new products, especially Tea, after the very encouraging paper just read to them by Mr. Armstrong. He thought many had made a great mistake in planting cinchona promiscuously through their coffee in good and bad alike. He was satisfied from his own experience that it materially affected the yield of the coffee. He said to all, protect and care for your good coffee, you have many portions of your estate which from aspect or climate do not give you a profitable return in coffee such as south-west faces. Plant them up, plant them closer than hitherto with cinchona, tea, etc. and thus do not waste the return of your profitable coffee on the unprofitable, but go into other products. They had the experience of Mr. Walker, who had told them that during his observations he had never known so low a temperature as we have had for the past 18 months or so little direct sun's ray. They had the result of Mr. Bosanquet's experiments in manuring, showing that good Coffee would respond to cultivation with only a fair season. They heard Mr. Armstrong who had just told them that he would not sacrifice good coffee even for tea. Having had bad seasons they could but hope for better, and with them he was confident that good coffee would be cultivated to their advantage and profit. He requsted them to support his resolution.

Mr. G. F. Walker said, he had the greater pleasure in seconding the resolution in that he felt certain it would be carried by a large majority and he trusted would act as a counterpoise to the report of their last meeting which they had that day animadverted on. This subject had, however, been so thoroughly threshed out at the late meeting that, as many of those there to-day had been there then too, he did not care to again take up their time by stating his views at any length. But of this he was convinced, not only from his own observations, but guided also by those of others, that good coffee would certainly pay them well, and that, while they must replace all unprofitable coffee by tea or other products, it would be foolish in the extreme to abandon the good coffee which they certainly had on very many estates. There was no reason why they should be led away by a panic fear about coffee more than about any other kind of cultivation

Mr. Greig said he was at one with Mr. Kelly's resolution so far as it concerned the introduction of new products, but the part referring to coffee, while most carefully worded, he considered to be in a great measure misleading, especially backed up by the mover's remarks as to the general appearance and prospects of coffee in Dikoya. The opinion, then to be recorded by that large and influential meeting he considered, to be of vital importance, and coming from so important an Association, should convey, as far as possible, a clear and honest estimate of the future of coffee. As he considered the resolution fell short of that end, he proposed the following amendment:—"In view of the steady decline in the product on of our coffee, and the hopelessness of ever adequately combating leaf disease, this meeting is of opinion that it is unwise to place any confidence in coffee, beyond the immediate future, and that every effort should be made before leaf disease places us in the position of older districts to replace our coffee with tea, for which the soil and climate of this district are pre-eminently adapted." He doubted if he should ever have been bold enough to have brought forward this amendment, but for the able and highly satisfactory paper Mr. Armstrong had just read to them. After what they had heard as to the actual results obtained from tea at similar altitudes to theirs, he thought there could be no doubt as to the course open to them. With returns based on actual experience, shewing, after allowing for many contingencies such handsome profits as R100 at R150 per acre, they might well sigh for a taste of them. An opinion seemed to prevail in the district that it was a mistake to talk publicly of the downfall of coffee. He said that this was a great delusion and that with leaf disease as active and virulent in our midst as ever it was, if not more so!—with no prospect of improvement but the reverse, he maintained that the sooner all this was realised by those interested the better, and that as soon as it was seen that coffee was no longer to be depended on, then, with such a trump card as Mr. Armstrong had placed in their hands, to show, would capital come back to the country, and with it, the much needed prosperity, but not *till* then. They had nothing to lose but all gain.

Mr. Sholto Skrine said: that it gave him great pleasure to second Mr. Greig's amendment, which he considered expressed far better than Mr. Kelly's resolution the real opinion of this district. They ought he thought to be very grateful to Mr. Greig for bringing forward this amendment for, should the resolution be carried, it would he was convinced, convey to the public a totally wrong impression of the real sentiments of the district on this subject. He seconded it the more readily in that he felt sure it would command the votes of the majority of those present there that day, more especially as it could not fail to have the support of that member of their district of whom they were all so justly proud, he referred to their planting member. It might be prsumptuous in him to count thus confidently on his support, were it not for that able paper which he had read to them at their last meeting in which he so clearly expressed sentiments in unison with this amendment. In order to show that he was not speaking hastily or counting without cause on Mr. Shand's support, he would now read some notes which he had taken from his paper that bore on this point. After calling their attention to the three different crises through which coffee had passed, Mr. Shand continued thus: "Our crisis is more serious than any other crisis in that fall in prices and financial difficulties are temporary troubles which time adjusts, but the failure of our land to produce crops from a disease which we have no prospect of curing, is a far graver matter or would be were it not for altered circumstances. For many years indeed until lately, it was an accepted theory that it paid the European to cultivate coffee in Ceylon, that anything else would ruin him, and that when an estate ceased to yield coffee profitably, it ceased to be of any value. We have changed all this and have proved that tea cinchona, cardamoms, and cocoa, &c. can be profitably cultivated, and many of the most valuable properties in Ceylon are those on which coffee has been exhausted." He finally sums up his able paper thus:—"Those who have the opportunity of going about the country, of seeing tea, cocoa, cinchona and other things thriving where coffee has ceased to be remunerative, of seeing lands at Polgahawelle and elsewhere which a few years ago were considered valueless, giving promise of splendid returns, must agree with me that it is not yet noon in Ceylon, and I am sanguine enough to think that with care and energy, on the part of the planter and help and sympathy from Government extended to all classes, we shall tide over our time of depression and place the island on a firmer basis than it has ever been on before." This, he said, was the substance of Mr. Shand's paper, and they would, after listening to these notes, admit that he was not overconfident in reckoning on Mr. Shand's support. They would notice that there was no word of the coming large coffee crop of that next year, of which they were all so sick, but the future to which Mr. Shand pointed was the future of new products and a future which he was happy to say he thought they all believed in. He was he said one of the oldest members of that district present there that day, and he had had the advantage of seeing coffee in Dikoya both in its days of prosperity and now in its adversity. Against his will he had been forced to the opinions he now held, which were, that coffee, as a profitable cultivation, was now a thing of the past. In support of those views, he maintained that, if they were to take the three young districts of Dimbula Dikoya and Maskeliya, they would find it difficult to point out among all the estates they contained, a dozen on which, if they were to deduct from their returns the value of cinchona bark sold, the yearly profits would have amounted to as much as five per cent on their supposed value during the last four years, and he feared that in many there had been a clear loss. He admitted that there were two gentlemen present there that day who could boast a longer residence in the district than he could himself, and they appeared to hold views diametrically opposed to his own. He referred to Mr. Walker and Mr. Kelly. He thought the sanguine views of the first-named gentleman might perhaps, be explained by the fact that he was the fortunate proprietor of an estate in that favored portion of their district known as Bogawantalawa, where, if they were to credit all they heard, every prospect pleased, even coffee with short crops and leaf-disease. Mr. Kelly's views were perhaps more difficult to account for, in that he was not so favored locally as his friend Mr. Walker, being the owner of an estate adjoining, if not actually belonging to, that despised portion of the district known as Lower Dikoya. Mr. Kelly had, though been absent from the district for the past six years and could hardly be expected to see as clearly as those who had been on the spot the complete collapse in coffee which was now so evident to most of them. He had not said half that might be said in support of the amendment, and felt he must leave it to an abler speaker to put before them its many advantages, and on resuming his seat again called upon Mr. Shand to rise and support the amendment.

Mr. KELLY rose to make a correction. Holding the report of Mr. Shand's remarks at the last meeting in his hand, he objected to the construction put upon it by the last speaker. Mr. S. Skrine would mislead them by reading only a portion of Mr. Shand's remarks, but these must be taken with the whole, and he now begged to read them what that gentleman had said at an earlier part of his address but which Mr.Skrine had passed by unnoticed. The following was the para he referred to:—"I do not take the gloomy view, I think. There are on most places fields which will go on yielding profitable crops of coffee, and I do not overlook the fact that with the favourable blossoming seasons of 1876-78, *i. e.*, after 6 or 8 years of leaf-disease, many old estates gave bumper crops. I do not despair of their doing so again, but in all our valleys there is a certain zone in which coffee never has, and probably never will be cultivated profitably, and, on every estate, there is a certain non-yielding acreage which is hampering the better fields to maintain." Mr. Kelly thought this put a very different complexion on Mr. Shand's remarks, and he read this that they might see that the rendering as given by Mr. Skrine was not fair. The amendment proposed to them was a hedging. It was nothing like the old resolution, but the whole question was one of such plain common sense that he left it to them to decide.

Mr. SHOLTO SKRINE thought that it would have been better if Mr. Kelly had allowed Mr. Shand to reply himself to the remarks he had made on his paper which, he thought he was quite capable of doing. He was perfectly willing to admit the accuracy of Mr Kelly's extracts, but he attached little importance to them himself, since Mr. Shand, in summing up his paper and in drawing attention to the grand and prosperous future in front of them (which was to be brought about by the introduction of tea, cinchona, cocoa etc.), carefully omitted coffee as a contributor to that result, and his silence on that point fully justified the inference he had drawn from his paper. As he could not but consider that his rendering of Mr. Shand's meaning was the correct one, he again called on that gentleman to rise and support the amendment.

The Hon. J. L. SHAND thought that, if Mr. S. Skrine read the whole of his paper instead of a part of it, and did not mix up the present and the future, he would draw a different conclusion from it. The hon. member then proceeded to amuse the audience by paying some ironical compliments to the last speaker on his maiden effort, and, as an older speaker, gave him some useful hints for future guidance.

The HON. SECRETARY said the debate had been a lengthy one, and he would not trouble the meeting by noticing the aspersions that had been levelled against his brother by the hon. member. They amused the opposition and did not hurt him and it was very like pouring water on a duck's back. There were however one or two points both in the resolution and the amendment of which he should like to speak. The mover of the resolution staked his cause on the permanence of *good coffee.* Now, this was a very vague way of putting it, for there might be many gentlemen present who would like to know what *good coffee* is. They all knew what it used to be. But the days of 8 and 10 cwt. an acre were over, and they had to be contented now with a *good* crop of 3 cwt. an acre, and a *bad* one of 3 bushels. Perhaps they might consider this an extreme, or, as it was the fashion now to call it, a pessimistic view of the case. Very well then, he would be quite satisfied to take an optimistic instance. He would take Warleigh. This was an estate that had always paid and was paying still. His earliest recollections of Dikoya were in 1872, when they picked a crop of 10¼ cwt. off Warleigh. This had been preceded by a very good crop, and a very good crop followed it. But there was a great difference between crops of 4,000 to 6,000 bushels off 120 acres, and 2,000 to 2,500 bushels off 180 acres. He quite admitted that with these better estates it was a case of "facilis descensus Averni." But the fall of the tide was being very clearly marked, and even these better estates were already getting into shoal water. True, their weather prophet, Mr. Walker, had assured them that the tide would rise again with his barometer, and, if he could only adjust the weather *to* his barometer, it would be a very fortunate thing for the district. Unluckily their faith in his skill, as a meteorologist, had been somewhat shaken since their last meeting, when he had announced that the north-east monsoon had set in. But a better test of this weather theory would be to compare its effect on other fruit-bearing trees. He had been over a good deal of seed-bearing tea lately, both in the Kalutara district and at Nawalapitiya, and had noticed seed in every stage of development from the size of a pea to the well-matured pod. This was just what years ago used to be seen in coffee. They had their small spring crop in April-May, and their regular crop pickings began in August and went on into February. Now-a-days, what few berries there were on the trees were all of the same size, showing that it requires a special combination of the most perfect weather and the most perfect wood to produce any crop at all. Again, had they had no bad seasons years ago—1873 was quite as bad a blossoming season as either of the two last. It followed also the largest crop the district had ever given, yet the crops picked in that year on the same estates were as much as both this and last season's crops put together. These facts, he said, pointed to a conclusion to which there was no gainsaying. They had the fate of the old Kandy districts before them, and were within a measurable distance of the same rapids in which the older enterprise had been engulphed. They had Mr. Walker's stroke oar, coffee, labouring away with a sprung blade, and he thought the sooner they got his dead weight out of the boat and settled down to their work at tea, the better. They must remember that he said nothing against the *immediate future* of coffee, the prospects for which might be considered to be good on properly worked estates, but Mr. Kelly must be presuming on their better judgment when he asked them to commit themselves to a belief in its *permanence.*

Mr. KELLY.—I did not use the word permanence.

The SECRETARY:—The words of the resolution amount to the same thing. It would be out of place in him to offer any remarks on tea, but the new product had been fairly launched that day, and it was a good omen for its future that this had been done without a single sceptic note having been sounded against it. But he would have them beware of Mr. Kelly's resolution, and the overtures he made to tea. They were told to plant their tea on their blown ridges and abandoned coffee, and leave all the fat of their land for coffee, already with one foot in the grave. He would ask them if this was a fair or reasonable way of commencing the new cultivation. On the other hand, let them take Mr. Greig's amendment, and what was there in it that was in the very least objectionable? He would not do them the injustice of supposing that anyone there really believed in the permanence of coffee, but he was quite ready to bow to the feeling that it did n't do to call a spade a spade. Mr. Greig's amendment lifted them comfortably out of this dilemma, without committing them to saying anything that would sound very foolish a few years, nay perhaps a few months hence, to have said about coffee.

Mr. G. F. WALKER said they had had such a confusion of metaphors, that he was at a loss to know how to reply. The Secretary had alluded to him as a "weather prophet." He wished that he were one. But unfortunately he could only record what had occurred in the past, and could not attempt to read the future. At the risk of wearying them he would again reiterate that they were really suffering from unseasonable weather here. It was not, that the seasons themselves had been so abnormal. No, it was the deficiency of sunheat during the past few years rather than an excessive rainfall—though that too had been excessive as regarded its distribution during the last 18 or 24 months. It was this continued want of heat that had rendered their soil sodden and cold, so that the root development of their coffee trees had been checked, and they were thus unable to crop properly. But even under these adverse circumstances, good coffee well cultivated was not only paying its way but was paying also for the introduction of new products everywhere; while they all knew of instances where coffee that had been highly cultivated for some time past was giving really good crops even now. Those gentleman who were supporting the amendment appeared to forget that in most instances good coffee had had to pay for bad coffee in time past. They proposed to remedy this by substituting new products for coffee in all fields where coffee was not remunerative, but that was no reason why they should throw good coffee after bad. Let them look at the high exposed land that had been opened in so many places. Would this land ever have proved remunerative? Even had leaf disease never made its appearance, there was much unsuitable land, that must have been abandoned, or replaced by some other plant than coffee. He trusted that the meeting would not be persuaded by the special pleading of the gentleman who had seconded the amendment: his argument appeared to him to resolve itself into this: coffee is bad and therefore it must be bad! They held as strongly as those who were opposed to them, as indeed the resolution declared, they must get rid of bad coffee as speedily as possible, but they would not let their good coffee go with it too, nor did he believe that that meeting would support so rash and suicidal a policy. The amendment implied that all good coffee should be dug out.

Mr. GREIG entirely failed to see that the amendment implied that good coffee should be dug out to make way for tea. Coffee was still their staple and they looked to it to help them considerably yet, but what must be clear to every one of them was that the ravages of leaf-disease were narrowing the area of their good coffee every year, naturally making what was left still more valuable. At the same time the decline was steady, and every season lost in planting up tea would make it all the more difficult of accomplishment in the future. With regard to seasons—while holding the opinion of our weather prophet in high esteem and (having kept a record of the weather at the lower end of the valley since 1877, he could for that time corroborate the valuable and interesting tables he had published), while admitting also that, but for adverse seasons, our crops never would have reached the low level they had done, and that a return to better ones would improve the crops on what good coffee was left. Still, this was altogether a secondary cause, the primary cause was going on, working its deadly insidious way, sapping our trees to the very core, and leaving them weaker year by year. No matter what change might take place in the seasons, there were thousands and thousands of acres in coffee that had been, but never would be, productive again. Then might he ask Mr. Walker how long they were to go on calling seasons abnormal before becoming normal? This cry of abnormal seasons had gone on ever since he came to the country, close upon 20 years ago.

The debate was then brought to a close by the Chairman calling for a division, when 52 were found supporting the original resolution, 6 voted for the amendment, and 12 were neutral.

The resolution was therefore carried.

"THE TROPICAL AGRICULTURIST."—The Chairman of the Ceylon Planters' Association is good enough to write to us of his own motion as follows:—"I have received the *Extra* number, containing Mr. Vincent's report, along with the usual number of *T. A.*, and I must say that, with its excellent map, this Extra is a splendid bonus to your subscribers, who have a very ample return for their subscriptions in the regular monthly numbers. These, as the work progresses, become more and more useful and interesting. I trust this liberal gift may help to attract many subscribers and thus reward your enterprise."

MR. W. J. FORSYTH, formerly of Dimbula and Maturata (a short account of whose travels since he left Ceylon we are promised for the *Observer*), is annoyed at the publication here on the day of his arrival of misleading information about his contracts and business in the London letter of the local "Times":—

He has personally inspected the hill country in various parts of Guatemala, and pronounced both soil and climate in different localities widely separated from each other to be admirably adapted for the growth of cinchona, and accordingly he has persuaded President Barrios to enter into an agreement with him, the main features of which are as follows:—Mr. Forsyth to be paid 3,000 dollars, or, say, £600, as an advance to enable him to proceed at once to Ceylon to procure seeds of the best kinds of cinchona, viz., *Succirubra Officinalis* and *Ledgeriana*. He is then to form nurseries at his own cost upon land in Guatemal selected by him and granted free by the Government; and, when the seedlings are fit for planting out, he is to deliver them at the places agreed upon, where preparations will previousl have been made at the expense of the Government and under Mr. Forsyth's general direction, he being paid for the seedlings at the rate of 5 dollars or about £1 per thousand. I am told that the total number thus agreed to be supplied 5,000,000 plants, but I am not aware whether there has has been any stipulation as to the proportion of the different varieties.

Mr. Forsyth's comment on this is that there is a grain of truth mixed with a good deal of which he knows nothing—the story, as told, not having come from him. Mr. Forsyth is shortly to visit India in connection with his Central American business.

Correspondence.

To the Editor of the Ceylon Observer,

ENQUIRIES FOR TEA LAND.

The Old Country, 8th August 1883.

Dear Sir,—An acquaintance of mine, who has some capital," would like to invest it in "Ceylon," provided he could procure land at a "*reasonable figure,*" in a "*healthy climate,*" suitable for growing such new products as tea, cinchona and perhaps cocoa. I will feel much obliged if you will kindly answer the enclosed queries in your next Overland issue.

Queries.—Is "forest land" "suitable for tea," still obtainable at an elevation of 2,500 to 5,500 ft., either from Government or from "private parties"? and would a man with "capital have any difficulty in securing a block at a reasonable figure, *within a short space of time?*"

2nd.—Is land suitable for "cinchona" to be had in the higher districts, at an elevation of say 6,000 to 7,000 ft., and could such be readily secured at a moderate price? OLD PLANTER.

[It is not easy to answer such questions specifically: forest land between 2,500 and 5,500 feet is undoubtedly scarce in Ceylon, and, unless the Government sells in the Adam's Peak district, there is no large reserve to go upon; but there is a good deal of land fit for tea between the elevations mentioned, in private hands. So with cinchona land 6,000 feet and over: the Crown will sell none, we suppose at present, but "Old Planter"'s friend might be suited from private reserves. It must be remembered, however, that the tea districts below 2,500 feet from Dolosbage to the sea at Kalutara, where there is much land for sale at £1 an acre, are found to be quite healthy for the European planter. Let "Old Planter"'s friend come and see for himself. This letter reminds us that gentlemen offering estates or planting-land for sale should advertise in the *Tropical Agriculturist.*—Ed.]

CINCHONA CULTURE: THE NEED OF FRESH SEED FROM SOUTH AMERICA.

Dikoya.

Dear Sir,—Thousands and thousands of cinchonas are planted out every year, and the results get worse and worse as years go on. Those planted out 10 years ago were few in number and planted mostly along roadsides, and to mark boundaries, but of those I believe fully 75 per cent grew into fine strong healthy trees; whereas *now* I don't believe 5 per cent of those planted ever grew into anything over 6 or 7 feet high at the most, and I don't think it is very hard to account for our present non-success. I feel convinced that the constitution of even the old original trees has become so weakened that plants raised from seed from them are not able to resist the excessive moisture and comparatively poor stiff soil which we have, and of course each generation of seed gets weaker and weaker as time goes on. To my mind our only remedy is to get fresh seed from South America, and I think it is high time we set about getting a good supply out without delay.

The successful cultivation of cinchona is of such importance to the colony that I should think Government would help us to get out fresh seed if no firm in Colombo can procure it. My ideas on the subject may be considered quite erroneous, though I have met several planters who agree with me, and surely the suggestion I make is worth a trial.—I am, dear sir, yours faithfully, G.

[Looking at the difficulties encountered by Messrs. Markham, Spruce, Ledger and others, we fear it may

34

not be very easy to get ripe seed from good trees. Can Mr. P. D. Millie get his brother to help Ceylon in the matter?—Ed.]

London, E. C. 17th August, 1883.

Sir,—"G." suggests that some one should be sent out to South America to try and get cinchona seed, and you put in an editorial backing up the suggestion.

Now, I thought I had made it clear that I had in Bolivia a first-class man collecting the very best seed that is to be got, almost every seed of which is germinating, and if there is one sort better than another, I am having it home. I have got a good stock of this seed which is sold at a rate which none who has tried it cavils at the price, owing to the large percentage that germinates, and I ask, what more is to be gained?

If any of your planters have any suggestions to make that they want some special tree searched for, well and good.

Mr. Ledger is here now, and I am seeing him frequently: he is also with Mr. Howard, but he can throw no light upon the question as to which is the most advantageous plant to grow in India or in the West Indies. It is as Mr. Howard says, a question of bark and the production of bark.

If your correspondent "G." has any samples or leaves which he wants sent out to the richest cinchona districts of South America, I will send them out for him and try and have them matched. I have here now numerous sheets on which the different varieties of cinchona have been attached in bloom, and in seed, and these have been before Mr. E. M. Holmes of the Pharmaceutical Society, and also Mr. Howard.—Yours truly, THOS. CHRISTY.

A STRANGE INSECT.

Matale, 25th August 1883.

Dear Sir,—By this post I send you a box containing to me a most singular creature. It is the first of its kind I have seen. I found it quietly resting on a rock this morning when my kangany came running after me and pointed it out to me whilst I was examining it. He said he had never seen anything like it before. Yesterday we were working in the same locality but saw nothing of it. He told me there were a short distance—a few coffee tree off—three or four more of them.

Do you happen to know anything of them? When I put a small twig to its hinder legs it clung to it so tenaciouly that I carried him all about the field. Ultimately bringing him from the bottom of the estate to the bungalow, holding on in this way all the time, I tried to turn him over on his back, but he, immediately, as quickly as it was possible for any thing to do—and this was repeated several times—recovered his position.

Weather here splendid for all kinds of work, and everyone using their utmost endeavour to make the most of what they have got to work with. On 10th, there was a very heavy rain-storm, 4·34 inches of rain having fallen, and for some days after there was rain more or less.—Yours faithfully, INHABITANT.

[Our entomological referee states that the insect "appears to be the larva of *Suana bicolor*, a large moth."—Ed.]

MR. JARDINE ON MR. STORCK'S CARBOLIC ACID CURE FOR COFFEE LEAF-DISEASE.

Udapolla, 27th Aug. 1883.

Dear Sir,—I have read Mr. Storck's letter (see page 213). It is not my intention to discuss the question as to the distance the utensils should be apart, as I have shown that with a tin with pure acid to each tree there was no result. So that whether my tins in the 2-acre experiment were close enough or not, does not matter. Further, willing to give the experiment every justice, I have for the last 8 months had 50 tins with pure carbolic acid placed under 50 trees, the trees being all close together, and the acid renewed four times within this period, and I exceedingly regret to say that I have not during this time seen the least difference between these trees and others not treated, not even in retarding the fall of leaf. All the conditions necessary for the testing of the power of the acid on the spores were, I think it will be admitted, present here, and as Mr. Marshall Ward states, that the only time the acid can have any effect is when the germinal tube is exposed to its influence before entering the stoma, surely here, if at any time, its results would have been apparent in the destruction of these germial tubes; but what do we find—frequent crops of healthy spores! Will Mr. Storck object that here the experiment was conducted on too small a scale, then I refer him to his own alleged cure of *two* Liberian coffee trees in a group of *five*, by hanging a phial with a 3 per cent solution of acid with water in their lowest branches! Mr. Storck wrote so positively, that I and others who tried his remedy were most sanguine of success, and reluctant to admit failure, and it was only when month after month went by, and we saw no mitigation of the disease, other than occurred naturally, that we were forced to the belief that carbolic acid vapour had no effect upon leaf-disease. Whether the carbolic remedy proves a success or a failure, Mr. Storck is entitled to the thanks of all Ceylon planters for initiating the experiments, and for the intelligence, patience and perseverance he has shown in conducting them. "It is better to have tried and failed, than never to have tried at all." Like many others who have propounded a remedy for coffee leaf-disease, Mr. Storck has been too sanguine, and has allowed his hopes to outrun his judgment; his having changed his method so often proves this, and that he was too hasty in his first conclusions. My hopes of any good resulting from further experiments are very small, but as Mr. Storck's thinks that some reparation is due from me I will willingly carry out his directions as contained in his letter of 6th July, and report results. The utensils I have been using are round tin cups, 4½ inches deep, 4 inches diameter at bottom, 4½ inches at top, fitted with a lid that overlaps the cup, one inch all round; the space between the rim of the cup and the lid is 1¼ inch.—Yours truly, WILLIAM JARDINE.

P.S.—Mr. Storck refers to the experiments of the C. C. Ltd. as the only one that was properly conducted. Have these experiments been reported? The experiments were, I believe, carried on in 15 separate estates and by 15 different gentlemen. If you could get those reports published they would perhaps be more conclusive than mine. W. J.

[We hope the Manager of the Company will publish the results of the experiments.—Ed.]

CEARA RUBBER CULTIVATION.

Bon Espoir, Dindamu l, 31st Aug. 1883.

Sir,—I shall be obliged if any of your correspondents can give me statistics as to the yield of Ceara rubber trees. The question before us now is "Will they pay?" They grow here vigorously. I have one planted in March (seed put down in February) now 6 feet 6 inches high. Another thing, does anyone know if it would answer as shade to coffee?—Yours faithfully, JAMES P. SMITH.

[Our correspondent may rest assured in securing through the *T. A.*, all the information within our reach: several short reports appeared lately and the results of further experience will soon be made known. Ceara Rubber is not to be the success that was at one time anticipated; but it is too soon yet to say it has proved a failure.—Ed.]

COFFEE AND WEEDS.

Dear Sir,—Coffee planting since clean weeding has been conducted on some of the principles of horticulture. Though everyone may not know the theory of horticulture, still they know something about it by practice: they know that nicely made beds kept smooth and clean look nice, and they know that if they want a good garden they must put in plenty of manure and in dry weather water night and morn. The water is put in to keep the plant provided with plenty of food, so that it will not take up water without a sufficient supply of food. If a plant takes up more water than a sufficient supply of food, it can only have impoverished sap. If it has impoverished sap as soon as it gets any bright sunshine the sap gets disorganized, and the plants get morbid, and mildew sets in. The watering in dry weather is done to enable the plant to feed itself, as a plant cannot take up its food without moisture. In coffee we might be able to supply the plant with manure, but we cannot water it in dry weather, so that we must turn from horticulture to what coffee-planting is called and that is agriculture.

In agriculture there must be an intermediate crop to regulate the moisture and thus benefit the main crop, that is, to keep the soil moist in dry weather and absorb the superabundance of moisture in wet weather, and thus prevent the main crop getting sick in wet weather and being starved in dry. In the above lies the whole secret of "what ails our coffee."

There is a time for everything, and now the planters have to learn when to weed and when not to weed. Those that do not know will, I have no doubt, be taught by their V. A.'s but do not forget that the white weed contains the very essential food of the coffee tree.—Yours truly, G. F. HALLILEY.

[We think Mr. Halliley may now rest on his laurels in the shape of a mural crown of white weed. Every planter will acknowledge that ageratum contains all the elements of coffee, which it abstracts from the soil. Could the weed be turned down into the soil, green and seedless, then we grant it would be valuable. But this weed has a fearful capacity for seeding early and plentifully and once it seeds the coffee elements are lost to the soil and the coffee tree. Hence the hatred of planters for white weed. Liebig advised the growth of lupins amongst coffee, but only to be turned over into the soil before the flowering stage. To leave weeds or a subsidiary crop to go on growing and propagating is as contrary to agriculture as to horticulture.—Ed.]

MR. HALLILEY STICKS TO HIS WEEDS AND SHEWS HOW THEY WERE TRIED AND PROVED SATISFACTORY.

Dear Sir,—Some ten years ago, I told the then manager of the Oriental Bank that planters must be allowed to grow weeds. He told people that I was visionary, but time has proved who was right. When Haputale was first opened, the cry was "that there was something wrong with the soil," that in time was forgotten, and since all districts have been kept clean, the cry has been "the weather, which is downright blasphemy,"* when it is not the weather but the cultivation that has gone wrong. It is not difficult to see how the cultivation went wrong. When the railway was opened, it was an easy matter for the Colombo people to come upcountry. The planter said that the man who kept his place clean got pushed on and soon found that unless he found the rule he would lose his situation or credit. In the *Ceylon Observer* of the 5th inst. there is an account of how coffee is cultivated in "Java," by which it appears "that they have no weeding during crop and for one month after, that during the blossom time they allowed no one into the coffee, and that coffee roughly handled is sure to bring on the leaf-disease." Is not the way coffee is cultivated in Ceylon, treating it roughly, by pruning it year after year whether it wants it or not and by keeping the land clean and thus making it

*Now that Mr. Halliley has begun to use hard words, it is time he should be shut up.—Ed.

sodden in wet weather and as hard as a brickbat in dry? Has anyone considered why coffee was called king coffee? May it not have been because it was found he did best with a carpet of weeds? Col. Money tells us that to cultivate tea profitably, it must have the humus of vegetable matter; how is that vegetable matter to be got without weeds? There are some who still insist in calling leaf disease a contagious disease. Mildew *causes* contagious diseases in animals, but when mildew is the effect in animals, the cause is poor living (as in the case of the famine-stricken of India) or from an insufficient proportion of some component part in the blood as in the case of skin-diseases. The mildew in the coffee is the effect and not the cause, the cause is improper cultivation. When boots get attacked with mildew, is it a contagious disease among boots or is it a natural consequence caused by the boots being damp and not brushed ?† Some have grown the coffee mildew on glass, have they tried to grow the boot-mildew ? They will find that they can, and glass often gets attacked with mildew as in the case when glass becomes cloudy.

Weeds have been tried in cocoa and I have been told that that cocoa was considered the finest of its age in the island. Weeds have been tried in Liberian coffee, and I believe that coffee has got so thick that it has killed the weeds, and weeds have been tried in both tea and coffee Arabica ; and has been found so satisfactory that all weeding contracts in that estate have been stopped.‡—Yours truly,

G. F. HALLILEY.

LABOUR FOR NORTHERN QUEENSLAND.

TO THE EDITOR OF THE "QUEENLANDER."

SIR,—In reading the speech made by Mr. Griffith at Mackay on the introduction of coolie labour into Queensland, he states as follows :—"The result would be the same as it had been everywhere elsewhere the same experiment has been made ; they would in the course of years (say thirty) do all kinds of labour for themselves."

The coffee industry has been established in Ceylon for a much longer period than above stated. On my first charge part of the coffee was forty-five years old, and although Ceylon is peopled with many races seeking their living in a variety of ways, yet you never see the Southern India coolie remaining there many years. They usually stay one, two, or three years and then return to their coast for a spell of about six months, again returning to Ceylon. They are recruited in Southern India for our coffee estates. To this work they come, and at it, through good and bad seasons, they remain, and first-class workers (men and women) they are. I am confident that if introduced into Queensland the white man who trusts to a superfluity of work for good pay will never have cause to regret such action. Although the rate of pay they receive on the coffee estates may seem low to colonial ears—namely, 9d per day per man, and 6d per woman yet when you come to consider how they labour in their own country for wealthy men for the sum of some 3s to 4s per month in kind, the pay as received in Ceylon is a fortune to them. They do not, as a rule, save money, but live from hand to mouth.

If black labour is essential to the opening up of your valuable Northern lands, and if sugar, coffee, cinchona, etc., are to be grown, such labour is absolutely necessary, and it behoves one and all to see that justice is done to the Northern lands, and by so doing the South will undoubtedly gian.—I am, sir, &c., H. ST. GEO. CAULFEILD.

P. S.—I have worked coolies for over thirteen years.

[Two corrections suggest themselves. Coolies who live on 9d per diem in Ceylon ought to get 1s in Queensland, in view of the higher price of rice, and surely a considerable portion of the coolies employed in Ceylon save money, some scrimping themselves of food in order to lay by.—ED.]

† Just so : what mildew is to unbrushed boots, weeds are to neglected estates.—ED.

‡ Where is this wonderful estate where weeds have been tried and found so satisfactory that their removal has been abandoned ? Let us have one such case and the results, rather than what the bank manager rightly called sheory.—ED.

FRESH FIELDS AND PASTURES NEW : THE SEYCHELLES.

(By an ex-Ceylon planter.)

Mahé, Seychelles, 20th August, 1883.

DEAR SIR,—I forward the enclosed extracts from the "Mauritius Mercantile Record" &c., thinking they may be of interest to your readers. It is possible that there may be some of Ceylon's practical planters who would like to give the "Seychelles" a trial. I would not recommend any to come here without a little capital, but those possessing R5,000, upwards could in a few years retire with a handsome competency. Let the young and unencumbered be the pioneers in Borneo &c., and endure the hardships such as are met with in Manitoba, New Zealand ; while the older hands and those with wives and children can settle in a country where life is congenial to their tastes and where soil and climate have been tried and found satisfactory. The islands are easy of access : two of the Messageries Maritime steamers call here monthly, one homeward and the other outward bound. I shall be happy to give what information I possess, to any of your readers who will place themselves in communication with me.—I am, dear sir, yours faithfully, E. H. E.

(*Mercantile Record.*)

Mahé Seychelles, 23rd July 1883.

SIR,—After nearly twenty years spent in Ceylon in the cultivation of tropical products, and two years in New Zealand and the Australian colonies, I was attracted here through reading a report on the Seychelles Islands written by Mr. H. Cockburn Stewart during the time that he occupied the position of Chief Civil Commissioner.

Since my arrival I have visited a large portion of the Islands, and I have no hesitation in saying, that I have never been in any country where vegetation is so prolific, or where agricultural productions respond more readily to the assistance of human ingenuity ; neither do I know any country where the inhabitants avail themselves so little of the great advantages bestowed upon them. Throughout the whole of the island (computed at 35,000 acres) there is scarcely an acre which could not be made productive and to yield a handsome return on the capital invested.

The climate is most salubrious ; the heat never oppressive ; the islands are not only entirely free from hurricane, but there are no winds of such a strong character as in any way to impede the successful cultivation of any tropical product that may be introduced ; the yield is large compared with that of other countries, the quality superior and labor cheap and abundant. As you are aware, hitherto the principal industry has been the growing of coconuts. For some years past a disease has affected the trees to such an extent that the annual yield has been materially diminished, and, although I am told that the disease is disappearing, yet I think the "the wish is father to the thought." I fear that unless proprietors turn their attention to the cultivation of other products, the future of the islands is to be viewed with considerable apprehension.

Some of the more enlightened of the land-owners have opened up a large area in coffee, cocoa, vanilla, cloves, &c. While admiring the courage and enterprise shown by those who are spending both time and money in setting this commendable example, I fear in many instances they will mee with loss and disappointment and prevent others from embarking in "the New Product Enterprise." It is not that coffee, cocoa, vanilla, &c. will not grow, but the coffee is affected with *Hemileia Vastatrix* and in the latter, there are certain elements in their successful cultivation that are being ignored, not intentionally, but through the want of practical experience.

At present the country is said to be in a very impoverished condition: there is a great cry of "no money." If there really be a scarcity of that commodity, there must be an unlimited supply of *credit*, for I have been in no country where the inhabitants are more cleanly and better clad or who show less signs of "the wolf being at the door."

There is a rumour current today that Sir John Pope Hennessy is expected to pay us a visit with the view of making an investigation into the present depressed state of the country. The Governor will receive a hearty welcome, and I venture to predict that in the future we shall look back upon the visit of His Excellency as being the cause of the "turn of the tide" in the wave of prosperity.

With the introduction of a little capital and the judicious selection of the land suited to the cultivation of the many various products which the islands are capable of sustaining, coupled with the assistance of a sympathetic Government, Mahe would become, acre for acre, the richest of Her Majesty's possessions; but without these desiderata the country will remain undeveloped, and, should the coconut-disease continue its ravages, "the ship will sink indeed."—I am, sir, yours faithfully, E. H. EDWARDS.

P. S.—To enquirers I shall be happy to furnish any information that lies in my power in connection with the islands.

SCALE INSECTS ON CINCHONAS.

Neddiwattum, Nilgiris, 21st August 1883.

DEAR SIR,—Knowing the very great interest you take in matters concerning chinchona, I am sending you by this post a small box containing branches of this tree which, you will observe, are attacked by a small scaly insect. I find that the tips of the branches are dying off, and draw the conclusion that this insect is sucking the sap from the bark and leaves.

Have you anything like this in Ceylon? Here, many thousands of trees are affected by this pest, and I would be exceedingly obliged for your opinion, as to whether there is any chance of its spreading, or if you think it now dead. I notice that only officinalis and hybrid trees are attacked so far. Some two months ago I noticed it first, and do not think it has spread in that time. Apologizing for troubling you, I am, dear sir, yours faithfully, W. ROWSON.

[Our entomological authority writes:—"The small scaly insect that is attacking Mr. Rowson's cinchona is one of the scale bug, of which there are so many species. He is right, I think, in concluding that the dying off of the tips of the branches is caused by the insect sucking the sap from the bark and leaves. Whether the pest will spread, or disappear, will depend probably on atmospheric conditions. I am afraid we must look upon these inflictions as a provision of nature to keep vegetation within bounds, but at the same time the evil may be encouraged by mode of cultivation. Unfortunately, the mischief is not equally distributed; for some cultivators suffer much more than others, and to a ruinous extent."—ED.]

TREE PLANTING IN MEXICO.—The Mexican Government has concluded a contract with Mr. Oscar A. Droege to plant 2,000,000 of trees in the Valley of Mexico within four years, commencing March 15, 1881. Half a million trees a year are to be planted in such places as the Government shall decide. The contractor pledges himself to establish a number of nurseries, and to have in them each at least 80,000 Ash, 35,000 Willows, 120,000 Poplars, 60,000 Eucalyptus trees, 60,000 Mountain Cypress Cedars, 60,000 Acacias, and 120,000 of miscellaneous varieties. The trees must be in plantations of from 50,000 to 100,000 each, and Mr. Droege has to maintain them for two years after planting. He is not compelled to plant trees along the highways, however. Three graduates of the School of Agriculture are to be received into the nurseries each year, there to study the science of forestry. He is also to raise fruit, and other useful plants, for free distribution. There is to be translated from the German every year a work on arboriculture of recognised merit. An inspector is to superintend, and Mr. Droege is to receive annually 40,000 dols. till the sum reaches a total of 200,000 dols.—London *Times*.

THE EUCALYPTUS AS A HAIR DYE.—Some strange stories, more or less authentic, have been told of the remarkable properties of the Eucalyptus, or blue-gum tree, of Australia; but the following is the most remarkable of all. According to the *Taranaki Herald* "the blue-gum leaves are remarkable for their peculiar dyeing qualities as well as their curative properties. A gentleman in New Plymouth was recently afflicted with a severe cold, and he drank copious draughts of the infusiton of blue-gum leaves. He was certainly cured of his cold, but to his utter astonishment, the hair of his head assumed a decidedly green colour, which, to say the least of it, renders his appearance very peculiar. He attributes this strange occurrence to the gum leaves, but he states that the fact of his being cured of a very dangerous malady has fully compensated for the slight inconvenience of having his hair dyed green."—*Planters Gazette*. [We give the story for what it is worth without presuming to question the accuracy of our Antipodean contemporary. Tell that to Verdant Green of the marines.—ED.]

LIFE IN NORTHERN QUEENSLAND: CEYLON PLANTERS "TURNING-UP THEIR SLEEVES."—An ex-Ceylon planter writes:—"I was nearly four months in Queensland before getting employment (I would have taken pick and shovel work in Brisbane at once on arrival, but friends strongly advised me to wait something better and gave me assistance in the meantime), but at last I would wait no longer, and fortunately an advertisement for a gardener near Mackay appeared in the *Courier*, so I applied and got the situation, on Foulden estate, under Mr. Robert Walker; the pay 25s per week and board. This I held for a year, and then gave it up to go and look after a mob of Kanakas over the River estate adjoining Foulden as I wanted to get "well up in sugar." The pay is the same at present. I have settled up for the time I was waiting out of employment when I first came, and consequently have not "banked" any money yet; but now your turn will come, and I will work on until I am perfectly clear of debt. There is a grand field open here for steady men who are not afraid of hard work—and work hard they must if they come here—and if they have their wits about them they can in a few years be in receipt of a very comfortable income. But they must be steady. Nothing is more common than to see men knocking down their hard-earned cheques at the first public-house they come to after receiving it. We have started a Good Templars' Lodge adjoining Foulden and River estates and it is already doing a great deal of good in the neighbourhood; I am 'W. Chaplain.' There are a good many Ceylon men knocking about here. J. Drummond a "brither o' Gang Warily's" is at Foulden; another, a Mr. Wickham, is working there; and still another in the same employ under Mr. Walker, at Farleigh, is agricultural overseer, a Mr. Bisset who left Ceylon about 1876 I think. There is also a Mr. Raymond from Ceylon in the M. M. Sugar Co.'s employ at Mackay. Let them come, but they must turn up their sleeves and *work*, and they will find it a grand country. This is a most extraordinary country for mislaying letters in the post. Only fancy, yours of 23rd February came to hand on 4th *instant*. Numerous others have gone astray. Pardon this long letter, but I could go on for hours."

AUSTRALIAN SEED WHEAT FOR INDIA.

Recent experiments have shown that really good clean Indian wheat is equal to any in the world. Mr. Cornish, editor of the *Madras Mail* and author of "Under the Southern Cross," recommends the introduction of seed wheat from South Australia, and he has himself introduced some for trial in the Madras Presidency, where only 23,000 acres are down in wheat against many millions in rice, cholum, &c. Mr. Cornish believes that the cultivation of this dry grain could be advantageously extended in the more elevated portions of the Madras Presidency. He writes:—

One can understand that a moist climate like Burmah would not be suitable for the cultivation of wheat, which, it is important to bear in mind, is a "dry" grain, that is, it can be grown without artificial irrigation; but why does the doctor jump to the conclusion that wheat cannot be produced on the plateaus of the Madras Presidency and in Mysore? There is no reason why Mysore should not produce some of the finest wheat in India, while I should not be surprised to find that the black-cotton soils of the Ceded Districts and Deccan, where the finest cholum is produced, would, if cropped with Australian seed, produce a wheat which would have no superior in the world.

The Australian climate is much more tropical in its character than that of the chief wheat districts in Europe and America, and hence one may reasonably infer that Australian seed, being as it were a climatised to the tropics, would thrive best in this country. The rainfall, climate and soil of the Adelaide wheat plains have a remarkable resemblance to those of our Indian plateaus, and it is a fair presumption, therefore, that as wheat has been found to thrive in one place it may succeed in the other. Dr. Schomburgk, the talented Director of the beautiful Botanical Gardens at Adelaide, tells us that the South Australian cereals are considered to be the finest grown in the world, the best specimens of wheat weighing 68 lbs. per Imperial bushel; and the fact that Australian wheats now occupy a higher position, and command a higher price, than those grown in Europe and America points to the conclusion that wheat improves in a tropical climate, and that it will ultimately find a congenial home over the greater portion of India.

It will astonish most people to learn from Dr. Watson that India is already one of the largest wheat-producing countries of the world. The Punjab produces from 10,000 000 to 13,000,000 quarters, Oudh 3,500,000 quarters, Central Provinces 3,000,000 quarters, and Bombay about 3,000,000 quarters. The production of the North-west Provinces is about equal to that of the Punjab. Thus the yearly production in provinces under British rule is from 30,000,000 to 35,000,000 quarters. The production of the United Kingdom is from 10,000,000 to 13,000,000 quarters. Austria, Italy and Spain produce, each about the same quantity. Germany produces about 18,000,000 quarters and France and Russia about 35,000,000 quarters each. The production of the United States is about 45,000,000 quarters.

The export of wheat from India rose from 2,195,550 cwts. in 1880, to 7,444,449 cwts., in 1881, and to 19,863,520 cwts. in 1882. At present the trade is confined chiefly to Northern India, but there seems no good reason why other districts, where wheat is known to be cultivated, should not share in the advantages of this important export trade, which may possibly assume very large proportions at no distant date.

But, as wheat suffers terribly from rust and smut in some parts of Australia, seed obtained thence should be "pickled" before being sown by being steeped in a solution of sulphate of copper, strong enough to kill the spores of the fungi but not so strong as to injure the germinating powers of the wheat. Mr. Robertson of the Madras Farm, however, describes sulphate of copper as preventing smut, but not rust. In certain places in Australia the latter (closely allied to *Hemileia vastatrix*) has done as much mischief to wheat as our leaf fungus has done to coffee. In truth all articles largely cultivated are liable to fungus and insect pests, against which war has to be waged, with variable results. In some cases, but generally only for limited periods, man has to submit to absolute defeat.

THROUGH THE TEA DISTRICTS OF NORTH INDIA:—No. VI.

(*By a Ceylon Planter.*)

TEA GARDENS IN DARJILING TERAI—HEAVY MORTALITY AMONG COOLIES AND GREAT DRAWBACKS—INDIGENOUS ASSAM SEED FOR THE CEYLON LOW COUNTRY.

KURSEONG.

The tea gardens in the Darjiling Terai, have not fulfilled the high expectations which were formed of them at their outset. With perfect lay of land, flat as in Assam, and possessing all the advantages of unexhausted soil and a very forcing climate, they are disappointing in appearance and in result. The reason of this is very apparent, the land consists mostly of a rich surface soil, varying greatly in depth but seldom approaching that of Assam, and below it lies a sub-soil of barren gravel and sand, excellent for drainage purposes, but ill-adapted for the support of a vigorous deep-feeding plant like tea.

During the early years of growth, the Terai gardens gave most satisfactory results, but when the plant is in fullbearing, the yield in many cases falls off greatly, and the vigour of the bushes decreases.

The Dooars, a young and rising district to the east of the Darjiling Terai, but similarly situated at the foot of the hills, has a better soil and gives greater promise of success. The unhealthiness of these districts is proverbial, and has been against them from the first. On one garden I was at, 100 coolies had died quite recently from cholera, and 200 had bolted in consequence, leaving an available force of 400 out of an original total of 700. Several instances have occurred quite recently of every soul leaving the garden for a time, including managers and assistants,—for their presence without coolies was of little use,—in consequence of the numerous deaths from cholera. Fever is too common a complaint there to call for remark, and new-comers inevitably suffer from it in a greater or less degree for some time. Europeans after a time appear to become hardened and accustomed to it, and throw off attacks after but a temporary period of suffering; but the constitution must become undermined in time by these attacks, and it is a significant fact that in the Terai, in parts of Cachar too I believe, and in many other localities, managers above 30 or 35 years of age are a small minority. It is needless to point out the many ways in which this state of affairs affects the cost of production of tea. Apart from the risk of loss of labour during crop time—for the unhealthiest months coincide with the busiest crop season—the inducements to managers and assistants have to be made commensurate with the risks to life and health. In a copy of the *Observer* which I came across by chance up here, mention was made of the fact that three planters had been engaged by a Calcutta firm for a term of years to work in tea gardens, the salaries were stated, and I think a remark was made that they appeared liberal, and that the gentlemen in question were fortunate in being offered them. I cannot but think that this remark was made without due weight being given to the conditions of life in an Indian upcountry district. It must be remembered first that in the plains water is as a rule undrinkable even after the most careful filtering, whilst the cost of aërated waters, an absolute necessity, is very great when they have to be transported from Calcutta as is usually the case. Servants too are a great tax on an assistant's income; "boys" to do the cooking and all the other work of a small bungalow are unknown, and several servants must be kept whose salaries though individually not higher than what is generally paid in Ceylon, amount in the aggregate to a large sum. Fairly generous living and good cooking are essential to the preservation of health in a trying climate, and how impossible it is for these conditions to be fulfilled on the salaries mentioned, I now know well. European managers and assistants are very highly paid on Indian tea gardens, and they thoroughly deserve the remuneration they receive. A young man from home on first joining gets, of course, a small salary R150 a month and several allowances generally, and has to manage as he can on it; but good experienced men in charge of good gardens get from R500 to R700 a month and a commission on the profits, which sometimes ranges as high as 10 per cent in addition; in the smaller gardens R350 and R400 and commission are very generally given on the plains. The reason of this is that in order to live in such a way as to have a fair prospect of preserving his health a man must have an income of this kind, and must spend a considerable proportion of it. I cannot therefore agree that the sums offered the gentlemen in question, considering that they had experience of estate management and were accustomed to cooly labour, were specially liberal, and this opinion was endorsed by several Indian planters who had heard of the engagements. There are, of course, some parts of the plains more healthy than others, and it is to be hoped that they have been fortunate in the locality to which they were sent.

As is very generally known, most of the Darjiling hill gardens, and some portion of those in the Terai, are planted with China tea. In Assam on the other hand, a few gardens have China on them, but they are the exception. The opinion mentioned in a previous letter as having been given by a leading Calcutta teataster, that a malty flavoured tea was only to be made from highclass indigenous plant, I have found to be quite erroneous. There is no question that at high elevations very choice flavoury teas are made from China leaf, many of them fetching the highest prices in the market; and in some situations, where the cold is great, hybrid plants do not yield in the same way as the hardy China bush. Extreme altitude apart, hybrid bushes are found to yield much more heavily in the hills than China, and the fact that the latter was so very extensively planted in the old days of tea planting is very generally regarded as a misfortune. In appearance the tea from a China bush is, of course, far superior to any other. The proportion of pekoe is very large, and there is not much coarse uneven leaf. The *liquor* has a very fine flavour, but not much strength. In some cases I was able to sample teas from China and hybrid bushes, grown on the same estate, and the latter was invariably the better tea of the two. The very high and cold portions of gardens apart, all new clearings are being planted with a good hardy hybrid.

The opinions expressed by planters as to the cause of the peculiar *malty* flavour, so much valued by brokers, possessed by some teas are varied and contradictory. In Calcutta, highclass plant and fine soil were given as the conditions, but many such teas have not got it, whilst in one case a tea from the rankest China had it in a marked degree. Another cause assigned was highfiring, but teas dried in a Gibbs and Barry's drier at a temperature of 700° had not got it. Blighted leaf, the stunted shoots from bushes suffering from "green fly" especially, was said to give a malty liquor by another, but I think this is questionable. A fourth planter of experience stated that by manipulation he could always produce teas of this character; a reference to the public sales of tea from his garden was conclusive proof against this statement. An instance was given me of a garden in the Terai, which for a few years, when young produced fine malty teas fetching a high price, but afterwards they entirely lost this characteristic, and it seems most probable that some quality in the soil is the chief cause. There is an immense amount to be learned yet about tea manufacture, and this point is one which is not as yet understood.

In Assam and the Terai, in all low-lying districts in fact, the success of gardens is known to depend entirely on the class of plant put out. In the early days of planting any thing was considered good enough, but now the very greatest care is taken in selecting seed, and the highest prices are paid for it. In the lowcountry, seed from cultivated indigenous Assam trees is the best kind to plant. Seed from the original jungle trees is very delicate and not so suitable for cultivation as the second generation. The lowest price at which such seed can be obtained is R150 (one hundred and fifty rupees) per maund, and much has been sold at R200. It is all bought locally, and in opening gardens in Assam and Cachar the first consideration is "how much seed can be afforded?" *Then* the acreage to be cleared is decided on.

There are two principal sources from which seed is obtained, the Towkok and Singloo indigenous gardens, but all is booked for a long time to come *locally* at such prices as I have quoted. From gardens which have not made a reputation as seed-producers, the very lowest figure at which high class indigenous seed can be obtained is R120, and when a man shows you a nursery in which such seed is sown he does so apologetically, seed worth R150 per maund locally being the recognized kind suitable for the plains. In sampling teas from the ordinary hybrid and indigenous plant, the difference was as marked as that between China and hybrid in the hills, the indigenous giving a much stronger and more rasping liquor than the other. In yield, the advantage is even greater (in one garden the China gave two maunds, the hybrid 8 maunds per acre), and one of the finest sights I saw was a five-year old garden from Singloo seed with a heavy flush on it. When talking about seed to men in Assam, remarks were often made regarding the planting of cheap inferior seed sent to Ceylon, and cases were mentioned of seed picked anyhow from low class bushes, to supply orders for seed at absurdly low rates. Plenty of good seed has gone to Ceylon of course, where fair prices have been paid, but, with the large extensions in tea now going on in India itself, Ceylon men cannot expect to get good seed for an inadequate price. Noacacherry, the place from which Rookwood, New Forest, and some other places in Ceylon got their seed, is known as one of the best sources for hybrid seed of a highclass in Assam.

Indigenous Assam seed, though undoubtedly the right plant for the Ceylon low country, is by no means suited for plantng on the hills; a vigorous dark-leaved hybrid is much better, and such seed is more easily procurable, and at much lower rates. Almost all gardens in Assam are more or less mixed, a certain proportion of low class plants being found everywhere and in order to ensure that the manager or assistant shall personally overlook the seed-pickers and make them take it only from the good trees (a course followed in all gardens which go in for selling seed), a fair price must be paid. It is very evident, in fact, that good seed grown locally has in many cases been sold below its true market value as ruled by what such seed would fetch in India itself.

T. C. OWEN.

THE LONDON TEA TRADE.

Referring to previous remarks under this head, we would like the tea planters up-country, who buy tea lead of *all brands* to state if every leaden envelope they make is uniform in weight. They should state the brand of tea lead they use, and we could then see if the different brands differed in weight for cases containing *the same cubic measurement*. If a recent correspondent's idea is acted upon, the mark and number will have to be placed on both the wooden case and the lid, to ensure the same lid being replaced, We should also like to know if the wooden case can be removed and replaced at pleasure as suggested by our correspondent; would not the leaden case bulge out and prevent this ?

THROUGH THE SOUTH SEA ISLANDS TO SAN FRANCISCO.

(By an ex-Ceylon Planter.)

TRADE IN COPRA—WESTERN LUXURIES IN PRIMITIVE LANDS—THE GILBERT ISLANDS.

On the 23rd September we sailed from Apia harbour and bore away to Tutuila, distant from Opolu about fifty miles, and dead to windward. The evening of the second day we arrived at Leone, one of the principal villages. In appearance it resembles the others on Opolu and Savaii. The houses are scattered about without much regard to order. Breadfruit and coconut trees skirt the shore. A little removed is the natural jungle and high hills. There is a Roman Catholic and Protestant mission. Two priests represent the former, and a Mr. Philips from the London Missionary Society the latter. From him I learned that the Mormons of Utah sent a mission to the island many years ago and had converted two villages to their faith. Their teachings had not found favor, however, and they did not extend their influence further. Mr. Philips had quite lately visited these Mormon Samoans and has succeeded in reconverting them to the Christian belief. This agrees exactly with an account I remember reading some years ago of the intention of Brigham Young of removing from the Salt Lake and settling with his followers on some Island in the Pacific Ocean. The idea was evidently abandoned as Brigham Young is dead and the Mormons are not there.

Mr. Philips is provided with an excellent library which must be a great boon, isolated as he is from all communication with the outer world. Both he and Mrs. Philips were very kind in providing us with an excellent tea and prescribing from their medicine-chest a few remedies that might be of service on our long voyage. The night was still and calm and as I sat on deck I saw a light burning in the house of Mr. Philips and knew they were composing letters to friends far away. I retired to rest and rose again when the wee sma' hours had come and gone. The light was still there ; and I wondered what a flood of heartburning, and rejoicing, hopes and confidences had found a vent through the medium of their hurrying pens.

At eight o'clock quite a budget of letters were given to me, to be posted on my arrival in San Francisco, which commission I am pleased to say was duly executed. We took up anchor and bore away close hauled. We found the fight a hard one against light trade winds and an ocean current.

We arrived at Manua, a small island which rises abruptly from the sea to a height of some 2,000 feet. Olosinga and Offoo islands are distant about five miles and are much less in size than Manua but equally steep and abrupt. Here I met one of the most intelligent men I had seen since my arrival in the Samoan group. Mr. Young is a halfbred, speaks English fluently and writes very well also. From him I learned that the total population of the three islands is about 1,700 souls and that they contribute towards the Church Missionary fund about 1,500 dollars in the year. This sum is a very large one when it is considered that the only means of getting money is from the able of copra. This trade is very limited and erratic. They hoard up all they can collect over and above what they require for their food, then exchange, or barter for knives, and other necessary tools, the balance is converted into cash and mostly handed to the treasury of the missionary fund. They are very devout Christians. In their own tongue they have morning and evening prayers at which times a chapter is read from the Bible. They sing very prettily and keep beautiful time. I hardly ever stayed at a village, but the most devout prayers were offered for my welfare and safety. It was close to the island of Olosinga that a violent submarine eruption happened in 1862. The sea was thrown up in a fountain-like column higher than the highest peak of Manua and returned again with immense fury. Happily, the irruption was as shortlived as it was violent. It did a vast deal of damage, thousands of fish were cast up on the shores. The smell arising therefrom was so very offensive that the people were obliged to desert and take refuge in Manua which luckily had escaped the infliction. Submarine fish of gigantic size were said to have been cast up. Dr. Turner, to whom the news was brought on the island of Opolu, succeeded in interesting some of the chiefs and induced them to send a large war-canoe to the scene and bring back the bones of those monsters. The expedition came to grief on the island of Tutuila, and a subsequent one arrived too late. The natives had returned to their homes and cast all offensive matter into deep water beyond the barrier-reef, and accordingly what might have been a pearl to the scientific world was entirely lost.

After we had got all the Manua copra on board, we dropped quietly down to Olosinga. But a heavy sea and dense black squalls hovering round prevented the captain from sending his boats ashore. The next day was worse, and a heavy gale was blowing. So we were obliged to dodge about under close-reefed tops'als. Towards evening we approached land when to our surprise we saw a canoe with three paddlers, who spent their giant strength, in urging *the little* bark against the wind, waves and tide towards us. I envied and admired them. They kept good time and acompanied their strokes to a boating-song, the hoarse deep notes of which were borne towards us occasionally. We backed our tops'als and lay to but they passed close under our bow and paddled like giant demons, for Manua. They, however, did not go far before a wave broke over and completely swamped them. A merry and hoarse laugh reached our ears and our anxious fears were dissipated for their safety. They arranged themselves on each side of the canoe and by a rapid jerking motion first one way then the other endwise the canoe was soon emptied. They got in over the end and were soon on their way rejoicing.

I remember being in a similar pickle in the harbour of Apia. The English consul and I crawled ignominously out to the top of the canoe more than half submerged. Here we flourish our paddles and cried for help. *I guess we Britishers* are not bosses in everything !

The sea soon subsided and the wind lulled. So after we shipped all the copra at Olosinga and Offoo, we shook out our top'sails and with a fair breeze and favorable current bore away for the Gilbert islands, distant about 1,200 miles in a northwesterly direction.

I cannot dismiss the Samoans without relating how my pride was snubbed. The moral effect thereof has been very great, and may be a useful lesson to others as well as myself. I was crossing from the north to the south side of the island of Savaii. On the afternoon of the first day, we journeyed up a fine rich valley along the bank of a small stream. There was no track and the valley narrowed till it was little more than a gorge. Overhead the jungle trees interlaced their foliage and cast a dense shade on tho ground. A calm and superstitious silence pervaded all things and had an influence on me mentally which was not cheering. I sat down on an adjoining log and thought that at last I had trod a part of the world where no other whitefoot had been save my own. I fairly hugged myself with delight. In the midst of my selfglorification, I noticed a something glinting. I approached the spot and saw where the sun's rays had penetrated the dense foliage reflected from off something bright. I stooped and picked up this something, and to my horror and surprize beheld an empty Worcestershire sauce-bottle. Here had not only been some one before me but all the luxury of a civilized community. My pride was awfully shocked. I called the interpreter and sighed and said "Let us go hence," and we went.

After ten days' sail, which was rather dull and monotonious, we sighted the first of the Gilbert islands, Tamana. We did not go on shore, but the natives came off in swarms bringing with them an abundance of fowls, and diminutive pigs and eggs. These articles we exchanged for tobacco.

At four o'clock in the afternoon we again sailed away for Nonouti (pronounced Nanooteh). The captain was rather doubtful as to whether it would be advisable to keep well to windward and steer between the islands of Peru and Taputeonea or bear a little westward and go to leeward of the latter island.

The former course was decided upon and we shaped our way so as to have Peru five to ten miles to eastward.

About 11 o'clock at night we were roused by a cry of breakers ahead. We were on deck in a moment and saw quite close to us curling white breakers and a little further off lights of natives fishing.

The helm was put down and we slowly veered round. Not a minute too soon however, for I could have cast a stone among the breakers without much exertion. We altered our course a little as we were quite at a loss to know of our whereabouts. Strange to say, at daybreak the same morning we were again roused by the same cry and beheld the same curling white breakers. This time closer than before. The moment was a most intense and breathless one and I inwardly blessed the dear old schooner for answering her helm in the smart way she did.

We got clear but almost shaved the reef. We did not much relish a wreck, although there would not have been much danger to our lives; but a sojourn on these hospitable (?) islands for a year or so was not a pleasant prospect. I had a little experience of this kind on a former occasion. In returning from the island of Vanu Levu Figu to Levuka on board a small schooner, the "Patience" we ran ashore on the Mokongai reef and although not totally wrecked had a rough time of it, accordingly did not want an extended experience.—I guess not as we say in the classics.

At half-past eight we took our longitude and found ourselves to the leeward or west of the island Taputeonea. According to our calculations we had made leeway of 32 miles in twelve hours, or in other words there was an ocean current running nearly three miles an hour to the westward.

If a trading vessel misses the island she is making for by a few miles, the only way to do is to bear away due north close to the wind 300 to 500 miles beyond the influence of the current, and then eastward and return again, as it is utterly impossible for a vessel to beat to windward against the current. The islands lying to the north of Taputeonea have been visited by an American survey ship; but all to the southward are marked on the charts as "position doubtful;" accordingly, a mariner navigating these seas cannot be too cautious and careful.

The next day we arrived at Nonouti where we stayed a few days.

In my next paper I will give you an account of manners, customs and laws of these islanders, which will be interesting; also an account of our passage thence to San Francisco.—W. J. F.

THE INDIAN TEA INDUSTRY.

(*Notes by a Planter.*)

In considering the future of the tea industry in India, and the prospects of its out-turn in the immediate future, there are more things to be taken into consideration than the mere details of weather, blight and such like temporary considerations, important enough though they be, when forming an opinion on the prospects of the passing season. Even these may be misleading, when, as in the case of tea, the period of the crop extends over many months. The weather changes, the blight gains or loses ground, and the prospects of the crop vary accordingly. A weather-cock, even when it has become so rusty that it will not traverse, may occasionally point on the right direction, by accident; but one that hangs on so loosely as to be perpetually shuffling and veering, without reference to the quarter whence the wind blows, can only serve to puzzle and mislead. In the case of tea, as in other industries, there are many indices to be consulted before an opinion could be formed as to which way the wind is about to blow, to continue the metaphor. The inducements old and new markets show signs of offering, either for increased demand or the reverse; the question of the cost and supply of labour on the sites of cultivation and manufacture; the action of the Legislature, as, *ex. gr.*, the passing of the Ilbert Bill, or new labour-laws; all these and other considerations have to be taken into account. Perhaps of no field for speculative talent more than that of prophecy can it be more aptly said, "Fools rush in where angels fear to tread." Deprecating all intention to pose as a prophet, I offer my readers the following remarks on their own merits.

* *

Tea bushes require from five to six years, according to class, soil, climate, situation, etc., to arrive at full bearing. This fact has an importance in our calculations as to the immediate prospects of the out-turn, in the matter of quantity. For instance, by watching the extensions made year by year, *i.e.* the number of additional acres put down under tea, one could, all things being reasonably favourable, form a fair estimate as to the percentage of increase in out-turn for some years to come, by allowing for each year its fair proportion of young plant to come into partial and full bearing. Unfortunatey, planters have thwarted this possibility by withholding in many instances the necessary returns applied for by Government. This is one of the results of the unhappy enmity the Government of India of late years have done all in their power to bring about between themselves and the European community in India. The eminent Judge Haliburton, of Nova Scotia, so well and widely known as "Sam Slick," and for some time a member of the British House of Commons, in speaking of the cavalier way in which the English Colonists abroad are treated by the mother country, said, "Colonists have no nationality. They have no place, no station, no rank . . . They are like our free niggers; they are emancipated, but they havn't the same social position as the whites. The fetters are off, but the caste, as they call it in India, remains. *Colonists are the Pariahs of the Empire.*" Times do not appear much changed since then, and what with one treatment after another of late years, planters may well feel that of the Indian Empire they are looked upon by their rulers as the Pariahs. Thus I do not wonder at human nature asserting itself in them by tempting them to show their sense of ill-treatment on every possible occasion, though I regret that in this instance it deprives me of the most trustworthy guide I could have in estimating the probable future out-turn of Indian tea.

* * * *

Without actual figures as to the acreage put down each year under tea in India, one has but a general knowledge as a guide, which, without allowing one to resort to figures, still permits of a rough estimate as to the rate of progress to be immediately anticipated, on the basis of acreage under plant. Going back to 1876

In that year the very high prices which had been ruling for Indian tea (and which had been encouraging large extensions being put down under plant), reached their maximum. Very large extensions were made and a very large area put down under plant in the cold season of 1876-77 in consequence. A further large area was planted out in the cold season of 1877-78, and a considerable area was added in 1878-79. Then came the crop season of 1879, when it was found that 38,173,521 lb. of Indian tea were valued, according to the Government Returns, at only R3,05,10,200, as compared with 34,432,573 lb. in 1878, valued at R3,13,84 235. Thus in 1879 we find a crop of 3,740,948 lb. *more* than in 1878 valued at R8,74,035 *less* than the smaller crop of 1878. Following up this appalling decline in value of Indian tea, we find that in 1880 the crop is put in the official returns at 46,413,510 lb. and valued at R3,05,42,400. Or in other words the crop in 1880 was 8,239,989 lb. in excess of the crop of 1879 and yet its total value was only R32,200 in excess of the latter crop, and this after the already severe decline in value in 1879 as compared with that of 1878! Naturally then in 1879-80, and ever since, the new area added yearly has been comparatively very small; the inducement of high prices having collapsed. Labour of a suitable kind has also become very difficult to get, and there appears no immediate prospect of my improvement in that respect.

* * * *

Thus, if the last *large* extensions were made in the cold season, 1878-79, it follows that when they come to maturity, say in 1884, we may expect to find the last *serious* increase in the out-turn of Indian tea for some time to come shown in the returns. The small extensions that have been made since 1878-79 will be handicapped, so far as their increase will affect the returns, by the yield from old and worn-out cultivation falling off, and, very possibly, by a certain quantity of new cultivation being abandoned from want of labour and other causes. I do not say that the maximum out-turn will be reached in 1884, but until high prices have again induced new large extensions, and until these have had time to grow and affect the returns, it is not impossible that unfavourable weather or blight may bring the out-turn of 1885 and subsequent years below that of 1884, provided 1884 has a favourable season. If all that is said against the Ilbert Bill be true, we have additional cause for not anticipating large extensions, but how far the effects of that Bill would prejudice extensions in the face of any important rise in prices it is impossible at this date to foresee.

* * * *

Ceylon tea promises to become a very serious competitor with some of the Indian tea districts, notably those in Assam and Cachar. Ceylon tea has the great advantage of being considered suitable for drinking alone, unmixed. Public opinion is a river which digs its own bed. We may occasionally moderate or quicken its course, but it is very difficult to alter it. Public opinion has decided that Assam and Cachar teas require blending, but has been more merciful to Ceylon teas. Were planters in Ceylon to show sufficient enterprise there is little doubt they could create a supply and a demand that might act as another serious preventive against extensions being made in both Assam and Cachar. *Verb. sap. sat.*

* * * *

In a paper recently read by Mr. G. W. Wigner, F. C. S., F. I. C. (President of the Society of Public Analysts before the London section of the Society of (Chemical Industry), the following remark on tea occur:—"Tea is remarkably prone to acquire any external odour from the air in which it is placed. It is, of course, well-known that tea *is* always packed in cases which are lined with lead. In the case of China teas the lead is tolerably pure, cast into sheets by pouring the melted metal on to one stone and dropping another stone on the top of it. This primitive method produces a sheet of somewhat singular uniformity in thickness, weighing about 2 lb. to 3 lb. to the square foot. Indian teas are packed almost exclusively in lead which is sent out from this country. It is not pure. It contains an admixture in most cases of tin, and sometimes a small proportion of antimony. These are added to enable the lead to be rolled much thinner, and the weight of it is not more than a quarter of a pound to the square foot. Before any injury can occur to the tea itself this lead must be either destroyed or perforated, or, at any rate, it must not be in an air-tight condition. It is obvious that, except in cases of neglect, all such goods would be packed in wood which was at any rate fairly well seasoned. Until recently only one kind of wood has been used for packing tea. This is a species known as 'toon' wood, and everyone who has ever seen a tea-chest made of it must be familiar with its general characteristics. It is easily worked, does not require to be stacked long to season, is free from smell, and not very liable to absorb water. The cases of injury with this wood have been of only occasional occurrence, and appear to have been determined much more by accidental circumstances than by even an occasional failure in the character of the wood itself. But of late years the supply of 'toon' wood has run short; the Chinese have had resort to other woods, and in Assam woods are being used at random." The rest of Mr. Wigner's paper was devoted to details of injury to teas, resulting, in his opinion from the wood of the cases absorbing moisture and causing the lead envelope to be attacked, white lead being often found in larger or smaller proportion on the wood next to the lead.

Planters no doubt will see in the above remarks by Mr. Wigner a repetition of some of the evidence of the chemists employed on the recent trial. In my opinion a very useful end might be served by obtaining information as to whether the parcels of Indian tea that arrive in an unsatisfactory condition have been opened in Calcutta or shipped direct from the factory to England. If it could be proved that all such teas had been opened for sampling in Calcutta, it would tend to prove that the source of the evil is the damp absorbed whilst the chests are lying in the Calcutta godowns, and doubtless this would lead to the proper remedy of what is now a more or less mysterious cause of depreciation. To talk to planters in such climates as Assam and Cachar, where the most seasoned woods, even in transit to the factories, will absorb a heavy percentage of moisture from the atmosphere alone, is to lay oneself open to the charge of offering impracticable advice. Yet a little care in storing the "shooks" in the driest place available may be found to repay the trouble. The reference to "toon" wood above, if it refers to the "toon" of Upper India, sometimes called the Indian Mahogany, is out of date, even for Upper India; mango wood in Upper India, and teak in Assam and Cachar, being now the woods of which the largest proportion of boxes are made on the better class of factories. All things being considered, teak amply repays its original high cost, by the safety its use tends to ensure.

The following is from a Welsh paper:—"Sir.—Oh, if you please, Mr. Editor, my brother Bill and I have had a dispute over something on a bill pushed under our door about 'given away.' It says—'Our system of business is to divide the profits with our customers.' It tells you that they give a teapot worth 1s 3d with a pound of tea at 2s 8d per lb. That 1s 3d is the cusomer's half of the profit, which leaves 1s 5d. Then subtract 1s 3d for the shopkeeper's half (1s 3d in 1s 5d will go once and two over), that leaves 2d. Now isn't that 2d what the tea costs? And isn't the profit on a pound of 2s 8d tea exactly 2s 6d. I say it is; and have worked it out on my slate. Bill says it is all bosh. Please, sir, I am top in the second class, and shall be up in the first tomorrow; Bill is only bottom in the third class.—I am, &c., Buttons, Dowlais."

CACHAR.

—*Home and Colonial Mail.*

TEA CULTIVATION IN DARJILING.

Mr. Owen's letters have led us to look up the rough pencilled notes we made during a visit to the Darjiling tea estates so long ago as March 1876,—seven-and-a-half years ago. From time to time we utilized in the *Observer* the information obtained, but our notes were never regularly "extended." In those days there was no railway and the chief means of conveyance consisted of Sikhim and Thibetan ponies, for which, to carry themselves and their baggage upwards from Silligori, travellers were dependent on old White of the Hotel at Kurseong: quite a character in his way. Tea, lead and other traffic upwards and tea downwards were carried by the short but wonderfully stout-limbed "paharris" or hill men, and the loads of lead they took up were wonderful. We should not like to name the weight a man carried, strapped to his back, while his only mode of resting was by means of a bamboo, the pointed end of which was inserted into the roadway or ground, while the other end supported the load. In resting, the men gave forth a respiration of pent-up breath, with a loud whistle. The coolies on the tea estates were mainly Nepaulese, whose first work on a new estate was to build themselves huts with the prevalent bamboo and long grass. Their money wages was low, R5.50, but selected "tea-makers" were paid R6 up to R12 per mensem. The women, stout and strong, generally did their full share of hoeing as well as other fieldwork, and it was curious to see a woman who sturdily plied the hoe, with a necklace on composed of perhaps R100 strung together and white and pink magnolia blossoms in her hair. Daughters are a source of wealth to a semi-Mongolian cooly, for "the custom of the country" is that each suitor pays the happy father R100 before he obtains his bride. With machinery provided, one cooly per cultivated acre was deemed sufficient. A European assistant was deemed requisite for every 800 maunds of tea produced. "A good burn" was desiderated, as the ground is wholly cleared of stumps, &c. The cost of cultivation we find noted as R52 per acre for the first year, and R30 per acre per annum subsequently. We were told that in the fourth year an estate ought to be "clear" [of debt] and worth £31 an acre. The odd £1 is curious, and our remark on the estimate of value was "far too low," while it was clear to us that the estate could not have possibly "cleared itself" in the fourth year. If it did so in twice four years, the result would be very good. We were told that 2 lb. of charcoal, costing 3 to 12 annas (5 a fair average) per maund, were consumed for every lb. of tea prepared. Large reserves of forest for charcoal and tea boxes were deemed necessary, and Mr. Owen has shewn that still further reserves are in some cases placed at the disposal of coolies for the growth of food crops. We find we had noted in regard to labour "Lower [Terrai] estates not so well supplied with labour. Regular monthly payments and no advances. Bad system of payment through Sirdars general." One of our notes is that each chest of tea cost R2 for conveyance to Calcutta, but we should think the actual cost of transit must have been considerably more. As in Ceylon, so in Darjiling, preference was given to forest land, but as a matter of fact, large areas of "chenaed" or "joomed" land were cultivated, the seed being dibbled in at stake. From a remark made by Mr. Southby of Selim estate, when we visited a Terrai property under his charge, that "holes had been made for every plant," it was evident that dibbling was the common mode of planting, and no doubt, it answered fairly in the black free soil, previously well hoed. In sowing at stake, so many as six seeds were actually, sometimes sown together and the temptation was often great to allow the resulting plants to grow up. But three seeds to each stake was evidently the general rule, for we find amongst our notes, "each cooly should put in per diem 600 seeds at 200 stakes." We find added, "even if planting at stake is adopted, large nurseries will be needed to fill up vacancies." So that with even 3 seeds to each stake, there were not sufficient plants to prevent vacancies. We saw black grub very bad on a low estate, but we suspect the great cause of vacancies is the climate: 150 inches of rain or even 200 in 4 or 5 months and then, too frequently protracted drought. On the occasion of our visit to Darjiling, no rain had fallen for nearly eight months; the "jorahs" [ravines] were waterless; cholera was rife and we and other visitors were deprived of a sight of Kinchinjunga, by the smoke which arose from hundreds of "jooming" fires, the bambus incessantly exploding with a noise like artillery. During that dreadful season fires on tea estates were common and destructive. Tea bushes, however, are not so liable to injury by fire as coffee bushes are. If burnt down they spring up again. When tea trees are very old, they renew after being cut down, but are not equal to what they were in their prime. One of our notes which now perhaps requires a ?, is that "the best tea is yielded by young bushes." Going on with our notes without much regard to system, we find we were told that "seven months plants should be eight inches high; that plants to supply vacancies should have balls of earth attached to them and that the tap roots should not be injured." We added, "Mr. Cave's idea that transplanted tea bushes are more liable [than those planted in situ] to run to seed, is no doubt true." Any shock increases the instinctive tendency to perpetuate the kind. To quote again:—"Manuring or addition of soil to steep land is indespensable, especially if the soil be a red one. Deep hoeing practised, the feeding roots of the tea plant, not being so near the surface as those of coffee." [The hoeing is not, however, permitted to approach too close to the root stem.] "Four-pronged forks seem preferable to kodalies, although perhaps not so much work got through with the forks." There were and we suppose there are no weeding contracts, in a region where weeds, or as the local term is, "jungle" are permitted to grow for a portion of the year at least, side by side with the tea. Some of our notes are significant: "Objection to terracing, that weeds are left to grow on the outer edge." [So it is in Java.] And again:—"Tall rank 'jungle' [chiefly iluk] not to be allowed to grow about the plants to make them grow lanky." We should certainly say in Ceylon, "by no manner of means," if we except Mr. Habiley and a few of his school. Further.—'Terraces should not be more than three to three-and-half feet wide, or the trees will get into the subsoil." Close planting, especially in the rows was the rule, ignorance and inexperience at the commencement having led amongst other errors to the planting of China tea so wide apart as 8×8. We saw some wonderfully-sized trees so grown on

Datooriah, (an estate the teas of which always top the market,) but the Superintendent informed us that the plants of a nursery, allowed to grow up thickly gave a much larger yield per acre than the big. thick stemmed bushes with all the soil. light and air at their disposal. Our good friend, Mr. Kerkhoven, of Sinagar in Java, had much to say in favour of his "hedge system": four feet between the rows for trenches and cultivation, but the bushes [China in his case] only one foot apart in the rows. We find we were informed that in Darjiling, "Trees were topped in the first year and that they were not allowed to grow [untopped] higher than two feet. The great object is to get the plants to spread and they should never be allowed to grow higher than 3½ feet." This was with reference to China plants on hill estates, for on a Terai property we saw bushes four feet high and over, with a grand spread of surface, but these were best Assam Hybrids. On this Terai estate, sal and other trees were allowed to grow for shade and we were told that the drip from them did no harm. Amongst our notes we find that "China bushes can bear rougher treatment than hybrids." Also that pruning is always done in the dormant season from November to March and that in plucking which is really a pruning two sets of leaves should always be left. Bamboo and cane which abound in the Sikkim forests, are valuable for tea baskets, as well as for building purposes. We took special notes of the paucity of estate roads and the absence of drains; as also of the large space occupied by factories and the general use of steam-engines. Steam-machinery is absolutely necessary on the low Terai and Dooars estates. We find that we have noted "tea land is first hoed to the depth of 10½ inches and when the stumps are taken out a second hoeing down to 18 inches is given." The land is therefore regularly trenched. A common mode of planting on the hill estates was said to be 3×4 which gave 3,630 trees to the acre, from each of which ¼lb. of dried tea [over 900 lb. per acre! seldom realized, we suspect] was deemed a reasonable return: The steeper and higher the land, the closer ought to be the planting. We noticed that the presence of mica in the soil was conducive to its porosity: we might have added to its instability if on hill sides in rainy weather. The pioneer planters had suffered much (two had just died from Terai fever) but unhealthy places were said to be improving. There was and is much room for amelioration, and we ought not to under-rate the great advantages of our salubrious hill climate in Ceylon. A note runs: "If in China the best mean temperature for tea is from 65° to 70°, the temperature of most of the mountain country of Ceylon is all that could be desired." While the danger of very high altitudes is the prevalence of mist, there is greater liability at lower elevations to alternations of drought and heavy rainfall [?] That the last note referred to Darjiling is evident from the remark which follows, that, "The usual February and March showers had failed in 1876." We then find "the Chinese have only half the rainfall and half the plucking that Indian planters get, but cheap labour [production by small farmers] is in favour with the Celestials." We find we have put a note of admiration after the statement that 1 maund (82 lb.) per acre was gathered from tea estates in their second year; but it is added, "above 3,000 feet, only one third of this." An altitude of 3,000 ft. in Darjiling, we may remark, is fully the equivalent of 4,500 in Ceylon. We noted that there was a universal opinion in favour of toon (red cedar) timber for tea boxes, that the lead-lining of boxes was deemed very expensive, that careful soldering was required and that hasty drying leads to burnt tea: good fires *covered with ashes* [?] are necessary." Then comes the interjected remark that coffee planters were not subjected to the annoyance of the "bulking" of their produce [?]. While withering was generally performed in the shade, we find it noted that "leaf plucked at 7 a.m. and withered in the sun, can be made into tea the same evening." Then as to hand-rolling which was then still the rule, "40 lb. green leaf (10 lb. dry) per man per diem can be rolled. Question if right to have given-up panning: seems to be necessary for coarse leaf." We suppose this question has not been quite settled yet, for it is stated that on Loolcondura (perhaps on other places in Ceylon?) tea is still "panned." Then we went on. "The rolling, fermenting and drying of tea are nice chemical operations. Hill tea is especially benefitted by good fermentation." We then noted that we had been told of the "superiority of brick drying dhools to baskets and that for 48 lb. tea only 40 lb. of charcoal while 66 for brick." The meaning of the compressed note we take to be that while 40 lb. of charcoal was necessary for the preparation of 48 lb. tea with baskets, the same quantity when used in brick dhools or stoves, sufficed for the drying of 66 lb. tea. In either case, our information that 2 lb. charcoal were required to cure 1 lb. tea must have been wrong. Every tea planter must rejoice that dhools and charcoal fires are no longer indispensable, although, no doubt, charcoal has still the great merit of being smokeless. We took a special note of "the wonderful hardiness of the tea plant," growing as it did in the latitude of Darjiling from little above sea-level (300 feet at Siligori) to over 5,000 feet. In Darjiling, protection is sought from the south and south-easterly winds which are hot and dry. "The cold of the higher altitudes retards flushes, but gives superior aroma. The regular flushes between March and November are six, with gleanings between." [We can generally double this.] In the good soils of Darjiling there are large proportions of organic matter and oxide of iron, with scarcely a trace of lime. Rich free soil is the best, while the black colour secures a hot temperature. [This proposition, supposed to be established by Franklin's experiments, has been recently questioned.] "There are sandy soils even in the Terai," on which, we may remark, that a gentleman familiar with China tells us that much of the tea in that country is grown on light sandy soil. So far our pencilled notes, but many others laid up in our memory have been embodied in writings which expressed the conviction then formed and never departed from, that many as were the advantages of Darjiling as a tea growing country those of Ceylon were superior. The results of seven-and-a-half years' further experience have more and more shewn that we judged correctly. The position has indeed so changed that instead of Ceylon tea planters going to India, it is the Indian tea planters who now resort to Ceylon. They come to see if the reports of our marvellous yields of leaf are true, and most of them, when they have seen have exclaimed: "The half was not told us." If only competition in growth does not send down tea, like coffee, below remunerative prices, it seems beyond doubt that there is a great and prosperous future before tea planters in Ceylon.

THE GREAT CINCHONA LEDGERIANA CONTROVERSY.

May surely be considered to be finally disposed of by the trenchant letter of Dr. Trimen which we give on page 282. Of Mr. Howard it may be said that his *bark* is better than his *botany*! Mr. Ledger also, on whose authority, the great Quinologist seems to lean, is a cinchona bark and seed collector—not a botanist. It is absurd, therefore, of the editor of the *Planters' Gazette*, to write as he does in introducing Mr. Howard's letter, namely:—

It will be seen that he (Mr. Howard) still maintains his opinion that the so-called *C. Ledgeriana Moens* of Dr. Trimen is only an inferior *Micrantha*, and in this he seems to be confirmed by Mr. Ledger himself, who certainly ought to be the best authority as to what is and what is not *C. Ledgeriana*. It will however, be very satisfactory to Ceylon growers to find that Mr. Ledger unhesitatingly recognized plants grown by Mr. Howard from Yarrow Estate seed as being true to type.

The writer has not yet taken in the fact so often stated in our columns, that the Cinchona Ledgeriana figured and described by Dr. Trimen is one precisely similar to those from Yarrow, grown from the same seed though on a different estate, St. Andrews. Mr. Howard's favorite test of bark analysis has also now been met in bark sent home from the St. Andrew's Ledgeriana trees. We trust, therefore, that we have seen the last of this rather profitless discussion.

SHELTER BELTS IN COFFEE,

With reference to the letter of "Blown Coffee" (page 283) we may say that of the value of shelter there can be no question, but the difficulty is to obtain it. Those who originally left belts or original jungle have in nearly every case cut them down and "planted up" the soil. It was often found that the winds just rose over the belts and tore down behind them. This was notably the case in the Lagalla district where coffee opened in fields surrounded by jungle, was blown to ribbons (all "vips and valking-sticks" as one cockney planter described them)—the wind when it got into the field, seemed as if it could not get out again. Then, not only did belts harbour weeds and vermin, but belts of original forest died off rapidly when isolated, and it is most difficult to grow foreign trees just where they are wanted on blown ridges. Shelter trees scattered over estates are on the other hand very detrimental to the coffee around them. We have gone in largely for shelter, natural and artificial, but we cannot say our experience has been very satisfactory. Others, who have been more fortunate, will doubtless respond to our correspondent's request.

THE CACAO (COCOA) ENTERPRIZE IN CEYLON.

We are pleased to learn that 150 acres of Crown land recently purchased near Nalande, in Matale North, were on account of a West Indian estate proprietor, Mr. Marshall, who, some months ago, visited Ceylon and was much pleased with what he saw of cocoa cultivation with Mr. A. Ross on Kowdapolella. The result is that Mr. Marshall has resolved to invest in old Lanka, and he is not inclined to allow any time to be lost, for, telegraphic instructions have been received from Mr. Ross to the effect that the 150 acres must be planted up by Christmas. There should be a good time coming for the Matale railway with the traffic in cocoa and other new products which will by-and-bye become available.

TEA SALES AND AVERAGE PRICES.

We are again reminded of the necessity of regarding the *averages* realized for whole invoices of tea as the most important feature in comparing sales. In our issue of Thursday we gave a list of names of estates of which sales were reported by the last mail; it so happens that the name placed *last* in our list is not only first of this mail's sales, but it shows the highest average yet obtained by any complete invoice of Ceylon teas, we believe. The average of the Koladenia invoice is 1s 9d, and though it contained only two descriptions, it contained, we understand, all the tea made, that is to say nothing had been withheld in the way of dust or broken tea. The total invoice was close upon 5,000 lb. This of course is very satisfactory and it is worthy of note that the estate is one referred to disparagingly in that reprint we made a few days ago from the local "Times," The Ceylon Company have of course reason to be pleased, but it may be that the sale was an exceptionally good one, and we should like to see the average repeated before saying much about it. Still it is important that planters and the public should get into the right way of looking at these things; that way is to compare *averages*, for there is no way in which they can better make comparisons. It is very pleasing to see Ceylon tea obtaining fancy prices above the highest paid for Indian growths, but the real merit is shown by the averages. We further learn that the Koladenia teas were bulked and packed in Colombo.

RUBBER CULTIVATION IN CEYLON: SUCCESSFUL COLLECTION OF THE PRODUCT: GILLIAT'S CUTTER, TINS AND PROCESS OF ELIMINATION.

Another clever contrivance has to be added to the long list of inventions by Ceylon planters for the more rapid, economical and successful performance of the work connected with the cultivation and preparation of New Products which, of recent years, have excited so much attention. But first of all it is satisfactory and reassuring to find Ceara Rubber trees brought forward again as objects promising financial success for the cultivator. So much was said lately of the difficulty of collecting the milk—or rather watery substance—to make it pay, that on many sides the cry was heard that Ceara Rubber trees were no good, and could not be made to pay, whatever might be the case with the other varieties. The Ceara trees to which the following experiments refer are growing on Peradeniya Estate from 3½ to 4 years old, 28 to 34 feet in height, planted 12 feet by 12, and already with their branches so interlocked that there is dense shade beneath. Mr. Gilliat, the manager, has a strong opinion from the result of his observation and experiments that shade is inimical to the quality of the rubber got from the stem and he would recommend planting 15 by 15 feet or even 20 by 20 as an experiment. Again he has found that the best time to cut or tap is immediately after rain, and Dr. Trimen fully agrees that the flow of sap will be greatest just before the flowering season.

The great *desiderata* hitherto with all who have experimented with rubber trees in Ceylon have been a satisfactory, economical mode of tapping the tree without injuring it, of collecting the milk and of securing it in a marketable form without the admixture of foreign substances or impurities of any kind. Mr. Dobree's knife was intended to be used for the removal (and replacement) of a portion of the bark—an operation which could scarcely be done without injuring the cambium. Mr. Wall tried skining the tree and then pricking it to induce the flow of the milk—a tedious and expensive process we should suppose. Certainly we have seen no instrument and heard of no means of tapping equal to that which Mr. Gilliat (the inventor) brought under our notice today.

By his little instrument, with the accompanying tins and the process for the elimination of impurities, we are very hopeful, Ceara Rubber cultivation may be made a very profitable branch of New Products' Industries in Ceylon and we trust Mr. Gilliat's ingenuity and patient experimentalizing will meet with the reward they deserve. Suffice it to say that a cooly with this little knife can make the requisite number of cuts down the bark of the rubber trees with ease and rapidity, without any material injury to the cambium. When made, the cut is about ⅛th of an inch open or wide by 1-16th inch deep: the cuts should not be nearer each other than six inches—that is trees on Peradeniya, four years old, 24 inches girth take four horizontal cuts; but Mr. Gilliat is very hopeful (and Dr. Trimen we believe agrees) that after a month's interval, four more cuts in the intervals may be made without injuring the tree, so giving a second harvest of rubber. An ordinary cooly can go over 200 trees a day with 4 cuts in each, and a little podian can follow with the tiny tins (specially made by Mr. Gilliat out of empty kerosine tins) which are stuck into the tree to catch the exuding rubber. Those tins can be made at 5 cents a piece. The most important part is however the chemical process by which all impurities are precipitated and lumps of pure white rubber, gradually assuming the pink colour on the edges so prized at home, are secured. Mr. Gilliat being more or less of a chemist, had experimented for months over this, until he found the spirit, a very little of which dropped into the day's gathering of rubber, secures the above result. The elimination is secured even if 24 hours elapse between the tapping and the application of the spirit. Dr. Trimen is highly satisfied with the result; and we cannot help thinking that the beautifully white clean samples of rubber shewn to us today will be priced as high as any in the home market. Mr. Gilliat is to lay them before the Planters Association. So far as his experiments have gone, from ⅜ths to ½ ounce of rubber per tree is about the gathering or say ⅞th ounce from the two cuttings with a month's interval. No one can yet say how soon the tree will bear another harvesting. The experiment has to be made; but there is no reason to doubt a satisfactory profit from rubber cultivation, when harvesting and preparation are done with the instruments and according to the plan invented by Mr. Gilliat of Peradeniya estate to whom all rubber planters owe, at least, their best thanks.

TEA, COFFEE, CINCHONA, CARDAMOMS AND ALOES CULTIVATION IN CEYLON.

(*From the Proceedings of the Maskeliya Planters' Association.*)

Saturday, 15th September, 1883.

MR. OWEN'S PAPER ON TEA, &c.

After the tasting and comparison of the different teas from Strathellie, Rookwood, Elfindale, Bunyan, Theberton, Awisawella and other Ceylon estates with those from Assam and Darjiling, the proceedings commenced.

The CHAIRMAN introduced Mr. T. C. Owen, reminding those present that this gentleman laboured under peculiar disadvantages as his paper would follow only a fortnight after one upon a similar subject and of a most exhaustive character read by Mr. Armstong before the Dickoya P. A.

MR. T. C. OWEN then proceeded to read his paper upon the cultivation, etc. of tea adopted in Assam and Darjiling as compared with that of Ceylon.

Mr. Chairman and Gentlemen.—The subjects which I propose to bring to your notice today deal entirely with those products which are suited for supplementing or replacing the cultivation of coffee, more especially at high and medium elevations. I must premise that I am not one of those who think that remunerative coffee cultivation is altogether a thing of the past, but this subject has been dealt with in such an able way by others, and I so fully concur in all that they have said, that any further remarks on that point are unnecessary.

Of the various products with which it is proposed to replace coffee, the one which is at present attracting the greatest attention is undoubtedly tea. Eight years' experience of its planting and cultivation in Ceylon, with the results of an extended trip through the Assam, Darjiling, and Terai districts, which I was able to make recently, have enabled me to form some conclusions on the subject which may be of interest to others.

The general conditions under which cultivation is carried on in Assam are utterly different from those which characterize the hills in Ceylon; the nearest approach to our circumstances being found in the Darjiling hill district, which therefore possesses a special interest for us. The land there is very steep, as steep as anything that is generally planted with coffee, but it is worked in a different way. In Assam and the Terai the land is perfectly flat, that which is suitable for tea consisting of raised banks of dry soil surrounded by swampy land unfit for cultivation. The soil in Darjiling is very variable. The upper portions of the hills are yellow clay with very little surface soil, but the clay seems to be especially rich, for the tea flourishes in it wonderfully. Lower down towards the ravines and rivers, the character of the soil entirely changes, and it becomes a rich black micaceous loam of great depth. In the Terai, the surface-soil is very rich and fertile, but underlying it at no great depth is a barren gravelly subsoil; the result is that when young the tea flourishes luxuriantly, but when old the results become disappointing. Assam has a very rich loamy soil in most places, which is exceedingly deep, 20 feet and more sometimes, and of a remarkably fertile character. It is evident that the success of tea depends on the depth and quality of the subsoil more than anything else. The Darjiling clay is very similar to what we are so familiar with in Ceylon, and the fact that tea sends its roots down into it freely and grows healthily, should make us confident as to its future in our stiff lands.

Now, this subject of soil is a very important one for us; its importance cannot, in fact, be over-rated, and the chief question we have to decide is this:—Is the Darjiling hill-soil of such a nature as to lead us to hope that our Ceylon tea will be a *permanency*? That our young tea will bear, and bear well, has been conclusively proved, as I shall show later: *will this last*. As I have said, the Darjiling soil is very variable; some is apparently very inferior to much of ours; (I speak as a practical planter, not as an agricultural chemist); some is superior to anything we have. As an illustration, I will take the Sing-toen estate. The upper portions of this garden are so stiff and clayey that a walk of half-a-mile down-hill, without a fall is a real feat. As we go lower, the clay becomes covered to a greater depth with a rich black micaceous loam. This garden is a very old one, and without manure of any kind the tea is yielding a better crop this year than it has done for a long time. The estimated yield is about 320 lb. an acre, a large yield for the locality as I shall show later. The manager tells me that the lower portions bear better than the upper, but the latter, in spite of having an inferior jat of tea in them, and in spite of a less favourable climate, bear well and pay handsomely. I have also seen land, very much of the same character as some of ours upcountry, a light loam, growing good and permanent tea in the same locality, and I unhesitatingly say that *if you have depth* you need have no fear of its future. The Terai is a most important instance of the uselessness of rich soil if an unfertile sub-stratum underlies it. We have not, as a rule, rich soil in these districts; we have nothing as good as the soil of the best localities in Assam, but we have better soil than some districts even in that favoured province (and as an instance I will name Gowhatty), and we have plenty of it. Those that have a good depth of such soil as I have described on their estates, although it is not apparently very rich and even though it is clayey, may plant tea without fear for the future; but I would warn you against shallow soils over-lying gravel or rock as sure to lead to disappointment.

In all the Indian tea districts there are great changes of climate during the year, to which we have no parallel down south. In October the approach of the cold weather begins to be felt, and in November and December there is a veritable winter characterized by snow on the upper Darjiling gardens, which causes a universal stoppage of all growth. In March and April there is a commencement of growth again, but this is not fully started till May. The consequence of this is that whereas in Ceylon we have growing and consequently plucking weather all the year round, in India they have only five really good crop-months. During these months their growth of leaf, and of weeds too, is of course far more luxuriant than ours. The unhealthiness of the Terai and Assam climate in the rains is proverbial, and I will not enlarge on it but merely point out that with expensive imported labour an epidemic means ruinous loss in every way, that with local labour it means wholesale desertion, and that it also means high and costly remuneration to Europeans and other employés.

In the matter of JAT we are behind India. The fatal error of planting China and low-class hybrid was originally made in all the Indian districts; but now public opinion has run to the other extreme, and in the plains none but indigenous seed, at R150 per maund, is bought, and on the hills a good high-class hardy hybrid is gone in for. And here I would warn everyone against being induced to plant China or low-class tea at any elevation in Ceylon. Hybrid of the right kind will grow well, and inferior jàt means a decreased yield and a comparatively weak tea. On Oononagalla this year I manufactured the two separately, and sent them to the London market; at a recent sale the hybrid tea was well reported on and averaged 1s $4\frac{1}{2}$d all round, whilst the China averaged 1s $2\frac{1}{2}$d and was spoken of as a poor tea. Very fine tea is made from China plant in Darjiling no doubt, but that from hybrid bushes is in every case finer when the two are grown together.

And not only this, amongst hybrid plants, the nearer the jàt approaches the indigenous type, the stronger and more telling is the liquor and the better the tea. I have proved by experience that this rule holds good for both Ceylon and India. Plant, therefore, the best class of hybrid you can get hold of in these districts, even though it entails an extra cost, which after all, spread over your acreage, amounts to a very trifling additional expense in opening, and you will never regret it. Coming fresh as I do from a country where I have seen old low-class tea being rooted out to give place to a better kind, I emphasize this statement.

As regards LABOUR facilities, Ceylon has a decided advantage. The rate of pay in India is considerably less, R3 to R6 a month for women and men; but then in Assam every imported labourer costs upwards of R100 for a three years' agreement, at the end of which a bonus has to be given for its renewal, whilst there are numerous costly and vexatious Government restrictions. (Refer to copy of forms). In Darjiling and the Terai, all the work is done by local labour which is very cheap, but here it is necessary in many cases to give over large areas of valuable land to the coolies for Indian corn cultivation (in one place I saw as much as 100 acres or more so treated); and this item, one which does not appear in any accounts, is a matter of some moment.

In TRANSPORT, the many advantages possessed by Ceylon over Assam are evident, but Darjiling in this respect, as in the matter of labour, is more on terms of equality with us. At present, the only means of communication with Assam is by a steamer-service on the Brahmapootra, which charges the most exorbitant rates for freight up, and which is scarcely more equitable in its charges for tea down to Calcutta. About three cents per lb. seems to be the lowest average cost for tea down from Upper Assam to Calcutta, and this would be higher when much land-transport is necessary. The freight upon tea lead, nails and all factory requirements is however the most serious item, and the one which makes all these necessaries so expensive when landed on the gardens. Darjiling, with its railway up into the district, is much better off in this respect, and were it not for its small yield would be a dangerous rival to Ceylon. The Dooars, a district situated at the foot of the hills, similar to the Terai but to the east of it, possesses almost the same advantages of transport and labour as Darjiling, and is better circumstanced in the matter of soil than the Terai. This is undoubtedly the rising district of India, and the one which will run us the closest in the future.

The Indian methods of PLANTING and CULTIVATION are very different from ours. Nurseries cover a much larger extent of ground, the seed being generally put in five inches apart to allow of ball planting which is universally practised. It was the general opinion that plants put out in the Ceylon way, without any earth about the roots which are sometimes lightly pruned, would not stand a chance owing to the excessive power of the sun when it does show during the rains. The general planting distance for hybrid bushes is 4 × 4, indigenous plants in the best land in Assam being put 5 × 5 and some times even 6 × 6. The first distance mentioned is by far the most general, and the one suitable for adoption in Ceylon, though very poor land of course might be planted closer.

As regards Planting, Mr. Armstrong has anticipated all that I had purposed saying on the subject. I have found by experience that attempts to suit lining-distances to that of the coffee is a great mistake. It is far better to line the field *de novo*, without any regard to the coffee trees, the lining rope being stretched along the ground. As to holing, I would always make the holes 15 in. deep, and have found that a deep hole does best, breadth is of little consequence; nine inches, about sufficient for the cooly to work in, is enough. A good lining-distance through coffee is $3\frac{1}{2}$ ft. up the lines and 4 ft. between them, and this latter distance should not be decreased except in very poor land.

Various schemes have been suggested as to the best way of combining Coffee and Tea Cultivation until the latter begins to yield. Now I would strongly dissuade anyone from attempting to raise certain lines of tea before others as sure to lead to trouble. For instance, some people plant lines of tea up between the rows, with a plant between each pair of coffee trees up them, intending in two years' time to uproot the coffee and put a tea plant in instead. This or any similar method will infallibly give great trouble, and probably result in a patchy garden. When supplies abound, the difficulty and trouble of keeping pruners and pluckers from touching them is inconceivable to those who have not experienced it.

Steep land in India is very commonly terraced. The lines of plants are made across the face of the hill and not up and down it, and the terraces are formed by a succession of hoeings along the lines. On stiff land terracing is dispensed with, and though no drains are cut there is remarkably little wash. The ground is always kept covered with a thick growth of weeds, which in the flats are kept down by constant hoeings, on the hills by sickleing. The land is so thoroughly impregnated with weed seed and the growth of all vegetation is so rapid during the rains that clean weeding is an impossibility, and these methods of cultivation are the only ones possible. Draining, too, is impracticable in many places when there is not a stiff sub-soil to cut into. The result of observation is to convince me that, whilst our present system of cultivation is the right and proper one and incapable of improvement as far as India is concerned, that adopted there is the only practicable one under their circumstances. Their system is of course a much more expensive one than ours, and, in spite of the fact that no cultivation whatever is required during the cold weather, the rains being the only time when hoeing is necessary, its cost is upwards of three times as much as that of clean weeding from the first. The growth of plants under the most favourable circumstances in Assam is about on a par with that in the Ceylon low-country, but under ordinary conditions I think it is hardly as satisfactory. This method of comparison is, however, a very unsatisfactory one and in view of the facts and figures now at our command, it is unnecessary. Suffice it that, broadly speaking, a two year old plant will be much the same size on a good Assam garden as on a Ceylon low-country plantation, whilst on the hills it is impossible to make any comparison between India and Ceylon, the advantage in favour of the latter being so astonishingly great.

The great point is, of course, YIELD. How does the Indian yield compare with that of Ceylon gardens? Amongst the numerous Assam gardens I visited, the best in every way, cultivation, jàt and soil, was the Borelli Company's, and it is known as one of the best in Assam.

The yield last year was $7\frac{1}{4}$ maunds or 580 lb. per acre. This and a few other gardens of specially fine character apart, 3, 4 and 5 maunds per acre represent the yield of the bulk of the good Assam plantations, say from 240 to 400 lb. (p. 297, *I. T. G.*) From my experience of the Ceylon low-country, I feel convinced that a yield as high if not higher than the exceptional one previously mentioned will be very generally got on good gardens, the average being much higher than that of Assam. But our more immediate subject is a comparison of hill-tea in the two countries, and on this point there can by no possibility be a difference of opinion. The ordinary yield in Darjiling is between 2 and 4 maunds per acre, the latter amount being considered remarkably good. There can be no question from the results already obtained that this will be very considerably exceeded in Ceylon, and we are all aware of numerous instances to show this. I need here merely refer you to the figures brought forward by Mr. Armstrong in support of this statement, which shew conclusively that his estimate of 400 lb. per acre for hill gardens is by no means an over-sanguine one. I think this estimate of yield, judging from your soil and climate and in respect of the results actually obtained elsewhere, is a very reasonable one and not likely to prove misleading. Actual figures and results apart, a visit to the Indian tea gardens is quite sufficient to show plainly their inferiority to ours; the period of growth during the year is very short, and at a high elevation is insufficient to force out any considerable quantity of leaf.

Regarding QUALITY of tea, there is little to be said in view of the very fine prices now being obtained by all properly managed estates. To anyone comparing Ceylon hill and low country teas with those from the various Indian districts, it is evident that ours possess a character of their own and that they are not altogether comparable to Indian. Our low-country teas have not the rasping pungency of Assams, and this difference is more marked in the coarser qualities than in the finer. Our hill-teas also have none of them the Darjiling flavor, but are characterized by a distinct hill-flavor peculiar to them. It is a peculiarity of Ceylon teas that those grown in the low-country possess a flavor combined with their strength which Assams lack. There is one fact very generally lost sight of in comparing the prices of Indian and Ceylon teas, and that is that most of the best marks are sold locally in Calcutta and do not of necessity appear at public auction in the London market at all. Though, therefore, the position already taken by Ceylon tea must be a source of satisfaction to all interested, we must not suppose that we have attained perfection by any means, nor must we imagine that India is already behind us in the race for quality (*I. T. G.* p. 503.) That there is in reality not much we have to learn is the conclusion forced on me by visits to numerous factories, in various localities, but yet there is something; and there were few gardens where something to improve or something to avoid was not noticeable. And here I must put on record and mention the excessive kindness and hospitality which is to be met with everywhere in India; not one single garden did I visit where everything was not thrown open to my inspection and where every information was not given.

I will now say a few words on MANUFACTURE, as far as Mr. Armstrong's paper leaves me the opportunity. The system of manufacture as described by him and practised by us agrees very closely with that in India. Falling trays for withering are not generally in use. In Assam large temporary iron-roofed sheds are erected, consisting of 2 or 3 stories, and in them the leaf is thrown. In Darjiling more permanent buildings are erected, and the leaf spread on flat round bamboo baskets, which are roughly made and ranged in tiers on racks to support them. I think our system is preferable, as being an economy of space. But I would advise that a portion of the withering-house be left free, and that here a number of loose bamboo trays be stocked, in which sun-withering when necessary can be arranged. In our damp climate it frequently happens that by the morning the leaf is still unwithered, and half an-hour's exposure to sun or light will finish it off and save time. Hand-rolling is unknown in India, as far as my experience goes, and even for the second rolling after fermentation a machine is employed. Regarding so-called fermentation—for I believe this to be a mis-nomer and that oxidation would be a more correct term—it is a good plan to mix the roll several times during the process, as this makes the colour much more even. In fact, in a hot climate, I would employ boys in turning the roll over constantly, and I have seen some of the best manufactured teas in Assam and the Terai made this way. It is not a bad plan, after machine-rolling, to sift the roll through a No. 4 sieve and ferment the small and big leaf separately; this well enable you to colour your coarse souchong leaf without overdoing the pekoe and broken. Where roll is constantly turned however (and it is quite practicable where colour is obtained in an hour or so) this sifting is unnecessary, an even colour being obtained without it.

As to Firing. A machine-dryer being generally purchased after the roller, the method of performing this work by hand is of some importance. The stoves recommended by Mr. Armstrong are better than the long open troughs sometimes used. But the system of firing in India is better than that that recommended by him. The shape and dimensions of the stove are similar, but the opening at the bottom is bigger, about 15 in. square. The air-hole, not alluded to by him, is a most important point, and on its size the efficient consumption of the charcoal depends. It should be about 9 in. high and 6 in. broad, and no grate whatever should be used. The whole bottom of the stove should be filled with charcoal and kindled until the mass is in a glow; then—and here comes the secret—the fire is masked by a thick layer of ashes, a stock of which is always kept on hand. In using a grate, the charcoal has to be lighted outside and brought to the stove glowing, to prevent the possibility of smoke from ill-burnt fuel, and a great loss of heat is entailed by this. 1 lb. of charcoal does 1 lb. tea by the Indian method, as against a bushel of charcoal to from 8 to 10 lb. by the latter system. Again, 24 and 26 mesh-firing sieves as recommended by Mr. Armstrong have been given up in favour of 12 to 16 meshes. The larger meshes allow the tea to fire quicker, and very commonly the broken pekoe is sieved out through them permanently, thus saving subsequent labour and the use of sieves during firing, at all times a troublesome method. I was told also, but cannot vouch for the fact, that burning was less common with a large than with a small mesh sieve, scorching being due to the wire getting too hot in the case of the latter. One man to six trays is the usual allowance, and each firer's tea is kept separate till the next day and weighed and even tasted separately sometimes. An Indian tea-house assistant can always point out his best firers.

Sorting is very commonly done by hand. With a China sieve (made of fine bamboo). I have seen a good man sift a whole bulk of teas through with a No. 10 only, all done by altering the angle of inclination of the sieve. In fact, much depends on the degree to which sieving is done, and work done with the same sieve by different coolies is not always similar. Much variety can be introduced into this work, but the great principle is to sift into as few qualities as possible.

Regarding Packing. In chests, split canes are an admirable substitute for hoop-iron, or small clips which just embrace the corners. With this substitute for hoop-iron, I certainly think factories near a cart-road ought to use chests, and so effect the saving in lead, cost of packing and draft which this means. As to wood for tea boxes, In India, Burmah teak is generally used; and out of all the numerous species growing locally, none is yet in common use. In Ceylon, I have always used Mallebodde, that despised tree which every one condemns. If seasoned properly and used soon, it is suitable in every way, being light, free from smell, and holding a nail well. It must not be kept too long however, or insects will attack it.

The arrangement of the Factory may well be left to the ingenuity of the manager, as it is generally a converted coffee store. The great points to be borne in mind are, that the withering-room should be immediately under the roof, and above all heat-creating machinery and stoves; that the engine-room or water wheel should be cut off as much as possible from the rest of the building; also that ample *light* should be provided for, everywhere.

In Tasting, all defects in manufacture become apparent, and by means of samples the work being done in any factory can be checked. I have here the Awisawella estate samples which gained the silver medal in Colombo, and of which the bulk averaged 1s $7\frac{3}{4}$d at the last sales, the broken pekoe fetching 2s $7\frac{1}{2}$d.; this was made under the immediate supervision of a gentleman who knew nothing of tea manufacture nine months ago.

In regard to Machinery I have a few words to say. In a small garden that will not give bigger accumulations than 1,600 lb. leaf per diem to be worked off, a "Universal" roller and a "Sirocco" are most suitable machines. It is, however, an axiom in India that rolling and firing power must always be provided for about double the quantity of leaf that has to be expected under ordinary circumstances, and I think there are few Ceylon estates where the machines in question would be found sufficient during a rush of crop or a continuance of unfavourable weather. Presuming therefore, that quantities of leaf up to 5,000 lb. will have to be dealt with, an "Excelsior" roller is the best machine to erect, but I do not agree that a multiplication of "Siroccos" is either economical or advisable as suggested by Mr. Armstrong. Kinmond's No. 2 Dryer costs £220 and does the work of exactly four Siroccos costing in the aggregate £340, the cost of erection of one machine as against four would make the divergence still greater. Teas from Siroccos are characterized by a very brisk full liquor, undoubtedly superior to those fired over charcoal; but having had opportunities of sampling them against teas from Kinmond's machine, I am strongly of opinion that the latter carries off the palm. A Kinmond's machine requires five coolies to work it; four Siroccos would require twelve coolies to keep them going. So that, in original cost, working expenses and efficiency of work, the policy of erecting one good machine is preferable to that of maintaining several inefficient ones, however satisfactory the quality of their work.

And now as to the machinery for gardens working off upwards of 10,000 lb. leaf per diem: two "Excelsiors," may be erected, or one "Haworth's" roller. This latter machine is very popular in Assam, and will roll 1,100 lb. leaf an hour. I believe the cost is about the same as an "Excelsior," but am not quite sure. The machine consists of three parallel rollers revolving very rapidly in the same direction. Between them the leaf, enclosed in a bag, is placed. This machine does excellent work. Of dryers to work on a large scale, there is none to equal Gibb's and Barry's. This machine consists of a long iron cylinder, made to revolve in its axis, and with a slight slope towards one end. Hot air is driven in to it by fans along a shaft which traverses it from end to end. The roll is put in at the upper end, and comes out at the bottom ¾ fired. The temperature of the hot air is from 650° to 700°, as against 275° for the Sirocco. To finish the tea off it is put through again from time to time as the ¾ fired tea accumulates, at a reduced temperature. Those who have sampled teas from these machines would be able to recognize the high-fired flavor and the peculiar twist of the tea, anywhere, and they like it better than teas from any other machine yet invented. The higher the temperature at which tea is fired the better the liquor, provided always that there is no burning; and under-firing arising from over-caution in manufacture is a very common fault with us. The cost of this dryer would be about R4,000 erected, and it requires about ¼ H.-P. to drive the fan, as does Kinmond's but it is unquestionably the machine of the future. I would add that for this enormous quantity of tea three coolies only are required.

As to Sifters, I believe as efficient an apparatus as anyone requires can be made and erected on the estate, without large outlays in patent machines, and I saw many of the former in India. The most favourite patent machine is Ansell's, and the saving it effects in the cost of sieving is very great: in the Borelli garden one such machine saved R750 expenditure during last year alone. It does not, however, do very effectual work, as the pekoe is not properly taken out; and I have seen tea put through it three times before it could be said to be thoroughly done.

To describe the numerous other forms of machinery and small appliances would take up too much time, but I hope to publish my notes on them shortly.

To sum up this subject, Machinery as applied to tea manufacture is universal in Assam, and, in forming our estimates in Ceylon, we might as well draw up the figures for coffee without pulpers, on the supposition that coolies would tread out the cherry with their feet, as against the advantages in every respect, including cost, efficiency, saving of labour for other works, economy of space, &c., &c., when compiling figures in connection with tea. Comparisons of cost with India, where machinery is almost universally employed, are misleading unless we credit Ceylon with the same advantages.

And now regarding the Cost of Putting Teas in the London market. What has gone before will have shown that, in respect of labour, transport and field cultivation, we have a great advantage over Assam, a slight one only over Darjiling. There is yet another advantage in our favour. During the protracted cold weather in India there is great difficulty in finding employment for the coolies. All crop work is at an end, hoeing is impossible, and the only work there is pruning. If therefore, there is no new extension in which to employ the labour, much of it has to be put to unremunerative works. In Assam with imported labour, the difficulty is especially great. The Government insist on the payment of coolies whether employed or not, whether sick or well, the four-days-a-week system is impossible. Now, in Ceylon, with our continuous growth which allows us to choose our own time for pruning, matters can be so arranged that no protracted slack season occurs, plucking in the first-pruned portions commencing before pruning is ended. What a great advantage this is will be appreciated by all who have in years gone by had to support large crop labour-forces with no work to give them. With the disadvantages enumerated the cost of Assam tea delivered in London ranges generally between 10d and 1s though often over the latter amount. Taking the lower rate at which the Borelli garden is quoted, and deduct 2½d for freight and London charges, we have a cost of 7½d f. o. b. in Calcutta. The average cost of the whole of the Land-Mortgage Bank's Darjiling gardens is 6½d per lb in Calcutta, shewing the advantage the latter district has as regards economy of working, for, in spite of a very much smaller yield, the cost of production is less by 1d per lb. Now, with proper appliances in the way of machinery, and with the various economies in the matter of working which come with experience, there is little doubt that gardens favourably circumstanced can put teas in Colombo for 30 cents or 6d sterling per lb a yield of 400 to 450lb per acre being given. In this case we have an advantage of ½d per lb over Darjiling, due to our superior yield, and of 1½d per lb over one of the exceptionally good estates in Assam, the majority being at far greater disadvantage. It will perhaps be thought that 30 cents per lb is a low estimate, but, judging from the cost of the various field works and of manufacture in the large Indian factories, I feel convinced that we shall be able to work for this when our estates are in full bearing and when we have provided ourselves with roomy factories and the proper labour-saving appliances. At present, with only a rolling machine and with much young tea, 36 cents per lb is what its production is costing me, and it is easy, to see how the 6 cents can be saved in the future.

It had been my intention at this point to enter into details regarding the cost of production, and to shew how the figures quoted above were arrived at; but, in view of Mr. Armstrong's recent paper in the subject, and of the very close approximaton between my figures and his, I will not do so. Mr. Armstrong gives the cost of production by hand-rolling as 39 cents per lb., with machinery 31¾ cents, both these estimates include the manuring of 50 acres and a yield of 400 lb. A slightly increased yield, or superior situation as regards transport, water-power, or timber supply would at once bring the cost to the figure I have quoted 30 cents, or even below it. In practice, the cost will be found to lie between these figures 30 and 32 cents, according to circumstances, with an additional 7 cents where machinery has not been erected.

The average of the four estates enumerated by Mr. Armstrong is 31 cents f.o.b. *without machinery*. With the proper appliances the cost would therefore be well below the figure I have indicated, but probably the estates in question have done no manuring, which, if done on the scale indicated would about cover the difference.

And now I am going to say a few words on the subject of Pruning and Plucking. The object of pruning is to secure as large a surface as possible for subsequent plucking, and it therefore follows from the growth of a hybrid bush, which generally has a clean stem for some inches above ground and, above that, lateral branches growing in an upright direction, the higher the level at which the bush is cut the greater the surface will be. Again, whilst all trailing side-branches should of course be cut off, it is evident that any shortening of healthy laterals is a curtailment of the size of the bush. that is, of its plucking surface. For some years in Ceylon we were in the habit of cutting our hybrid bush at 2' 6" and over, *never under* (exceptional circumstances apart) and were thus enabled to get a large plucking surface at this height and this system, graphically described by Mr. Armstrong, is the one I most strongly advocate and have always practised. When the late Mr. Cameron took up his work here, he changed this method in all the estates under his management, and introduced a severe cutting down system. Now the effect of cutting down young bushes, and at present I am confining my remarks to these, is to immediately induce a rush of wood supported by all the youthful vigour of the tree; if this is allowed to grow up, a new tree will be formed and will be supported by the mass of foliage on the new growth. If however this is plucked and kept at a low level, sufficient foliage is not maintained to nourish the tree and promote a healthy growth of root and stem. The only circumstances under which low pruning, stick pruning as it is called, is resorted to, is to remedy the effects of injudicious plucking and pruning on old worn-out bushes. In one case only did I see this plan resorted to in India. An old piece of tea, the upper branches of which had got gnarled and hard was cut down to within one foot of the ground, the growth which succeeded was however allowed to attain a height of 2 feet, to mature in fact, before it was touched. This remedy would of course never have been necessary; the trees could never have got into this condition, had a proper system of selecting wood and cutting out all that had got hard and unprofitable, been followed out at the yearly pruning. With young tea, however, the great point is *easy treatment*, if a permanently profitable bush is required; and in succeeding years, with proper scientific pruning, cutting down should never be necessary. Mr. Armstrong has laid down a few concise rules on the subject, which all should study carefully and follow consistently, and I will not attempt to confuse matters by giving a repetition of his advice in other words. China tea has, of course, to be pruned in a very different way to Assam hybrid: the former is a bush, the latter a tree, and as such they have to be treated.

The style of Plucking depends greatly on the pruning which has preceded it, on the type of plant, on the climate, and so on. In this work again, Mr. Cameron introduced a new system, very different to that which we had always followed previously. It is generally considered that the point of his system was the plucking of the whole estate in eight days, but this is scarcely correct. The perfection of work theoretically would be a round of the estate at even a shorter interval; the point is, what is the description of shoot allowed to be plucked at each round? We might go round the estate every week taking shoots with five leaves and not less, or we might, at similar intervals, take a leaf and a bud as our minimum, and both would be weekly pluckings. In India the system of severe pruning and close plucking in question has been tried and was discarded years ago as being fatal to the well-being of the tree. The matter was made a subject of discussion by me with several of the leading Indian planters, and in every case the system was condemned in the most unqualified way as being a very seductive one, giving fine strong teas and a good immediate yield, but as being absolutely fatal to the future of the plant. Now, the fact of the system having been such a fatal one in India has been stated by many—and I believe Mr. Cameron did not deny this himself—but it is maintained that in Ceylon circumstances are different, and that the system, though a failure there, will succeed here. I uphold that in Ceylon an easier style of working the tree, one which draws less upon its energies, is essential for its well-being, and for this there are good and sound reasons. With a very vigorous growth, concentrated so to speak into a few months, such as they have in India, severe plucking will, it is reasonable to suppose, be answered by determined efforts on the part of the tree to form wood: this is the case, but the result of the treatment is that the tree wears itself out in a few years, sulks and has to be allowed a rest before it can be made to yield again, whilst liberal applications of manure are required (in one case, and I here allude to the Chittagong estate which Mr. Cameron was in charge of, a year's rest was necessary after two or three years of this treatment.) If this is the case in India, is it not reasonable to suppose that the same system, extended over the long flushing period of Ceylon bushes, with the less vigorous growth which accompanies them, should have an even more fatal effect? I cannot think there can be two opinions on the point, and from what I have seen of the results of the system in the low country and in the hills too, I feel convinced that disappointment is in store in the future for those who continue to take too much out of their bushes by hard plucking following the severe pruning. I have seen stretches of tea in the Ceylon low-country, after a few weeks' dry weather, looking as if a fire had run over them where Mr. Cameron's system of plucking has been strictly adhered to. It is obvious that unless sufficient leaf surface is left on each shoot, the circulation of sap *cannot* be maintained, and hence on the occurrence of the first trying weather the whole shoot, on which depends the crop, and on the vigour of which depends the quality of our pruning wood for the succeeding year, is irremediably ruined. Just as we must treat our young trees easily, by topping them at first at 3ft to 3ft. 6in., with a view of preserving the foliage on which their vigour and health depends, so must we throughout the season, and until the last few pluckings when less care is required, systematically leave a sufficiency of leaf-surface on the shoots that are yielding us our flushes. In plucking as in pruning, Mr. Armstrong and I are advocating no new system, we are simply maintaining the one which we, with Mr. Taylor and others, have always consistently followed, and on which have attended results which, *as a permanency*, will be yielded by no other in India or Ceylon.

There is another point in which some difference of opinion appears to exist. I refer to the Plucking of the *sides* of the bushes. In view of the principle previously enunciated, that yield depends in plucking surface, it is evident that this practice is a bad one, and injurious to the growth of young trees. Under certain circumstances, it may be indulged in, but I have seen it practised and advocated in Ceylon where its effects could not but be injurious in the extreme. There are places where young tea so treated is seen dotted at intervals over the ground, instead of covering the hill side with *trees*, visible as such even after pruning, and I have even seen an endeavour made to cure the defective yield by *supplying* what ought to be a sufficiently closely planted field. The effects of this treatment, justly deemed murderous by Mr. Armstrong, are so obvious that it is strange they are not apparent to every one. Coming from Indian tea, they strike me forcibly.

In respect of Manuring there is nothing of importance to be learnt in India, and we shall have to gain our own experience. In some cases no doubt manure is applied, but these seem very exceptional. There is one more important point to be mentioned, the Extension of Tea cultivation in India as affecting our future prospects. An influential firm in Calcutta is now engaged in the most extensive opening operation in Cachar and the Dooars. I forget at the moment how many thousand acres are to be put into tea within a few years, but the extent is considerable. In Lower Assam and in Darjiling, it is difficult if not impossible to get land, all that is available having been taken up long ago; but in other districts the openings are very extensive. I do not think however we need be afraid of this competition. At present prices, it is only by severe economy that good dividends are paid by Indian Companies, whilst we can well afford to produce tea and gain a fair profit, even should a fall of 2d per lb on the present market rate have to be faced.

In this case, I do not wish to make a statement without ample proof in the form of facts and figures to support it. Mr. Armstrong has here again forestalled me by showing that at his figures a nett price of 1s in Colombo, or say 60 cents, is equivalent to a profit of R120 per acre, or, without manure expenditure, R152 per acre. Now, our present sale prices are showing averages of from 1s 3d to 1s 8d and over, well made teas rarely averaging under 1s 4d. A fall of 2d per lb. therefore would still leave a margin of profit which should be sufficient for any proprietor. Now let us see how such a fall would affect Indian Companies. The Borelli Company gave 8 per cent last year with a profit of 3¼d per lb; Jorehaut 8 per cent at 1¾d per lb; Doom-Doomca, 5 per cent at 1¾d per lb. The Darjiling Companies at an average price of 1s 3½d gave

6 per cent, whilst the average price of 15 million lbs. tea as given by Messrs. Thompson & Co. is 1s $1\frac{3}{4}$d. I will not multiply instances, those I have fixed upon including some of the most flourishing concerns, and what the effect of a considerable fall of price in their dividends would be is evident. "Low prices" is even now the burden of most reports. I have here the reports and statistics from which these figures are taken, and shall be happy to shew them to any one who cares to examine them.

Finally I must add my testimony to that of others, and state that I consider these districts judging from my Ceylon and Indian experience, to be well adapted to the cultivation. The lay of land is perfect for a hill district. The soil is in spots poor and not likely to grow good tea, but the large bulk of what I have seen has depth and is eminently suitable, whilst the lower portions of the district, judging from what I am told of their general character, could scarcely be better. That there can be no fear as regards elevation Mr. Armstrong's figures have conclusively shown, and the elevation of much of the Darjiling tea adds weight to the testimony. The white clay which is found in the flats in some localities should not, in my opinion, be planted; the free soil of the hill-sides being much more suitable.

I should like to say more on this subject and many others in connection with tea, but time will not permit and I must pass on to other matters.

CARDAMOMS.

I will now make a few remarks on the subject of Cardamom Cultivation. This product, when planted in proper situations, is about the most profitable that we have in Ceylon at present; in unsuitable sites however it is usually an unmitigated failure. Shelter is essential to it, and it grows best in hollows, protected from the monsoon winds, and where there is generally an accumulation of rich soil. It does not bear well in poor gravelly soil, but prefers a rich loam. An important point regarding it is the question of shade. This should not be too thick, so as to exclude light and air, but should be partial only, and in such places cardamoms thrive best. Whether or no any extent of it can be planted in the open is as yet an undecided question with many. My personal experience is against it, as I have found that the growth of the plant is slow and the racemes very short when much exposed. In some cases individual plants in the open are found bearing fairly well; in other cases they do not bear at all in such situations, but it would seem as if a partial exposure only to the sun is not much against them. As to their cultivation amongst the coffee, there can be little doubt that it would be a success where the latter is thick, affording effectual shelter to the young plants; but in such situations the coffee as a rule repays cultivation, and does not require to be superseded by anything else. In a few words, plant cardamoms under forest-shade on any suitable land, but regard its cultivation in the open and amongst coffee as an experiment only. There need be no fear as to its bearing powers at this elevation, as I have cardamoms bearing freely above the elevation at which coffee ceases to crop. I would also mention that in the low-country, at a few hundred feet only, they are bearing well. In a recent letter to the *Observer*, on the subject of cardamoms, published during my absence from the island, and couched in somewhat vague and incoherent phraseology, the writer states that the villagers have not the best variety of cardamoms, and that the somewhat obscure but very valuable so-called "Mysore" species should be rooted out. I merely allude to the matter to re-assure those who may have been misled by this rash statement, for, in the Kotmale, Peradeniya and Kandy villages, Malabar cardamoms are freely cultivated, and those who know how to distinguish them run no risk in purchasing bulbs from these sources, whilst in high elevations the Mysore bears much more freely than the Malabar species. In good soil, cardamoms should not be planted too close, 7×7 in most cases, and 8×8 when the soil is exceptionally rich will be found right. Holes 18 in. wide and 12 in. deep should be cut, and the plant put in shallow, the earth not above the collar. This latter point is very important as deep planting is fatal. In purchasing bulbs, the closest supervision should be exercised, and all that are cut about and injured (and the Sinhalese are very careless in this matter) should be unhesitatingly rejected, double bulbs also should always be insisted on, and two single ones instead, such as the contractor will sometimes offer, be refused. The plants will begin to throw out racemes in 18 months at low elevations, but in these districts it will probably be $2\frac{1}{2}$ or 3 years before they begin to do so.

The cultivation of cardamoms is a very simple and cheap matter, the stools must be kept clean and free from debris of all kinds, especially when the plant begins to throw out racemes. Weeding after the ground is covered will be found unnecessary, for nothing grows under their shade; it, is however, desirable to send a few coolies occasionally to clear up open spots and corners which sometimes get dirty.

In order to make the most of the crop to get the highest value possible for the yield of the small acreages we generally possess, the somewhat expensive method of cutting off the capsules with scissors must be undertaken, and they must be picked when first turning colour, before they are fully ripe. Ripe fruit invariably splits, as also a very large proportion of what is taken off without its stalk. The difference of value between split cardamoms and those which are alone fit for the home market is very great, as much as R1 for the former and 9s for the latter in some cases. As regards yield, I have got crops varying from 120 to 300 lb. per acre. The cost of putting cardamoms in Colombo is 40 cents per lb., the average price from 5s to 6s, a calculation of R2 per lb. *nett*, is therefore, very safe. The profit which these figures leave is an ample one, and is shewn in the appended estimate drawn from *actual results*.—[Mr. Owen here introduced and explained the estimate appended to his Manual.—ED.]

CINCHONA

I will now say a few words on Cinchona, though I feel that after Mr. Christie's recent admirable little essay there is not very much to be said. The advance in practical experience regarding this product has been very great, and in many cases I fear very bitter, during the last year or two. We have learned where cinchona will *not* grow, and that is an important point gained. I must, however, differ from Mr. Christie in one point. I do think there has been a very serious deterioration in the vitality of the stock, and I may state that Mr. Gammie, from his long experience of cinchona cultivation at Darjiling, is of the same opinion. On the Rungbee plantation which includes periodical plantings since the original old trees were put out, there is a most marked falling off in the vigour of the trees in successive years. In this case, close-planting is certainly not the cause, nor is clean weeding, the trees growing very wide apart in a wilderness of jungle. Climatic influences are not a satisfactory explanation, the period during which cultivation has been carried on being so extensive. From my experience in Ceylon, I feel convinced that the trees we are now cultivating from seed grown in the island have not the same vigour as the original parents first planted, and that the second generation is even more enfeebled. It also seems to me that as a rule, the parent trees do not now produce progeny with the same vitality as in years past. The remedy for this would appear to be fresh blood. Regarding the hybrids, a class of plant originating locally, the case seems different, and it would almost appear as if nature were pointing the means by which the gradual extinction of the local cinchonas is to be avoided. This subject and many kindred ones connected with the cultivation of cinchona and the harvesting of its bark, are of great interest, and I should like to enlarge upon them, but time is short, and I must bring this paper to a close.

Speaking generally, it would appear that the most profitable way of cultivating our land in the future is to keep up the very best portions only of our estates in Coffee, and to cultivate these highly, spending what we can afford upon them. The bulk of the coffee might then with advantage be lined and planted with tea, suitable portions of the land being kept in cinchona. To cardamoms, any available forest of the right character might be devoted. On many estates there is unfortunately no forest, and the fact must be faced that for tea cultivation considerable forest reserves are desirable. When no wood is obtainable, the use of coke, or fuel brought up by railway will be necessary, and this difficulty and the necessary expense must be faced from the first, and should on no account be ignored or forgotten. It may be of in terest here for me to state that tea dryers require 2 lb. wood to each 1 lb. tea, as a rule; therefore, a 250 acre estate, yielding 100,000 lb. tea, requires 200,000 lb. or 90 tons wood per annum *at least*, practically more; where water is not available, a calculation must also be made regarding the fuel required for the engine. For the planting of bare ridges and stiff unfruitful ground where cinchona does not thrive, a product is required. I would suggest Aloes, for the cultivation of fibre plants is undoubtedly an industry to which we shall have to turn our attention in the future. The aloe once in the ground, all expenditure ceases, save perhaps a few weedings round the plants until they are established. Advantage has been taken, by those whose cue it appears to be to run down all present and future enterprise, of the somewhat enthusiastic way in which the wholesale planting of New Products is advocated by many; and, now that their success is established beyond doubt, it is stated that they are being planted wholesale, in suitable and unsuitable localities alike, and further disappointment in the future is predicted. Now far be it from me to advocate the planting of any product in an injudiciously wholesale manner; tea, hardy plant though it is, will not pay on washed exhausted soil, nor on our poor shallow land, and such localities had better be allowed to grow up in jungle after the establishment of some hardy plant, such as the aloe, which is able to hold its own against all other growths. The selection of the portions of estates which are to be maintained as coffee, or planted with tea, cinchona and cardamoms, is a matter requiring judgment and experience, and on the degree of these qualities that is brought to bear on the subject will depend much of the future success of the estate. It is, of course, a matter to which no rules are applicable, and one to call forth all the powers of proprietors or their advisers.

Gentlemen,—I have done. In view of the too recent publication of Mr. Armstrong's able and comprehensive essay, my humble effort appears at the greatest disadvantage; but I trust you will make every allowance for the fact that, at a few hours' notice and in the brief space of a portion of a day, without any notes and other means of reference, I have had to re-write the greater part of this paper, so as not to come before you with a mere repetition of anything said by that gentleman, and with a view to make my statements supplementary to his, and hence of value and interest to you. If you consider that I have been, in however small a measure, successful in this task, the difficulty, of which I only appreciated yesterday when I entered upon it, I shall feel amply rewarded.

T. C. OWEN, Oononagala, Madulkelle.

The paper which was received with much applause, gave rase to the following questions.

MR. TENCH asked if Hybrid Assam might safely be planted after pulling out China as recommended, to which Mr. Owen replied that he had seen this done in India with success.

The CHAIRMAN wished to know whether estates without timber could, in Mr. Owen's opinion, profitably purchase fuel and timber for tea crops; whereupon Mr. Gray remarked that coals could be delivered in the district for R50 per ton, that as one pound of coal would fire two pounds of tea while it takes two pounds of charcoal to fire one pound of tea, it was evident that coal could be used as cheaply as charcoal.—Mr. OWEN was unable to decide upon this as he had not gone into the question, but he added if Mr. Gray was correct in his figures it would seem worth the trial.

Mr. CHRISTIE next asked Mr. Owen whether he considered Maskeliya a district suitable for the cultivation of tea; to which Mr. Owen replied that if the land was judiciously selected, the white clay being left alone, tea should pay very well throughout the district.

A cordial vote of thanks to the reader of the paper was proposed and carried unanimously.

THE JOHORE LAMA PLANTING COMPANY LIMITED.

Last Saturday afternoon, a party of the directors of this company, along with a few friends, left Singapore on a visit to inspect the company's estate at Gunong Pantie. At 5 p.m. they embarked in the steam gunboat "Pulai" belonging to H. H. the Maharajah of Johore, which was lent for the occasion through the kindness of Inchi Ibrahim, Datu Bintara Dalam of Johore, who is one of the directors of the company, and who formed one of the party. After touching at Pengarang in order to take on board Mr. W. W. Bailey, the Superintendent of the company's plantation, the "Pulai" steamed slowly up Johore river. It was a fine moonlight night, and the banks of the river, covered with dense jungle and mangroves to the water edge, looked extremely beautiful in the soft light of the moon. Towards midnight, however, a dense fog came on, and the worthy Captain, Hadji Kassim, deemed it prudent to cast anchor till daylight When the sun rose the fog cleared off, and the "Pulai" sped on her way to Kota Tinggi on the east bank of the river about thirty miles from its mouth. From this place there is a good road to Gunong Pantie, which is about seven miles distant in a north easterly direction. The party accordingly landed and went first to a neat bungalow belonging to Mr. Garland, Surveyor to the Johore Government, where they were met by the company's local manager, Mr. Turpin. At Kota Tinggi there is a large Chinese village of about 1,000 inhabitants, rather dirty, but as usual cheerful and industrious; there is also a police station. Close to the latter are the ruins of the tombs of the ancient Sultans of Johore, which are well worth a visit. Some of the carved stones which once ornamented these tombs have been removed to Raffles Museum, but many still remain, and H. H. the Maharajah has taken measures for the preservation of the ruins from further spoliation.

Having procured a bullock cart to carry supplies, and a pony trap for those who chose to drive, most of the gentlemen preferring however to walk, the party proceeded to the plantation. The day was cloudy with occasional showers which rendered the air cool and pleasant.

The road to Gunong Pantie was made by the Johore Government in order to open up the country, and the result of this enlightened policy is that the district through which it passes is one of the most flourishing in Johore. The road is lined on each side through its whole extent with gambier and pepper plantations, and there is no doubt that had it not been for the facilities afforded by the road, these plantations as well as the extensive plantation of the Johore Lama company would not have been undertaken. The first part of the road is level, but as it approaches Gunong Pantie it begins to rise, and after the sixth milestone it is pretty steep. The party, having left Kota Tinggi at 10 o'clock, arrived about midday at the bungalow of the estate which is situated on the low ground, and thence proceeded to inspect the property. After leaving the bungalow the road winds among the hills; and is in some places overshadowed by large jungle trees and bordered with beautiful ferns and wild flowers.

Gunong Pantie is a cluster of hills, the highest point of which is about 1,600 feet above the level of the sea. "Pioneer," as the company's plantation is called, is situated partly on the low ground and partly on the slopes of the hills at a considerable altitude. It consists of about 850 acres, but the company has the right of acquiring additional ground in the vicinity at a fixed moderate rate. The company acquired the property about a year ago, at which time there were about 40 acres planted with cocoa and Liberian coffee. The plants on that portion of the estate shew a considerable growth, and the directors and their friends were extremely gratified on witnessing the healthy and vigorous appearance of the plants. Many of the cocoa plants, although not more than three years old, are now bearing, and there appears every prospect of a full crop being obtained in the course of another year. Since the company commenced operations, upwards of 100 acres more have been cleared and partly cultivated, and the nurseries are well stocked with young plants ready for being transplanted. Mr. Bailey, and the local manager, Mr. Turpin, deserve great credit for the energy and activity they have shewn in making such good progress, in spite of the difficulties arising from the scarcity of labour and otherwise. It is to be hoped, however, that when the Indian Immigration Ordinance comes into force, the labour difficulty will be in great measure removed, and the progress of the company be even more satisfactory than it has hitherto been.

After inspecting the estate the party returned to Kota Tinggi, where they were hospitably entertained by Mr. Freeze the assistant of Mr. Garland. At 7 p.m. they re-embarked in the "Pulai" and returned to Singapore, where they arrived at 4 a.m. on Monday. The night was again clear and bright and the voyage homeward most enjoyable.—*Straits Times*, Sept. 6th.

MR. OWEN'S PAPER ON CULTIVATION IN INDIA AND CEYLON.

No greater possible compliment could be paid to the correctness and completeness of Mr. Armstrong's account (page 251) of local tea culture and manufacture than the statement made by Mr. Owen, that he had to recast and re write a large portion of his paper (page 273) so as to avoid repeating what his predecessor had written so well that he could not improve upon it. The only material point on which Mr. Owen differs from Mr. Armstrong is that of the preference given by the latter to a large Drier over the several Siroccos recommended by Mr. Armstrong. This preference and the special mention of Mr. Kinmond's machinery is due, we suppose, to Mr. Owen's satisfactory personal experience, as well as to what he saw in India. Jackson" machinery, however, seems to be largely used and to give satisfaction. Mr. Owen also suggests improvements in firing. What Mr. Owen records as the results of his visit to India and his observations in the tea districts of Assam and Darjiling will be received with respect. Indeed, the distinguishing value of Mr. Owen's paper consists in the comparisons he is able to institute and the conclusions he feels justified in drawing so largely favourable to Ceylon. While the plucking season in India is really limited to six months, and the yield per acre is not higher than an average (Darjiling and Assam together.) of about 250 lb. per acre, we are able to gather in Ceylon nearly all the year round, and Mr. Owen fully endorses Mr. Armstrong's full bearing averages of 600 lb. per acre for low estates and 400 lb. for those at the higher altitudes such as the vast majority in Maskeliya and the surrounding districts are situated in.

As a consequence of our higher yield and our other great advantages of suitable labour and facilities of communication, Mr. Owen has no hesitation in pronouncing that Ceylon tea, with distinguishing merits of its own, which have already placed it in the front rank, can be placed on the London market at a cost materially below what our competitors in India, with all the advantages of being so long before us in the race, can manage. This is certainly a complete and astonishing reversal of the relative positions which the vast continent and the small island were supposed, until quite recently, to occupy; and we cannot doubt that great sensation and much discussion, in the "Gardens" of Assam, Cachar and Sylhet, Darjiling, the Terai and Dooars, will be the result. But there are the figures: to be analyzed, questioned and tested by all the facts established in India and Ceylon. Much of the soil in India is superior to ours, and in parts of Darjiling the money wages of labor is lower than anything we can compass in Ceylon; but our climate, once decried by Indian planters because of too much moisture and no winter, gives us great advantages for the growth of leafage, while our means of communication and nearness to sea-port place us far ahead even of Darjiling. Mr. Owen believes in a cost of production so low as 30 cents of our Ceylon currency, by which the rupee is divided into 100 cents. Our Indian friends will better understand the figures when we state them as being less than one third of a rupee, which would be 33⅓ cents or 5⅓ annas equal to 8d per lb. if the rupee were worth 2s Mr. Owen's 30 cents are, however, as nearly as possible the equivalent of 5 annas equal to 7½d as we used to count before silver was so terribly depreciated, but now more nearly represented by 6d. If we can place our teas on board in Colombo at this rate, we shall have an advantage of ½d per lb. over Darjiling, of 1½d over one of the most successful estates in Northern India, and fully 3d per lb. we should say over the general average of Assam, Cachar and Sylhet estates. If we can keep down prices as indicated and go on improving the already acknowledged good quality of our tea, it seems to us that we can keep ahead of every other tea country in the world; while, if some unexpected scourge does not affect tea as the fungus has affected coffee, those engaged in the pursuit may look for adequate rewards of their enterprise, industry and skill. Our Indian neighbours will notice that as one result of our climate, so favourable for continous growth, we in Ceylon will not be embarrassed to "find work" for our labour force in a slack season. Fields can be pruned at such intervals as to secure steady average work, except perhaps in the height of the south-west monsoon, June-July. But even in those months we have known good flushes gathered. One other grand advantage of tea culture is the ability of the plant to send its roots down into that clayey subsoil, so common on the mountains of Ceylon, excellent in quality although so stiff mechanically as to account largely for the failure of cinchonas. On such soils tea may be calculated on as a "permanent" cultivation, while fertilizing substances can be used to keep up the nuture on lighter soils and improve the yield from the richer, if stiffer, clays. Of course, planters who chave any China or semi-China bushes growing, will act on their own judgment, after hearing Mr. Owen's decision in favour of indigenous Assam in the lowcountry and best hybrid everywhere else to the absolute extirpation of China. All we can say is that, with all respect for Mr. Owen, we mean, with reference to a very fine and well-bearing patch of Darjiling China which exists on the estate in which we are interested, to act on the advice of Mr. Anderson of Assam, who said, "I consider it an advantage that you have a small portion of China to mix with and improve the appearance of the hybrid leaf. The brokers look much at appearance." On the other hand, those opening estates, had better, doubtless get the best jâts possible. We may say that nothing can excell the plants grown from Assam Company's seed which, beginning with 1874, we and others obtained at intervals through Messrs. Schoene, Kilburn & Co. of Calcutta. The other point on which we feel inclined to disagree with Mr. Owen, is his sweeping censure (following in Mr. Aitken's wake) of the late Mr. Cameron's system of pruning. There can be errors in the neglect of proper pruning as well as in carrying the process to excess. Most of what Mr. Owen says on details of culture and manufacture are, however, worthy of respectful attention and will receive it. The effect of Mr. Owen's deliverance added to that of Mr. Armstrong, cannot but be encouraging to individual planters and beneficial to the interests of the colony. While we cherish the trust that coffee will recover itself, there is great ground for hope in the vigorous youth of the tea enterprise.

BRAZIL AND THE COFFEE TRADE.

(From the *South American Journal*, August 16th)

Coffee is to Brazil what cotton is to the Southern States of America—its staple production, and both owe their culture to slave* labour, the conditions of cultivation and cropping being also similar, probably coffee the easiest of the two, the chief difference being that cotton requires moisture for the trees, whilst coffee plantations are chiefly on hilly ranges, from whence the forest has been cleared, and where the best coffee is grown. Another similarity is the largeness of production in both cases, a constant augmentation of stocks, and a consequent low

* No: Negro labour, the cotton of America happily being no longer grown by slaves.—Ed.

range of prices, which almost sets competition at defiance. Both articles have also risen to their existing state of prosperity during the present century, and they seem destined to outlive it, the one a condiment, the other used in the process of manufacture, its influence spreading over the globe, and here the comparison ends.

Of course the staple productions of Brazil are coffee and sugar, the former taking the lead, and the soil and climate suitable for each differ, the latitude of Brazil from north to south admitting of both at the same time, without disadvantage to either. This is of itself a great physical advantage, which, as we have observed on former occasions, might be availed of to cultivate other articles of consumption, now imported into Brazil at considerable cost; first and foremost, corn, towards the cultivation of which little effort has yet been made, although there are the examples of India and the River Plate to encourage them, besides other article of daily consumption, to which allusion has been made. Whlist the southern States of America defy competition with their cotton, the northern States are equally potent with their corn and provisions, so the great elements of prosperity are united, while Brazil trusts almost entirely to one, or at most to two articles, sugar and coffee. It is true that the populations differ widely, and the astonishing rapidity with which the latter has developed itself in the States, sets all calculation at defiance. In a recent number of the "Times" this picture is forcibly drawn as follows:—

American statisticians are the most industrious of their industrious class. They have recently, according to the account we give this morning from our Philadelphia Correspondent, been engaged in summing up the figures of the migration of the last half-century into the United States. No investigation can be more interesting to their countrymen. Immigration on a large scale imports wealth in the shape of grown and trained human beings. Every adult immigrant represents to his new country the cost of maintenance and education down to the date of his arrival. In addition, there is the substance, little or much, which he brings with him. Very few come without something. After all the uproar excited by rumours of pauper immigration into the United States, the most jealous inquiry has detected only fifty who could fairly be described as paupers. A land profits materially by immigration. In innumerable other ways immigration essentially affects it. Every immigrant is an emigrant also. He is in process of constructing a fresh home; and his old home contributes a large part of the moral and intellectual framework. Extraordinary as has been the American power of assimilating European elements, they exert an influence in turn. Whatever the fabric of American society and character is, it would have been something very dissimilar except for the European immigration of the past fifty years. Within the fifty years from 1830 to 1880 nearly ten millions of Europeans have swelled the population of United States. Immigrants multiply faster than native Americans. Much more than their apparent proportion of the increase of the American population from the seventeen millions to which it has risen in 1840 to the fifty millions of 1880 may be set down to them. To this tremendous influx is to be traced the difficulty of fixing the qualities of American nationality. The character would be still less stable if particular ingredients did not regularly predominate in the human imports. Germany and the United Kingdom furnish the bulk; and the rest are quietly absorbed. By the United States statistics England is deprived of its priority in favour of Germany. But when, in conformity with ordinary rules, British immigrants are reckoned together, they are seen to outnumber those from any other State. They naturally amalgamate more readily with the native population of the same extraction, and help to keep the general current of national life in its existing channel.

Of course Brazil possesses no such advantages, and her slave population has operated against emigration almost confined to Portugal, but latterly Germans and other nationalities have been added to the Brazilian population.

Whilst, therefore, Brazilian coffee challenges the production of the world, it is clearly her interest to study other cultivation in such articles as will at all events meet the requirements of her own people, which would be a positive saving of revenue, and help to mitigate the evil of low-priced coffee, which may be looked for for some time under the competition that exists. The extension of railways from the interior of the provinces to the seaboard will soon show what can be done towards supplementing the requirements of the Empire in a physical sense, and we must wait this event to determine what other internal appliances will be needed.

CINCHONA IN JAVA.—According to the official report on the Government Cinchona culture in Java for the 2nd quarter of 1883, the weather, owing to continuous drought prevailing, proved during that period very favourable for crop operations, the bark collected amounting to 172,293 Amsterdam pounds, the increasing yield of that product necessitating the building of an additional artificial drying house. The report also notices the circumstance that cinchona cultivation in Java is extending, as shown by the increased demand for seeds for the Government plantations, this extension being ascribed to the unsatisfactory result of coffee growing there of late. On almost all estates in West Java and on many in Mid and East Java, cinchona is gradually being cultivated on land formerly set apart for coffee culture.—*Straits Times, September 13th.*

WATERING.—When to apply water to growing plants and when to withhold it is a very important lesson to be learnt by any one who has plants, few or many, under his charge. The soil should never be allowed to become too dry, or there is danger of the water when applied passing clean through without wetting it. When this happens plants will parish for want of water, even when it is regularly given. On the other hand, water should not be poured promiscuously into pots until it is ascertained whether they require it or not, or through excessive application of it the plants will suffer. The subject is a difficult one to the inexperienced, but careful observation will surmount it; and when it is understood that safety and satisfaction can only be realized by striking the happy medium an effort will then be made to become acquainted with the indications which should control the operation. In warm weather, and when plants are making vigorous growth, absorption by the roots and evaporation otherwise speedily exhaust moisture from the soil, and as a matter of course waterings need to be made more frequently at such times. It is an operation requiring to be done carefully and intelligently. Careful watering does not mean that it should be given in driblets, but enough should be given at a time to thoroughly moisten the whole of the soil. It should then be withheld until the soil has become dry again, never, however, allowing it to be so much so as to cause the plants to flag—conditions which can only be arrived at by careful attention and experience. Water should always be given before the soil has lost its moisture, and before the occupants of the soil show any signs of a failing supply. As a rule, except in winter, water is best administerted early or late in the day.—*Queenslander.*

Correspondence.

To the Editor of the Ceylon Observer,

MR. HOWARD ON C. LEDGERIANA.

Royal Botanical Gardens, Peradeniya, 12th September, 1883.

SIR,—It had been my intention to continue to abstain from entering in any way into the discussion recently raised over my paper of November 1881 on *C. Ledgeriana*, at all events until the communication of Mr. Howard to the Linnean Society calling in question the right of our Ceylon plant to bear that name should be published. The matter in dispute is, in my opinion, a purely technical one, depending for its right appreciation on a knowledge of the application of the rules of taxonomic and descriptive botany, which are of no general interest. My paper was addressed to botanists through the medium of a technical periodical: I cannot in its discussion travel outside of the botanical boundary.

But it would now seem that I may not have to engage even in any scientific controversy, since Mr. Howard, in a letter to the "Planters' Gazette" of August 16th, after telling us in italics that he has "*corrected*" the paper he read at the Linnean Society, goes on to give up the botanical position altogether. He now informs us indeed that his term "Ledgeriana", was not intended as the name of a variety or form of *Cinchona*, that in fact it did not apply to a plant or tree at all, but "was meant to include all the *bark* of a certain rich quality grown in Java from Ledger's bag of seeds, and called such in trade." Now if this were really the case, I need scarcely say that such a name could not possibly claim any sort of recognition by botanists, and I should have taken no notice of it in my paper. Mr. Howard's attempt to thus shelve his botanical responsibility will, howevernot square with the fact that he obtained from the late Dr. Weddell—one of the best authorities—a Latin diagonsis of "*C. Calisaya, var. Ledgeriana*, How." drawn up in due technical botanic form; and published it in his "Quinology" in 1876. It is by this that he must abide: in it there is not a single word about the bark, but it is attempted to define the variety by the form of the leaves and panicles, and the white flowers. We now know these distinctions to be quite insufficient for the purpose; but this was all the published botanical information existing when I drew up fuller and more accurate characteristics from living specimens of adult trees.

With all respect for my friend, Mr. Howard, I do not think any regret would be felt if he were really to abandon the *botanical* questions connected with cinchona; whilst, on the other hand, we must all hope that he may long continue to "approach the subject from the side of the bark" only, and thus further contribute to our knowledge of Quinology. It is perhaps, now time to remind people that though a man may be a skilful chemist and a very successful manufacturer of quinine, it does not follow of necessity that he should be also an authority on the botany of one of the most difficult genera that ever perplexed the systematist. With the best intentions, this *Ledgeriana* bewilderment is by no means the first confusion which Mr. Howard has been the author of, by attempting to do that for which he has not had the requisite training. There is nothing surprizing in this, and it may be safely said, without ceasing to be grateful for the splendid volumes we owe to his liberality, that from the botanical stand-point it is in many respects to be regretted that Mr. Howard ever attempted to tackle questions of technical scientific botany, for dealing with which he is so little qualified.

In the letter to the *Planters' Gazette* we are told that the "true Ledgeriana"—the *tree* this time, I presume, not merely the bark—is to be restricted to the "*Rojo* of Ledger" and the "*Tata*" of the Indians. The latter name cannot but remind us of the Nilgiri "*Pata,*" a recently blown-up fallacy, which was also backed by Mr. Howard in opposition to good botanical evidence. No information which might help us to know this "Rojo" when we see it is given by Mr. Howard, beyond the remark that the leaves turn red when they wither—a rather ordinary phenomenon. The *bark* side of the present question I may safely leave to the planters; merely remarking that I fail to see how, on the principles of classification he advocates, Mr. Howard can place the ordinary grey barks and barks affording from 8 to 13 per cent. quinine sulphate, with an almost total absence of inferior alkaloids, under one and the same species, *C. micrantha*.—I am, sir, yours faithfully,

HENRY TRIMEN.

To the Editor of the "Planters' Gazette."

SIR,—My time has been much occupied in the last two weeks in Quinological pursuits, and in returning your papers I send some brief notes. I am correcting, whilst passing through the press, my contribution to the subject, which will shortly be published by the Linnean Society. To this *so corrected*, I must refer you in place of newspaper reports. I am availing myself of a visit of Mr. C. Ledger to this country to go carefully into the whole question with him and Mr. Holmes, the Curator of the Museum of the Pharmaceutical Society, and with others interested in the cultivation of Calisaya.

It will interest your readers to learn that Mr. Ledger is quite satisfied with my plants derived from the Yarrow estate (Ceylon) as representing his *Rojo* or red sort; resting his opinion on the characters I pointed out at the Linnean. He says that the beautiful richness of the foliage remains, especially in those parts of the tree which are least exposed. It is this sort to which the Indians attach so much value that they cross themselves when they meet with a tree of it and call it the *Tata* or "Father" tree, believing (as I think not without reason) that it has a beneficial influence on all around and that all will be found "Calisaya" or true bark.

Mr. Ledger cannot tell what this word means, but Dr. Weddell, who spoke the Indian language, says (in his "Histoire," p. 31) that it means "the red sort," "Colli signifie, en effet *rouge*, en langue Quichua, et *saya* pris au figure, veut dire 'sorte' ou 'forme,'" or (as I gather from Tschodi's German Dictionary of the language), *Colli*, "the red of glowing embers." *Saya* "*Stehen*," Mr. Ledger fixed upon a slab of Calisaya in my possession nearly three quarters of an inch in thickness as the true and highly prized *Rojo*. He tells me that Dr. Weddell had heard of the white flowers, and sought for them, but without success. To obtain this "red sort" has been the special aim of Mr. Ledger, and by *special* policy he was able to defeat the jealous tactics of the Indians, who boast that no one who obtains true seed shall leave the valleys alive. They either supply inferior qualities or destroy the germinating power. They laid wait for five days for Mr. Markham, who escaped through a Providential circumstance; and they poured boiling water on my friend Dr. Weddell's plants, who was profoundly affected by the outrage.

This *Rojo* is, then, the true *Ledgeriana*, as, in looking over my old letters, I fully recognize. Mr. Ledger sees it represented in my Plate IV. or the *Macho* form A. He does not see it in form B., or in the plant I have from Darjeeling which I think is probably the same B. form. I have in all, nine specimens of Java trees from Ledger's seed through the hands of M. Moens. There are different varieties in these, which Mr. L. does not recognize, but which are reproduced in specimens from British India. I should say, that his faithful Indian employed his own sons in gathering seed from fifty trees in different places, and the different collections got afterwards mixed together. The whole appeared to me to represent Weddell's var, microcarpa.

Mr. Ledger entirely rejects my *Micrantha Calisayoides*; as also Dr. Trimen's Plate. The colour of the changing leaves he says is exactly that which I copied from nature in the Calisaya Anglica, and the rich colouring of the leaves is perfectly given *there*, but the form of the leaves is, as above described in form A. When, as in the C. Succirubra, the leaves turn this rich red colour, it is generally connected with rich colouring in the green of the leaves. This is a feature on which Ledger lays great stress, and it appears that many of the leaves assume this tint at the time of flowering. Hence the term *Colli* (Quichua) *Rojo* (Spanish) *Rouge* (French).

Now, is this "red sort" a different species from the calisaya? It is not distinguished by the bark, for where the *Tata* trees are found (single amongst the *manchas* or patches) all the bark is good, owing, according to the Indians, to some connection with these chief trees. This is what I find in the specimens sent me by M. Moens from Java. Most are of equal quality to the true *Rojo*, some superior, others indicating, by proportions of quinidine or of cinchonidine, the influence of inferior pollen.

The slab which Mr. Ledger pointed out as typical *Rojo* I have marked *Zamba*, a name belonging, as I thought, and Weddell confirmed this, to his *var. Microcarpa*.

I cannot make all this fit in with what is called "*correct* botanical description," which seems to be consistent with leaving out all allusion to the bark in the description of a bark tree; as in Bonpland's most confusing account of his *condaminea*. The Spanish botanists and Weddell were most particular to collect samples and carefully to describe the bark. I have approached the subject *from the side* of the bark, and consequently consider this the chief factor in the problem. I think practically cultivators will agree with me in this. My term "Ledgeriana" was meant to include all the bark of a certain rich quality grown in Java from Ledger's bag of seeds, and called such in trade. But the true *Ledgeriana* must be the *Rojo* of Ledger, and again I ask what is that? It is the form A of my Quinology, that is, the *Macho* form, distinguished, as Weddell shows (p. 31 Histoire) all such forms are by richer colouring (the purple or the under-side, however, is accidental); and, as I think, by its furnishing prepollent pollen needed to keep up the superior strain of these best qualities. Without this, they would degenerate, as in an analogous manner is the case with animals. The Indians, by long observation, are nearer the mark than the scientific botanists!

These are questions for practical cultivators. By a kind of reversal of the process above hinted, my gardener obtains for me *degenerate* cucumbers, *i. e., without seed*, and consequently sweeter, and devoid of the strong principle which disagrees with some persons. By careful fertilization, he keeps up the strain of my melons; and by artificial impregnation, requiring skill, he succeeds in growing beautiful pods of Vanilla, equal to the best in the market.

I would always have a sprinkling of *Tata* trees in my plantations of Calisaya, and should then count on having *all* of what the Indians call true *Calisaya* quality.—I remain, yours, &c., JOHN ELIOT HOWARD. F. R. S., F. L. S

INDIGO CULTIVATION IN CEYLON.

12th September 1883.

DEAR SIR,—The best ground for indigo culture would probably be found in the Mannar district. The plant grows wild there in many places, but not in very large quantity; I do not remember seeing more than about half-an-acre in the spot. Irrigation would, however, be needed for its successful cultivation, and at present that is impossible in the district.

Unless a large area were cultivated it is unlikely that indigo would be found to pay. Considerable expense must be incurred in erecting suitable buildings and vats for extracting the dye, and when once built these would need a large supply of raw material to keep them going. Still, with a sufficient acreage under cultivation, there is apparently no reason why indigo culture should not yield as good profits in the Mannar district as in India, provided always that a good supply of water could be depended on for irrigating the crops.

If the culture were found to pay, the surrounding natives would probably soon provide a considerable amount of raw material as in India. It would pay them better than paddy, and a new industry would thus be started in which the smaller cultivators could articipate.—Yours faithfully, HENRY PARKER.

COFFEE CULTURE AND SHELTER.

14th Sepetember 1883.

DEAR SIR,—In these days of tea coffee and cinchona being unutterably damned by those who must get their living by them, can a coffee planter who still believes with Mr. Shand and Mr. Armstrong and other people who do not yet apply the big D. to coffee, venture a few questions about coffee?

I have it in hollows bearing well; coffee on ridges blown; coffee in other places, even in flats, blown; and I believe without any but the smallest practical experience in belts—*artificial* belts. My partners and predecessors having gone in for acreage *versus* quality and having left only the smallest patches of jungle to shelter large fields, which they do not shelter more than to show what they would do, if more frequent. They are not sufficient to shelter some, indeed, most of the fields.

Will some of your readers, who have not had "20 years' experience" and therefore may not unutterably pooh-pooh a poor "seven years experience" advocate of belts, give me their experience of shelter-belts for exposed coffee—coffee which is green and nice looking from November till June, which would bear if sheltered, which blossomed in July, only to shrivel up in August, in the wind. In England we shelter fruit trees and even gooseberries. Here, is it *absurd* to anyone except those who do not believe, that if we help ourselves nature may help us?—

"BLOWN COFFEE."

CEARA RUBBER EXPERIMENTS AT PERADENIYA.

Peradeniya, 19th September 1883.

DEAR SIR,—I have made a further trial of rubber on old Peradeniya estate, and I took 18 trees as they came (leaving out only the small ones, and not big enough to tap) with the satisfactory result of just over 10 ounces of pure rubber. I also made a trial on one tree that I tapped on the 11th of this month, and succeeded in getting one ounce and one-eighth in nine days; and the milk flowed most freely. This is surely an encouraging result.—Yours faithfully,

H. A. GILLIAT.

MR. HALLILEY'S THEORY OF CONTAGIOUS DISEASES: HE IS SCEPTICAL REGARDING TEA AND SANGUINE ABOUT COFFEE IF CULTIVATORS ARE ALLOWED FREEDOM.

DEAR SIR,—Contagious diseases in animals are caused by mildew generated from carrion, putrid filth, rotten grain, fruit and vegetables.

Leaf-disease is not a contagious disease. Had it been, one of two things must have been the result, either it would have disappeared long ago, or it would have killed all the coffee. But as neither has occurred, it is proof that it is not a contagious disease but a natural consequence; and had it been a contagious disease, Mr. Marshall Ward would have found the germ of it where he first looked for it, and that was in the sap of the tree: and the proof that leaf-disease is a natural consequence is that it disappears and returns when the tree gets into a condition ready to receive it. There is just now a great rush to plant tea. Those who have not done so and have coffee land I would advise to look before they leap, and not allow themselves to be led away. If they look at a map of Ceylon, they will see that there is sufficient suitable land which if planted will produce more tea than the world's demand, and then what will be the price of Ceylon tea? The average price of good sound common congbb. last year in bond in London was four-pence-three-farthings Will tea pay at that, and what will a tea estate be worth with tea at that price? There is nothing like coffee if we can get the means and are allowed to cultivate as we know how. With the means and allowed to cultivate as we know how, we can produce coffee for a great deal under fifty shillings a cwt., and should coffee go down to 50s. a cwt. it will shut Brazil completely up, and then what will be the price of our coffee?—Yours truly,

G. F. HALLILEY.

[We confess we do not understand Mr. Halliley's idea of contagion. Leaf-disease can so readily propagate itself by its spores, that it certainly is contagious. No man with any pretensions to scientific knowledge (except Monsieur Montclair) would ever think of looking for the germs of an external parasite in the sap of a tree or in "internal blisters" as the Frenchman did. No doubt tea can be overdone; but we should be glad to believe that Mr. Halliley is right about coffee in Ceylon reviving.—ED.]

"C. R." who wrote so largely (page 214 *T. A.*) about *calisaya verde* and *morada*, quoting, over and over again, all that Markham had written, is especially auxious to disavow any desire to advertise seed imported by himself; in fact he had none for sale when he wrote his last letter. We accept his assurance that he is merely anxious to prevent Ceylon being swamped by bad Bolivian seed; just as we and others would wish to prevent sloe leaves being substituted for tea, or rubbish for good coffee.

CINCHONA.—An important fact to be noted by cinchona planters is that barked trees coppice more freely than unbarked trees. The reason for this is probably that the shock occasioned the tree by the removal of its bark stimulates the vital activity of its roots. That such is the case is more advantageous than otherwise, as a tree can be barked until it shows signs of decay, when coppicing may be adopted, and the process of harvesting repeated over a series of years.—*Madras Times*, Sept. 14th.

CEARA RUBBER GROWN IN COLOMBO.—A well-known Colombo Broker has favoured us with the following report on the piece of rubber taken and prepared from an 18 months' old tree in Maradana:—"I return you the Gilliatt sample of indiarubber. It is *very* good, much better than the best of previous samples. But I cannot get any reliable valuation. ———'s people—one of whom seems to have had some experience in rubber—would like a good lot of this quality as a sample shipment. Until we can do this it will be difficult to get a good practical idea."

COAL FOR TEA PREPARATION.—At the Maskeliya meeting this question came up and Mr. T. Gray spoke in favour of coal versus charcoal. But in view of the inevitable smoke, would not coal be objectionable? We should think that coke (for which some of the Sirocco driers are specially adapted) would be preferable. The carriage of coke would certainly be less costly than that of coal. We should like to learn the results of the experience of those who have tried coal or coke, as fuel for drying machines; for we do not suppose coal would answer for the ordinary furnace or stoves?

COFFEE.—The present method employed of preparing coffee for the market is to be deprecated. The sensible Arabs dry their coffee in the pulp, which preserves the aroma of the berry, and the secret of the flavour and value of the *Mocha*. If dry cherry is sent to the curers here, they at once class it as native coffee, and its value is depreciated. Drying coffee in the pulp will scarcely find favour, because the mode of preparation for the market must be altered, and the machinery modified, but the quality will be so greatly improved that the cost of new appliances ought to be of secondary consideration.—*Madras Times*, Sept. 14th.

TEA CULTIVATION IN CEYLON will indeed make a wonderful start next year, if it be true as we hear that while one Colombo planting firm is getting 2,000 maunds of seed from Northern India, on account of themselves and their constituents, and another has invested in R50,000 worth of seed.

CEARA RUBBER.—The following is the opinion of Dr. Trimen on Mr. Gilliat's process:—"All I can say about your cutter is that having had the opportunity of seeing it used on Ceararubber trees, I consider that it does very well what it was intended to do, viz.: secure a large flow of milk with very little injury to the cambium and young wood."

NUTMEGS.—There is a possibility of large fortunes being made in New Guinea (remarks the *Pioneer Mail*) by the cultivation of the nutmeg. The nutmeg tree is found in great abundance in that island, and gives its name to one of the finest pigeons in the world, a bird as large as the hen turkey. Since the collapse of the nutmeg at Singapore we have been indebted, for the most part, to our old rivals, the Dutch, for nutmeg and mace. But the nutmeg trees of Singapore were importations; the tree was not so indigenous to the place in New Guinea. The cultivation is, or was, the most profitable of anything we know of, surpassing cinchona and coffee in their best days. Singapore owners of nutmeg plantations—mere compounds planted with the handsome tree—used to realise their £4,000 or £5,000 a year; but in one dark and memorable year the trees were all stricken with a blight, and numbers of planters enjoying large incomes were reduced to poverty. The tree became white and leafless, a vegetable skeleton; and no attempt to revive the cultivation of the nutmeg at Singapore has ever proved successful.—*Sydney Mail*, August 21st.

EDUCATION AND AGRICULTURE IN INDIA.—In an article on "the net results primay education" the Lahore *Civil and Military Gazette* remarks:—An enquiry into the subsequent history of the 3,014 ex-students, as far as they could be traced, showed the curious result that, although a great majority of their parents had been—of whatever caste—connected with agriculture either as landlords, tenants, labourers, or as a secondary pursuit, their sons, who had been to school, almost invariably showed an aversion to agriculture in any form. As the primary system of education was mainly intended for the agricultural classes, this fact is worthy of note. The proportion of parents and sons according to profession, is as follows:—

	Agricultural.	*Non-Agricultural.*
Parents ...	61 per cent.	39 per cent.
Sons ...	21 ,,	79 ,,

Mr. Nesfield has a curious but not impossible theory. At the rapidly developing rate of Hindu boyhood, his muscles have become relaxed and his constitution enfeebled, by sedentary life, so that he is unable again to take to hard field labour in the sun; and the same desuetude of manual labour, at the most impressionable age, makes him disinclined or unable to take up any form of skilled artisan work, of which his father, although unable to read or write, is by constant practice for his youth, a master. In support of this theory that, for artisan work, school-teaching is not merely useless, but positively detrimental, Mr. Nesfield gives a list of the seventeen leading hands in the Oudh and Rohilkhund railway workshops at Lucknow—men employed as fitters, turners, blacksmiths, brassmoulders, and other high-class crafts, many of them with seventy or eighty men under them. Out of these seventeen men, sixteen were wholly illiterate, and the seventeenth only able to just read and write.

EGGS AS FOOD.

The Boston *Journal of Chemistry* says that eggs, at average prices, are among the cheapest and most nutritious articles of diet. Like milk, an egg is a complete food in itself, containing everything necessary for the development of a perfect animal, as is manifest from the fact that a chick is formed from it. It seems a mystery how muscles, bones, feathers, and everything that a chicken requires for its perfect development, are made from the yolk and white of an egg; but such is the fact, and it shows how complete a food an egg is. It is also easily digested, if not damaged in cooking. Indeed, there is no more concentrated and nourishing food than eggs. The albumen, oil, and saline matter are, as in milk, in the right proportion for sustaining animal life. Two or three boiled eggs, with the addition of a slice or two of toast, will make a breakfast sufficient for a man, and good enough for a king.

According to Dr. Edward Smith, in his treatise on "Food," an egg weighing 1¾ oz. contains 120 grains of carbon, and 17¾ grains of nitrogen, or 15·25 per cent of carbon and 2 per cent of nitrogen. The value of 1 lb. of eggs, as food for sustaining the active forces of the body, is to the value of 1 lb. of lean beef as 1,584 to 900. As a flesh producer, 1 lb. of eggs is about equal to 1 lb. of beef.

A hen may be calculated to consume 1 bushel of corn yearly, and to lay 10 dozen or 15 lb. of eggs. This is equivalent to saying that 3 1-10 lb. of corn will produce, when fed to a hen, five-sixths of a pound of eggs; but five-sixths of a pound of pork requires about 5 lb. of corn for its production. Taking into account the nutriment in each, and the comparative prices of the two on an average, the pork is about three times as costly a food as the eggs, while it is certainly less healthful.

CURCAS OIL.

This oil is the produce of the seeds of *Jatropha Curcas*, a bush native of India. Singular are the names which this oil bears; they certainly prove the extensive use of this oil, known especially as a purgative. We note some of these names:—

Purgeernoten-olie.	*Oleum Cicinum.*
Hellen-oil.	*Huile de Pignon d'Inde.*
Huile infernale.	*Pinhoes de purga (Brazil).*
Huile de Médicinier.	*Bay bherinda (Hindostan).*
Huile de Purgueria.	*Bataendaros (Ceylon).*
Purging nut-oil.	*Nepalam (Telliugu).*

The seeds of this plant are in shape like the ricinus-seeds, but in general they are larger. The taste is like sweet almonds with a puugent after taste. When chewed they excite vomiting and act also as a purgative. The seeds contain 30 or 40 per cent of oil, of which the composition is as follows:—

Oil	37·50 per cent
Organic matter	50·40 „
Ash	4·80 „
Water	7·20 „
	100·00 per cent

Here too the organic matter contains albumen, sugar, gluten and caseine.

The oil is clearer than linseed oil and colours less. It is thinner than ricinus oil; the specific weight is at 15° Celsius 0·815. It solidifies 12° below freezing-point.

This oil is much used for burning and for soap-boiling; while in England the African sort is used as a lubricating oil for machinery.

In India this oil is also used medicinally, both inwardly and against eruptions of the skin.—*India Mercury.*

THE TAMARIND.

(*From a Correspondent.*)

An Indian contemporary observes that Tamarind, chiefly the produce of the southern districts of India and of the northern parts of Ceylon, has of late become an article of export to Europe, and he anticipates a rise in the price of this article. Although tamarind is plentiful in Jaffna, and more especially in the Vanni districts, it is not an article that is given away for nothing. There is a local demand for it, being almost an indispensable condiment or rather ingredient in the composition of all Indian curries, and a small quantity is also exported coastwise and beyond sea. The tamarind is a very mild and healthful aperient, and Europeans who have had the ripe fruit assure us that the pulp dissolved in cold water and taken as a beverage is a sure relief in chronic pile complaint.

But the great drawback in Jaffna is that few persons could be found to grow trees which do not promise an immediate return. We say it not only of the *tamarind*, but of the *margosa*, the *illuppai* and the *palmyra* as well, that with the denudation of the ancient *topes*, the trees have become comparatively few. We assume that increasing poverty is the cause of this. In days of old, the well-to-do land-owners had large tracts of land planted with *palmyra*, and where there was found a *tamarind* plant, an *illuppai* or even a *margosa*, it was carefully tended, pruned, guarded and grown as a thing of immense use. Now-a-days all land available is levelled and devoted to tobacco or dry grain, and scarcely one out of a hundred cultivators could be found to patronise the larger trees. Even if a tree or a sapling is found somewhere in the grounds, it is cut down and got out of the way as a thing that "cumbereth the ground." In vain did we plead with several of these vandals to spare a young tamarind or an illuppai plant. We were laughed at as those ignorant of the value of land and the purposes for which it ought to be utilized. There may be a degree of ignorance on one side, but really what is to become of land when all the old trees are cut down and destroyed? When that able and energetic officer, Mr. W. S. Murray, superintended the Police and Fiscal's departments, he caused a number of these productive and useful trees to be planted on roadsides and Government reserves. But we call upon those who own hundreds and thousands of acres to give some attention to this subject, and at least plant the barren and unproductive tracts with illuppai, tamarind, and other indigenous trees.

NOTES ON MURANGAI OR MURUNGAH.

BY E. M. HOLMES, F. L. S.,

Curator of the Pharmaceutical Museum.

There can be no doubt, I think, that the plant known to Mr. P. S. Brito under the above names* is the *Moringa pterygosperma*, Gaertn. The name is variously written by different authorities as Marung-gai (Waring), Mooringay (Jesudasen), or Mooringhy (Drury), and the specific botanical name is the Latinized version of the same word. My friend Dr. Ondaatje, of Ceylon, informs me that it is called the "drumstick" tree on account of the curious pod-like fruit, which, when ripe, is white, and bears some resemblance to a bone or short stick. The properties of the plant closely resemble those of horseradish, for which Dr. G. Bidie regards it as a perfect substitute. On account of this similarity, it is called by the Anglo-Indians the "horseradish" tree. The leaves, flowers, and immature fruits are sometimes used as a culinary vegetable, and are considered by the native doctors in India of value in the treatment of diseases of the liver and spleen. The juice of the fresh leaves is employed to hasten the suppuration of boils. The fresh root is rubefacient and even vesicant, but its application causes great pain. The decoction of the root bark has been given as an emmenagogue, but is said to be liable to produce abortion. The rubefacient and stimulating properties of the plant are also turned to account in the treatment of paralysis and leprosy, epilepsy and hysteria. A great deal more might be said about the medicinal properties of the plant, but all that could be adduced might be summed-up in the above quoted opinion of Dr. Bidie. The plant yields a volatile oil, to which its properties are believed to be due. The oil has a very disagreeable odour, and is said by Broughton to be different from either oil of mustard or oil of garlic. Dr. Ondaatje informs me that so far as his knowledge extends, and he has practised in Ceylon for thirty-six years, the leaves of the drumstick tree are never used in that island in the treatment of hydrophobia, nor is the plant known by its Malayan name, Marung-gai, nor its Tamil name, Mooringa, but by the Hindu one, Sohunjana. He is of opinion that the leaves would not have the slightest therapeutic value in the treatment of hydrophobia. The tree is a very in-

* Mr. Brito's article appeared in a previous number of the *Lancet.*

interesting one from a botanical point of view, being allied to the *Leguminosæ* in habit, and, indeed, was erroneously included by Linnæus in the genus *Guilandina*. It resembles the plants of this family in having compound leaves, stipules, and flowers which chiefly differ from those of the tribe *Cæsalpinæ* in the odd petal being inferior, in the one-celled anthers, tricarpellary ovary, and anatropous ovules. In the last two characters it approaches *Violaceæ*, as well as in the three-valved fruit, parietal placentation, and hollow apex of the style. In properties, it resembles the *Cruciferæ*, *Capparidaceæ* and *Resedaceæ*. By Grisebach it was placed in the *Capparidaceæ*, and by other botanists it has been compared with the *Polygalaceæ*, *Bignoniaceæ*, and *Sapindaceæ*. In the classical "Genera Plantarum" of Bentham and Hooker, it follows *Sapinadaceæ* as an anomalous genus of doubtful affinity. It is not surprising, therefore, that from description alone Dr. Trail should have referred "Murungai" to the *Leguminosæ*. Specimens of the pods and root bark can be seen in the museum of the Pharmaceutical Society of Great Britain.—*Lancet.*

THE LACQUER (SAME ROOT AS THE INDIAN LAC?) INDUSTRY OF JAPAN.

The subject of a correspondence between the Kew authorities, the Secretary of State and the Indian Government, Packets of seed had been sent to Madras, of which it is said:—

Mr. Quin states that these particular seeds were obtained "from trees which undergo a very severe winter, being almost buried in snow for several months."

The tree, however, will doubtless do equally well in a less rigorous climate. Mr. Quin further states that the wax used in the north of Japan is all made from the berries of *Rhus vernicifera*.

The identification of the tree and its history are thus afforded by Mr. Thiselton Dyer:—

I am desired by Sir Joseph Hooker to draw your attention to the steps which have been taken by this establishment to obtain information as to the lacquer industry of Japan. As you are aware, its products are highly esteemed by all lovers of art, but up till the present time practically nothing has been known as to the methods by which such beautiful objects are obtained.

From the statement of Kämpfer (1712), it has been accepted by botanists that the varnish, which is the basis of all lacquer work, was obtained from incisions in the three-year old stems of a tree indigenous to Japan, known as *Rhus vernicifera*. Beyond the fact that the tree is cultivated as coppice wood, the information of Kämpfer does not go, and up to the present time our knowledge of the subject has been a complete blank. Thus Balfour in his Cyclopædia of India (1873) states that "the manner of preparing it (the varnish), and the mode of applying it, is and is likely to remain a secret." It had been supposed that the Japanese lacquer tree was identical with a common Himalayan species of *Rhus*. Dr. Brandis points out, however (Forest Flora, page 121), that the Himalayan tree is not "known to yield any varnish;" and Sir Joseph Hooker in elaborating the *Anacardiaceæ* for the Flora of British India (ii, page 11) has, in describing it under the name of *Rhus Wallichii*, decided that it is not identical with the Japanese species. The lacquer varnish tree of that country is apparently unknown in India. It seems worth while, therefore, to draw the attention of the Government of India to the fact, as seed could doubtless be easily obtained from Japan, and there are many parts of India in which the tree could be cultivated.

In its lac industry India possesses an art which is closely allied to that of lacquering. It can scarcely be doubted that the latter is equally adapted to the methods and habits of the natives. Its results are, in an economic point of view, infinitely superior to those in which lac is used.

At the instance of Sir Joseph Hooker, the Foreign Office caused an elaborate inquiry to be made by its officers in Japan into the whole subject. The result will be found in a report by the Acting Consul at Hakodate, dated Tokio, January 13th, 1882, which has been printed and laid before Parliament. I am now to suggest that copies of this report, together with this communication, should be printed and transmitted to the Government of India, in order that some attention should be attracted to the subject in that country.

The very complete collection illustrating the report has been transmitted to Kew and exhibited in the Museum of Economic Botany (No. 1). It has been pronounced by experts in Japanese art to be of exceptional interest and quite unique of its kind. A portion of the expense incurred by the Foreign Office in getting it together has been defrayed from the grant made to this establishment by the India Office for the sustentation of the economico-botanical collections relating to India.

We trust some of the seeds has been sent to Ceylon, as it might succeed at Hakgala and similar elevations.

THE COFFEE SEASON IN COORG.

The Rev. G. Richter has furnished the Madras Agri-Horticultural Society with the following interesting reports, dated Mercara, 25th July 1883:—

With the end of July we are in the midst of the working season of the year, and may conveniently take a retrospective and prospective view of agricultura affairs in Coorg with the result, that in general we may mark the past with the stamp of 'cruel disappointment' and bestow on the impending crop the summary predicament of 'substantive hope,' and may the Supreme Giver of all good things spare us from another disappointment! I speak of course chiefly of the cultivation of coffee, in which the interests of the Coorg planters are centred. In my last report,* dated the 1st September 1882, I had occasion after a tour through South Coorg to write in high terms of the remarkable freshness and luxuriance in the appearance of the coffee trees, owing to high cultivation and the very favourable season in the Bambu district, and my impression was, as shared with many planters, that with few exceptions, the forthcoming crop throughout Coorg seemed to be a good one; but at the actual ingathering it proved a lamentable failure. From a comparative statement of estimated and realized crop from a number of estates, I deduce the fact, that on an average only half of the estimated crop was realized, and this in a year when the coffee market at home had reached its lowest level for years past. Agents who had to fill chartered vessels or recover heavy advances, and proprietors who had to improve the credit side in their Banker's books importuned unfortunate superintendents or managers to account for the serious failure; but I doubt whether any one has given a satisfactory reply. It is said, that the want of rain in April prevented the full development of the berries from the earlier blossom which had led to great expectations, and that the succeeding dense foliage of the trees, induced by the heavy monsoon, prevented the planters from verifying the amount of crop estimated on the blossom, and only the picking time revealed the actual shortcoming.

There is, however, no fear of a repetition of the disappointment concerning the coming crop. Planters have become more knowing and more cautious in their estimates; but the general opinion is, that with but few exceptions, there is substantial ground for expecting a good crop. The early March rains brought out a splendid blossom, which was supplemented in April and May, and seasonable showers effectively accelerated a vigorous swelling of the wellset berries, and unless these should drop off by some unforeseen calamity a good crop is ensured. The weather hitherto has been all that could be desired, especially for planting operations, light rain in June, but ample and sustained rainfall in July, without too much wind or hot sunshine. The rainfall in Mercara was 1 inch 83 cents in March; 4·59 in April; 4·14 in May; 20·84 in June and 45·02 up to date (25th) in July or 76 inches 42 cents. In 82 rainy days, the greatest amount gauged within 24 hours being 4 inches 75 cents on the 12th July. In the Bambu, the rainfall is about one-half that of Mercara.

The flowering season of the coffee trees is always a critical event, and anxiety mixed with hope and fear predominates till the verdict is passed: 'The blossom has well set.' The normal conditions of 'a good blossom' appear to be, early showers in March to invigorate the

* Not published in the Society's Proceedings, but in the *Madras Mail* of 5th September 1882.

flow of sap in the trees and to form well-developed flower buds; during the ensuing blossom which lasts but two or three days sunshine after a foggy, steamy morning and a few light showers soon after the blossom has passed away. But sometimes the rain falls too early and brings out a January or February blossom which may set well, provided the succeeding months are not too dry. On the Mercara plateau and the Sampaji valley rain generally keeps off and a late blossom is the rule, often exposed to heavy showers, and the question arises. in how far these affect an efficient fructification. Some planters say in such a case the pollen has all been washed off and there is no crop to be expected. Others prognosticate failure from stunted flowers, where, for want of sufficient rain, the petals of the corolla are small and of a yellowish colour; most planters naturally expect from a perfect flower the best results, and yet I have heard a practical and most successful planter utter the paradoxical dictum: 'the finest blossom, the worst crop.' How are these adverse opinions to be reconciled? Perhaps by laying not too much stress on the appearance of the blossom, but take into principal consideration the natural condition of the trees as effected by cultivation apart from the weather. For my own satisfaction I have ascertained that in a well-developed flower bud fructification may take place in the state of æstivation or just before expansion into the full blown flower. The experiment is easily made by removing the stamens just before the flower bud opens and marking the bud for after observation.

The great difficulty planters have to contend with this year is the scarcity of labor. At this busiest season, but few coolies have come in from Mysore, where their protracted field work for want of timely rain detains them, and are they not amply supplied with money from the planters' advances? On weedy estates the weeds enjoy a high holiday and the prospective manure from this source must gladden the hearts of weed-favouring planters! It is to be hoped, that the cooly question will be urged to a satisfactory solution by the planters. After the loss of a million of souls of the cooly class in Mysore by the late famine, the increasing demand for labour in the coffee-producing districts of Southern India must open up new sources of labour supply. Why should coolies emigrate to foreign countries with the prospect of semi-slavery; or why should statistics lament the increasing over-population in India, when remunerative work under easy circumstances is to be found near the coolies' doors? It is the large proprietors who should turn the tide, and direct cooly immigration into Coorg from new centres of supply.

It was presumed that the abnormally heavy monsoon of 1882 with 203 inches of rainfall, or 83 inches more than the average of the previous five years, and the consequent vigor of the coffee trees, should have shaken off the *Borer pest*, but it maintained its destructive sway with unusual severity in a sporatic manner all over Coorg. Perhaps a sense of false security on the part of the planters gave the insidious enemy new vantage ground. I have observed, that wherever dense shade of the right kind (Family Ficus and Cedrela) had long been established on a highly cultivated estate, the damage from borer has been less, but nowhere is the enemy to be disregarded, but summarily to be dealt with.

Having formerly referred to the judicious method of shading as now practised in Coorg, I would allude to the important question of *manuring*. I think all planters are agreed, that, wherever practicable, the best manure for coffee is a compost of imported atificial—bone dust, oilcake, superphospate of lime —and local, natural manure—vegetable and animal—and the more cattle manure the better; but they disagree as to the method of application. Some advocate direct manuring of each individual tree into semi-circular holes at some distance from the stem; others are for terrace-manuring behind each tree on steep land; others are for broadcast, manuring, with after digging or forking in. I have seen the application of all these methods, and where the proprietor can afford the generous treatment of broadcast manuring on a comparatively clean estate and on gently sloping coffee fields, I prefer this method, as it produces a highly nutritive soil, accessible to the rootlets in all directions; but it does not suit, either the means of all proprietors, or every lay of land. One thing, however, is certain and applies to all cases, that, if planters go to the trouble and expense of crushing steaming, and pulverising bones, and oil cakes, these manure particles should be kept asunder by a proper mixture with the soil, and thus be made accessible to the rootlets for assimilation and nourishment to the utmost extent and not be thrown in heaps or lumps into the holes round the trees, as is so frequently done.

Next in importance to coffee is *Cinchona Cultivation*, (I think, for the reason stated by Mr. Markham, Cinchona should be spelled with the initial Ch.) which now assumes large proporations in Coorg. It is strange, that an industry, so liberally undertaken by the Madras Government and so profitably worked and retained when successful, should have taken so long in gaining ground in Coorg.

For the last 15 years, Cinchona cultivation has been advocated in my season reports as a means of shade for coffee and as a supplementary source of income; but only the late coffee crisis in Ceylon and the resolute and energetic determination of planters there to open up to new economic resources, and especially Cinchona cultivation has given a decisive impetus here, to follow their steps. Now Coorg can boast of large Cinchona nurseries and nothing less than Ledgeriana will satisfy; however, all the principal varieties are represented. Even shrewd natives want now 'the new and best kind' and soon we shall have estates, where Ch. Ledgeriana, verde, condaminea, robusta, succirubra, &c., &c., will be counted by lacs instead of by thousands as now. Also the Coorg Forest Department vies with the planters, and the Mercara Firewood Plantation is being stocked with Cinchonas, and varieties of seedlings are raised in flourishing nurseries. I have seen most vigorous Cinchona plants in North Coorg, and as fine ones may be seen on some estates in the Sampaj Ghat, and in South Coorg, and the Perambadi Ghat, and since in has been ascertained that Ledgeriana succeeds best at an elevation of about 4,000 feet about sea level, Coorg seems to be the very locality for this valuable species, and there is great hope for the re-occupation of abandoned coffee estates for Cinchona cultivation.

From an official statement, it appears that 8,68,725 Cinchona trees are spread all over Coorg, covering an area of 1,086 cases acres, most trees have been put down among coffee, and in a few cases separate plantations have been formed on lands originally taken up for coffee. One planter alone owns two lacs of Succiruba, 70,000 of Condaminea, and 40,000 Ledgeriana! In my experimental garden near Mercara, I find that Ledgeriana seedlings planted in July 1881, along with Succirubras of the same age have out-grown the latter in height and general vigor.

It may be worthy of remark, that whereas the first shaved bark of 5 to 12 years old trees of Succirubra grown in the same experimental garden sold last year at 3s. 8d., per pound; the renewed bark shaved in October last fetched at the late sales in June only 2s. 4d. Whether this difference in prices is attributable to the general depreciation of Cinchona bark, or a special deterioration of the second shaving, I am unable to say, but opinions are expressed to the latter effect.

Systematic cultivation of *Cardamoms* in suitable localities has also fair prospects of success and men of pluck and energy are setting to work to redeem lost fortunes. Mr. Graham Anderson's example of success in Cardamom cultivation in the Munzerabad District is highly encouraging, and with the established fame of the Coorg, or Malabar Cardamom in the Home market, even a moderate crop will pay, and the prospects of the present year are favourable.

Rubber cultivation is still in its infancy; but I have seen *Ceara* trees already bearing fruit in South Coorg, and as at one time the castor oil tree was recommended for quickly growing, and temporary shade, so the Ceara may gain favor for the same purpose and yield the precious juice besides, its growth is most rapid and its handsome lobed leaves are umbragious.

Of the *Grevillea robusta* or silver oak introduced by me in 1876, one of the trees nearly 50 feet in height, blossomed for the first time at the end of May, but I am afraid the monsoon will interfere with the ripening of the seed.

My *oil-palms* (Elais Guineense) and Pithecolobium Saman are in a flourishing condition, but a nursery of the former proved a failure.

The new variety of *Eucalyptus*, the seed of which I obtained from the Society, has nicely come up and the plants are now over a foot in height; also the *Clematis flammula*, the seed of which you kindly sent me in January, has grown to the same height and promises well.

The harvest of *rice* last year proved satisfactory and prospects at present are favourable."—*Madras Mail.*

USEFUL PLANTS IN PARAGUAY.

Yerba Maté, the tea of South America, is noticed in a report on the useful plants of Paraguay. If all thatis said of the qualities of the plant be true, we are not surprized at its popularity; but we confess to being staggered at figures for a consumption of more than 100,000 lb. Another matter of surprise is that no attempt seems to have been made to prepare the Ilex leaves after the fashion of tea-making. We extract the following from the *Gardeners' Chronicle*:—

From a report on the commerce and finance of Paraguay, the following notes on the vegetable products of the country are gathered. Tobacco, it seems, is one of the principal articles of export, and it is said to be cultivated by nearly the whole population of Paraguay. The approximate quantity of production is calculated at 5,500,000 kilog. per year, and it yearly tends to make progress. Although the Argentine Republic, and, on a smaller scale, Uruguay and Chili, are the chief markets for Paraguayan Tobacco, yet as these countries have themselves for some years past taken to cultivate this article, it is to presumed that the said countries, on improving and increasing the cultivation of Tobacco so as to produce enough for the consumption of their own inhabitants, will find it to be in their interest to protect their own industries by Custom-house measures against the entry of foreign Tobacco. It is consequently very important for Paraguay to find a European market for its Tobacco produce; but the quality will have to be considerably ameliorated before the Republic can hope to succeed in this. Smoking is universal, and is indulged in alike by men, women, and children; the women make up the cigars, and it may be said that since the war, which all but annihilated every man in the country, the women are employed in nearly all agricultural pursuits.

Tobacco can be cultivated anywhere in the country, but the places best known for the excellent quality grown are Villa Rica, Itacomé, Luque, and the banks of the river Apa. The *peti-hoby* (a blue Tobacco) and the *peti-pará* (yellow) are those which are cultivated with the greatest care. The former, coming from Villa Rica, is used for home consumption, and the latter (*peti-pará*) for export purposes. The Tobacco seed used in Paraguay was originally introduced from Havannah, with the exception of the *peti-hoby*, the original of which is unknown. The *peti-pará*, which contains 6 per cent. of nicotine, is highly esteemed and generally smoked by the natives. At Luque a species of Havannah Tobacco is grown, which in its quality resembles the Brazilian Bahia Tobacco. It is stated that the whole ground at present under Tobacco cultivation in Paraguay does not exceed in the aggregate a square league of land.

Next in importance to Tobacco, if not of greater value, is the cultivation of Yerba, or Paraguay Tea (Ilex paraguayensis). The Yerba fields hitherto worked are those those situated in the northern and southern districts of Paraguay. The northern fields ase State property, and are leased to the cultivators by the Government, the lessees paying a license tax of trifling amount.

The southern fields were granted by Government to lessees for a term of ten years, from January 1, 1880, on condition that the Government should receive the sum of 12 dol. (£2 8s.) for every 25,000 English pounds) produced by them. Yerba-maté is at the present time exclusively consumed in the Republics of the River Plate, Uruguay, and Chili. There seems a strong reason to suppose that at some future time Yerba will become an article of export to Europe.

From a translation of a paper on the subject published in the *Revue Scientifique de Paris* by M. Louis Conti, some interesting facts may be gathered, amongst which may be mentioned the facts that the quantity annually exported from Brazil may be reckoned at 30,000,000 kilos, or 300 000 metrical quintals, and that from Paraguay about one-sixth that amount, or about 5,000,000 kilos, or 50,000 metrical quintals. In one province alone of Brazil, viz., Parana, 15,000,000 kilos are exported annually; added to this the quantity required for home consumption must be taken into account, and thus the total consumption of Yerba-maté in each year may be put down at 500,000 metrical quintals, or 50,000,000 kilos.

"The virtues of Yerba-maté as a mild stimulant are well known, and it possesses nutritious qualities in no mean degree. It may be said that in certain parts of South America it constitutes nearly the whole sustenance of field labourers when engaged in the outdoor pursuits. It has been noticed that in towns certain persons take little else in the way of food and especially women, who are in the habit of taking from ten to twelve cups per day. All authors who have treated on Yerba-maté from the early publications of the Jesuits to the more modern works of Bonpland, Mantigazza, Parodi, Barbier, and others, are unanimous in stating that the nutriment afforded by Yerba-maté suffices to sustain the system during a prolonged interval of labour. The consumption has increased fivefold within the last forty years."

A comparison is drawn between the cost of Coffee cultivation and preparation and those of Yerba; while with the former the processes of pulping, roasting, &c., have to be gone through, with the latter the processes are simple and rapid, and can be completed in from twenty-four to thirty-six hours. "A slight scorching of the leaves caused by rapidly passing through a fire, lit with aromatic wood, the sprouts no which they grow, completes the first operation. The next consists in suspending small branches of these sprouts at the height of 2 metres from the ground beneath the roof of a shed open to the air on all sides in such a way that these branches form as it were a ceiling. In this position they are exposed during fifteen or twenty hours to the action of a fire kindled beneath them with sweet-sented wood, which burns briskly without yielding any smoke; afterwards the scorched sprouts are coarsely ground, and this forms the last operation which Yerba-maté undergoes in the forests before being transported thence to the towns and villages. It is then finally prepared for transport to its place of sale. So trifling indeed are the operations to which the Ilex leaf is submitted in the forests themselves, that in a couple of days a few men accustomed to the task can dry between 3,000 and 4,000 kilos of Yerba."

On the subject of durable and ornamental woods, the botanical origin of which we know so little about, it is said that the country is indescribably rich in such woods, suitable either for building or industrial purposes, but for the want of an easy accommodation they cannot as yet be sent to European markets. The requirement seems to be the providing of small but powerful cargo vessels of very light draught, and capable of carrying when loaded about 400 tons. Quebracuo wood is referred to as being a very hard wood, weighing 38 kilos per cubic foot, which is sent in large quantities to France. It is useful for tanning and colouring purposes as well as for railway sleepers. This appears to be the Red Quebracho (Loxopeterygium Lorentzii.)

All fruit trees of temperate countries, such as the Pear, Apple, Fig, &c., besides those of hot climates, such as Orange, Banana, &c., are cultivated at Paraguay. Orange are so plentiful that they merely have a nominal value. The price of 5,000 Oranges delivered alongside the vessels in the river Paraguay is 5 dols. 75c. (£1 3s. 1½d.) during a period of abundance. The price increases only when the fruit is getting scarce. In the Custom-house Returns for 1881 Oranges figure in numbers in the export list at 47,917,700, and in value at 47,917 dols. 70c. (£9,583 10s. 10d.) These Oranges have an excellent flavour, and are shipped in enormous numbers to the Argentine markets, chiefly Buenos Ayres.

There are three varieties of Sugar-cane cultivated, two of a white and another of a darker colour, the latter of which grows to about the same size as the large white variety, resists the cold better. Sugar-cane grows admirably throughout the country and everywhere, without its being necessary to irrigate the plantations, which last from eight to nine years. This industry, however, is in a primitive state, and remains stagnant at the present moment from want of capital and enterprise. The consumption of *cania*, the rum made from the native cane, is enormous throughout the whole country. Once planted the cane may be said to yield juice during ten or eleven consecutive years. In spite of the excellent quality of the Sugar-cane, and the favourable nature of the land for growing it, Paraguay consumes annually on an average from 15,000 to 20,000 arrobas (from 375,000—500,000 lb.) of foreign sugar, and with the heavy import duties at present existing in the Argentine Republic and in Monte Video it is difficult to see how Paraguay will be able to profit by exporting this valuable article, more especially as sugar-producing and cane-planting have been taken up during these last few years on a large scale in the Argentine province of Tucuman. The total produce of the sugar-growing Argentine province is calculated for the year 1882 at 1,500,000 arrobas (37,500,000 lb.). The two sugar mills which at present exist in this country are generally idle, owing to want of capital and to a deficient supply of the prime material, viz., Sugar-cane; so scarce is the latter that plantation will have to be formed for the purpose of producing cane for these two mills, which are on a scale sufficient to supply the whole of Paraguay with sugar.

The Coffee of the country is of an excellent quality, although its flavour is somewhat bitter. At present it is grown on a very limited scale, owing to the scarcity of capital, and to the length of time which is requisite before the cultivator is able to reap any benefit. It is calculated that on the average a period of five years or so must elapse before Coffee plantations are ripe for their first harvest. Indigo is of a regular quality, and the extraction of the dye is easily effected. M. Balansa, a French naturalist, settled in Paraguay, has begun planting Indigo with considerable success, some samples of which were to be sent to Europe for examination.

There is an endless supply of fibre-producing plants equalling the Indian jute, and the only thing required to make its preparation for the European market a most important article of export, is machinery to separate the fibre from its vegetable envelope, in the plant called Caraguata (Eryngium) [? a Bromeliad]. A certain Palm-leaf produces a filament rather superior to the proceeding, but perhaps the very best of anything yet known is the fibre obtained from the Pino guazii." This is described as Urtica utilis. For a long time past, it is stated, the native have been in the habit of taking a string of remarkable fineness and strength from the two indigenous plants—the Caraguata and the Elvira. This thread is used for making cordage, and samples sent to England have been valued at £24 per ton. Up to the present it has not been worked on a large scale, from the impossibility of obtaining machinery to properly extract the fibre. A cordage maker at Buenos Ayres has, however, it seems, succeeded in producing the necessary machinery, and intends putting it up in the Argentine colony of Formosa, a province of the Gran Chaco. Should this machine succeed, a valuable article of export would be produced, of which Paraguay could furnish several thousands of tons yearly.

A bark called Curuguay is described as being very abundant in the country. It contains a large proportion of tannin, and is very valuable for tanning purposes. There are, however, no tanneries in Paraguay.

Besides the articles already referred to, the report says that "there exist, unknown to the world in general, a variety of drugs, medicinal plants, gums, &c., which have yet to be explored."

MATE OR PARAGUAY TEA.*

BY DR. THEODORE PECKOLT.

This plant, which belongs to the holly family (Ilicineæ), has several names in different parts of South America. In the Guarani language it is called *Caa*, which is the Indian word for leaf. The prepared leaves were named by the Spanish "yerba" (herb), and the infusion "mate"† from the native name for the vessel in which the tea is made, and the drug is now generally known as mate in Brazilian commerce, although the Spaniards call it "yerva mate" or "yerva de palos." The name "congonha" has been said by some writers to be applied to mate, but this is an error, for the Brazilians understand by the names "congonha mansa" and "congonha brava," other trees belonging to the same natural order, which are used as a substitute for mate when it is not easily procurable.

The plant was first briefly described by St. Hilaire, in 1822, when he gave to it the name *Ilex pacaguriensis*, which he altered in 1826, to *Ilex Mate*, subsequently publishing the first name again in 1833 and this is now adopted in the 'Flora Brasiliensis.' In 1824 the plant was described in detail by Lambert, under the name of *I. paraguensis* and the plant illustrated from specimens obtained from the Jesuit Missions. The synonyms stand as follows:—

Ilex paraguariensis, St. Hil.; *I. Mate*, St. Hil., *I. paraguayensis*, Hooker, fil.; *I. paraguensis*, D. Don.; *I. paraguariensis*, *a*, *obtusifolia*, Mart.; 3, *acutifolia*, Mart.; *Cassine Gongonha*, Raben.; *C. Gouguba* Guibourt; *Chomelia amara* Vell.

The mate plant attains the height of an apple tree, becoming even larger in favourable situations, but when cultivated and deprived from time to time of its leaves, it remains small and forms a mere bush. The leaves are shortly stalked, simple, wedge-shaped, obovate or elongate-lanceolate, toothed, dark green above, paler beneath, shining, of leathery consistence, 1 to 3 inches long, and ½ to 1½ inch broad. The flowers are axillary, situated on one to three times forked peduncles, white, and of similar size to those of the common holly. The calyx consists of four nearly orbicular sepals with a four-parted corolla and four short stamens, the ovary being crowned with a four-lobed stigma. The fruit is red and of the size of a peppercorn, containing four seeds enclosed in a slightly glutinous pulp, but often one seed only is developed. The home of the Paraguay tea plant is said by Martius to lie between 18° and 30° S. latitude, but the district in which the tree grows most luxuriantly is between 21° and 24° S. latitude in the watershed of the Paraguay river on the west, and in that of the Parana on the east, and it is here in a zone between the Serra Amambuhy on the south and the Serra Maracaju on the north that the best and most highly prized mate is prepared.

How long the South American Indians had been in the habit of using mate is not known, but when the Spaniards seized the province on the rivers Paraguay and Uruguay they found this custom prevailed there exactly as first mentioned in the writings of Azara, who stated that the tree grew wild in different parts of Paraguay. In proof of the high estimation in which it was held by the Indians it may be mentioned that the name "caa" which signifies in the Tupi language a tree or plant, was given by way of distinction to mate, that being the tree valued above all others. The use of mate does not appear, however, to have extended to extra-tropical districts, but to have been confined to the more intelligent tribes known now under the name of Guarani Indians. Nevertheless, when these people were driven further north by Europeans, they do not appear to have carried the use of the drug with them, probably thinking it not worth while to obtain it from a distance and from a hostile people when they found a substitute close at hand in the Guarana plant.

The extensive use of mate in South America at the present time is probably due in great measure to the Jesuits, who encouraged its use, finding that it restrained the desire of the Indians for spirituous drinks, while its cultivation, collection and preparation gave employment to converted Indians and brought wealth to the order. In the Jesuit Republic, the Indians were not paid in money but in produce; 4 lb. of meat, a definite amount of Indian corn and 1 oz. of mate were allowed to each family.

After the expulsion of the Jesuits, the preparation of mate was continued in the Paraguay Republic under the administration of the Dictator Francia and his successors, until the Dictator Solano Lopes was killed in battle with the Brazilians in 1870. An overseer was appointed over the work who also was paid in kind, receiving for each aroba of the tea natural produce of the value of ⅛ ounce of gold. Since 1870 there has been free trade in the article, which renders an increase of the trade very desirable. At the present time mate is used only by about 12,000,000 of people, and the consumption amounts to about 8,000,000 pounds.

It has been stated that mate is not prepared solely from *I. paraguariensis*, St. Hil., but that the leaves of other species are mixed with it.

In 1842, Sir W. J. Hooker pubished in the *London Journal of Botany* (vol. i., p. 30) an exhaustive account of yerba mate, together with the characteristics of the different varieties which he considered identical with *Ilex paraguariensis*. This paper strengthened the previous opinion of Miers that probably more than one species was used in the preparation of the tea. The investigations made by Miers and the monk Leandro, Director of the Botanical Gardens in Rio Janeiro, confirmed by Bonpland, indicate that six different

* Abstracted from a paper in the *Zeits. d. allg. öster Apot.-Verein*.

† The word is not accented, as sometimes written.—T. P.

species are used for the purpose:—1. *Ilex theezans*, Bonpl., growing in Paraguay, Entre Rios and Brazil; 2. *Ilex ovalifolia*, growing in the neighbourhood of Rio Pardo; 3. *Ilex amara*, Bonpl., on the mountains of Santa Cruz and in the forests of the Brazilian province of Parana; 4. *Ilex crepitans*, Bonpl., in the interior of Santa Cruz and the banks of the Parana river; 5. *Ilex gigantea*, Bonpl., on the banks of the Parana river. This is the "caa-una" of the Guaranis. 6. *Ilex Humboldtiana*, Bonpl., in the province of Rio Grande do Sul. This is the "caa-unina" of the Brazilians. The last four species, more especially *I. amara*, yield the "caa-chira" of the Guaranis and the "caa-una" of the Brazilians. Martius, however, in the 'Flora of Brazil,' states that in the central districts of Paraguay, where the *I. paraguariensis* is especially abundant, only the leaves of this species are used; in other districts the various species of *Ilex* are similarly employed.

It is certain, however, that *I. paraguariensis* is the only species in cultivation, but this is carried on to a very limited extent as the wild plant is still abundant. The Jesuits planted the tree because they found that under cultivation the leaves had a milder and more pleasant taste. For cultivation the seeds are carefully freed by washing from the glutinous matter in which they are imbedded, without which treatment they would not germinate, this office being probably performed in a natural state by birds, since the Indians believe that the seeds will not germinate unless they have been voided by birds. The young plants are taken out of the hotbed when about 6 inches high and planted out about 12 to 15 feet apart, in a damp, somewhat marshy ground, so as to allow of a small trench being made around the plants in which water can collect. They must also be grown under the trees which afford shade, as the young plants are easily killed by a strong sun. When they are about 3 to 6 feet high some of the shade plants are removed, and in four years the leaf harvest can be begun. The young trees should not, however, be entirely deprived of their leaves lest they should not be able to recover. In the seventh year they will yield 30 of 40 kilos of leaves. It is calculated that on 220 square metres of land one thousand six hundred trees can be grown, yielding on an average 35 kilos of leaves per tree, or about 25,454 kilos of leaves, valued at 190,000 marks per 100 square metres. The cultivated plant remains a small bush and never reaches the stature or size of the wild tree. The cultivation of mate has been carried out with much success in the province of Parana by Dr. E. Westphlen, and it promises to be successful in the Dutch colony of S. Leopoldo in the province of Rio Grande do Sul, where the plant grows luxuriantly.

The trees has been planted in the Cape of Good Hope and seems to succeed well there, as well as in Spain and Portugal. The quality of Paraguay tea depends upon the time of year in which it is collected, the leaves possessing most aroma when the fruit is nearly ripe. In the Argentine Republic and in the Brazilian province of Rio Grande do Sul the leaves are collected from February to the end of July. The new shoots are put forth in August, but at that time it would ruin the trees to gather the leaves. In the forest of the Brazilian province of Parana and Santa Catherina the harvest is collected from March to the end of September. In Paraguay it begins in December and continues till August. About a month beforehand the collectors set out in caravans with their wives and children into the forests where the mate trees are abundant, and make their encampment.

The first operation is to prepare a torrefier, which is made in the shape of an arbour. The twigs are cut off from the branches and slightly scorched by drawing them quickly across the fire. The twigs are then collected into bundles suspended over the torrefier, a small fire of dried wood being kept alight beneath. In about two days the drying is completed, the ashes are removed, and in the spot where the fire was an ox-hide is spread out, on which the leaves are beaten from the twigs with a wooden blade. The dried leaves are then powdered and packed in wooden cases made out of hollowed trunks of trees.

In the province of Parana the leaves have lately been dried in large wrought-iron pans, in the same manner as Chinese tea, or in specially constructed ovens in which they can be prepared so as to retain more aroma; they are then powdered by machinery and sifted; this kind of mate obtains a better price.

Another form in which the leaves are prepared is by carefully separating them from the stalks and twigs and roasting them, but this is not so much esteemed as the powder, except in Chili, where the leaves are preferred.

In the South American Republic and the Brazilian province of Rio Grande do Sul, mate is packed in serons of ox-hide holding 30 kilograms, and in half-serons, containing 15 kilograms; this packing gives to the mate a disagreeable flavour which detracts from its value.

In Parana it is packed in cane baskets; these are lined with dried grass, called Jacaes, and contain 50 to 60 kilograms. The mate in leaves is here sold at 280 to 290 reis (about 56 pence), powdered mate is sold in thick and better woven cane baskets, containing in a half-seron, 15, and as a seron, 60 kilograms, the price being 10 to 12 per cent more than the leaves.

In the Spanish Republic three different sorts are sold under the following names:—

1st. Caa-cuy, or Caa-cuys: these are the new leaves of the scarcely developed shoots. They are of more delicate texture, and of a yellowish colour. They possess an agreeable and pleasant flavour, but are seldom met with in commerce.

2nd. Caa-mirim. This was the chief product in the time of the Jesuits, and consists of the leaves carefully separated from the twigs and stalks, the mid-rib of the leaf being also removed. This kind is chiefly esteemed in Peru, and principally exported there by the Brazilians. It is called Herva mansa.

3rd. Caa-guacu, or Caa-una, or Yerva de Palos, is the most inferior kind, consisting of the large and old leaves with the twigs and fragments of wood, and possessing a strong and bitter flavour.

In Rio Janeiro two sorts are known to commerce, mate in leaf and mate in powder. In order to test the quality of mate, the merchant takes a small quantity in his hand and blows upon it. If the greater portion is blown away he considers that it has been heated too much and thus deprived of its strength. If it is not easily blown away it is then considered of good quality.

Mate has been the subject of several analyses. In 1836 Trommsdorff anaylsed mate and found tannin, two resins extractive matter, and a substance which he believed to be an alkaloid, but he possessed too little material for complete investigation.

In 1843 Stenhouse found in mate an alkaloid and proved that it was identical with caffeine.

In 1850, Dr. Rochleder investigated Paraguay tea and found the reactions of mate-tannic acid to be identical with those of coffee-tannic acid.

Lenoble, who, as well as Dr. Rochleder supposed mato to be produced by *Psoralea glandulosa*, named the crystalline active principle he obtained from it, "psoralein."

He also found in it wax, albumen and volatile oil.

According to Dr. Byasson, mate contains as much caffeine as the best Chinese tea. The variety which he experimented upon was Caa-guacu. He found also a viscid substance resembling birdlimo, soluble in ether; this he considered to be a fatty body of the nature of a compound ether whose alcohol was allied to cholesterine.

His analysis was as follows:—

	Grams.
Caffeine	1·850
Substance resembling birdlime, fat substance and colouring matter	3·870
Complex glucoside	2·380
Resin	0·630
Mineral matter	3·920
Malic acid	Not estimated

Robin has examined several different kinds of mate The amount of caffeine in young leaves dried without special care was 0·02 to 0·03 per cent.

Mate prepared by the Indians and containing twigs and fragments of fruit yielded 0·16 per cent, and mate from the Mission of the Province of Corrientes, 0·14 per cent The peculiar tannic acid, which Dr. Byasson did not find, varies between 1 per cent and 1·6 per cent. The ash of young leaves varies from 0·12 to 0·2.

Professor A. W. Hoffmann, of Berlin, found 0·3 per cent of caffeine. The average of the published analyses indicates about ½ per cent of caffein, that of Indian tea being 2 per cent. The value of mate, as in the case of tea, depends not merely upon the caffeine but also upon the tannin and aromatic principles. He considered the tannin to be identical in every respect with that found in tea.

The aromatic principle has not been isolated, but by dry distillation a volatile oil is obtained, which belongs to the phenol group and is soluble in alcohol.

In 1877 the mate-tannic acid was examined by Dr. Pedro N. Arata, who found that the tannin of mate, while analogous to that of coffee, was not identical. The chief differences noticed by him are as follows:—Lime water gives with the coffee-tannic acid a small precipitate soluble in excess, but an abundant insoluble precipitate with the tannin of mate. This, however, does not hold good with all samples of mate, the precipitate being sometimes soluble in an excess of the tannin. Coffee-tannic acid gives by dry distillation pyrocatechin, while the tannin of mate yields in addition to pyrocatechin the isomeric body resorcin.

Coffee-tannic acid is soluble in 52·84 vol. of alcohol, while mate-tannic acid requires 73·66 vol.

Dr. Arata considers that coffee-tannic acid may be regarded as dioxyparacinnamylic acid, whilst mate-tannic acid must be classed in the group of oxyphenylpropionic acid.

Soubeiran and Delondre state that mate contains the same essential constituents as the coffee leaf, and in greater amount than the coffee seeds, which I can confirm after numerous experiments with large and small quantities.

In the years 1860 to 1865 I analysed mate and Congonha leaves. My analyses were made with fresh leaves of the *Ilex paraguariensis* from the Orgel Mountains in Neufreiburg, and roasted and unroasted leaves from the province of Parana.

In the air-dried leaves from the Orgel Mountains I found the following substances in 1000 grams:—

	Grams.
Stearoptene	0·021
Volatile oil, extracted by ether	0·099
Fat and wax	19·800
Green colouring matter	10·900
Chlorophyll and soft resin	20·966
Brown acid resin	48·500
Caffein	6·398
Bitter extractive matter	2·033
Sugar	39·266
Extractive matter and organic acids	8·815
Mate-tannic acid, pure	27·472
Mate-viridic acid, crystallized	0·024
Albumen, organic acid, inorganic salts, dextrin, etc.	47·660
Moisture	166·660
Cellulose and lose	601·386

In 1,000 grams of air-dried little twigs of the *Ilex paraguariensis* from Neufreiburg I found:—

	Grams.
Green soft resin and chlorophyll	9·400
Brown acid resin	19·700
Caffein	2·579
Mate-tannic acid and extractive matter	30·000
Extract, cellulose and water	938·321

In 1,000 grams of air-dried leaves from Parana, from which the roasted mate is prepared, I found the following substances:—

	Grams.
Stearoptene	0·019
Volatile oil, obtained by ether	0·179
Fat and waxy substance	18·800
Green colouring matter	10·800
Chlorophyll and soft resin	51·200
Brown acid resin	84.500
Caffein	16·750
Aromatic substance	2·500
Mate-tannic acid, pure	44·975
Mate-viridic acid, crystallized	0·025
Extractive matter	63·130
Saccharine extractive matter, sugar	6·720
Albumen, salts, dextrin, etc.	36·102
Moisture	101·600
Cellular matter	557·700

In 1,000 grams of commercial mate from Parana I found:—

	Grams.
Volatile oil, obtained by ether	0·026
Caffein	5·550
Chlorophyll and soft resin	6·100
Brown acid resin	25·502
Mate-tannic acid pure	16·785
Pyromate-tannic acid	1·465
Mate-viridic acid, crystallized	0·024
Extractive matter	16·610
Caramel-like extractive matter	1·370
Salts, dextrin, etc.	18·189
Cellular matter and moisture	908·379

The ash of mate analysed by Dr. Busse and Herr Riemann was found to contain potassium, sodium, magnesium, oxide of manganese, calcium, aluminum, iron, phosphoric acid, sulphuric acid, carbonic acid, chlorine, silicic acid; but the analyses vary so much in different samples as to lose some of their value.

I found in leaves of mate gathered in Neufreiburg—

	Per cent.
Oxide of manganese	8·958
Sodium	10·062
Potassium	14·615

Whereas these were not found at all by the above-mentioned analysis in leaves obtained from Rio.—*Pharmaceutical Journal.*

NATAL CURATOR'S BOTANIC GARDENS' REPORT.

January 1st, 1883.

To the President Natal Botanic Gardens.

SIR,—In handing you my Report on the work of these Gardens for the past year, I would remind you that I assumed the Curatorship on the 1st March last, and, therefore, this report refers only to the time between that and the close of the year.

* * * *

The work of naming the plants is being gradually proceeded with, the late Curator gave me the names of upwards of 400, and a small portion of these were labelled, the remainder I have got by degrees, until now upwards of 600 are named and all of these have attached, to one specimen at least a number which corresponds with the number in a book kept in my office. I have also laid out the ground in blocks, lettered from A to R, and the register also contains a list of the plants in each block, so that there can be little difficulty in future in finding any plant which may be wanted. In addition to this I have arranged an alphabetical list, and to each name is appended its number and the letters corresponding to the blocks in which the plant is to be found. This part of the work is now completed so far as the plants are known to me; but there still remain a number of trees which cannot be certainly named until they flower; a period which, in some cases, may never arrive; and also some, of which I have no description in any book in the Library, and in respect of which I have been compelled to ask for assistance from the Director of Kew Gardens, which assistance, I am pleased to say, has been very readily promised. I have received an importation of Smith's imperishable labels, which are now in their places, and I hope to be able to procure more from time to time, until all the plants are legibly named. The catalogue of plants in the Gardens is in progress, and I hope the present year will witness its completion.

I received in March last from Dr. King, Director of the Botanic Gardens, Calcutta, a number of plants of *Shorea* or *Vatica robusta*, the "Saul" tree of India. Some of these I distributed to persons likely to value them, and some I have kept in the Gardens, but I have become convinced that the climate of the coast is not suited to the plant; and as I find that in India it flourishes best on hilly slopes up to 3,000 feet, I am sending three or four plants to a locality where I hope they may have a better chance of success.

I received from Kew seeds of *Argania sideroxylon*—a valuable tree—the "Argan" of Morocco, some of which we planted, and of the remainder I distributed about twenty packets;—our own all failed by damping off, but at least two of the persons who had seed have succeeded in rearing them, and one gentleman informs me that he has several healthy plants, so that I hope we may be successful in establishing so valuable a plant. The late Curator informs that the seeds of this plant have been introduced before on several occasions, but that they have always either failed to germinate or damped off afterwards, and I think that in this case also the coast climate is not suited to the plant; but I have distributed the seeds widely, and hope to hear that others, besides the two I have mentioned, have been successful in rearing it. The "Liberian Coffee," about which so much has been said and written, appears to me to be unsuited to our climate. The plants flower and bear fruit, but the berries remain so long upon the trees before ripening, as to lead me to think that the plant requires a climate both hotter and moister than that of Natal for its successful cultivation.

The trees of *Trachylobium Hornemannianum*, which yield the gum copal of commerce, look remarkably vigorous; one of them bore a moderate crop of legumes, a large number of which failed to mature, still there remain a few from which I hope to raise plants for distribution. The plant appears well suited to the sandy soil around Durban, but how its cultivation would answer commercially I have at present no means of ascertaining. The trees of *Manihot Glaziovii*, the plant yielding the indiarubber known as "Ceara Scrap," also seem to flourish, and I hope during the coming season to rear a few specimens of this valuable plant for distribution. I am sorry to say that the attempt we made last season to rear plants from cuttings was a total failure; but with the information obtained from Mr. Horne, of Mauritius, as quoted in the Kew report for 1881, I hope to be more successful in the coming season.

The herbarium belonging to the Gardens is not in a state which renders it of much use to the student. The specimens are unmounted, and old newspapers supply the place of both species sheets and genus covers; but I have gone carefully over it and arranged the specimens in botanical order, and hope at no distant date to have them all poisoned and properly mounted. The collection has been increased by the receipt from Kew of a donation of a large parcel of South African plants, all of which have been intercalated with the collection, and I am slowly adding to it specimens collected by myself. So far, I cannot say the herbarium has been much consulted by anyone but myself, only two persons have expressed any desire to see it; but I hope as time goes on and students of botany are more numerous, that the collection of South African plants, at any rate, will prove to be of considerable value, and some proof that this hope is not without foundation, I may here state that I have during the year named upwards of 200 dried plants which have been sent to me for that purpose, and I propose by this means to increase our collections, as I shall expect for the future that sufficient material be sent to enable me to retain for ourselves one specimen of each species sent for identification. And it should also be remembered that the herbarium will always be of considerable value to the Curator of the Gardens, even though the public should not consult it at all. Numerous additions both of plants and seeds have been made to our stock during the past year, as will be seen by the following list. I notice that it has been the custom in some previous years to enumerate the plants received in this way as additions to the collection, and as a large number of the plants so enumerated are not now to be found, and no record of them exists except in these reports, I have come to the conclusion for the future not to take credit for any importation of plants until in my opinion they are fairly established. In my next report, therefore, I propose to furnish a list of those plants we may have successfully introduced during the year 1882.

I am much indebted to the proprietors of the *Tropical Agriculturist* for the numbers of that very useful publication which have reached me regularly through the post, and to E. M. Holmes, Esq., Curator of the Museum of the Pharmaceutical Society of Great Britain, for the copies of the *Pharmaceutical Journal*, which arrived in due course, and often contained information of much value in carrying on the botanical work of the institution.

The meteorological observations have been taken with regularity and care, and abstracts have been forwarded each month to the two local newspapers.

Abstract of Meteorological Observations for the Year 1882.

The Mean Barometric Pressure...	30·168
Do. Temperature in Shade...	68·8
The Total Evaporation...	47·63 in.
Do. Rainfall	36·21 ,,
Do. Number of Days on which rain fell	93
Do. do. Thunderstorms	31

J. Medley Wood, *Curator.*

COCOA-NUT FIBRE.

Within the last twenty years a vast extension of the economic uses to which this valuable fibre is put has taken place. The term "coir," usually applied to this material, is the Anglicized form of the South Indian "kayaru" cord or twine, and not applied in India to the raw fibre, which is called in the Tamil language "savuri." The fibrous husk or rind of the cocoa-nut is easily stripped from the nut while yet green, by striking it on the point of an iron spike, and then is steeped in salt or brackish water, where it lies for several months, until the softer portions of the husk rot away, and the strong fibre alone remains. This is taken out, beaten with a stick to seperate and clean the fibre and twisted with the required number of strands into rope, or woven into matting, while the stiffer fibres are made into brushes and other articles of domestic utility. The fibre is pressed for shipping into bales weighing 200 lb. each. The attempt has been made to prepare the fibre from the dried husk in England, but without success.

Much of the coir fibre used in England is brought from Ceylon; but a large and increasing quantity is now exported from Bombay and the Western Coast of India. The supply is not inexhaustible; but as prices rise, cultivation is encouraged, and as the growth of this palm is along the sea coast, where other crops cannot be grown, the trade is a profitable one.

Factories for the weaving of coir matting have been opened by English and American firms at Allepy, Quilon, Colachel, Cochin, &c., and turn out a considerable quantity of goods. Spinning is not attemped here, being more cheaply done by hand at the places where the fibre is produced. Along the coasts of the backwaters and canals many people may now be seen busily engaged in scraping and cleaning the fibre and twisting it into yarn. In the factories the yarn is first sorted to its various shades and qualities. The warp is made by boy running backwards and forwards, then it is flattened and smoothed for weaving, by being run through heavy rollers. The weaving is laborious work, performed by men, who earn two or three rupees a week at it. The web is again rolled to give it some finish, wound securely in a roll, and marked. Large profits have been made in this manufacture in India. But it can now be carried on so much better in England, with the machinery and appliances available here, that large quantities of the yarn are exported. One firm in Lancashire have introduced steam loom weaving of this material. The various shades of fibre—cream-coloured, reddish brown, and blackish—which vary greatly according to care and skill in preparation, are first carefully separated, and cocoa-nut matting is now made of fine quality, with pretty shades of colour and in pleasing patterns, so as to be available for higher uses than the very coarse makes, and the material is most durable. The yarn is also plaited by machinery into cinnet or belting. Cables made of coir bear exposure to salt water better than anything else, the tannin which it contains preventing the fibre from rotting; they are exceedingly light and buoyant, as well as elastic. Even the refuse and broken fibre can be turned to account for stuffing mattresses, and is used in horticulture, &c., as no insect will touch it. The exports from Travancore of this material form a large proportion of the trade of the district, and amounted in 1879-82 to nearly 150,000 cwt., valued at 13¾ lacs of rupees (say 137,290 pd. St.) and paying to the Government a duty of 68,000 rupees Of the cocoa-nuts themselves, nearly 9,000,000 valued at nearly 260,900 rupees, were sent away. Other products of this palm exported, as oil and copra or dried kernal, were valued, the former at 322,100 rupees, and the latter at no less than 26½ lacs of rupees, making a total value of the export of products of the cocoa-nut palm, from Travancore alone, of 46¼ lacs of rupees (nearly half a million sterling). Some thousands of tons are also exported from Cochin. That trade certainly is very profitable for India.—*India Mercury.*

CINCHONA BARK SALES IN MADRAS.

A correspondent writes:—In connection with the "Tropical Agriculturist" it probably may interest you to know that Messrs. Oakes & Co. (Madras) are instructed to hold a fifth local auction sale of Government cinchona bark. The date has not yet been decided upon, but we will not fail to advise you in due course.

For your information we have pleasure in sending, under a separate cover, a summary of the four sales of Government bark already held by Messrs. Oakes, and you will see what remarkably high prices were realized, as compared with those at the times ruling in the home markets. Referring to a remark we recently noticed in the "Tropical Agriculturist" to the effect that the Government had bought in a quantity of bark at one of these sales, we beg to say that your informant must have been misinformed, as the whole of the bark sent to Messrs. Oakes & Co., has, we learn, been disposed of and a large quantity of private bark besides.

ABSTRACT OF AUCTION SALES OF CINCHONA BARK ON ACCOUNT OF H. M.'S INDIAN GOVERNMENT FOR 1882-3.

OAKES & CO., Auctioneers.

Exchange Hall, Madras,
1st September, 1883.

A TRIP THROUGH SOME OF THE CINNAMON (AND COCONUT) DISTRICTS, CEYLON.

Having had occasion during this month to pass through some of our favourite cinnamon districts on business, I lay a few notes of my observations before your readers. First in order of merit, though not in the order of my visit, comes Goluapokuna, the premier cinnamon estate. The extent of this magnificent property is 1,100 acres, about a half of which is under coconut, not planted in the usual style amongst the cinnamon, but in separate fields alternating with cinnamon. This estate is superintended by Mr. Raoul Piachaud, the oldest and most experienced Cinnamon Planter in the island, whom I was very glad to meet after a long interval, and who is looking as buoyant and youthful as ever. As assistants he has Messrs. Nicholas and Campbell, the former a son of the Rev. Nicholas, and the latter a son of the late Mr. A. Campbell, of the P. W. D. The estate is in two divisions each division being under the supervision of an assistant, and as the working accounts and produce of each division are separate, and the cinnamon is separately shipped, a spirit of healthy rivalry is fostered between the assistants to work economically, and turn out the best samples of cinnamon. The quilling of cinnamon here has gone as near perfection as possible; the average number of quills to a pound of all the qualities reaches about 35, while minus the 4th quality the number averages about 45 to a pound. Your readers, who do not deal in cinnamon, can form some idea of the fineness of the quills, by being told that the cinnamon sold to the Fort houses averages from 15 to 20 quills to the pound! Everything may be overdone, as I believe this is, for quantity is undoubtedly sacrificed to quality. Work like that I have indicated takes a deal of time to do, so unless the estate can command an unlimited number of peelers, all the crop cannot be taken in during the season, and the peelable sticks become coarse. I suppose Mr. Smith, the rich and fortunate possessor of this splendid estate, does not mind this, as long as his cinnamon tops the market. By the way, it is right to mention that the rate of payment to peelers on this property, as on Mr. Rajapakse's too, I believe, is higher and very naturally than on the generality of estates. While other estates pay 16 cents for the quilling of the first three qualities of cinnamon, and 12 cents for the 4th quality, this estate pays 21 cents for what is termed superior cinnamon, 19 for the first three qualities, and 12 cents for the 4th quality. As the 4th quality of cinnamon on this estate is about the thickness only of what is known as 1st in the Fort houses, I conclude that the coarser sticks are scraped, and the out-turn of chips is very high.

The coconut topes belonging to this estate are very highly cultivated. They are ploughed at intervals, and the trees manured with bones, castor cake and cattle manure. The question that naturally arises in one's mind is, why should coconut trees be manured with castor cake when coconut poonac, a product of the tree, is available? I cannot answer the question, for I have nothing to do with the management of the estate. If, like the Horrekelly estate and the estates of Messrs. Gabriel Croos and Akbar, machinery were erected for pressing and combing fibre, heaps of available manure could be had in the resulting poonac and coir dust. And if the hundreds of acres of swamp which intersect the estate be used for Paddy cultivation, hundreds of cattle could be stall-fed under the very coconut trees, with poonac and paddy straw, so that not a particle of the valuable dung or urine would be wasted. They will be applied direct to the trees, saving the cost of application, all that is needed being ploughing to thoroughly mix the manure. The Decauville Railway, which can be easily laid down and worked, and as easily taken up on this flat estate would be very useful to transport crop, cattle-food, &c. That a go-a-head coffee planter, with new-products on the brain, has something to do with this estate, becomes evident after seeing the attempts made to grow the various kinds of Rubber, Cacao, Liberian coffee, &c. No part of this estate is suitable for the growth of any of the products I have named, as most of the estate is sandy, and the bungalow is situated on a cabook hill, through the soil of which hardly anything but the roots of large trees could penetrate. As Ceara Rubber is said to grow *anywhere*, perhaps the sandy soil, if it does not exactly suit it, will permit of its growing. The Visiting Agent of this estate evidently believed, without reservation, the wonderful growing powers attributed to Ceara Rubber when it was introduced, for I see a water-logged swamp, more fit to grow the Sago palm than Ceara Rubber, planted with this product. All I can say of the plants are that they are growing. Perhaps the Agent will triumphantly say that, after all he is not as gullible as he seems to be; but the plants are as yellow stunted and sickly-looking as plants could well be. You may remember that Mr. Borron put some cuttings of Ceara in a bare rock and heaped pieces of rock in them, to see whether they would grow if pressure were on them. Being disgusted that the cuttings did not grow, he communicated his disappointment to the *Observer*. As I have to notice the appearance of a few other estates before reaching Negombo, I had better proceed.

Kimbulapitiya, which adjoins Goluapokuna, is another fine property. The old and venerable part-proprietor of this estate, Mr. Young, lately came by his death under very painful circumstances in Kandy. With that plucky spirit which is the birthright of the Britishers, he indulged in a form of exercise which hardly became his years. Though repeatedly warned by his friends, he persisted in riding a spirited horse, till he was thrown down and died. This property is under the supervision of Mr. Carry, a son of the late superintendent, another old planter who died recently. It does not appear to be so carefully worked as its neighbour. If the superintendent took a leaf out of the book of experience of his neighbours and went in for high shade for his cinnamon, by topping off the low, overhanging branches of the large trees, it would add greatly to the appearance of the estate, and to the growth of the cinnamon under them. On looking over these old cinnamon estates, one is struck with the utter absence of roads on them, and wonders how efficient supervision is compatible with this want. This estate is said to possess a splendid field of coconut-palms, the nuts of which are said to be superior in thickness of kernel to those of even highly-cultivated Goluapokuna.

Between Kimbulapitiya and Mr. John Carl Fernando's estate, lie a few small pieces of low-lying cinnamon land belonging to natives. The carefully trimmed and impregnable (to cattle) cadju fence on Mr. Fernando's estate, arrests attention. This style of fence is as cheap and effective as one could wish to have, and withal it is pretty. Cadju nuts are planted along the line of fence about a foot apart; when about a cubit high, the plants are bent down and twisted one with another. Shoots are thrown out by these, which in turn receive the same treatment, till you get up your fence to the required height, when all that is done is to trim the fence. Through this fence no animal larger than a hare can creep. I suppose this fence grows best on sandy soil, as I have planted the nuts on soil which is not sandy, and two years' growth hardly reaches a cubit. This estate has cinnamon and coconuts growing together, a mistake on poor sandy soil, and the look of the coconut trees suggests that thorough draining has been too long delayed. Perhaps better management than a conductor's, although more expensive, would have assured better cultivation. The few other large properties passed before Negombo is reached, also suggest that sufficient importance is not attached to thorough-drainage in low-lying and swampy situations. Negombo is at last reached. The appearance of the highly ornamental street lamps is striking. They supply a great want on dark nights. The town is clean, and trade appears to be brisk.

From Negombo I must "hark back" to Heneratgoda, as the journey I undertook was from that station to Mahara inland, *via* Ekele. The first cinnamon estate met with is Galla, at one time a crack estate. It has passed through strange vicissitudes. It was at an early period in charge of that veteran cinnamon planter, Frederick Schrader. It is generally believed that Messrs. Stevenson and Lawrance made their money by this estate, having bought it at a low figure, and sold it after a few years' residence on it to Denis Aratchi, till then a conductor on an adjoining estate belonging to the Messrs. Armitage, for somewhere about £14,000. It was when managing this estate that Mr. Stevenson first tried the English market with chips. His effort met with success, and the high prices for cinnamon then ruling so stimulated this new industry, and gave it so firm a footing that growers, in spite of plain figures being placed before them, and the opinion of grocers and respectable agents in England, still cling to the trade in chips with a blind tenacity. Owing, it is said, to this estate being purchased with borrowed capital, the recent low price of cinnamon, and the prodigality of a member of the old man's family, the condition of this place has been going from bad to worse, till one sees acres and acres of once fine cinnamon quite snuffed out. What remains is quite stunted in growth, the result of long-continued neglect. Some agreement was lately entered into by which the creditor or his agent, either took over the property or advanced money for its working; but up to date no appreciable difference in the state of the estate is to be seen.

Next in order comes the estate once belonging to Arbuthnot & Co., and till lately superintended by Mr. Raoul Piachaud of Goluapokuna. When this estate was for sale seven or eight years ago, offers, it is said, were made for it reaching up to £16,000. The agents were willing to close at this figure, when Mr. Piachaud wrote valuing the place at £18,000. Offers rose till Messrs. Loos, Staples and Wijeyesekere took over the property at that figure. This was during the time of high prices—when there were instances of gambling in cinnamon lands. Before, it is said, the money was paid down, the present owners offered £21,000, and so became the purchasers of this fine property. So that the other three each received £1,000 simply for their pluck in offering £18,000 for it. This estate does not seem to be quite so energetically worked now as before, probably owing to continued low prices for cinnamon.

Still another instance of high price for cinnamon land. A choice 100 acre block of the first noticed Gallá estate was bought 5 or 6 years ago at the rate of R850 the acre. This fine compact property and the Ekele estate, which belonged to the late Mrs. Drieberg, are perhaps the most carefully-worked cinnamon estates in the Island. The Planter-Proprietor is a firm and consistent believer in high cultivation, and, notwithstanding depressed times, these properties are as clean as a well-kept garden and attract the attention of every passer-by. You may remember having taken over lately from the *Observer* a para. written by a man from the hills, who had gone to the Jaela resthouse for a change, and who in his walks passing these properties was struck with their order, as regards weeding and pruning. His experience is the experience of every passer-by. Mr. Drieberg received his first training as planter on a coffee estate of the Messrs. Rudd, under Mr. Forbes Laurie. On his mother purchasing Ekele estate from the estate of the late Mrs. Raymond, he went up to serve his apprenticeship under Mr. Piachaud. As after results shew, the training he got was useful. The cinnamon of these estates, as can be seen by the published price lists, comes third in order, Goluapokuna and Mr. Rajapakse's cinnamon being first and second; but, as I said in my last, they obtain a special-quality of cinnamon by paying special prices. While there I saw the cinnamon Mr. Drieberg was preparing for the Show, and I think he can safely challenge the world to beat the samples, seeing that the cinnamon cultivation is confined almost exclusively to our tight little Island. Although he did not get the Gold Medal at the Exhibition, he fully deserved it, and he has the satisfaction of knowing that the sympathies of the public are entirely with him. While on this subject I thing it not fair to Exhibitors that those sending exhibits should sit in judgment on what they send. Perhaps you may be aware that Mr. Drieberg was the Gold Medalist at the previous Show, and was awarded the Gold Medal at the Melbourne Exhibition together with Mr. Rajapakse.

While at Mr. Drieberg's bungalow, an old peeler with recollections of the Dutch period dropped in. He recounted his experience as a peeler under the Dutch rule. There were no regular gardens then, and cinnamon grew in the jungles. A census of the peeler population was kept, and every head of a family was ordered to deliver at the Government stores a certain quantity of cinnamon annually, the cinnamon to be cut from wherever it was growing on Government or on private lands. At the appointed time the village Headman was to accompany the peelers with their cinnamon to Colombo, when each man's cinnamon was weighed and taken over. The poor unfortunates who from idleness or any other cause, delivered a quantity less than that ordered, were publicly whipped at Galle Face, ladies being assembled at the "upstair house" to witness the whipping.

The Dutch knew the requirements of the outside market and all the cinnamon they had in store beyond requirements was burnt. (A lesson for cinnamon growers of the present day on scraping chips.) It is not to be supposed, the old man said, that this compulsory labour was done gratuitously. Each of the registered families received a bushel of rice, a measure of salt, and 7s. 6d. monthly. With a chuckle, and an attempt at a twinkle of his now sightless eyes, the old man related how they, the peelers, made capital of their calling. Enjoying as it did the monopoly in cinnamon, the Government watched all bushes wherever growing with a jealous care, and promptly and severely punished all those guilty of destroying a cinnamon bush, even those on private lands. Whenever a man felled a piece of jungle to cultivate it, a peeler would on the sly scatter a few branches of cinnamon on the land, and go to his hut and charge the goiya with willfully destroying a cinnamon bush, and as proof point out to him the branches scattered on his newly-opened land. To purchase silence, and save himself punishment, the frightened land-owner would give the man a bribe of rice, coconuts, &c. So that a peeler in those days must have been a privileged individual. This old man with commendable foresight has provided for his funeral, which cannot be very far off, considering his great age, by having a coffin built for himself. He has also given the customary *dhana* or almsgiving for the repose of his soul. So that now all he has to do is to die.

Leaving Ekele, I drove along the Colombo road to the Mahara Station. This fine road always admired for its evenness, is now in a most wretched state, and is a succession of ruts along both the wheel tracks. Travelling as I did in a hackery, it was far from comfortable. Just as one wheel got out of a rut the other entered into one, giving the hackery something of the motion of a pulper sieve. As a result, however forward I might be sitting, a few jerks brought me to the back of the hackery, and just as I was about to be pitched out, I gathered myself and moved forward, only to go through the same movements again. As this pitching-out process was going on incessantly, you may gather I was pretty well shaken before the turn to Mahara was reached. It served me one good turn. It made my liver, which was getting torpid, act; but the remedy was worse than the disorder.

Between Jaela and the Mahara turn a good few cinnamon estates are passed. First in order comes Mr. De Breard's, a fine compact little property, which will not suffer in appearance or in the working, if visited oftener: but it is said to abound in snakes. Bolawatte, a fine property, looked peculiar, as travellers along the road were able to "overlook" the property, owing to the short growth of the cinnamon. There is a wonderful change in the appearance of the place now—it seems to be growing. Kapuwatte is an estate in which cinnamon and coconuts are grown together. The unsuitability of the land to grow the products together is clearly indicated by the sickly yellow colour of the coconut branches. The local agent of the former owner of this property is said to have given it to the present proprietors at a figure lower than others offered for it. The great harm done to valuable properties in the hands of greedy lessees, is shewn in the weedy state of this place. Welisara estate too looks neglected. Mahara being reached and my notes ended, I must say good-bye.—*Cor.* "Ceylon Examiner."

COFFEE CULTURE IN JAVA AND BRAZIL.

(*As discussed in the India Mercury.*)

An observation in reference to the article "Brazilian and Java Coffee" by Mr. Ed. Lemos, appearing in the *Algemeen Handelsblad*, 19th July 1883.

The very comprehensive article will no doubt have excited the curiosity of all, who directly or indirectly are concerned in the coffee-culture in the Dutch Indies, and I believe many readers will be glad to know, what data concerning Netherlands India can be placed against those of Brazil. As far as they regard the private Coffee-culture in East Java, I am acquainted with them, and will readily state them here.

a. In Eastern Java there were on January 1st 1883 leased out 243 allotments, forming together 93,956 *bouws* or about 56,671 hectares. They are scattered over the different Residencies, as follows:—Rembang 2 allotments, Soerabaya 9, Passaroean 79, Probolingo 19, Bezoekie 16, Banjoewangie 4, Madioen 29, Kedirie 94, and are mostly destined for Coffee. To compare the area of the soil in East Java, *fit* for the Coffee-culture, and which is at the disposal of individuals or *enterprisers*, with the so much greater cyphers stated by Mr. Lemos, can in my opinion, be of as little use, as it can be for those who are concerned in the cereal products, to compare the number of hectares fit for corn-culture in Hungary or Russia with that of Netherland. The main points we have to keep in view, are: 1st, the costs of production; 2nd, the quantity of the production per tree; 3rd, the quality.

b. The length of life of the Coffee-plant is equal to that of Brazil. Concerning the productiveness, Mr. Lemos states that in Brazil more than 1 milliard of Coffee-trees produce on an average 400 millions K. G. of coffee. If we say 400 millions K. G. on 1 milliard of trees, we get per tree 0·4 K. G. In East Java they reckon to have a very bad crop, if from trees of at least 5 years old, one obtains 1·6 kattie (= 1 K. G.) per tree. A much larger produce very frequently occurs.

c. The manner of planting is very efficient. The manner of preparing is still open to much improvement.

d. The supply of labour in the Coffee districts is continually on the increase, from the voluntary impulse of the natives, and even in a greater degree than the employment of that labour. The consequence of this was, that for 1883 the general clearing-costs were cheaper than for 1882.

e. The costs of production are, in proportion to the obtainable produce, very trifling. As however, Mr. Lemos gives no cyphers on this subject, a comparison is impossible.

f. Mr. Lemos says that there is reason to suppose, that the present prices for the culture in Brazil are in general nearly remunerative. In East Java there is not only reason to suppose, that in the main the present prices are remunerative, but better still, we have the certainty that they are profitable.

All this, and especially the heads mentioned under *c.* and *f.* give therefore to those interested in the Coffee-culture in East Java an inducement to look to the future with confidence.

For the rest, the correctness of Mr. Lemos's observation that the interests of Netherland and of Brazil are in many respects identical, is too obvious, to require any further confirmation; and those interested in the Coffee-culture in Netherlands India cannot too highly commend the Centra da Lavono, for the trouble they take to promote an increase in the consumption of Coffee.

Hilversum, 21st July 1883. F. DE. RIJK.

COFFEE-CULTURE: No. II.

Partly in rectification of a less correct statement in the article of Mr. de Rijk, which we mentioned yesterday, and partly in completion, Mr. C. W. Groskamp gives in the *Handelsblad* of today, in his turn, the following particulars about the coffeeculture in East Java.

1. Mr. de Rijk says concerning the productiveness of the coffee-tree: "In East-Java it is reckoned as a very bad crop, if trees at least five years old yield 1·6 katti (= 1 kilo)." This statement is in my opinion too favourable, there are, indeed, cultivators who make on an average 1·6 kattie, and even 2 katties per tree, but in a general view, good and bad crops, and first rate or inferior enterprises must be taken promiscuously, and the average yield be assumed to be 1 katti (= 0·62 kilogr.) per tree: which even then amounts to more than the average yield in Brazil.

2. Mr. de Rijk says, speaking of enterprises in East-Java: "We have the certainty that they are more remunerative." Many would think it, no doubt, of more value, it this were proved by cyphers. I therefore deem it not irrelevant to offer a few cyphers, which, though a rough estimate, are however derived from my own experience. A coffee enterprise of 500 *Bouws* in East-Java will require the first four years, by a gradual planting of 125 Bouws per annum, for plant, etc., a capital in round numbers of 200,000 guilders.

Taking the produce of the 5th and 6th year together at 5,000 piculs, the returns of this are quite sufficient to cover all expenses and interests during those two years assuming an average production of 1 kattie per tree (as above), this gives over a planting of 500 Bouws (reckoning 100 trees per Bouw) a produce of 10 piculs per Bouw, or 5,000 piculs.

Against this the expeuses will be:—

a. Wages for gathering *f* 7,20 p. pic.	*f* 37,500
b. Preparing „ 2,00 p. pic.	„ 10,000
c. Conveyance to harbour for shipment „ 1½ p. pic.	„ 7,100
d Maintenance of Enterprise say *f* 50 p. B.	„ 25,000
e. Administration, etc. at *f* 1,500 per Month	„ 18,000
f. Lease-hold (good will *f* 5 p. B.	„ 2,500
being total in round numbers of	*f* 100,100

Thus the product will stand in 20 guilders p. picul, delivered, at the place of shipment.

By the private enterprises in East-Java the W. J. preparation is exclusively followed. With the present low prices of coffee, assuming the value of it to be 35 guilders (which is not too high, as this year in Java several crops were sold at a total average of 40 guilders per picul in the parchment, which is equal to 50 guilders p. pic. for peeled coffee), we obtain a produce of 17,500, which, after deduction of expenses at *f*100,000, leaves a profit of 75,000 guilders, making 37½ per cent of the requisite capital. It need hardly be added, that by a rising of the coffee prices the profits would be considerably greater. Hence it appears plainly that, in spite of the present low coffee prices, the prospects of this culture in Eastern-Java are encouraging.

THE COFFEE-CULTURE AGAIN: No. III.

Bitte...

"Im Caffee bin ich der Dritte."

Two gentlemen taking an interest in the Coffee-culture, Mr. F. de Rijk and Mr. C. W. Groskamp, have delighted me and perhaps many others with their views of the Coffee-culture.

My delight at the favourable prospects of these gentlemen had perhaps been converted into melancholy, had not my hard-heartedness stood in the way. Yet, indeed, my delight was not unalloyed.

When Mr. de R. a man fancies he knows what's what, when our own vanity and other "*dummer Leute*" have stuck us up, it is not pleasant to have to confess all at once, to have been found wanting.

He who grows two halms where formerly grew one;—he who can produce double the quantity of Coffee where a decent Coffee farmer—no blockhead mind!—was fain to rest content with the half, deserves the gratitude of posterity. That however does not prevent one's feeling a little injured to be taken down a peg or two so unmercifully. But knowing the callousness of editors, who have to hear so much at the office, and perhaps at home be pestered with lamentations on bad management and bad weather, I will spare you further bothering selfish complaints. That I do not, however, complain without cause, I hope to prove to you, and begin with saying that Mr. de Rijk calls the produce of a tree in East Java *bad*, or that it is called bad, when one tree yields 1·6 kattie = 1 kilogramme.

Mr. Groskamp finds this a little too bad, and would rather say 1 kattie, that is more than one-third less; and now I, as the minimum sufferer, must acknowledge that, with a *good* crop I have never been able to produce more than ½ at most, and in very exceptional cases ¾ kattie per tree. That is desperate for my vanity. Of course I have occasionally plucked from one tree 2, and even from some giant-tree, as much as 7 katties, but you would probably call it shooting with a very long bow indeed, if I should call that an average production.

According to the reports published every year, it appears that Government does not gain, on an average, more than 0·3 to 0·4 kattie of coffee per tree. Private plantations give a little more, plus minus 0·4—0·5. In Ceylon (which was sometimes held up as an example for us, but which did not exactly come up to my expectations when I visited there in 1875), the average yield is not higher than about 0·7 kattie.

Brazil certainly produces three times as much coffee as Java; Ceylon the half, or a little more.

I have here before me a calculation of expenditure and receipts of a coffee enterprise, commencing with clearing of waste ground. Not very long ago it did service at an Office that wanted to put money in such an enterprise. This estimation would take up too much place, even for a supplement for insertion in a newspaper.

So concise as the one furnished by Mr. Groskamp I never beheld, nor ever shall behold. In my time, between 1870—1880, we planters were very much pleased, if from 6 or 700 bouw of fruit-bearing trees, we gathered 5,000 piculs; and now Mr. G. comes with 125 *bouws* with a yield of 2,500 piculs, viz., 5,000 pic. in two years. This gentleman states 125 *bouws*, the *bouw* 1,000 trees; makes exactly 125,000 trees: 2,500 pic. each year, two years running from 125,000 trees, makes exactly 2 katties per tree. That clinches. And then Mr. Groskamp twits Mr. de Rijk on 1·6 kattie being one with another rather too much. Mr. Rijk too speaks of the fifth year. Expenditure, according to Mr. G. 100,000 florins, 20 florins costs of production per picul. Receipts 35 florins per picul = 175,000 florins. That clinches too. All prime quality, no doubt.

If the coffee prices go up, this profit increases. Of course! As true as a body is still alive an hour before his death. *Wie Mausendreck und Coriander läuft alles durch einander.* It is quite confounding. On 125 bouws 5,000 piculs are produced in two years, with cost of production at 20 guilders per picul. Remains per year 37,500 guilders. But if Mr. G. makes later one kattie per tree, the costs of production are only diminished with the costs for gathering, preparing and delivery. The maintenance, the administration and good-will remain the same for 2 katties, or 1 kattie per tree. On a tree's producing 1 kattie the profit falls from *f* 37,500 to about *f* 14,000. So if Mr. G. comes to an equal crop of 0·5 or 0·6 kattie per tree he is done for.

Mr. de Rijk says:—The expenses of production in proportion to the obtainable product are very trifling. Above, they are fully one-half of the produce of the coffee. With such a produce much can be afforded. It is worse when one pays only 10 or 15 guilders costs of production, and get *no* coffee or very little.

I should now say with that Representative, when there was a question of abolishing the export-duty of 2 guilders per picul, "well, they can afford it."

But I might well say with Mr. C. Bosscher: where 20 guilders are paid for working-costs, fruitful enterprises will be able to carry on a languishing existence; if younger enterprises only lately begun, they must go to ruin, no new ones will arise, and private coffee-culture in Java will soon fall back into its former insignificance (namely at the present state of prices). Mr. Joosten says in the *Gids* of June 1882 "......... and if the cypher of the present quotation have taken away all chance of profit in the planting of coffee, on an average, the planting will not cause a very great loss to the planter-pessimist."

I could indeed quote many who are of this opinion, I know that many a one wavers at the present state of coffee prices, namely, existing and beginning enterprises, even in the Oosthoek. I know not whether the above-named two gentlemen are, or are to be coffee-planters, but I am thankful for their endeavours to inspire confidence in the future. I shall be most happy to receive further statements concerning their coffee enterprises, if they have them, or should ere long obtain them. I direct the attention of Companies, officers and private waste-ground buyers, to the favourable results to be obtained in the Oosthoek, and hope that all this may tend to redress the shaken credit, and put an end to all the palaver about awful Coffee years.

Do you, Mr. Editor, who are always ready to advocate in the *Handelsblad* the abolition of export dues—do you think that it is of so much consequence for coffee? Let us not be over-anxious. Presently another Representative will come and say, "Indeed? On a coffee-enterprise of 125 bouws, in two years, a profit of 75,000 guilders is cleared, and then you prate about the necessity to abolish an export duty of 2 guilders per picul of coffee!" Allow me, in the meantime, to thank you for the space you have kindly allowed me in the service of a cause, which, as a matter of course, could not be exhaustively treated.

H. JOH. SMID.

THE COFFEE-CULTURE AGAIN: No. IV.

In the *Handlesblad* of 25th July, I gave a few comparisons between the coffee-culture at Brazil and in East-Java. These comparisons induced Mr. C. W. Groskamp and Mr. H. Joh. Smid, to publish their observations on the same subject in the same paper respectively of the 27th July and the 30th July. Though much obliged to these gentlemen for their observations, for altercations on so important a subject as the coffee-culture must lead to useful results, yet I must enter upon further discussions to prevent any eventual misapprehension.

In the first place, as regards Mr. Groskamp's observations, I became aware, in reading over my article, that there stood "a bad crop" instead of "*no* bad crop," I meant therewith to say, that it is a crop with which one may rest satisfied. Whether this was a mistake in the copying, or an erratum, I cannot now ascertain; but this is not of much consequence. Mr. G. at any rate concludes with acknowledging a profit of about $37\frac{1}{2}$ per cent per annum, and therefore will not deny my conclusion, viz., that those interested in the coffee-culture in East-Java, can look forward with confidence to the future.

In the second place, looking over the article by Mr. H. Joh. Smid, it struck me immediately that his name is unknown to me among the coffee-planters of East-Java. I am indeed aware, that Mr. H. Joh. Smid is a very meritorious person, and that he has done a great deal to improve the coffee-culture in Middle Java (or West Java?) but that notwithstanding, as I am unable to give an opinion about, say, the vintage in France, so is Mr. Smid as little able to be acquainted with the condition of the coffee-culture in East-Java.

To be able to form an idea of certain conditions in a country, it is necessary to have been there. Mr. H. Joh. Smid must excuse my saying so. It does in the least detract from his merit, and above all, he must not think that the profitable results obtained in East-Java, can make him, who has laboured in Middle Java, fall short in any way, and, as he says, sets him down a peg or two. Fortunately, I see that he, too, has sometimes gathered 2 and even 7 katties ($= 4\frac{3}{8}$ K. G.) from one tree. A pity that it seems to occur but very rarely in Middle Java.

But to return to the matter itself, I must inform Mr. H. Joh. Smid, that I am not accustomed to write anything that I cannot prove by facts, and therefore I am ready to submit to his examination, and to all who take an interest in the matter, the proofs of the facts, which are too voluminous to publish here.

To conclude, I have one observation more on Mr. Smid's statement; he says:—"Brazil certainly produces three times more coffee than Java; Ceylon the half or more than the half."

The true cyphers are: for 1881-82:—

Brazil Rio...	3,800,000	piculs.
" Santos	1.500,000	"
" Bahia	135,000	"
Java	1.224,000	"
Ceylon	478,000	"

Hilversum, 20th July 1883.

T. DE RIJK.

THE COFFEE-CULTURE IN EAST JAVA: No. V.

Mr. H. Joh. Smid gives in the *Handelsblad* of 31st July some ample animadversions on my observations concerning the private coffee-culture in East Java. Those animadversions bear the mark of Mr. Smid's being ignorant of, or very imperfectly acquainted with, the present condition of the private coffee-culture in those parts, and evidently show that he tests my data by the conditions and results obtaining in Middle Java. I, however, presume that the territories in the so-called *Oosthoek*, so eminently fertile and well-suited for coffee-culture, cannot be set on a par with Middle or West Java, and thus that it will not do to measure them by the same standard. It would also appear that Mr. Smid has read my observations but very superficially. Where I, for instance, base my calculations on an enterprize with a planting of 125 bouws per annum (thus 500 bouws in the course of 4 years), Mr. S. changes this simply into an enterprize with a total planting of 125 bouws, and then deduces his inferences. In this manner it is of course very easy to arrive at very improbable cyphers; but such arguments have in fact no value whatever. Mr. S. does not grow two halms, where there is only room for one; but where there are four, he sees but one.

Now a few observations, partly in refutation of Mr. S., partly for further elucidation of the cyphers given by me. The average produce from the 7th year was stated by me to be 1 kattie per tree, or 10 piculs per bouw, and Mr. S. seems to think this exaggerated.

It is little to the purpose what is made in Middle or West Java or in Ceylon, still less what the average produce is of the government plantations, as it is notorious that these latter cannot be set on a par with the private enterprises. We have here only to do with the *Oosthoek*, and where enterprises of p. m. 8 years standing, as: Soemboel, Boemie, Redjo, Madoe, Ardjo, Ampel Gadeng, etc., can already show crops of 14 to 20 piculs per bouw, I presume that an average produce of 10 piculs per bouw as assumed by me, is fully justified. As capital required for setting an enterprise of 500 bouws on foot, I had assumed in round numbers 200,000 guilders. This rested upon experience during the undertaking of five such enterprises, and I took about the average of these. To give a detailed estimate of the charges of such an enterprise, would, as Mr. S. rightly observes, take too much space even for a supplement to a paper, and consequently I forebore doing so. As, however, Mr. S. does not mention the figure he arrives at by his calculations, I may assume it does not differ much from mine. The cypher assumed by me of 1,000 trees per bouw is perfectly correct. In the *Oosthoek* many enterprises known to me are planted at intervals of 8×9 feet Rijnl. The bouw=500 sq. roods Rijnl or 72,000 ft. gives 1,000 trees per bouw. Apparently these intervals are very large; but considering the fertility of the soil, and considering the great and rapid growth of the trees, many planters regard such space as necessary. The produce of an enterprise of 500 bouws is assumed by me, the 5th and 6th years taken together, to be 5,000 piculs. As was observed above, Mr. S. speaks, instead of this, of 125 bouws, and bases thereupon his reasoning. My estimate was based upon the produce obtained from an enterprise in which I myself am concerned.

This enterprise, 600 bouws in extent, produced the fourth year 1,120 piculs, the fifth year 2,200 piculs, and the sixth year 4,200 piculs. So if I state as the yield of the 5th and 6th year together 5,000 piculs from 500 bouws, no one can accuse me of exaggeration.

It is difficult to state the exact average prices, which enterprises of the *Oosthoek* made of their produce, for they are mostly consigned to Holland for account of the planters, and not sold in Java. As far as I know, the coffees of the enterprises Soemboel, Molwardjo, Kandangan, Soekoredjo and Ayerdiugin, together plus minus 26,000 piculs were sold this year at Java at prices varying from 35 to 45 guilders per picul in the parchment. Say the average price is 40 guilders, adding 25 per cent to bring it to the price of peeled coffee, and the produce would be *f* 50,00 per picul. In my calculation, however, I only assumed a value of *f* 35,00 per picul, which everyone must thus allow to be a very moderate computation.

On a production of 10 piculs per bouw, the costs of production were stated by me to be *f* 20,00 per picul inclusive of the charges of administration, maintenance, and lease, and not as Mr. Smid would make it appear, only for charges of gathering, preparing and desptching. Mr. S. says further that with a crop of 1 kattie per tree (so 10 piculs per bouw) the profits fall to 14,000 guilders, and that one is "done for" with a production of 3·6 kattie.

To set this assertion, made without any corroborating cyphers, in its true light, I here add a calculation of how the matter would really stand with a produce of 0·6 kattie.

This gives 6 piculs per bouw, or for 500 bouws a total of 3,000 piculs at *f* 35	*f* 105,000
Costs for gathering, preparing, etc., per contra would amount to	*f* 33,000
Administration, maintenance and goodwill	45,000
Together	*f* 78,000

Leaving thus a balance of about *f* 26,000.

Yet this Mr. S. calls "being done for"!

I have not wished to follow the style of argument of Mr. Smid, but to give cyphers and proofs, where these were necessary, to corroborate my assertions. I fancy then to have sufficiently made out, that, whatever may be the less favorable conditions under which private coffee-culture may labour in other parts, this is not the case in the *Oosthoek*, and that those who are interested in it may confidently meet the future. C. W. GROSKAMP.
—*India Mercury*.

MASKELIYA AS A TEA DISTRICT.

At the late meeting, (see page 273) after several questions had been put to Mr. Owen and answered (after his paper had been read), the Chairman said, "Do you consider that the Maskeliya hills are suitable for remunerative tea cultivation." Mr. Owen answered :—"From what I have seen of the Darjiling district (and it is to that country that I would compare the Ceylon hills), I am decidedly of opinion that the greater part of these districts is exceedingly well suited, and that where there is depth of soil, permanency should attend proper cultivation : in some places the soil is shallow and poor, and these are not likely to prove remunerative under tea, but this remark applies to certain fields of limited extent only." This is important enough to deserve being repeated with Mr. Owen's *ipsissima verba*.

RUBBER CULTIVATION IN CEYLON.

(*From the Proceedings of the Planters' Association at Kandy.*)

Friday, 21st Sept., 1883.

Mr. GILLIAT said a great deal had been said about the possibility of producing cerea-rubber in such a form as to send it home to make it best pay. He would now venture to lay before the Association samples he had succeeded in getting during experiments he had been making lately on the Peradeniya estate by the courtesy of Mr. Huxley who was manager there. He had invented a knife, which he was not in a position to show publicly yet, but it would soon be ready and he hoped it would meet with the approval of rubber planters. By this knife there is no necessity to remove the outer bark, and the cut can be made straight down as high as the operator could reach. A cooly simply got up the tree, and, placing the knife as high up as possible, took one straight cut down the tree within 3 or 4 inches of the ground. Dr. Trimen was present at the first trial and he expressed his satisfaction with it. He had partly invented a tin to be placed underneath. Dr. Trimen is of opinion that there is little or no injury done to the cambium which, he thought, they ought to avoid. The milk flowed very freely and it was then collected by a cooly and by a certain process he took out all that crude rubber oil which was a constant source of trouble to planters. By the elimination of this crude oil the rubber, he believed, could be landed in England perfectly white. In his first experiment he succeeded in getting ⅝ of an ounce to one tray, from a tree 2½ years old.—Mr. Huxley was present and he would correct him if that was not right. The operation might be repeated in 30 days. On his return from Colombo the other day, it struck him that he would try another experiment on his trees that he had experimented on 9 days before, and the result was most satisfactory. He had 1½ ounces on the second tapping, in 9 days. The argument against it would be that the punishment to the trees would be too great to go on at that for any length of time, but he considered that if the trees were of fair age, say 3 years, and of vigorous growth, it might be possible to tap them every 30 days. But this as all in its infancy and he could not guarantee that. It was certainly satisfactory to know that the milk flowed so freely. On Wednesday last he tapped 18 trees in 53 minutes and got 10 ounces of pure rubber. He estimated that a good man and a cooly, fully up to their work, on fair ground, could tap 200 trees a day. He had brought samples for the inspection of his brother planters which he should be very happy to lay before them. (Applause.)

Mr. Gilliat then handed round samples of the rubber he had taken and answered any questions made with reference to them.

Mr. Huxley said he might say he tapped three trees and each took five minutes, and in that time he got from them 3½ ounces of rubber and also over half an ounce of refuse rubber, and one of these trees he had tapped three days before.

Mr. Gibbon :—May I ask the age of that tree?

Mr. Huxley :—It was four years old.

The Chairman (Mr. Wall) :—I think we are very much indebted to Mr. Gilliat and Mr. Huxley for the information they have afforded us. This is a subject which has been hitherto rather a perplexing one and one of which there has been no definate solution arrived at. I have myself personally given a great deal of attention to this matter and I arrived at the conclusion —very probably a premature one—that any plan that materially interferes with the bark, especially anything that cuts through any length of the bark, even though it should not cut into the cambium, is very objectionable. I have trees so treated, perhaps severely, a year ago and those trees are scarcely of any value at all owing to the difficulty of tapping the bark that has been renewed over the wounds. The experiments I have hitherto made are not of a nature to justify any conclusions. The experience of a life which has been in a considerable measure devoted to experiments of a scientific nature has taught me not to draw any conclusions until the matter has been under my notice sufficiently long to justify some conclusions. The efforts I have made have been in various directions, I have used tools of every kind, and given them all up. In the first place I have endavoured, without cutting deeply into the bark at all to take a slight shaving off. The object of that was to lay bare as many of the lacteals as possible without making any injury to the bark, and I found so far as my experiments went that I could get no more milk from the portion that was laid bare to a considerable area, than I got by a cut, and when I tried trees of the same age which had been grown in the same soil and which were in fact, contiguous to each other, I found to my surprise, that the pricking of the bark, without any other interference,—I have employed a pricker somewhat resembling a comb but much larger, and having its teeth more asunder, and by a single stroke of the pricker, which has a handle on to reach from the top of the tree to the bottom,—I found I got as much milk from these punctures as I did from the cut in the bark, or from the exposure of the lactials. That is the result of any experiments so far as I have carried them. I therefore have looked upon it as almost a settled question in my own mind that if you can get by a puncture a sufficient quantity of milk, especially if you get as much that way as by a cut, you may repeat the operation much more frequently and with much less damage to the tree. Visiting trees I had tapped the morning previous, I found them on the following morning, as far as could be seen, to be perfectly healed. The experiments with the prickers and the results of them will be laid before you as soon as they are ripe for it, to see how far this mode of extraction can be carried out. There is no doubt that with regard to the preparation of the milk we are deeply indebted to whomsoever it was who suggested the application of a little spirit, for it is marvellous how quickly and effectually it operates. Up to that time our plan was to take a cake of milk and after it had congealed sufficiently to bear a little pressure, to give a little squeeze and this squeezed out the fatty matter which impairs the value of the rubber, and this can be repeated till the rubber assumes a hard and merchantable form, but I am not prepared to say it is so white or pure as this (referring to a piece of Mr. Gilliat's rubber). The experiments our brother planters are carrying out will be most important, and, as I said before, as soon as the result of my experiments is such that I can offer it to you with confidence, I shall be very ready to do so, but in the meantime I only report progress up to date. I am sure the meeting will join me in thanking Mr. Gilliat and Mr. Huxley (cheers.)

Mr. Gilliat : There is one point I have missed, and that was to tell you that we cannot say whether any profit can be made on it until we have a quotation from London. It seems to be impossible to get one in Colombo ; of all our merchants we have not one who is an expert in rubber. I tried on Monday in Colombo but there was no one who could give me a quotation, and so it was sent home and we shall get a quotation from London. We know there is no injury done to it by this process. Of course I shall be very happy to lay it before the Association when everything is ready.

Milk Powder, mixed with powder of beef, is reported as having been used successfully by Dr. Dujardin-Beaumetz in keeping up the strength of consumptive patients. For use both articles are dissolved in ordinary milk, and the stomach is said to be very tolerant of mixture.—*Queenslander.*

Out of Season Coffee Blossoms are the subject of a letter (Sept. 26th) from the Kotagaloya division of Dimbula to the following effect :—"There is one particularity, in connexion with our unhappy coffee trees, that I have not seen commented upon, though it seems to me of great importance, and of vast influence on the crops or rather the absence of crops : I allude to the immense extent of untimely blossom. In the last six months there has been a constant succession of blossom throughout all the parts of this district that I have seen. If a quarter of this blossom had been productive, we should have had very large crops, but some of it never gets beyond the spike stage, and none of it ever produces fruit. Today there are many patches on this estate white with well-developed flowers, but, like their forerunners, I expect they will come to nothing, the trees look very well, and in former days such a show of flowers would have given promise of at least 2 cwt. an acre, but now it only excites a fear that its presence will be very injurious to the production of the blossom that should appear in its due season. A notice of this fact from you may bring about discussion." It looks as if the debilitated trees were following their instincts in favour of reproduction, by exerting all their strength in the formation of blossom with a view to fruit, which after all they have not strength to form and mature. The fact gives us a new view of the terrible effects of the fungus, aided no doubt, by the abnormal seasons. Planters who have studied the question will no doubt express their thoughts on the causes and the remedies of plenty blossom and little or no fruit.

MARKET RATES FOR OLD AND NEW PRODUCTS,

(From LEWIS & PEAT's London Price Current, August 30th, 1883.)

IMPORTED FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White	Slightly softish to good hard bright	£7 a £8 10s
Yellow	Do. drossy & dark ditto	£5 a £5 15s
CINCHONA BARK— Crown	Medium to fine Quill	2s a 3s 6d
	Spoke shavings	6d a 5s
	Branch	8d a 2s 6d
„ Red	Medium to good Quill	6d a 3s
	Spoke shavings	5d a 2s 8d
	Branch	8d a 1s 6d
„ Twig	...	½d a 3d
CARDAMOMS, Malabar	Clipped, bold, bright, fine	6s 6d a 7s 3d
	Middling, stalky & lean	3s 6d a 5s

WHAT AILS CEYLON COFFEE?

Our correspondent "Swaddy" (on page 316) does not believe that the action of *hemileia vastatrix*, deficiency of sun-heat or the ravages of grubs, are the direct causes of the evil. He does not exactly say that to excessive forest-felling is due the abnormal seasons from which we have suffered, although he leaves room for that inference. But he distinctly charges on the indiscriminate felling of forest the absence of pollen-carrying bees by which in old days the coffee blossoms were cross-fertilized. Deprived of the aid of the bees, the trees, already degenerated from the use of unsuitable seed in the formation of nurseries, took to self-fertilization with further disastrous results. The trees thus weakened became an easy prey to the fungus, the spores of which, our correspondent holds, were always present although in too small quantity to be noticed. If our correspondent means that the spores were present amongst the cultivated coffee, as well as on the wild coffees of our jungle, we must express our scepticism. All we know of the spores of *hemileia vastatrix* leads us to question the possibility of their remaining latent when they once found the way into the expanses of their special food. We can understand coffee trees being weakened as the result of a bad choice of seed, and it is just possible the bee-theory may be also correct. On this latter point we should like to have the opinions of other observers. As far as blossom to attract bees has been concerned, there was surely always more blossom on coffee estates than bees could find in the jungles, except in the years when the *nilu* flowered. But our correspondent's theory is that it was the weakness thus engendered which invited and led to the attacks of *hemileia vastatrix*, and, when the trees had been further weakened by the operations of the leaf-fungus, their roots suffered in sympathy, and the grubs (thoughtful and benevolent organisms) came into the field to restore the equilibrium of foliage and roots by eating up those portions of the latter which had commenced to decay. Facts seem to us to be against the assumptions of "Swaddy." In 1869, when the fungus was first observed on the coffee estates of Ceylon, there was a large proportion of naturally vigorous coffee in existence, which received the support of liberal applications of manures: indeed, it is to the manures, especially castor cake, that the editor of the *Indian Agriculturist* attributes the appearance of *hemileia* and its ravages! When the fungus once commenced to attack the cultivated coffee, it dealt impartially with the youngest and most vigorous trees and the oldest and most "shuck." All were alike the objects of attack, although naturally the young and vigorous trees suffered less at first from the loss of repeated crops of foliage and were longest in shewing the full effect of the weakening process. If our correspondent says that the substitution of unbroken expanses of coffee for unbroken expanses of forest rendered the coffee specially liable to attacks of fungal and insect enemies, we are with him; and he and others, if they choose to trace abnormal and ungenial seasons of sun-hiding clouds and blossom-and-fruit-destroying rain-storms, to the same causes, instead of to great cosmic and cyclical influences which will by-and-bye bring "a change," they are at liberty to do so. We need only mention that while such a careful observer as Mr. Giles Walker traces much of the ailment of our coffee trees to deficient warmth, Mr. Vincent, the Forester, apparently determined in the face of all evidence to support a foregone conclusion and a so-called scientific theory, insisted that in consequence of extensive forest-clearing, the temperature of the Ceylon coffee region has been raised! *We* believe in cycles of wet and dry weather; cold and hot; and, while the everlasting hills stand up against the sky, we cannot attach much importance to all the forest that has been felled in the mountain region of Ceylon. We *know* that the absolute rainfall has not been lessened. But for the fact that *hemileia vastatrix* appeared almost simultaneously over the greater portion of the Eastern world, we should be strongly inclined to suspect that the immediate cause of the outbreak of the fungus in Ceylon was the destruction, in clearing and planting operations, of so large a portion of indigenous trees of the coffee tribe. We leave that point for consideration. What is certain is that in May 1869, now over fourteen years ago, the fungus found out where its food lay in abundance, that it commenced its ravages and that the effect has been disastrous beyond that of all other causes put together. We have heard the theory propounded that fungus came on the leaves, because grub had already done harm to the roots. The answer is that *hemileia vastatrix* has been virulent where grub has been unknown. But in some districts—in many, we fear—grub is a terrible evil, and we only wish we could accord with this writer's idea that the insects attack exclusively withered or dead roots. If anything, they unfortunately prefer fresh, vigorous rootlets as their food. Black or brown bug has recently re appeared in some force to add to the troubles of the sorely tried planters. But our belief remains unshaken that the fungus did not come merely because our coffee trees were weak, but that their ever-increasing weakness is owing to its advent. In some mysterious way the fungus —which is not so much a disease as the cause of disease—discovered great expanses of its favourite food, and from that day to this it has fed on the life-blood of the coffee trees, until some of them are depleted almost to death, while all are more or less sick. If we could only get rid of *hemileia vastatrix*, we could deal with grub and bug and endure and recover from the effects of abnormal seasons. As to breeding in-and-in and self-fertilization tending to invite attacks of the fungus, let us look at the case of Liberian coffee. We got seed of this specially robust species of coffee direct from Liberia, and yet it has been as badly attacked with the fungus as the Arabian coffee which has been propagating itself here for many generations. No: we do not think the mystery of the advance in force of *hemileia vastatrix* has been solved by adducing the growth of coffee from in-and-in-bred seed or self-fertilization from the absence or paucity of bees, or by any other theory than that which indicates that *somehow* in 1869 it discovered our coffee fields, took possession and has refused to be ousted. As it came like a shadow, we only wish it would so depart. Then we should confidently hope for a real revival of old king coffee. We have a right to suggest the possibility that the visitation has been providential and designed, apart from its primitive aspect, to compel the cultivation of a variety of products instead of one. Indeed, we have a strong belief in that direction. Nevertheless, the immediate effects are very grievous, and our duty is none the less to combat with, and, possible, to overcome and banish the scourge, so that, at least, what is left of our coffee may be healty and fruitful.

MR. HOWARD ON CINCHONA LEDGERIANA, DR. TRIMEN AND BOTANICAL ETIQUETTE.

In the paper contributed to the *Pharmaceutical Journal*, and which we reprint on page 303 *et seq.* Mr. Howard has, as in all he has written about the cinchonas, embodied a large fund of interesting and useful information. It is, in truth, acknowledged universally that to no man now living is the world more indebted for reliable information on the fever barks than to Mr. John Eliot Howard. It is, therefore, the more to be regretted by those who like ourselves revere Mr. Howard, for the goodness of his personal character, as well as for his knowledge in a department of science which he has made specially his own, that he should have permitted feelings of annoyance at an imagined slight to get the better of his better nature so far as to lead him to bring against two of the first botanists of this or of any age, Hooker and Trimen, the charge of describing as *Cinchona Ledgeriana* what was really a grey bark—what Mr. Howard calls "*micrantha calisayoides.*" Mr. Howard now admits he *may* have been mistaken, and we suspect there will be no difference of opinion, even amongst his best friends, that he was grievously mistaken. Dr. Trimen may, equally with Mr. Moens, have committed an error in separating the *Ledgeriana* plant from other *calisayas* and erecting it into a new species. If the supereminent qualities and botanical peculiarities of the plant did not entitle it to this distinction, then, doubtless, Dr. Trimen was guilty of a breach of botanical etiquette, in superseding the name which had previously been applied to it, "CALISAYA *var.* LEDGERIANA, HOWARD." But apart from other peculiarities, Mr. Howard's own bark-test seemed to entitle the plant to a separate position. While none of the ordinary yellow barks give more than from 3 to 6 per cent of quinine, more than double the highest figure has been obtained from the trees distinguished by the name of the adventurous bark-collector, who performed for the world the great service of sending the seeds of this, the best, as yet, of the cinchonas from the western world to be cultivated in the eastern. But, equally with Hooker, Trimen is utterly incapable of confounding the very highest form of cinchona with the very poorest, mistaking the king of the yellow barks for a miserable *micrantha*. Mr. Howard claims for Mr. Ledger the sole right to decide what is and what is not *Ledgeriana*. We scarcely think that Mr. Ledger would claim for himself such unerring discrimination, because some of the very best trees grown from Ledger's seed in Java and in Ceylon, have no trace of the red leaves to which Mr. Ledger attaches so much importance. But granted Mr. Ledger's judgment as infallible, then his verdict in favour of the plants grown from Yarrow seed by Mr. Howard, is decisive in support of Dr. Trimen's typical Ledger, for it was grown from a portion of the same seed which gave Yarrow its fever plants. On the question whether Dr. Trimen was right in erecting Ledgeriana into a distinct species, describing and figuring it as such and so depriving Mr. Howard of the credit, which he evidently highly prizes, of having his name for ever associated with it as a variety of Calisaya, "Calisaya —*var.* Ledgeriana, Howard"- we are scarcely competent to decide. But we believe,—indeed it is certain that Mr. Moens, who has had far more and better oportunities of observing the Ledgerianas in every stage of their existence, even than Mr. Ledger himself, agrees with the separation. What we contend for, in the interests of the simple truth, is that Dr. Trimen figured and described an undoubted and typical Ledgeriana, and that Mr. Howard was as untrue to himself as to botanical science in asserting that such men as Hooker and Trimen were capable of mistaking a bastard grey-bark for the very prince of the yellow barks. As far as classification by appearance and quality of bark is concerned—a most important matter commercially and therapeutically, and to some extent scientifically (for the settlers in Australia with the sanction of botanists such as von Mueller, distinguish the Eucalypti as stringy bark, iron bark, &c.)—Mr. Howard's judgment must ever be received with the utmost respect. But clearly, he must himself admit that he is not infallible in purely botanical classification by the characteristics of flowers, fruits and leaves. For he is now compelled to alter his verdict of the hybrid origin of *Calisaya Anglica*, which, with its grand red leaves, was hailed by Mr. Ledger's Indian servant as "*Tata! tata! tata!*": one of the "fathers" of the very best cinchonas. Hybrid or not, we suspect, *Calisaya Anglica* is well worthy of being fully tried by planters, and in view of our experience and observation in India and Ceylon, we must take leave to hope more from hybrids, even the result of crosses between succirubra and ledgeriana, than Mr. Howard would allow us. The question is one to be settled by experience of which we have had so much already as to be able to decide, that hybrids between *succirubra* and *officinalis* are likely to be more valuable, from robustness of habit and yield of alkaloids, than either parent. It seems probable that still better results will be obtained from the intermixture of ledgeriana with the succirubras, and, perhaps, with the crown barks. Nor is it impossible that a hybrid between ledgeriana and micrantha, might turn out well. In any case, Dr. Trimen figured and described a true ledgeriana, of which we have many in Ceylon, the barks of which yield to analysis, from 6 to 14 per cent of pure quinine. Those giving the higher results are, no doubt, the *macho* or male, and extra robust forms of the tree, to which the Andean Indians attach so much importance. It must be a grand sight to see one of the glorious *rojo* trees, about which Mr Ledger is so enthusiastic, towering in its native forests to a height of 150 feet! The age of such trees must in some cases extend back to close on the era of the Spanish conquest! If only a man like Mr. Owen, with all his experience of the cinchona plants as cultivated in the eastern world, could visit the original habitats of the plants on the Andes, he might discover a cinchona even better than the Ledger. In any case he would decide on the correctness or otherwise of the statement, which seems to us incredible, that the habitats of the succirubras and the calisayas are more than 1,000 miles apart. One inference we draw from what Mr Howard says about the researches of Weddell. We cannot doubt that this eminent man discovered the trees we now call ledgeriana and sent home specimens of their bark. But he was not fortunate enough to meet with, or at any rate, to gather, the seed. That was left to the adventurous bark-collector, Ledger, through the agency of a native assistant, who ultimately fell a victim to the vindictive feelings of his countrymen. But Weddell, the great explorer and describer of the yellow barks, lived long enough to describe "*Cinchona calisaya* var. *ledgeriana* [Weddell *pro parte* How.]," and in this description we cannot see any reference to the bark? Whenever the history of the cinchonas is written and by whomsoever, to Mr. Howard, in association with Weddell must be assigned the credit of first describing scientifically the characteristics of Calisaya Ledgeriana. The mere erection of the plant from a variety to a distinct species, cannot possibly deprive Mr. Howard of that glory any more than of that which his vast erudition and most careful, extensive and fruitful researches entitle him to. But we suspect the leading authorities in the botanical world will endorse Dr. Trimen's action in recognizing the extraordinarily rich yellow bark as a distinct species. There is, not only the very thick, rich bark, on which Mr. Howard himself dwells, but other distinctions which seem specific: such as the leaves always having the broadest part, at or about the middle, flowers small, drooping or divaricate, flower buds not at all, or very slightly widened at the end and never abruptly enlarged there, the corolla somewhat inflated in the middle. The bronzed or olive-orange tint of the unexpanded leaves, bud and young shoots, was also indicated by Mr. Trimen as characteristic of Ledgeriana. As to seed coming true to type, Ledgeriana is no more free from a sporting tendency than are the calisayas to which it is allied. If Mr. Howard is right, however, Dr. Trimen's plates and descriptions must now be considered as "entirely superseded by Mr. Moens' own description and definition of the *Cinchona Ledgeriana* Moens in "De Kina Cultur in Azie." But, if we mistake not Mr. Moens, as distinctly as Dr. Trimen, has claimed for Ledgeriana the position of a distinct species, instead of a mere variety of the yellow bark. We have received Mr Moens' book while we are writing and we see that quite as much as Dr. Trimen he separates "Cinchona Ledgeriana, Moens," from "Cinchona Calisaya, Wedd," and all the other calisayas. It is quite true, as Mr. Howard has pointed out, that he shews, besides the highest form, two others, A and B, but he shews them as varieties of Ledgeriana, not of calisaya. It will be seen that *calisaya* is derived from *colli, red* the colour of the bark (which is more red than yellow) but especially of the leaves of this species. If Mr. Ledger saw pink and white blossoms on the same tree, it seems clear that the mere *colour* of the blossom cannot be decisive as to the quality of Ledgerianas. As a matter of fact, one of Mr. Moens' best trees has pink blossoms. According to Mr Ledger, however, the bright scarlet colour of the leaves is of as much importance as the specially dark green of the surface. We cannot quite understand whether Mr. Ledger meant to indicate that the leaves are bright scarlet on the under surface while dark green above, in their normal state, or merely, (what seems more probable) that the usually dark green leaves assume a bright scarlet colour, when the trees are in blossom or when from age, drought or other cause the leaves begin to wither. We may say that the leaves of *all* calisayas in Ceylon, assume a brilliant scarlet colour in withering. So that we should rather trust to peculiarities of blossom and fruit which are very marked: the blossom always looking to the ground and the fruit vessels being very minute. In looking at the plates, (phototyped from nature,) in Mr. Moens book, the shortness in proportion to breadth of the seed vessels of the best forms of Ledgeriana (Mr. Moens' Nos. 22 and 24,) is most conspicuous. Mr. Howard says he has not yet in bark from British India, met with a specimen of the true *rojo*, but we know it to be a fact that the first bark sent from the Nilgiri plantations, which although from trees or rather bushes, grown from Ledger's seed, Mr. Howard could not recognize as Ledgeriana, sold for 12s 8d per lb. It was seed from such bushes which gave us in Ceylon the undoubted Ledgerianas of Yarrow, St. Andrews, Mattakellie and other places in the island. Mr. Ledger did not recognize Mr. Howard's *micrantha calisayoides*, at which we are not surprised, for we have never seen it mentioned until in this controversy Mr. Howard represented it as specially familiar to Hooker and Trimen. Can the latter tell us what the plant is, if it really exists in Ceylon.

Since writing the above, we have seen in the *Planters' Gazette* extracts from an article by Dr. Paul, the Editor of the *Pharmaceutical Gazette*, which while acknowledging, in view of letters from Mr. T. N. Christie, that Dr. Trimen's plant is recognized as *C. Ledgeriana* in Ceylon, he states that the specimens sent by Dr. Trimen to the Museum of the Pharmaceutical Society "are considered by some not to be typical ledgeriana, but more probably hybrids of officinalis and calisaya." What does Mr. Howard say to such hybrids, being so much better than both parents as to give up to 14 per cent of quinine? The planters, in any case, would look more at the results than at nice botanical distinctions. And surely Dr. Paul is too critical in doubting the claim of one of Mr. Christie's plants to the title of C. Ledgeriana, because, while giving 8·32 per cent of quinine, it also gave 1·12 of cinchonidine. Our own opinion is that the plant described by Dr. Trimen, is identical with C. Ledgeriana, Moens, and that whatever resemblance it may have in foliage to *C. micrantha*, it is, in quality of bark and quantity of pure quinine, as superior to any of the grey barks as gold is to lead. If those who doubted Dr. Trimen', specimens judged rightly, then it follows that hybridization between *calisaya* and *officinalis* in Ceylon has given the colony and the world a bark equal to that of the best yellow bark known! The idea must comfort Mr. Kuntze, who classed all the Indian cinchonas as hybrids. But we do not believe in the hybrid theory of the origin of the Ceylon ledgeriana. It is the real "Simon Pure."

BRIEF NOTE ON CALISAYA LEDGERIANA.

(*To the Editor of the "Pharmaceutical Journal," Sept. 1st.*)

SIR,—I think it will tend to the enlightenment of your readers if I state at once what is my contention in the Calisaya controversy to which you have directed their attention. It is simply this, that Mr. C. Ledger's "*Ledgeriana*" is a legitimate Calisaya, and not a new species. Of much less importance are the observations I have made as to Dr. Trimen's plates and description of the plant figured in the *Journal of Botany*. These are entirely superseded by Mr. Moens' own description and definition of the *Cinchona Ledgeriana*, Moens' in a very valuable work 'De Kina Cultuur in Azie,' which, through the courtesy of this gentleman, I have just received; and to which, in the conclusion, I shall again refer.

I have always understood that by an unwritten law of botanical science the privilege of naming a plant belongs to the botanist who first observes and properly describes it; always supposing that he has regard to what has previously been known about the subject. This rule, which common sense appears to sanction, is in danger of being disregarded in India.

The name and history of Calisaya bark has engaged much of my attention in the last few weeks; as I have availed myself of a visit of Mr. C. Ledger to this country (on his way to Australia) to re-investigate the whole question, which it was my pleasure to study many years ago with my lamented friend Dr. Weddell.

The 'Histoire' (*a*) of this distinguished naturalist is a treasury of really scientific investigation. It is not, however, by any means exhaustive; as in his first voyage he did not observe the best kind of his *C. Calisaya*. In his second journey (*b*) to the gold districts of Bolivia, he obtained specimens from the Yungas and from Larecaja of the bark of the finer sorts which are now in question. In his subsequent notes, 'Sur les Quinquinas', he further describes these. (*c*)

Dr. Weddell did not invent the term Calisaya, but adopted it as the term 'generally in use'. He says that

(*a*) Paris, 1849.
(*b*) 1853.
(*c*) 1869.

it was indiscriminately called Colisaya, Calisaya and Cuilsaya. Further (*d*) :—" It is to this species that we owe the most precious of all the barks employed in the healing art, (*e*) that which has always been known in commerce as the Quinquine-Calisaya, and of which the origin had remained completely unknown in a botanical sense."

I have in fact a fine specimen (*f*) (which I bought with the rest of Pavon's barks) called *Quina de calisaya* (ascribed by that botanist to *C. lanceolata*, a very different bark). It is of Weddell's *a. vera* quality.

Dr. Weddell proceeds thus :—

" In spite of the different explanations which authors have given, the etymology of the word " Calisaya " is still very obscure. M. Humboldt thought it came from the name of the province from whence it was first derived; but well-informed persons have assured me that such a province never existed! In the department of La Paz, where it is found abundantly, it still most frequently bears the name of Colisaya or Calisaya ; and I am disposed to think that these designations have been applied to it on account of the red colour which the external face of the bark presents when drying, or probably (*bien*) of that which its leaves have sometimes. *Colli* means really *red* in the Quichua language, and *saya*, taken in a figurative sense means sort or form. The red maize is called *colli*, gara, or *culli* abbreviated.

Weddell lived some time amongst the Indians and studied their language,(*g*) which seems to have some elements of affinity to the Sanscrit. After consulting Tschudi's dictionary, I have no doubt that Dr. W. is right, and that it means " the red sort." Mr. Ledger says the word means " red " in Aymara as well as in Quichua.

Now it is exactly this red sort, called in Spanish, *rojo*, of which Mr. Ledger has always been in search, hearing of its superior qualities from the Indians. Mr. Ledger tells me that Dr. Weddell sought for the white flowers, which are distinctive,(*h*) but without success. Mr. L. endeavoured to assist Dr. W., but it is easy to understand, in conversation with him, the difficulties which beset the path of inquiry. Mr. L.'s explanation of the term *rojo* is, that the leaves turn this colour whilst the tree is flowering, changing to a dark purple before they fall.

The trees under these circumstances present a magnificent appearance, visited by multitudes of humming birds and bees, and the older ones adorned with the beautiful cryptogam, *Hypochnus rubrocinctus*(*i*) (Ehrenb.) The presence of this used to be considered in trade as indicative of the best kind of Calisaya. Specimens so found in my possession date from 1853.

This description especially applies to the finest and most luxuriant trees, which probably raise their heads above the surrounding forests, and present their white flowers, fraught with pollen of superior power for cross fertilizations, to the access of the useful visitors above named; also perhaps to more frequent damage by frost.

The Indians call them " tata " (father) trees, and believe they are so important to the rest that where they are found all the bark around will be Coli-saya ; and they cross themselves when they meet with them. They think that without them all would perish.

Dr. Weddell says of his first sort " *C. vera.*" " The variety which I have been describing is the most frequent. It bears in Bolivia the name of *Calisaya amarilla*, *C. dorada* or *C. anaranjada.*"

That is to say the *Cinchona Calisaya vera* described and figured as such by Sir Joseph Hooker, *Curtis's Bot Mag.*,

(*d*) ' Histoire,' pp. 30, 31.

(*e*) ' La therapeutique.'

(*f*) Dating probably from last century.

(*g*) ' Voyage dans le Nord de Bolivia,' p. 555, Weddell, 1853.

(*h*) It seems impossible to overcome the jealousy of the Indians about these trees and it is easy to understand that it is a work of difficulty to get even sight of the flowers, unless when the tree is cut down. Mr. Ledger assures me that he has seen pinkish flowers on one tree, of which the flowers were white towards the summit. Dr. Weddell related to me that on one occasion he had to fell three trees in order to bring to the ground one (of I know not of what sort) whose flowers he wished to observe.

(*i*) Figured by Fee 'Sur less Cryptogrames,' Tab, v.; also by Goebel, *Pharm Waarenkunde*, Taf. xv.

from a tree at that time (1879) flowering in my possession. This tree, which is still so flourishing that I have difficulty in keeping it within the narrow compass of my stoves, represents probably very fairly this sort then very abundant, now practically extinct, but in one district extensively replanted, owing to advice given by Mr. Ledger some twenty years ago.(*j*) Mr. Ledger does not recognize my tree, owing to its large leaves, but approves some of my young plants of *Ledgeriana* from the Yarrow Estate, Ceylon and also in part those from Mr. Thomas Christy's seed from South America. All these belong to the next division of Weddell and the bronzed appearances of the young tips which summer has brought on my young plants, and which is much rested on in Ceylon, may be looked upon as a ready mode of discrimination of the second sort from the *a. vera*. The rich velvety appearance and ciliated margin of the young leaves are also useful to this end.

I proceed with Dr. Weddell's description of this second variety :

" Another sort of bark remarkable for the dark shade of its external face, which is often wholly of a vinous black, bears the names of *Calisaya zamba*, *C. negra* or *C. macho*. I have remarked it particularly at Apolobamba in Bolivia, and in the province of Carabay in Peru."

He did not then describe this further, but I have from him an excellent specimen of the flat bark, marked *Calisaya zamba*, gathered at that time, and I learned from the same source how to distinguish this superior quality.

In 1869 he describes it more fully(*k*) (see the original) and adds :—" I brought this variety of Calisaya in 1851 from the mountains which rise above the river of Coroico, an affluent of the Mapiri, one of the most important in the department of La Paz. The cascarilleros of the country have pointed it out to me as giving a bark superior in quality to that of other varieties growing in the same places, and I confess that I have been happy to see this appreciation of the native (l'homme des bois) confirmed by Mr. Howard. It is, in effect, from a bark recognized by him as identical with that which I have described that my eminent friend has obtained the largest proportion of quinine which has yet been found in a Quinquina, that is to say about double the quantity which M. M. Delondre and Bouchardt indicate as the average yield of the Calisaya. The shade, more or less purple, of the under part of the leaves gives to this variety a character of resemblance to the *C. Boliviana*.(*l*) I have not seen its young leaves, but it appears to me that they must have much analogy with those of the variety which I have just named. Perhaps we may also consider as giving a representation of it the figure 2 of the plate which accompanies the article published by Mr. Howard on the barks brought from Bolivia by the merchant Don Pedro Rada" (*Journal of Botany*, January, 1869). This plate was coloured in accordance with some plants derived from Mr. Ledger's seed, then in my possession.

Now all this description of the *Zamba* and of Rada's *Negrilla* agrees entirely with Mr. Ledger's *rojo*. He at once recognizes Weddell's specimens and mine as such, nothwithstanding the vast distances between the different habits.

Mr. Ledger wrote me, (*m*) " The seed sent by me in 1865, ' Calisaya red bark,' is not (as you say) the *morada* of the Spaniards ; it was the *rojo*."

When I examined this bag of seeds I pointed out that it belonged to *var. microcarpa* of Weddell, and was consequently of good quality. It was not, however all *rojo*. This is proved by the germination of the seeds in Java, for out of some six or eight varieties obtained, only one is acknowledged by Mr. Ledger as his true *rojo*. This is figured in plate IV. of my ' Quinology.'

It is comparatively scarce. In the same letter he writes, " I always understood the red bark, Calisaya, to be the

(*j*) I have specimens of the bark from 1849 downwards. That which is now imposed upon the public as flat Calisaya bark, judging from a specimen given me by Mr. Lescher (who has exposed this fraud) is *Cochabamba* bark, according to Ledger, or *C. Australis*.

(*k*) *Annales des Sciences Nat.*, T. xi., 347, xii., 54.

(*l*) This is very remarkable in the *morada* and the *Rubra venada* of Mr. Christy.

(*m*) December 22, 1874.

best of all in its yield of quinine. For one tree of the *rojo* you will find fifty of the Calisaya. The leaves of the *rojo* are of a bright scarlet colour, and of darker green on surface than those of other good descriptions."

This richer green colouring of the leaves, changing very naturally to red bright in decay, is much rested on by Mr. Ledger, and I have no doubt finds its explanation in the term *macho*, which Dr. Weddell applies to this sort, *Calisaya zamba C. negra* or *C. macha*. (*n*) The two first imply the very dark colour of the upper side of the slabs of bark, which are now rarely, if ever, seen, and these terms are probably forgotten and quite unknown to Mr. Ledger, though not to Rada, who called his fine slabs, the like of which have never been seen since, *negrilla*. I am sorry to hear that Mr. Rada has suffered so much in health, partly from wounds received from the wild Indians on his voyage down the rivers, that he is not likely to undertake another such expedition. The trees from which these were taken were from 120 to 150 feet in height.

I now come to the term *macho*, (*o*) which Dr. Weddell explains thus :—"The flowers of the Cinchona present in the relative greatness of their sexual organs variations very interesting to study—not only on account of the frequency with which they present themselves in many species, but by the curious circumstances which (parfois) accompany them. If the stigmata are protruded the anthers are almost sessile in the middle of the tube of the corolla; if, on the contrary, the anthers raised on their filaments appear at the mouth of this tube, the style then is found reduced and the stigmata occupy the place before held by the anthers. In a word the development of the style and that of the stamens are constantly in the inverse proportion the one to the other; and not only that of the male organs is always accompanied by the simultaneous development of the floral envelopes, but, a fact very worthy of remark, other parts of the plant appear to feel this predominance of the strong sex. The leaves, for example, may be more richly coloured, the mark more robust. Now, the cascarilleros, who very certainly never occupy themselves with the details of the flowers, have, nevertheless, remarked in the aspect, in the produce even, of these (*p*) bark trees such differences, that they have had the idea of distinguishing them by the epithets, male and female (*macho y hembra*), and since my attention has been awakened to this subject, I have been not a little surprised to find a coincidence between this epithet of *macho*, so naively applied by the natives (les hommes des bois), and the predominance of the male system of which I speak.

I think I now see the reason why Dr. Weddell did not proceed in the description of this variety. He found it, indeed, "un peu embarassante," to make a distinct variety, still more a species out of the *macho*. To distinguish thus, the bull amongst the herd might appear pedantic!

Weddell's 'Histoire' was published in 1849. When afterwards, in 1869, he saw his way clear to define his *C. calisaya microcarpa*, he gives a description intended (?) to be include (*q*) all the forms of small fruited Calisaya, at all events the zamba and zambita (he drops the term macha). The pubescency under of the surface of the leaf seems more marked in Weddell's plate than elsewhere and he does not give (as not having seen) the flowers, but it seems to me that not only Mr. Ledger's *rojo*, but all that might imperfectly be called Colli-saya, the *verde* of Mr. Christy, (*r*) the *C. Boliviana* and other forms may all be called Weddell's "second sort." I do not know the form which he defines "*subtus pubescentibus*;" this, strictly speaking, excludes all the other forms.

My publication of *C. Calisaya*, var. *Ledgeriana*, is too inclusive, as taking in all the varieties recognized as such by Mr. Moens. I am sure that this gentleman, to whom we are all so much indebted for his able analyses, and I myself specially for his most carefully prepared herbarium, will see that it belongs to Mr. Ledger, and to him alone, to define what is the true *Ledgeriana*. It is then my form A, the *macho*, exclusive of form B and form C and other forms now existing in Java and in Ceylon from whence specimens (received from T. N. Christie, Ceylon), are now in the Museum.(*s*) They are (?) *microcarpa*, but not *Ledgeriana*.

The bark of the true *Ledgeriana* is that which was sent me by M. Van Gorkom; typically resembling Weddell's *zambita*, from the province of Yungas, now before me. Of this extraordinarily rich bark a certain portion has come in trade, but probably a larger portion, from very inferior trees (still called *Ledgeriana*). The recent specimens from the Amsterdam Exhibition, now in the Pharmaceutical Society's Museum are miserable; but I have taken care to forward a true specimen. It will be seen at once how much these differ. I have not met with any yet, from British India, of the true *rojo*.

I also ask the Pharmaceutical Society's acceptance of original specimens from the herbarium of Mr. Moens, of the form A, from which my plate of the true Ledgeriana was drawn;—and also of other forms.

Mr. Ledger does not recognize my *Mycrantha calisayoides* nor Dr. Trimen's *C. Ledgeriana*, Moens. As we have no description of the bark of the latter, nor any analysis as far as I can learn of the bark of the tree itself, I may be mistaken in associating the two; for the rapid degeneracy of sorts when, in cultivation, the beautiful natural arrangements are interfered with, begins to open a new chapter in the history of the culture; which it would scarcely be pleasant, though perhaps necessary, to write; and hybridism leads to endless confusion. The pollen of the Bolivian *micrantha* may have affected some of these sorts.

I do not agree with Dr. Otto Kuntze in regarding hybridism as the source of improvement (quite the contrary), but he has perhaps done good service in pointing attention to the subject of cross-fertilization.

I look upon the *Ledgeriana*, not as a species, but as one form of Dr. Weddell's second division of the species, and as being the Calisaya *par excellence*, the true red sort.

I have been surprized with the high appreciation by Mr. Ledger (and as he tells me by his Indian servant) of my plate of *Calisaya anglica*. The leaves and flowers are both too large for *Ledgeriana*, but the colouring, to which I attended myself, as taken from a tree flowering with me, represents exactly (it seems) the rich appearance of the leaves.

Mr. Ledger's Indian exclaimed with admiration, and delight on seeing my plate that it was *Tata, tata, tata*. I have looked back to my description of its parentage ('Quinology, p. 87) and to Mr. Broughton's letters of 1872 and find that "the seed was gathered from two trees of the same red under-leaved variety of Calisaya,' and this again from Ledger's seed. The idea of its being a hybrid must be abandoned if no interference of pollen had taken place in India. The distance between the nearest districts in which the Succirubra and Calisaya are found is, in a direct line over 1,100 miles. No possibility of the interference of the pollen of these two can arise in their native habitats.

I find that I cannot conclude this notice without more reference to technical botanical description than I intended to introduce into these pages.

I present then the diagnosis of Dr. Weddell, as definitive of the true *rojo* bark of Mr. C. Ledger.

Cinchona calisaya var. *Ledgeriana* [Weddell, *pro parte* How.]. (*t*) "C. foliis elliptico-oblongis vel fere oblongis, obtusis obtusissimisve, haud raro ante apicem nonihil angustatis s. constrictis membranaceis, utrinque viridibus vel subtus pallide purpurascentibus nervis simul rubris, axillis sat distincte scrobulatis, panicula florifera ovata, corollis albis, *antheris subexertis* (saltem in specim. obviis); panicula florifera subcorymbosa, densa, capsulis ellipticis (9-12 millim. longis) puberulis."

This it will be seen by comparison is not the *A. micro-*

(*n*) 'Histoire,' p. 35.

(*o*) 'Histoire,' p. 21.

(*p*) Mr. Ledger says "they judge of the good *rojo* slabs by their relative greater weight. The relative weight and thickness of bark alike characteristic of true *Ledgeriana*. I well remember purchasing and packing, in 1852, more than 120 tons of *Calisaya vera* bark. Out of all that quantity I was only able to pick out 2 tons of *rojo* or *morada* slabs. You also can verify my statement by your own practical knowledge."

(*q*) *Annales des Sciences Nat.*, vol. xi., p. 5.

(*r*) A distinct and very valuable form, Weddell's *C. Calisaya oblongifolia* (see *Sciences Nat.*, [5], t. xii., p. 5).

(*s*) See *Pharm. Journ.*, August 11, 1883.

(*t*) 'Quinology, E. I. Plantations,' p. 85.

carpa, of Weddell.(*u*) It is my form A, (Plate IV.), exclusive of B and C. It is only in part the *C. Ledgeriana Moens*, since it is exclusively the *macho* form. Indeed, in other respects it does not apply to some forms which both Mr. Moens and I had considered "*Ledgeriana*." I am much pleased to see that Mr. Moens includes, amongst these, two varieties, *a Cinchonidinifera* and *b Chinidinifera*. This is an excellent step in the right direction, and worthy of Mr. Moens' fame as a chemist, thus to distinguish these forms. If I understand right, my *Calisaya Anglica* stands under the first of these. It is *Cinchonidinifera*, and my Plate IX. *Quinidinifere*. Indeed I am ready to believe that it is very nearly, that he at once fixes upon it as right in the general colouring and aspect; but then it is very decidedly *Hembra* and so cannot come under Weddell's diagnosis. May it not (*pace* the botanists) be as nearly related as male and female of any race of animals? (*v*)

Much yet remains to be put before those interested in the subject in connection with the highly important work of Mr. Moens, which I hope you will review for the benefit of your readers.(*w*)

JOHN ELIOT HOWARD.

(*u*) Mr. Moens objects rightly to the defective colouring of my plate Plate IV., which is the fault of my artist. Plate X. I took from nature.

(*v*) "Hybrids (?) between *Succirubra* and Ledger, found amongst Ledger seedlings, have been found to contain 10 to 12 per cent. of sulphate of quinine, so that while possessing the robustness of the one they have been blessed with the richness of the other."—"A Java Proprietor" *Ceylon Observer*, July 27th, 1883. I thought the Ledgers were kept select from crossing with *Succirubra* in Ceylon. Surely these plants are from *Calisaya Anglica* crossed with real *rojo*, as above.

(*w*) Although we are aware that Mr. Moens has published such a work, we have not received a copy, and have only recently had an opportunity of seeing one accidentally in the pharmaceutical exhibition in Vienna.—ED. PHARM. JOURN.

THE CEYLON PLANTING ENTERPRISE:

OLD AND NEW PRODUCTS, RUBBER IN HAPUTALE: COCOA; TEA-TASTING OF CEYLON TEAS; LETTER FROM MR. LEDGER ON FRESH CINCHONA SEED, &C.

Those who may still be sceptical as to the vitality of the Planting Enterprise in this Colony ought to be referred to recent issues of the *Tropical Agriculturist*. In continuance of the instructive and thoroughly practical paper on Tea Cultivation read by Mr. Armstrong before the Dikoya Planters' Association, we lately presented our readers with Mr. Owen's still more comprehensive Essay dealing not only with tea culture in Ceylon as compared with Northern India, but treating of the combination of coffee, tea, cinchona, cardamoms and aloes on one plantation. Scarcely had the local public time to digest all the valuable and encouraging information thus afforded, before a series of experiments conducted on Ceara Rubber trees at Peradeniya claimed attention as showing that a "new product" which had latterly fallen into disrepute, really promises to do all that was originally prognosticated of it for Ceylon The inventor (Mr. Gilliat) of a very suitable knife for tapping such trees, whose samples of prepared rubber are the finest yet seen in Ceylon, explained his mode of collecting and preparing the rubber at the General Meeting of the Association on the 21st Sept. and the interesting discussion which resulted will again show readers that nothing is likely to be overlooked in this Colony at this time of day connected with tropical products As if to further strengthen the hopes based on rubber, a few days ago a Haputale planter wrote:—"By today's tappal I send for your inspection a small parcel of Ceara rubber, taken from trees from 1 to 2½ years old, each cake was a day's collection, and from the same trees every successive or alternate day. As there are 10 cakes, each tree shows the marks of being ten times tapped within a fortnight. This, of course, was merely an experiment over a small area, to see whether frequent and successive tapping injured the trees, or lessened the flow of rubber. It appears to have done neither, but the difference in quantity from the older trees over the younger ones was so great that for the present I have given up the idea of tapping until the whole acreage (over 40 acres) is over 2½ years old, and meanwhile I contented myself with collecting the seed from the old trees, as I find that to sell them at R25 per bushel pays me to gather them." The "cakes" are splendid as regards size—the largest Ceylon samples we have yet seen.—but the rubber is not clean and our broking referee for rubber, reports it insufficiently elastic: the samples are, however, like and equal to the Mozambique quality which sells at 2s. 6d. per lb. Samples are to be sent to Europe at once for report. We may expect erelong to have the report on these Haputale samples both from London and Germany, and it is pretty evident that we are now in a fair way to turn the rubbers growing, we suppose, to the number of some millions in the country to some practical gain. During the commercial season which opens on the 1st proximo, we may expect to see "rubber" occupying a satisfactory place in our export table.

Another new product "cocoa" (cacao), of which but 3,600 cwt. have been exported in the season just closing is certain to show a large Ceylon "next year." The high esteem in which Ceylon cocoa is held has by no means fallen, and we have heard of a local sale lately at over R53 per cwt. But, after all, tea is the most generally favoured and, indeed, most promising of our new products.

In addition to the encouraging news brought back from India by Mr. Owen, we have just had a series of tastings in Colombo of Ceylon teas by Mr. MacLaren (of Messrs W. Moran & Co., Calcutta, one of the first houses in the trade), and the general result is that already Ceylon tea planters have little or nothing to learn from the expert, whether Indian planter or tea taster.

The samples tasted by Mr. MacLaren, included teas from the following estates:—

1. INDURANA.—Bulk of useful character, considerable quantity per acre probably, liquors well, no fault to be found with it. Nominal value as unassorted 11 annas = 1s 5d.

2. SEMBAWATTE.—Perfect tea, make of leaf being all that is wished. Proportion of Pekoe contained in it is fair. Liquor pungent as well as with flavour. Nominal value 1s 8d.

3. RUANWELLE.—Shows rather large proportion of coarse leaf, but is well manufactured and shows remarkably good fermentation. Flavor of this tea will sell it well, though it is a little deficient in strength in consequence of large proportion of coarse leaf. Nominal value about 1s 3d to 1s 4d.

4. ATHERFIELD.—Leaf very well rolled: but shows such a large quantity of Pekoe tip that it is doubtful if sufficient outturn per acre to pay could be got with such fine picking. Liquor comes out strong without much fine flavor. Nominal value as unassorted might be down at 1s 9s to 1s 10d; but principally on account of largo proportion of tip.

5. MARIAWATTE.—Broken mixed: This is all that is wanted as a broken tea. It is useful either by itself or for mixing. Leaf good style and first-rate liquor. Probable London value 1s.

6. MARIAWATTE.—Pekoe: This tea is slightly overclassed, well-made, but it is really a fine Pekoe Souchong.

Liquor has both flavour and strength. Is altogether a desirable tea and shows perfect fermentation. Value 1s 7d.

7. MARIAWATTE.—Broken pekoe: Though the leaf is a little irregular, the liquor comes out with such strength that it is a tea that will be eagerly competed for in any market, and if such manufacture can be continued for any quantity, no further attempt to improve should be risked. Nominal value 2s 8d.

8. S.—Pekoe this tea is perfectly rolled and judging from appearance of leaf it will probably be worth about 2s 6d.

9. Orange Pekoe.—This is a fancy tea which it would never pay to manufacture, a small quantity might possibly sell at 8s, but the ordinary market value for any quantity will likely be about 4s 6d.

10. K.A.W.—Pekoe souchong, a useful tea containing a good amount of pekoe which with advantage might be passed through a No. 6 sieve and put into pekoe proper. Liquor desirable. Value 1s 1d to 1s 2d.

11. Pekoe.—Leaf well-rolled, liquor both flavory and fairly strong. Value 1s 5d to 1s 6d.

12. Broken Pekoe.—Tea desirable in all respects, strong useful liquor 2s 6d to 2s 8d.

These teas No. 10, 11 and 12 show remarkably good fermentation, but have another recommendation inasmuch as the assortment gives such a useful style of tea and such a profitable average. This result is not obtained by close plucking as the yield per acre is fully up to the average of other gardens in Ceylon.

BLACKWATER—PEKOE SOUCHONG.—Leaf well-rolled and contains a large amount of pekoe leaf, which with advantage should have been included in the pekoe. Desirable liquor, pungent and flavory. Nominal value 1s 7d

PEKOE.—Leaf very desirable in appearance. In fact a really handsome tea, full of orange tip. Fine pungent liquor. Value 3s to 3s 3d.

BROKEN PEKOE.—Extra handsome orange pekoe leaf, full of tip. Fine strong liquor 5s to 5s 6d nominal. The last two mentioned are of a fancy description, but whether it would be policy to manufacture for such a fine assortment is doubtful, as there is only a limited demand for such sorts. But the manager must of course be the best judge of this.

GENERAL REMARKS.—In only one instance in all the samples has there been an appearance of over-firing, and in no case any symptoms of sourness. But the samples from one or two gardens would have been valued higher if the leaf had been rather less fermented. The flavor is not equal to what it will be later on in the season. This is likely in consequence of the leaf having taken a long time to wither during the continuance of wet weather. In manufacture, the teas show a very great improvement as compared with those sampled by me a year ago. (Sd.) JAMES MACLAREN, Messrs. WILLIAM MORAN & Co., Tea Brokers, Calcutta.

Tea planters all over Ceylon will feel indebted to Mr. Mac Laren for the above valuable report: the valuations are very much in accordance with the prices obtained by account sales yesterday from London.

In this connection Mr. Glasse, the experienced ex-Assam tea planter, who is on his way from England, will no doubt be surprized to find how far we have advanced, but we trust that he and other visitors, if they have nothing to teach our planters, will at least be the means of inducing English merchants and capitalists to turn to Ceylon as the rising tea-producing country. The business in seed this year between Ceylon and India is likely to be extensive; but already the local supply is being largely utilized. We are disappointed with the new edition of Colonel Money's Book on Tea, for the miserably meagre—in fact, incorrect and absurd—chapters he devotes to new countries cultivating tea, outside of India and China. Colonel Money has but the faintest idea of what is doing in Ceylon although it sends 1½ million lb. tea into the home market this year and will double this quantity in 1883 4; moreover, he does not appear to be aware that Java has taken an important position as a tea-producing country for many years back; while Japan is also, by him, very meagrely referred to. Evidently, a good TEA-PLANTERS' MANUAL is a *desideratum*, and we believe a new Edition of an Essay prepared for us by a Nilgiri planter, revised by Mr. T. C. Owen, will be found as good as any, at least by Ceylon planters.

The feeling which is rapidly springing up among Ceylon planters and merchants may be illustrated by what was said to us today by a cautious experienced man who was as much depressed about prospects a year ago as the most pessimistic of us. He said: "I begin to feel that not an acre of old estates need to be abandoned; no matter what the soil and climate, something can be got to grow profitably from among the variety of products whose cultivation and preparation we are now rapidly mastering." This has also been the feeling with which Mr. J. B. MacIntyre, after twenty years' absence, returned from a brief visit to the Hunasgiriya and Kandy districts He expressed himself greatly surprized and gratified with what he saw of tea and cocoa, and already *believes* in them as articles of profitable cultivation in Ceylon over considerable areas of existing plantations.

Cinchona is regarded in a more uncertain light; but if not a product to place full dependence on, it has certainly proved itself a most useful and profitable adjunct in a very large number of cases, and no one in our hill-country should refrain from giving it a trial. On an old estate near Kandy, from a patch of five acres, the shavings of the cinchona trees—and very light shavings too—netted £110 last year, and as we have often said many of our coffee planters have only been enabled to tide over the period of greatest gloom by the aid of their patches of cinchona. Old coffee itself is by no means to be put on one side, while there are "two-box" gatherings of cherry still noted in the land and while good paying crops—even if few and far apart on this side of Nuwara Eliya—are still to be found in almost every district. Nevertheless, attention will now more than ever be given to the cultivation of coffee only in such fields as have been proved suitable; in the rest some other product—whether tea, cocoa, rubber or aloes for fibre—will gradually be substituted. With the approach of increasing difficulties for the planters of Brazil and Central America as lately intimated in the London *Times*, it will not do for their brethren in Ceylon and Southern India to look on their coffee-fields as altogether worthless, especially where the trees are still vigorous and bear perhaps 2 or more cwt. of crop per acre in spite of unfavourable seasons. Let us hope that the season now closing indicates the lowest ebb for coffee in Ceylon, and that a gradual revival in our exports of the old staple may now take place even though the maximum for the country be placed at only half (or 500,000 cwt.) of what it used to be. With 300,000 to 400,000 cwt. of coffee (and prices for "middling plantation" not under 80s per cwt.) in addition to increasing exports of the new products, this colony ought to do very well and speedily secure the larger proportion of the prosperity of ten years ago. During season 1883-4, however, we cannot expect that the higher of these quantities will be made up: the shipments being generally expected to be about 375,000 cwt. although it is not easy to say yet what the Uva spring crop may do.

In respect of the future of cinchona planting in Ceylon, it is scarcely necessary to remark that the discussion raised by Mr. Howard over Dr. Trimen's "Ledgerianas" once again referred to in our columns is attracting a good deal of attention to the importance of, as far as possible, cultivating the best kinds of cinchona; and in this connection we must mention a letter we have had from Mr. Ledger himself. This gentleman, whose name is properly identified with the most valuable of barks, the seed of which he was the first (at considerable personal risk) to get away from South America, was about to leave London for New South Wales when he wrote on 1st September instant. We may quote Mr. Ledger's letter as follows, so as to place his purpose in writing to us fairly before local as well as home proprietors of Ceylon plantations:—

"I see in *Observer* how it is suggested that fresh seed of the ledgeriana cinchona should be obtained. Well, although I have left S. America I could point out how the said seed could be obtained. I leave here for Sydney, N. S. Wales on the 13th instant. Although 65 years old I am active and in robust health and would like above all things to dedicate myself to cinchona cultivation—as manager of a cinchona estate. I have some *practical* experience. I am no botanist; neither have I chemical knowledge of plants. Should any company or private party require my services as manager, I should be glad to go to Ceylon as such for a term of 5 years. Conditions as follows:—[The conditions can be learned on application to this office.—ED. *T. A.*] Mr. Howard is of opinion that my services in the manner indicated would be acceptable. Please address Mr. Charles Ledger, Sydney, N. S. Wales, Australia.—Yours respectfully, C. LEDGER."

Fresh seed of the best kinds from South America for use in Ceylon and Southern India is a *desideratum*, even though Mr. W. J. Forsyth has come to the East in order to get the seed with which he is to commence cinchona cultivation in Central America. Mr. Thomas Christy, of Fenchurch Street, is at present the only agent available, and he is doing good service through his collectors in Bolivia; but it is possible that confidence in Mr. Ledger may induce enquiry of him as to the nature and probable cost of the supply he refers to as being obtainable through him.

TEA AT HIGH ALTITUDES.

It is an important fact that teas from "Tommagong" estate, Kandapolla, have realized excellent prices in the London Market, such as

	s.	d.	
Broken Pekoe souchong ...	2	1	per lb.
Pekoe souchong	1	2½	,,
Broken mixed...	1	0	,,
Broken tea	0	9	,,
Dust	0	7	,,

We believe the altitude of Tommagong is not under 6,500 feet. We *know* that on Portswood tea is doing so well at an elevation of fully 6,700 feet, that the proprietor has arranged for very considerable extensions. Now it tea succeeds so well at such high altitudes in Kandapolla, we do not see why it should not be equally successful over most portions of Uva, where the rainfall varies from 70 to 100 inches. In the report of the Spring Valley Company, the statement was made that the plants grew but did not flush. Before this experience is accepted as conclusive, we should like to hear the results of prunings at different periods of the year. We are very sanguine that Uva will yet be as celebrated for its cacao and tea as it has been for its coffee. The proved success of tea would be a strong additional argument for the extension of the railway. Meanwhile it is clear that tea will grow and yield well on the Uva side of Nuwara Eliya up to close on 7,000 feet.

AGRICULTURAL EDUCATION IN CEYLON.

We append the new scheme for Agricultural Instruction in Ceylon drawn up by Mr. Green, Director of Public Instruction. It has now been sanctioned by the Executive Council and it is well that our readers should know exactly what is officially sanctioned. Many people already say that Part II. of Mr Green's scheme will be a failure, because though the Native Agricultural Society may agitate, yet no actual support will be given to anything practical, and no young men will come to the school of agriculture for fear of being "made coolies of." We trust this unkind way of foretelling failure may be belied, and it is well that Mr. Green has endeavoured to dispel this fear by providing for a really high English Education, as well as a more agricultural training in the school of agriculture and if he (the Director) can further induce the Government to provide that (after a few years' warning) nobody should made Mudaliyar or Muhandiram of a Korale, unless he has some knowledge of agriculture, then we feel sure, the school will soon fill. If it fills and succeeds, the Director may make it part and parcel of the Royal College, though separate in buildings—like "the modern side" now so common in great schools at home. Any way, if it fails the Director has clearly done his best. And let the leaders of the Ceylonese remember that Government can then say: "You cried out for Agricultural Education—we have offered it to you. If you don't take it, why, don't complain of Government doing nothing any more." We are, however, not without hope of success,—and for the following among other reasons:—We learn that the result of Mr. Green's speech at Kandy at Trinity College has been that 15 applicants have come foward for 30 ploughs, and he is getting some of the light Swedish ploughs, over from Saidapet, where Dr. Robertson has after a long trial reduced them to a minimum of weight and cost.

SCHEME FOR AGRICULTURAL EDUCATION IN CEYLON.

PART I.—Preliminary Education in all Government Schools.

1. Preliminary and Theoretical Agricultural Education shall be provided in all Government Vernacular and Anglo-Vernacular Boys' Schools, by means of such text-book or text-books as shall from time to time be approved by the Department of Public Instruction.

The subject of Agriculture shall be compulsory for boys in the Standards VIII, VII, VI and V but any boy in any other Standard may take up Agriculture if he pleases.

2. Teachers under training in the Normal School shall, from the date upon which these rules come into effect, be required to pass in the text-book or text-books mentioned in clause I; and such text-book or text books shall form one of the subjects for the annual December examination for certificates now required for Government school-masters: and no Government teacher shall hereafter receive the certificate of the Department of Public Instruction, unless he shall have been awarded at the above-mentioned certificate, examination not less than 25 per cent of marks in Agriculture.

PART II.—THE COLOMBO SCHOOL OF AGRICULTURE.

3. A special school to be called "The Colombo School of Agriculture" shall be opened in January 1884.

4. For the present, the Colombo School of Agriculture will be held at Colombo in that portion of the buildings of the Normal School heretofore assigned to Anglo-Vernacular Student Teachers.

5. The object of the Colombo School of Agriculture will be to provide a superior and suitable education for the sons of native gentlemen, and more especially land-owners. With this view the teaching will embrace:—(1) The higher branches of English. (2) Mathematics. (3) Agriculture. (4) Botany. (5) Chemistry.

The study of the Agriculture will be divided into:—

(1) *Theoretical Agriculture*, which will be taught by means of lectures, text-books, and examination papers.
(2) *Practical Agriculture*, which will be taught and illustrated by practical lessons and experiments on a practising farm to be connected with the School.

6. The School of Agriculture shall be under the management of the Department of Public Instruction. It will be immediately presided over by the Principal, who shall be an English gentlemen duly qualified, with the assistance of under masters, native or othewise as occasion may require.

7. As a general rule no boy under sixteen years of age nor over nineteen will be admitted to the School of Agriculture; but exceptional cases may be specially considered by the Director of Public Instruction. Boys will have to be tested by a preliminary examination before they are allowed to enter the School.

8. Thirty boys can be taken as boarders under the immediate care and supervision of the Principal. Out of these thirty students fifteen may be boarded and educated at a reduced charge of R5 per mensem upon the recommendation of the Government Agent of the Province in which their parents reside. For the remaining boarders a monthly fee of R10, which will include all charges of board and education, will be charged. A limited number of day-scholars will also be admitted to the School of Agriculture: and for these a fee of R2 per mensem will be charged.

9. The terms and holidays of the School of Agriculture shal be the same as those of the Royal College.

10. The course of instruction at the School of Agriculture shall extend over three years, and shall be divided into three stages,

STAGE I. (FIRST YEAR.)

English.—As in standard VIII of Government English schools.
Mathematics.—Arithmetic to the end of decimals and Book-keeping. Algebra to the end of simple Equations Euclid I to III.
Theoretical Agriculture.—Text-books, lectures, &c.
Botany.—Histology Physiology and Classification,
Chemisty.—Chemical Physics and Inorganic chemisty.

STAGE II. (SECOND YEAR.)

English.—As for Cambridge Local (Junior).
Mathematics.—All the rules of Arithmetic. Book-keeping. Algebra Euclid books I-VI.
Agriculture.—Text books and lectures, and practical teaching, experiments in drainage, manures, ploughing, &c. on the practising farm.
Botany.—Agricultural and Economic.
Chemistry.—Inorgamic and organic.

STAGE III. (THIRD YEAR.)

English.—As for Cambridge Local (Senior.)
*Mathematics....*Algebra, Euclid, Mechanics and Trigonometry.
Agriculture.—Practical teaching on the practising farm, cultivation of a plot of ground by each student as provided in clause 11.—Lectures.
Botany.—Arboricultural and Horticultural.
Chemistry.—Organic.

11. In the 3rd stage, a particular plot of ground on the practising farm will be assigned to each student. the tillage, manuring &c. of which will be conducted entirely under the student's supervision and directions. No student will be obliged to work himself, unless he wishes to do so, but he will be allowed to supervise and direct a *goyya* working under his orders. Prizes will be given to those students who best conduct the working of their plots.

12. In addition to the above prizes, there will also be awarded prizes after the examinations at the end of each Term to the student who obtains the highest marks in each of the subjects taught in the school, namely. (1) English; (2) Mathematics, (3) Agriculture, (4) Botany. (5) Chemistry.

But no prize will be given for English, Mathematics, Botany, or Chemistry, unless the student obtaining the highest marks in these subjects shall have also obtained not less than 25 per cent of marks in Agriculture.

H. W. GREEN, D. P. I.

Office of the Director P. I., Colombo, 8th August, 1883.

COFFEE AND CHICORY; AND TEA.

In the twenty-sixth report of the Commissioners of Inland Revenue for the year ended March 31st, 1883, it is stated that the quantity of chicory brought to charge continues to diminish, and it has been still further affected by the Act 45 and 46 Vict., cap. 41, passed in August of last year, which repealed the duty formerly chargeable on any other vegetable substances prepared under the general name of chicory, but which are now taxed by means of a label required to be affixed to every package containing any ingredient other than coffee or chicory, and mixed with or used as a substitutes for coffee. The duty is one half-penny for every quarter of a pound. In the year ended March 31st, 1882, the quantity of chicory charged with duty was 2,869 cwt., and in the year ended March 3rd, 1883, the amount was 2,803 cwt. showing decrease of 66 cwt. With regard to coffee-mixture labels, the Commissioners of Inland Revenue publish a table giving the number of coffee-labels issued up to March 31st, 1883, and the amount of revenue received. The number of half-penny labels was—in England, 1,122,613; Scotland, 32,343; Ireland, 285,349—total, 1,440,305. Penny labels—England, 749,702; Scotland, 13,895; Ireland, 38,837—total, 802,434. The net amount of revenue received from this source for the United Kingdom was during the year referred to 6,344*l*. 2s 2½d.

Turning from coffee to tea, it is to be noted that a complaint from an Assam tea-planter appears in *The Times* of today. He writes arguing greater facilities for transport between the tea producing districts and Calcutta, and states that at present the cost of transport on agricultural implements between the two places is five times as great as the freight to be paid on them from England to Calcutta. Your tea planters are certainly blest in the absence of such enormous disabilities, and, if only Sir Arthur Gordon can see his way to extending with a liberal hand the means of rapid and cheap transit to and from the many districts in Ceylon available for the growth of tea, you will have little to fear from any amount of competition by the tea planters of Assam.—*London Cor. Sept. 7th.*

TEA AND THE PLANTERS OF CEYLON.

(*Glasgow Herald, Sept. 6th.*)

The planters of Ceylon have for the last few years been in a depressed state owing to the failure of the coffee tree to yield crop through the weakening effects of leaf-disease (*Hemelia Vastatrix*). A silver lining has, however, appeared in the cloud which has been hanging over the island. Ceylon tea is exceeding their utmost expectations, and it has been satisfactorily proved that Ceylon can grow this product equal in quality to India, and at a greater profit to the planter. Five-year-old gardens are yielding as much as 800 lb. per acre of dry tea, fetching good prices on the London market. It is stated that owing to this large yield, a cheaper labour force, and better communication with the seaports than what the Indian districts have, the teas can be placed here at a considerably less figure than by other tea-producing countries. As a consequence, coffee land is being replanted with teas and large acreages of new land are being opened up in all parts of the island. It is estimated that at the end of this year there will be about 20,000 acres under tea, and the next few years will see this area enormously increased.

Mr. William Cochran, of Dunblane, Perthshire, writes:—Any ex-Ceylon planter or other individual interested in the fortunes of that fair island, referring to your "Commercial Notes" of Monday, must feel gratified to learn that the pecuniary gloom is now being dispersed through the success which is attending the planting and preparation of tea there. For so youthful a tea-farmer a return of 805lb of the finished article per acre from one area of 45 acres is most encouraging, and will undoubtedly lead to future planting upon a large scale. In connection with this pleasing result I wish you to place on record the circumstance that in the month of April 1867, a friend of mine, who had studied tea preparation elsewhere, and observed that Ceylon was well suited for the industry, interviewed some of the chief people in London connected with coffee planting or interested in that island, and urged the desirability of adding tea to its other products, as coffee farming was even then in an unsatisfactory condition. He explained how the industry was managed in China and India, and offered his services to start a tea garden as a model, or a number, in their midst. To everything he said respectful attention was paid, but not one of the gentlemen addressed would consent to make a beginning, and all had numerous objections to offer. He was told, for example, that the Ceylon planters knew nothing about tea farming; that their estates were already fully occupied with coffee; that labour was too expensive to admit of the fragrant leaf being grown and manipulated to advantage; that, in short, the game was hardly worth the candle, with other equally erudite remarks, politely enough expressed, to get rid as soon as possible of the innovator. His arguments thus fell upon sceptical ears, and nothing followed for several years, until the pinch of the various coffee-plagues came, when they were recalled to memory, and tea planting began to spread. It is, therefore, so far satisfactory that the advocate of industry who, 16 years ago, could point to hardly a single disciple lives to see his suggestions extensively carried out in Ceylon, and that he rejoices to believe that this enterprise may speedily be the means of saving its surviving planters from utter ruin. This anecdote seems to be not without some application to the proposal to conduct tea and silk farming on a large area in the north of New Zealand, which has been before the public for the last four years. At first the suggestion was received by many with smiling incredulity. A species of mild and harmless opposition followed, succeeded by much grave wagging of official Colonial heads;

yet although only one-fourth of the period required by the Ceylon planters to make up their minds has elapsed and it has been unaccompanied by the spur of dire necessity, there seems every prospect that these lucrative industries will soon spring into being in Auckland, under the wing of the New Zealand Chasericultural Company, upon a scale commensurate with their importance.

CEYLON AGRICULTURAL ASSOCIATION.

PROPOSAL TO INTRODUCE NEW VARIETIES OF BREADFRUIT.

Mr. W. H. WRIGHT said (Sept. 20th) he wished to bring a matter before the Association. He thought it was time that they asked Government to get such things as would be beneficial to Ceylon, and there was one thing in particular which it was very desirable to introduce into Ceylon. He might say that there are seven or eight varieties of bread-fruit grown in the Fiji islands, which are far better than the kind we have here. The bread-fruit we have got here is of a very inferior description, and he heard that it was only used for feeding cattle with. He proposed that they should introduce the better kind and ask Government to do so through Dr. Trimen. If the Association thought it was necessary that he should undertake to rear the plants in his garden and under his supervision, he would do so. If Government would not help them, he would volunteer to go halves with the Association, if it would join him in introducing the different varieties of bread-fruit. (Applause.) He thought they had a right to ask the Government to pay half, and they might pay the other half. He was sure they would all join with him in this matter: it was for the benefit of the country, and why should they not do it? It was a thing really necessary for the natives: the common bread-fruit at present cultivated was not very good, and why should they not have the better kinds?

Mr. W. P. RANESINGHE seconded the resolution.

Mr. S. R. DE FONSEKA (Kalutara) thought the proposal was a good one, but he would like to know what the expenses connected with an application of this kind would be.

Mr. W. H. WRIGHT said a wardian case might cost from £18 to £20. If the Association could not afford to get it out, he would do so himself. (Applause.)

Mr. S. R. DE FONSEKA thought the Association would gladly join in such a matter and bear a portion of the expenses. But, in the first instance, application to Government should be made without any guarantee of payment, because the Government was bound to do a thing like this, and a representation from an Association like theirs would, he thought, carry great weight with it. The bread-fruit, would be very nourishing and very useful. He thought they should ask not only for the introduction of bread-fruit, but also for other useful products. He had a great pleasure in supporting the resolution.

MAHA MUDALIYAR DE ZOYZA remarked that there was an article on bread-fruit cultivation in a recent issue of the *Observer*.

Mr. M. D. COCKBURN:—The Association has been so often taunted with doing nothing that I am glad Mr. Wright has introduced the subject. As Mr. Wright has been so good as to undertake to cultivate the plant I think it is but right that the Association should bear the whole cost. It would be more generous on the part of the Association to write to Government and say that we are prepared to bear the whole cost than to allow anybody else to have the credit of introducing this variety, which should belong entirely to the Association. I have much pleasure in supporting the resolution.

The following resolution was formally put and carried unanimously:—"That this Association is of opinion that Government should be requested to introduce into this island new varieties of a superior kind of bread-fruit than exists at present in the island and and which are said to be found in the Fiji Islands and elsewhere."

BALMER, LAWRIE & Co.'s INDIAN TEA AND WEATHER REPORT.

Calcutta, 15th Sept. 1883.

Our last report was dated 1st instant; the weather during the past fortnight has been rather more favorable, but from nearly all tea districts we have reports stating that already there are signs of the cold weather coming on; in this case the outturn will be most seriously affected, but it is to be hoped that the present appearances are only temporary and that planters may be cheered by a good October.

ASSAM.—DIBRUGHAR.—Recently the weather has here been favorable for both growth and manufacture, although some more rain would have been beneficial; at the beginning of the week ending 4th instant, the heat was very great, but later on some heavy showers with violent thunder storms and high winds reduced the temperature slightly; most gardens are still behind with little chance of picking up unless September and October, bring exceptionally fine weather. The rainfall is several inches less than last year to same date, and there has been no long spell of really hot weather; there have been fogs in some parts, which prognosticate an early close of the season.—Sibsagar.—Satisfactory reports reach us from this part, the weather having been good for leaf, and the gardens pulling up somewhat in consequence; the mornings and nights are rather cool for the time of year and on three or four mornings there were dense fogs; during the day there was warm sunshine and leaf is spoken of as being fairly abundant and of good quality. Most gardens are very much behind in outturn to date.—Jorehaut.—The weather here is very changeable; towards the end of last month there was a considerable fall of rain, and it was hoped that if this were followed by hot weather, arrears would be brought up; but planters fear that not only will they be unable to make their estimate, but the outturn will be under last season; the nights lately have been really cold.—North Lakhimpur.—On the whole the weather for the last half of August was disappointing and the constant changes from heat to cold are not very favorable for growth.—Nowgong.—Most gardens here are still much behind and the prospects for this month are far from favorable, as the weather is cold and wet.—Mungledie.—The weather here has been favorable, with the exception of being a little too cold; leaf has been at a standstill and gardens are going fast behind. During the last 10 days of August, it is reckoned that gardens must have fallen behind 50 per cent. from the corresponding period of last year. There is every appearance now of the approaching cold weather, the sky being clear and nights cold, while leaf is stunted and hard.

CACHAR.—Most of the lowlands in this district have been again flooded, and in some parts the water was up to within 3 feet of the May floods, and the paddy crops have suffered badly. The latest reports from Silchar are that the water had fallen ½ a foot and the weather was once more hot and dry; on the 7th instant there was a slight shock of earthquake. Blight is still bad on some gardens and the leaf is coming out small and light; there are signs of an early close to the season. Round Hylakandy similar bad weather seems to have prevailed; heavy rain and floods.

DARJEELING.—September has opened well for tea, news of warm weather with occasional showers reaching us from most parts of this district; gardens showed again this month on part of the ground lost in July; but it is feared the season will close early. At Hopetown some planters still complain that the bushes do not flush freely and fear there is little chance of picking up, now the season is so far advanced; the weather seems satisfactory for both cultivation and manufacture so that the gardens with a full supply of labor should get in a fair crop of tea this month. In the neighbourhood of Jore Bungalow the week ending 8th instant was favourable for manufacture; and there is some improvement noticed in the quality of the tea made over that of August. At Kurseong, during the latter part of the fortnight ending the 10th instant, there was bright sunshine with intervals of slight showers. The rainfall to date was below the average and the season threatens to close early. Many of the Terai gardens are suffering from blight—chiefly mosquito blight—which is worse than has been known in the district and is still spreading. The weather is not so favorable here owing to the short rainfall, and the outturn is behind on most estates, probably 2,500 maunds less than last year. In the Dooars the weather has been favorable with hot sun and occasional heavy showers.

KUMAON.—The weather here continues close and steamy which is favorable for tea.

DEHRA DUN.—Alternate rain and sunshine have been conducive to the growth of fine flushes, and most gardens are pulling up towards their estimates; the bushes appear healthy and are not troubled with any pests.

KANGRA VALLEY.—There has been plentiful rainfall over this district lately, but the register is still nearly 30 inches lower than last year to the same date.

CHITTAGONG.—The rains seem to have broken up and there is now plenty of sun with an occasional afternoon showers; the nights have been cooler than is usual at this time of the year, and leaf does not come so freely as could be wished.

CINCHONA:—MR. MOENS' GREAT WORK ON "KINA-CULTUUR IN AZIE,—"

Valuable as the letterpress is,—must be deemed chiefly and pre-eminently excellent on account of the fact stated on the Dutch title-page in the uncouth words "Met 33 platen en een Kaart." Like that of most well educated Dutchmen, Mr. Moens' patriotism does not go the length of asserting a high place for the language of Holland, with whatever grand events and noble principles the rugged "low Dutch" may be associated. The feeling is that anything written in facile French, or still better in finished and comprehensive English (and Mr. Moens speaks English quite like a learned Englishman), could be not only better expressed, but would be certain to secure an immensely larger audience. Had the wishes alone, therefore, of the accomplished head of the Java Cinchona Gardens been consulted, we believe, he would not have been described on the title page as "Directeur de Gouvernements Kina-Onderneming in Java"; nor would English readers be puzzled by the conundrum of "Uitgegeven door de Vereeniging tot bevordering der geneeskundige wetenschappen in Nederlandsch-Indie." From such jawbreaking syllables as the above, we have arranged to get some of the more valuable portions of Mr. Moens' great work translated. Meantime, the "33 platen en een Kaart" need no translation. The one map receives an additional interest from the awful volcanic outburst which has concentrated on the Straits of Sunda and the bordering lands of Bantam in Java and the Lampongs in Sumatra, the wonder and sympathy of the world. Any one looking at the map here given of that portion of the Preanger Regencies of which beautiful Bandong is the centre and which includes the Tankoebanprahoe ("Upturned-boat") cone and the "Malabar" ranges, all alive with subterannean fires, the smoke and effluvia of which are patent to the sense, might well ask, "Has the Dutch Government deliberately chosen the slopes of still active volcanoes as the sites of their experimental cinchona gardens?" The answer would certainly have to be in the affirmative. Forest land at what was deemed the best elevation, with rich virgin volcanic soil, a climate and other conditions analagous to those which distinguished the Andean home of the fever plants, were present in such positions, and as to the risks of volcanic and earthquake catastrophes, Government and their servants could not well decline what the millions of their subjects daily dared. When, under Mr. Moens' kind and intelligent guidance we visited the Nagrak and adjoining plantations, we could not help at last exclaiming, "With what strong smelling substance have you been manuring your cinchonas." The Director smiled and said, "No need for manure here: look up to the top of the Tankoebanprahoe. You are within the influence of the fumes from one of the largest volcanic craters in Java or the world, to closer acquaintance with which I shall by and bye, introduce you." Mr. Moens was as good as his word, and while memory remains unimpaired we can never forget the awful scene in what was literally a lake of fire and brimstone, of soda and seething mud, of volumed smoke and steam and gushing geysers. The fumes, though, not pleasant, cannot be deleterious, for so far from those exposed to their influence suffering, Mr. Moens related with great glee, the case of one of his subordinates whose dwelling was so close to the lips of an active volcano that he could not preserve a photograph of his family, while every article of silver or white metal became black as ebony. This man was promoted to a better district, but he actually petitioned to be left in the enjoyment of what had become his native air! A glance at the Map will shew that all the government cinchona plantations of Java, are on the sides of or amidst volcanoes which often give warning by earthquakes and shakes and tremors, that they may at any moment burst out into fury such as that amidst which Krakatau was engulfed and Anjer and so many other towns, destroyed and the surrounding country devastated. If we have not the deep rich soil of Java in Ceylon, we are not liable at any moment, by means of forces ever and obviously at work, to be blown into space or sucked down into an inferno of scalding mud. All honour to those who, amidst such scenes and in view of such possibilities, calmly work on in the service of humanity and science. We have the result of this calm and courageous perseverance, in the work of Mr. Moens and the bountiful plates, most of them actual phototype reproductions of the species and varieties of the cinchonas, which the Government of Java was the first to introduce into the Eastern World,* their original disappointment with *C. Pahudiana* being amply recompensed by the subsequent marvellous success of *C. Ledgeriana.* Prominent amongst the sign-boards in Batavia city, we found that of "Woodbury Brothers, Photographers," and we learned that these were the artists whose name has been stamped on a process for perpetuating photographs, and by means of which Mr. C. Lang of Buitenzorg has reproduced photographs of specimens of the various cinchona trees and their different parts with an absolute fidelity to nature, such as is of incalculable value to Botanical science. Mr. Lang is connected with a splendid Government Museum and Library at Buitenzorg, adjuncts of the famous Botanical Gardens, in which the Governor General's residence is situated. The Museum and Library building must have been erected or re-erected in the time of the able man, who after serving as Secretary of State for the Colonies in Holland, became Governor-General of Java, for we found the name "Charles F. Pahud" engraved on a memorial stone in front of the fine building. It must have been vexatious to this eminent man to have had his name associated with a species of Cinchona, the cultivation of which, from its low yield of alkaloids has now been abandoned. Such are the uncertainties even of science. Holland and Britain commanded the services of men, eminent as botanists, but it was to a bark collector, confessedly ignorant of botany, that the world owes the introduction into the Eastern world, (Mr. Moens "Azië") of the prince of cinchonas, LEDGERIANA.—Before proceeding to notice the "platen," however, we must advert to one feature in the "Kaart," which as it is not explained in the index, might puzzle beholders. In 1880-81 a destructive murrain prevailed in Java, which threatened not only to destroy the cattle belonging to the Malay peasantry, but to put a stop to the great rice culture for which the services of cattle are essential. To stay the ravages of the epizootic the Dutch rulers of Java adopted the heroic expedient of running a bamboo fence and establishing a cordon right across the island. When we passed from the infected districts into that of Bandong, (at the top of a mountain commanding a magnificent view,) we were stopped to be disinfected, we and our driver and the ponies, by the application of a black

* They introduced the first "Kinas" in 1854, while the British did not succeed until 1860.

wash to the soles of our boots, and to the feet of the driver and horses. We again came upon the fence and a military guard house at the mouth of the Tankoebanprahoe crater, while at Bandong we met a field officer in command of the military who enforced the quarantine. The fence, impervious to cattle, is represented on the Map by a line of * * *s. and going right across the top of Tankoebanprahoe, about 6,000 or more feet above sea level, we suppose. Nothing could prove more strongly than such a measure as this the value of cattle, chiefly buffaloes, to the rice culture of Java: a culture which gives a superior grain to that obtained in Ceylon and a great deal more of it in proportion to seed sown. And before noticing the phototypes of the cinchonas, we may also say that the appropriate design in gold on the front cover of the book (claret colour) is a sprig of Ledgeriana, showing foliage, flowers and fruit.

Of the 33 plates, two are in the body of the book. The first represents an establishment for the peeling and preparation of the bark of trees which have been cut down after the old coppicing fashion. There is then a very valuable phototype giving the characteristics of seventeen specimens of bark of the various cinchonas; Ledgeriana as well as other bark being shown natural and renewed on a scale of ½ the real size. It seems to us that there is a strong outward resemblance in the barks of succirubra, the true calisaya and Ledgeriana. The renewed barks in every case seem less granulated or rugged than the original: at least they reflect light less and present in the phototype smooth dark surfaces. Plate No. 1 of the 31 placed at the end of the book, represents Mr. Moens seated in front of a fine grove of his famous Ledgerianas, which were about 12 years old when the photograph was taken in 1880. It is now 18 years exactly, since the wonderful windfall of seed was purchased from Mr. Ledger in October 1865.

No one looking at the picture, or who has seen the reality, can agree with Dr. King's description of the trees as "rather shabby looking." He must have seen them after drought. When we saw them in August 1881, they looked well and flourishing, covered thickly with small green foliage: not a trace of red in the adult trees, though plenty of that colour was shewn on the leaves of some of the younger plants. A good magnifying glass applied to the phototype brings out correctly the character of the small, pointed, green foliage. The habit of growth of the calisaya tree figured is very different, the branches going out much farther from the stems before they turn upwards: the calisaya is altogether more bush-like. The foliage seems also far less dense, and this is still more markedly the case with C. Josephiana, while C. Haskarliana has a fine head of foliage close to the top of the tree. The specimens of C. Officinalis pourtrayed seem to confirm the character of "spindly" applied to this species by the planters of West Java. In other portions of the island, however, Mr. Moens recently found C. Officinalis growing well. A group of C. Lancifolia gives the idea of branches of leaves scattered over long, thin whips of stems and twigs. C. succirubra comes out true to its massive pyramidal form. The trees photographed have been stripped and mossed. The small grove of C. Micrantha looks very handsome, and it is a real misfortune that this, the poorest of the fever trees, should so closely simulate the characteristics of foliage of the finest. The leaves are velvetty and purple coloured, but they are altogether too big to be mistaken for Ledgeriana. C. Caloptera makes a tree with a fine head; while C. Cordifolia has either got very large leaves, or the camera must have been placed very close to the specimen photographed. There are thus 11 pictures of the mature Cinchona trees as they are seen growing. Plate XII gives (on a scale of ⅓rd the original size) in three sections the foliage, flowers and fruits of what Mr. Moens, no doubt regards as his best and most characteristic specimens of the true Ledgeriana, and its varieties, his No. 9; 15 and 24. A picture on a larger scale (½ the natural size) of the leaves and reproductive organs of "C. Ledgeriana, Moens," with no number, follows, and gives us a perfect idea of the forms and veining of the leaves of true Ledgeriana of the best type. Those who have been in a position to make careful comparisons, are able at once, apart from the velvetty look and feel of the leaves of the calisayas to distinguish them from those of C. Officinalis by their more rounded ends. But besides being thickest in the middle, the leaves of true Ledgeriana are so sharply pointed as in this respect to resemble more closely C. Officinalis than C. Calisaya. When we come to the separate figures of the reproductive organs, we find those of Nos. 22 and 24 chosen to represent the highest types of Ledgeriana, while Nos. 9 and 15 with much more elongated seed vessels are classed as "Var A. et B."* The flowers and seeds of all the inferior calisayas, and others, including the red, crown and grey bark seem larger and more elongated than those of C. Ledgeriana, which are short and the seed vessels stout. The pictured foliage of C. Pahudiana and Hasskarliana, indicates the nearer alliance of the latter than the former to the yellow barks. The sharp-pointed foliage of C. Officinalis with the dense flowers and fruits are well shewn; while C. Lancifolia seems to approach in foliage to C. Succirubra which is capitally pourtrayed, even to the cabbage-like shape and corrugations of the leaf. The large, velvetty leaves of C. Micrantha are also well shewn; while C. Caloptera in foliage closely resembles C. Lancifolia. C. Cordifolia, on the other hand, as far as leafage is concerned, might be taken for C. Lancifolia. There is, finally, a good engraving of the plan of a conservatory for grafted plants and the mode of grafting Ledgeriana scions on to Succirubra stocks is well shown.

Our readers will thus see that merely the illustrations of Mr. Moens' book are very valuable apart from the narrative and descriptive matter, of which the more important portions, such as especially all that refers to the Ledgerianas, will be translated for and printed in the *Observer*, from time to time.

MR. THOMAS CARRITT, who undertook to represent the Calcutta Tea Syndicate at the Amsterdam Exhibition, has also visited Rotterdam, Antwerp, Copenhagen, Stockholm, St. Petersburg and Moscow, on behalf of that body. In Amsterdam, Rotterdan, Antwerp, and Moscow he has succeeded in obtaining suitable agents to accept consignments of Syndicate teas on favourable terms.—*Indigo Planters' Gazette*, Aug. 14th.

ARTIFICIAL GUTTA-PERCHA.—A German patent has just been taken out for the manufacture of artificial gutta-percha. The enormous demand for the latter article has rapaidly sent up its value; so that it is not surprising a substitute has at length been found. This is composed of powdered copal, sublimed sulphur, oil of turpentine, and petroleum. The mass is heated in a boiler provided with a stirring apparatus to a temperature of 150deg. centigrade. It is then allowed to cool to 38, when it is mixed with a weak solution of casine in amonia water, to which wood spirit has been added. It is then heated to its former temperature and boiled with a solution of nutgall. It is stated that tho artificial gutta-percha cannot be detected from the real article, and that it wears equally as well, while its price is much lower.—*Australasian.*

---

* No. 9 is classed as "var cinchonidinifera," from the proportion of the second alkaloid to quinine which it yields; while No. 15 is put down as "var chinidinifera."

Correspondence.

To the Editor of the Ceylon Observer,

THE TEA PLANT:—ITS CEYLON ALLIES.

Budleigh, Salterton, Devon, 6th Sept. 1883.

DEAR SIR,—On the subject of a letter which appeared in your weekly issue of the 11th ultimo, headed as above, I have a very clear recollection of the great excitement of the late Mr. W. McCulloch, who was then in charge of Carolina estate, and I believe a good botanist, at having in the year 1844 discovered at a place called Paddepola in the Ambegamuva district (where I was then stationed), a specimen of what he termed "indigenuous tea," and this I conclude is the same genus, as that sent to you by "Planter" from Ambegamuwa.

The late G. H. K. Thwaites always gave it as his opinion that, Ambegamuwa was the district most especially suited both as regards soil and climate to the cultivation of tea. This product appears to be the rage now, but I still believe that, if favourable seasons returned (and there is no good reason why they should not do so), the old staple would still prove the best friend to the planter. I do not wish to damp the expectations of those who are embarking in tea cultivation; but in conversation with an expert, a short-time since in the city, he gave it as his opinion that tea paid everybody *but* the producer—and I am sorry to see this opinion agrees with the article of your issue headed "How the Gilt is taken off the Gingerbread."

I trust that your new Governor, will, with reference to the extension of the railway from Nanuoya to Uva, see with the eyes of those, who have the true interests of Ceylon at heart, and advocate strongly the prompt adoption of the original scheme.—I remain, dear sir, yours truly, H. A. EVATT.

[Capt. Evatt was formerly in the Ceylon Public Works Department. The Mr. McCulloch referred to, had been, we believe gardener to the Emperor of Brazil. The plant he noticed is very common; not a true tea, but exceedingly like the dark-coloured China variety. It has a curious tendency to grow up with tea plants in nurseries.—ED.]

CINCHONA BARK FROM SUCKERS.

Dindamull, 13th Sept. 1883.

DEAR SIR,—Can you give me any information as to the quality of bark grown from suckers taken off cinchona trees. Will suckers yield as good bark as seed? My home friends write me that they have been told that suckers grown from coppiced trees are not so satisfactory as seedlings, and infer that the quality of bark is inferior.—Yours faithfully, JAMES W. SMITH.

[Provided the "suckers" are allowed to grow to four years old or over, we do not suppose there can be any inferiority, but planters who have had experience of coppiced trees can better answer this question. Mr. Halliley of Clarendon can speak of trees coppiced more than once, and we believe with very satisfactory results.—ED.]

TEA CULTIVATION IN CEYLON: IMPORTANCE OF SUPERIOR SEED.

17th Sept. 1883.

DEAR SIR,—There can be now little doubt that in the course of a generation our infant industry, tea, will have superseded all other productions in a great degree and have become the principal export from Ceylon, and it behoves us as the introducers or pioneers of its cultivation to do all that lies in our power to ensure the success and permanency of the new undertaking. Our planters are proving themselves capable of thorough manipulation in the manufacture of the invigorating leaf, and with the climate we possess to help them conjointly with their agricultural attainments (of no mean order), its production in paying quantities may be taken as an established fact.

But there is one point connected with the cultivation of the many varieties of economic plants that have been and are being grown in this island, which has never received the attention it deserves, and on looking closely into the matter, it seems almost incomprehensible why such an important factor in the typical perpetuation of the species under cultivation should have been so neglected. I allude to the utter want of any attempt on our part to maintain the continuance of reproduction of the species under cultivation on scientific grounds, in such a manner as to ensure that the plants for future clearings shall be, if not actually superior to the parent trees, at any rate their equal, and to reduce the possibility of any deterioration in succeeding generations to a minimum. In fact, no pains or trouble should be spared in endeavouring to increase the suitability of the future generations of the tea plant for the use they will be put to.

Now, if we turn to the mother-country we will find that the attention both agriculturists and horticulturists there pay to this subject, at once shows it to be one of vital importance, and it has by degrees come to be almost a science in itself. No farmer or gardener would for a moment think of obtaining whatever seed he might require, in the haphazard way we do, from any parent stock that appears to be of good quality, for he has found by bitter experience that those qualities are transient, and that his only way was to obtain the seed he required by the *combination of carefully selected varieties of the same stock.* To most, this was a matter of great difficulty; for to be successful, an undivided attention must be paid to the subject, and to meet this difficulty these enormous seed establishments and nursery gardens have sprung up during the past half-century, and that they were requisite has been proved by their success.

It must not be inferred from the foregoing that I am advocating the erection of similar establishments in Ceylon. If tea happened to have been an annual, I believe they would have been found necessary, but what I do feel is required, is that the quality of any seed I might purchase either for myself or my employers should be undoubted, and that there would be no fear of the plants from such seed being inferior to the parent. That a large percentage of the cinchona seed sold in Ceylon during the past few years may be characterized as rubbish, few will gainsay, and a small proportion of tea seed may be classified in the same category. I have been victimized in both quite unwittingly on the part of the seller, and it is for the purpose of endeavouring to commence a movement to counteract this tendency of plants to produce inferior seed that I now write.

The manner in which this desired result is to be obtained, I must leave in abler hands than mine to determine. All I can do at present is to draw attention to the want, and if this want be generally admitted, there is little doubt that a satisfactory solution to the problem will not be long of coming. In the meantime, I would suggest that those who are making small plantations for seed-bearing purposes, should not confine the same to one kind of seed; for instance, if indigenous Assam be required, the parent trees should be from seed from different sources (indigenous), and planted out alternately in equal proportions; if hybrid, they should be composed of different hybrids of the best class, with a few indigenous or China plants through them, according to the elevations for which the seed will be required; this in any case cannot but be beneficial.—Yours faithfully, SWADDY.

CHARCOAL, COAL, TEA AND MR. T (EA) GRAY.

Maskeliya, 20th Sept. 1883.

DEAR SIR,—What Mr. T. Gray said at the district meeting held on the 15th inst. was, relative to firing tea by machinery, "That 1 lb. of coal would fire 2 lb. made tea, and that 1 lb. charcoal would only fire 1 lb. tea" Charcoal costs on an average *now* 1 cent per lb., and coal will be delivered for R50 per ton, including all charges—when we have the railway to Dickoya, Mr. Gray meant of course—*cost* of wood for the charcoal is not included in the 1 cent per lb., merely *cost of labour*; at *present* 1 lb. charcoal costs ¾ cent. As wood gets scarce, it will cost a good deal more. The Sirocco-man says, "when using coal-fuel, this apparatus generally turns out at the rate of about 2 lb. of dried tea, to each pound of fuel consumed." Mr. Gray did *not* say at the meeting that it takes 2 lb. charcoal to fire 1 lb tea. He knows better from daily experience. The worthy man who sent you the particulars of the meeting made a mistake. When he has to make his own charcoal, he will know better.—Yours truly,

ANCHOR BRAND.

COFFEE CULTIVATION AND WEEDS: NEW PRODUCTS AND HOW TO MAKE COFFEE PAY.

Maria, 20th September 1883.

DEAR SIR,—I quite agree with you. Mr. Halliley should rest quiet now and let those who wish to try his remedy to grow weeds to bring coffee round. I for one will not try. I hold small weeds *when* manuring coffee in holes to be a help to other manures. If manure is thrown over the surface, then mixed with surface-soil and *small* weeds—bring all into hole—other times keep estate clean. Estates with a very rich soil will stand weeds, but in poor soil, as I know from personal observation in my neighbourhood, even when forked under, the system is a failure.

On the other hand if shade is grown—jak, sooria, croton, demata, milila, &c.—and the roots of the trees are all cut off for 18 inches below ground and branches cropped or trimmed when required to ripen the wood on the coffee, you will then bring up the nourishment which has passed the coffee into foliage, which afterwards drops off and is the best assistance to other manures you can give the coffee.

I have noticed for the last three months we have suffered a good deal by loss of coffee leaves and crop; this I cannot lay to leaf-disease, as we have very few spores about and as the trees under shade carry their crop and leaves well. I firmly do believe the cause to be something unusual in the rays of the sun, and am now planting croton as a shade and product all over the coffee. I have had many visitors, and one and all are satisfied that we have the crop. All they can find fault with is that we have bad patches here and there. Considering some of the coffee 50 years old and more in parts, and as we know of their having given previous years heavy crop, we on the estates here can make every allowance, especially as we know these trees will recover and give us good crops again. I have supplied all my Arabic coffee with Arabic coffee plants, in which my faith is not in the least shaken. I can however show splendid cocoa throughout the coffee, cinchona and tea along roads, and pepper and vanilla around trees—a native coffee vanillery and a cardamom field. So we do not neglect new products, but never will I neglect Arabic coffee while it gives me such handsome returns. I firmly maintain that surface-manuring with patent manures in past years, with cinchona planted through the coffee, not changing our pruning season when our weather seasons changed, had more to do with short crops now than abnormal seasons.

In surface-manuring you retain old and make new rootlets near the surface. The slightest change of weather will be felt by the rootlets; in dry weather they lie dormant, in too much wet, they are weakened. If you grow weeds, they eat up your manure; but if you cut air or manure holes one foot in depth, then mix your manure and soil as above described, you will feed and strengthen middle rootlets and get roots to go further down in the soil. The holes to be half-filled in the lowcountry so as to catch as much rain-water as possible as well as wash in the high country, fill your hole and stamp it in the rainy season; but leave holes open as long as possible in dry weather; prune now in September all superfluous wood, then prune again in March or April in upcountry and in January and February in lowcountry.

For how much of the present hard times are *some* of our Visiting Agents to blame. Very often they have a man employed to superintend large estates with insufficient experience who can suggest nothing when they come round, and their hurried visits over estate will seldom enable them to find out the wants. Some gone mad on Liberian coffee, some on rubber, some on tea and some on cardamom, ordering these to be planted perhaps in very unsuitable land, or to be dibbled where holes ought to have been cut and some assistance with manures given; if a failure, then they run down the country. Ceylon is my adopted country, and I can prove in many instances the country is run down as played out, whereas it was only the ignorance of those in charge to work the estates as they ought to be worked in; often false economy, laziness, ignorance, or some wild goose hobby, where common-sense, thoughtfulness and a few extra rupees spent in proper time would have done the needful and good profits made. I admire a reading like Mr. Armstrong's experience, gained by careful thought and work. We have other good planters in Mr. Taylor of Looleondura and Mr. A Ross of Aluwibare. It is men of that stamp we want, and I hope there are many more in Ceylon like them; these men are able and willing to work up their estates and not bother with estimates, same as myself on Maria, yet I am sure they make their estates pay better than if they had an elaborate estimate cut down by a V. A. and afterwards by Colombo agents, both of whom do not know the actual requirements so well as the superintendent if he is a good, thoughtful, steady planter of sufficient experience.—Yours truly,

J. HOLLOWAY.

COFFEE CULTURE: MANURING FOR THE BLOSSOMING SEASON.

20th September, 1883.

DEAR SIR,—Will some of the independent members of our planting community try the effect of manuring for the blossoming season as well as for crop, for it is really as much required at that time. If some of them would try the experiment and report results, they will be found of value at this period of short crops. Flowering is an exhaustive process requiring a large amount of nourishment, and the sugar planter is so well aware of this that he cuts his canes before they flower, lest the process should exhaust the juice and therefore rob him of his labour and profits. A greater quantity of the nourishing sap than is generally imagined is required to support the flower, and as the roots can only take a certain amount from the soil, it follows that, if this h to go to nourish the leaves and branches, the flower must starve, and as a result the plant will either not flower or produce inferior blossom. The production of flowers by a plant differs from the production of foliage in this respect: that flowering consumes the stored-up products of the plant without giving anything in return. A leaf takes carbonic acid from the air, and gives out oxygen under sunlight; a flower, on the contrary, gives back the carbonic acid and water to the air. Fruiting and seeding are also strains on the vegetative life of the plant, but not so great as flowering;* and, moreover, the plant in these stages of its existence does not waste what it gets, but stores the nutriment up in the seed for the use of the young plant yet unborn. The green fruit acts like a leaf, as under the action of the sun it gives out oxygen; but when ripe, the respiratory function alters, in so far that carbon dioxide is exhaled, while oxygen is absorbed. In chemical composition, too, fruits at an early age agree very closely with leaves, their structure and functions being very much the same. The fruit during the process of ripening requires, like the flower, a large amount of sap to support it. Hence, a plant which begins to flower and fruit early rarely produces large fruits, and is sometimes killed after the first efforts have exhausted the strength of its constitution. Gardeners, being aware from experience of this peculiarity in vegetable physiology, nip the flower buds of rare fruit-trees, until they have acquired sufficient vigour to bear the strain of fruiting; and when they wish a tree to produce large and juicy fruits, they prune it of all superfluous wood which might use up the nourishment required for the support of the flowers and fruit. Now, we have always been accustomed to manure for crop only, and, generally, during the slack time after pruning, the amount of manure depending on the estimates of crop already framed, and at that time the trees had sufficient stamina to produce healthy blossom. But when leaf disease got the upper hand, the blossoms deteriorated, and no attempt has been made to help them; still, where manure has been annually and systematically applied during our term of depression, there has always been enough remaining in the soil from the previous application, whilst the blossoming season was passing, to assist a blossom or two to perfect itself, resulting in crop sufficient to satisfy the owner. If we go a step further, and manure for blossom also, the returns will be greatly increased; and there are few proprietors who have continued manuring operations on the crops they have been picking these last few years, who would not be willing to procure a larger quantity of fertilizing material, if the increased quantity of crop on the trees justified the expenditure.—Yours faithfully,

"SWADDY."

MR. OWEN'S PAPER ON TEA PLANTING: A LITTLE CRITICISM.

Nawalapitiya, 24th Sept. 1883.

DEAR SIR,—I was a little surprized to read in Mr. T. C. Owen's able paper on tea cultivation that the tea of the Land Mortgage Bank's Darjiling estates cost only 6½d in Calcutta.

On reference to the August number of the *Tropical Agriculturist*, we find that the Darjiling gardens of the Land Mortgage Bank produced 527,840 lb. tea, which cost in Calcutta £24,302 1s 6d and taking the rupee at 2s as done in the Bank report, this represents an expenditure of 11d. currency, or 45 cents per pound.

I quite agree with you that Mr. Owen's remarks on the late Mr. Cameron's pruning were too sweeping. It would be interesting to hear how Mr. Cameron's system of plucking has succeeded. With all deference to Mr. Owen I believe a slight modification of Mr. Cameron's system will be the best for Ceylon tea estates.—J. W.

[Is it not a fact that there are three systems of tea pruning, and consequently of plucking, practised in Ceylon? First, shall we call it, the old fashioned "Taylor-Armstrong-Owen" mode, as opposed to the Cameron plan which is called too severe, and that between these may be placed the plan observed on Galbodde estate and perhaps on the plantation of our correspondent? Who will describe the three modes to us with the differences between each?—ED.]

"MR. F. D'A. VINCENT'S REPORT ON THE FORESTS OF CEYLON"—GALLE AND MATARA DISTRICTS.

Balapitiya, 24th September 1883.

DEAR SIR,—In reading over Mr. Vincent's most interesting report, I can't refrain from pointing out that in para 97 part II he is not exactly "in order!" Had Mr. Vincent, a few miles on the Galle side of Hinidum, got out of his boat and taken the trouble to go a mile or two into the Crown jungle, which runs down to no great distance from the banks of the Gindura, he might have seen jungle that would have done his eyesight good! Timber "proper," *i. e.*, timber of that quality and in such quantities as would supply the P. W. D. of the Southern Province for many a year to come, timber that if I'm not greatly mistaken would meet all the requirements of the P. W. D. and hereby making it possible to do away with the necessity of importing one single stick from any other province whatever.

Mr. Vincent furthermore recommends the reserving of the Beraliakanda and Batapola "forests" to meet future wants, and calls them fine forests! What may be in the Beraliakanda forest, I am not prepared to state; but I can safely say that in the rather fine looking scrub which Mr. Vincent is pleased to call "forest"—at Batapolla—there is not one single tree that would turn out a bridge pile or beam, that would be accepted by the P. W. D. nor is it likely that there ever will be! The forest I have referred to as being near the Gindura contains ironwood, uberia, milla, mendora and pottuhal, kinds suitable for any purpose the P. W. D. may require timber, besides other valuable kinds such as wanamie, tawena, keena, del, &c. one tree of which containing as much wood as half-a-dozen of the Batapola trees!

Mr. Vincent has "proved" that the commonest sorts of timber sells well! It strikes me that had he to pay for the placing of it in the market, it would not have been the timber that was well sold!

Mr. Vincent has evidently had the greatest part of his information from village headmen,* whose interests, I believe, would suffer if the truth came out! The village headmen did not of course tell Mr Vincent that one or another of their number had a finger in supplying any timber required on any of the provincial or minor roads, in fact in everything wanted for Government uses. Something was of course to be praised, and they thought no great harm could be done by praising up the Batapola "forest."

I think I can safely say that there is no timber that the P. W. D. would make use of (except jak, and that is to be found in private gardens only) on the land you'd enclose if you drew a line from Galle to Nagoda, then on to Elpitiya, and on again at that distance from the coast as far as Bentota—this land being covered more or less with a healthy sort of scrub composed of the sort of timber that the Sinhalese could make the cattle-sheds, &c. Mr. Vincent refers to!—Yours faithfully, SYLVANUS.

* Surely in each province, the Foresters gave Mr. Vincent the best information they could?—ED.

TEA AND TEA-MARKS.

Rookwood, Deltota, 25th Sep. 1883.

DEAR MR. EDITOR,—I am glad to see, by Messrs. W. H. Davies & Co.'s letter in your issue of 20th, I was mistaken *this* time in supposing my estate mark had been pirated upon. I certainly did sell that firm 3½ chests of *Pekoe* souchong on May 16th last, with shipping mark "D." and estate mark "Rookwood" as usual, but I could hardly suppose this small invoice was for the Lane. With reference to other remarks, I should say purchasers of tea were quite justified in selling under the mark, or distinguishing name, on the chest, when they bought it, but not justified in using the particular mark of that estate if not affixed by the seller. I would however warn tea-growers that piracy of marks, locally, does take place. Many instances have been brought to my notice, and in one case the lowest China Congou as sold in the Pettah was sent to me in what was apparently one of my estate packets of Pekoe-souchong blend. It behoves us to be on the look-out, and I hope this little storm may not have been in vain.—I am, yours faithfully,

C. SPEARMAN ARMSTRONG.

DEGENERACY OF COFFEE FROM THE CHOICE OF INFERIOR SEED AND THE SELF-FERTILIZATION OF THE PLANTS IN THE ABSENCE OF BEES, ACCOUNTS FOR THE PREVALENCE OF *HEMILEIA VASTATRIX* AND ALL THE TROUBLES OF CEYLON AND INDIAN COFFEE PLANTERS?

DEAR SIR,—I have been prevented by various occurrences from supplementing before now those letters you published for me in the *Tropical Agriculturist* Vol. I. pages 15 and 310, regarding the probability of leaf-disease and decrease in cropping capabilities of coffee being ascribed to the degeneracy of the plant induced by the self-fertilization of the flowers on the parent tree, and I intended to have traced back to its source the prime cause why the flowers should have been forced to receive this self-fertilization instead of the more natural and acceptable cross. I will now however, as such a lengthened period has elapsed since those letters were written, reverse this procedure.

It is well-known that where large areas of one species of plant are under cultivation disease in some form or another is generally sooner or later developed, and the causes when finally determined vary considerably with different productions, sometimes from overcrowding, often through the mistaken introduction of varieties which are not suited to that soil. The cultivator in most cases endeavours as far as he is able to reduce the possibility of disease becoming epidemical, by the careful selection of new stock for the replenishing of his land from distant localities possessing similar attributes to his own soil. We, in Ceylon, have not done this with that care which is essential to success. Beyond selecting our seed from healthy trees giving a good sample from estates near at hand, little or no trouble has been exercised, and I am afraid it must be owned that, where clearings and many of them have been opened simultaneously in one district, seed was usually obtained anywhere and anyhow so long as it was put into nurseries in time, and it is to this very extensive manner of opening up fresh land that I ascribe all our present troubles and difficulties.

In 1856 there were 80,950 acres opened for coffee, and in 1869, when leaf-disease was first reported, this acreage had more than doubled itself, being then 176,467 acres—this in a period roughly equivalent to five generations of coffee; but during this same time the coffee in bearing had increased from 64,000 acres to 160,000 acres, or had nearly been trebled. Since then it has averaged about 5,000 acres per annum increase.

I may put my theory as to the derivation of leaf-disease into four stages:—first, to the wholesale destruction of forest; secondly, reduction in the number of bees present; thirdly, inefficient fertilization; and, lastly, the consequent fitness for the reception and retention of disease. The first needs no remark from me. Your "Directory" furnishes full statistics of the enormous acreage of forest-land that has been felled and opened for various purposes, and the diminution in the number of bees (that have by these means been expelled from their homes) must be marked enough even to the most unobservant; how seldom now does one note the swarms passing overhead compared with previously—they are in fact comparatively rare—and how rarely does one see honey in the planter's bungalow—not because his taste for it is less or the native's desire to appropriate it for his own use grown stronger, but simply because it is so seldom procurable; and this proves the absence of bees. Fertilization of flowers such as coffee blossom is chiefly through the agency of insects, bees occupying the principal position as instrumental in effecting it, and it may be seen at once from the manner in which in coffee the style is prolonged so far beyond the stamens and its slight droop towards the lowest petal of the corolla, that it is admirably adapted to be fertilized by the means of bees which generally alight on the lowest petal, and so first have to brush past the stigma, thus depositing pollen from some flower they have visited previously upon it, and then, after passing the style on their way to gather nectar from the centre of the corolla, come in contact with the stamens, the dollen from which fertilizes the next flower they visit. All hermaphrodite flowers accept pollen from another one of the same species in preference to their own, but fertilization can of course readily result from the application of their own pollen; and Darwin has conclusively shown that the progeny of self-fertilised flowers possess less vigour than the parent plant and are more susceptible of disease, and in those plants that have many seeds the number produced is very much smaller.

The loss of vigour, unless watched for in the young coffee plants, would be at first very difficult to ascertain and would easily pass unnoticed, but the coffee would be steadily fitting itself more each generation for the recipience of any disease. We have no reason to doubt that the spores of *hemileia vastatrix* have always been present though in inappreciable quantities, and thus it might be some time before a spore would chance to be blown upon a plant that had arrived at that stage when it becomes a suitable host and then the production of fresh and numerous spores would naturally be rapid. It was as far as I know on a young clearing, or at least on an estate of no great age where *hemileia vastatrix* first declared itself, though I believe it must have shown in several places about the same time as other clearings would offer the same facilities for its development, and once fairly started the rapidity of its increase would be very great for a variety of reasons, from the immense numbers of spores that would now be set free to commence their baneful progress, compared with what had previously been in existence, and from the quantity of land injudiciously selected and opened, and not suited for coffee cultivation, where disease would readily find a home, and subsequently arrive at such an overwhelming force that coffee generally is attacked. Leaf-disease having thus established itself, what is more natural than that it should be followed by other ills. Let us take, for instance, grub, adopting the decayed root theory. We all know too well the continual loss of leaf, and how the separate organs in the tree are thrown out from performing their proper functions by this loss, how as the twigs and branches died back a corresponding quantity of the roots were not required, decay commenced, and there was the proper food in quantity for grub to thrive and increase on. The recovery of some coffee from the attacks of grub might be accounted for by the prevalence of leaf-disease fluctuating in a measure with the weather, and where the ravages of disease ceas d for a term, the balance between leaf and root would be restored and the tree would improve slowly, the grub in fact having pruned away the diseased roots. In Dolosbage, in 1878, the coffee in places used to die out in small patches that increased annually, and, no doubt, was the result of this decay in the roots, followed by very wet weather ; this would cause canker in the tap-root, by the other roots not being able to absorb the moisture collected round them, and so spread from tree to tree as is seen in orchards at home. That *H. V.* has affected the bearing capacities of the coffee is undoubted, and this quite apart from the alteration in the seasons we are at present experiencing ; microscopic investigation reveals that both in old and young coffee the pollen is often immature at the proper period for fructification, and sometimes is entirely absent ; this cannot be laid at the door of seasonal influence.

It is an old saying that misfortunes never come singly, and the truth of it is exemplified in our case by the manner in which the seasons are so to speak out of joint. The bearing wood is from this cause green and immature when wanted, and, when the trees do their best to crop, the blossoms are rendered abortive by a semi-deluge ; if some succeed notwithstanding in being able to set, it is in great part rotted off whilst still green by superabundance of wet. But this may really be, in a measure, a blessing in disguise for those who possess coffee of a superior stamina, and which would succumb if allowed to bear as formerly, since being so weakened by successive attacks of disease an average crop would be too much for it to sustain ; and I cannot believe that such coffee is also doomed. The hand of man is unconsciously making provision for the survival of the fittest, by in a great many instances having to abandon land, and by planting up other weakly portions with tea and other products preparatory to the removal of the coffee, and he is aided by nature in this work by the collapse and death of plants through excessive weakness or from the attacks of grub or from the adverse weather. As this destruction of degenerate plants proceeds, a corresponding reduction in the multiplication of disease-spores must ensue until the minimum is reached, by which time the strength and excellence of the remaining trees will be fully established ; and this will be the proper time for the use of Messrs. Storck's and Schrottky's applications, so as to cause the permanent eradication of *Hemileia* with perfect success. This followed by the liberal application of manures and high cultivation, and no stinting of any kind at the first so as to complete the cure, and then the old capabilities of the coffee for bearing will be resumed for the natural term of its existence. When this latter arrives, Ceylon as a coffee producing country will be a dream of the past, as all the land suitable for its growth will have long before been taken up for other products ; but the lesson we are at present learning of planting different productions throughout the one area, or, in more homely phrase, of not putting all our eggs in one basket, will have begun to bear fruit, and Ceylon, like a phœnix rising from its ashes, will possess every prospect of a much more brilliant and lasting future.—Faithfully yours, "SWADDY."

RUBBER :—FURTHER IMPROVEMENTS IN HARVESTING.

New Peradeniya, 2nd Sept. 1883.

DEAR SIR,—I send you in a match-box a sample of Ceara rubber eliminated by a completely new method. The milk was taken from a tree tapped on the 18th of Sept. I found the milk flow freely, and also that the cambium in the previous cuts was renewing as well as could be desired. Will you kindly shew the sample to the broker who saw the Haputale samples and ask him his opinion ; also keep the sample sent you at the disposal of Messrs. J. M. Robertson & Co.—Yours faithfully, H. A. GILLIAT.

[The Haputale rubber cannot be compared in quality to the splendidly clean and elastic piece Mr. Gilliat sends : no spirit was used by the Haputale planter, but he got *quantity*. We are now writing to ask him to try and get 80 or 100 lb. weight from his trees which would be readily bought here and sent to Europe as a shipment to try the market.—ED.]

CINCHONA BARK ANALYSIS.

COMPLAINT OF A CINCHONA PLANTER AGAINST THE ANALYSES MADE IN AMSTERDAM.

(Translated for the "Ceylon Observer," by J. D. V.)

To the Editor of the *Bataviaasch Handelsblad*.—Dear Sir,—I feel sure that you will confer a favour on all cinchona planters by giving the following statement a place in your columns, as it will serve to show how our business is sometimes managed in Europe, and that it is of much importance to us to secure the services of some one in Amsterdam, who besides having an extensive knowledge of all that relates to quinine, should also possess the advantage of being a conscientious man.

In September 1881, it was thought advisable to uproot 4,000 cinchona plants of five years' growth, as from neglect and other causes they had not come on well and injured the general bark of the plantation. They yielded about 1,800 kilograms of bark. Before the sale, samples of this invoice were analyzed by Messrs. d'Ailly & Sons of Amsterdam, and the result was as follows :—

	Quinine.	Chinchonidine.	Other alkaloids.
Root bark	0·9	1·5	1·26
Stem do.	0·8	0·1	0·4

The analysis made here in India, although not sent with the invoice, gave :—

	Quinidine.	Chinchonidine.	Other akaloids.
Root bark	0·9	1·6	1·6
Stem do.	1·1	0·9	0·9

In November 1882, I began to uproot the other well-grown trees, then six years old ; and in February last, 90 bales, weighing about 5,500 kilograms were shipped. Samples of this invoice were also analyzed by Messrs. d'Ailley & Sons, and gave as follows :—

	Quinine.	Chinchonidine.	Other aokaloids.
Root bark	0·4	0 8	2·04
Stem do.	0·26	0·2	0 7

Whilst the analyses made in Java and forwarded with the invoice, showed the mean out of fifteen samples to be :—

	Quinine.	Chinchonidine.	Other alcaloids.
Root bark	1·3	1·4	2·9
Stem do.	1·4	0 9	1 9

It is not necessary to point out to you the inconsistency of these results obtained by Messrs. d'Ailly & Sons. I feel, however, very grateful to the o gentlemen for the insight they have thus afforded us, the cinchona planters. According to those analyses, we should do well to harvest our bark before the trees complete the age of five years, as immediately on attaining that age the percentage of quinine in the bark begins to diminish.*

I must not forget, dear Mr. Editor, to mention that the bales sent in 1881 and 1883 bore different marks, so that it was impossible for the above-named gentlemen to know that the bark derived its origin from the same enterprise. But more than this: notwithstanding that succirubra bark contains considerably more alkaloids than the bark which I shipped yet, *mirabile dictu*, the latter fetched the same price, and in some cases higher prices.

When it is considered that the succirubra bark, is *par excellence* the pharmaceutical bark, we must come to the conclusion that the purchasers have set at naught the analyses of Messrs. d'Ailly & Sons, and that they have considered the bark I shipped suitable for the preparation of quinine.

Assume the price of sulphate of quinine to be 150 guldens per kilogram, then according to the analyses made in Java (compare *s. v. p.* with that of Messrs. d'Ailly & Sons) the purchasers have paid about 1 gulden per kilogram and for every 1 per cent of sulphate of quinine, whilst, according to Messrs. d'Ailly & Son, 4·50 per kilogram and for every 1 per cent of sulphate of quinine should have been paid, seeing that the bark fetched 1·60 guldens per kilogram.

If the analyses made in Amsterdam were correct, the purchasers stood to lose 300 guldens per kilogram of sulphate of quinine.

I think that by the above I have fully established the great need that the cinchona planters have for a trustworthy chemist, such as Bernelot Moens, to attend to their interests in the mother-country.

The editors of other Indian newspapers are most earnestly requested to take the matter up.

I thank you before-hand for the place which I feel sure you will give this representation in your extensively circulated sheet, and I remain with the greatest respect.—Yours most willing servant, W.

[Translated from the *Bataviaasch Handelsblad*, 8th September 1883.]

TEA IN CEYLON.

DEAR SIR,—The thanks of all interested in Ceylon are due to Messrs. Armstrong and Owen for their valuable papers on tea cultivation, which as far as can be seen at present is to be the chief agent of our return to prosperity.

Mr. Owen's remarks on the late Mr. Cameron's system of pruning and plucking seem to be backed up by weighty reasons; though it seems probable that such a system in a latitude where the tree is forced to take a season of rest at the end of such a vigorous course of plucking, without producing any of the breathing leaf it required, might be attended with more disastrous results than in Ceylon.

Does it not suggest itself to you after reading Mr. Owen's paper that the fact of over cropping being possible, tends to equalize the value of tea in the hills with the lowcountry as regards yield. In the lowcountry the climate is capable of forcing out an amount of leaf which neither the trees nor soil seem able to stand permanently, whereas at higher elevations, a more vigorous style of treatment might with safety be adopted, the vigour of trees and quality of soil warranting without fear of exhaustion, even a heavier yield than in the lowcountry.

If Ceylon has the decided advantage over India represented by Messrs. Armstrong and Owen, there can be little doubt but that we shall ere long see capital diverted thither which would have been invested in opening new gardens in India and that we shall ere long see many here with the object of investment.

In view of this, would it not be lending a helping-hand to coffee estate proprietors by increasing the value of all existing properties if Government refused to sell any fresh land for the present? I do not think you could have had this view in mind when you deprecated the withdrawal by Government of the lots lately advertized for sale; but as there seems little doubt that existing coffee estates are as well suited for tea cultivation as new land, it is an important one not only to estate proprietors and to the credit of the colony in preventing abandonment of cultivation of coffee estates, but also to the Government railway.—Yours truly, MERCATOR.

In calculating cost, it must not be forgotten that we cannot rely upon present exchange; and the 6d per lb. cost of production may again become 7½d.

* What will the well-known quinologists Bernelot Moens, Howard, &c., say to this discovery of Messrs. d'Ally & Son.

MR. OWEN ON THE PRUNING AND PLUCKING OF TEA.

Oonoonagalla, Madulkelle, Sept. 29th 1883.

DEAR SIR,—If your correspondent "J. W." will kindly read "Darjeeling Tea Company" for "Land Mortgage Bank," an error which crept into my MS., he will find my figures about correct (vide *Indian Tea Gazette* of June 16th, 1883, page 276). The former Company is a very flourishing concern, the latter is not so, and in all comparisons I have alone selected Indian plantations of the former description.

I am sorry that he and you should agree that my remarks on the late Mr. Cameron's pruning and plucking are too sweeping. It must first be remembered that Mr. Armstrong in Dikoya was addressing an upcountry district and alluding solely to hill tea, and that I premised my remarks by stating that I alluded to tea as it was fitted for replacing coffee in the coffee zone. The systems of pruning which are advisable on the hills and in the lowcountry are by no means identical. The vigorous and rapid growth in the latter case necessitates a much severer mode treatment than in the former. I had intended going fully into this subject in the course of letters on Indian tea, but your correspondent's remarks force me to say a few words in defence in anticipation. Those with whom Mr. Cameron most fully discussed the subject state that his intention was to cut the bushes across in a few successive years, after the pruning, in the mode advocated by Mr. Armstrong. The principle which guided him was that of cutting down the bush to commence with, and then for successive years, their number depending on circumstances, cutting through the young red wood of the previous year's growth, for it is this wood which gives the most vigorous crops. The *system* is identical with that advocated by others, but we maintain that with young tea at a high elevation, the bush should not be cut too low. Apart from this subject, the great point is that the severer the pruning, the easier should be the successive plucking; and the severer the plucking the severer does the following pruning become in order to remedy its effects. Now, had the lowcountry places pruned by Mr. Cameron, been allowed to grow well up and been lightly plucked, there would be good pruning wood this year, and the bushes could be cut across above last year's level, with the result of a large crop. I have been told by one who knew Mr. Cameron intimately that he saw that the plucking had been too severe and admitted it freely. What is the result? That the places in question have to again in many cases prune lower than last year, *because* the close plucking did not allow of the formation of good pruning wood. Your correspondent asks what is the main result of the plucking. I say, thin wood unfit for the knife. Now Mr. Cameron's object in this plucking was an evident one and has been beyond measure successful. He has made fine teas which have raised the reputation of Ceylon as a tea-producing country to the top of the list; with this light thrown on his object, we see plainly the result he was aiming at and can appreciate its success, whilst all interested in Ceylon tea will reap the benefit. Were Mr. Cameron still alive, he would institute a different system of plucking this year from last, and it was to warn those who might think that a *continuation* of the work of last year was possible that I spoke strongly on the subject. There are not three systems at present generally practised, but one system differing in its details according to elevation and other circumstances, and modified greatly by Mr. Cameron for a *special object* as now appears.—Yours faithfully, T. C. OWEN.

RUBBER HARVESTING.

2nd October 1883.

DEAR MR. EDITOR,—Can you enlighten me on one point regarding Ceara Rubber cultivation. Your correspondents on the subject, all mention the results of tapping rapidly, but has the rubber tree been tapped and after the lapse of a year been *tapped again* with the same encouraging results, as I have heard that the second year's tapping results in a complete failure.—Yours faithfully, B. B.

[The Rubber industry is not old enough in Ceylon to settle this point yet, and planters are hoping to have fortnightly, rather than annual, tappings. —ED.]

A DEFENCE OF MR. CAMERON'S SYSTEM OF PRUNING TEA IN CEYLON.

SIR,—I have read with much pleasure and no little profit Messrs. Armstrong's and Owen's essays on tea, lately published in your paper. Though the former gentleman prefaces his letter with the remark that he refers only to plant tea above 3,000 feet, we lower country tea-planters have still found plenty to interest us in his cheery paper. Mr. Owen's six weeks' experience of the Indian tea plantations is also instructive. But I have been greatly surprised that none of my brethren possessing the pen of a ready writer, who still, in spite of Mr. Owen's strictures upon it, believe in Mr. Cameron's method of working and manufacturing tea (probably because they know *what* that method was) have not taken up that weapon on behalf of their late chief. But since they are "silent still, and silent all," my unwonted pen must endeavour to do some justice to a man whose experience of Indian tea cultivation extended over nearly four times as many years as Mr. Owen's has weeks. Mr. Owen says:—"Mr. Cameron introduced a severe cutting down system in pruning." Now, to the "gentle reader" that would, I imagine, give the idea that Mr. Cameron's "murderous method" was an annual one. Had Mr. Owen ever talked with Mr. Cameron on the subject, or asked anyone who had done so, he would have learnt that Mr. Cameron's reason was this: on coming here, he found bushes 7 to 8 feet high, with "hard and gnarled" stems 4 and 5 feet high. These he cut out, in order to shape the bush, a process that would have been unnecessary had we had the benefit of his experience a few years earlier, and which will not be again necessary, we trust, for some years to come. Had Mr. Owen seen the results of *not* cutting out the hard wood, he might with reason have said he had seen tea looking as though a fire had passed over it. Again "Magister docet," "the master teaches," that Mr. Cameron intended to ruin our trees, or render a long rest necessary, (as we are told he did in India) by an over severe system of plucking. As you, sir, and everyone else who had the benefit of Mr. Cameron's experiences are aware, on his arrival here, he found the state of Ceylon tea, with the exception of a *very* few estates, at such a low ebb, in the London (or any other) market, that he thought it necessary to pluck considerably finer than he would otherwise have done, to try and raise the prices from the depths into which they had fallen, or rather from which they had never arisen. When this was accomplished, his purpose was to pluck coarser leaf, and allow the flush to run a little longer. This intention, I believe, his other superintendents as well as myself are now carrying out. How wonderfully soon he succeeded in raising the prices let the current brokers' reports testify. Can Mr. Owen put his hand on his heart, and say, that the fine price lately realized for "Avisawelle" teas would have been obtained, if that estate, and, say, two others were the only three in Ceylon sending respectable teas?

I am told that Mr. Owen has lately made a tour of the Yatiantota and Avisawelle estates. Did he find Elston looking as if a fire had past over it, or as if it were unable to do its duty in the coming year as a well behaved tea estate should? Did he find Atherfield? Ruanwelle? Dunedin? Sembawatte? Strathellie? I have lately taken the same tour, and none of them struck me in that way. Sir, "I" too (as the gentleman said when he had impeached Warren Hastings) "have done"—and, now, Mr. Owen, having done my duty as far as in me lay, to my late V. A.'s memory, permit me to take you by the hand (I have met you so often in print that I feel as though I knew you personally, as I hope to do some day) and thank you cordially for the many useful hints in your paper. I take it we are both equally anxious for the welfare of Ceylon tea at heart, but let us agree to differ on certain subjects, as I don't think you will convince me and I am sure I shall not convince you, and let us see whether your "flat plucking surface" or my "all round the hat" business will first land us in that happy position of 1,000 LB. AN ACRE.

P. S.—I am not interested, I regret to say, in cinchona or cardamoms, but any hints Mr. Owen can give me as to pepper, chillies, vanilla, and nutmegs, will be most gratefully received.

COFFEE-GROWING IN SOUTH AND CENTRAL AMERICA.—The London *Times* of Sept. 7th gave prominence to the following paragraph of special interest to the planters of Ceylon:—"COFFEE CULTIVATION IN SOUTH AMERICA.—It appears that the high rate of wages which prevails on the Isthmus of Panama is attracting labour, and making the production of coffee unprofitable in Costa Rica, Columbia, Venezuela, and even Brazil. Only in Spanish Honduras and British Guatemala can coffee now be said to be profitable. The planters in Nicaragua, according to latest reports, have a difficulty in clearing their expenses. In countries farther south an annual loss is incurred, while in Brazil the shrinkage of the crop has attracted the serious attention of the Government. Wages have gone down in Honduras and Guatemala, and if the present depression in the price of coffee continues, the coffee planters of Brazil, Columbia, Venezuela, Costa Rica, and Nicaragua will be ruined, while the more fortunate planters of Mexico, Guatemala and Honduras will have all they can do to hold their own. Notwithstanding this gloomy outlook, however, coffee in Mexico is still believed to be the coming industry, because the railways running from the United States will bring the plantations into direct communication with the consumers. This advantage, together with fairly cheap labour, should prove decisive in the trade, supposing Mexico to have equal facilities with other coffee-growing countries, such as Costa Rica, Ceylon &c."

MR HAY ON THE TEA ENTERPRISE IN CEYLON.

Marc Antony prefaced a speech which moved his hearers to a "sudden flow of mutiny," by declaring, "I am no orator, as Brutus is." And so Mr. Hay deprecates the idea that he possesses the strength of style of an Armstrong or the fullness and facility of an Owen. He has just given in plain words his ideas of pruning and plucking, and they will be none the less valued if the graces of style are, as Mr. Hay modestly supposes, absent. Mr. Hay was unfortunate in being compelled by illness to leave the island for a time, just at the period when a considerable number of estates were arriving at the bearing stage, and the late Mr. Cameron was correspondingly fortunate in the time of his arrival. There can be no question that—whatever his antecedents or his system may have been—Mr. Cameron gave a new and brightly cheerful aspect to the tea enterprize in Ceylon and the prospects of those engaged in it. We can only regret that he is not here to speak for himself, as Messrs. Armstrong, Owen and Hay follow each other in more or less caustic criticism of what they deem his over-severe system of pruning and plucking. There are a good many tea-planters who consider such criticism as *ultra vires* (spelling the second word with a *u* instead of an *e*,) and who pass it by as a digression or parenthesis, in matter which would remain very valuable were the surplusage deleted. As far as Mr. Hay is concerned, he did good service to the tea enterprize before the advent of Mr. Cameron, and long may he be spared to point to other estates besides those he names, as strong proofs of the good effects of the Hay system of harvesting tea. Due value will be attached and careful attention will be paid to Mr. Hay's weighty words on plucking and pruning; but we suspect that more sensational than any figures of speech which the tea expert could have used, even if he had resorted to the Mandarin dialect of the Chinese language, will be the effect of the bare arithmetical figures he gives to indicate the cost of opening 250 acres of tea land in Ceylon. Instead of the exodus we have been lamenting, we may look for an immigrating rush, especially of Indian tea-planters. They will open their mouths as well as their eyes at the statement that for a net cost of R271 per acre, the area of land named can in Ceylon be brought into bearing in its third year, fully planted, quite clean and perfectly pruned; supplied with a tea house costing R3,000; a water wheel at R1,500; an "Excelsior" Jackson's roller at R1,690 and a Kinmond's Dryer at R2,860, besides extra pulleys belting, &c. But their amazement will reach a climax when told that in the fourth year the estate will yield 80,000 lb. of tea (320 lb. per acre,) which valued at 60 cents Ceylon currency, (less than 9 annas per lb.) will realize R48,000 and leave a profit of R21,045 on the year's working. At this rate of progress and calculating on 400 lb. per acre in the fifth year, that year would see all capital and interest reimbursed, an estate free of encumbrance and money to the good. The natural feeling will be "Too good to be true!" Mr. Hay, however, with his credit as a tea planter at stake asserts that he has gone into no extremes; and judging by what has already been done in Ceylon, while hoping that tea may be spared any similar attack of blight to that which (only temporarily, we hope,) dethroned coffee, there seems no ground for impeaching Mr Hay's sanguine and cheering estimate. If *hemileia vastatrix* has discovered coffee, the Ceylon planters have discovered tea, and there is good reason for hoping that we are now experiencing the first effects of that tide which taken at the flood will bear the colony on to renewed fortune. There is, of course, a reverse side to the picture as to all others. Well let us have both sides fully before us; weigh all the evidence *pro* and *con* and see how the index points. At present it seems to stand steadily at "TEA AND PROSPERITY."

MR. C. A. HAY ON THE TEA PLANTING ENTERPRISE IN CEYLON.

SHOWING HOW A 250 ACRES TEA ESTATE, FITTED WITH ALL NECESSARY MACHINERY AND APPLIANCES, CAN BE BROUGHT INTO BEARING IN THE THIRD YEAR AT A NET COST OF R217 PER ACRE, WHILE GIVING A PROFIT OF R21,000 IN THE FOURTH YEAR; SHOWING ALSO HOW THE TEA SHOULD BE PRUNED AND PLUCKED.

DEAR SIR,—I have read with much pleasure both Mr. Armstong's and Mr. Owen's papers on tea, and in nearly all that has been written I agree with both gentlemen except with regard to pruning.

Mr. Armstrong considers that at first pruning (or topping as it is called in the island) the bushes should be cut across at 3 feet, as it is from this height that they begin to form themselves, and the wood below to thicken; at the next pruning where 2 or 3 inches new wood is left the bushes are too high to be plucked properly by small children, and thus get damaged by their pulling down the shoots and, when unable to get at the flush, push their way into the centre and break off the delicate lateral branches.

The system I have always carried out has been (both in India and Ceylon) to equalize the whole of the young tea at 15 or 18 months old to 18 inches, and I have then left them until the end of the 2nd year (of course if the new growth is very vigorous a little leaf can be plucked a month or so before the second pruning); by doing this the upward tendency of the growth is checked, and the side branches begin to expand; also from every single stem cut, from two to three new shoots will grow, and thus form a good plucking surface. As the bushes can only grow in the width of half the space they are planted in, let it be 5×4, 4×4, or 4×3; it stands to reason that if they are 2, 3 or 4 feet high they have just the same actual space to grow in, then why have bushes formed at such a height that they cannot be properly plucked by children of whom there are so many on estates, and who generally bring in quite as much leaf as the women?

At the second pruning I would again cut straight across the bush leaving at least 4 inches of new wood. I would carefully clean out all whip wood, bangy [hard] growths on the stems, and cross growths, and cut back close to the stem any branches inclined to trail on the ground. I would on no account cut back any of the lateral branches, but let them grow unchecked until they are the same height as the shoots first plucked after this pruning.

At the third pruning I would recommend no particular height but take the bushes at their widest part and cut these; the cooly has only to cast his eye at the outside of the bush he is going to prune, and, having found out the spot, he should first of all cut out the centre branches, then, always cutting towards him, go round the bush until he has got it to look flat, and then he should cut out as on other occasions all whip wood, bangy growth and cross growths, letting the centre be if anything more exposed than the outside. Should there be any white wood he ought to cut this out nearly down to the stem or branch from which it springs; then a new shoot will grow, and, when up to the height at which plucking has begun, can be checked; but on no account should any flush be taken that is not above the point at which pruning has been carried out; by doing the work in this way the bushes need not be cut down until they become too high and will keep free from crows' feet.

On commencing plucking in the 3rd year I would give the coolies sticks of the desired height to pluck at, so that they could make no mistake; the bushes having been pruned to 22 inches, a stick 28 inches would be quite long enough and would be a guide to show them that nothing under that height was to be taken. I would take the tip, first leaf, and ½ the second, and, when the flush was inclined to go or had gone bangy, I would take the *first leaf* only leaving the bud to develope; by doing this a bangy flush is very often forced on and does not harden up its leaves. On no account would I let the coolies pluck the side-leaves unless above the level of pruning.

I would make the women pick off all seed and flower each round for the first three or four rounds, so as to give the bushes nothing to do but to make wood and flush; if seed is required keep a piece apart for that purpose, if possible keep your bushes free from seed if you want them to flush well.

As I may not be understood when I say "if the flush is inclined to go or has gone bangy," I mean if on account of raw, nasty weather the flush is not inclined to grow but instead of a tip appearing after having developed the last leaf there is only an open leaf at the top of the flush, take this if soft and put in the basket, if hard throw it away.

About the begining of the rains, May-June, I would change my mode of plucking and instead of taking the usual 2½ leaves I would pluck three full leaves with stalk attached at one time; by doing this the leaves do not cling together in the baskets, and, when spread on the withering trays dry and wither in half the time that leaf plucked in the usual way does, the only thing against this is that the next flush does not come on so fast, but the difference in manufactured tea makes upfor this.

Just before the close of the season or before pruning, I would not be too particular as to the number of leaves left on a shoot, but would take everything that would make tea as the weather is uncertain and if you think of leaving a shoot for next round because too short, you find it has by that time gone hard.

Along with Mr. Owen I condemn the late Mr. Cameron's system of plucking young tea in its 2nd year and consider it ruinous and bad, because no young bush can develope and make strong wood for the future if it is worried and plucked until it has the appearance of a worn-out heather-broom. By this system of taking off everything that can be got very fine tea is made, and it is no wonder that such high prices are got by some estates, and it astonishes me that prices even double have not been got.

For the first three months after pruning, pluck very carefully; begin by getting sufficient good wood for next pruning and, when you have that at each round after taking the tip, first leaf and half the second, see that you have two fully developed leaves under what has been taken; after this one-and-a-half is quite sufficient then towards the close of the season pluck as I have before recommended. By working in this way, the bushes will spread and very soon touch and there will be a good plucking surface. After carefully watching the bushes in Ceylon I have come to the conclusion that it is impossible to harm them (after the new wood has grown well up) by careless plucking as is the case in India; the only thing that happens is that the next flush is delayed, but I have seen in this country the very eye-buds taken out before pruning so that the women might go to other work, and pruning having been delayed and the weather become warm all hands have had to go and take off a good flush from bushes that were never expected to flush after such treatment.

Estates that were pruned and plucked under my instructions up to the arrival of the late Mr. Cameron, have done well and are now capable of giving much more than they ever would, had they been treated harshly in their infancy. Gallebodde, Mariawatte, Allagala and Agrawatte show as fine bushes as one wishes to see and are all clean grown and cover the ground. I have always been called a coarse plucker by the late Mr. Cameron, because I let my flush run long and took an extra leaf-making to souchong; yet the Windsor Forest averages have been good. I allow my yield was more than it should have been, but circumstances over which there was no control was the cause.

As you mention in your paper that on the last-mentioned estate, there was a bush 14 feet by 10, I can verify the fact; and this was arrived at by careful pruning and each year drawing the bush out by leaving the side-shoots until they were above the level of pruned surface. When pruned last by me the height was about 2 feet 8 inches and yet it was this width. I would not have written this had you not asked me, as I am no great hand at putting my ideas and opinions on paper; if you think it worth anything let it see the light of day or if not the light of the fire.

I enclose an estimate for bringing a tea estate into bearing in its third year and have added the fourth year as well; it is supposed to be in an accessible district and opened from an adjoining estate. I have provided for making tea by machinery in the third year and for having proper factory and all conveniences. Of course there may be errors, still I have done my best to estimate everything at an ordinary average and have not gone to extremes either way.—Yours faithfully,

C. A. H.

Estimate of cost of opening out a Tea Estate of 250 acres, of which 100 acres is in the first year and 150 acres in the second, in an accessible district.

Cost of 300 acres of forest land at say R20		R6,000

1st Season:—1st July 1883 to 30th June 1884.

Felling and clearing up 100 acres at R15 ...	R1,500	
Cutting pegs, lining, holing, filling in, at R22·50 ...	2,250	
Planting and supplying (say 10 per cent) ...	480	
Weeding, for 16 months at R1 ...	1,600	
Nurseries for 25 maunds seed ...	1,750	
Roading in ordinary cases at R4 per acre ...	400	
Draining with fair amount of blasting at R9	900	
Lines for coolies: 10 rooms permanent R400 20 rooms temporary R200 ...	600	
Contingencies, (Survey, tools, medicine, stationary, etc,) ...	500	
Superintendence ...	1,000	
		R10,985

2nd Season:—1st July 1884 to 30th June 1885.

Felling and clearing up 150 acres ...	R2,250	
Cutting pegs, lining, holing and filling in ...	3,375	
Planting and supplying ...	800	
Weeding 150 acres for 16 months and 100 acres for 12 months ...	3,600	
Nurseries for 40 maunds seed ...	2,800	
Topping 1st 100 acres at R2 ...	200	
Roading 150 acres and upkeep of roads in 100 acres ...	650	
Draining 150 acres and upkeep of drains 100 acres ...	1,400	
Additional lines (permanent) 16 rooms ...	640	
Superintendent's bungalow and furniture ...	3,000	
Contingencies ...	1,000	
Superintendence ...	2,600	
		R22,315

If the bushes are well-grown after pruning towards the close of the season, some leaf might be plucked and sold to the nearest estate.

3rd Season 1st July 1885 to 30th June 1886.

Weeding 250 acres at R1 ...	R3 000	
Nurseries and supplying ...	1,000	
Topping 150 acres at R2, pruning 100 at R4·50	750	
Upkeep of roads and drains at R2 ...	500	
Permanent tea house 100 by 20 completely fitted ...	3,000	
Contingencies ...	1,000	
Superintendence, including tea house man	3,800	
1 "Excelsior" Jackson's roller £130 plus 30 per cent freight &c. ...	1,690	
1 No. 2 Kinmond's Dryer £220 do do ...	2,860	
Pulleys, belting, shafting, &c. &c. ...	750	
1, 20 feet Water-wheel, and pit ...	1,500	
Cost of Plucking, Manufacturing, Packing, &c. 30,000 lb. tea, (240 lb. from 100 acres 40 lb. from 160) by machinery at 16 c. per lb. ...	4,800	
Transport charges to Colombo at 2 c. ...	600	
	25,250	
Cr. By value of 30,000 lb. tea at 60 cts. per lb.	18,000

COFFEE CULTIVATION IN CEYLON:

MANURING AND PRUNING.

From the Proceedings of the Dimbula Planters' Association.

Friday, 28th Sept., 1883.

The CHAIRMAN, addressing the meeting, stated, the business now before the meeting is the report presented, and which will be read to you by Mr. Keith, who acted as Secretary to the Sub-Committee. It speaks for itself, and I will make no remark on it, except to say that, as far as I know as one of the Committee, the enquiry has been carried on, and the conclusions drawn, without bias. That individual members of the Committee may have extreme views, I will not deny, but, I am, I think, right in saying that the Sub-Committee as a whole is not biassed for or against cultivation. There are, however, some points which, I think, should be borne in mind in discussing this subject, and, consequently, in considering this report ; and they are these, that, generally speaking, in the district we have estates growing coffee solely and on many of them unfortunately, mortgages and other debts. A state of things has arisen that makes it impossible to sell estates, and we must work them and pay off the debts by working them ; the question then presents itself to us, how can this best be done ? Some say, no doubt, by planting tea and cinchona ; and, gentlemen, I do not wish to say anything against planting tea and cinchona, but I do say this, how are we to live and pay interest on loans and also plant tea and cinchona, if our coffee gives no yield ? and I fear we have found out during the last three years that, if coffee be not cultivated, it will not bear. I hope it will not be inferred from what I have said that I look upon coffee as a means only for planting new products. Far from it, for I venture to say that in Dimbula there are many fields of coffee which, properly cultivated, those interested in them would be sorry to see planted with any other product. But I wish to point out as distinctly as I can that it is impossible for those who have determined to supersede coffee with tea and cinchona to ignore and neglect their coffee. We have in many cases been disappointed with our coffee, but, as far as I can judge of the present state of things in the district generally we must look upon coffee as our bread and butter, or perhaps more properly speaking, as our curry and rice, and cinchona as our beer and whiskey. We may be able to do without beer, but we cannot do without bread and butter; so that gentlemen, it comes to this : all of us coffee planters, cinchona planters and tea planters must face the question how can we best make our coffee pay ? It was with this view that the sub-committee was appointed and I think that you who read the report carefully will see what style of cultivation has given the best results. With regard to the advisability, or I would rather say the vital necessity of cultivating our good coffee or not, look back on the results of the working of the past three years. We learn some lessons which should not be ignored by us ; for instance, what has been the result of neglecting coffee altogether? The result has been no crop at all, and I venture to say that, three years ago, few of those who determined to stop cultivating their coffee anticipated the result. They may have thought that in place of getting 5 cwt. per acre they would get 3 cwt. per acre, but did not anticipate getting 3 bushels per acre or not enough to keep an estate in any sort of cultivation. And what again has been the result of neglecting your coffee so far as carrying on necessary works out of season in order to plant and work cinchona. It has resulted in disappointment in very many cases it has been leaving a reality to run after a shadow ? I do not mean to say we should not plant cinchona, and that largely, but, looking back, I feel sure that loss has been sustained by neglecting coffee works at their proper season. And now, gentlemen, having explained to you what the points for consideration are, namely, that having coffee estates, we must try and determine how best to make them pay in the *immediate* future, for this is of vital importance to many of us You will now hear the report read.

The report was then read as follows :—

REPORT OF SUB-COMMITTEE ON MANURING AND PRUNING OF COFFEE.

The principle adopted by the Sub-Committee in the inquiry they have undertaken has been to find out from reliable sources, verifying where possible the information given them, the actual results of the cultivation of coffee in the district, it being their wish to lay before the Association, not their views or opinions on these points, but actual facts as far as they can be arrived at in an inquiry of this nature, so that it may be possible for anyone who reads this report to form his own deductions. With this view they have sent a set of questions (which will be found in the appendix) to estates which they considered methodically cultivated and from their position representative. These questions have been fully and in many cases carefully answered, and the Sub-Committee take this opportunity of expressing their thanks to the managers of estates referred to for so readily giving them information. The Sub-Committee have made an abstract of the answers they have received and have tabulated them in the appendix under the different questions. Names of estates are not given, but each estate that has sent answers, has for the purpose of this report had a number given it, which is the same whenever the estate is re-referred to. The following are the results arrived at by the Sub-Committee from the information they received :—

MANURING.

Question 1. The general range of crops resulting from manuring appears to be from 3 to 10 cwt., and the average 5¾ cwt.

2. Crops from unmanured coffee nothing to 2 cwt.

3. Cattle manure and bones appear the favourite, in fact steamed bones and bone meal in various mixtures have given the best results. Castor-cake is regarded by some as a dangerous manure.

Question 4th. Various methods.

Question 5th. January to April for cattle manure, but some advocate after the blossoming season. Artificial, April to August. Cost of artificial manure R45 to R70 according to the quantity applied including application.

Remarks.—We find from the answers given that in some cases the oldest fields bear the best, some managers speak of the disappointment they have experienced in manuring and cultivating generally, fields with a western exposure and wind-blown ridges, and the Sub-Committee venture to express the opinion that much disappointment in cultivation of coffee arises from unsuitable land being worked in coffee, while if this unsuitable land was planted with other products the general results from working coffee would be much better.

The estate managers in the Wallaha district and its neighbourhood who have replied to the questions referred to, look upon grub as the chief cause of the late sudden failing of the crops.

PRUNING.

Question 1st.—In answer to this question, pruning immediately after crop with one exception. Handling from May to August, and October to November.

2. A knife handling in some cases looked on as good.
3. Moderate to heavy the general opinion.
4. Found unpruned coffee results bad. Cost of pruning and handling R10 to R14 per acre.

G. A. Talbot	Wm. D. Bosanquet
W. B. Jackson	Wm. Keith
W. Smith	J. Cantlay
Thos. Mackie	James Sinclair.

APPENDIX.

QUESTIONS ON MANURING.

Questions referring to seasons 1880-81, 1881-82, 1882-83.

Question 1st.—On your estate what crop was picked from fields manured in preceding year?

Answers received.

Estate Elevation.	No.	*District division.*	
4,400 ft.	1	Rail Gorge.	Manured in September and October 1881, told on the blossom of 1883.
4,000 to 4,600	2	Lindula.	6 to 8 cwt. per acre but generally uneven.
4,500	3	Lindula.	5 to 1 cwt. uneven.
3,200 to 4,300	4	Dimbula.	Crop much more than on unmanured.
4,000	5	Lindula.	Manured between years 1876 & 1880 gave 5¼ cwt.
4,500	6	Lindula.	Crop by manuring during the last four years only an average of 3½ cwt. For four years previous to 1880 with same cultivation average of 8 cwt. No cinchona in coffee previous to 1880.
3,900 to 4,200	7	Dimbula.	2½ to 7 cwt.
4,000 to 5,000	8	Agras.	4 to 10 cwts. but less now.
4,200 to 4,600	9	Agras.	5½ to 3½ cwt.
4,300	10	Lindula.	3 to 5 cwt.
3,200 to 4000	11	Dimbula.	¾ to 8 cwt average 1881 5¼, cwt av. 1882 6¼cwt.
3,100 to 4300	12	Dimbula.	In favour of manured, nearly all the crops came from manured coffee.
3,200 to 4000	13	Dimbula.	Cattle manured 8 to 6 cwt. Artificial 6 to 4 cwts.
4,000 to 5000	14	Agras.	Favourable to manuring 4½ cwt.

Question 2nd.—What from the unmanured fields in the same years?

Answers :—

1. No answer given.
2. Considerably under manured.
3. Very little, one field gave 3 cwt.
4 As a rule very little.
5 2 cwts. per acre.
6 No answer given.
7 ½ to 1½ cwt.
8 No unmanured coffee.
9 No account kept.
10 No answer given.
11 Average 3 cwts per acre.
12 Very little crop from unmanured fields but exposure must be taken into account.
13 1½ to 4 cwt.
14 No unmanured coffee.

Question 3rd.—What manure gave the best; and what the worst results?

1 No answer given.
2 Cattle-manure or sombreorum the best cocoanuts poonac the worst.
3 Best plain bones or bones and sulphate of ammonia, worst coconut poonac.
4 Cattle-manure and bone-dust or steamed bones the best. Blood and guano the worst.
5 Bone-dust and steamed bones the best. Castor-poonac the worst.
6 No reply.
7 Castor-poonac and bones, and cattle-manure the best.
8 Cattle-manure, bones and poonac and Cross' manure.
9 Cattle-manure only applied.
10 Cattle-manure, bones and wood ashes the best. Peruvian guano the worst.
11 Cattle-manure and bones as bulk the best. Crossman & Paaluis' as artificial the best.
12 Cattle-manure and bones the best; bone meal and cocoanut-poonac next best.
13 Cattle-manure best; lime worst.
14 Cattle-manure the best; vegetable stuff and lime the worst.

Question 4th.—What mode of application have you found to answer best?

Answers :—

1 No answer.
2 Do.
3 For artificial, semicircular holes above tree; bulk, square holes between every four trees.
4 Saucer-shaped holes dug with a fork and scraped out with hand.
5 Soluble manure scratched in on surface; and regular manuring semicircular hole one foot from tree.
6 ———
7 Circular holes for artificial; and square for bulk.
8 Generally holing, but occasionally digging.
9 No opinion given.
10 Circular holes.
11 Forking.
12 Close to the tree, must be varied in its application.
13 Holing the best. Digging gives the quickest results.
14 Cutting large holes between four trees.

Question 5th.—What months have you found to be the best for the application of (a) bulky manure, (b) artificial? In answering the above questions kindly give the approximate cost of cultivation including manure, also the elevation and exposure of the fields in question, as well as the age of the coffee with any other information such as the weather report of the blossom seasons that you think may be useful to the Sub-Committee.

Answers :—

1 Cost of manure and application R45 per acre.
2 August and September the best for artificial; cost R45 to R50 per acre. Cattle-manure applied August and September and cost R90 to R100.
3 No answer. Grub the chief cause of short crops.
4 Bulky manure January; artificial April, May. Cost of bulky R50 to R60; artificial R40 to R50.
5 Regular manuring immediately after crop.
6 ———
7 Cattle manure January; artificial manure April and May. Cost: cattle manure R80 per acre, artificial R45. The oldest coffee is the best, and fields with eastern exposure gave nearly all the crops.
8 Bulk January and February, and prunings buried. Artificial June and July. Cost of cultivation including manure but not superintendence, crop expenses or buildings R47 per acre. Artificial manure cost R50; bulk R55.
9 Cattle-manure June to August; cost of application R25.

10 Early in season before end of April; cost of manure R60 to R70; applied R12 to R15.
11 Bulky manure as soon as possible after blossoming season. Artificial April to August. Cattle-manure cost applied R70, artificial R48 to 50. Total expenditure R120 per acre.
12 Early manuring January to June; cost of cultivation with cattle manure R150. Artificial R125, and average cost of estate R110.
13 Bulky manure January: artificial April and May; cost cultivation of fields R90 to R100.
14 After pruning.

PRUNING.

Question 1st.—What months have you found to be the best for pruning, and what for handling with a view to the following crop?

Answers:—

1 No answer given.
2 January, February, March and April for pruning; May, June and July for handling.
3 Commence pruning in January; handling in August.
4 ... ...
5 January and February pruning; May and October handling.
6 Early pruning; handling when required.
7 January, February and March pruning; June, July and August handling.
8 Pruning immediately after crop; handling May and June and August and September.
9 January, February and March pruning; May to July and October to November handling.
10 From 1st April pruning.
11 January to April pruning; June to August handling.
12 Early pruning; August and September handling.
13 Early pruning; handling in May.
14 Pruning as soon as possible after crop; handling just before crop.

Question 2nd.—Have you tried pruning twice in a year and with what results?

Answers:—

1 No reply.
2 Believes in knife handling.
3 Unsatisfactory.
4 Two prunings a year.
5 No.
6 In favour of knife-handling, but not to regularly prune
7 No.
8 Have not tried it.
9 Do.
10 Unfavourable.
11 Have not had occasion to do so.
12 Have not tried it.
13 Not tried it.
14 Do.

Question 3rd.—Do you prefer heavy or light pruning?

Answers:—

1 No reply.
2 Medium to heavy.
3 Object to the term.
4 Light pruning.
5 Heavy pruning immediately after crop.
6 Heavy pruning early in year if necessary.
7 Moderate pruning.
8 Moderate.
9 Heavy pruning.
10 Does not give an opinion.
11 Moderate pruning.
12 Heavy pruning does not like.
13 Fairly heavy pruning.
14 Heavy pruning particularly on western slopes.

Question 4th.—Have you had any good results from coffee not pruned at all?

Kindly give the approximate cost of the different operations you refer to.

Answers:—

1 No reply.
2 No good results; cost R10 to 12 per acre.
3 Do. cost R12·50 per acre.
4 Not tried; cost not given.
5 No good results; cost R12·50.
6 Do. cost not given.
7 Pruning and handling. R10 per acre.
8 No pruning and handling; R10 per acre.
9 No answer; cost pruning and handling, R14 per acre.
10 Pruning and handling, R14 per acre.
11 No fields unpruned; cost R10 per acre.
12 No good results; pruning cost R7 per acre, handling R3.
13 No unpruned coffee; cost pruning R7; handling R3 per acre.
14 Bad results; cost not given.

CINCHONA CULTIVATION.

To initiate a discussion on CULTIVATION OF CINCHONA and the best mode of Harvesting Bark, the CHAIRMAN proposed the following resolution:—"That the best mode of Harvesting Bark is to shave the trees every six months, between 3 and 5½ years; but that, after that age, it is unwise to shave trees, unless they have not, up till then, showed signs of seeding.

Mr. ARTHUR CAMPBELL thought that no rule could be laid down as to the age at which a tree can be shaved with advantage, so much depended upon the growth of the tree, consequent on quality of soil and other causes. He had shaved trees 5 and 6 times, and thought it quite possible a well-grown tree might be shaved 50 times. He had tried varied experiments such as fore-shortening the branches baring the roots &c. with various success, but had not yet been able to obtain reliable information on the advantages of covering after shaving.

The SECRETARY gave the result of an experiment in covering, showing an analysis of 3·86 per cent for covered bark, against analysis of 3·26 per cent for uncovered bark.

Mr. JACKSON stated that he had shaved trees in the ordinary way from 3 to 5 years old, and that it had answered well, but that just now we were trying what he believed was a still better plan and re-shaving these trees and leaving alternate strips (he always left one strip in shaving) and expected to be able to shave in this way every 3 months. Of course this is Howard's plan.

Mr. MARTIN gave statistics of quantity of bark obtained by coppicing trees in a clearing on Nannoya estate planted in 1864, in extent 2¾ acres:—

⅔rds coppiced in	1874	yielding	7,057 lb.
⅓rd do.	1878	do.	6 457 lb.
⅔rds recoppiced	1879	do.	13,000 lb.

To date with ⅓rd standing 26,514 lb.

Experimental acre:—

	Trees.	lb.		S. Quin.	
1881 shaved in May	1,742 =	705	showing	2·76	per cent
1882 do. do	1,610 =	516	do.	4·42	,,
1883 do. in Feb.	1.600 =	600	do.	3·09	,,

Mr. PATERSON gave it as his opinion that it was not advisable to shave trees oftener than once in 12 months, his experience was chiefly derived from officinalis and he had obtained these results from trees 11 years old:—

Original shavings	1·96 per cent.	Sulph.	Quin.	
1st renewal	5.76	,,	,,	,,
2nd do	7 05	,,	,,	,,

Other members gave their experience.

Mr. CAMPBELL proposed, and Mr. JACKSON seconded the following resolution:—"That a Sub-Committee be appointed to draw up a list of questions and form a report on cinchona culture in Dimbula."

Mr. ANDERSON proposed, and Mr. ELPHINSTONE seconded:—"That the following gentlemen form the Sub Committee:—The Chairman and Secretary and Messrs. A. Cantlay W. Smith, A. Campbell, Jackson, Martin, Symonds, Maitland and Paterson."—Carried.

C. J. SCOTT, *Hon. Secy.*

THE DIMBULA PLANTERS' ASSOCIATION ON COFFEE AND CINCHONA.

(*See Report on page* 322.)

The great district of Dimbula has well followed the efforts of the two sister districts to diffuse valuable information connected with the planting enterprize. Tea, so fully dealt with at the Dikoya and Maskeliya meetings, did not, on this occasion, form a subject of discussion. Attention was mainly directed to the old and important staple, coffee, which was the subject of a careful report, while a subsidiary discussion brought out some valuable facts regarding cinchona, specimens of what we may hope to see when a report similar to that on coffee is prepared by the competent sub-Committee appointed for the purpose. When the various district Committees have completed the discussions and reports on which they are now engaged, it might be well for the Central body to appoint a Committee for the purpose of bringing the scattered information into a focus,—facts independently obtained from estates and districts beyond the scope of the districts which have taken action, being embodied, and a general report founded on the whole. In this way trustworthy information might be recorded and issued in the most authoritative form possible.

Meantime it will be seen that facts collected in the Dimbula district make altogether in favour of what might be regarded as the foregone conclusion, that coffee, fairly sheltered and with a good exposure, still responds appreciably to manuring, pruning and cultivation generally. Coffee entirely neglected has not only gone down in amount of yield, but has in many cases, absolutely ceased to yield fruit.

No intelligent and experienced planter, we suppose, will deny the value of continued, systematic high cultivation. But there are several difficulties in the way. In the first place, the planter has to answer the question, "Where is the money to come from?" and in the next, "If I can even procure the money to enable me to manure liberally and cultivate carefully, will the results be commensurate with the expenditure? May not the effects, mainly, of the application of manure, (costly in itself and costly in application,) be to feed cockchafer grubs below ground and the spores of the insidious, life-exhausting fungus above?" Some planters who most believed in and practised manuring, have ceased to apply fertilizing materials, not merely because of paucity of means, but because their experience had shewn that a liberal application, especially of cattle dung to the coffee bushes, went chiefly to feed grubs snd *Hemileia vastatrix.* In the worst of such cases, no doubt, fruit-bearing was increased in some degree, and the strength of the trees largely upheld in their life and death struggle with insect and fungal plagues. But if, year after year, the returns from cultivated land, continue to be less and less in proportion to the expenditure, what wonder if heart and hope fail and cultivation is neglected? Hard beyond measure is the case of the large class described by Mr. Talbot, who have only coffee to rely upon, and who, disappointed of the looked-for returns from their one product, are not able even if they were willing to supersede or supplement it by new products. The deductions from facts collected in Dimbula, however, are that, while unmanured coffee has gone down to from 2 cwt. per acre to nothing, the crops from manured coffee range from 3 to 10 cwt. per acre: the average being $5\frac{3}{4}$ cwt. Such being the result, the great question is the cost of the manure and its application, as compared with the value realized by the crops gathered. Information in this direction is not afforded, nor do we get definite figures for the cost of cattle manure, which still holds its position with such artificial manures as steamed bones and bone meal, which, in various mixtures have given the best results. The cost of artificial manuring varies from R45 to R70, or taking the average, R57, somewhat over the average selling price of a cwt. of good plantation coffee. If the result of such expenditure should be to raise a production of only 2 cwt. per acre to an average of $5\frac{3}{4}$ cwt., there can be no question that the operation is not only paying but very profitable. The most striking result of the experience of planters, since the advent of *hemileia vastatrix* is the disfavour into which oil-cakes—coconut and even white castor poonac—have fallen. In Dimbula the once favoured substances are put out of court. In this connection we may mention what we heard when recently on a visit to "the Agras." A gentleman who owns a coffee estate in that district, owns also a coconut oil establishment in Colombo, and the statement was that, finding no market for the oil-cake, he reduced it to ashes, which ashes he applied to his coffee bushes, with the result of putting on them a crop estimated at 10 cwt. per acre. It would be important to obtain the details of this case, because it seems just possible that oil-cakes or other substances objectionable in their raw state, (as tending to the generation of fungi or grubs, or otherwise,) might give good and paying results, in the concentrated shape of ashes. That the oldest fields should pay the best, may be due to the fact that the bushes being planted before the fungus pest appeared to infect and weaken plants in the nurseries, have been able better to hold their own against fungus and grub and wind. But western exposures have sometimes, in Dimbula given the best crops of coffee, while fields with an eastern exposure have yielded only disappointment. The decision is just as clear in favour of judicious pruning and handling (the question of allowing weeds to grow was not raised.) as in that of manuring, and the average cost per acre is given at R10 to R14. The average cost of manuring with preparations of bones, therefore being R57
and of efficient pruning and handling 12

we get a total for the main items of cultivation of R69 or say R70. This is only R30 short of the old orthodox allowance of R100 per acre per annum for the cultivation of a coffee estate. With reference to the case of one regularly manured estate where crops went down from 8 cwt. per acre prior to 1880, to half that average subsequently, it would be interesting to know if the cinchonas put in, in 1880 were the cause of the decrease. We certainly doubt it. There may have been the gradual debilitating effect of the fungus, aggravated by absence of warmth, or as in Wallaha, grubs may have been responsible for the decrease of 50 per cent. The other details of the best times and modes of manuring and pruning, will receive the attention of planters and no doubt due note will be taken of the *fact* that one Dimbula planter, who evidently is nothing if not critical, objected to the "term," heavy or light pruning. As alternatives were mentioned, the scope of the objection must remain a mystery. We hope the objector made up by his presence the majority of one by which the publication at once of the report was carried.

The discussion on cinchona at the Dimbula meeting certainly elicited facts directly adverse to the recently broached doctrine that bark deteriorates with repeated shavings. Look at Mr. Paterson's experience with trees 11 years old :—

Original shavings	1·96 per cent sulp. quin.	
1st renewal	5·76	,,
2nd do	7·05	,,

But while Mr. Paterson advised only one shaving a-year, Mr. Jackson found the system of leaving a strip and shaving every three months, answer well! Mr. Arthur Campbell had shaved trees 5 and 6 times and believed a well-grown tree might be shaved 50 times. The Chairman contra, would shave every 6 months (the happy medium between 12 and 3,) from 3 to 5½ years, but stopping at once if the trees showed signs of seeding. Query: would it not answer to deprive the tree of the flower stems before the blossoms expand? Of the benefit to be derived from covering trees, no sufficient evidence seems to have been afforded. If, with safety to the tree and without deterioration of quality or lessening of quantity of bark, the covering process can be disregarded, a source of considerable expense will be got rid of. The absolute necessity of covering after shaving is at least doubtful, but we must wait for the promised report, which we trust may be equally founded on facts and as definite and decided as that on the manuring and cultivation otherwise, of coffee. I shaved trees are left uncovered, however, it seems certain that shaving in very rainy or stormy weather should be avoided. The Dimbula planters have evidently a better opinion of the permanency of the fever trees than the anonymous pessimist who favoured us with his opinion recently. Tea seems destined to be the plant of the future, but neither coffee nor cinchona is dead yet, and planters will feel grateful for the information regarding both these products contained in the proceedings of the Dimbula Planters' Association.

MR. GILLIAT'S LATEST SAMPLE OF RUBBER.

The following report is sent to us :—

"The rubber is sound and clean, and the best I have yet seen in Ceylon. I attach no value whatever to the white colour. In fact, this is the first sample I have seen of so light a colour, and I believe I have seen every kind of rubber known to the trade; what I like with this sample is its fresh and healthy look, which recalls to my mind the strong sound rubber from Borneo and Madagascar with which I would class it, but more so with Madagascar. I do not know what the prices of Nossibe (Madagascar) and Borneo rubber are now in Europe; but, should think that this sample in question should fetch the same price as the bet qualities from the said island, as it compares favourably with them as regards cleanliness. Rubber must,in the first place, be clean, free of sand, or in manufacture damage may be caused—a little bark mixed up is of no great consequence, as it can be easily worked out. As regards colour, I repeat that it is not of consequence to a manufacturer at home.

"*Para.*—This rubber which at the time I was in the trade fetched 2s 6d against 1s for Madagascar, 7d and 9d for West Africa, is almost *black* or dark-brown. I am surprized nobody here as yet has tried to initiate the Pará process, *i.e.*, smoking the rubber. There is no doubt that the smoked Pará, which in manfacture gives scarcely 3 per cent to 5 per cent loss, possesses the greatest strength, and will always top the markets. Smoking is feasible. I tried it a few years ago with the sap of some indigenous *ficus* kinds, and, though my experiment was not a complete success, it convinced me of the feasibility of the thing. Local sample received. 1 cwt. wanted for practical test in Europe."

The foregoing ought to be a valuable hint to Mr. Gilliat and those concerned.

THROUGH THE SOUTH SEAS TO SAN FRANCISCO (*Continued*).

(*By an ex Ceylon Planter.*)

THE GILBERT ISLANDS AND THEIR PEOPLE.

At the conclusion of my last paper, we were bowling along with a fair wind to leaward of Taputeowen, after our narrow escape from wreckage on the reef. Quite a swarm of boats were sailing after us, the occupants crying aloud for tobacco and offering any thing in exchange that their island produces; strings of coconuts, copra, fowls and pigmy pigs were held out temptingly to view, but to no purpose. We sailed on in stately indifference, and soon left the canoes far behind us. Towards evening we approached Nanouti, but too late for anchoring. All night we were compelled to make short tacks under the lea of the island in dangerous proximity to the reef. We dared not stretch out beyond the shelter as the current would have swept us away, and we should have been obliged to hold to the north in the manner I described in my former paper.

Towards evening of the day following we dropt anchor in 12 fathoms of water, and were at once boarded by a white man who lives here alone isolated from his kind and self-banished, the reasons for this best-known to himself; he collects copra from the natives, which he sells to traders. The total proceeds have never amounted to more than ordinary wages, so that he cannot hope to accumulate a fortune, or eventually enjoy a rustic cottage at "home" with a good wife and sundry necessary evils, as I once heard a crusty old bachelor call all children. Be this how it may, we soon completed all our work and were again off. Our stay here was four days altogether so that I had time to stroll about and see all that was worth noting. We skirted to leaward in preference to going to windward, and pointed our bowsprit in the direction of Apiamama. This island is the most frequented by trading-schooners, and is the one I was most desirous of seeing. Our captain too was equally anxious as he had business of a profitable nature in prospect. But the fates decreed it otherwise and we were doomed to disappointment as the sequel will show. At about ten o'clock we crossed the equator, and approached the island of Aranuka about six miles from the "line." We were unable to make the windward of the island on our present tack, so we bout ship and stood off again for three hours, and again returned on our original tack. In doing this, we crossed and recrossed the equator. This very seldom happens. In fact, I am sure there are few sailors even who have crossed the equator three times in one day. We found that instead of making any head way we were drifting rapidly away to the west. This was very tantalizing as Apiamama was not more than 15 miles distant to windward and yet we were unable to get there.

Aranuka looked very pretty and inviting. There was nothing to be seen but the white beach and cocount-tree forests. Kuria is quite close, not more than three miles away. It is much smaller in size, equally crowded with coconut palms, and seems a younger sister of the larger island. They appeared so very queer to me, these little oases in the midst of a wilderness of waters like warts on the surface of the mighty ocean. A thrill of pity for the inhabitants thereof passed through my mind, and I inwardly rejoiced that a kind Providence had chosen my birthplace in a less isolated country and among a more civilized people. Poor things, happy in their ignorance. Happy, too, in their limited wants and absence of vicious habits. I question if they are not to be more envied than pitied. It is only when aboriginals of new countries come in contact with more advanced (?) natives that they quickly deteriorate, morally sink and rapidly become extinct. History shows this. The aborigines of Tasmania are now a matter of history. It is only quite recently the very last of them died and within the memory of old settlers they were as numerous and prosperous race. The same law is at work among the Maori in New Zealand. I remember well the time when the Pah, near the mouth of the Tairie river, numbered some hundreds of Maori, and now there is scarcely one left to tell the tale. The same canker is busy with the Australians. The Samoans too are not so numerous as they were, and the Hawaians are fast being numbered with the past; also many other races that I have no knowledge of would swell the number, and add further evidence in proof of what I say. As it was quite hopeless to attempt Apiamama, we steered for Bu Taritari, which we reached in due course, sailed inside the lagoon and anchored in water as smooth as a duck-pond.

This was the last of the islands we visited previous to leaving for San Francisco. Before describing these curious people, it will be well to mention that Mr. Philips and another representative of the London Missionary Society in Samoa are the authorities for much of what I have to say. The latter, whose name I forget, had visited one or two of the islands in the "John Wesley" vessel, and had got his information from a resident missionary who was the first to try and convert these people to Christianity. This gentleman's labours had only been for a period of eighteen months, so that not much progress had been made in that respect. All I learned from them was confirmed by my own observations.

The Gilbert islands are also known by the names of the Kingsmill and Line islands and are situated almost immediately on the equator and in about 165° to 175° west longitude. They number altogether some thirty islands, Taputeowen being the largest of all. The total length does not exceed 30 miles, and in no place is it half-a-mile wide. To describe one island is to describe all. Their uniformity and similarity is one of the most peculiar and striking features of them. They are mostly all crescent-shaped with the bow facing the direction from where the trade winds blow, namely easterly. To the leaward they are encompassed with reefs, which form a natural breakwater extending from end to end of the island. But nowhere is any reef or reef-patches to be found to windward. These reefs vary in distance from the shore. Some are five or six miles away, others twenty. At no part of the reef are they quite bare at low tide or sufficient water on to float a large-sized schooner over at high tide. From this it will be seen how very dangerous it is to approach them from the leaward; especially as the land cannot be seen further from the deck than eight or ten miles. The charts give the distance as eight miles from deck and twelve aloft. This inability to see land from any distance is of course entirely owing to their flatness. In no part of any of the islands is the land ten feet above high-water mark. They are much longer in proportion to their width. In no place did I see the land further than half-a-mile from sea to sea. The soil is simply the absence of all soil—sand intermixed with decayed vegetation can scarcely be dignified by the name of soil. There is no basin to receive or retain water in, and accordingly when rain falls it is quickly absorbed in the sand and disappears. The natives have no means of retaining a supply, and have in consequence to do entirely without fresh water. I wonder if there is any other people in the world who are similarly situated. I never heard of any, and would thank any one who could inform me on the subject. I remember reading, from Livingstone's travels of a race inhabiting the deserts of Central Africa who had to dig through the sand to obtain water. These places were situated very far apart and the water supply very limited; but I never heard of a race who lived, thrived and increased in a country where there was no fresh water whatever. This appeared so very odd that I shall not be at all surprized at some readers' incredulity. Such persons I refer to the sea charts, and a careful examination of the conformation of these islands, I feel assured, will convince them of the truth of what I say. Wells can be dug, and are dug, but not to obtain water. Water flows, but is quite brackish, in fact, no more fit for drinking purposes than sea-water. These well-like excavations are dug out with great labour to a depth of four feet and at the bottom a little taro is planted which is carefully nursed and attended to and is mostly used by the patriarchs and kings. The only substitute for fresh-water which the natives have is young-coconuts, the water of which they freely use. The only tree grown is the cocoa palm, if we except a few breadfruit trees, which have only lately been introduced, and a rude cabbage-like tree, called a *pandana*, which bears a kind of fruit. The natives chew this fruit, the juice of which is very sustaining. A few shrub-like trees stunted in their growth completes the whole vegetation I saw. I make no mention of a little grass, if a wiry-fibrous and sapless growth can be called grass.

The food of the natives consists mostly of coconuts prepared in various ways. Of fish they have a goodly supply. They are very expert fishermen. Their canoes are well adapted for their purpose. They resemble the Sinhalese canoe very much, having the same outrigger. There are no nails used in the construction. Every thing is laced together with fibre prepared from the coconut tree. They have sails also, mostly of calico, but many of a material I could not recognize, neither could I find out how it was made or where it was brought from. Their dress consists of coconut fibres woven together and tied round the loins. The laws which govern them are as strictly carried out as in any civilized country. Some of the islands have a king whose authority is as absolute as any potentate we read of in the centre of Africa. The king of Apiamama has Aranuka and Kuria under his control, and woe betide the unlucky subject who dares to offend his august majesty! Touching this I remember what was told me by the two American ladies I referred to in my first paper. They had landed and were received with all the dignity fitting the occasion. His august majesty forgot for a time his position, and gaped like the common herd. The ladies were ushered into the palace (?) and everything the kingdom produced was placed at their disposal. But their enjoyment was tempered by a very offensive effluvium arising from the back of the house and floating through the building. They made their excuses and hurried to the fresh air. Refreshed with the sea breeze they enquired from a native who spoke pigeon-English the cause and were told that a few days before their arrival, His Majesty had occasion to be offended with two of his numerous wives, and had clubbed them; also, to prevent future annoyances and as an example to the others, he had them placed in two boxes and perched conspicuously behind his house. Of the truth of this, these ladies afterwards assured themselves.

His Majesty was touched with a tender feeling towards one of the ladies, and offered one hundred tons of copra and quite a host of pigs and poultry if the captain would sell her. To appease the king, he was told the matter would be taken under consideration and that when the vessel was emptied the captain would return for the copra and bring the ladies with him.

What I have above related I believe to be perfectly true. On other islands, the natives rule themselves by a kind of Parliament, composed of a number of old men, one chosen from each village. Human life is most sacred to them. If life is taken the murderer at once must fly to the Parliament-house, which is also a sanctuary. Here he is perfectly safe from the enraged relations, until a Council is called and the case enquired into. But no crime I was informed, murder or other, was punishable with death. This Council had jurisdiction over everything, but could not deprive a man of his life. Every man owns or has an interest in a certain number of cocoanut palms, and according to the extent of his guilt or enormity of the crime he may have committed, he loses a percentage of his interest in the ownership of these palms. If the criminal is entirely deprived of all ownership, he is then reduced to slavery; or what is considered slavery with them. He has no means of sustenance and is entirely dependent on the charity of others. One day he may be compelled to go to sea and fish all day long or work hard at house-building or whatever may be required of him. These slaves are always looked upon with contempt. The scanty leavings of food, which are grudgingly handed them, is a continual reminder of their condition and crime. Labor-vessels which come to these islands always find willing recruits in these outcasts, criminals or slaves, or whatever other name may best express their condition.

These islands are very thickly populated, in fact they are credited with being the most thickly peopled lands in the whole world, that is to say where the land on which they live produces all that they consume. This may appear surprizing, but I believe is perfectly true. All the islands are simply crowded with natives.

The physical character of the islanders is as widely different from the Samoans as it is possible to be. In colour also they differ. In this respect they resemble the Tamils, but the Samoans are much lighter than the Sinhalese. To describe them describes exactly the Indians of Central America. They are short in stature, sinewy, and square across the shoulders. They have broad flat-like faces mostly, and a determined look about them. The expression is not soft, gentle or amiable; their disposition I would judge was anything but yelding. In this respect again they are in marked contrast to the Samoans. Their reputation in this particular quite agrees with my opinion. I have had numerous instances related to me of the reckless disregard of their own lives when their feelings were outraged or jealousy aroused. An instance came under my own notice. The first mate was ashore on one occasion on the island of Manouti and showed his admiration for a pretty native woman in a way to excite the jealousy of her husband. He, regardless of consequences, charged down among the boat's crew, knife in hand, and would certainly have done mischief, had not the mate thought discretion the better part of valour and skipped nimbly into the boat just in the nick of time to save his bacon. Noble civilized man! The native was ultimately appeased, but with great difficulty.

I have already mentioned the marked likeness between the Central American Indians and these people. There was one industry I saw them very busy with, which struck me as very remarkable, and was the only work I noticed them doing outside their immediate requirements, and that was the making of hats. The hat was very little different to the well-known Panama, and equally well done. The fibres were somewhat coarser, but extremely well woven. I have seen the same hats in course of being made in Central America, and the process was exactly the same. This is very remarkable, and cannot be other than interesting to that section of the scientific world who make the human family their special study.* Every native wore one of the hats I describe. There is one thing patent, these islanders were never instructed in the art of how to make these hats, for the simple reason there has never anyone visited them to show them how, except a few labor-schooners and petty traders, the captains of which were as ignorant how to weave these very ingeniously contrived hats as I am. It must also be remembered that it is only quite recently that they have been visited even by traders. Accordingly, the only solution of the problem is that the natives brought a knowledge of their industry with them. And what conclusion is more natural than to suppose they are an off-shoot from the people they most resemble in character and physique, and whose very industry is the *only one* they have any knowledge of? How they were ever transported from the continent of America to these out-of-the-way islands is a question which will naturally occur to any one. In this, I am pleased to say, I have also very important evidence. I shall only refer to the trade winds and ocean-currents which set directly from the continent. Any one can assure himself of this fact who cares to glance at the charts. There are authentic instances of sawn logs of timber being drifted away from Puget Sound, with the firm's name stamped on the log, and washed ashore here. Now, what is more natural than to suppose that, if a log will drift 3,000 miles across an ocean, a canoe or boat will drift or sail much quicker. I could illustrate much further, but I must now conclude. In my next I shall tell you of further adventures across the North Pacific to San Francisco, at which place we arrived a few days before Christmas. W. J. FORSYTH.

* Professor Bickmore of the Academy of Sciences has written a good deal about the races of Polynesia, but I think differs from me about where these people immigrated from.—W. F.

PLANTING IN SARAWAK: CINCHONA, COCOA, COFFEE, CARDAMOMS.

Matang Augt. 19th, 1883.

My dear Rajah,—Thinking you may like to hear how things are doing up here, I send an account of what I have done since I first arrived in Sarawak as regards planting. I commenced felling a 30 acre clearing in August 1882 intending to plant Cinchona Succirubra, of which variety I had brought 3lbs. of seed from Ceylon; this seed I sowed in Kuching, but it came to nothing almost, as I was only able to get about 300 plants, of which I have now only about 40 left but these ones are doing so well that I have every reason to believe that this cinchona will be a great success in country. Not having sufficient plants, I allowed this 30 acre clearing to grow up again and am now busy clearing it up. I have already finished about 10 acres and have got the same lined and holed, and by the end of this month I hope to have the whole acreage ready for planting, that is lined, holed and the holes filled in with surface soil. I shall plant 6 feet by 6 feet at first, which will take about 40,000 plants and when finished, if I can afford it, I shall double the number by making it 6 feet by 3 feet. I have, I fancy, about a quarter of a million of Succirubra plants, of which about 80,000 are thoroughly well hardened and ready for putting out. I shall shade each plant with bark; it is an expensive process, but it pays. I have already in this clearing 40 original plants, the highest of which are about 6 feet high and very strong and healthy. Also about 200 other plants about a year old and now some 3 feet high; these are also very healthy and vigorous. I have also in this clearing about 200 ceara rubber trees, about 20 feet high and still growing very fast, and some cocoa plants, but the latter are growing very slowly owing to the continual attacks of grasshoppers.

10 *acre clearing.*—This clearing is at an elevation of 2,500 feet and is regularly planted 6 by 6 with the valuable ledgeriana species, the plants were put out last April and now *average* about 1 foot in height; now that the roots have taken a hold of the ground the plants are growing grandly and have a beautifully healthy look. There are 12,000 plants in this clearing, but when the rain sets in I am going to double the number by planting 6 by 3. The soil here is the finest I have seen and the natural drainage perfect owing to the quantity of decayed granite in the soil. Adjoining this 10 acres I have felled another 10 acres, but have not yet burnt it off as it is not sufficiently dry. I hope to get a burn this month. I shall plant this 6 by 3 with ledger plants, of which I have about 60,000, very healthy and well hardened and about 8 inches high. I shall have, when this is planted, 20 acres of cinchona leogeriana planted 6 by 3, equal to about 50,000 trees, each tree at 3 years of age being worth *at least* 50 cents.

Cocoa clearing.—This is at an elevation of 400 feet and contains about 1,000 trees. The highest being about 4 feet high, but the majority of plants are much smaller and do not look as if they would come to much. I am afraid the tap roots were bent in planting.

Clearing for Coffee.—This is just below the 30 acre clearing and has not yet been burnt off. I have about 5,000 very fine Liberian coffee plants in the nursery to put in. This clearing is about 5 acres, and I hope to burn off this month.

Cardamom clearing.—About 1 acre in extent, planted 7 feet by 7 feet under natural shade, the small trees only having been felled. The plants are growing very well and are looking very healthy. Mr. Awdry has a half share in this, as he gave me the seed.

Nurseries.—In the lower nursery I have about 100,000 succirubra plants, and 30,000 cinchona hybrid plants.

In the middle nursery 50,000 succirubra 5,000 liberian coffee. 2,000 cardamom and about 20,000 ledgeriana seedlings, about 200 or 300 of which I raised from the Java seed kindly procured for me by Mr. Hardie. In the nursery near my house I have 100,000 succirubra plants, some divi divi seedling, 1 lb. of cardamom seed, some croton oil seed some sapan dyewood seed, 200 cocoa plants of a valuable kind (to judge from the cost of the seed), some vanilla cutting and 20 screw pines. The cocoa, vanilla and pines came by last mail in a wardian case. I know nothing whatever about vanilla, but have written for directions.

In the top nursery I have about 60,000 very fine ledgeriana plants. This is all I have to tell you, Rajah, as regards work done. I have still a lot to do, but hope to get it finished in another month or two.

I should like to put out 20 or 30 thousand ceara rubber seed. I can plant them in the present clearings and along the roads and boundaries; they require no care and may turn out of great value, as the demand for rubber at home is exceeding the supply.

The following is the total expenditure to end of July 1883

In 1881	$340.75
In 1882	674.75
In 1883 7 months	1,126.75

a great deal of this has been spent on seed.

I have been promised 5 lb of ledgeriana seed in the Autumn by Mr. Gammie of Darjeeling. L. PEAKE.

—*Straits Times.*

STEARINE, GLYCERINE, CANDLES AND SOAP

from the oils of the coconut and African palm were thus noticed by Mr. Leopold Field, in a lecture before the Society of Arts. The Mr. Wilson referred to, is the eminent chemist so long connected with Price's Patent Candle Company, Mr. G. Ferguson Wilson, a brother of the late Mr. David Wilson of Colombo, Ceylon:—

One of the great obstacles to commercial success in the manufacturing of stearine was the difficulty of disposing of the oil which was a waste product, and would have remained so, but for the wise step of removing the duty on soap. It is now, however, almost as important as the stearic acid, being employed for making what is known as pure oil soap, an article in immense demand among dyers and bleachers.

The next process—that of acidification—requires a short history, by way of preface. Till now, only tallow had been employed for making stearine, though, in 1836, Messrs. Hempell and Blundell took out a patent for making candles from saponified palm oil. These, as you see by the specimen, give a fair light, but are dark in colour and are greasy to handle, and never became popular. In 1829, Mr. Soames had taken out a patent for pressing coconut oil, obtaining a solid and a liquid. This coconut stearine was a decided improvement upon pressed tallow, but the candles made from it still required snuffing, and consequently were never extensively used. The composition of coconut oil, as already shown (Lecture III), differs very considerably from that of palm oil and tallow; the proportion of glycerine is comparatively small, and the fatty acids very numerous; some of them, as *caproic* and *caprylic*, are volatile at low temperatures and give very pungent vapours, especially when the candle is blown out, which, of course, tended to render this candle objectionable. It was not till Mr. Wilson brought out his composite candle, which I have already described, composed of the coconut stearine and the new stearic acid, that they became popular. Their sale is still very great, though the composition of the present composite candle differs materially from those first introduced under that name. In 1840, Mr. Gwynne planted a process of distillation *in vacuo* for fatty bodies, and also for distilling fatty acids, under atmospheric pressure. Though the principle was mainly the exclusion of air from the apparatus and was valuable, the working was not found practicable. In 1842, Messrs. Price & Co.—under the name of W. C. Jones—patented the process of distillation of acids from coconut oil alone, and also after combination with lime. Very beautiful candles were made by this method, but were still subject to the same complaint of those of stearine, namely, of evolving vapours. The candles made of the product of distillation from the coconut lime soap were free from all defects, but their cost was far too great. Various experiments were tried, and patents taken out; but we cannot stop to consider any till we reach the patent of Messrs. Wilson and Gwynne, in 1843, which embodied the suggestion of M. Fremy, to heat oils with acid instead of alkali; only, instead of following his recommendation that the vessel should be kept as *cool* as possible, the patentees recommended a high temperature, and distillation under superheated steam. The process will be best understood from the actual description. Tallow oil is subjected to the action of strong sulphuric acid at a very high temperature, in the proportion of 6 tons of the oil to 7 cwt. of acid. By this means the glycerine is converted into sulpho-glyceric acid, with evolution of sulphurous acid, and a certain amount of carbon. After the acid treatment, the black mass in the vessel looks anything but promising. A little washing, however, frees it from the residual charcoal and acid, and it is then transferred into a still, into which superheated steam plays, and this, with the aid of gentle "bottom heat," distils over the acid. Here is the raw palm oil of a golden-yellow colour. Here the black mass produced by the acid treatment, and this firm white substance the product of distillation. In the still a black thick pitch remains, known commercially as palm pitch. What has come over is pure palmtic acid. The medium runnings of the distillate are the best. The first and last are not so good, and are used for inferior candles. From this palmtic acid the finest composite candles are now made. Price & Co. subject their distillate to hot pressure, and obtain the "Belmont Sperm" thereby. You will remark the beauty of their appearance, and the clear lustre of the flame. I have here burning, side by side, a candle of tallow, and a candle of stearic acid, with equal wicks, and you will perceive at once the difference made by the exclusion of the glycerine. I have forgotten to mention, in the description of the palm oil the kernel of the nut, from which is obtained a very large amount of oil, equal to, if not exceeding, the quantity produced from the fruit. The composition, however, is quite different, being, in fact, almost identical with that of coconut oil, which it replaces in any instances, especially in the manufacture of soap, for which both these oils are abundantly employed. So much for the saponification and distillation process. Mr. Tilghmann, in 1854, took out a patent for the separation of fats into acids and glycerine by heating with water under pressure. He suggested pumping the mixture of fat and water through a coil heated to a temperature exceeding 600° Fahr., and at a pressure of 2,000 lb. to the inch. Messrs. Wilson and Payne patented a method by which superheated steam passed into the fat at ordinary pressure effected the separation, and distilled both acids and glycerine. By resubjecting the latter to this process, Mr. Wilson obtained the beautiful glycerine for which Price's Patent Candle Co. have so high and just a reputation. I cannot dilate as I should like to upon the uses and beauties of this beautiful alcohol. They form part of that branch of chemistry known as saponification, a wide reaching and deeply interesting subject. However, Mr. Tilghmann's idea has been amplified, and on the Continent a great part of the stearine is made by what is called the autoclave process. The tallow and palm oil are introduced into a stout copper vessel provided with a stirrer, into which superheated steam is passed till the pressure reaches 250 lb. on the inch. After several hours' agitation at this pressure, the separation is complete. Each of these methods has its particular advantages, and is applied to certain specialities of stearine, in the choice of which experience is the only guide. I have on the table samples of candles produced by all the methods I have named, and many more (which will be particularized in the last lecture on candles). I cannot conclude without drawing your attention to the great results which have followed the discoveries of Chevreul and Wilson. Had it not been shown that by these processes the worst and darkest greases can be forced to yield a clean and beautiful substance, palm oil would have been almost useless to the candle-maker. As it is, over 40,000 tons are imported annually into England, and no doubt, far more into the Continent and America. The kings of the countries where the palm tree grows find that the labour of their subjects, in collecting the fruit and extracting the oil, is far more remunerative to them than the selling of these subjects into slavery. Being as keenly alive to their own interests as any white men can be, they have become humane as a matter of business. By encouraging the influx of European goods in exchange for their native productions, they have brought about their own civilization far more rapidly than could have been effected by the simple spiritual pressure of missionaries unendorsed by self-interest. There are many other varieties of tree oils, such as the Cahoun palm, the Bassia butter, and others of which I have already given the names and compositions, and of which you see specimens on the table.

Those for whom the history of the stearine industry possesses sufficient interest would do well to read Mr. G. Ferguson Wilson's excellent lecture on the subject, delivered before the Society of Arts, in 1852, and a paper read a short time subsequently, in amplification of the lecture. For the major portion of the above information I am indebted to these records, written by one who should, perhaps, rank next to Chevreul for the share he has taken in promoting this gigantic industry.—L. F.—*Pharmaceutical Journal*, September 1st.

NEW FIELDS FOR ENTERPRISE.

We have received from a Ceylon planter who left a few months ago for British Burmah the following letter :—

Model Duke Estate, Tavoy, 3rd September 1883.

Since I left Colombo I have had a considerable amount of sailing. Having been too late for the Rangoon steamer at Madras, I had to proceed on to Calcutta and from thence by Bahadad steamer to Rangoon. I had the pleasure of seeing the Chief Commissioner at his own house in Rangoon, and he received me with the greatest kindness, and in no way embarrassed me with his importance. He explained to me that he is ready to make road and rail directly he sees planters take *bona fide* steps to cultivate. He spent last year over two *lacs* of rupees in introducing coolies to British Burmah and has increased the number by 30,000. Mr. Smeaton, the able Secretary, at the shortest notice gave me all the information required to proceed to Tavoy and Nyadoung. Since then I have been up at Prome by the State-Railway, and from thence up within 30 miles of Mandalay in Upper Burmah in a three decker, commanded by an Aberdonian. I will give you more news when I have more time. I was put in possession, and am now busy at work again, have got the foundation of my bungalow cut out already, and am now busily employed clearing for nurseries. I had fifteen Ramasamys in my force the first day I commenced work: any number of coolies offering daily, and they are working cheerfully and are in splendid health. My letters have gone astray, and papers also, but I am now in a fair way to get them. *I miss the "Observer" terribly.* The Rangoon papers have little news, and mostly only a lot of "squabbles" and "advertisements." There is a magnificent opening for a good paper, and I trust to see a branch of the *Observer* in Rangoon soon. Rangoon is a rising town, and no mistake. Deputy Commissioner Duke sends you the plan of the hill tracts by this mail.

The plans referred to have been forwarded to us by the Deputy Commissioner of Tavoy, and can be seen at our office. In forwarding them Mr. Duke writes to us as follows :—

Tavoy, 3rd September 1883.

Sirs,—I have the honor to forward herewith two photo-zincographed copies of the plan of the Nat-yay-doung waste-land grant blocks surveyed last season: at present only three blocks have been taken, viz., Nos. 1 and 2 by Messrs. Schwalky and Lovell, and No. 3 by Messrs. Theobald (Junior) and Dixon. Nat-yay-doung is about 55 miles from the town of Tavoy, but only about 37 miles from the Tavoy river where the British India steamers anchor. There are two Government bungalows there for the use of planters who wish to prospect the land, and a six-foot road has been made from the steamer anchorage to the Nat-yay-doung plantations, which will be made into a sixteen foot road this season; at convenient distances along the road there are Government resthouses for the use of travellers.

Mr. J. D. Watson of Agrapatana, late of Ardallie estate, has inspected the land, and is of opinion that any tropical plant now cultivated in Ceylon can be grown with advantage on the Tavoy waste-lands now being opened out.

Mr. Watson has obtained a grant for about 200 acres of land on another range of hills nearer Tavoy, and has commenced operations already.

Any information you may require regarding the land, &c., I shall be most happy to supply you with.—I have the honor to be, Sirs, Your most obedient servant,

C. J. W. DUKE,
Deputy Commissioner, Tavoy.

The waste-land, traced out into sixteen blocks, consists of over 5,000 acres on hilly, sloping land, rising from one to fifteen hundred feet elevation on the west, to from one to four thousand feet on the east; the Nat-yay-doung range forming the north-eastern boundary; the land is in about 14° north latitude.

REPORT ON THE GOVERNMENT CINCHONA ENTERPRISE IN JAVA FOR THE 2ND QUARTER 1883.

(*Translated for the Ceylon Observer.*)

The past quarter was characterized by a continuous drought, which commenced on the last half of April. This drought, though causing some damage to the young plants, was very favorable for harvesting. The export of the produce of 1883 amounted to 159,293.* Amsterdam pounds, while about 20,000 pounds more are lying ready for packing and dispatch on the plantations and in the packing-houses. At present cart-horses are alone used for the transport of the produce. Since the substitution of horses for buffaloes, consequent on the prevalent cattle-disease, less difficulties have been experienced with the transport. The charges for freight might even be somewhat reduced without disturbing the transport. In order to proceed without interuption with the steadily increasing production of the harvest, a beginning was made with the building of a second place at Nagrak for the artificial drying of the bark. The supply of labor was on the whole quite satisfactory, and equivalent to the funds available for the enterprise. At Nagrak however, where, on account of the steadily increasing production, a greater number of work-people are needed without interruption for the harvesting, there was a deficiency. Means are being taken to rectify this. The large rainfall of 1882 was not favorable for the blossoming of the original Ledgerianas, so that but little seed was gathered from those trees. The Government enterprise possesses, in its extensive nurseries at Tjinjiroean, which were laid out last year, sufficient supply of plants for at least a year in case of need. Large quantities of typical descendants of Ledgeriana were supplied to private persons during the past quarter. The supplies have taken place in consequence of the Government order No. 23 of 28th June 1883, by which it was ordered that the Ledgeriana, succirubra and officinalis seed produced on the Government gardens and not required there should be sold to the highest public bidders. On account of the small supply of Ledger seed of original trees, the forthcoming sales will at first consist almost entirely of seed of typical Ledger descendants. Amongst the plants obtained from that seed a proportion of hybrids and widely differing varieties will be met with. If the plants are carefully picked out in the nursery beds, and the bad sorts separated or at least not mixed with the typical plants, there can be no doubt that pure Ledger plants can be obtained from the seed of the descendants. It will be judicious to plant closely, so that after some years the evidently inferior trees can be dug out without harm to the plantation. The cultivation of cinchona by private persons in Java is increasing steadily, as shown by the manifold inquiries for Ledgeriana and succirubra seed. According to advices received, the extension of the culture is specially due to the bad results which the coffee culture has of late yielded. On almost all the estates in

* Not 172,293 as given in *Straits Times* the other day.—ED.

West Java, but also, though in less degree, in Mid and East Java, the cinchona cultivation is gradually occupying the land of the failing coffee culture. The artificial increase of Ledgeriana by means of grafts in nursery boxes gave good results this quarter also. In the nursery at Tjinjiroean there are about 10,000 grafts of trees which on analysis appeared to contain more than 11 per cent of quinine. The existing nursery houses at Tjinjiroean, although almost entirely used for artificial increase, have appeared to be not sufficient for the requirements, and orders have therefore been given for building a new large nursery-house. The grafts on succirubra in the open air were entirely staked. The results were so continuously unfavourable that the making of further experiments has been discontinued. In spite of all endeavours to overcome the disease, serious injury has been continuously caused by the *Helopeltis Antonii*. The comparatively small plantation of grafts and cuttings at Tirtasari suffered most therefrom. Next to the catching of the so much dreaded insect and the isolation of the affected fields, a vigorous working of the soil and a thorough manuring, whereby the plants put forth new forces for further growth, appear to be the only means for combating the plague. The analyses of the specimens of the harvest of 1883 were made over to the chemist. A. A. Maas Geesteranus, appointed Assistant Director of the Government Cinchona Enterprise. The results obtained will be detailed in a future report.—Van Romunde, Director, Government Cinchona Enterprise.—Tjinjiroean, 9th July 1883.

New Products in Haputale: Rubber and Crotons.—A Haputale planter writes:—"I do not care to tap to any extent until the trees are older, as the quantity of rubber from the older trees is considerably in excess of the younger. I was all through my croton clearing this morning and was so pleased with the marvellous growth of the trees and the very large crop on them that I purpose planting up 25 acres this or next month."

A bushel of corn weighing 56 pounds will yield between 28 and 30 pounds of glucose, or grape sugar, and in adulterating sugar from 18 to 20 per cent of the grape sugar is generally used. In Europe potatoes are generally used for the manufacture of glucose, and the manufacturers find larger profits than from corn. A plant called *manioc*, a native of South and Central America, is said to produce 56 pounds of glucose to the bushel. As this plant yields over 500 bushels to the acre, it is not improbable that *manioc* may be the "sugar cane" of the future. The so called Brazilian arrow-root and topical of commercial are made from the cassava or manioc plant.—*Rio News.*

Tea Packing.—It seems absurd for each estate to have its own dimensions for chests of 100, 50, or 20 lb., and a very slight expense in procuring a mould for the lead lining, and a little unanimity would enable superintendents to order or make their boxes with a regularity and sameness that very probably would effect the law of bulking in London, besides saving in cost of manufacture and saving in lead. If 10 chests 24×19×12=50 cubic feet = 1 ton, shipper's measurement, it would be a size to adopt; and lead sheeting 25×37 or 25×19 would exactly suit the chest without wastage. Combination would permit of boxes being made by machinery, when both make, strength, and appearance tell, for no hand-made box can compete with the machine-made, and the having to alter the machinery to suit every man's taste is a cause of further expense in manufacture. Carpenters must live and expect at least a rupee per diem, so that if a reduction in cost of package is made, it must be in adopting the machine-made, and to effect this at its minimum charge, uniformity in size and combination is all that is needed. Timber cannot become cheaper; indeed, as years roll on and our tea enterprise expands it will be a serious question as to where the suitable supply is to come from, and those who take the precaution to plant up waste and denuded lands with trees that may be utilized some 10 years hence will find their labour not in vain.—*Cor.* "Local Times."

Ceylon Teas: Gallbodde Topping the Market.—We refer to the sales list elsewhere by which it will be seen that for "broken pekoe" Galbodde, 3s 1d has been paid—the maximum reached for Ceylon teas. (Well done, the Ambagamuwa iron stone and clay soils!) The whole break equal to 72 chests averaged 1s 11d. Culloden "orange pekoe" also got a good price 3s 0½d. We learn that it is becoming quite the fashion now in many parts of the "West End" to drink no tea but "Ceylon"—Ceylon tea, in fact, is likely to become an aesthetic rage, and the qualities selling at 1s 6d and over are so rapidly sent into consumption that it is impossible to get any quantity to buy in the market. A London merchant wishing to send Ceylon, in place of Indian tea, to South Africa in fulfilment of an order, was told, 'none available at present': demand above supply!

Progress of British Burma.—In area British Burmah is 3½ times the size of Ceylon, and Burmah has the grand advantage, besides others of possessing some of the richest rice lands in the world. The population of the two countries is exactly the same, but in trade and revenue the Indian Commissionership is far ahead of the Ceylon Governorship. The summary regarding the land which Mr. Bernard rules is as follows:—"The Administration report of British Burma shows the progress of the province to be little short of marvellous, and that, despite the intense indolence, or rather hatred of labour, characterising the Burmah people. Out of 87,220 square miles of fertile soil barely 5,660 are cultivated though most of the cultivable area is within easy reach of the railway and of navigable rivers or the sea. The population increased 36 per cent. in the 8½ years previous to the census of 1881. As illustrating the wonderful fertility of the soil, it is pointed out that in a single orchard the following trees were in bearing at the same time—the cocoanut, the areca, the Coreau mango, orange, lime, mango-steen, pineapple, black pepper, plantain, and coffee. The soil is suitable for sugar-cane, tobacco, and cotton. The hill slopes afford every facility for the production of tea coffee, and cinchona. Petroleum abounds, and iron tin, lead and antimony are plentiful, while the supply of forest trees is infinite and their variety inexhaustible. The local demand for tobacco is prodigious—every man, woman, and child smokes. From 40,000 to 80,000 cigars are sent every month to England, and a large supply is imported into India. Yet with all these advantages of soil most of the tobacco is brought from Madras, so great is the repugnance of the people to work. Notwithstanding this apathy, the increase of prosperity is astounding; 885,338 tons of rice were exported to Europe in 1880, being an increase of 85,000 tons over that exported in the previous year, although prices fell 20 per cent. If the export duty on rice were abolished, this trade would be developed still further to an amazing extent. As compared with 1870, both imports and exports have considerably more than doubled. The total trade in 1870 amounted to £10,263 000; while that of 1880 was £22,222,000. The revenues have increased in the same period from £1,232,066 to £2,360,000; the local and municipal revenue having more than trebled. Burma paid a surplus of £767,000 to the Imperial Government in 1880-81. The incidence of taxation on the population of 3,736,771 is Rs. 6 3 annas per head. So little is this felt that every family in Burma on the average spends £12 yearly on jewellery and imported luxuries. Bullion to the extent of a million and a-half annually is absorbed in the province, in addition to the great amount spent in charity and amusements."—*Allen's Indian Mail.*

COFFEE TO THE FORE.—A planter writes:—"No doubt we shall soon restore confidence in Ceylon again, and probably business will be on a sounder footing than it has ever been before. I am still a firm believer in coffee Arabica in suitable localities if you have only the means to cultivate properly, but it is only here and there now-a-days that you see estates getting anything like fair play, and I am sure that quite as much harm has been done by wilful neglect and starvation during the past few years as by either *H. V.* or bad seasons. Here in Dikoya, in spite of the season, I have as fine a crop as you could really wish to see over a large acreage—whilst ———. However, *comparisons are odious*, and folks that are letting their estates go to the wall don't thank you for telling them so."

THE VALUE OF BONES AS A FERTILIZER and the constant waste of much valuable fertilizing material which goes on in India are well-known facts. Spasmodic efforts have been made from time to time by energetic Collectors like Mr. Halsey, or by Agricultural Departments, to popularise the use of bones as a manure amongst the agricultural classes, but with very ephemeral success. The latest contribution to the literature of the subject is a letter from Mr. McMinn, C. S., formerly of these Provinces, but now a Deputy Commissioner in the Central Provinces, addressed to the Secretary of the Agricultural Department to the Government of India. Mr. McMinn reviews all the facts connected with the fertilizing qualities of bones of which indeed there has never been any question; he points out that the probable loss in British India from the non-use of the bones which lie near every village amounts to twelve million pounds sterling; and he graphically describes the results of misdirected efforts on the part of Government to improve the cultivation of cotton in the Wardha district, where "model farms, Special Commissioners, annual reports, introduction of foreign cotton, cotton-gins, pumping apparatus, and English ploughs show the result only of abandoned works, crumbling masses of machinery, and the ridicule of the surrounding peasantry. Mr. McMinn argues that if, instead of trying experiments in "nursing every variety of exotic into a sickly existence," Agricultural Departments were to pay some attention to utilizing the valuable fertilizing materials that are now absolutely wasted, the addition to the agricultural wealth would be incalculable. The low outturn of cotton is simply due to a want of stamina in the plant from which the large number of pods decay before reaching maturity: the application of bone-dust would supply the necessary stimulus, and instead of a miserable outturn of from 40 to 100 lb. of cleaned cotton per acre, over 400 lb. might be obtained by the use of 3½ cwt. of bone manure. If Messrs. Buck and Bennett can suggest any device by which the "phlegmatic but observant and industrious Indian peasant can be induced to stimulate in a distinct and powerful degree the crop he grows, by means of the waste substances lying round him," a very important problem will have been solved. Religious prejudice has to be overcome, apathy to be aroused, conviction to be established, before Ram Baksh will gather the bones from the village Golgotha; pound them in what Mr. Pogson calls a *dhanke*, or the ordinary pestle with which bricks are broken up or rice husked; convert them into a compost by the addition of ordinary manure, and use them in his cotton-fields. There is, however, this much to be said, that of the practical utility and profitable character of Mr. McMinn's proposals there can be no question, and no opportunity should therefore be lost of bringing home to the cultivator at least what can be done at little cost and with the simple means at his disposal.—*Pioneer*, Sept. 19th.

DESTRUCTION OF COFFEE AND CINCHONA BY HAIL.—We learn from Mr. Robertson, late of Wevebedde, that a coffee and cinchona field on Uva estate has been greatly injured by a local shower of hail—the succirubra trees were broken in two and the coffee denuded of leaves. The field, in fact, looks as if a fire had passed through it. Although hail-showers are not unknown in Ceylon, it is very seldom damage in this way is sustained.

SUGAR CROPS IN SOUTH AMERICA.—Our Pernambuco correspondent, writing on the 28th ult., says:—"Most of the sugar estates are now at work, but so far entries of new sugars are on a very limited scale—entries during the fortnight amounting to 5,051 bags. There is only a small amount of sugar in packers' hands, and no sales of importance have yet been effected, although some small parcels have been taken over, principally for shipment to Liverpool. This season's yield, both here and in the adjacent provinces, will prove an abundant one."—London *Times*, Sept. 15th.

ALL THE COFFEE grown in the New World has sprung from a single plant, which a French naval officer carried to Martinique in 1720, depriving himself of water when parching with thirst in order to nourish his coffee plant. From this one tree it is said, all the American tropical colonies obtained their seed, which has multiplied to such an extent that Brazil, Mexico and the West Indies produce as much coffee as Java and Ceylon.—*Rio News*. [As much! Brazil, with the aid of slave labour, unhappily, produces more than all other countries together.—ED.]

A NEW MANURE.—A correspondent writes:—"I am making some very careful experiments in manures—chiefly saltpetre, which I believe will be found most effective, and being in such small compass, carriage will not amount to much. Experiments on the Government farms at home point strongly to nitre being the chief fertilizer; also to the necessity of the ground being covered with some quick-growing crop during rains, when the loss of nitrates by drainage is very heavy. I am sowing in Sirgooja oil-seed, which grows very quickly, and I then dig it in a month afterwards. I believe this is one of the cheapest and most effective ways of manuring."—*Indian Tea Gazette*, Aug. 14.

SOME interesting results of experiments by Dr. Liebenberg, as to the influence of lime on the germination of seeds, have recently been published in the journal of the Vienna Academy of Sciences. It appears that the seeds of many plants require the presence of lime in the soil during the germinating process, or the seedlings die from want of it. It is likewise shown that many other plants do not fail to germinate freely and well without the presence of lime in the soil. Dr. Liebenberg also points out that plants which fail to grow through the absence of lime in the soil do not fail in consequence of the injurious effects of any other matters that may be present, but because lime is essential to their healthy growth.—*Queenslander*.

QUININE.—The following extract from the *Public Ledger* will be read with interest:—"The last contribution of modern Chemistry to Science is the production of Quinine from Gas tar. Professor Fischer, of Munich, has succeeded in obtaining from distilled coal a white crystalline powder, which, as far as regards its action on the human system, cannot be distinguished from Quinine, except that it assimilates even more readily with the stomach. Its efficacy in reducing fever heat is said to be remarkable, even rendering the use of ice unnecessary. The importance of such a discovery as this consists, not so much in the actual fact achieved, as in the stimulus given to scientific research by the opening up of a new channel of investigation. The romance of Gas tar is evidently far from being exhausted. In addition to the sweetest scents, the most brilliant dyes, the most powerful disinfectants, and even Prussic Acid, are some of the numerous and wonderful products of its decomposition."

OUR BOOK SHELF.

The Cinchona Planters' Manual. By T. O. OWEN.
(Colombo: A. M. and J. Ferguson, 1881.)

Few plants have been so fortunate or unfortunate in having so much written about them as the *Cinchonas.* Ever since their successful introduction into India, now some twenty years since, the Cinchonas have had showered upon them books and pamphlets innumerable, and where we find such voluminous writings, it would be strange indeed were there not matter of varied quality, and some that could be dispensed with altogether. Mr. Owen's book is very complete in the several branches of Cinchona literature, facts gathered from various authentic sources, such as the works of Dr. King, Dr. Bidie, Mr. McIvor, and the reports of the Indian and Javan Governments, all of which are acknowledged by the author.

The book is divided into six parts, the first part being devoted to the physiology of plants, gathered, as we are told, from Church and Dyer's "How Crops Grow." The second part treats of the alkaloids, the species and varieties, to which a large space is given, and the next part on the choice of land, felling, clearing, weeding, planting, &c. In the fourth part manuring and harvesting are considered; and parts 5 and 6 the diseases to which Cinchonas are liable, and the estimates of Cinchona planting are digested. In all these matters careful details are given.

The book no doubt will be very useful to Cinchona planters, more particularly the practical part. Its greatest fault. perhaps, is the extent of the book, numbering 203 pages, too voluminous for many planters to wade through; but on the other hand it appeals also to those who, though not actual planters, are interested in the progress of the Cinchona culture.—*Nature.*

COLA NUT.

(Guru nut; Ombené seed), *Cola acuminata*, R.Br. (Sterculia acuminata, P. Beauvois). Nat. Ord., Sterculiaceae.—The Cola Nut tree is a native of tropical Africa, where it attains a height of about forty feet. The leaves are lanceolate, four to eight inches in length, one to one-and-a-half inches broad. The flowers have no corolla, but a pale yellow calyx, spotted with purple. The fruit is about the size of a citron, and contains 5 more or less globular seeds, as large as a horse chestnut, of a somewhat fleshy consistence, externally of a reddish, violet, internally of a dark-violet color. The taste is astringent and slightly bitter. Prof. J. Attfield found the nuts to contain 42·5 starch, 6·33 albumen, 2·12 thein (caffeine), besides gum, sugar, mineral salts, etc. Later Heckel and Schlagdenhauffen found theobromine, a considerable quantity of glucose, and that caffeine exists in the free state, thus combining the best qualities of caffeine and cacao.

From time immemorial Cola Nuts have been of inestimable value to the inhabitants and so highly prized that they are used, much as cigars with us, at present to the stranger or guest, as a sign of welcome, friendship and protection; moreover, where the nuts are not indigenous, no business can be transacted without a few of them being previously eaten. Formerly no marriage gift of the bridegroom to the father would be deemed acceptable for the purchase of his daughter, unless it comprised a considerable amount of Cola Nuts. Europeans become quickly used to it, and find it quite as imperative a necessity of chewing it as the natives themselves. This is easily explained by the relatively large amount of caffeine which they contain, the habitual use of which is necessary in the tropics.

It is asserted that to those who chew and eat Cola Nuts, all food and drink, and even brackish water, have a pleasant taste. The use of these nuts is said to support the strength, allay inordinate appetite, assuage thirst and promote digestion. They are further stated to render those using them capable of prolonged fatigue, in the same manner as coca leaves.—*A New Idea.*

[NOTE ON COLA BY EDITOR.—In our recent visit to the West Indies, we found the Cola Nut (*Bisy-Bisy*) quite often offered for sale by the negroes in the market place at Kingston. The fruit is *not* so large as a citron, the pod being somewhat triangular and somewhat curved like the letter S; the color is dull green, and it rarely contains more than three seeds. It is esteemed in Jamaica as a cure for drunkenness, and it is said that any one in a condition of intoxication or even in delirium from it, will be promptly sobered and quieted. It is being cultivated by the planters to some extent, and there is an increased interest in it taken by the planters as a future crop of value.]

TILLAGE AND EVAPORATION.

A few years ago a contemporary announced with great positiveness the discovery that cultivation of the surface soil promotes instead of retarding evaporation, and is, therefore, labour worse than wasted, so far as it had previously been supposed to help in retaining moisture. Experiments by Professor Stockbridge, of Amherst, were subsequently published, which seemed sufficient to confute the position above referred to, and to establish the correctness of previous teachings on the subject. And now Dr. Sturtevant, of the State Experiment station at Geneva, reports the following experiments, which is similar in result to those of Professor Stockbridge, though not conducted in precisely the same manner:—"The question of drought is one which periodically engages attention, and any means by which its injurious effect may be mitigated should certainty be known to the farmer. That cultivation by forming a loose soil upon the surface which acts as a mulch, conserves the water to the soil, is a fact which is well established, and should be more commonly appreciated. For the purpose of offering numerical values which shall express the influence of cultivation, we have tried the following experiment:—Oak boxes of 1 cubic foot capacity were made of half-inch stuff and thoroughly soaked with oil. The bottom being removed, the frame was worked down into the earth in the corn field, and the bottom afterwards put in position. We thus had a foot cube of soil in its natural position. The surface of the earth in one box was left undisturbed, while the surfaces of two boxes were kept cultivated. By weighing these boxes the gain or loss is assumed to measure the evaporation which has taken place from each. From 26th July to 1st August, six days, the cultivated soil evaporated at the rate of 906 gallons per acre less than the undisturbed soil, or less 151 gallons daily per acre. From 1st August to 10th August, nine days, the cultivated soil evaporated 2,367 gallons per acre less than did the undisturbed soil, or less than 263 gallons daily per acre. During the whole period, from July 26 to August 10, fifteen days, the saving of water effected through cultvation figured up 212 gallons daily per acre, or, expressing these facts in another from, the undisturbed soil lost per acre from July 26 to August 10, 4,243 gallons; the cultivated soil 1,060 gallons. In calculating our results to the acre by multplying the evaporation which has taken place from a square foot of surface by 43,560, the unavoidable errors are correspondingly multiplied, and while duplicate s ries can never be expected to give precisely the same numerical results, yet the one fact becomes unquestionable—that through cultivation we are enabled to conserve to th· soil a large amount of water during a drought. Indeed, observation through extended periods of drought, also plainly shows the superiority of fields that have been well cultivated over those where cultivation has been neglected. *Cultivator and Country Gentleman.* [Are we to accept the converse of the proposition and abstain from cultivating soils which suffer from wet?—ED.]

A TREE YIELDING BALSAM OF COPAIBA IN THE GHAT FORESTS OF COORG.

This promises to be a valuable discovery Its history is rather a curious one. Mr. A. L. Tod, who for some years has been resident in these forests, happened on a tree two or three years ago, which when cut into yielded an oily liquid, which gushed out copiously from fissures in the heart of the tree. He did not think much of it at the time, but a month or two ago, I shewed him a compilation of information all about rubbers, published by Messrs. A. M. and J. Ferguson of Colombo, the editors of that useful periodical, *The Tropical Agriculturist.* Amongst the various papers about rubbers collected in their little book is one by Mr Cross relating his experiences whilst hunting up Ceara and Para rubbers, and also a short account of the Balsam of Copaiba tree. On reading this Mr. Tod said at once that his oil tree behaved exactly like the Copaiba tree described by Mr. Cross. He did not know what the tree was like, nor where to look for it. Luckily, however, he was making a clearing for a teak plantation at Kootampolle, at the bottom of the Perambadi Ghaut, so orders were given to the fellers to report any tree which spouted any liquid from its centre. It was not long before one was found, and some of the liquid collected. It was a thick oily substance of a claret red. On comparing it with the medicinal Balsam of Copaiba, I find the latter is not so thick and is a yellow colour, and also has a more pungent odour, though there is no doubt that our liquid has the characteristic smell in a less degree.

I have just returned from an expedition to Kootampolle, where Mr. Tod and I had a great search for the tree. The clearing had in the meanwhile been burnt, and the tree therein charred, so that we had little to go on, except the leaves which had been gathered from it, and on cutting into the trunk we saw the structure of the wood. We also noticed that it was not a buttressed tree. These two points were indeed all we had to go on for a long time, for in these heavy evergeen forests, it is very little that can be seen of the leaves of a tree unless of very peculiar shape. The first day we were quite unsuccessful. The second we began by searching this clearing, and soon found several stumps which had the liquid still standing in them, so it was evidently a fairly common tree. We then looked very carefully round the edge of the adjoining jungle, and at last found a tree. After that it was comparatively plain sailing as we soon caught the characteristics of the bark and habit of trunk, which is pretty nearly all that one has to go on in these forests.

Unfortunately the tree has neither flower nor fruit at this time of year. But Mr. Tod is going to have one felled every now and then until he can get the flower. The leaves are somewhat like the *Pterocarpus marsupium*, but very irregular in size, varying from 2 to 5 inches, also in shape, being sometimes lanceolate, sometimes ovate. I enclose a few specimens.

I am sending the liquid home to be reported on. From the second tree we operated upon, we obtained two different liquids. The one, the thick oily stuff already described, and the other a yellow watery fluid with a very disagreeable smell. I thought at the time, that this would turn out to be the true balsam of copaiba, and so sent off some of it to England, as well as the the oily fluid. But on further examination I fear it is useless.

I will send the London report on the liquid to the "Forester" as soon as I receive it.—F. B. D.—*Indian Forester.*

CINCHONA CULTIVATION NOT A FAILER IN CEYLON.

SIR,—In the present financial depression of this island, I think it incumbent to enter a protest against the way in which this product, or rather its cultivation, has been cried down in the local papers. Those who have been successful remain silent, while those who have not have been very busy throwing dirt on the cultivation of a product which, with prices 20 per cent below the present low rates, still promises to yield a clear return of R200 per acre. This is more than the best managed tea estate could ever give. It is all very well to talk of what tea is going to do, but in all probability, but for the return cinchona has given in its early and infant stage of cultivation, by which many have tided over their difficulties, a serious crisis would have occurred, shutting out the chance of even tea having a fair trial. When banks and merchants ceased to render pecuniary aid, cinchona was expected to do everything—even plants of 18 months' growth—and because cinchona did not choose to grow everywhere, and in whatever style each man chose to plant it, therefore cinchona is a failure. The failure is attributable to bad and unsuitable soil, however rich in other respects, bad aspect, clayey subsoils, dibbling and planting, and too close planting. A soil found unsuitable need never be replanted. Will any proprietor of a cinchona estate in a good district, having, say, succirubras 6 feet apart and officinalis 4 ft. apart,—the estate 6 years old, if of succirubra or 4 years old of the latter,—show that his return per acre of shavings at present prices gives him less than R150 profit? Though I know that my neighbour plants succirubras 3 ft apart, I am certain, when he barks his spindly walking-sticks, he will not get more in weight than I do from my stout trees 6 ft. apart. As to richness of bark, it is not difficult to decide who will succeed in the end. Yet he has set an example to others, and this wretched close planting is still going on. Instead of a forest of succirubras, we are to have sheets of something very like hemp fields. Had I the opportunity, my next clearing of succirubras will be 8 ft. apart, interlined with officinalis or calisayas to be *rooted up* in their 4th year. To proprietors of genuine cinchona estates or clearings allowed to grow to mature estates, it is a matter for congratulation that the present low prices are the result of over stocking the market with twigs and shavings of tender trees. It has had the effect of completely shutting up those who have not the suitable land or means to carry on a cultivation similar to growing peas and bringing them early to market.

Whatever may be said of coffee, cinchona has not turned out a failure. The money it has brought to the island and the progressively increased export, gives the lie to this sweeping assertion. No one has yet been ruined by a cinchona estate, so long as he has had the means to maintain the estate till the trees, properly planted as to distance, &c., have attained 5 to 6 years' growth. Within the last few years much has been learnt as regards choice of land (all forest land not being found suitable) elevation, distance of plants, &c., and the cultivation is being now properly conducted. I have no doubt that tea and cocoa will yet come to this island's aid, but the day is far distant before cinchona in suitable localities will cease to yield their proprietors a clear profit of anything under R150 per acre, and no one can grumble at such a return. I base my calculation of this return on the supposition that the inferior red bark sells at 50 per cent less than it does now. Every effort must be made to avoid shaving trees, no matter of what kind, under 4 years' growth.

T. S. S.

[NOTE BY EDITOR.—We think our correspondent is very sanguine, and more, that he cannot have had much experience in districts other than the one in which his own estate is situate. To say: "Whatever may be said of coffee, cinchona has not turned out a failure. No one has yet been ruined by a cinchona estate," is not exactly consonant with existing facts, though we quite admit that, when cinchonas will grow, they are very remunerative, but—where they will not? Though much dying-out might doubtless have been prevented had more suitable soil and better seed been selected, many estates that had every care in this respect, added to wide planting, have died out by thousands.]—Local "Times."

TEA LAND IN CEYLON.

The question has been raised as to whether it is more advisable to look to our coffee estates as an investment for the intending tea planter, or whether it will be more advantageous to open new land at lower altitudes. Mr. Owen, both in his letters from the tea districts of India, and in his paper on tea cultivation in Ceylon, speaks of the clayey soils of the hill districts as possessing special advantages over lighter micaceous soils, but whether he considered our clays as equalling those of Darjiling does not appear very clear. There is no doubt that we have in some districts the light yellow friable clay, of which Mr. Owen makes mention in his Indian letters, but there is also some of our clay soil of a very different character, scarcely so suitable as the above—heavy solid clay that would puzzle the roots of a tea plant to force their way through.

It need not, however, be a question of planting up coffee land, though we believe that near upon a hundred thousand acres of such could be had. The maritime provinces present a far wider field for the tea planter of the future: all the land available may not be of the quality described by Mr. Owen as most suitable for this cultivation, but the extent is on the whole so large as to leave an ample margin for poor soil. In the Western Province there are fully one hundred and fifty-thousand acres of Crown jungle, in the Southern Province a hundred thousand; but none of all this is designated as *forest* in Mr. Vincent's report;

he says there are isolated blocks worthy of that name, but too trifling to be shown on such a small scale; he therefore treats it all as scrub: the only tracts of forests colored in on his map as such, are the large tracts of timber reserves in the Northern districts of the island.

We may take it for granted that there are in the south-western districts of the island a quarter of a million acres of land, the soil of which is more or less suitable for tea having an ample rainfall. There are also a hundred thousand acres available in the mountain zone amongst the coffee districts, and, if, as an experienced tea planter from Assam says, the rainfall in Uva is sufficient for tea, then we may add considerably to the area. It is believed, moreover, that the lands about the Kanthalai lake with their rich deep soil have a sufficiency of rainfall for this cultivation, with a distribution fairly spread over nearly every month in the year.

The report on the Forests of Ceylon, recently published, is accompanied by a map on which are laid down figures denoting the rainfall in the different localities which is of much more importance than any coloring to denote heavy jungle, because scrub jungle, and what is known as mookelana, from which all the good timber has been taken, serves well for tea, with an adequate rainfall. There is, in fact, scarcely any jungle remaining in the south-western districts in which there is good building timber: all such has been thinned out long ago by dealers and petty headmen. It is more than probable, however, that there still remains a good quantity of timber that would serve very well for coffee-casks and tea-chests, though even such trees are fast dissappearing from the vicinity of roads and rivers.

With the feeling now existing in favor of replacing unprofitable coffee-land by tea where the soil warrants doing so, there will be a very extensive addition to this new cultivation without any demand upon Crown land; but, if capitalists are to be attracted to the island for this new enterprise, it will be in the direction of Crown jungles, not so much by reason of their greater suitability, but because, as a rule, the proprietors of coffee-lands, or their mortgagees, will generally prefer putting such into tea previous to selling them, when they may be disposed of as tea plantations in crop.

Notwithstanding all the disappointments that have met Ceylon planters, it will yet be shewn that our island offers to the man of capital more real advantages than many other colonies in the matter of investments. The island is most conveniently served by numerous lines of steamers from all parts of the world, with a harbor safe and convenient at all seasons; with a railway and first-class roads that carry the investor into the heart of the best land in the country. No pioneering is needed, all that has been done long ago; and, should he prefer Crown jungle to old coffee-land, the selection is ample, and access easy by river or road. There is no malarious climate in our tea districts, which, as a rule, are, with ordinary precautions, as healthy as any of the mountain zone, thanks to our unfailing sea-breezes. This accessibility is all in favor of cheap transport, which, instead of forming a formidable charge, as in some Indian districts, does not amount to more than a cent a pound on the tea shipped. There are other advantages which we possess over the tea districts of India, which cannot fail to tell in the future, and should influence those who hesitate where to embark their spare capital. What to do with the accumulating savings of the world, must become one of the most serious problems of the day. It will be our task to assist in its solution.—*Ibid.*

TEA IN CEYLON AND INDIA.

Mr. Owen has professedly dealt with tea cultivation in the two countries, and his observations throughout took that direction, and naturally so, in his advice to planters as to what to do and what to avoid. He tells us of some things that are better done in India than in Ceylon: of other things that are better and cheaper done in Ceylon. The result of the visit of a practical planter to another country where the same industry is carried on as in his own land, must be of advantage; for while he will be confirmed in some practices, he will be careful to avoid others. And thus Mr Owen, in his paper on Tea Cultivation in Assam, Darjiling and Ceylon, places before us very fully and carefully the advantages and disadvantages under which each labors. If Ceylon has not the depth and richness of soil to be found in Assam, we have a climate far more suitable for frequent flushes of leaf. We consequently produce far more per acre, and, notwithstanding nominally dearer labor, we grow the leaf at a lower cost, and with cheaper transport we put it on board for less money than is done in either Darjiling or Assam.

Likening our coffee zone to Darjiling, and our lowcountry to Assam, we can show in either of these a better yield of tea than our Indian friends; and, without indulging in any but well-established facts, we are warranted in taking the cost of teas as below any grown in the most favored districts of India, and, if we are not mistaken, very much below that from a large number of estates heavily weighted with a huge capital sunk and very costly establishments. We suspect Mr. Owen left out of his calculations the item of interest, and this, we suspect, in the majority of cases makes a very material addition to the cost of the tea produced. The best proof that it must be so lies in the fact that so few tea estates show any but the very smallest dividend.

In speaking of the peculiar rich clay sub-soil of Darjiling, the writer of this essay may perhaps be thought to infer that the clay sub-soils of many of our coffee estates within the mountain zone may be equally suitable for the production of tea; which would assuredly be a mistake. The Darjiling clay is of that soft yellow description—very seldom met with in Ceylon —which clay is very easily penetrated by roots of the tea plant, whereas the clay on much of our hill zone is hard and compact, and almost impervious to any but the most vigorous roots.

It is admitted that estates in the Yatiyantota, Avisawella, and similar low-lying districts will generally, under proper management, yield fifty per cent more than those in higher altitudes and on old coffee land. This may be partly owing to the plants being newly-opened land, partly to the more favorable nature of the climate, but the fact remains beyond question, even by the most sceptical or pessimist writers. The most that can be said by those who are compelled to admit the accuracy of these figures is, that it has yet to be ascertained whether estates can continue to produce at the heavy rate they are now giving crops. There are, it is true, no estates in the lowcountry of any mature age, but as regards tea within the mountain zone, both Looleondura and Rookwood are able to show what can be done with tea in the eighth year of its production. It is, of course, an open question as to the time that must elapse before our tea estates will require help in the form of manure, but this much is certain, that facilities for transport are materially in our favor.

A writer in our paper some short time ago urged the preference for old coffee estates to new jungle land for tea. Without attempting to solve this question, we may remark that the extent of coffee land for disposal in the market cannot be large. There is, no doubt, a good extent of such land in the hands of estate-owners, but it is more than doubtful whether the larger portion of this will not be converted into tea properties by their present proprietors. If tea-planting is to be taken up extensively during the next few seasons, there will be no alternative but to resort to Crown jungle in the maritime provinces, where an abundance equal to any demands likely to be made upon it may be found. Selection will be necessary as regards soils, of which there is a great variety, but, as regards rainfall, we have sufficient data to enable us to say how far the tea pioneer should go. Eighty inches of rainfall during the twelve months suffice for tea cultivation, provided the fall be fairly well-distributed. Taking this datum for guide, we may include a large portion of the Uva country within the future range for tea cultivation; for, although there is frequently a long spell of dry weather in Uva, of, say, three months' duration, this will have no other effects than that of a wintering, such as they have in India for five or six months. If eighty inches of rain, spread over nine months of the year, are sufficient in Uva, the question will arise whether there are not other districts, yet unthought of, that may be turned to profitable account for tea.—*Ibid.*

A MANUAL OF INDIAN TIMBERS.

BY J. S. GAMBLE, M.A., F.L.S.

We are ashamed to say how long a copy of this excellent work has been daily staring us in the face, but no one knows better than the author himself that the *Indian*

Forester is not often overburdened with that always much-coveted, hourly-sighed-for commodity—LEISURE. To review this book adequately would require several long consecutive notices, and many entire days passed among the several thousand specimens forming the unique collection of woods at the Forest School. We had vainly hoped to have been able to make for ourselves this leisure, but *kismat* has been too strong for us hitherto, and rather than delay any longer, we will at once attempt to give some idea of the book to those of our readers, who are so unfortunate as still to be without a copy of it.

The idea of writing such a work arose during the preparation of wood specimens for the great Paris Exhibition of 1878. Such a large number of specimens of undoubted botanical determination was collected, that the opportunity was seized of supplying a "good stock to the Royal Gardens at Kew and to other museums both in Europe and America;" as well as type collections, for reference and study by Indian Forest Officers, to the various Conservators' offices in this country. The next and almost simultaneous step was to prepare a work embodying a correct description of the structure, properties and uses of these various woods.

Every circumstance was favorable for the preparation of such a book. The number of species represented in the collections was large, and included very nearly all the more important ligneous plants growing within the territories ruled over by the Viceroy of India. Moreover, nearly every species was represented by several specimens grown in various portions of those territories under various conditions of soil, climate and locality. A well-organized workshop was at hand, superintended directly by Mr. Gamble, assisted by Mr. Smythies, and during part of the time, also, by Dr. Warth, both of whom were specially deputed to aid Mr. Gamble. And last but not least, Dr. Brandis, the FATHER OF INDIAN FORESTRY, was there present with his great knowledge and vast experience to start the work and direct its progress.

The chief points of information recorded under each species are, to us, as nearly as possible, the author's own words—

1. The scientific name, with synonyms.
2. Selected vernacular names.
3. Description of the wood.
4. Geographical distribution, briefly.
5. Record of all available information regarding rate of growth.
6. Results of all experiments on weight and strength that it was possible to quote.
7. General uses of the wood and of other products of the tree.
8. List of specimens used in identification and description.

Besides this, "some attempt has been made to notice even the species which have not been described. In some important genera, a list of known species and their geographical habitat has been given, in other genera other species of note have been mentioned, and, whenever possible, notes regarding the uses and qualities of the wood and the other products of the trees so referred to have been added.

The most important, as it is the truly original, portion of the Manual is the description of the wood and bark of the trees and shrubs noticed. These descriptions were usually dictated by Dr. Brandis, after full discussion with Messrs. Gamble and Smythies. The generic and family characters were not discussed and established until constant practice had given facility in seizing at once essential difference of structure. For the descriptions of the later received wood specimens, as well as of those given in the *addenda* Mr. Gamble alone is responsible, although he adhered throughout to the original plan adopted.

The main object of these descrptions is confessedly to enable the reader to identify by their means the species of any wood of which he is ignorant; but Mr. Gamble very rightly warns him, "that there is no regular rule for determining orders and genera by means of the wood, for in some cases the structure of the different component genera or species present characters of a very dissimilar type." But the same absence of a *regular rule* as regards the structure of flowers and fruits is the great stumbling-block over which 99 out of 100 students of systematic botany come to grief. Would it be then rash to suggest that we have perhaps not yet hit on the right method of examination and description of wood structure, and that we are still in what may be called the Linnæan stage of our subject? And may it not be that the systems of classification now adopted by botanists will at some future time have to be modified by their successors being compelled to admit among essential characters differences of structure of the wood.

But without making any heretical suggestions, we more than *hope* that, "with a rather wider acquaintance with the woods of India, we may be in a position to draw up an analytical table for the woods which are most chiefly in use in India, similar to that given at the end of the French Forest Flora." And we hope that Mr. Gamble himself will forge for us this analytical key.

No Indian Forester, Engineer, Planter, Agriculturist or Merchant should be without a copy of this Manual of Indian Timbers. We are proud that the Indian Forest Department has within it the brains and industry to produce such work. To Dr. Brandis (who will never cease to have claim to the gratitude of Indian Foresters), to Mr. Smythies, and last, but not least, to Mr. Gamble, who has to his sole count written half the book, and edited with conspicuous success the whole of it, we owe a world of thanks. In the words of the old Roman Commonwealth, *Bene meruère de re publicâ.—Indian Forester.*

CINCHONA CULTURE.

Cinchona planting, looked at in a "will it pay?" light, is a most enticing form of tropical agriculture. The writer of this has had over eight years of practical experience in its cultivation in the island of Ceylon; and a few words with regard to that island, and the introduction of cinchona there, will not be out of place just now in your columns.

Ceylon, as most people know, is a great coffee country; one of its districts alone contains nearly 45,000 acres, and, when one comes to consider that coffee is usually planted 5ft. by 5½ft. one can grasp what 45,000 acres of coffee shrubs means. Many handsome fortunes have there been made and marred; the writer in one year took off a property of some 500 acres £21,000 worth of a crop; but from the year 1878 till now Ceylon has been suffering more or less from a complete change of seasons. I do not attribute the falling-off of crops so much to leaf disease, from which the coffee has been suffering, as to this change.

For some years prior to the advent of these bad times the fortunes to be made in the planting of cinchona had been the theme of planting conversation, but no one, all being so wedded to King Coffee, would think of giving such a new-fangled idea a trial, and one case is quoted in which an old and experienced planter, still in Ceylon, wrote to the agents of the property under his care advising them to give cinchona a trial. They thought him mad, and, had he not been a man who was much respected, he would have stood a chance of losing his situation. The last time I saw this self-same property it was one, so to speak, field of cinchona; and its old manager has, on his own property, some of the richest quinine-yielding cinchona trees of the Ledger variety that there are to be found in Ceylon.

Gradually the giving of cinchona a trial crept in. First of all it was used to line the road sides, then to define the various weeding contract boundaries, all the weeding being given out in contracts at rates varying from 2s. to 3s. 6d., and even much more, per acre. Soon all the bad patches of coffee came to be used up for cinchona, then here and there amongst all the coffee, and finally land has been felled and cleared for the growth of cinchona alone.

For the better qualities of cinchona bark there is a steady value and growing demand, as the following statistics will show (from "Notes and Statistics of Cinchona Bark," by John Hamilton):—In the year 1870, the amount of bark imported into Great Britain was 2,535,565 lb., and value £218,565; whilst in the year 1881 the quantity was 14,040,096 lb., of a value of £1,814,501. This bark did not come from any one country, but from all parts of the world, and principally from the United States of Columbia. From Mr. T. C. Owen's book (a valuable one) on cinchona, we find that whilst in 1870 the value of Ceylon total exports of cinchona only reached £5, in the year 1880 it was £120,000, thus showing the opinion Ceylon planters held of it.

The first step is to procure seed, and great care should be taken to secure such from good sound trees, avoiding seed from those cankered. And here I may be pardoned for digressing in saying that the dry climate of Queensland (as compared with Ceylon, where the damp, causing the death of thousands by canker, is the chief enemy the cinchona has to encounter) will, in my opinion, be the climate *par excellence* for cinchona. I would advise Indian seed, or seed carefully gathered from reliable sources in Ceylon. It is easily germinated, usually coming up in three weeks. The plants after a time are exposed to the sun and rendered hardy, and should be transplanted when about 8 in. to 9 in. in height. With cinchona, unlike many other products, an immense quantity can be secured to the acre. On its first trial it was planted too widely apart, and now for the planting of the *Officinalis* variety I woul l advise 3 ft. by 3 ft., or 4,840 trees to the acre. The *Succirubra* being a much larger variety, cannot be planted so closely, but 5 ft. by 5 ft. would be a satisfactory distance. The *Officinalis* variety grows best at an elevation of from 4,000 ft. up to 6,000 ft., and a corresponding climate to these elevations, especially the first, would be found in my opinion along your northern shores; the latitude for these elevations in Ceylon is 7 at 6,000 ft. In Ceylon the mornings and evenings are generally cold, sometimes very much so, and the heat at mid-day very intense. At these elevations the *Officinalis* would thrive immensely, were it not for the prolonged bouts of rain it gets.

Ceylon agriculturists do not use the plough, but having lined off their ground 3 ft. by 3 ft. they proceed to hole, and the larger the hole up to 18 in. the better; this, of course, is done in a land where labour is plentiful, but this work may with truth be said to be the only expensive part of cinchona culture; the land being opened, the cinchona needs no further attention for two or three years, beyond keeping the ground clear at first so as to give the young plants a start.

The first trees planted on a large scale in Ceylon were allowed to attain to some five years' growth before any decided plan of action was hit upon with respect to the harvesting of their valuable bark. First of all coppicing was tried, but planters did not like to see five years' growth and more laid low; and in some instance, and at certain elevations, the suckers sent up from the stool did not grow as well as could be desired; and if the suckers did not come on, by the time that this fact was demonstrated, the roots below ground had lost all the valuable properties of their bark, so that in certain localities it was the best policy to uproot the trees bodily. The writer once cut out some 23,000 trees, averaging four years old, and on taking the bark off stem, roots, branch, and twigs, the yield per tree was slightly over 1 lb., whilst over a few thousand of the larger, or five-year-old trees, the yield was $1\frac{1}{2}$ lb. per tree. Each tree was cut out with its roots attached (the root bark being very valuable); the trees were then carried to the nearest road, where the roots were sawn off at the stool. These roots were at once carried to a pool of water and cleaned prior to being barked. The man now takes his tree, and cutting off all branches—on which the women operate (whittling off the bark—taking care, however, not to include wood with bark), the man being left with the stem only—and proceeds to slice rings round it, about 18 in. apart, and then, making a perpendicular cut between these two rings, he inserts anything that will lift the bark without breaking it—either a piece of flat wood, or a steel instrument with a top like the ladle of a spoon, only flat. The bark, being full of sap, comes off easily, and a good hand will cut out his own trees and bring in about 50 lb. to 60 lb. of bark a day. The bark is now dried in the sun for three or four days, and will lose in the first days, drying about half its green weight, and when thoroughly dry will be about one-third of its original weight. The yield from these 23,000 trees fetched an average price in the London market of 4s. 4d. per lb., and some parts of the stem quill, taken off as described, fetched 6s. 6d.

The planters being in difficulties as to the best mode of harvesting, an Indian authority—Mr. M'Ivor—came to the rescue, and advised the leaving of the trees, securing the bark by the stripping process, and covering over the stripped part with moss. This method proved unsatisfactory, being too severe to be put into general use, and has since given way to a much better process in every respect The trees are now spoke-shaved with a two handled shave, set to any required depth, and the amount of bark that can be secured per man per day is truly astonishing; 200 lb. and more has been taken from the larger variety of cinchona (*Succirubra*), but I consider 80 lb. per man from three to four year old trees of the *Officinalis* variety a very good day's work.

With the spoke-shaving process there came a flood of knowledge. First of all it was proved that the second shaving gave a richer yield in quinine than the first, and that each shaving thus increased in value. It was also proved that two harvests could be secured in fourteen months, and that the sooner it was secured the better, for after an eight months' renewal it began to retrograde. The yield of bark is also found greater on each succeeding shaving, the writer's experience putting it at one-fifth—thus, 25 trees gave 10 lb. on the first shaving, and eight months afterwards gave 12 lb; these trees were only shaved up a height of 3 ft. Many planters have gone in for shaving trees that are not quite two years old, and have apparently done no damage. The shaving sells for an average price of 2s. per lb., * and from $2\frac{1}{2}$ to 3 year old trees about 3 oz. of dry bark could be counted upon with safety. Some planters cover over their shaved trees (the process causing a quicker renewal of bark and a richer secretion of quinine); but I had 150 acres of shaved trees under my charge, none of which were covered, and the bark after such treatment fetched as fine prices as could have been desired.

Many Ceylon planters have gone in for lopping off the lower branches, and even those midway up the tree, thus securing a little bark, but at a ruinous sacrifice. I would strongly advise the growth being left natural.

The writer once secured considerably over 200,000 young plants from 2 lb. of seed—which is very small, flat, and light, showing germ in centre. Good seed could be secured for about £2 per lb. of the *Officinalis* variety, whilst the *Robusta* variety costs as much as £5 to £10 per lb., but Ledger seed secures fabulous prices, even going up to over £80 per lb.

I write this article with the view of encouraging the planters and moneyed men of Queensland to give this product a trial. Opinion or indifference here cannot possibly be stronger than it was in Ceylon, or the reliance in sugar stronger than was the reliance in coffee; and yet the day came when many a poor hard-working fellow would have been gazetted, had he not some years before put his faith in cinchona, and his bark bearing him safely over the breakers, he could afford to wait for the turn of the tide.—H. ST. G. C.—*Queenslander.*

REPORT ON THE PROGRESS AND CONDITION OF THE ADELAIDE BOTANIC GARDENS AND GOVERNMENT PLANTATIONS DURING THE YEAR 1882.

R. SCHOMBURGK, DR. PHIL., DIRECTOR.

MEDICAL PLANTS.—The demand by invalides for medical herbs becomes more frequent, and it is gratifying to be able to supply them. Inquiries are especially made for the following, viz.:—The common English Broom (*Cytisus scoparius*, Link), of which a decoction is used in dropsy; the leaves of the Mullein or Shepherd's Club (*Verbascum Thapsus*, Desm.), a decoction of the leaves being recommended by some of the American papers as a remedy against consumption; the globular Spurge (*Euphorbia pilulifera*, Linn.,) a native of the tropical regions of the new and old world. It is found growing in Queensland, and a decoction of the plant is said to be used with the best results in asthmatic complaints. It would be a beneficial discovery if these domestic remedies were really effective.

WATTLE FARMING.—I again call the attention of the farmers to the cultivation of the wattle. If properly and systematically carried out, it will beyond doubt become a profitable speculation. Tanning material becomes scarcer, and the prices for such rise constantly. In my former reports I have given detailed accounts regarding the cultivation of the wattle. It seems that in Victoria

* Not now.—ED.

the cultivation of this useful tree is successfully carried out. Why could we not do the same in South Australia, where the most prolific kind, *Acacia pycnantha*, Benth., is a native? Although the following remarks have been made in my former reports, I repeat them here:—"The dangers to the "wheat crops are too many to compete with, and it is not within the power of the farmer to avert them. Why not grow other products besides wheat?"

PALM HOUSE.—Although it is satisfactory to observe the rapid and luxuriant growth of the plants, especially the palms, at the same time it is to be regretted that in a short time many will have reached the roof of the wings of the house, and it will be necessary to cut them down, as the palms will not stand topping. *Phœnix*, *Ptichosperma*, *Kentia Corypha*, *Pritchardia*, and *Livistona* will have reached the roof in a short time. The *Cycadeæ* and *Pandaneæ* have increased in size and beauty, and some flower and fruit to perfection, especially the different species of *Encephalartos*. The growth of the fine specimen of *Latania borbonica*, in the centre group of the dome, is striking, and it is gratifying that the height it still has to grow before reaching the roof of the dome is sixteen to seventeen feet. The same luxuriant growth is observable in the fern trees; and, indeed, all the plants contained in the house. The climbers along the rafters, the grotto covered with the delicate species of asparagus, viz., *Asparagus plumosus*, Hort. Bull, *falcatus*, Linn., *virgatus*, Hort. Bull., *racemosus*, Willd.—become more effective every year. Notwithstanding the great heat we had often to contend with, the temperature in the house has seldom been above 90° which is no doubt attributable to the great development of the plants, which increases their exhalation considerably. The terrace around the Palm House, with its numerous flower-beds, produced, notwithstanding the ungenial season, an animated picture. The *Phlox Drummondii*, Pansies, Petunias, and Lobelias developed to perfection.

Two thousand five hundred and forty-one packets of Australian seeds, including many seeds of forage plants, were sent to kindred institutions and agricultural societies, viz.:—Madras, Bombay, Hongkong, Singapore, Calcutta, Marseilles, France, and the neighboring colonies. As usual, the supply of cut flowers and boughs for decorations on public festivities, ecclesiastical and ornamental purposes, and of plants and cuttings to the juveniles of different schools for their annual flower shows, has again been profuse; and I may here remark that it is a very laudable attempt of the school teachers to inspire our young people with a taste for floriculture, and it always gives me pleasure to assist in this praiseworthy object. The Agricultural and Horticultural Societies have, as hitherto, been assisted with flowering plants for their perodical shows; but I must again mention it is always a sacrifice, the plants suffering from the burning gas and the knocking about they in most cases receive, from which it takes them some time to recover.

MUSEUM OF ECONOMIC BOTANY.—Since my last report 758 new objects have been added to this popular institution, which is more appreciated by the public than I even expected, and I again repeat that old and young take a lively interest in the many objects which show, not only how vegetable products can be turned to account for our use and convenience as articles of food, construction, medicine, or art, a knowledge more readily obtained by exhibiting the economical and commercial plants in their raw states, side by side with the articles into which they have been converted by the labour and skill of man.

MEDICAL PLANTS.—A collection of medical drugs, gums, resins, containing 244 objects, has lately been added; although a good many plants in the collection have been rejected from the pharmacopœia, they still retain their place in rustic practice and as household medicines. Several of the plants are merely used by the people of the countries where they grow, and are in high repute by the native physicians, but the drugs have not found their place in any western pharmacopœia. Our collection, therefore, contains medical plants from all parts of the world which are used by the inhabitants. The medical plants belong to widely different orders, and it will be noticed that in some orders many particular medical properties are prevalent, viz.:—*Labiatae, Umbellatae, Compositae, Leguminosae*, and *Rubiaceae*. The latter contains the very important genus *Cinchona*, from the bark of which the sulphate quinine is produced. Through the munificence of Mr. Thomas Wiffen, London, our Museum now possesses a valuable collection of twenty-two different barks of the most important varieties used in the manufacture of sulphate quinine. It contains the following barks, viz.:—Yellow flat bark, yellow quill bark, Columbian bark, Pitayo bark, New Granada bark, Carthagena bark, Indian crown bark, Indian renewed crown bark, Indian yellow bark, Javan yellow bark, Javan crown bark, Indian red bark, &c., &c. The barks from the cinchona trees introduced and cultivated in East India, Neilgherry Hills, Madras, Java, Borneo, and Jamaica; the climates of these countries seem to be well suited for the growth of these valuable trees, and strange to say these barks contain a larger percentage of quinine than those of the South American forests. A very interesting fact is that the Indian renewed bark yields more quinine than any other bark, viz., 6·8 per cent of sulphate quinine. The renewed bark, as its name implies, is the young bark which has grown over the stem after the original has been partly stripped off. In the third year it has become sufficiently developed to be detached from the stem, and has been found to be much superior in quality to the original bark from the same tree. The wholesale destruction of the cinchona forests in South America, by stripping the whole bark off the stem or by cutting down the trees, is now avoided in the countries where the cinchona has been introduced, by stripping only one part of the bark of each tree, which will renew itself without injury to the tree. The labels of the medical plants show the popular and botanical names, country, and a condensed description of the properties, the diseases for which they are used; and the collection is arranged according to the natural system.

The Introduced Plants in our Gardens and Fields.

Of intertropical fruits only a few kinds prosper with us, viz.:—The Loquat (*Eriobotrya japonica*, Lindl.), Guavas (*Psidium pyriferum*, Linn, and *pomiferum*), and bananas partially. Even the pineapple must be grown under glass. Most of the fruits from other parts of the globe thrive luxuriantly in South Australia, and come to such perfection in size, and frequently in flavor, as is hardly known in other countries, and many fruits are found to improve materially by the change, the climatic conditions being manifestly favorable to them. On the plains grow Apples, Pears, Apricot, Peaches, Nectarines, Medlars, Oranges, Citrons, Lemons, Plums, Cherries, Figs, Quinces, Mulberries, Almonds, Olives, and Grapes; while in the hills and gullies are also grown Strawberries, Gooseberries, Currants, Raspberries, Walnuts, Chestnuts and Filberts to great perfection. The Apples grow to a great size, but do not always possess the same fine flavor as at home, and contains more acidity. The apple-tree suffer much from the attack of the American blight, for which no radical remedy is at present known. The trees which grow in the hills or in very rich soil suffer most, and at last succumb to this scourge. The Pears grow to perfection, and maintain the same flavor as in the old country. The fruits of the Peaches, Apricots, and Plums reach to a large size, and contain a good flavor. The Cherries do not attain the perfection and flavor of those at home. All the stone fruit producing trees are shortlived, especially those of the Peach, Plum, and Apricot, which scarcely live fourteen to sixteen years. This early decline may be owing to the quick luxuriant growth and early excessive bearing of fruit, circumstances which produce over-stimulation and early exhaustion. The finest grapes are grown in the plains and slopes of the Mount Lofty range facing the plains. Here they grow to a great size, and the summer months ripen them to the greatest perfection. The wine produced often contains 25 to 30 per cent. alcohol. No doubt the South Australian wine must obtain a character in foreign markets. For the last nine years the *Oïdium* has made its appearance in our vineyards, but not with such damaging results as in Europe. Also the *Phylloxera* has appeared in the vineyard of our neighbor colony, Victoria, to an alarming way, and a good many vineyards have already been destroyed. From this it will be seen that the Australian vignerons, like the European, have to contend against the two greatest scourges which can invade a vine-growing country. The cultivation of the Olive is a great success, and the oil is considered perfect. All vegetables can be grown during winter and autumn on the plains, but in no comparison so successfully as in the gullies of the hills, where the finest vegetables and other culinary herbs are raised throughout the year in great abundance. Cauliflowers about two feet in diameter are often seen in the market; Cabbages, Turnips, Asparagus, Artichoke, Leeks, Onions, Beet, Carrot, Endive, Rhubarb, Lettuce, Celery, Cucumbers, Sweet and Water Melons, and Pumpkins growing to an extraordinary size, and of good flavor. Cucumber, Water and Sweet Melons, grow most luxuriantly in virgin soil, but if grown on the same spot several years running (although manured) the fruit degenerates in size and flavor, and ultimately fails altogether. The South Australian cereals, especially the wheat, which is considered to be the finest grown in the world, are pretty well known. When a new-comer visits for the first time our agricultural and horticultural shows, and observes the fine display of flowers, fruits, vegetables, and cereals in their utmost perfection, he must consider South Australia a favorable land; and it is indeed surprising that our fickle climate, with its extremes, drought and hot winds, can produce such developed specimens of Nature's gifts.

A GLANCE AT THE PROSPECTS OF CINCHONA CULTURE.

We read in the *Handelsblad*:—

It is a remarkable phenomenon that, at the time of the introduction and the prosperity of what is called the *cultuurstelsel* (culture-system) in the Dutch Indies, the Indian Government allowed the opportunity to pass of adding to their cultures the cultivation of the cinchona tree.

Just at that time, when attention both in Netherland and India was almost exclusively directed to the procuring of tropical productions on government account, and to the encouragement of Dutch commerce, there existed the greatest inducement to make the trial, which afterwards proved so successful, whether the soil of Java was suitable for the cultivation of that exotic.

There was no lack of disinterested endeavours to stimulate Government to do so. The men of science feared that in those regions where the cinchona tree is indigenous—that is the mountain districts of the tropical part of South America—the spontaneous or natural store of the plant would soon be exhausted, while there was no reasonable hopes of seeing the consumption supplied by timely and regular planting. Thus there might easily be a dearth of Peruvian bark, already such an expensive drug. Therefore it became necessary to look out for other regions where culture on a great scale would secure a constant supply.

As early as in 1830, so before government engrossed the coffee culture, the propriety was suggested of procuring in Peru plants and seeds of the cinchona for transplantation to the soil of Java. The proposals were taken into consideration, but went no further. Such men as G. J. Muller, Vrolik and Miquel, added their instances to those who had gone before them. Government was then already made to relish more and more the idea of increasing the advantages which government husbandry already produced, by securing the immense profits, which a product so high in price and subject to so little competition, as Peruvian bark might be made to yield.

Indeed, if the Indian Government could have been induced in 1835, for instance, to make the desired trial, they would have reaped advantages, compared to which all the profits derived from coffee culture are as nothing. For years together they would have shared with South America the monopoly of the cinchona produce. Even by important supplies from their side, thanks to this monopoly, the market price could not have fallen considerably.

But the Indian Government remained dilatory for years. Not till 1851 did they bestir themselves. But then the fit time was passed, at any rate for culture on a grand scale. Not only was the passion for government culture greatly cooled, but there was also a great scarcity of able hands. The population of the mountain districts were already more than they liked every where enrolled in the coffee culture.

In consequence of these circumstances the Government cinchona culture has remained very limited. From the very beginning it was and remains restricted to the Residency of the Preanger-Regencies, or rather to a very small portion of it. The Resident of those party, Mr. Van der Wijck, (subsequently *Raad van Indie*, at present settled in this country and well known as a writer on political subjects), convinced the Government of the necessity of employing only *free labourers* for the new culture. Later, when more extension was given to the planting, a reaction partly took place, on the pretext that *free labour* was not to be procured. The manager, Mr. Junghuhn, who was full of ardour for the success of the culture, but rather careless of the rights and wants of the population, required in 1858 serfs to labour for wages, while even materials, such as bamboo, atap for thatching the sheds, were obtained by requisition. The inspectors of the culture were even authorized to claim the labour wanted. But as we said above, the golden days of obligatory culture labour were passed. On the representations of the Government officers, that the new culture greatly impeded the population in their own husbandry, Government receded, to the great annoyance of the officials in the cinchona culture. Fortunately Junghuhn's successor, Mr. K. W. Van Gorkom did not share the narrow views of his *personnel*. The cinchona culture became free. Only exceptionally might serfs or vassals be required, and then only by the manager himself. This, too, soon proved unnecessary. Labourers, used to the work, and therefore far preferable to serfs, soon presented themselves in sufficient numbers, and the work in the cinchona gardens was and remained in truth "free labour."

If then circumstances have conduced to the government cinchona culture's being conducted on a limited scale, and the produce, therefore, insignificant, yet, in another respect, it plays a highly important part. It is, it may be said, the parent of our private cinchona culture in Netherland India.

Fortunately, Government soon came to see, that now the opportunity for conducting the cinchona culture for the sake of the treasury was passed, they could not do better than promote it as much as possible for the sake of individual industry. Therefore it was enacted in 1869 that the introduction of the cinchona culture must be based merely on "humaneness", and that the endeavours of government tend to spread the culture over the whole of the Indian Archipelago, and to make it a national culture. The plantations laid out on government's account in the Preanger-Regencies, were to be made subservient to this object by cultivating fit plants and seeds for dissemination.

This liberality of Government, that has been largely profited of, deserves the more estimation, as the product of the Government's plantations are generally of an exceedingly good quality. It is remarkable that not only the bark of the trees cultivated in Java, can, as to quantity and quality of the desired drug, bear comparison with the growth of South America, but that also the seed cultivated in Java shows no tendency to degenerate or to assume any qualities departing from the original. The experience already gained sets this above all doubt.

The period when the government thus placed their treasure at the disposal and for the benefit of all, fell in nearly with the enactment of the Law on Leases, *erfpachtswet*. Thus with respect to the cinchona culture, it became possible to obtain, along with the grounds, the necessary plant or seed. No wonder then that this circumstance, combined with the favourable prospects, should have led to the planting of a number of cinchona gardens. Most of these are found in the nursery of the new culture—the Preanger-Regencies. Middle Java numbers, as yet, only a few, while in the *Oosthoek* (in the Tenger Mountains and in the Malang) several such enterprises have been started of late years.

If then we may expect that this branch of agricultural industry has a promising future, it is still to be regretted, that so many years have been allowed to pass by unprofitably. For, indeed, the great profits it can yield from the present rates of the product, are menaced by the competition consequent on the extension of the culture in our own dominions, but in the first place by the competition of British India. Though the cinchona culture was introduced there about the same time, or rather later, than in our possessions, it has there attained a much greater extension. The planters there have had no occasion to wait till Government—as it was with our Indian Government—could resolve to afford them an opportunity of tilling maiden ground. Especially at Ceylon, the cinchona culture has attained great proportions, to which, it is true, the poor results of the attempts at coffee culture have largely contributed. On the Continent of British India, vast plantations of cinchona are found in great numbers, which are still too recent to yield any produce of importance. As far as is known, Ceylon exported in 1880 more than five hundred thousand K. G. of Peruvian bark, the Continent above two hundred thousand. The export from Java, as far as it is known, amounted in that year—that is the whole Government produce, inasmuch as it was brought to market for public auction at Amsterdam—to only one hundred and twenty-five thousand K. G. Thus British India has the lion's share. But what must become of the proportion between the cost and market price of the product, when, in some ten years, Java alone will number perhaps more than forty enterprises, which will supply the market with a hundred thousand K. G. of bark each per annum? In the Preanger alone, the number of these enterprises already exceeds twenty.*

The Civil Officer who was last at the head of the Government Cinchona enterprise in Java, Mr. J. C. B. Moens, has written a Treatise on the Cinchona Culture in Asia. This treatise has been published by the Union for the Promotion of Medical Science in Netherland India, at Batavia. This voluminous quarto, abundantly illustrated with plates and engravings, may rightly be termed an elaborate production. Therein the writer, qualified by his extensive studies on the subject, and especially by his own personal experience, treats exhaustively of the history of the culture, the manner in which it is practised, the different kinds of cinchona, the trade carried on in this product, its chemical properties, etc. It is a matter of regret that the high price of this splendid work (36 guilders), rendered necessary by its being published in India, precludes a more general diffusion.

Of course the greater part of this labour falls under the domain of strict science, whether of agriclture, botany or chemistry. Of very general tendency, however, is the author's endeavour to solve the question: Can the cinchona culture bear the extension which is already given to it, and which will no doubt continue to be given it? In other words, must the spirit of planting and furthering this culture be encouraged or moderated? The cinchona culture does not *promise*, but *yields* golden profits to the happy owner of plantations, who can at present bring to market a product of good quality. But is it reasonably to be expected, that they will still be able to do so in ten or twenty years hence?

We need be very thankful to Mr. Moens for having arranged his occupations so as to be able to give informations on the subject, and not less for the thoroughness and accuracy that distinguish those informations. The following extracts will give some idea of this.

The writer supposes, that a land of three hundred *bouws* (two hundred and ten hectares) is to be tilled for the cinchona culture. This land is waste woodland in the high mountains, mostly 1,200—1,800 metres high, and must therefore, before planting, be cleared and rendered fit for tillage. Annually 60 *bouws* are cleared. After four years the land begins to yield, but it is not till eight years that the produce has attained its height. Therefore after eight years the full crop is enjoyed of one-fifth of the area, and after twelve years, of the whole. And, as we have shown, by a careful treatment of the cinchona tree, a full crop can be expected for a number of successive years.†

* It is computed that in the eighth year, and a series of successive years, a *bouw* planted with cinchona trees will yield 300 K. G. of bark. An enterprise of 400 *bouws* would then yield, at least, the above produce.

† It is known that, at least in Dutch India, the cinchona tree is never felled or rooted out. The bark is stripped off in part, in long slips, to the cambium, and the bare patches covered with moss or any other fit material. Under this a new bark forms, which is often richer in alkaloid than the original. Or else (and this is the new method, which seems to answer even better), the bark is carefully *scraped* off, but so, that the cambium remains covered with an exceedingly thin coating. Then the reproduction of the bark can be left entirely to nature.

Mr. Moens has learnt by experience that, when the culture has to contend with no particular accidents, and the soil be well chosen, one *bouw* of cinchona plantation can yield annually 300 kilos of dry bark. He has here more especially in view the sort most in demand, the so-called *Ledgeriana* which seems to possess the richest quinine percentage. How long, says the writer, the production can remain at the same rate, is not known, but if care be taken to fill up large gaps, occurring in the plantations, immediately, with fresh plants, there is no reason to fear that it will decline.

A *bouw* will then produce on an average 300 kilos of bark annually. What is the gross value of this?

The results of the auctions held at Amsterdam in 1881, were for the *Ledgeriana* from *f*12. 50 to *f*15,—of the *Officinalis* *f*5.—à *f*7.—, of the succirubra *f*2.—à *f*4.—Inferior sorts we will leave out of account, as they will no longer be cultivated. Let us take as the average result the price of *f*8 à *f*10, then the gross value of an annual crop would be *f*2,400 or *f*3,000 per *bouw*.

This result, even for a fertile tropical land is enormous. The sugar culture yields under the most favourable circumstances 100 or 120 piculs per *bouw*, valuing at about *f*14, thus *f*1,400 à *f*1,680. The produce of one *bouw* of land planted with coffee, is much less still; even though the crop can be forced up to 12 or 15 piculs per *bouw*, the gross value, even with most favourable market prices, must remain below one thousand guilders.

Are the costs of cinchona culture particularly high? No. They may be rated as pretty well equal with those of the coffee culture. The clearing of the waste land is in both the main point. Expensive buildings, or establishments of a technical character are not required in either case. The costs of maintenance are not particularly high, either for a cinchona or coffee garden. The cropping demands much care with the cinchona tree, but with the coffee trees this is no less the case. The preparation of the product for delivery is, in neither of these cultures, of a complicated or expensive nature. Only the cost of labour may vary considerably, as, in the high mountain regions, where the cinchona culture is most at home, hands are scare, and can only be obtained by the attraction of high wages.

Mr. Moens gives a stimulated account of the costs of a cinchona establishment such as he supposes. He computes for the first year *f*20,000, for the second *f*21,000, for the third *f*23,000, for the fourth *f*22,000, the fifth *f*24,000, all without counting the interest. Then the planting is concluded, but the costs of keeping in order, surveillance, etc. have become much higher. At least the writer computes that the outlay of the sixth and following years will amount to *f*23,000 a year, plus 50 cents per kilo of the bark to be won. The estimate is based, as to wages, on the present state of the Preanger-Regencies, where the day wages are 25 cents. It will be well not to reckon too much upon the maintenance of these low wages.

For the rest we have only one observation to make on the writer's estimate. He has brought into account no costs of seed and plants. These are at present obtained gratuitously from the Government plantations, and it is possible that this may continue. But this must not be too much depended upon. And in case a change should be made in this, for any reason whatever, then it will be no easy matter to obtain seeds of the good sorts. Probably some planters may apply themselves to growing the seed themselves and laying out young plantations for sale to others. But prices will be sure to be very high for an enterprise, that must begin by planting 300 times 2,300 trees, (this last figure expresses the number of trees required for one *bouw* of land).

Thus after six years, the enterprise as sketched by Mr. Moens, will have stood him in *f*133,000 plus the interest. A few years later it will yield 90,000 K. G. gross value *f*720,000 à *f*900,000. Reckoning the freight to Europe, insurance, diverse expenses of sale, etc. largely at 25 p. c. the nett receipts would still amount to five à seven hundred thousand florins per annum, and that for a long period. Though one should abate one-half for miscalculations and disappointments, yet the cinchona culture remains a goldmine, provided the article can be disposed of at any thing like the prices assumed. The question, therefore, is: will not the extension of the culture too much depress the prices of the product?

Mr. Moens sums up his views in the following four theses or predictions.

1°. The relatively small quantities, which India (British India included) will produce in the first 3 or 4 years, will have little influence on the prices, as the consumption has not only increased continually during the last ten years, notwithstanding the high prices, but is evidently still susceptible of extension.

2°. Should the quantities, after the period of 4 years become so considerable as necessarily to depress the price, because the consumption does not increase as rapidly, the immediate consequence will be, that a number of sources in South America, not being able to bear the appressive costs of transport, will cease to flow. A very rapid decline of prices will thus be prevented.

3°. Should the production in India become in 12 or 16 years so considerable, that she alone will be able to supply the whole world with the alkaloids required, then the exportation from the primaeval forests of South America will gradually become impossible, because, by the decline of the prices the transport-costs of *f*1.80 à *f*2.50 per K. G. will become unpayable.

4°. Should the production in India, and in other places where cinchona can be cultivated, become at length greater than the consumption, then will begin the contest between the enterprises mutually. In this contest the victor will be he who has cultivated the most quinine-bearing sorts, and whose plantations have been most economically planted and managed.

It seems to us, that there are several objections to be made to the justness of these theses. A decline of prices would injure, and perhaps destroy, the South American cinchona trade, because the costs of transport would be too high. This is perfectly correct, if the *bark* alone could be transported; but this is not at all the case. There is nothing to prevent the Americans from applying themselves to the preparation of quinine, and this they will no doubt do when forced to it. If they have then only to send the quinine to Europe, (or to other parts of America) the costs of freight will be a matter of very little importance. In our opinion, it is just to be expected, that in the case of a considerable decline in the market-price of quinine, the competition from America will be more severely felt than at present. For of course they will endeavour to make up by greater produce, for the lower profits. They will there also learn to make exertions for organizing a more regular culture, and providing better means of communication between the forests and the export harbours. It seems to us a serious mistake to suppose that the home-country of the cinchona plant should succumb without an effort to her rival in Asia.

According to Mr. Moens, the consumption of quinine salts for the whole world in 1872, was computed at 70,000 K. G.; at present it is computed at 120,000 K. G. The writer expects a considerable increase. He says: it is not so long ago that quinine was considered in Europe a very dangerous medicament, only applied in the greatest immergency, while now its innocuousness and eminent curative qualities are fully recognized. Besides, an important diminution in the price will of course increase the consumption, also in veteranary practise.

To a certain degree all this must be conceded. Yet it must not be overlooked, that the use of medicine always remains a matter of coercion. The price of the drug, therefore, influences its use much less than other articles. Besides this, it must be remembered that, by better observing the precepts of hygeine, the requirements of medicines, especially of specific medicines, may decrease. And if, as the writer expects, fevers be in the future more powerfully combated by the administration of alkaloids extracted from cinchona bark, then it may also be expected that the illnesses will be sooner subdued and be less prevalent. This, then, might counterbalance the more frequent employment.

As to the price more especially, it must be borne in mind that sulphate of quinine can never become a very cheap medicine, because the costs of preparation are so high. Though the bark be at a low costprice, the product from the laboratory *must* cost sundry guilders to indemnify the manufacture.

The present consumption of quinine, we learn, amounts to 120,000 K. G. per annum. The writer, as we have also seen, reckons that a cinchona plantation as sketched by him, furnishes 300 K. G. of bark per *bouw*. It is 300 bouws large, and so produces 90,000 K. G. of bark. At the same time he supposes the bark to contain 5 per cent. of quinine; therefore the plantation yields 4,500 K. G. of quinine. So there will be only 27 enterprises required to supply the present necessities of *the whole world*. But Java alone numbers, even now, about thirty such enterprises, though most of them are in their first phase. Not every one of these plantation is 300 bouws in extent; and, to be sure, they cannot all of them succeed. Yet, if Java is now striving to export as much quinine as the world can desire, what must then be said of the abundance produced by British India and Ceylon, whose cinchona plantations surpass, in extent at least, five or ten times those of Java, not to speak of the South American superabundance.

What increase of consumption can bear up against this?

Mr. Moens asserts somewhere, that the cinchona bark can, at a push, be furnished by the planter at one guilder per K. G. We can believe it. An enterprise, succeeding from the very beginning, may work without loss at such a price; but who, with such scanty prospects, would run the risk of a partial or complete failure? But independently of this, nothing guarantees that even this low price will prevail. If once the time dawns that the consumption cannot come up to the production, that the impulse to sell increases while the stock accumulates, then one guilder per K. G. is no more a minimum price than one dollar.

Our conclusion, therefore, is, that great caution is advisable. It is as good as certain that, in consequence of the extension of the cultures, the quantities of available cinchona will be trebled, quadrupled, nay quintupled, in a few years. The consequences of this *must* be that the market prices will more and more conform to the cost prices. The disposals will most probably become so unimportant, that it will be difficult to make good the costs of production. Circumstances may eventually become so critical, that at any rate for a certain time, transactions will have to take place at a considerable loss.

Of course the Cinchona Culture has a future also in Netherland India, but it must move in a limited sphere. The restricted consumption renders over-production doubly dangerous. After the great impulse to new plantations, which has manifested itself especially in British India, moderation has become necessary, if we would not that all the capital funded in these expensive enterprises be irrevocably lost. —*India Mercury.*

FERTILIZE your orange and lemon trees. Irrigation is a good fertilizer, and has been about the only one used in Southern California. The few who have put all the fertilizers to be held in their orchards, have received handsome returns for the expense and labor. The orange and lime tree should have not only proper location, good soil, free from scale, but abundant irrigation and fertilization. If to the foregoing admonitions be added perfect cultivation, judicious pruning, a careful gathering and assorting of fruit, shipping to best market when the fruit is ripe, there is no crop that will pay as well as orange and lemon growing in Southern California.—*Rural Californian.*

TEA IN CEYLON.—An Indian tea planter of experience, who some years ago visited Ceylon, writes to us from Darjiling. I hope your planters will beware of inferior jâts and particularly the China kinds. Many gardens here have made a fatal mistake in putting in the wrong variety—a mistake which it takes years to rectify, if indeed the expense of replanting can be borne. From what I recollect of your climate, it is less cold with you than with us at the same altitude; so that doubtless you will be able to go higher up your hill-sides than we can. Our highest gardens do not give nearly the yield that others in low districts like Assam give, but, as a rule, we got better prices, and have to economise working expenses as much as possible. I don't know how you are planting, but personally I very much object to planting at stake, for it not only causes a great waste of valuable seed, but never gives an even clearing. It is much better to make a good nursery and put out good-sized healthy plants, make your hole *as deep as possible*. However, I have no doubt you will soon be up to the ropes and end by teaching us!"—"Local Times."

CORN MEAL, as everybody knows, is the best and cheapest feed for fattening all kinds of poultry. The meal should be fed raw one day, made into a stiff dough, and cooked the next. Feed every four hours during the day, beginning early and ending late, and give as much at a time as will all be eaten immediately, and no more. Season plentifully with salt as persons do their food, and add a slight sprinkle of cayenne occasionally. These condiments serve a double purpose—that of improving appetite and digestion and the quality of flesh for the table.—*Rural Californian.*

COPPER AND CHOLERA.—Referring to the paper read before the French Academy (as reported in your last issue) on copper as a preservative against cholera, it may be worth while to state that when visiting the great copper mines at Fahlun, in Sweden (probably the oldest and largest in the world). I was informed that cholera had never appeared there, and that so well was the fact known, that on the last visitation of cholera in Sweden some members of the Royal family took up their abode in Fahlun to escape the disease. The atmosphere was there loaded with copper fumes to such an extent, that not a trace of vegetation was visible on the hills surrounding the town; so that this really seems to confirm by experience on a large scale the theory alluded to.—WATER R. BROWNE.—*Nature.*

COCOA CULTIVATION IN CEYLON.—Dumbara, Sept. 19th.—The cocoa in this district is now quite an established enterprise, and it may be said of the valley now that where there is coffee, cocoa will be found growing amongst it. Large preparations are now being made in many of our stores for the more general preparation of cocoa, which hitherto has been but secondary to coffee. Upon Pallekelly there is a large new clearing planted alternately with cocoa and coffee. Some parts appear almost too closely planted in some parts of the districts. It would be very interesting now to obtain some information regarding the many new kinds of cocoa growing more or less throughout the lower coffee districts. As far as my experience extends, one old variety or species is the only kind in the Island which has inside a white kernel, the others all having rose or purple interiors. Many of these are very much hardier than the original, indeed most are, but their shells and pods are also much thicker. The great idea here at present is the removal of shade, which is being largely undertaken; indeed some estates have almost cleared the whole away. As a rule the Dumbara planters have not begun pruning their cocoa, and herein they differ from their Kurunegala friends, who undertake it on nearly all their estates.—*Cor.* "Local Times."

EXPERIENCED gardeners and orchardists frequently state that boiling water, applied with a syringe to oranges, and fruit trees generally, covered with scale and other blights, will remove every trace of the insects without working any injury to the tree. An instance has just been made known to us in Southern Queensland, where soapsuds were used so hot that the person applying them had to protect his hands with a cloth while he worked the syringe, and he has found the remedy effective, and to the tree harmless. A correspondent of the *Mark Lane Express* writes as follows with reference to the effects of hot water on plants:—"I read in some of the papers lately about a Frenchman restoring the vigour of weakly pot plants by watering them with water at 140°. It was not with the idea of proving the value of this plan, which I doubted at the time, but to prove the reputed effects of hot water on insects, that I lately made the following experiment, which has had a rather singular and unexpected result, so far confirming the Frenchman's experience. Some six or seven weeks ago I dipped a narrow-leaved croton in water at about 130° for about a minute or more, and afterwards set it in its place and waited the result. In twenty-four hours or less every leaf, embryo bud, and insect was quite dead. I expected the leaves to go, but not the numerous small buds that were showing on the stems. However, all were killed, and the plant itself seemed killed to the root for three weeks, when it began to push freely from the old wood all over, but the new leaves were not the leaves of *C. angustifolius*, but of the broad-leaved variegated croton, only much greener and healthier than that variety usually is. The old dead leaves were still on the plan white and bleached, and in this condition several of my neighbours saw it and were much struck at the metamorphosis. The true leaves of *C. angustifolius* are now coming again at the points of the shoots."—*Queenslander.*

RUBBER IN ASSAM.—The area of Government forests in Assam at the end of the year 1881-82 was 8,011 square miles, made up as follows:—

Reserved forests...	...	2,066 square miles.
Protected ,, ...	...	659 ,,
Other ,, ...	...	2,799 ,,
Forests beyond revenue limits ...	...	2,187 ,,

The area under plantations at the end of the year was 1,151 acres, as against 1,107 acres at the end of 1880-81. The total area was distributed in the following proportion:—

Caoutchouc plantations...	...	912 acres.
Teak ,, ...	...	170 ,,
Other ,, ...	...	31 ,,
Sowings of Nahor and Ajhar	...	38 ,,

The teak plantations at Kulsi and Indiarubber at Balipara are reported to be progressing favorably. A very large number of the rubber trees at Balipara are now over 9 feet in height, and by constant care and attention they have been protected from injury. The licenses given during the year to extract rubber from the district forests, which were sold by auction, realised an income of R26,846. Some of the licenses are reported to have realised immense profits, in spite of the competition of foreign rubber, and of the facility with which the trees can be tapped in any part and the produce sold as foreign. Besides the Balipara plantation, there are a number of old rubber trees in the Chandwar reserve on which experimental tappings are to be made to ascertain what amount of juice can be safely extracted, the age at which tapping can be begun, and the effects on a tree of judicious tapping.—*Friend of India.*

CINCHONA.—R. W. Giles (London) sums up his investigation in the pharmacy of cinchonas with the remark that the fluid extracts of the present day possess agreeable astringent properties and are quite acceptable as vegetable tonics, but do not fully exhaust the bark. He calls further attention to the very important statement of the late Dr. Pereira that cinchona made its reputation as a febrifuge by the use of a species of cinchona which was not rich in quinia, but which contained a large amount of cinchona, and that the preference for quinia is solely due to the mere chance that it happened to be the first alkaloid discovered. *A New Idea.* [NOTE.—This confirms what we—and, of course, not we alone—have maintained for many years, that the *best* way to administrate Cinchona is to give what is well-known as the *crude alkaloids*, obtained by pricipitating an acidulated decoction of the bark with soda; this precipitate contains pretty nearly every substance of any medicinal activity. In our opinion equal parts of the three barks (yellow, pale and red) should be taken, and three per cent (of the bark) of concentrated muriatic acid; that is, for every one hundred pounds of bark take three pounds of acid and sufficient water to boil the bark in at least twice. In regard to Fluid Extracts of Cinchona, however, we do not agree at all with Mr. Giles—knowing as we do from experience in our works that we are enabled practically to exhaust the bark and present it in fluid extract form.—ED. NEW IDEA.]

SULPHATE OF QUINIA.—The French Secretary of War requires sulphate of quinine to stand the following tests:—

1. It must be white, uniform and in crystals.
2. Calcined in a platinum crucible it must leave a residue not larger than 1-400.
3. Heated to 212°F. it must not loose more than 12 per cent water.
4. It must dissolve completely in 50 parts of water at 212° F. The solution must be perfectly clear, and alkaline to red litmus paper.
5. It must dissolve completely in 80 parts of 85 per cent alcohol at 60° F.
6. It must dissolve completely in cold acidulated water.
7. It must not contain either quinidine, salicine or other extraneous matter.
8. Its composition must be:—

Quinine...	... ...	76·25
Sulphuric acid	... ...	9·42
Water set free at 212° F. ...	...	12·00
Water remaining at 212° F...	...	2·33

9. Not more than 2 per cent of cinchona are allowed.—*Union Pharmaceutique* 1883.

TEA-PLANTING PESTS.

With our past experience of the "enemies of the coffee tree" and of other tropical products, no one in Ceylon could have been sanguine enough to expect that our new and promising tea industry would continue long to be free from enemies and pests. "In the sweat of thy face shalt thou eat bread" would not be true of the Ceylon tea planter if all were to continue *couleur de rose*. Our correspondence columns today shew that the enemies of the tea bush are already making their appearance and we are asked to give some information on the subject.

We suppose black grub must be the worm from which tea suffers in China and for which shells of shrimps are used as a remedy (see letter of "Goiya" page 352). The existence of the vermiceous pest and the use of the crustacean remedy are alike new to us. It would be interesting to know how the shrimp-crusts are applied, because if merely broken the effects on the worms may be entirely mechanical. If the shells are finely pounded or burned, we do not see why lime from other sources might not be equally efficacious. Can "Goiya" or any other correspondent afford further details of the China pest and the American remedy? Where did the Chinese obtain shrimp-shells before communication with California was established ?*

Much more serious as a tea pest is "red spider" which is sure to affect tea culture in Ceylon as it has affected the same culture in India and elsewhere. We recently saw it at a high elevation in Uva, but we did not take the grave view of its existence when an old planter (the Visiting Agent of the estate in question) held. We mentioned recently the opinion of an Indian planter that the wetness of our climate would be against persistent attacks of this pest. Some tea leaves have reached us from Maskeliya with a query "What is there on the tea leaves? The thing is alive." Our entomological referee decides that "the thing" is "red spider," *acarus telarius* The insect is no new thing in Ceylon, any more than in conservatories and on cultivated produce all over the world. Attacks of this "blight" affect tea adversely in India for one or two seasons, and then the enemy departs. We have never heard of the blight becoming chronic and generally disastrous like *hemileia vastatrix* in the case of coffee. It is especially amenable to the sulphur, or sulphur and lime treatment, in conservatories, and we believe on estates also. One good thing we see stated about "red spider" is that it chiefly affects the older leaves. It differs from the coffee fungus in always appearing first on the upper portion of the leaf, and the outside leaves of a bush are attacked first. On this as as on all other subjects planters give the most opposite opinions. We have quoted the opinion of an Indian planter that we have too much rain for the abiding of this pest, and in the index to the Tea Cyclopædia we find, "brought on through sudden changes in the weather; continuous rain the best remedy for; cultivation and rain in themselves not a remedy for this; favourable influence of cultivation and rain, by giving strength and growth to the bush, assists in enabling it to withstand; plain water syringed well through the tree a remedy for; syringing with thin mud and blue clay a remedy for; water no use as a cure for,' and so on. Lime is stated to be a remedy. One planter recommends that the trees be allowed to grow for a time without plucking; another advises severe pruning and the burning of the prunings. A stiff solution of clay no doubt smothers the mite, as the itch insect is said by some to be smothered by sulphur applications and not killed by the chemical effects of the sulphur. The difficulty would be the cost of syringing mud clay or water. Clay and cowdung mixed well with water are stated to be a remedy and "cold ash" is noted as a preventative. Early pruning is adduced as one cause; also bad cultivation, but it sometimes attacks the best cultivated estates as severely as the worst. Not merely is want of manure blamed, but fresh manure is said to be a cause. Hard plucking is one of the causes enumerated, and light plucking and late pruning recommended as remedies; proper plucking, manuring and giving sufficient rest to the trees, the only way to keep it off; shaking the bushes a remedy; throwing clods a remedy. "Putrid soil" is several times referred to as a cause, and water as the only remedy. We can find no more agreement amongst Indian planters as to the cause and remedy of red spider, than amongst Ceylon planters as to the cause and cure of our coffee fungus. We must just hope that the tea pest (red spider) may never become prevalent with us. If it does, we suspect there will be no better remedy than a mixture of lime and sulphur. Of course, all the defence which good, careful cultivation can give, the tea will get.

* After writing the above, we referred to the Indian Tea Cyclopædia, where the statement embodied in our correspondents's letter is quoted, with the remark added: "The matter is curious if true."

NEW PRODUCTS IN CEYLON:

LOWCOUNTRY PLANTING REPORT:

LIBERIAN COFFEE—PEPPER—CACAO—TEA—VANILLA—FRUIT—RUBBER—NUTMEGS, &C.

Estate near Henaratgoda, 100 feet above sea-level, Oct. 7, 1883.

The result of the south-west monsoon, has been abundance of rain, but very little wet weather. The general character of the season was alternate sun and shower, varied by a fierce storm, from time to time, and spells of dry weather of from eight to twenty days. I had only about 60,000 tea plants to put out; I began in April, and availed myself of every suitable day, or part of a day, yet it was near the end of August before I finished, and I was caught more than once, in hot sunshine, with from 500 to 1,000 plants out of the ground.

The COFFEE has sustained a series of attacks of *H. V.* individually slight, as compared with that at the end of last year, but very injurious to the crop. When the fruit was the size of peas, as much as one-third dropped from the trees seriously affected. I live in terror of another severe attack before the crop is ripe.

I believe it is fully established, that CACAO requires a deep light loam, and perfect shelter for success, but even within those limits, this plant is somewhat puzzling in its conduct. I have trees here as fine as I can imagine any of the same age to be anywhere, but within 20 feet of the finest and with no perceptible difference of soil or shelter, I find it absolutely refuses to grow. I planted 12 acres this season, chiefly at stake and under partial shade, but on the whole, it is not over and above satisfactory—nothing to compare with a small extent on another place, where it was a complete failure four years ago, from sheer ignorance of what it wanted. I had the promise of a large crop on the best trees early in the season, but most of the pods failed, probably from unfavourable weather, at the most critical point of time; there are still however, some trees bearing from 50 to 100 pods.

About 18 months ago I proposed to try and get pepper-vines to attach themselves to the rocks, and to that end got several coolie loads of cuttings. As I knew nothing of the matter, I left it in the hands of the village people, who never own themselves ignorant of the management of any plant that grows. In consequence of trusting to them, the whole thing seemed a failure, chiefly owing to the fact, that they brought me branches instead of stems, a very small percentage of which rooted, and the few that did so, took upwards of a year to make stem. The few that did ultimately take a start, have attached themselves to the rocks, and are now in some cases ten feet high. Those I have planted this season with better skill, are getting on as well as could be desired; some of those put down in June, being now three feet high. It gets on best, on a northern exposure, and only attaches itself to the rock, where there is a dark scurf of foreign matter on the surface. The longer the slip the better, and it should be all covered except the terminal bud, and two leaves.

An authority on VANILLA cultivation, gives five feet as the length of vines necessary to yet a good strong plant in a reasonable time. At the Government Gardens those vines are sold at one cent an inch, so that each plant would cost sixty cents, which at 1,452 to the acre, would be R867. This is the way Government encourages new products! I began with a rupee's worth, cut into eight inch lengths, and I think on that foundation, I may with great care, get a quarter of an acre in seven years, allowing for failures. I believe vanilla is a highly remunerative product when once fully established; but few, I fancy, will go into it in Ceylon under existing conditions.

The best kinds of PINEAPPLES, are easily propogated when a beginning has been made. If properly treated by removing the suckers, when they attain the size for planting out, an old stock, is almost inexhaustible. The Kew pine is, however, a slow coach as it takes two years to ripen its fruit, and a great deal of care and labour to protect it in the final stages.

I have got a small percentage of tho hundreds of orange plants out of danger from their special foes, catterpillars and crickets, and when once they get a fair start, they come on rapidly. It is a curious fact, that while the oranges, have been destroyed in hundreds, not a lemon plant has been touched. The natives say that the orange tree, takes eight years to bear; if my memory serves me honestly, I have seen it in bearing at five years upcountry, and I have a lime tree here that has fruited within four years.

I cannot boast of much success with NUTMEGS: 800 seeds only produced 250 plants, and three-fifths of these, have perished since planting out, and only a very few are really thriving! Everyone who ventures on experimental agriculture, must pay the teaching, those who are not in a hurry to make a fortune will prefer paying small fees, when the same knowledge can be gained from one pole as from twenty acres.

CARDAMOMS grow here, but not as I have seen them elsewhere. At two years from seed the roots are large, the stems are very slender, numerous, closely-packed, and the tallest under four feet. I fancy the small patch of about fifty plants has not been suited either with soil or shade.

Having grown the WAX PALM and the talipot in nursery beds, I have experienced nothing but disappointment, in transplanting. I therefore decided to put the seed of arekanuts where they were to remain. My former experience with the native variety of this plant was not encouraging, but this season has been very favourable and I have 18½ per cent of fine healthy plants; some of the seeds came up in six weeks, others took six months.

I cannot say much about TEA, yet it is only a little over eight months since the first seed. The plants hung fire a long time after transplanting, and some of them have not made a start even now. Some plants left in the nursery are from 18 to 30 inches, with 7 inch leaves, and the most forward plants in the field are 20 inches.

I fear Mr. Gilliat's, are not the last words to be said about CEARA' RUBBER. It seems probable that any tree, untouched till four years old, will yield a good deal of sap, however tapped, but the fresh bark, that closes over a cut is different from the original, and extends in width with the growth of the stem. My experience is, that little or nothing is to be got by tapping this fresh bark. I need more light before forming any fixed opinion, but my latest experiment is with horizontal incisions, which appear to me less permanently injurious, than the vertical. [Mr. W. J. Forsyth tells us that in Central America, the rubber gatherers make horizontal incisions.—ED.]

MR. STORCK'S CARBOLIC ACID CURE (?) FOR COFFEE FUNGUS.

Mr. Storck, (see page 349) notwithstanding the adverse or at least sceptical verdict of those most deeply interested, claims that the results of the experiments on Claverton estate, Dikoya, with his carbolic acid "vaporizers" proved the success of his method. In this he follows Mr. Schrottky, who insisted that *his* "powder" system—so severely condemned by Mr. Storck as involving the carriage and application of 75 per cent of foreign and useless matter—had succeeded, although the planters could not see it, look as sharply and as hopefully as they might. Mr. Schrottky could not complain that his system did not receive justice in its application, because he was personally present to superintend the experiments with both the powder and the vapour, the latter specially being thunder which he had stolen from Mr. Storck: so Mr. Storck insists. Mr. Storck has not had the advantage of being present in Ceylon, but if he has not come to *Hemileia vastatrix* the fungus has gone to him and we really must insist in this case on the application of the proverb "Physician heal thyself." When Mr. Storck has succeeded in banishing the fungus from the coffee of Fiji, or from his own coffee on his Rewa River plantation, he can with better grace appeal to the Ceylon planters for aid in carrying out his system, or rate them for imperfect action and want of perseverance. The system is not so costly as to prevent Mr. Schrottky from carrying out and pointing to a successful experiment, if success is possible. In answer to his complaints that in the Dikoya experiment there was a mingling of Mr. Schrottky's powders with Mr. Storck's vapours, we have to adduce Mr. Jardine's careful experiments with the vapour alone, and in increasing strength as Mr. Schrottky's own views developed. Mr. Jardine is at this moment carrying out Mr. Storck's most recent instructions and with the strongest possible motives to command success, if that were possible, in view of the virulence with which *Hemileia vastatrix* has attacked that species of coffee from which so much was hoped under the belief that its big leathery leaves of Liberian coffee would be able to resist the insidious foe. Mr. Storck advances an argument based on the want of success in banishing the potato disease, to show the unreasonableness of the Dikoya Committee in expecting premature results. But the argument really makes against Mr. Storck's own contention. The potato is an annual, and the seed can be changed with each crop. If all the wealth and skill and science of Europe have not, under so much more favourable circumstances, succeeded in extirpating the potato pest, what likelihood is there that coffee planters in Ceylon or anywhere else, where the coffee fungus exists, should be more successful, when the subject of attack is perennially in the ground and constantly producing crops of fresh leaves as prey for the spores of a fungus gifted with a power of reproduction which numbers fail to represent? If carbolic acid vapour is really fatal to the coffee fungus, then Mr. Storck must be prepared to advise a resort to measures not merely heroic but sublime. Instead of pottering with a few "vaporizers" on isolated estates or all the estates of a country, he must demand a resort to such a use of his remedial agent as would envelope in an atmosphere of carbolic acid gas, not only Ceylon, but Southern India, the Straits of Malacca and even Sumatra and Java. But if volcanic fumes of sulphur and soda and other active chemicals have not prevented the continued spread of *Hemileia vastatrix* on the coffee of Netherlands India, or prevented the ravages of the insect "blight," *Helopeltis Antonii* on cinchona and tea in the region of constant volcanic action, have we a right to assume that an atmosphere of carbolic acid gas—even if it could be borne by human, animal and the higher vegetable life,—would extinguish the fatal fungus? It does not seem that we have a right to expect anything of the kind, and yet it seems certain, from the failure of all topical applications to secure more than the temporary exemption of coffee from its worst foe, that our only hope now lies in such a change in atmospheric conditions as will either destroy the fungus and all its spores, or reduce this prime "villain" of the vegetable world to its former insignificance and innocuousness. We are in the hands of the Ruler of the seasons and the agencies of nature, and we must trust in His benevolent interventioo; while doing our best. We hope soon to hear the results of Mr. Jardine's latest experiments in accordance with Mr. Storck's directions, and we have no doubt, the planters of Ceylon will be glad again to hear from Mr. Storck, when, instead of plausible scientific arguments to shew that carbolic acid vapour *ought* to succeed as a remedy for *Hemileia vastatrix*, he is able to point to "a perfect cure" if not in the whole coffee culture of the Fijian Archipelago, yet in the coffee of Belmont estate, on the Rewa River, where, if anywhere, Mr. Storck's system can be carried out, to the minutest detail as Mr. Storck could wish.

THROUGH THE TEA DISTRICTS OF NORTH INDIA.—No. VII.

(*By a Ceylon Planter*).

TIMBER FOR TEA BOXES—THE SIKKIM CINCHONA PLANTATIONS.

Notwithstanding the fine stores of timber which exist in many parts of the Indian tea districts, but a very small number of estates utilize them for the supply of tea chests. The importance of having thoroughly well-seasoned wood for this purpose is obvious, and has always been insisted on; but it seems very strange that amongst the numerous species in the Indian forests none should be found sufficiently suitable to come into universal use. I met one Assam planter who has sawmills and who goes in for supplying estates with chests, but this kind of enterprise seems quite the exception. As a rule, tea chests are made of teak from Burmah, which must be very expensive when the excessive cost of transport up to Assam is considered. Teak makes very good boxes no doubt, but I feel sure that good suitable wood could be found in India for the purpose. In Ceylon, there has been some discussion on the subject, but the difficulty appears to have been overcome as all estates use local woods. The tree which I have found most suitable is Mallebodde *if properly treated*, and therein lies the secret. It is light, inodorous and holds a nail well. It is liable to the attacks of insects, but it seasons very quickly, and, if used as soon as ready makes capital boxes. Many other woods are well adapted to the purpose, and are used by the Companies who supply chests in Colombo; but Mallebodde is found in almost every locality where tea is grown, and, hence, its suitability for the purpose in question is a matter of importance. The seasoned Hal chests now advertized by the Ceylon Company are very cheap, and, for estates situated near a railway station, preferable to boxes made on the spot, but for plantations with long road transport the importance of having a suitable wood near at hand is great.

To any one visiting the Darjiling district, an expedition to the Government cinchona plantations is most interesting. Mungpoo, where Mr. Gammie lives is about 17 miles from Kurseong. The road runs along the top of a ridge of the mountains for a considerable distance, and is a beautiful ride. It is mostly through forest, abounding in ferns and orchids of infinite variety, and of different forms to those commonly found in Ceylon. The Government cinchona plantations occupy a vast stretch of country, and are under the charge of several Europeans. The soil is in most places very rich, and remarkably free and porous, whilst the general features of the country are steep and bold to a degree. The most noticeable plantation is one of hybrids near the superintendent's bungalow. These trees are about four years old and are raised from seed of the original hybrid or "Ignota" trees which appeared in the parcel of seed formerly sent from Hakgala to Darjiling. Eight forms are recognized amongst these trees as being distinct and characteristic, and representations of each have been analyzed with the result of figures ranging from ·97 to 6·12 crystallised quinine sulphate. The worst of these forms, known as No. 4, has been entirely eliminated from the plantation, so that its flowers shall not contaminate those of the more valuable kinds. It is characterized by large light green leaves, and is the form which most nearly resembles succirubra in appearance. The richest form No. 7, giving 6·12 crystallized quinine sulphate, is a small broad-leaved free-growing tree, with some officinalis characteristics. At a considerably lower elevation than this is situated the famous Ledgeriana plantation. These trees are not as large as one would expect from their age, they having been raised from cuttings of the original trees from Ledger's seed. Their most remarkable characteristic is the great girth of the stem and the extreme thickness and weight of the bark, which can be taken off literally in slabs. These trees were all covered with blossom when I saw them, and promise a very abundant crop of seed shortly.

In another portion of the plantation is a Ledgeriana clearing, the plants in which were raised from seed. A strange feature in this planting is the large number of Calisaya Javanicas amongst the true Ledgerianas. They are, although only about three years old, blossoming profusely, and are easily recognizable by their large flowers and flower branches. The general appearance of the cinchonas is rather disappointing, the growth not being equal to what we are accustomed to in Ceylon, but the wholesale dying out to which we are so liable appears to be little known. I hear canker is very common, but it is purely local in its effect and does not necessarily kill the tree, or materially affect its growth. Mr. Gammie has found a marked falling-off in the growth and general health of the cinchonas, the original trees being superior in every way to those raised from them, and the successive plantings being each inferior to its predecessor. This appears to be a very general impression in Ceylon, and it is interesting to note that, in spite of the extreme care and liberal expenditure bestowed in the Government cinchona gardens, this experience in regard to them has been the same as in our case. As with us too, the hybrid cinchonas are markedly superior in growth and general health to the succirubras alongside them, and, in consequence, their more valuable forms are alone being propagated in addition to the Ledgerianas which occupy the first place. The system of cultivation pursued is what has been described before except that hoeing is dispensed with. The jungle is allowed to grow freely under the trees, and is kept within bounds by periodical "cuttings." Terracing has been tried, but was not found a success, and the terraces are now being levelled in consequence. All the plantations hitherto are on what we should call "chena" land, but the soil is so rich that the trees do not appear to suffer in any way from exhaustion of soil. The cold weather of last winter, which damaged the branches of the forest trees near the Darjiling station to such a great extent by the weight of snow on them, appears to have killed back many of the succirubra primaries, which have a strange appearance in consequence. It is striking that in spite of the wonderful financial success of this undertaking, and of the Darjiling Cinchona Company, which exactly faces Rungbee and Mungpoo across a wide and deep valley, none of the Darjiling Companies have embarked in cinchona cultivation to any great extent. A few young trees are to be seen along road-sides in some places, but anything resembling what we should call a "clearing" is unseen. It is no doubt fortunate for us in Ceylon, that this cultivation has not been largely extended by private individuals in the Darjiling district, for with the large amount of suitable land which could no doubt be found and with the comparative immunity they enjoy from premature dying out, we should be faced with a formidable rival to what is now a struggling enterprise, owing to low prices. Another point in which Darjiling experience coincides with ours is regarding the utilization of land for a second crop of cinchona. This appears to have been a failure when tried, and, in consequence, all such land is, in the Government territory, planted up with timber trees, and, when private land, with tea. I was told that tea planted in old cinchona land did not flush as freely as that in the original chena, but probably a more extended experience will show that when the tea roots penetrate deep into the subsoil this inferiority will disappear.

There are some very fine Ledgeriana plants in the various nurseries, said to be nearly half-a-million in number, and, in order to dispose of these, a new plantation, at a distance of 40 or 50 miles across the Seesha river, has been formed for their reception. I was shown some plants raised from so-called "calisaya" seed sent from Jamaica by Mr. Morris, and which it now appears are ordinary officinalis. It seems strange that such a mistake should have occurred, but, apparently, the Jamaica "calisaya" trees which we have heard about must be what we know as "officinalis."

Carthagena bark plants have been tried at various elevations and in various localities, but without success. There was one specimen left near the bungalow which did not look healthy, and which it is to be feared will soon succumb. T. C. OWEN.

[Of course small-sized and inferior teak can be used for tea-boxes, but, as teak advances in price, other woods must be used. Mr. Peale, a well-known tea planter, has described the best known Indian woods and their uses in a series of contributions to the *Indian Tea Gazette*. Railway extension in Ceylon will enable estates with no reserves of timber to obtain tea boxes, fire-wood, coals, coke, &c. at cheap rates.—ED.]

BALMER, LAWRIE & CO.'S INDIAN TEA AND WEATHER REPORT.

CALCUTTA, 2nd Oct. 1883.

Little change has taken place since our last report which was dated 15th September; the chances of an early close to the season are more apparent, and reports from most districts tell the same tale.

ASSAM.—Dibrughar :—Last month opened with very hot weather and want of rain; later on rain fell in most parts but is still far short of last year's fall. There are signs now of an early close to the season and estimates on many estates cannot be realized. Jaipur:—Last month began with a favourable fortnight for tea, rain falling in the morning followed by afternoon sunshine; the nights have been rather cold. Sibsagar :—In the early part of last month there were several heavy thunderstorms here, accompanied with much rain and strong gales of wind; dense fogs in the mornings with rather cool days and nights point to an early close of the season. The weather has been fairly favourable although more rain was wanted and bushes in some parts appear to be quite shut up. Jorehaut:—Rather better news reaches us from some portions of this district and September is regarded on the whole as a satisfactory month; it is of course too late now in the season to make much impression on the shortcomings of the earlier months, but there is a probability of some of the deficiency being made up. North Lakhimpur :—The weather is on the whole rather too cold in this district and the frequent changes in temperature have been unfavourable for leaf. Nowgong :—The nights are cold and the leaf hard and irregular in consequence; about 20 inches more rain has fallen than last year to the same date, but the result of the season is not anticipated to be so favourable. Mungledie :—No rain has fallen in this district since the last reports were written us. There is no accounting for the peculiarities of this season; some gardens are doing well, while others, in the same line of country, are absolutely doing little or nothing and losing 50 per cent. weekly. Generally the gardens are doing badly, and the little leaf there is, is hard and dry.

CACHAR.—There has again been a good deal of rain over this district, but the reports are not on the whole unsatisfactory so far as leaf is concerned, although signs of the cold weather being near at hand, are apparent.

DARJILING.—The weather has been favourable for tea lately, although some managers complain of the leaf being hard and leathery, and there are signs in this district also of the season shutting up soon. In the Terai the crop promises well, there being little or no blight but more rain is wanted. From Kurseong we hear that the weather has been cold and unfavourable, with heavy mists; since the 23rd ultimo, rain has fallen daily about 4·25 inches. Mosquito blight is still very bad on some gardens.

KUMAON.—The weather here continued cloudy for some time, but latest advices report bright and sunny days, so that the rains are now evidently over.

DEHRA DUN.—We hear that the weather here has been all that could be desired, plenty of rain and good sun having favoured the gardens which are mostly doing well.

KANGRA VALLEY.—The rains are over in this district and the temperature is much higher than usual average at this time of year; the tea is doing fairly well.

CHITTAGONG.—The weather has been very irregular lately, some concerns having had little rain while others had constnat shower.

TROPICAL AGRICULTURE.

The Tropical Agriculturist : a Monthly Record of Information for Planters of Coffee, Tea, Cocoa, Cinchona, Indiarubber, Sugar, Tobacco, Cardamoms, Palms, Rice and other Products, suited for Cultivation in the Tropics. Compiled by A. M. and J. Ferguson of the *Ceylon Observer* : (London : J. Haddon and Co., 3, Bouverie Street, 188..)

A bulky volume containing thirteen monthly numbers and occupying more than a thousand pages can hardly fail to contain a large amount of varied and useful information, especially when it deals with such a subject as tropical agriculture. Not only tropical but subtropical regions are laid under tribute, the latter being represented chiefly by Southern Australia, New Zealand and China, while Ceylon and the various provinces of India receive, as might be expected, the greatest share of attention. There are, moreover, abundant references to several oceanic islands which have within recent years been invested with more or less political interest. Thus of Fiji it is stated that the planters are chiefly concerned in growing sugar-cane, coffee and cotton, and though it is claimed that the first-named is indigenous, the best kinds of cane] grown in the plantations have been introduced. The Sea Island cotton is easily cultivated, but the production has lately fallen off, the quotations being too low to tempt the planter. Tobacco answers well, and it is believed that cocoa, tapioca, ginger, pepper, and all sorts of spices, camphor and vanilla, might also be profitably grown. Madagascar appears to have bright agricultural prospects before it, as it is admirably adapted to the cultivation of sugar and coffee, and indeed as a sugar-growing country it seems likely that it will before many years leave Mauritius in the background. The small islands between Madagascar and the mainland are enthusiastically spoken of as a new planting region "situated in a most salubrious climate, between the southern tropic and the line, they are admirably adapted for the cultivation of sugar, coffee, vanilla, cocoa, spices, cloves, and other products, many of which are pure articles of luxury, and will always command a high price in the European market."

Judging from the space allotted to them and the amount of interest that appears to centre round them, the staple crops of tropical agriculture are tea, coffee, cocoa and sugar; cinchona and tobacco; indiarubber, cotton and gums, to say nothing of rice. Of the first group, tropical countries may rest fairly securely in the cultivation of tea, coffee, and cocoa, and although the sugar-cane is largely planted in the southern United States and the sugar-beet is so extensively grown in Europe, yet we gather that sugar cultivation is a thriving industry in India, Java, Mauritius, the Malay peninsula, Queensland, Fiji, Brazil, Jamaica, and Trinidad. Cinchona is of course a highly popular subject, and from this volume alone a very large amount of useful information may be gleaned. On account of the rapid development of the electrical industries and of the increasing use of elastic tires for wheels, the demand for indiarubber and gutta percha is continually increasing, and this will no doubt be met by the extended cultivation of these products. The official papers relating to the introduction of the Para and Ceara rubber plants into India are reproduced; the original seeds which were obtained in South America were sown at Kew, and the young plants sent hence to the East, but the precarious nature of the undertaking may be inferred from the fact that only about three per cent of the seeds germinated. It is pleasant to read here and there spontaneous testimony to the value of the Royal Gardens at Kew and of the Indian Botanic Gardens.

Of controversial subjects the coffee leaf disease attracted most notice, considerable space being devoted to the reports and letters of Mr. Marshall Ward, and to the discusssion arising therefrom. On p. 15 is a complacent suggestion that as crops cannot always be got from the branches of the coffee tree they might be got in another form from the roots by grinding up the cockchafers that there abound and selling the beetle powder, mixed with a little coffee, as real coffee, carrying on the entire manufacture in Ceylon to prevent any tampering on the part of dishonest middlemen in London! This pleasant notion is based on the assumption that "the British public will consume anything not absolutely dirt that is sufficiently adulterated to suit their palates." *

The marked contrast between our home agriculture and that of the tropics is afforded in the very few and scanty references to live stock of any kind. English agriculturists are continually more and more on their flocks and herds and less on their corn crops for remunerative returns. There is, indeed a solitary reference to Aden cattle, which are bred inland, and derive their name only from the port whence they are shipped. They have a high reputation as dairy stock, and have been used with success for crossing with some of the Indian herds on the Government farm at Saidapet, Madras. The only allusion to sheepfarming is to that of Australia.

Of course, in such a volume as the one before us, the matter is necessarily of a very heterogeneous character, but it is all concerned more or less directly either with agriculture itself, or with the economic and industrial aspects of the art as pursued in the hotter regions of the globe. As a record of the experience of tropical planters, of the difficulties and drawbacks of climate and of soil they have to contend with, of the good or indifferent results which have attended their efforts at acclimatisation, of the measures they have adopted to minimise the evil effect of insect or fungal attacks, and not less as an interesting historical summary of the progress of tropical agriculture, such a work as this carried out on the lines on which it has been begun cannot fail to possess a permanent value. Young men especially, who, having learnt something of the art of agriculture in the stern school of British farming, would fain try their skill under a tropical sun, will find collected here a large mass of useful information such as perhaps it would hardly be possible to obtain elsewhere. W. Fream.

—*Nature*, September 13.

* Of course the writer of the letter referred was perpetrating "a goak"—which the reviewer does not seem to see—and was rightly sarcastic at the expense of English consumers, who, for the sake of cheap prices, so readily buy up adulterated stuff.—Ed.

TEA: NOTES BY A PLANTER.

(From the *Home and Colonial Mail*, Aug. 31.)

It appears remarkable that the one distinctive ocular test of Indian tea has never been used by those whose interest it is to assist its sale by every method within their reach. China tea is a small tea in leaf. In order to assist the grocer to get rid of his China tea, by rendering it possible for him to make it more saleable, *i. e.*, by the judicious addition of a proportion of Indian tea, planters have up to date been bolstering up the sale of China tea, at the expense of their own credit. Have they not been breaking their tea through sieves in order to produce the small teas they find in demand? Why is there this demand for small teas? It is not solely that the prejudices of the consumer should be considered. It is before all things in order that Indian teas may be similar in size of leaf to China teas, and thus admit of their being blended with the latter. Thus the superior article is being used to assist the sale of the inferior, and to gain credit for the inferior at the expense of the superior. This is simply a suicidal system on the part of Indian tea-producers. It may have assisted them whilst their enterprise was in its infancy, but it is not time that Indian tea should be received on its own merits? To continue in such a course for all time would be too much expect of the producers of Indian tea. Surely the day has come for them to reap the real and full advantages of the purity and other recommendations of their teas. Let them use the excellent party-cry they have, viz., "Large leafy teas are sure to be Indian teas, as China bushes *cannot* produce such teas." By this they not only aim a blow at those who raise their inferior China teas at the cost of the credit of the Indian article, but they will also economise in the manufacture by discontinuing the breaking-up process. At the same time they will benefit the quality, as by the avoidance of the unnecessary handling and exposure of the teas much of the delay before packing would thus be saved. It is not necessary to point out to planters the importance, in the damp climate of Assam and Cachar, of thus being able to pack so much sooner than is possible when bulks of broken teas have to be made up. With so much to recommend the cry of *Big-leaf*, it is only a question of time ere its advantages are realised and made use of. One other detail occurs to me. Much of the prejudice in England as to Indian teas being too strong to drink alone is owing to the use of the tea-spoon in measuring the quantity put into the tea-pot. Indian teas are certainly much stronger than China teas. To those who adhere to their accustomed number of spoons-full, the extra strength is often against Indian teas, as it appears never to occur to the good people to put less in the pot! By sending home big-leaf teas, so much less in *weight* would go to the spoon-full that possibly the prejudice as to excessive strength would be heard less of in future.

One may have one's own views as to the quality of soil and the judicious selection of site necessary for economic tea cultivation. Nooks and corners may do very well for teas for the use of the peasants' own household in Japan, but it strikes me that I recollect seeing some very fair sized patches of tea-cultivation in Japan a few years ago. But the statement that each farmer can raise enough tea from ten or twelve bushes to meet the wants of a family of eight persons set me making calculations. This is the result. I took a list of thirteen of the leading Assam gardens, and added up their yield per acre, and divided the sum by thirteen to get an average of the yield per acre in Assam. I find this is to be 357 9-13 lb. Let us say 350 lb. for the sake of argument. Let us allow 16 square feet to each bush; that would in round numbers give us about 2,700 bushes per acre. According to this it would take between seven and eight bushes to produce a pound of tea in the best tea climate in the world. Thus at his outside limit of twelve bushes, our contemporary considers the allowance for a family of eight persons to be $1\frac{1}{2}$ lb. of tea for their year's supply or 2 oz. per *mensem*. Perhaps some one may care to carry the analysis further, and tell me what fraction of a leaf this would allow *per caput, per diem*. The planter-reader will doubtless find his interest in the above extract fully kept up to the end. It is not *intended* "to be read sarcastic" by the writer it is perhaps necessary to state.

* * * * *

One result of the growth in popularity of Indian tea at home is to be found in the circumstances that a cup of tea which tastes like tea is not so rare as it was in restaurants and tea shops. One company, which owns a number of shops in and about London, opened originally for the sale of pure bread, has vastly added to its trade by selling tea and coffee of drinkable kind. This latter branch of the business has grown mainly because Indian tea has been largely used, and the coffee has been really well made.

THE ASSAM COMPANY.

Your directors lay before you a report on the operations of the Assam Company for the year ending 31st December, 1882. The quantity of tea packed amounted to 2,304,807 lb, which was 297,393 lb. less than the superintendent's estimate. The expenditure during the year was £112,435, being £8,325 less than the superintendents, estimates. It will thus be seen that the cost of production in India was $11\frac{1}{4}$d. per lb., against $10\frac{1}{2}$d per lb. for the previous year. This increase is to be regretted, but it is attributable to the short quantity of tea made. The trees have now recovered from the severe damage that they sustained, and the whole of the plant has been maintained in efficient working order. The results of the year stand thus:—

	£	s	d	£	s	d
Receipts.						
Tea sales, net proceeds..........				£116,371	13	1
Tea seed sold in India..........				6,599	9	8
Sundry receipts in India..........				1,409	9	5
Interest and sundries				284	13	9
				£124,665	5	11
Outlay.						
Expenditure in India in rupees at par ..	£112,435	7	2			
Less Exchange ..	13,600	7	4			
	£98,834	19	10			
Expenditure in England ..	£ 7,893	9	4			
Total expenditure				£106,728	9	2
Net profit				£17,936	16	9

The profit this year amounts as above to £17,936 16s 9d to which is to be added the sum of £1,017 6s 9d balance of undivided profit from last year, making a total of £18,954 3s 6d which enables the directors to pay a dividend of 10 per cent. for the year and to carry £238 3s 6d forward.

Comparing the results of 1882 with those of 1881, it will be seen that while the crop is less by 61,086 lb. the garden expenditure has increased by £8,770 9s 9d so that the cost of the tea laid down in London is about 1s 0 7-16d per lb. including all charges. The margin of profit made is 1d. per lb., which gives £9,643. The seed, &c., yield the balance, £8,293, or say 5 per cent. from tea and 5 per cent. from tea seed, &c.—*Home and Colonial Mail.*

THE TEA TRADE OF CHINA.

In the series of commercial reports by Her Majesty's Consuls in China, just issued, there are some interesting particulars on the general state of the tea trade at the treaty ports. Mr. G. Jamieson, Consul at Kiukiang, states that the tea crop of 1882 proved to be above the average, both as to quality and quantity. High prices were paid for the earlier and choicer kinds, and the outturn to the foreign exporter was, on the whole, favourable, or, perhaps, to put it more accurately, less disastrous than in many previous years. Buyers in China are slow to appreciate the fact that owing to the Indian competition, common China teas will not bear anything like the prices that used to be paid ten or fifteen years ago. Every year, as the tea season comes round, warnings and expostulations continue to be addressed to them, but somehow the desire not to be outdone by one's neighbour, or that perennial hope which is ever rising in the tea market as elsewhere, carries men beyond the bounds of prudence. Common congou has often been sold in London of late years at prices which it is calculated would not cover the bare outlay for labour in China. Mr. R. J. Forrest, reporting on the trade at the port of Amoy, says it would seem that unless the quality of Amoy teas is improved their production for export to the United States must gradually cease. At the prices realised for about half the crop of the past season (that is all the lowest grades) the teas did not pay for the cost of picking and packing; and so discouraged are the native hongs interested in this trade that the majority of them are giving it up entirely. The gradually lessening prices that have ruled for these teas for some years past have left the growers so impoverished that they have not funds to provide the cost of the care of the plantations, which is so absolutely necessary in order to obtain tea of good quality.—*Home and Colonial Mail.*

THE FIRST PADDY CROP in Burmah has been harvested, and the second crops of cereals and vegetables have been benefited by two days' heavy rain.—*Madras Mail*, Sept. 29th.

THE JESSIE ESTATE.—On Saturday last the Official Assignee sold by auction the casuarina plantation known as the Jessie Estate, at Ennore, the property of the late Mr. Augustus Arathoon. The estate was purchased by Dr. Currie, for R7,500.—*Madras Mail*, Oct. 2nd.

INDIAN AND LOCAL TEA SEED.—A planter, who has lately received seed from India and from plants locally grown, the results of seed from India of good jât, reports the locally grown seed as so much smaller in size than that direct from India, and that the number of seeds in a maund of the locally grown exceeded by at least 30 per cent the number in a maund from India. Does the smaller size of the seed at all indicate deterioration? or how can the fact be explained? Have any other planters instituted comparisons?

Correspondence.

To the Editor of the Ceylon Observer,

MR. STORCK AND HIS CURE FOR COFFEE DISEASE.

Belmont Estate, Rewa River, 11th Aug. 1883.

Dear Sir,—The final report of the Committee appointed to inspect the carbolic acid treatment for leaf-disease on Claverton, Dikoya, has just reached me, but, as to their decision on the practical value of results, I beg to differ with the gentlemen signing the report.

First of all, the adventitious effects of the dusting, which process *is* Mr. Schrottky's own, are credited with a good deal more than they deserve, seeing that the projector himself only claims efficacy for one dusting for 16 days at the outside, and that thus the two dustings only cover one month out of the five. Directly after the cessation of the action of the substance used, reinfection and propagation of the fungus from the adjoining fields would go on as before. I have denounced direct applications from the very beginning as laborious, expensive, and under the influence of the weather always uncertain and therefore unreliable and hopeless.

The Committee further state that "this treatment was after 10 days supplemented by what Mr. Schrottky calls *his* permanent system of evaporization." (The italics are mine) It seems strange to me, that although Mr. Schrottky never thought fit to publicly acknowledge it, no one notices it that what he represents as *his* permanent system is in reality *mine* in every part?cular except the immutability of the substance contained in the vessels, which, if further impregnated with carbolic acid, would immediately become fluid or semifluid and make it identical with my own *earlier* invention. Mr. Schrottky had no conception of a permanent treatment before the appearance of my several papers on the subject as his various abortive efforts show previously to adopting mine, to (as he ingenuously terms it) "supplement *his* dusting process." My permanent system once *properly* established, requires no supplementary dustings.

The Committee again state that "an abnormally heavy fall of leaf took place which had apparently no connection with leaf-disease, but favoring the belief that some change had come over the wood itself; that (perhaps from the weakening through disease) "trees are unable to carry their leaves to maturity as should be the case with naturally healthy coffee." How near the truth ; and still how disappointing the final deductions drawn : the fact being that the new and improved wood carried its leaves longer than under the influence of the ever-recurring attacks of disease, which made the fall of leaf taking place long after the denudation of adjoining fields all the more remarkable. The wood had been nourished into improvement by the disease-free leaves, but then the exhausted leaves were pushed off to make room for a stronger and still more lasting coat, provided the treatment which caused the first improvement were continued. And now we have what in the estimation of the gentlemen of the Committee seems to be the most important part, viz , "appearance of wood with reference to the setting of blossom." Here we have a body of gentlemen who from their calling may be presumed to have some insight into the nature and working of plant-life, but who after an active treatment of only five months expect to find an improvement in the *setting of crop* forsooth—on a field which in all probability has suffered from the ravages of the fungus ever since it was planted, *i.e.*, for from 7 to 10 years. Now, if every vestige of *H. V.* was to disappear tomorrow from some cause artificial or natural, no man having witnessed the effects of the fungus, and claiming no more than the most superficial knowledge of plant-life could expect a practical, that means in this case, *commercial*, improvement of the kind at least for some time to come. The age of wonders is past, and not even the Creator of all things, who has in His infinite wisdom subjected the well-being of all his creatures, creeping or growing, to wholesome rules could encroach thereon or set aside the most insignificant one of them. I have in a previous paper stated that "when your trees have once recovered far enough under my treatment to keep their leaves and the tide has turned, nature herself will, combined with ordinary care, help your trees to recover farther than they declined." But it has never entered my boldest fancies to expect them to resume all their unimpaired natural functions at the end of a few months, of freedom from disease except, perhaps, quite young fields which have only suffered for a limited time. Nor could the setting of blossom or its absence be considered an infallible test of the value of the treatment against fungus, since, as every planter knows, it at all times more or less depends upon extraneous conditions. It is like expecting a man just recovering from a long and exhausting illness, to resume his office-chair or his hoe, as the case may be, the day after his doctor has pronounced him convalescent, the very time when rest and attention to physical wants are most important to ensure final recovery.

The gentlemen of the Committee then proceed to state that "apparent results of the experiment must still be very much matter of opinion," and that "it must be admitted that the coffee treated has been unusually free from disease," and that "the treatment has to some extent been efficacious ;" but they are uncertain whether the effects noticed were those of the dustings "killing the spores above the ground." Where else?) "*Mr. Schrottky's* permanent treatment' (the italics are mine) "or a pure matter of accident. With regard to the evaporization of carbolic gas having proved a failure elsewhere, such an assertion can only be made assuming the trials with it to have been strictly in accordance with my directions, which to *my* knowledge none of them were. One gentleman employs vessels of the jam-tin pattern, of scarcely more than half the evaporating surface I have from the first insisted upon ; and another makes a certain number of vessels, just sufficient to cover *one* acre, do for *two*.

In the face of all this and the above report of the Committee, I now and here claim *that the fact of a good and sufficient remedy is established and the conditions of award fulfilled* by the results of the experiment on Claverton ; and that the gentlemen of the Committee in speaking of *practical* results should have said *commercial* results, which are dependent on the value of the former. Morever, I maintain that there has not yet been a sustained genuine effort made by any planter or body of planters to thoroughly and impartially test *my* system or Mr Schrottky's. I would really like to know what the planters of Ceylon expect—magic? I have none for them. But unless they either faithfully carry out what I have suggested to them, or learn to think for themselves, their glorious industry is doomed. The death-knell rang when one of their number found sporepatches on the smooth, hard, dense *epidermis* of green-growing berries, surely the last stage towards and plain indication of the ultimate physical exhaustion of the very species in your island. Nor need you console yourselves with the idle hope that some fine morning you may wake and find the fell fungus gone. The disease of the potato in Europe, of far greater importance in the economy of the human race than your staple product, has now defied every effort of savant and husbandman for nearly forty years.

Now, after the manifest success on Claverton estate, the time has come when your Planters' Association should again take the matter in hand earnestly and repeat their petition to Government for a grant-in-aid for the carrying out of a systematical, thorough and *sustained* trial with a better chance of obtaining that assistance which the planting public are unable or unwilling to give, than on a former occasion, when the value of my system of permanent vaporization was, as far as Ceylon is concerned, only problematical. Should it come to the realization of such an energetic movement, I will come over and superintend it in person. I am on the trail of another important agent, and the planters of the East shall have the benefit of anything that by lengthened experience and dogged perseverance on my part may yet be accomplished. Finally, to prevent any farther confusion in the minds of operators as to the relative nature and proprietorship of the two systems of vaporization, I will give the following short sketch :—

Mr. Schrottky's system is a periodical, manual, and direct application to the trees, of a carbolized powder, very much resembling the sulphur and lime treatment and partaking of nearly all its defects. This material is bulky (entailing the carriage of about 95 per cent of waste matter), laborious and expensive in application, and uncertain in its effects because dependent upon the weather. It can only be used in dry weather, whilst continuous or protracted rain may utterly prevent the observation of any degree of regularity in the periodical applications, allowing the fungus nver breathing time when it would be most important to check it. Mr. Schottky's permanent system is an *adaptation of my own* for another form of his powder, which still entails the transport of at least 75 per cent of waste useless ballast and a considerable amount of manual labor for repeated stirrings up of the material in the vessels, which is calculated to act for a fortnight. In reality Mr. Schrottky has no more claim to this permanent treatment than I have to his process of dusting.

My own system is entirely atmospheric and automatic ; it works in all weathers and works best when most required, that is, during close muggy days and sultry showery nights. My latest improvement, the hollow vertical cylinder placed on to the bottom of my pattern vessel and covered with bagging or blanketing, trebles the evaporating surface and ensures the spontaneous evaporation of every volatile particle contained in the acid. The vessel can receive a supply for three months, but, according to my observations, and until I can get an acid manufactured for this special purpose, I think monthly supplies of about two ounces of crude acid at a time the most effective. If two ounces are found in excess, you may either lengthen the periods of supply or break off in the charge.

My system should not cost more than £2 10s 0d per acre for the first year and less than half of that afterwards. The saving planters will experience in the matter of weeding, because there will always be more of that on a field of bare trees than on one carrying its full foliage, will go a long way to cover the expenditure of the treatment.

A great deal more might be said on the report of Claverton Committee, but I will not further encroach on your good nature, and remain, yours very faithfully,

JACOB P. STORCK.

CONTEMPLATIONS OF A COFFEE-TREE.

SIR,—"There's life in the old tree yet," said one Dorai to another as they walked past me, pointing to a few ripe berries on the end of my solitary leafy branch. "Well," think I to myself, "so there is, but for how long ?"

Under my present treatment, I can feel about a dozen grubs gnawing away at my roots, my leaves are diseased and drop off me, and a colony of ants is destroying my stem under the moss with which I am now covered. A big, tall sucker (almost the only green part about me) is sapping my strength, and yet I'm alive. Well, well, times are indeed changed with me. Time was when the Dorai would have got the sack for treating me so, but anyway does now-a-days. My own opinion is that I could stand one or perhaps two of these afflictions, but not the lot; they do for me. The grubs would not trouble me very much, if I had plenty of foliage to give me strength to spread my roots, as of old ; neither should I feel very much the leaf-desease, if the grubs would only leave me alone ; but to be attacked root, branch and stem, and starved into the bargain, *is* a trifle too much for my constitution. Though from here I can see fields, and fields of vigorous fellow coffee-trees, older than I, covered with crop and leaves, because either the grubs have left that part of the estate, or leaf-disease has spared it, and they have had some nourishment given to them. I am truly a nearly rootless, leafless, moss-covered, neglected old coffee-stump; but better times are coming, perhaps have come already. I know from the conversations I now and then overhear that some planters think the worst is past, and that I and my fellows are now worth looking after and caring for a bit; and, to be candid, that's my own opinion too. For a week past, the air has been full of sulphurous vapors, which of course has had some effect upon me. I feel as though I had been physicked, but that comes only to help the turn in my condition which has already taken place. Why, the treatment which I have received for the last three or four years would have killed me in my best time, years and years ago ; and I'm now getting on for thirty, still I'm alive. Only take a bit of care of me and see what I shall be next year. What are you laughing at ? I only said "next year."

I shall not be sorry to have a neighbour or two, so long as they don't come too near to me and will keep themselves to themselves on the opposite hill, or the other side the river from me. My roots won't stand any familiarity on the part of any other root whatever. I want all my ground to myself, or I cave in. I'm one of the trees just *above* a cart-road, so I can overhear a good deal of talk as planters go up and down, which I'll perhaps make a note of and let you have from time to time. I wish I was a tree just *below* the road—they seem as though they never had been anything the matter with them. Well, the big, hot road protects them, and feeds them and warms them. Why can't I be protected and fed and warmed ? I would give crops then, seasons or no seasons, the same as they do. Then I want pruning, which to me is the same thing as keeping yourself clean. Cleanliness keeps up your circulation, and pruning saves waste of my sap and guides and forces it into new wood. A few weeds don't trouble me so long as they are kept within bounds, and are not allowed to get too big and harbour strangers. The white-weed and I have grown too long together not to have become a bit reconciled to each other, but my roots soon find out other intruders. The least interference with them tells at once on my complexion. Hullo ! there's a gang of coolies all about us. Now what's going to hapen ? Whisk ! off goes that terrible sucker—Pooh ! what a relief.

Now the saw is half through me—off it goes ! six inches of my top, and the moss and the ants are forcibly cleared away from me, and all this in September. I feel better already. Now all those dead and half-dead tough branches are cut off, and though there is not much of me left I feel like a new tree, for what there is of me above ground is now healthy and vigorous. These rains are already forcing me to bud and shoot, and I think new roots will keep pace, as the worst month for my enemy, leaf-disease, is past. I do hope you'll come and see me next ——— well, I won't say it if it makes you laugh. I have been watching that Tea a good deal and have a good many remarks to make about it, on some other occasion ; and about that Cinchona too. Ugh ! I shudder when I think of all the harm it has done to me. It's killed more coffee than it's value would restore. However, it seems *we* are in luck on this estate, for I overheard the Dorai say he was going to stick to his coffee as long as his coffee will stick to him ; and as it's paying all the expenses this year, he's in the right.

I overhear people who talk about what's in the papers nearly everyday, and so I'm as well-informed almost as though I read them myself. Armstrong and Owen have been lecturing on tea, and very well they have done their work. If we go on at this rate we shall have them coming over from Assam to learn instead of to teach. Just as I finish I hear of a paper, by a Mr. Swaddy, all about bees and origin of leaf-disease, about which I know something, to be discussed in my next. AN OLD COFFEE-STUMP.

COFFEE PRODUCTION AND CONSUMPTION.

Edinburgh, 8th September 1883.

DEAR SIR,—It seems to me that the chief evil which Coffee Planters are, in prospect, threatened with is over-production. The world, generally, supplies more coffee now than can be consumed, if we may judge from the present state of European Stocks, which were :—

On July 3rd, 185,950 Tons.
August 8th, 192,600 ,,
September 4th, 225,207 ,,

while the stock of Coffee in London alone, on the 4th September, was 30,247 tons.

As the new crop will soon be coming forward, we may reasonably expect that the heavy stocks will be very considerably increased, before the close of the year, and that we must consequently accept of prices at a considerable reduction, especially for middling and inferior qualities. Of course very fine samples will always obtain high prices, but this is no criterion of the general state of the market.

Perhaps this "canker," that has attacked our cinchona trees, may ultimately be all for our good, in preventing over-production of bark. Even now, it is with bark, as with coffee. Only fine samples of bark realize high prices. Inferior sorts, and trash, are in two senses, a *drug* in the market.—Yours truly,

P. D. MILLIE.

MR. MOENS ON CINCHONA BARK SUPPLY.

Pangonandjens, Pasoeroean, 18th August 1883.

DEAR SIR,—On page 46 of the *Tropical Agriculturist* I noticed a translation out of the *Soerabaia Courant*, about the new book of Mr. Moens. As the latter part of it does not give a fair idea of the words of Mr. Moens, I now send you a translation of the opinion of Mr. Moens of cinchona prospects, literally translated out of his book.

You will see that he did not write that "in 12 to 15 years you will supply the world." Mr. Moens has so many friends in Ceylon and British India, and is there so much respected and valued by cinchona-planters that perhaps they would not find it fair in his book he should quite ignore them.

You see by enclosed translation that he does speak of *India* supplying the whole world, but of course means Ceylon and British India as well as Netherlands and East India.

It would be a good thing for English planters if the book of Mr. Moens was translated into English. It is the best book about cinchona I know. Every page is full of the most trustworthy information.—I am, dear sir, yours truly, T. O. HOLANDER.

(*From Mr. Moens' Book.*)

Resuming my opinion about the influence which the now rapidly extending culture of cinchona will have on the trade in quinine, I suppose I can say as follows:—

1st. The relatively small quantities which India can produce the first three or four years will not materially affect the prices, because the consumption not only has steadily increased the last ten years, notwithstanding the high price of quinine, but is probably yet capable for largely increasing.

2nd. If the quantity of bark, after about four years, is so important that it necessarily must depress the price, because the consumption does not increase as rapidly, the immediate consequence will be that many sources of South America will stop, because they cannot pay the heavy cost of carriage. A very rapid fall in the price will thereby be prevented.

3rd. If, 12 to 13 years hence, the production in India is so important that *India* alone can supply the world with the necessary alkaloids, then the export out of the primitive forests of South America will be at last quite impossible, because then, with lower prices, the cost of carriage of three to four shillings per kilo cannot be paid.

4th. If at last the production in India and other places where cinchona is grown, is getting larger than the consumption (which is quite possible), then commences the mutual struggle of the different Cinchona estates. In that struggle will be conqueror he who grows the sorts yielding the most quinine, and whose plantations are formed the cheapest and get the best management.

I am quite convinced that it is rather hazardous to look into the future of the trade in quinine. This trade is yet in its infancy, above all if we see how largely the strong extending culture is modificating it, and it is very well possible that trade will bring us many surprises. here we at present do not guess of and that make at fault the most exact calculations."

[There are several reasons for the recent heavy fall in the prices of bark :—1st, the flooding of the market with *cuprea* bark; 2nd, the enormous quantities of twig-bark sent from Ceylon ; and 3rd, and mainly, the ring formed by the leading alkaloid manufacturers to keep down the prices of bark while keeping up the prices of quinine. A reaction has already set in, and we cannot doubt that the use of cinchona alkaloids will largely extend in the wide fever regions of the earth and amongst the huge armies of the Continental Powers.—ED.]

INDIGO IN CEYLON.

Kurunegala, 22nd September 1883.

DEAR SIR,—"Enquirer" in your number for September believes that there are no indigo plants in Ceylon but would be grateful for any information on the subject.

The indigo plant (*Indigofera Tinctoria*) Sinhalese *evari* is indigenous and grows wild in many parts of the island, but is nowhere cultivated. It is gathered in this state by the village dhobies who prepare an inferior kind of indigo called *nil* (blue) for use in washing. I was also successful preparing the dye, from plants growing in my *kotuwa* (garden), under the directions of our family dhoby who initiated me into the mysteries of the indigo vat.

I do not know why it should not succeed in Ceylon under systematic cultivation, and, as it is an important crop either for the manufacture of dye or as food for stock (cows are very fond of it), I will now briefly describe its culture.

Indigo cultivation is attended with many difficulties, for when it first appears above ground it is a very small and tender seedling. A heavy fall of rain or a powerful sun is equally destructive in this stage of its growth.

Soil, &c.—It succeeds best in a rich loam, but does with any soil with proper manuring. I have seen it growing wild in very poor soil. The land should be broken up well as early as September, or earlier if possible, and deeply cultivated to insure a first-rate crop; it should be free from weeds as the plant requires the fullest liberty for its rapid growth. Shortly before sowing, the soil must be reduced to as fine a tilth as possible by the liberal use of the plough roll and harrow, to form a good "bed" for the seed.

Its place in Rotation.—Mr. Robertson of Madras thinks that it should succeed to and precede a grain crop such as maize or cholum or sorghum.

Seed and Sowing.—Indigo seed is very small and from 10 to 15 lb. per acre is required. The seed-time is about the middle of November and fresh seed carefully gathered from the first growth should invariably be used to ensure success in germination. The crop must be sown an inch deep in lines (which is done by means of a seed-drill), but not broadcasted to facilitate after cultivation, which should consist of several bullock and hand hoeings to keep the soil loose and free from weeds.

Manuring.—Undoubtedly, refuse from the vat is the best manure for indigo, but, in the absence of this, farmyard manure may be used with a top dressing of lime.

Growth and Cutting of the Crop.—As stated above, the indigo on its first appearance is a very delicate plant, but once through this stage it is as hardy as ever. The crop will be ready for cutting about the beginning of March; after the crop is cut the land should be bullock-hoed once or twice before the 2nd cutting which is in May, followed by a third in June. On average soil these cuttings would probably yield per acre 200 bundles measured with a 7 ft. chain; this would be worth nearly R30 in Madras. Two maunds of dye could be prepared from this, which would bring about 90 rupees into the hands of the manufactured at a very small charge for manufacture (R2 only per maund)

Hoping that "Inquirer" will give indigo a fair trial and publish the result in your columns,—I am, dear sir, yours faithfully, A. W. JAYAWARDENE.

[In the first place, we are sceptical as to indigo, any more than tobacco, chillies or pine-apples, being indigenous here. In the next place, there seems little encouragement to try a crop which, requiring rich loam or manuring, yields a crop worth in its green state only R30 per acre, or R90 when manufactured. We scarcely understand the threefold value if the manufacture is so simple as represented. What we do know is that all previous trials in Ceylon have been failures. Mr. Lemarchand, an old Bengal indigo-planter, made a trial in Jaffna, and the plant was eaten by "poochies." In Northern India, suitable soil and the best appliances are abundant, and the supply could easily be doubled if there were a remunerative market. But aniline dyes and other substances now compete with indigo, and the consumption is not like that of tea, rapidly progressive. There can be no harm in trials however. There are extensive fields of indigo near Singapore, grown by Chinamen to supply dye for the dark blue cloth which "John" so greatly affects. Our people here like gayer colours.—ED.

SHRIMP SHELLS AS A TEA MANURE AND INSECTICIDE.

Colombo, 27th September 1883.

DEAR SIR,—Now that tea is growing to be a considerable industry in Ceylon, and, like coffee, is perhaps obnoxious to the ravages of insect pests, it may be interesting to cultivators of the product to hear of something which is eminently favorable, not only as a manure to promote the growth of the plant, but for the purposes of purging grub pests. This consists of the shells of the shrimp. Large quantities of these are shipped to China from the Coast of California, where shrimps are caught in vast numbers. The Chinese employ the shells as a manure, and as a poison to the worm which works such destruction to the plant. The Chinamen state that this is the only remedy at present known for the tea pest.

The shrimp is not an uncommon commodity in Ceylon, and it might repay agricultural economists to devise some method of conserving and utilizing the shells in the extermination of insect pests.—Yours truly,

GOIYA

BORER ATTACKING TEA.

Rakwana, 28th September 1883.

DEAR SIR,—Under separate cover I am sending you two pieces of a branch from a tea tree that I pruned yesterday. Is this some new tea pest that is going to visit us? or has it ever been seen in Ceylon before?

Strange to say, it apparently neither effects the growth nor the look of the bush at all, but perhaps I was lucky enough to discover it before any real harm was done.—Yours anxiously, J. P. T.

P. S.—I fancy you'll find the insect that has done all the damage in the centre of the largest piece, the ends of which I've corked up.

[This is an unmistakable and apparently serious case of borer, the insect having been evidently hard at work by ... post. Allowed to carry on its operations to their close, we suspect the tea would not only be affected but killed. We hope the pest is not prevalent and that it will not spread. Our entomological adviser states that the boring insect is the red borer described by Nietner in his "Enemies of the Coffee-tree" (page 14)—second edition.—ED.]

CINCHONA AND OTHER SEED.

4th October 1883.

SIR,—Kindly permit me to correct a few mistakes that occur in the footnote to my letter appearing on page 214.

1. I did not say, or, as far as I am aware, imply, that "seed merchants" could not procure genuine calisaya seed of the better kinds from Bolivia, or any want of good faith on their part. The only mention I can find made in my letter of any of the fraternity was with regard to an offer that had been shown me, from one of them, of seed from the *same estate* that Ledgeriana came from. I did so under the impression it was to call attention to a point of no little importance to growers, and, as what he says it is manifest should be reliable, I don't see how I could have done the man a kinder act. What, though, I did say and quoted evidence in support was "I cannot alter my belief in the impossibility of procuring other than spurious seed through the medium of any professional *seed collector*, or commissioned agent, and as solely a business transaction; *though not here at all meaning to imply that those by whom I notice it stated to have been thus procured, at all doubt the merit of the supplies they have received*. However, it is a point open to discussion, and it will be interesting to receive evidence of how far I am right or wrong. "Any one possessing the opportunities I named—whether a seed merchant or otherwise—unquestionably stands an equally good chance of procuring genuine seed;—but I hold it to be a *desideratum* that he does possess them.

2. You remark that "the proof of the superiority of my seed can only be afforded by the resulting plants." The thing I especially desire—and it was the main object of my letter—is that the plants from *all* calisaya seed now being obtained from Bolivia, be it by whom it may, should be carefully watched and criticized by our best authorities that their merit may as far as possible be determined. If it be that the enterprise here and in India is to be sustained in the future by large importations from thence, I think everyone will be with me in saying—and I think, sir, you will yourself agree in doing so—that, with the earlier experiences of Java in memory, this is essential.

3. In quoting Markham, it was in regard to a question which I am unaware has been before broached (and, as I believe him, a reliable authority) as to whether "Zamba Morada" was not in reality the name of a variety of *ovata*—and not, therefore, a Calisaya at all—or whether the name was used in connection with *both* species. The whole group of ovatas being *practically worthless*, it seemed to me a point of sufficient importance to call attention to.

4. You mistake me in saying that "I was especially anxious to disavow any desire to advertise seed imported by myself." That could not be though as said already it was not the motive that prompted me to write the letter published.

5. I did certainly say that I had no seed for sale (or have I yet) but added "it is perfectly true that I expect some soon" and "though probably a very limited quantity as before." I am especially anxious to point this out to avoid a false impression that will naturally be caused should I soon wish to make a public offer of any.

6. My remarks in reference to sloe leaves and coffee rubbish—and I am anxious as they have been alluded to that they should be given in full—were, "Whether it clash with my own interests or not, I wish equal success to any one who can or does introduce genuine seed; but I have as good a right to object to having the market swamped with spurious supplies as you yourself, or any one here, to know your coffee or tea driven out by paper paste beans (as the last invention!) or manufactured sloe leaves, regarding it equally as a fraud on myself and the public."

These remarks were general ones; I simply want to enjoin caution as regards imported seed, let it be by whom it may, and I think have adduced sufficient evidence to prove the necessity of it. I trust you will allow me here to add that I think it especially fortunate, and I am heartily glad to see Mr. Ledger himself again coming forward—wishing him all success—for, certainly, no man, when it is considered what he has done for the enterprise throughout, it may be said, the *civilized world*, and in recollection of the altogether inadequate pecuniary return afforded him, has so thoroughly earned a right to support and confidence, and a fortune on it.

7. In my letter published, owing to a mistake in punctuation, I am made to speak of *C. verde* as the finest cinchona known. A fullstop placed *before* instead of *after* "the finest cinchona known," and it will be seen to apply to C. *Morada*. For the reasons afterwards given, I cannot regard *M. verde* as generally the most valuable variety, through it may be found best suited for very low elevations.

C. R.

CATERPILLARS ON TEA.

Dikoya, 5th October 1883.

DEAR SIR,—By post today I send you a few out of many thousand caterpillars which have completely denuded some tea trees of leaf. I do not fear a tangible pest of this nature, but, as it is new to me and may be so to others, I should be very much obliged to you if you would kindly find out for me what they are. I am keeping some to see what they turn to. PLANTER.

[This is the larva of a moth, probably *Sephisa Cingala*, but our correspondent should send a few down in the chrysalis state for identification.—ED.]

CINCHONA BARK: A HINT TO PLANTERS.

Colombo, 8th October 1883.

DEAR SIR,—The prices of cinchona bark in London have fallen no less than fifty per cent, within the last three months; they are now low enough to curtail the export of bark from South America in timey In the meantime it should be the policy of ever. planter, who can by hook or crook manage it, to allow his bark to increase in value on the trees. Like wine or spirits, its value increases the longer it is kept; nay, it is better than these, as there is no charge for warehouse rent. If the market at home is flooded with weak shavings, a recovery in prices cannot take place. As long as the price of quinine is eight shillings per ounce, five-pence and six-pence per unit of quinine are not the fair values of bark.—Yours truly, A MERCHANT.

TEA VERSUS COFFEE.

DEAR SIR,—Excuse me, sir, just for a moment, but I *must* have a word with "An Old Coffee Stump": Look here, stumpie, what are those remarks you are going to make on me?—out with them—what 's the use of all this babbling and moan? you 're run out, done up, not worth a dump: not but that there are a *few* respectable families doing well, but in the main you know, it 's no use, you must go; we both *can't* live together.

What do we care for leaf-disease or grub (or you for the matter of that)? we are strong and healthy immigrants on a new soil, and having left red spiders and green flies behind us* are *bound* to have a good time of it here, ha! ha!

You and the cinchonas don't seem to have pulled together very well: now that's curious; for my part I am on very friendly terms with them, and in fact they tell me that my presence has been doing a lot of good to them, my strong tap and lateral roots opening up the soil and enabling them to throw out new roots and get along capitally.

I don't profess to know much of your diseases, but I am not surprised the planters should turn to us. Look at the money they have spent on the very best doctors and medicine for you and no good has been done, and you were then left to Nature, hoping that some good might come of that; but no go: you *won't* exert yourself. Ingrate, bah! LEETLE TEA-PLANT.

* Both exist in Ceylon, but as yet neither has shown badly.—ED.

PLANTING UP COFFEE ESTATES WITH TEA, TEA ESTIMATES, &c.

DEAR SIR,—I heard a passing planter remark today that nobody had taken the slightest notice of Mr. Northmore's mathematical demonstration of the practicability of getting tea into line by planting it in amongst the coffee according to his sketch, for the simple reason, said he, that it is a perfectly useless suggestion, as there are not two estates in Ceylon *lined both ways*. The better plan is (to save new lining) to strike a base line at right angles to existing coffee lines from which to work up and down, letting the *direction* be always the *same* as the coffee, though different in width; ergo: if a cooly starts work from this base line at a peg exactly in the middle of the working line, he will have no difficulty in following it up or down, putting in the tea according to a measure he carries with him. If he starts flush with the coffee, or if he starts one foot to the left of his coffee line, or one foot (or more or less) to the right, he can keep this distance in his eye the whole length of the line. Here, of course, the old coffee lining will be the guide as to direction. Sometimes that is wild enough, but new tea lines, probably, would not be better done than these old ones by the old planters.

As regards tea ját:—The science of evolution shows that the embryo and young of all species of animals and plants have features characteristic of their remote origin, which wear away and disappear as they attain to maturer age. Now some of my seeds—obtained from the same source—came up nearly jet black, while others came up to the surface quite a light yellow. Is it worth while to carefully sort these out and keep them separate? Are the jet black seedlings not from an inferior *stock*? and the dark coloured ones generally, in proportion as they are so coloured? This was a question put to one durai the other day, which he said he could not answer. But he said he had read Mr. Hay's paper on pruning and plucking tea, and his estimates; all of which, he said, were after his own heart: short and practical and to the point, *multum in parvo*; and, as a lesson to tea planters, quite worthy to rank alongside Armstrong's and Owen's. They have all had their fling at poor old Cameron, because I suppose, the time is come when it is necessary to give his system its quietus; but, that done, it is time his memory were left to rest in peace. He was the right man providentially sent to Ceylon at the right time. * * * [We have omitted a passage for reasons which we are ready to explain privately.—ED. C. O.] He set matters right for the time being, as cultivation was needed in his day. Had he lived, it is only fair to suppose he would not have been a single step behind the experts of today in adapting his system to the added years of his estates. He was of a most open, generous disposition, concealing nothing, but imparted to everybody and anybody all he knew gratuitously for the asking.

As regards Mr. Hay's estimates, the opinions I have heard expressed are that they are fair, and that the man who could realize them in actual working from beginning to end would be fortunate. Perhaps *a trifle more* added to 1st year's "Superintendence," to "Cost of Land," and generally to "Interest," to "Contingencies," to "Felling and Clearing," "Weeding," "Transport" and "Money Charges"; and just a shade taken off "Returns per Crop" (to make all safe and sure), then these estimates would be applicable to all parts of Ceylon, and bring up the total cost per acre to the traditional R250 to R300, or say, after this, R275 as the maximum cost over three years. That is for an entirely *new estate cut out of new land*; and this reminds me that one weak point is the very first, thus "*cost of land*." Tea planters will be more fortunate than coffee planters have ever been if they can secure blocks of land in quality and quantity to order. Mr. Hay could or would scarcely buy *exactly* 250 acres and then fell and plant every stick of it! He should have made his block 400 or 500 acres at least to meet a fair allowance of patana and reserve, &c., and this would have doubled his first item, "cost of land." But now occurs the question to many minds: what items in these estimates would be *saved* by the proprietor of an existing well-found coffee estate of the same acreage which he intends forthwith to convert into a tea estate? say these :—

Felling and clearing 250 acres ...	R3,750
New roads	1,050
New drains	2,300
New lines	1,200
New bungalow	3,000
Half cost of new tea-house ...	1,500
Total	R12,800

Allowing all other things to be the same even to the "cost of land" (as the old estate may have at least that much debt upon it) the final result would be :—

From Mr. Hay's total ...	R72,359
Take the above	12,800
	R59,559
Less profit by tea sold	18,000

R41,559 ÷ 250 = R167 per acre.

Mr. Hay shows that a *new estate*, bearing average crops of R320 per acre, will, after the end of the 3rd year, give a yearly profit of R21,000 on a capital invested of R54,000, or about 39 per cent per annum. Against this, based upon these same estimates with the same expenditure in the 4th year, but with only 300 lb. of tea per acre (deducting nothing for "new lines," or from the item "manufacturing") the above calculation shows that 250 acres of converted coffee land, bearing only 300 lb. per acre, will, on a capital of R42,000, pay a yearly profit of R18,000 or 44 *per cent per annum*!

In the latter case, too, some coffee, cinchona, and other established new products would in all probability contribute their quota to effect a considerably better result!! *Which is best?* Without being particular as to who spoke these speeches, they were overheard by AN OLD COFFEE STUMP.

P. S.—MR. HAY'S ESTIMATE, October 10th.—I owe this gentleman an apology for carelessly misrepresenting him in my last paper, in the matter of the acreage of his block. After taking a few notes I had sent to the paper away, but on its return find he had provided for more land than he cleared, by 50 acres, which I overlooked and stupidly did not give him credit for. It does not affect the comparison of cost of opening old estates and new land, but reflects on Mr. Hay's forethought, for which I am sorry and would like the offending paragraph omitted, if indeed it is likely to be published at all. AN OLD COFFEE STUMP.

THE *TROPICAL AGRICULTURIST* AS THE PRACTICAL ORGAN FOR THE PLANTING INDUSTRIES AND AGRICULTURE GENERALLY OF THE ISLAND.

9th October 1883.

DEAR SIR,—Questions have been asked about the best way of economizing the expenditure of our Kandy Association. It has been suggested in more than one quarter that the annual book of proceedings might be dispensed with as more ornamental than useful; while on the other hand, some branch associations have been proposing to do a little publishing and printing on their own account. You, sir, on the other hand, have called on the parent P. A. to collect the papers recently read and discussed at district meetings, to get up a report on them and to re-publish the whole in the same book of proceedings which some people seem to think might be abolished.

It seems to me that you, as well as the leaders of the different Associations, are rather inclined to spend more money over paper and ink than is at all necessary. The papers which are so much the talk of the planting districts just now have not only been given in the daily papers but I have seen copies in a handy pamphlet form of some of them. If this is not enough, there is a still handier repository for all information useful to planters in the *Tropical Agriculturist*, and I cannot, for the life of me, see why it should not be made the organ of every planting or agricultural committee and association in the country, to the great saving of the outlay required for duplicate and triplicate printing, and of the time of secretaries and committees in compiling separate reports and annual volumes.

For instance my copy for October of the above periodical has just reached me, and in it I find Mr. Armstrong's paper on tea, with the discussion on it and on coffee at the Dikoya Planters' Association; also Mr. Owen's valuable paper and the discussion at the Maskeliya Planters' Association, both given in full with your own remarks upon them; also the discussion on india-rubber at the Kandy Planters' Association; and I have no doubt in the November number I shall find the Dimbula Planters' Association's papers on coffee and cinchona with Mr. Hay's letter and a discussion on tea.

Now what on earth more than this is required by my fellow planters or our Associations? I think we might drop spending another cent on separate publications, for so far as the political and personal proceedings of the Kandy body are concerned it is surely quite sufficient that they be recorded in the daily press? There can be no handier volume in which to record the practical work of our planting meeting than the *Tropical Agriculturist* with its convenient index. I might mention that in the October number, besides the above, I note several of Mr. Owen's letters on the tea districts of North India, a great deal about coffee in Java, about cinchona, dwarf palms, vegetables, various useful plants and new products. Altogether a volume of the *T. A.* ought to be worth half-a-dozen of any that the Kandy Planters' Association and its branches can compile and put forth, and I, for one, will vote to make the *T. A.* our representative agricultural organ and to save one considerable item of outlay in the Kandy accounts.—Yours faithfully, COMMONSENSE.

CEARÁ RUBBER: GILLIAT PROCESS.

Goonambil Estate, Wattegama, 9th Oct. 1883.

DEAR SIR,—By parcel post I send you a sample of Ceará scrap rubber obtained yesterday afternoon from five trees, three to four years old. Mr. Gilliat, who was formerly in charge of this estate, was good enough to come up and conduct the first of a series of experiments according to his lately discovered method, and it was simply astonishing how quickly the rubber was, so to speak, precipitated (coagulated) when submitted to the fluid preparation which forms part of the inventor's process.

To set at rest, once for all, the doubts and enquiries of certain parties, I may mention that there is no spirit of any kind used in the process, and a perfectly pure sample of rubber results after a little washing and pressing.

Accompanying sample is forwarded for the opinion of the broker who saw the Haputale rubber, and who was kind enough to give you a report on Mr. Gilliat's last Peradeniya sample.

The milk flowed wonderfully freely down the channels made by the ingenious yet simple knife, and, if the trees had been tapped in the early morning we should probably have got nearly double the quantity, for it was ascertained some time ago that early morning is *the* time for tapping.

These trees were severely tested twelve months ago in the presence of Mr. Gilliat, Mr. Mackwood and the writer, and have been experimented on once or twice since, but the quantity of rubber obtained today exceeds all the previous tapping put together.

The knife is thus shown to be effective, and we may surely conclude that the trees were *not* weakened by former trials.

In another month we shall make further experiments, and, if you think worth while, I will send you results.

That rubber cultivation will pay in Ceylon is almost a certainty now, which will appear at once to any one who sees this remarkably rapid, inexpensive and simple method of collecting and elimination.

Mr. Gilliat informs me that we may expect the cambium to be closing over within a fortnight.

It may be interesting to add that the knife was used on the renewed bark of a cut made only *seventeen days* ago, and the milk flowed as freely from this as from original incisions.—I am, dear sir, yours faithfully, C. G.

No. 2.

Peradeniya, 9th Oct. 1883.

DEAR SIR,—I enclose you a sample of rubber for your inspection got by a totally new process. It is from a tree 14 months old, and the tree has been tapped five times in one month. Do you think this sort of rubber will be favourably received by the manufacturers at home.—Yours faithfully,

H. A. GILLIAT.

[Our report is as follows :—" The sample of rubber sent by "C. G." is very good clean elastic, and worth 2s 6d. But the only practical way of dealing is with a big cake of about 100 lb. Mr. Gilliat's sample I return too. I and those who have seen it are surprized that it should have been sent at all, as it appears to us to be manufactured stuff from Europe. —Verb. sap. !"—This is surely not the case : Mr. Gilliat is simply experimenting, not "drawing anybody's leg" ?—ED.]

COFFEE CULTIVATION IN THE PANWILA DISTRICT BY MR. HOLLOWAY.

Maria, 10th October 1883.

DEAR SIR,—We have had some splendid showers lately. Our coffee has stood the dry weather during September with the heavy crop on some estates very well, and crop is now ripening up fast. It does one's heart good to go around the estate having trees of Arabic coffee laden with cherry in all colours, from dark green to red, and to see the cocoa trees full of pods in all stages. Our bean is very large this year. Let Mr. Skrine or his supporters of the coffee-going-out stamp come here, and we can prove the reverse. Coffee is now steadily improving. When Mr. Storck can prove his theory of curing leaf-disease with a continual changing system (which no one that I know of, cares to follow), then let him attack my style of treating it which I have found effective in checking the disease and giving good crops, proof of which can be given. My challenge to visit this estate and satisfy one's self is still open, and always will be, to any one.

As regards Mr. Halliley's saying I had a kick at him, I can only say it is far from me to have a kick at anyone who, I can see, takes an interest in coffee or any other product. I simply give my experience as I try everything on a small scale first. He is further wrong in mentioning "Raxawa." Maria is the only estate on which I have been enabled to do the work and apply manure as I believed best. With us here a continual carpet of weeds has been found bad, and weeds of two months' growth forked under did no good. Small weeds have done good, used as I described. I go further : with all due respect to Professor Liebig, full grown weeds, *ageratum*, if applied in a hole by itself near a coffee tree, do more harm than food; they will assist *fungoid* growth, and are not fed on by the coffee rootlets as other manures would be, but by mixing weeds with other leaves and swamp or manure and disinfectants they are a capital manure. —Yours truly, J. HOLLOWAY.

CULTIVATION IN JAFFNA.—A visitor to the Northern Peninsula well remarks :—"It is a *treat* to see the careful Jaffna cultivation—all MADE soil tilled with the utmost care. If only the Sinhalese would imitate them." This is very true, for the industry and skill of the Jaffna cultivators have long been proverbial ; but the curious thing is that the Jaffnese so cling to their over-populated peninsula and do not go up into the Wanni, to cultivate and possess the extensive area of waste land awaiting cultivation there! This is the direction into which the enterprise of the Tamils of the North ought to be directed.

THE STOCK OF RUBBER at Pará on the 31st ult., according to the report of Gonçalves Vianna & Co., was 282,000 kilos, and cacao 1,412,000 kilos. The July receipts of rubber were 535,000 kilos, against 500,000 kilos in July 1882. A statement recently appeared in the Pará papers showing that the rubber gathered along the Rio Javary all came from the Peruvian side, the Brazilian side apparently producing not a single kilo. It has since been discovered, however, that there is a very good reason for all this—and that is the Brazilian export taxes. The Brazilian product is first carried across into Peruvian territorry, where *guias* are obtained with which to evade these export duties, the Peruvian imposts being much lower.—*Rio News*.

INDIAN TEA AT AMSTERDAM.—The following extract is taken from a communication received from the Secretary to the Tea Syndicate :—"It is hoped that a consignment may be forwarded ere long to the Amsterdam Agents, and it has been arranged to send a small shipment to Antwerp, where it is proposed to introduce the sale of Indian tea made up into packets of about 1 lb. each, which is the method recommended by the Agents in that city. The Committee have been favored with a letter direct from Mr. Royle, dated the 22nd ultimo, in which he states that there is no doubt of the success of Indian tea in Amsterdam after a short time, as every one appears to like it, and there are constant demands for supplies both small and large. The Committee are much indebted to Mr. Royle for the trouble he is taking for them in disposing of tea on behalf of the Syndicate in patent lead foil packets obtained from London. It is also stated that agencies have been opened in Amsterdam, Rotterdam, Antwerp, and Moscow, and that pending contributions from subscribers to the Syndicate, which were not forthcoming with sufficient promptness, the purchase of tea in London for supply to the Amsterdam Exhibition has been authorised. It may be hoped that the efforts of Mr. Royle and the Tea Syndicate will lead to an extension of the market for Indian tea in Europe, and will be supported by tea planters."—*Madras Mail*, Oct. 3rd.

TEA AND LIBERIAN COFFEE IN RAKWANA AND MOROWAKA DISTRICTS, CEYLON.

On Stubton estate, there is a plot of Liberian coffee, of, I think, 5 or 6 years of age, which the proprietor assured me continued to bear largely, though, unfortunately, there is not the same demand now for seed that there was two years ago, when the writer even was a customer. After breakfasting at Stubton, we went on to Barra, which will soon be better known as a tea estate. The manager very kindly permitted us to see his tea-rolling machinery and tea-house. The old coffee-pulper stands at one end of the pulping-house, and a continuation of the same driving machinery gives the motive power to one of Jackson's tea-rollers, which occupies the further end of the establishment. This machine consists, roughly speaking, of a table, over which a large hand is made to revolve with a double concentric motion, horizontally. The leaf, when ready for rolling, is put in at the top, and is subject to a certain pressure that continues so long as the machine is at work, and can be accelerated if necessary. The hands—if I may apply the phrase—are fluted radially, so that the tea-leaves cannot slip about in the course of their eccentric rotation. From what has been said, it may be easily understood that the manner by which the tea is rolled in the roller is very much the same as by hand, except in the vast difference as regards speed and quantity. I was also shown, in addition to tea, some cocoa; and finer pods I should think could not be procured. One pod in particular I should think was fully ten inches in length, so that Rakwana may yet be able to add this product to the fast advancing tea. At Barra store I saw being loaded into carts quantities of plumbago, which, I understand, is abundant in the district, and of very superior quality. From Springwood estate we started next morning for Morawak Korale, passing through the Rakwana estates as far as Vegeria, from whence we took the road through the forest into old Abbey Rock estate on the other side. Ellengowan estate, or that part of it through which we passed, has a splendid crop, better than anything than I have seen this year outside Uva. Poor old Vegeria looks very sad, and the elephants even have seemingly taken it over, for we found their marks up to within a short distance of the bungalow. On the Morowak Korale side these huge beasts have been walking about like cattle, feeding on the Mauritius grass that swarms about the old abandoned properties. After partaking of some refreshments that we had brought with us, we reached Kooroolagalla estate, and halted there for the night. This property, once old coffee, is now fast becoming a tea estate, and, thanks to the kindness of the superintendent—Mr. Spearman—we had a glimpse at his tea-store. Nothing can be more different from a coffee-store than a tea-house. The first is all drafts of air; the second all heat, charcoal sifting, weighing, sorting, rolling, firing, tasting, packing, and what not besides. Here, the mind and the body—the latter, particularly including the pores of the skin—are ever at work, and judgment is exercised upon every operation. Can this be said of coffee? There was a time when it might have been ventured in reply to my question, but now-a-days the store grounds are covered with cinchona bark, and the white parchment peers from a remote corner, with a brownish blush upon it, as if ashamed of its own insignificance! From Kooroolagalla we were conducted as far as Campden Hill estate, where we were shown some superb machinery. A water-wheel, 20 feet in diameter, that once pulped most flourishing coffee, now drives Kinmond's wonderful roller and drier. The first of these contrivances differs from Jackson's machine described above, chiefly in its being vertical instead of horizontal in its action. Two large solid wheels are brought together by means of a screw at the end of the shaft of one of the wheels. Into the space between them, which is also closed round by a sliding casing the tea leaves are thrown in, and the whole closed up by a door above. The wheels are then set in motion, both revolving in the same direction, but once a little faster than the other, so as to impart the requisite twist to the leaf. After a few minutes, during which time the machine indicates its speed, it is brought to a stand-still, a lever is moved, and out fall 200 lb. of beautifully-rolled tea. As well as I can remember, this machine did 200 lb. in 10 minutes—a fact sufficient to show the saving of labor by its use. Close to the roller, just described, stands the drier. This consists of a series of enclosed trays, through which hot air, from the furnace below, is driven backwards and forwards till it reaches the chimney at the top. Two fanners, each making 500 revolutions to the minute, force the air through, which, according to the thermometer attached, can be raised to 650° of temperature, and, even at that great heat, Mr. Booth assured me the tea could not be burned. With such perfect machinery, and all in such perfect order as Mr. Booth has it, it is only a queston of time, for the cost of manufacture against value, to decide the advantages of machine work over hand-manipulation; and in fact, this is not far to seek, when I say that, comparatively speaking, only a few people were at work in the store, turning out a large quantity of stuff, and passing in through its various manipulations. I cannot close this subject without recording my thanks to Mr. Booth for the kindness with which he showed me everything, and the pains he took to explain details that might pass the notice of a novice in tea. The success of tea appears now to depend on its manufacture, and, if this difficulty can once be mastered, owners may, I think, safely rely on a good return, provided they do not get carried away by inflation and speculation.—"Local Times."

Poultry.—Give your fowls a reasonable share of attention; furnish suitable accommodations; get and keep the right breed; save only the earliest hatched pullets for laying; furnish as great a variety of food as possible; feed as much as they will eat; give green and animal food of some kind in winter; keep the hens quiet and comfortable; don't allow them to be worried or frightened; keep clean and fresh water at hand always.—*Rural Californian.*

Mr. Taylor's (Mr. McIntosh's gardener) method of making sulphur water for destroying mildew on Vines and other plants may be usefully described in his own words:—"I put as much sulphur as will lie upon a shilling into the middle of my left hand, add a few drops of rain water, and mix very smooth with the finger of the right hand, than wash my hands in four gallons of tepid rain water. As soon as the sun is off the house, the Vines, &c., are syringed with this. I have tried a teaspoonful to four gallons of rain water after the Grapes were stoned, but found it too strong to continue daily." Milddew is rather prevalent in the house in question, and the above is found the safest and best way of dealing with it.—*Journal of Horticulturae.*

Eucalyptus in Malaga.—The British Consul at Malaga says the cultivation of the Eucalyptus has of late attracted considerable attention in that province, which has been deprived of all but fruit trees in order to supply the constant demand for charcoal, caused by the extensive use of this fuel for cooking purposes. Large numbers of Eucalyptus in a healthy and flourishing state may now be seen along the line of railway from Malaga to Bobadilla and in other places, and they are reported to have been effective to some extent in destroying fevers in the low districts, which were formerly uninhabitable. These trees are also successfully used to form avenues and afford protection from the sun on the roads near the city.—*Gardeners' Chronicle.*

Sulphur in Bitumen.—From the abstract of the meeting of the Paris Academy of Science in your last number (vol. xxviii. p. 408), M. B. Delachanal appears to consider that the presence of sulphur is peculiar to the bitumen of the Dead Sea, and from this he deduces a theory as to its inorganic origin. In some experiments which I had occasion to make this summer on the bitumen of the Great Pitch Lake of Trinidad, I found that this substance contained a very considerable quantity of sulphur. Several per cents of the volume of the gas obtained by its destructive distillation consisted of hydrogen sulphide. The orgin of this asphalt is generally considered to be organic, but I am not aware whether the entire absence of calcium salts from its ash, a fact which was proved nearly a century ago, and has since been confirmed, has been explained on this theory.—Hugh Robert Mill, Edinburgh, August 27.—*Nature.*

HOUSEHOLD RECIPES.

BY A VIRGINIA LADY FOR THE "SOUTHERN PLANTER."

GREEN TOMATO PICKLE.—Take one peck green tomatoes, peel, cut in slices, sprinkle with salt; let them stand 24 hours; pour off the water. Take 1 quart chopped onions, 1 ounce alspice, 1 of ginger, 4 of white mustard seed, 1 of cloves, 1 of black pepper; all beaten fine except cloves (which must be whole); 2 pounds brown sugar; put the tomatoes and spices alternately in a kettle, cover all with strong vinegar, and boil till the consistency of marmalade.

CHOPPED CABBAGE PICKLE.—Nine tablespoons mustard seed, one-quarter pound salt, 1 light tablespoon cayenne pepper, 5 ground black pepper, 6 celery seed, 3 alspice beaten fine, 2 *teaspoons* cloves, 1 tablespoon mace all beaten fine, 3 tablespoons ground mustard, one-quarter pound horseradish scraped fine, 1 pound brown sugar and 12 onions and 6 gallons cabbage shreded as for slaw; cover with vinegar and stir till done.

DELICIOUS PICKLE.—Drop your cucumbers, etc., in brine strong enough to bear an egg; let them stand six days, wash in fresh water, and drain all night. Put them on a slow fire with vinegar and water enough to cover them and for one-half bushel cucumbers piece of alum size of partridge egg; cover closely with grape leaves and let them remain on fire till green, closely covered; let them remain for a night, and next day drop in spiced vinegar prepared *ten days before*, thus: Five gallons vinegar, 5 pounds brown sugar, 2 pounds white mustard seed, 2 pounds white ginger, one-half pound ground mustard, one-half pound black pepper, one-half pound tumeric in a bag, one-quarter pound nutmegs, one-quarter pound mace, one-quarter pound alspice, one-quarter pound cloves, one-quarter pound celery seed, one-quarter pound angelico, 3 dozen onions, which must be sprinkled with salt for a day, drain water from them, wash in vinegar, and drop in pickle pot.

SUGAR AND COFFEE IN SAMOA.

An interesting official report has been published concerning the resources of Samoa (Navigators' Island), and we note that experts both for sugar and coffee planting have favourably reported upon the capabilities of the islands for these industries. The coffee plant has been in existence there for some years, and, growing luxuriantly has proved the suitability of the climate and soil, but it has never been scientifically treated, and in consequence is not as yet an article of commerce. Sugar-cane grows wild all over the islands. Some coffee planters and speculators visited Samoa during the past year with the view of settling, should they find the country suitable for their several purposes; but the moral impossibility, under the present circumstances, of obtaining an indisputable title to any parcel of land they might buy, deterred them from risking their capital. The native tenure of land, so intricate and complicated, and the inclination of the natives to effect wrongful sales with a view of reclaiming the land subsequently, make speculators very chary of investing money in property that may at any time be disputed, perhaps at one time on account of neglect of some native custom not noticed at time of sale, and not provided against; and perhaps at another time by some relative presenting himself, who was absent at the time of sale, either intentionally or accidentally, and questioning the validity of sale on account of his not having given his consent, and having received no part of the purchase-money. The total absence of hurricanes, or indeed of any winds strong enough to cause damage, make these islands more suitable for the growth of sugar-cane than many other parts of the world, where the whole crop is liable to be destroyed in one blow. In starting a plantation in Samoa, after acquiring the land, the greatest difficulty would be in procuring labour. The supply of Polynesian labourers is visibly falling off, through the disinclination of natives to go to Samoa to work, and the greater advantages and comfort offered them in other parts, such as Queensland and Fiji.—*India Mercury.*

WEEDS.

In common with many other farmers, I have found it exceedingly difficult to keep my Mangels—under which crop I have at present on the farm about 30 acres—free from weeds. I have, however, about 8 acres of Mangels under experiment, on land which has grown nothing but roots for more than forty years, and here, in consequence of the careful attention which it is absolutely necessary to employ in carrying out an experiment, the Mangels are almost entirely free from weeds. The farm Mangels have been heavily dunged, and when the plant was fairly established about 1¼ cwt. of nitrate of soda was applied as a top-dressing. In walking over the two fields I have been very much struck by the more rapid progress of the experimental roots as compared with those grown in the ordinary cultivation of the farm, and the fact has led me to consider how far the growth of the latter has been retarded by the presence of the weeds. Assuming that the soil contains a sufficient supply of alkalies and phosphates, it may be said that the weight of the crop would depend upon the amount of nitric acid which the Mangels could take up from the soil. The nitric acid may be derived from various sources—(1) from the stock of organic nitrogen in the soil; (2) from previous applications of manure; (3) from the manure applied in the present season; (4) from the nitrate applied as a top-dressing. Now as weeds take up large amounts of nitric acid, their roots and finer fibres when destroyed underground may nitrify and serve as food for the Mangels grown this year. But the bulk of the weeds which are destroyed by hand, or by horse-hoeing, remain on the surface, and do not nitrify until they are ploughed under the soil. This conversion of nitric acid into organic nitrogen in the form of weeds, instead of crop—although in some cases unavoidable—becomes a source of considerable loss, and in my own case I have very little doubt that on some parts of the field the weeds have taken up as much nitric acid as was contained in the nitrate of soda applied as a top-dressing, and that the crop of Mangels will be so much the lighter for the loss. The rapid appropriation of nitric acid this year by weeds is very apparent in our Wheat fields where the plant is thin. When the crop is in bloom it usually takes but little nitric acid from the soil, but if at this time the surface soil is moist, nitrification takes place rapidly, and a field which was comparatively clean when the Wheat was in bloom, may have become one mass of luxuriant weeds when the crop is cut.—*Sir J. B. Lawes, in the "Agricultural Gazette."*

HOW TO FEED POULTRY.

BY R. EDMUNDS, ORLEANS CO., LA.

It is a very easy matter to incur a serious loss annually, where a good number of fowls are kept, by injudicious feeding. All kinds should have a sufficiency of food without being overfed. If the birds are kept in a state of semi-starvation, the hens lay but few eggs, and those intended for killing become so very attenuated that a very considerable outlay is necessary before they can be brought into proper condition for the table, and when there they lack tenderness and delicacy. To feed too liberally is wasteful, and in the case of laying hens decidedly objectionable; for a hen, when it becomes very fat, ceases to lay freely, and is subject to various ailments, and an overfed cock becomes lazy and subject to death from apoplexy.

Full grown fowls should have just as much as they will readily eat and no more. Barley, either whole or in the ground state, is fairly acconomical, used either alone or in combination with other food. Oats and oatmeal are of especial value for fattening for the table. Indian corn or maize is, perhaps, one of the most economical foods for poultry, and has the advantage that, owing to the size of the corn, sparrows are unable to rob the fowls. Pieces of bread and vegetables of all kinds may be utilized, and scraps of meat chopped up rather small are of great value in feeding fowls shut up in the small yards where they are unable to obtain worms and insects.

Potatoes well boiled and mixed up with sufficient coarse pollard or bran, when scalded to form a rather stiff paste, are useful for helping out the corn.

As a rule, fowls kept entirely in enclosed yards should have three meals a day; the first to consist of soft food, prepared by the admixture of boiled potatoes, kitchen scraps, bran or pollard, and barley or oatmeal, and for the other two meals corn of some kind is decidedly preferable. The soft food will be all the better if it is mixed over night and placed in an oven, so that it may be warm in the morning. The preparation of sotf food is undoubtedly troublesome, and those who have but little time should feed entirely with Indian corn. A constant supply of fresh, clean water is essential, and a moderate quantity of green food, such as cauliflower, cabbage, lettuce, broccoli leaves, and turnip tops should be thrown into the yard daily, otherwise it will be difficult to keep the occupants in a thoroughly healthy condition.—*Farmer, Field, and Fireside.*

THE BOUGAINVILLEA.

[This splendid flower ought to be more common in Ceylon than is now the case. A couple of plants brought by us from Howrah (received through Dr. King's kindness) in April 1876, have long been sights of glory at Abbotsford, at 4,800 feet elevation. A recent experiment has shewn that it will succeed in Colombo. It surely ought, for Batavia, with a similar climate, blazes with the beautiful bracts.—ED.]

This magnificent climber is now common in many parts of India, and as it can be obtained without any difficulty from any public gardens, no garden, however small, should be considered complete without it. In some of our large public gardens it has been so extensively planted that it completely overshadows everything else, and after a casual visit. one is apt to leave with the impression that it contained little besides the *Bougainvillea.* I strongly advise owners of small gardens to guard against this mistake. A few plants judiciously disposed, will produce a much better effect than when large numbers are employed.

There are several species and varieties, all natives of tropical South America. The most of them have been introduced into this country, but only two of them are as yet common. *Bougainvillea glabra*, a species with stiff straight spines, and bright shining leaves is the one most frequently met with, and as it is the only one that flowers all the year round, it may be considered to be the best. As is well known, the flowers of the *Bougainvillea* are small and inconspicuous, and their whole beauty lies in the coloured leafy bracts surrounding the flowers. Those of *B. glabra* are of a bright mauve, faintly tinted with pink, and are produced all the year round, but in greatest profusion during the cold season. An inferior and almost spineless variety of *B. glabra*, with pale pink bracts is sometimes met with. It is a handsome object when covered with its delicate looking bracts, but as it only produces them during the months of February and March, it is greatly inferior to the more common variety which flowers all the year round. *Bougainvillea spectabilis* is the other species frequently met with, and is easily distinguished from *B. glabra* by its formidable hooked spines and rough hairy shoots and leaves. Its bracts are somewhat larger than those of *B. glabra*, and are of a purplish mauve. They are only produced during the months of February and March, and although of a more pleasing colour than those of *B. glabra*, it is not to be compared with the latter for general usefulness. *Bougainvillea speciosa* is one of the uncommon species we possess. Its bracts are of even a deeper mauve than those of *B. spectabilis*, and when more abundant and better known, it will no doubt prove a favourite variety. It flowers during the greater part of the cold season, and may be placed next to *B. glabra* for general excellence. A species named *B. lateritia* has been lately introduced. Its leaves are slightly hairy, and the bracts of a bright brick red. It is a very distinct species and, as it flowers profusely from September until the following April, it is well worthy of a place in every garden.

The *Bougainvilleas* fortunately flourish in this country with little care and attention. They will grow in almost any soil, but attain greatest perfection in a light, rich and open loam. They appear to greatest advantage when planted beside a large open-branched tree, and allowed to ramble over it at will. When this situation can be given, it should always be used in preference to any other. It also looks very well trained up against a wall, or when grown on a bushy shrub in the centre of a grass plot or lawn. When planted beside a tree the pruning knife is seldom or ever required, but when planted in either of the two last-named situations, it may be used with advantage. Circumstances often require them to be kept within due bounds, and as the use of the pruning knife does not in the least interfere with their flowering propensities, no one need feel any scruple in removing surperfluous wood. The *Bougainvilleas* are propagated by layers made in the rains or by cuttings made from ripened wood in the cold season. Both methods answer very well for *B. glabra*, but for all the other species I have mentioned, layering is the only certain method of obtaining a stock of young plants. I have raised all the other species by cuttings, but never was able to get above fifteen per cent of them to strike root. As far as I am aware the *Bougainvillea* never ripens seed in this country. All the flowers I ever examined seemed to be perfect, and I cannot give any satisfactory reason for its nonproduction. —W. G.—*Indian Forester.*

THE PHYLLOXERA.*

In a French entomological periodical cited by the *Vigne Américaine* occurs a succinct statement by a very eminent authority, M. Lichtenstein, as to the Phylloxera in France, from which it may be of interest to extract some portions. It is generally known that the disease is occasioned by a small homopterous insect of American origin, observed first in 1868. The genus Phylloxera is one of the best known, and the seven species of which it consists have the most curious difference in their respective life histories. Adapting itself to altered circumstances of climate and food the Vine louse, Phylloxera vastatrix, which in America feeds on the native Vines, such as *V. Labrusca*, *V. æstivalis*, *V. riparia*, and other species, has here completely altered its habits of life. Instead of running its career in the space of a year, partly in the galls of the leaves, partly below ground on the roots, terminating the cycle in the form of an egg, in which state it remains during the winter, the Phylloxera in Europe remains attached to the roots for a long series of years, perhaps indefinitely, thus bringing about, if unchecked, the complete destruction of the Vines.

The very fact that the Vine louse is American, that it lives in America on the Vine, and yet that the Vine in that country is not destroyed, led observers to say—If there are Vines in America, it must be because the Phylloxera does not kill them as it does the European Vines. Nevertheless, in spite of this obvious fact, learned men proscribed the American Vines, and directed against our microscopic enemy all the batteries of chemistry. The entomologists for the most part merely shrugged their shoulders, at this senseless struggle of man against the insect. If the destruction of hurtful insects—even much larger and more easily attacked than the Vine louse—were possible, there would have been no such things for years past as flies, gnats, fleas, &c. All that can be done in the way of war against such enemies must be on a small scale and within limited areas. We may close our doors and windows, fumigate our houses, sprinkle insect powder over our clothes, and use other insecticides; when the enemy attacks our crops we may substitute one crop for another; when the Wheat is destroyed by midges, &c., we may substitute forage crops, which the Wheat insects will not attack and *vice versâ.* The trees of foreign origin in our gardens and promenades, as, for instance, the Plane, do not suffer in the same way as the Poplars, the Elms, or the Ash, which, being native trees, are attacked by native insects. This, however, is a statement that must be accepted with a considerable amount of reserve, for it is but too true that the introduction of new plants seems to whet the curiosity and stimulate the appetite of some of our garden pests. Slugs, of course, come to mind first and foremost, but M. Lichtenstein is specially speaking of insects. He mentions, however, the Ailantus and the Horse Chestnut, both foreigners, and which, according to his theory, should be free, comparatively at least, from insect visitations. We fear, however,

* The Phylloxera was first observed in this country by Professor Westwood in 1863, but was not described by him till 1869, when it was figured at p. 109 of our volume for that year, and again at p. 687. The leaf-galls were figured at p. 185, vol. viii, 1877. Incidental notices as to appearance and treatment have repeatedly been given in our columns and in those of our contemporaries.—ED. *G. C.*

that English leopard and English goat moths are not so complaisant to the foreigners as they ought to be, nor the chermes to the Spruce, nor the coccus to the coniferous trees. If we make the necessary allowances, however, M. Lichtenstein's statement may pass, and also his assertion that man successfully defends himself against insect attacks by his intelligence and forethought, never by direct action.

It is evident, he continues, that one can crush a fly or suffocate a few thousand Vine lice with bisulphide of carbon, but every one who knows what the reproductive powers of insects are, well know that the complete destruction of any insect whatever is as impracticable as the quadrature of the circle. The difficulty, then, must be evaded and the first method to be adopted in the case of the Vine is to plant Vines capable of resisting the Phylloxera. It is obvious that American Vines resisted the louse and the structure of the roots affords the explanation of their immunity. This much ascertained, the next point was to select the variety of Vine best adapted to particular soils and climate, there being great differences in these particulars in the vineyards of France. The fruit of the American varieties is far inferior as to flavour to that of the European kinds, but by grafting the best European kinds on American stocks, in the course of three years the cultivator may obtain a crop. In the first year an American cutting is planted, in the second this is used as a stock, in the third the scion bears fruit. Care must be exercised in selecting stocks suitable for particular districts, for the variety that is fitting in one place is not so in another.

Mr. Lichtenstein sums up by dissuading Vine growers from expending money on insecticides, and by counselling them, on the other hand, to cease from making war directly on the insect, but to pull up their French Vine stocks and plant American in their places. Twenty thousand hectares are thus annually reconstituted in the South of France, and the Vines are splendid.—*Gardeners' Chronicle.*

AGRICULTURE IN MOZAMBIQUE.

The only agricultural industries that can be said to have firmly and successfully established themselves in the province of Mozambique, appear to be those of the cultivation of the oil-producing plants, *Amendoim* and *Gergelim*. The production of these, says Consul O'Neill, together with the collection of indiarubber, calumba root, and orchilla weeds, forms five-sixths of the total exports of the province. This cultivation, and the labour requisite for the collection of the latter products mentioned, is conducted solely by the natives. Efforts have been made from time to time, by the Portuguese and other colonists, to introduce the cultivation of other produce for which both the climate and the soil are especially favourable, but none have been thoroughly successful. Of the greatest importance have been the endeavours in various parts of the coast to raise sugar, opium, tobacco, and coffee. As the cultivation of *amendoim* and *gergelim* is entirely in the hands of the natives, it follows, as a natural consequence, that every stage of the working is of a most rude and primitive kind. The thousands of acres that are utilized in the cultivation of these seeds are cleared in great part with an axe of native make, of tomahawk shape, and with an edge hardly two inches in length. In some parts particularly in the European settlements, a species of bill-hook is also used for clearing the undergrowth, but these two form the only tools of the Makua forest clearer. The vast area of country cleared is then turned over by both men and women with a rough and clumsy hoe, also of native make, the slow working of which entails an enormous and unnecessary consumption of labour. In the sowing of *amendoim*, holes are made in the ground some little distance apart, generally three or four feet, to allow space for the creeper to radiate. This is usually done with a sharp-pointed stick. One seed—care is taken that it is only one, as the natives declare that growth of two or three will stangle each other—is then dropped in each hole, and the earth stamped over by the feet. In the sowing of *gergelim*, the seed is broadcast as with grain, and scattered thickly over the ground. The sowers are then followed by others with hoes, who work the seed roughly into the ground, stamping the whole in with their feet. Care and therefore much labour is required to keep the ground clear of weeds that spring up in this climate and soil with astonishing rapidity, and throughout the growth of both these plants, the plantations are carefully tended. In the reaping or collection of *amendoim*, the plants are simply pulled up by hand, and the tubers taken off as with the common potato. They are then laid out to dry in the sun, and when thoroughly dried, are shelled by hand for the extraction of the seed, an operation requiring considerable time and patience. With *gergelim* the plant is in some districts literally reaped, but singly and by hand, with an ordinary knife. In others the plants are simply pulled up out of the ground; in the latter case they are then cut about a foot down the stem. The plants are now tied into small bundles, which are stuck in the ground in the sun till thoroughly dried, when the seed will drop readily off. Large mats are then spread on the ground, the bundles taken up and shaken vigorously over them till all the seed have thus been extracted. With both *amendoim* and *gergelim* the seeds are then packed in baskets of native manufacture, and carried on the heads of blacks, in some cases a distance of fifty or sixty miles, to the house of the coast trader, there to be bartered for cloth, beads, powder, &c., and to be stored till an opportunity occurs. The sugar cane is cultivated by the natives upon most parts of the coast where alluvial soil exists, but only in insignificant quantities, and to be used by them as a sweetmeat, or for the purpose of chewing. The only part of the province where its growth has been attempted upon any considerable scale is in the rich soil of the Zambesi delta, and by the Portuguese planters of that district; numerous plantations exist there, and cane grows luxuriously upon them. The only use, however, to which the cane has, up to the present time, been put, is that of the distillation of spirits. Consul Baring says, that beyond the Zambesi, there are many places in the province eminently adapted for the growth of the sugar cane, and which possess easily accessible and secure ports for discharge and shipment. Amongst these may be mentioned Mwambi Bay (Pomba), Mwendazi (Mwemba), the western shores of Nakaha and Nihegehe, on the branches of Fernao Veloso Bay, and the country to the south and in the vicinity of Mokambo Bay. Tobacco, though cultivated as an article of commerce for export, has not met with much success, as the passion for the weed has become deeply rooted in the natives of the coast and interior, so that it is cultivated by them in many parts of the province for their own consumption, and forms a regular article of sale and barter amongst themselves. The tobacco leaf is dried very carelessly by the natives, and is made up in a peculiar way, as follows:—It is first plaited, and when the plait has reached a length of three or four feet, it is wound up in the form of a spiral. Gradually drying in this shape, it preserves its form without any binding, and it is unwound and cut off in the short places when required for use or sale. This mode of preparation is invariable among the Makua and Yao, between the Roouma and Zambesi. Consul O'Neill says, that "were the natives instructed in some simple method of drying and pressing the leaf, the valuable product would be probably brought down by them in considerable quantities, affording, as it would do, a larger margin for profit than does the culture of oil seeds, and it might become a regular article of colonial manufacture and export." Among the many plants useful to commerce that grow wild on the coast land and interior of Mozambique, may be mentioned the castor-oil plant, the senna plant, a species of sarsaparilla, the capsicum, or common red pepper, used by the natives with their food, but as yet not gathered by them for sale, in spite of the efforts of some merchants to induce its collection; and the pine apple, the fibre of which has been lately proved to be a valuable substitute for flax.—*Journal of the Society of Arts.*

THE COFFEE-DRYING SYSTEM VAN MAANEN.

As the above system is just now a subject of controversy regarding its effect on the coffee-prices, we will enter upon a short description of it, though we are sensible that many of our readers are already acquainted with it.

We should have liked to illustrate the affair with a few cuts, but that there were several objections to this on the side of the inventor himself. So we shall have to confine ourselves to giving but a general idea of the arrangement, and showing the advantages it has already proved to possess in all respects, by its being generally adopted in Java. Every affair recommends itself on its own merits, and as this is undoubtedly the case here, we may conclude that how much may have been written against it, the arrangement has a great practical value, and offers many advantages over the ordinary manner of drying in the sun on plastered trays.

Most drying-houses, as they are at present, are of no use for drying coffee and other tropical productions, the temperature in them not being sufficiently equable. In dyeing-houses, tanneries, etc., this can be obviated by shifting the objects there, but with coffee this is downright impracticable, the volume not allowing of it.

To meet all requisites, a drying-house must answer to the following conditions:—

1°. Cheapness and simplicity of arrangement, so that it can be fitted up without difficulty by native work-people.

2°. Avoidance of all machinery whatever, which cannot undergo repairs in those mountainous districts, and would require technical supervision.

3°. The arrangement must be destined and calculated to dry any required quantity of coffee.

4°. The drying must be effected within a fixed term, or number of hours.

5°. A certain temperature must not be exceeded.

6°. The temperature must be all over at the same degree.

7°. The beans must be all of an equal dryness, and hardness, without injuring the colour or the aroma.

8°. The use of all kinds of wood and refuse must be practicable for drying purposes, and the least possible quantity of fuel in proportion to the volume to be dried.

9°. The escaping air, on leaving the apparatus must have absorbed the greatest possible quantity of water.

10°. The operation must not require any great number of work people or close supervision, and must be able to, be left to any body.

Mr. Van Maanen has succeeded in compassiog all this and in setting up an establishment, with which every one who has adopted it, is highly gratified. As to the establishment itself, it consists in a building, which is warmed by flues serving also as smoke conduits. The building is square, or oblong according as the local situation, or the quantity of coffee to be dried, may require, and the drying is effected by a supply of outer air, heated by contact with the flues, and which escapes after absorbing the moisture of the coffee. As the coffee-bean is pretty large, and there is consequently sufficient space between the beans as they lie, to allow of the heated air to escape directly from between them, without its having insufficiently done its work which is also the case if the air be supplied at too quick a rate, it is clear that the regulation of this—which cannot be fixed by theory, but only by long and expensive experiments—constitutes the great merit of this method, securing besides a great simplification of the preparing process, and moreover a great advantage to the agricultural interests. The costs of drying are, indeed, thus reduced by fully 5-6ths of the previous amount. There is no longer any risk of the coffee spoiling by constant rains or other causes, and there is the advantage besides that the product may be sold nearly six months earlier, which is no unimportant saving of interest on capital. The greatest objection originally raised against the method Van Maanen, to judge by the discussions in some papers, carried on by apparently incompetent judges, was the high temperature and the fear entertained that this would injure the quality of the coffee; but this has by no means been verified, nor is it at all possible, provided it be not carelessly treated; for it is always in one's power, by applying more or less fire, to regulate the heat of the air as one thinks proper.

Of course Mr. Van Maanen gives a temperature (70° Celcius) at which the coffee can be dried and ready for despatch exactly in 24 hours. This temperature is not too ,hgih as in it none of the particles of the coffee decompose or volatlize. The vegetable albumen solidifies in it, and prevents influencing by fermentation the quality of the beans. The time of 24 hours was rendered necessary by the nature of the operations in the establishment, and because many persons conditioned so. But what prevents effecting the drying at a lower temperature? It may, indeed, last a little longer, but this drawback might be met by building an establishment of somewhat larger capacity than is strictly necessary. Coffee in the pulp (cherry) dries perfectly in a temperature of 50 degrees Celsius, or 122 Fahr. within 55 hours. Coffee in the parchment, at 70° C. or 158° Fahr. in 24 hours; at 6° C. or 140° Fahr., in about 30 hours, and at 50° C. or 122° Fahr., in about 36 hours. Now as the ordinary temperature in India is about 130 à 140 Fahr. at the hottest time of day in the sun on plastered trays, it is clear that in a similar temperature, artificially produced, the coffee can never spoil, but that if such should be the case, it must be attributable to other causes, and more especially to carelessness of treatment, exceeding the stated temperature, and most of all to a prolonged drying-process, after the bean has already parted with all its moisture.

This process Van Maanen is also recommendable for cocoa and other productions.—*India Mercury.*

THE HOP AND ITS CULTURE.

BY JAMES PINK, F.R.H.S.

The successful culture of the hop in Victoria and Tasmania being an already accomplished fact, frequent inquiries are being made by agriculturists as to its suitability for cultivation in this colony. This is a matter on which little can be definitely stated, as beyond a few isolated plants here and there no systematic experiments with regard to its culture appear to have been attempted. I am of opinion that the hop might be cultivated here with every success in some localities and in suitable soils, providing a sufficient water supply be at hand for purposes of irrigation in dry seasons; and in these progressive days of diamond drills and hydraulic pumps this should prove no obstacle.

Very little is known of the early history of the hop plant. It is not mentioned in Scripture, and neither the Greeks nor the Romans appear to have been acquainted with the hop as we know it. It was introduced into England from Flanders about 1524, when it met with opposition from the ignorant and superstitious, just as nearly two centuries later the Scots opposed the introduction of the potato, on the grounds that it must be a sinful plant because it was not mentioned in the Bible.

The hop, like its congener hemp, is a good fibre plant, and in Sweden the manufacture of hop-yarn and linen has long been an established branch of industry.

The hop plant (*Humulus luputus*), belonging to the Cannabinaceæ, is diœcious, the male and female flowers being produced on separate plants; the hop of commerce being the flower of the female plant, consisting of a leafy, cone-like catkin.

The hop delights in a rich, deep, well-drained soil. I have seen it growing well on the London clays, and also in the stiff clay lands of the weald of Kent and Sussex, and better still in the deep sandy loams of East Kent and Surrey. It is a gross feeder, and, therefore, requires large quantities of manure. So far as soil is concerned, the hop should do well in the deep red soils of Toowoomba, and in the district of Redland Bay and Cleveland, where there is good deep soil with an open subsoil. From what I am told of the land on the Blackall Ranges, it should be well adapted to hop-growing; but not having visited the district, I cannot speak from personal observation.

The hop sets are planted in hills, three sets in each hill in the form of a triangle, the hills being in rows about six feet apart each way; but in this country it would probably be of advantage to plant the hills six feet apart in the row, leaving eight feet between the rows—thus requiring about 4,500 sets per acre. Sets are cuttings taken from the crowns of the old plants, and are either planted direct into the hills or placed in nursery beds, where they remain one season before planting out. Bedded cuttings are undoubtedly the most satisfactory, giving the earliest returns, often producing from three to four cwt. of hops the first year; whereas when fresh cuttings or sets are used, no produce can be expected the first season. The plants are about three years in arriving at full-bearing maturity.

The land should be well prepared by manuring and deep ploughing, and the hills well broken up with a spade before planting; the sets being put in by means of a dibble. The hop plant is very sensitive, and no weeds must be allowed to grow about it. During the growing season the horse-hoe should be kept frequently at work between the hills.

Where cuttings are planted no sticks are required the first year, the vines being allowed to spread over the ground, but of course the plant should be encouraged to make foliage. Where bedded sets are used it will be necessary to provide sticks above six feet high for the vines to climb. If the plants have done fairly well, the second year they would require poles. The old style of poling hops was that of putting three or four poles to each hill according to the strength of the plants; but during the past ten years this system has been superseded on most well-managed plantations by others considered to be more conducive to productiveness and the general well-being of the crop. Some of these improved systems are protected by patents. One of the best of the various improvements I believe to be that of putting two stout permanent poles to each hill, about 16 feet high. About four feet from the ground, a small piece of hooping is nailed on the pole, into which is inserted the point of another shorter pole, the tip of which rests between two spikes on the summit of the corresponding permanent pole in the next row, thus giving an angle of about 40° or 45°. This is a great convenience in every way; besides the saving of labor in poling, at picking time instead of the heavy poles having to be pulled out of the ground, the standing poles have merely to be lifted out of the hooping. Strong soft string, or even galvanised wire, is sometimes substituted for the slanting poles, which is of course much cheaper, and appears to answer equally well. Another method is to fix stout poles in rows across the ground at intervals, like telegraph poles, and about 18 feet high. A row of poles is placed between every fourth and fifth row of hills, and on the top of the poles a six-strand twisted galvanised wire is twisted. In this case a strong permanent stump is driven in the ground at each hill, into which a staple is fixed. Four slighter wires are then stretched from the staple in the stump to the upper wire, two wires going to the high wire on the right, and two in the opposite direction; thus every row of poles with the upper wire serves four rows of hills. The slight wires are attached to the wire at the top by means of strong iron hooks. These hooks and the wires are previously prepared by the workmen in wet weather, when they cannot be employed in out-door labor. This is no doubt the most perfect system now in use, for various reasons, which space forbids me to refer to separately here; and though the method may appear rather complicated on paper, it is in reality easily worked, and I shall be happy to personally explain it more fully to anyone wishing to make the experiment. One of the largest hop-growers in East Kent—on whose plantations experiments were systematically carried out with all known methods—once told me that on his ground 2 cwt. more hops per acre were gathered under this system than from any other portion of the plantation.

The winter dressing and cutting back of the hop plant is of as much consequence to the hop as pruning is to the grape. For this operation the hills should be opened by removing the soil with a steel fork, so as to leave the surface roots and crowns of the plants quite bare. The operator then takes the exposed roots and cuts them back hard to the plant. Roots growing downwards should not be cut, but all roots spreading outwards around the plant may be cut away, and fresh fibrous rootlets will then be formed. The crown of the plant should then be cut back to one eye, just as the grape vine is cut under the short-spear system. After pruning, the top hill is covered over with two or three inches of soil and allowed to remain until the young shoots commence to grow. As soon as the shoots begin to rise and bend, the shoots will require directing to the poles or wires, as the case may be. Two or three vines are sufficient for each pole or wire, and the vines should then be tied lightly to the support by means of bast rushes, or any soft substance. Here, the material of old sugar mats, split into narrow strips, would answer the purpose admirably. When the poles or wires are furnished with the two or three good growing vines, all that remain should be cut away, thus concentrating the whole power of the plant in the vines that are to bear the future crop. I apprehend that the growth of the vines in this colony would be very rapid, thus requiring constant attention in directing and tying until they are beyond reach, when they will be strong enough to take care of themselves. In England the hop-tying is usually undertaken by the wives of the farm workmen. It is done by contract at the rate of about 15s. per acre. It is usual for the farmers in the hop-growing districts, when engaging workmen, to stipulate that the wife undertake to tie hops.

In England the hop crop is a very precarious one, as it has many enemies and risks to encounter during its growth, the greatest of all being a wet, cold summer. In hot, dry summers the crop is usually abundant. Should a few cold nights occur about July the plants become stinted in growth, and this is usually followed by an attack of what is known as "hop-lice," a variety of green aphis. Perhaps the greatest and most dreaded of all enemies to the hop crop is the "mould" or "mildew," which, having once attacked the plant, spreads very rapidly throughout the whole plantation. The usual remedy for this is flour of sulphur, which is generally applied at night while the dew is on the bines, by means of a machine provided with fans, something in the way of a winnowing machine. The sulphur is placed in a receptacle provided, and as the machine is drawn by a horse between the rows, the sulphur is driven out by the fans with great force, filling the whole air with the fine powder, which gradually settles on the foliage attracted by the moisture. This checks the mildew to a great extent, but does not exterminate it. Like all other plants, certain varieties of the hop are more subject to blight than others. Amongst the best varieties are Early Goldings, Early Prolifics, Kent Colegates, Canterbury Goldings, Jones', and the Cox's Grape hop, so called from its growing in bunches like grapes. The male or "brick-hop," as it is generally called, is very seldom grown, as its produce is of no value; nevertheless some planters have a small proportion of male plants distributed through their plantations, say, one plant in every twentieth hill. These plants have no influence whatever on the hop crop, and are only grown by farmers of the old school; and they follow the plan from no other principle than "'twas my father's custom, and so it shall be mine." Of course, if seed of the hop is required, the male plant is indispensable.

The hops are produced on the lateral branches of the vine, and are usually fit for gathering about a month after making their appearance. At that time the hops commence to change color and look a little brown, smell fragrant, and become bitter to the taste. They are then considered ripe and fit for gathering. The hops are gathered by women and children, the occupation being considered very healthy, and is undertaken by all classes; thus acknowledging that "there is dignity in honest labor." When gathered the hops are put into large bags, and conveyed to the oast for drying, pressing, and preparing for market. The average contract price in England for building an oast is about £100; but the preparation of the hops for market is a subject which, if of sufficient interest, must be dealt with in a separate paper.—*Planter and Farmer.*

THE CINCHONAS AT THE AMSTERDAM EXHIBITION.

BY F. HARWOOD LESCHER, F. C. S.

Among the marvellous products of nature and art from the Dutch East Indian Colonies, now being shown at Amsterdam, nothing is more interesting than the cinchona barks from Java, exhibited by the Government from the Royal plantations. This island is so richly endowed by nature that we must always reproach the Congress of Vienna with taking from us our conquest of 1811 by Lord Minto and Mr. (afterwards Sir Stamford) Raffles. After enjoying the monopoly of the spice trade of Java for 250 years, the Dutch, as a practical people, are now developing the cinchona plantations; and this is now becoming such an important question that I made some inquiries in Holland on its commercial aspects.

The Cinchonas are so arranged as to form a handsome exhibit. In the centre are large flat specimens of the barks, and at either side logs of wood with the barks still attached. These logs, 4 feet long, of various diameters, and worth careful notice, are specimens of the following:—

Cinchona Calisaya var. Ledgeriana, or *C. Ledgeriana*, as it is here called, making it a distinct species. Diameter about 5 inches. The bark, grey in colour, has a pale, sulphurous efflorescence, and but few transverse lines.

C. Officinalis.—This log is twisted, as if it had grown up with some large creeper; about 6 inches in diameter, rough and rugose, with many and rather deep transverse splits in the bark.

C. Pahudiana.—The bark of this species presents a curious appearance of irregular stains of various shades. Its cultivation is now neglected, from its poverty in alkaloids; discovered by Hasskarl, it was largely cultivated at first in Java, but fortunately not so in India.

C. Micrantha.—About 4 inches in diameter; the bark has circular whitish patches and a quantity of pale-coloured lichens.

C. Lancifolia.—This bark is pale grey, with no lichens, but reddish stains scattered over the whole surface.

C. Caloptera.—Much resembling *C. micrantha*, but with a distinct reddish tint in places.

C. Calisaya Javanica.—A large log, about 9 inches in diameter. This bark has a yellowish tint, approaching to reddish brown, with no lichens, but rough in appearance; a tree of this size would give a flat bark.

C. Hasskarliana.—Much resembles the discarded Pahudiana, but with decided transverse marks; its name, disputed by Dr. De Vrij in 1874, is now well recognised.

C. Josephiana (or *C. Calisaya Josephiana*).—The wood is nearly a foot thick, and the bark has very deep clefts.

C. Succirubra.—This has a rusty colour; half the bark has been removed, and when the log was cut down was renewing itself. It has reddish stains, like some skin disease, and many transverse lines, which, meeting the longitudinal ones, cut up the bark into little dice-like squares.

No specimen of *C. calisaya Anglica*, called by Howard *C. Anglica*—a hybrid between *C. calisaya* and *C. succirubra*; and specimens of renewed barks, with their alkaloidal yield at various times, would have been valuable.

Cultivation.—This is now yearly rapidly increasing in Java. The valuable *C. Ledgeriana* cannot be grown at high elevations, as the more hardy Succirubra, robust and of quicker growth. The Pahudiana and Caloptera are neglected, and have but little commercial value in Holland. The practice, introduced by Heer J. C. Bernelot Moens, of shaving off the rich outer bark, as near as possible to the cambium layer without injuring it, is much followed, as these shavings are easily dried and packed. Another method consists in taking the bark from a part of the matured tree and mossing over the stripped place until the bark is renewed. Coppice shoots and tops are also cut down and the bark dried.

Commerce.—The examination of these barks from a scientific point is very useful, but from a commercial point of view their investigation is even more interesting, for I believe that commerce in its many-sided aspects is a field for the exercise of the highest faculties of the mind. The results of my inquiries as to what cinchonas are actually sent from Java to be sold in Holland are as follows:—This list is that of a part of the crop of 1882, now lying for sale in the city of Amsterdam, with the quantities for sale about the same time last year.

	1883. Bales.	1882. Bales.
Cinchona Succirubra	762 ...	299
„ Calisaya Schuhkraft ...	417 ...	352
„ „ Javanica	56 ...	173
„ „ Anglica	13 ...	—
„ Hasskarliana	20 ...	88
„ Officinalis	43 ...	47
„ Lancifolia	42 ...	14
„ Ledgeriana	516 ...	190
Totals	1,860	1,163

The plantations of Malabar, Kendeng, and Tangkoeban Praoe all produce the first three, also Officinalis and Ledgeriana; Calisaya Anglica comes from T. Praoe, Hasskarliana from Malabar and T. Praoe, Lancifolia from Kendeng and Malabar. Of the 1881 crop sold in 1882 no Calisaya Anglica came over, and then Hasskarliana came from the three plantations, and Lancifolia from T. Praoe only.

The bales of barks are marked respectively M. K. and (coming from T. Praoe) PL and PN.

Analysis.—The following table gives the richness of these barks and their alkaloidal yield, and shows us that this is the true standpoint for selection of barks, not alone for quinine manufacturers, but also for pharmacists everywhere:—

Bark.	ANALYSIS.				
	Quinine.	Cinchonidine.	Quinidine.	Cinchonine and Amorphous Alkaloid.	Total.
C. Succirubra (a)—					
Shavings- - - -	1·3	5·0	—	2·9	9·2

History.—Weddell, in 1848, brought *Cinchona calisaya* seeds from South America, which germinated at the Jardin des Plantes, Paris, and in 1852 live seedlings were sent through the Dutch Government to Java. Daniel Hanbury says that the first important attempts at cinchona cultivation were made by the Dutch.*

J. C. Hasskarl was sent to Peru in 1852 from Holland, and brought over seeds of *C. calisaya* in 1854.

a Succirubra contains generally a little quinine, much cinchonidine, no quinidine; about 2·0 to 3·0 cinchonine, and 0·6 to 1·0 amorphous alkaloid.

b These *Calisayas* contain all the alkaloids, none up to 2·0 of quinine; 1·0 to 2·0 of cinchonine, and 0·2 to 0·6 each of amorphous alkaloid and quinidine.

c Officinalis.—The renewed bark is rich in quinine, though not so rich as last year, when it contained 4·8; no root bark came last year; it contains about 0·5 cinchonine, and very little quinidine except in root bark.

d Lancifolia contains no quinidine, about 1·5 to 2·5 cinchonine, and 0·5 amorphous alkaloid.

e Ledgeriana that last year did not contain above 8·0 quinine, contains up to 9·3 (and total alkaloids 10·3) this year. It is a wonderful bark, especially containing very little or no cinchonidine, quinidine, or cinchonine; the richest in quinine has the smallest quantities of them, and also of the amorphous alkaloid.

* "Pharmacographia," Hanbury and Flückiger, 1874, page 311.

Dr. J. E. de Vrij, formerly in chemical charge of the Java plantations, was a great power there for good, and Heer J. C. Bernelot Moens, as "Directeur der Gouvernements Kina-Onderneming op Java," has proved himself a successor of genius.

In 1862 plants were sent to Java by Mr. William Graham McIvor, Superintendent of Cinchonas at Nilgiri, of *C. succirubra*, *micrantha*, and *officinalis*, and in 1865-66 seeds were obtained of an excellent variety of *C. calisaya* in Bolivia by Charles Ledger, and these have produced trees yielding an extraordinarily rich bark.*

One of the most interesting triumphs of modern science, as practically adapted to commerce, is in the "shaving" process of Moens, and the removing in alternate ribbons of the bark, as adopted by McIvor; for bark invariably renews when the cambium layer is uninjured, and in twenty-two months, or less, a renewed bark appears, thicker and, which is a very important point, much richer than the natural bark of the same age.†

Thus not only do most species improve under cultivation, but when art steps in, a bark is produced far richer than is found when nature is left to herself.

To show the demand for these barks on the Continent for pharmacists, I extract the following descriptions from tho list of one of the important Paris wholesale druggists:—

Quinquinas.

Succirubra, quill,	containing	4·0	total alkaloids	(1·5 quin. sulph)
„ broken,	„	6·0	„	(1·6 „)
Java Malabar,	„	7·8	„	(2·7 „)
„ long bold quill		—		(2·0 „)
„ *Calisaya Schuhkraft*	„	3·9	„	(1·3 „)

Ledgeriana, according to analysis of quinine.

Practical Conclusions.—It will be interesting to consider what practical lesson we can derive from the examination of these barks as regards those that we ought to employ, and especially in respect to the yellow bark that we at present make use of.

Now the authorities are clear on this point.

The British Pharmacopœia of 1867 (edition 1880, page 82) states that 100 grains of yellow cinchona bark should contain of pure quinia not less than 2 grains.

The French Codex of 1866 (page 80) says that 1,000 parts of this quinquina calisaya should furnish 35 to 40 parts of sulphate of quinine.

The United States Pharmacopœia, 6th decennial revision, 1882, page 79, under *Cinchona flava* (calisaya bark), gives as its definition:—"The bark of the trunk of *Cinchona calisaya*, containing at least 2 per cent of quinine." The latter is not the sulphate, but the pure alkaloid quinia.

The British Pharmacopœia standard, in my opinion, is not too low an alkaloidal strength. Does now the usual flat yellow calisaya bark of commerce and of daily use in England come up to this standard?

On this point all our authorities are at one. That calisaya bark has deteriorated of late is the opinion of those of the wholesale trade who have examined these barks.‡ The opinion of an authority on this matter, Dr. B. H. Paul, is conclusive: "The officinal yellow bark and the flat calisaya bark were almost invariably worthless as far as the presence of quinine was an element of value. The flat calisaya bark of commerce now really contained nothing more than a little cinchonine, 1½ to 2 per cent, and was not at all equal to the character given in the Pharmacopœia, and it required to be replaced."§ Mr. D. Howard says: "Yellow bark is flat and yellow, but resembles in little else the calisaya bark of a few years back, and must lead to disappointment if substituted in medicine for true calisaya."‖

Indeed, it is probable that tho flat bark we now receive is not *Calisaya* at all. I am informed that it may probably be from *other* species, brought down from the grey bark district to Para by the rivers flowing thence, the navigation having been somewhat recently opened. Another possible source of this bark may be *C. Australis*, from South Bolivia.

But with what shall we replace this bark? for, if our British Pharmacopœia is to be of any value as an authority (and as a whole we are justly proud of it), it ought not to be ignored on such an important article of our materia medica.

Mr. E. M. Holmes advocates cultivated in preference to South American barks, especially on the ground of the larger average yield of alkaloids.*

Professor F. A. Flückiger strongly recommends *C. succirubra* as being most suitable to adopt as official for pharmaceutical purposes.† It is a hardy plant, growing quickly (a tree in Java of this species attaining the height of 63 feet in fourteen years), and is fairly rich in alkaloids. It grows readily in many climates: *Cinchona succirubra* does well in the brush shades of the Melbourne Botanic Gardens, standing there even under 32°. In these gardens, years ago, cinchonas were already raised by the thousand.‡

Dr. Paul says that, judging from the amount of quinine, a very good type of this cinchona is being now cultivated in Jamaica.§

But no real arguments have yet met the strong objections to *C. succirubra* of Mr. John Eliot Howard, our greatest authority on this subject. His opinion is shortly expressed in the following words:—"In this species the bark deteriorated beyond a certain age.‖

Mr. Howard has proved that there is a distinct noxious ingredient in this East Indian red bark. He has explained the pernicious effects of the rapid oxidation of the cinchotannic acid, fine samples containing 2 per cent of alkaloids, mainly cinchonine and cinchonidine: the truest red bark in India will come to this by age. "The propagation of so many millions of trees of what is called *C. succirubra* in India is against all cautions and in neglect of all the information I have been able to reproduce from the careful Spanish botanists."¶ And again, in his description of red bark, Mr. Howard says, "Quinine, which formed a considerable portion of the whole, is now greatly diminished. . . . . The chief part of this troublesome and noxious residuum I now suppose to be paricine."**

Then, again, *C. succirubra* is very prone to form *hybrids*; now Mr. Howard says, "On the other hand, it is an undeniable fact that the best results have been obtained from plants of which the genealogy is known and the succession kept perfectly pure. . . . . For another striking illustration of the above statement I should refer to the *C. calisaya var. Ledgeriana* in Java. Of course the genealogy of this tree is perfectly known, and has been described in my 'Quinology.' There is not the smallest reason for supposing it a hybrid, and the exceedingly rich production of pure quinine, alike in the three forms I have given, stamp it as a peculiar species."††

But if we turn to the true *C. calisaya*, of which several varieties, now classed as separate species, are cultivated in Java and Ceylon, we find exactly what we require. We can get nothing finer than the barks that come from the seeds collected by Charles Ledger's faithful servant Manuel, in Bolivia, from particularly fine old trees, some supposed to be 500 years old.

My conclusions are, therefore, as follows:—

1. We ought to abandon the present flat yellow barks that appear in our markets.

2. The evidence is against the East Indian red barks. [Certainly not when renewed.—ED.]

3. Besides the use of some of the good analysed South American quill yellow barks (the examination of which does not arise in this paper), we find what we require in a mixture of calisaya barks from the East, viz., the unrivalled *Ledgeriana*, mixed with other true calisayas, so as to give a bark that is not below the strength given in our British Pharmacopœia.

And, as a last word, I cannot do better than give what Mr. J. G. Howard says on this very point:—

"On the whole, I think it is evident that the true *Calisaya*

will assert its supremacy as the prince, or, as I should call it, the queen, of all cinchonas. Such, indeed, is the import of its name, as 'the best of all barks' for the production of quinine."*

FALSIFICATION OF SULPHATE OF QUININE IN PARIS.

The trial of Henri Constant Lacombe, who was accused of having adulterated a quantity of sulphate of quinine, and of having sold such adulterated quinine to the "Assistance Publique," came on for hearing in the 8th Chamber of the Tribunal Correctionnel de Paris, on June 21, M. Bagneris, president.

The accused, who was described as a druggist, of the Rue des Francs Bourgeois, Paris, forty years of age, was charged under the article 1, section 182, of the law of March 27, 1851, and 423 of the Code penal.

It appeared, according to the statement of the Procureur de la République, that the contract for the supply of sulphate of quinine to the Pharmacie Centrale des Hôpitaux had been awarded for 1882 to a M. Pressac, and this was the person first of all proceeded against. Pressac, however, declared that he had been only the intermediary and *prete-nom* for Lacombe, and the latter accepted the whole responsibility and exonerated Pressac from all complicity in the affair.

The contract was for 50 kilogrammes of sulphate of quinine, to be delivered in monthly parcels. In December last the attention of the director of the Pharmacie Centrale des Hôpitaux was specially directed to the supplies received in October and November, and a more minute examination of the supply was entered upon than had previously been made.

It was found that the supplies previous to October were satisfactory, but that the box received at the end of October contained a fraudulent mixture of sulphate of quinine and cinchonidine; that one of the boxes received in November, which had been opened, but had not then been used from, presented on the surface a layer of sulphate of quinine 12 to 15 centimetres thick, the remainder consisting of a fraudulent mixture; that the last box received at the end of November, which was still intact and sealed with the band of the contractor, was similary filled—namely, with a top layer of pure sulphate of quinine and about four-fifths of a fraudulent mixture.

Lacombe had stated, in explanation, that he had the agency for the Milan quinine factory, and he declared that until the mouth of October he had supplied no quinine but theirs. In October, he said, he wished to send in some quinine of the manufacture of Taillandier, but, as he had that in boxes of different shape and capacity from those of the Milan factory, he had given orders to mix together the two boxes of the Taillandier quinine with two boxes of the Milan quinine, and to fill with the mixture four boxes exactly similar to those previously furnished. He had noticed, too, that the Taillandier quinine was of a finer appearance than the Italian product, and therefore he had given instructions that a certain quantity of the former should be kept back from the mixture and put on the surface of each boxful.

His assistant, who was charged with carrying out these instructions, had in error taken two boxes of the Milan factory, labelled "solfato di conchinina," and had used these instead of "solfato di quinina." So Lacombe accounted for the falsification, maintaining that he had never had a thought of committing a fraud.

But the Procureur declared that his explanation was not admissible. In the first place, the supplies had not been made in those boxes to ensure uniformity. The boxes sent in before October weighed 7 to 8 kilos. The four sent in during October and November weighed only 5 kilos. each. Secondly, the principal substitution was not cinchonine, as he had stated, but cinchonidine, a fact verified by the analysis of the director, and confirmed by the independent analysis of MM. Riche and Jungfleisch. The Assistance Publique had returned the falsified quinine to Lacombe, and had demanded to be supplied with Pelletier's quinine in substitution; and when afterwards samples of the mixed products were demanded at Lacombe's warehouse, the accused had given them such as was required for the purposes of his defence, and in no wise conformable to the supply which had been recognised to be adulterated.

The Assistance Publique had produced a bottle of sulphate of quinine, which had been sent to the Hôpital Bichart, in which the experts had found 43 per cent of sulphate of cinchonidine. That hospital had only been opened on December 1, and it was shown that the supply of the quinine must have been made out of one of Lacombe's later deliveries.

It was shown that in August last the price of the Milan quinine was 400f. per kilo., with a prospect of advancing. Lacombe's contract price to the Assistance Publique was 374f. per kilo., and it was suggested that the accused had recourse to this fraud in order to save himself from loss.

His books showed that he had bought 10 kilos of Taillandier's quinine on September 20, 1882, at 365f. per kilo, and it was also shown that he had bought 8 kilos of cinchonidine in June and July from a M. Schiffmann.

In answer to questions put to him by the Court, the accused said:—

I am not guilty. I took the contract to supply the sulphate of quinine at 374f. per kilo., but it was wholly the result of an error on the part of my assistant that the cinchonidine of the Lombard house was substituted for their quinine.

M. Falconaigne, on the part of the Milan house, showed that the Fabrica Lombarda could not be in any way responsible for the affair; that it had even suffered by the publicity which had been given to the facts; and he demanded that the accused should be required, in addition to his punishment, to pay for a certain number of insertions of the judgment, especially in the medical and pharmaceutical journals.

After a speech from M. Boyer for the defence, the Tribunal gave judgment, in which it was stated:—"That the falsification having been committed in regard to an article which the accused knew was to be used for the diseases of patients entrusted to public charity, no extenuation could be admitted. Lacombe is therefore condemned to imprisonment for one year and to 50f. penalty. And the Court orders that this judgment shall be affixed to the number of twelve copies, one of which shall be attached during twenty-four hours to the door of Lacombe's warehouse, and that it shall be inserted in full, at Lacombe's expense, in the following journals:—*La République Française, le Temps, le Figaro, le XIXe Siècle, le Rappel, le Petit Journal, l'Union Pharmaceutique, le Répertoire de Journal, de Pharmacie et de Chimie, le Gazette Hebdomadaire, le Gazette des Hôpitaux*, and *le Progrès Médical*."

Lacombe to pay the costs of the action.—*Chemist and Druggist.*

THE INDIARUBBER TREE is doing well in the Northern Territory. It is likely that the product will soon become an article of export.—*Planter and Farmer.*

LAST YEAR the firm of Messrs. Merriton, Tait, and Watson, of Glasgow, manufactured no less than 9,100 tons of sugar machinery for Australia.—*Sugar Planter.*

SANITARY REASONS FOR THE USE OF SUGAR.—Dutrome calls sugar "the most alimentary substance in nature." Dr. Rush says sugar affords the greatest quantity of nourishment, in a given quantity of matter of any substance in nature. Sir John Pringle tell us that the plague has never been known to visit any country where sugar composes a material part of the diet of the inhabitants. Dr. Cullen is of opinion that the frequency of malignant fevers of all kinds has been lessened by the use of sugar. The celebrated Trouchina recommended *eau sucrée* (sweetened water) for almost every malady. Dr. Frothergill was very anxious that the price of sugar should be so far reduced as to make it accessible for the common people. Dr. Franklin had taken large quantities of blackberry jam for relief from pain of the stone, but discovered at length that the sanitary property resided wholly in the sugar. Sugar has been found to be an antidote to the poison of verdigris, if taken speedily and in abundance. It has been said that sugar injures the teeth, but this opinion does not deserve a serious reflection. The plentiful use of sugar is one of the best preventatives of the disease produced by worms. Nature seems to have implanted a love for this aliment in children as if it were on purpose to defend them from those diseases.—*San Francisco Merchant.*

* "Yr.-bk. Pharm." 1880, page 500.

COST OF TEA MANUFACTURE: HAND AND MACHINE MADE.

The writer who signs "An Old Coffee Stump" (page 353) notices the silence of planters in regard to Mr. Northmore's calculations for planting tea amongst coffee, and he attaches a certain significance to the fact. But our experience is that occasionally accident or caprice seems to settle the amount of discussion which may occur with regard to even more important matters. For instance, a gentleman whose authority is high in matters affecting tea told us a few days ago that Mr. Armstrong, first, and Mr. Owen following him, had represented the saving in the preparation of tea by machinery as compared with hand manufacture by a sum which really represents the total average cost of the manual process! He had also spoken to numerous tea planters, not possessed of machinery, who all agreed that the average cost of the preparation of tea by them was about 5 or 6 cents per lb., but none cared to question the sanguine estimates of the tea lecturers showing that about an equivalent amount could be saved by the use of machinery! This is about the most extraordinary case of reticence and the least justifiable we ever heard of. The question demands discussion and settlement How is the comparison instituted? Is the capital cost of water-wheels, rollers, driers and sifters counted from the first? If so, of course, the large saving of cooly labour in rolling, drying and sifting will only tell after a time, when the machinery has by speedier, more certain, better and *more* work "paid itself." That machinery secures better and more equal work and saves much cooly labour, night work, danger of burning tea and even stores, is certain. How, therefore, are Messrs Armstrong and Owen shown to have erred, in calculating, as the saving by machinery, a sum equal to the full cost of manufacturing "by hand"? We "pause for a reply."

TEA MACHINERY AND TEA MANUFACTURE: THE PLUCKING OF BANGHY BUDS.

We should think that tea planters will have a unique opportunity at the Calcutta Exhibition of comparing most of the machinery in use, or offered by inventors and engineers for use, in the preparation of tea. Arrangements can probably be made to obtain supplies of tea leaves, kept fresh by means of ice for the trials of the various machines. Meantime we are somewhat puzzled by a paragraph from the *Scotsman* referring to machinery constructed by Messrs. Greig & Co., Edinburgh. They have invented a machine which, if it proves successful, will enable planters to dispense with the large amount of horizontal shelf space at present required for the process of "withering" the green leaves as plucked and brought from the field. We believe we are right in saying that on the proper completion of this proces depends the final quality of the tea, no matter how carefully the subsequent processes of rolling, "fermenting," firing, sifting and packing may be carried out. Messrs. Greig & Co. have invented a machine of combined drum, fans, stove, pipes, iron chambers and hot air by means of which "the withering and drying process is carried on equally without firing the tea." The tea leaves, thus withered and dried, are then placed in a cutting machine, "which cuts the leaves into small square pieces of suitable length to roll up for the market, and very much diminishes the waste from broken tea and dust." What do experts and brokers say to this process, by which, practically, the whole of the leaf and most of the tips would be converted into *cut* tea? Looking at the persistently higher prices realized by "broken pekoe" over pekoe which is not broken, are there not arguments in favour of Messrs. Greig & Co.'s cutting process, especially if it causes a saving in dust, now so troublesome a factor in tea preparation? The withered, dried and cut tea leaves are then placed in bags to be rolled, but we see nothing about fermenting and firing? Perhaps, the tea, after being rolled and fermented, is put back into the withering and drying machine to be finally fired? The paragraph, however, passes on from the roller to the sifter, for which too much is claimed, By means of trays with different sized meshes, sifting machines can divide tea into any number of sizes, but the final sorting requires human intelligence. For instance the top sieve in Messrs. Greig & Co.'s machine cannot possibly discriminate red leaf from black. What it does is to arrest all leaves beyond the size of its meshes, and so with the succeeding trays. Stalks and red leaf may have to be picked out by hand, even from amongst the pekoe, although, no doubt, in diminishing quantity as the size diminishes. The use of asbestos, plumbago, or mica packing, so as to dispense with oil, is, no doubt, a great improvement in the case of a substance so delicately sensitive and absorbent as tea. Personally we have never seen tea rolled in bags, and in writing to Mr. Owen about Messrs. Greig & Co's roller we expressed our fears lest the bags, saturated with the expressed tea juice, should become filthy and sour. Mr. Owen responded thus:—

"I used to think bags a drawback, but don't now, after seeing Haworth's bag machine. If washed daily, the bags seem quite clean and free from unpleasant smell. There is no spilling and no mess from a bag roller, so that in some ways it is cleaner."

The paragraph about Messrs. Greig & Co.'s machinery, with interesting notices of the tea machines from the *Indigo Planters' Gazette*, will be found on page 374 In reply to the statement, which we noticed, that the saving represented by Messrs. Armstrong and Owen as arising from the use of machinery was exaggerated, Mr. Owen offers the following explanation:—

"The mistake your informant (*Observer*, 11th inst.) has fallen into is I think quite plain. Hand manufacture is 10·5 per lb. (rolling &c. 6·5, sorting &c. 4); machine is 4·16 (rolling &c. ·66, sorting aod *refiring*, where the saving is per *drier*, 3·50). '5 or 6 cents per hand manufacture' as quoted must *exclude* sifting, refiring and packing, evidently, and hence has arisen his error. The saving in *all works by machinery* being equivalent, *not* to the *total* of manual manufacture, but the total *excluding* the important works sorting, refiring, packing, cost of chests, lead, &c., &c. The 'gentleman of high authority' ought to have been more careful in his statements; as he puts it, the cost of all hand manufacturing, 5 or 6 cents, his informants *must* have dispatched their tea unsifted in gunny bags! Mr. Armstrong's figures are for a water-wheel and full machinery erected as *capital expenditure*. That provided, the saving in hand-work is $6\frac{1}{2}$ cents per lb. roughly or a total cost of 10.5 (*not* 5 or 6 cents) against 4 16"

As to the question put to us by a correspondent in another column about plucking tea buds hardened by wind, our practical, personal experience does not enable us to speak, but we have read much on the subject, the result of which seems to be that if a bud hardens it had better be plucked and thrown away. Plucking is an operation, on the proper and cautious or reckless performance of which the quality of tea and the success of tea plantations largely depend. But here no machinery can supersede the action of the human hand as guided by the brain, and unfortunately the process has to be entrusted largely to persons not distinguished for excess of intelligence or conscientiousness. With a system of payment by results ("nerricks" or tasks), therefore, the great and constant danger is that plucking will be indiscriminate and severe. The question of dealing with buds is one to be settled by the European manager, aided by a good conductor, a careful kangani, and picked men from amongst the pluckers. All experienced and candid planters must agree with Col. Money that alike in plucking as in pruning perfection is unattainable. An approach to it can be secured only by the most unremitting personal oversight and teaching of the labourers by the superintendent and his assistants, European and native. The great object should be to take off the closed leaf or bud from the top of a first shoot before it has had time to harden; if it *has* hardened, the decision seems to be, remove it and cast it away. The only dissident is "An Old Planter," in a recent *Tea Gazette*, who says:—"If it be bhanji flush, *i.e.* only two leaves developed, pluck only ¾ of the softest leaf." But, curiously enough, neither in Col. Money's Essay nor in the *Tea Cyclopædia* can we find a word regarding wind as the cause of bhanji buds or leaves. The word wind does not occur in the index of either! There is, therefore full scope for the discussion of local observation on this head. To show, however, how experts may differ! We have quoted with approval Colonel Money's statement as to the difficulty of securing careful plucking. A writer in the *Tea Cyclopædia*, after showing the evil effects of *twi ting* instead of *nipping* off the flush, continues,—"To make coolies pluck well is one of the planter's easiest tasks. All he has to do is to go round and personally shew each sirdar [kangani] and each cooly how to pick; and if he finds his orders not carried out, to fine the sirdar his day's wages, and the cooly his or her wages, and any extra pice due to them for plucking over and above the maximum number of pounds fixed for a day's work. Extra pice should never be given till after the first flush has been plucked." Fining and stopping pay are, no doubt, useful disciplinary processes, but that by resort to them it becomes an easy task to secure good plucking, we take leave to doubt. The European superintendent must, as frequently as possible, pay surprise visits to the plucking gangs to see that they are not stripping off everything, instead of plucking with discrimination.

THE DECLINE OF COFFEE.

In the Wynaad District, we may infer, gold has had a hand in extinguishing coffee, for on those estates which have been sold to gold Companies, the coffee has been entirely neglected. Cinchona, where it has been planted, may thrive, though it is liable to the depredations of similar pests as attack coffee, but, on the other hand, it does not require the annual picking, weeding, pruning, etc., that are needed for coffee. The trees will grow if left alone, but we do not hear of fresh plantings of cinchona where mining is being carried on. It is bad enough for coffee to have nearly died out in the Wynaad, but we read also that in Ceylon the same thing is going on. It appears that there the coffee planter is in a very bad way indeed. The leaf-disease first made its appearance in the island in 1870, and for some time confined its visitations to every other year, allowing an interval for the planter to pick up hope again with alternate good and bad seasons. Latterly, however, the blight has appeared every year, and has resisted all scientific attempts to expel it, and the result of four years' successive leaf-disease is that a great many planters have left the island to seek their fortunes elsewhere, not being in a position any longer to fight against a foe which it appears hopeless to overcome. Those who remain in Ceylon are turning their attention to cultivation other than coffee. Tea and cinchona are the prime favourites, though plants from which sugar and jaggery, are produced and cinnamon likewise engage attention. These with pepper, rubber and tobacco, would, there is every reason to believe, thrive in the Wynaad. Coffee has certainly had a long trial in India, some estates being now nearly half-a century old. Time was, when collossal fortunes were reared from the bean. The diseases and pests which now decimate the trees have changed all this. Meanwhile Brazil continues to supply the market with coffee, which is a very fortunate circumstance for consumers of the beverage. Leaf-disease is still unknown there, and new coffee districts are opened up every year. Sumatra and Java already produce large crops of coffee, and in British Burmah the Commissioner is endeavouring to make Tavoy a coffee-producing district. It is by such means as these that the supply will be kept up. It may be that like the potato, coffee requires fresh land after a certain number of years, and perhaps in a cycle of years the time may come round when Ceylon and Wynaad will again be flourishing producers of the berry which is now such a source of vexation and disappointment to the planters there.—*Madras Times*, October 5th.

MR. MORRIS'S VISIT TO ST. HELENA.

Just prior to Mr. Morris's departure from St. Helena for England a very large attendance of the gentlemen of the island took place at the Castle, in answer to a circular invitation from His Excellency the Governor, to hear an address from the Director of Public Gardens and Plantations at Jamaica on the results of his visit to St. Helena to report on its agricultural capabilities. The proceedings were opened by the Governor, who expressed his pleasure at finding so large an attendance, but regretted that through an oversight it had not been clearly stated that the meeting was open to ladies, many of whom he had heard would have been glad to attend. Although Mr. Morris's visit had necessarily been a very brief one, he made himself so well known and such a welcome visitor to the country gentlemen that any introduction or introductory remarks seemed to him almost unnecessary. Mr. Morris's services at Ceylon and at Jamaica had been so eminently successful that many other colonies were eagerly seeking visits and reports from him, and therefore, considering the small size of St. Helena, it was matter of congratulation that such priority had been given to that island.

Mr. Morris, after stating the objects of his visit, proceeded in an able manner to describe various plants in the island which might be cultivated with little cost and great advantage, and to point out others which he believed could be profitably introduced. He stated that a report would be prepared in full for the Right Hon. the Secretary of State, and that it would no doubt be circulated in St. Helena for general use. The address lasted nearly an hour, and was listened to with unflagging interest and pleasure by the audience, and we fear we cannot do justice to it by attempting to condense it into a few paragraphs. We are, therefore, glad to know that the information will be soon given to the public in an authentic and detailed report, but some of the principal points touched on were as follows :—

He saw much that was promising and encouraging in the soil of St. Helena, but it appeared to him that much of the ground under cultivation had been exhausted from the want of proper treatment in the way of manuring and trenching. That the subsoil should be well turned over and exposed to the air, and also treated with lime some time previous to planting it. He then spoke of several plants common in the island which might be made a source of profit. The plant *Fourcroya gigantea* (commonly called the aloe) was one to which immediate attention should be given. It was growing luxuriantly in rocky ground and in places not generally used for gardening, which was a great advantage, as its cultivation need not encroach on the more valuable parts of the island, and he exhibited a leaf (apparently 12 feet in length) as a specimen of its growth in the island. Much attention was now being given to it in Mauritius for the production of fibre, and Jamaica also had commenced its preparation, and machinery had been introduced there for that purpose. The fibre produced about £37 per ton in the London market, and there was no reason why St. Helena should not reap some advantages from it. There was one peculiarity in the plant which Mr. Morris said he had not noticed in any other which was that the flowers of the plant developed themselves on the parent stem into young plants, which, when they dropped on the ground, were at once ready for planting. A machine for converting the leaves into fibre could be obtained from Mauritius at a cost of about £50; and if the plantations were made on the sides of the hills, and the machinery placed in the valley below, there would be little expense required for conveyance of the leaves, which was a great desideratum, as by means of wires the bundles of leaves could be easily got down from the hill to the machinery, as he had witnessed was done in Ceylon. He regretted that failure had attended the preparation of the fibre from the New Zealand flax, but he thought something could still be done with it, and at least that the leaves could be reduced into pulp and prepared for England, to be manufactured into paper; but on this subject he would make some further inquiries.

Mr. Morris then exhibited a specimen of the *Aloe vulgaris*, better known as "Semper vivum." This also grew plentifully in the waste grounds of the Island. He had found a good specimen of it growing well even on the top of a stone wall in the Rupert's Valley. This was the plant from which the aloe used in pharmacy was obtained. The juice from this aloe was obtained by a simple, easy process, and formed an article of profit to many, poor persons in the Barbados, where it was gathered often by fishermen in the following manner, which he had seen :—They provided themselves with a large pot and three or four short troughs made by nailing a couple of pieces of board to each other at right angles; these troughs are placed so as to run into the pot. In the troughs the leaves were placed after the two ends of the leaf had been cut off. The men then go out to their fishing, and on returning next day would find that the juice from the aloe had been gathered into the pot. If the leaves were not quite exhausted they were again cut and allowed to run for another day until the pot was nearly filled. A fire was then made under the pot, the boiling driving away the watery substance from the juice, which at last attained the consistency of glue, when it was taken out and secured in bottles or gourds, or any other vessel, and sold at about 6d per lb. to the Barbados merchants, who exported it to England and obtained a remunerative return for it.

In regard to coffee, Mr. Morris stated that the trees he had seen were neglected for want of pruning, and that the ground round the trees should be cleared and broken up, but that the soil and climate were very favourable, as shown by the growth and appearance of the trees. A gentleman in the island had told him that from two acres he had sold 30*l*. worth of coffee. This was a very fair return. He thought it could not be grown to a sufficient extent for exportation, but that enough could be grown for consumption in the island and for supply to the passing ships, and would have an advantage over imported coffee because that was saddled with many charges in the shape of freight, &c.

He spoke also of tobacco at some length, giving the fullest details as to its treatment, the nature of the soil required, the situation of plantations, and the preparing and manuring of the soil by enclosing small spaces and keeping cattle shut up in them for a month, and afterwards ploughing the soil so as to pulverise it thoroughly. He gave his experience of the culture of tobacco in Cuba, and thought the island might well produce tobacco instead of importing it from the United States. He also animadverted on the culture of the orange, stating that they could never get orange trees to thrive unless they dug holes 3 feet deep and 3 feet wide in ground free from stones and the roots of other trees. (In fact, he said no valuable tree should be planted where other trees' roots would come in contact with it.) As a remedy for the parasitical disease called apis, he advised either smoking of the tree by means of a smouldering fire under it, or the use of tobacco water by means of a garden syringe, which he said would be found efficacious. The disease of pumpkins, melons, peas, cabbages, etc., was also treated on, and the immediate burning of the plants as soon as the leaves begin to turn white was recommended. By careful attention to this the parasites would to a great extent be exterminated. He strongly recommended that new ground should always be used for pumpkins instead of the old holes.

The culture of sorghum was recommended. Mr. Morris thought it would do better than the sugar cane; it was absorbing attention in the United States, and he believed if application was made to the Colonial Office in England for seed it would be sent to St. Helena. At Oakbank he had found a tree called the carob tree (*Ceratonia Siliqua*), the only one growing on the island. He strongly recommended its introduction and cultivation to a large extent on the sides of the valleys as the fruit was nutritious food for cattle. He also recommended the introduction of the guango tree (*Inga Saman*) the fruit of which was highly nutritious for cattle. It would grow in warm and dry situations, and was of easy culture. The cashan (*Prosopis juliflora*) was found to be invaluble in the West Indies in times of drought, and, as St. Helena had so often suffered from droughts, he strongly advised the introduction of this valuable tree at once. He advised the planting of trees on our hillsides, so as to attract moisture. He felt sure the Government would help them in every possible way if they did but show that they were trying to help themselves. After a few other remarks Mr. Morris concluded his address amid exceedingly warm marks of appreciation by the audience, who listened to him with very great attention.—*Colonies and India*, Sept. 21st.

NEW FIELDS OF ENTERPRISE: A FORMER CEYLON PLANTER IN ONTARIO, CANADA.

Stronachallan, Meaford, County Grey,
Ontario, 17th August 1883.

I have for some time intended to write you, but somehow have always put it off. However, better late than never, I have now been in this country for over a year, and must give you some of my experiences of it. When I left England, I fully intended to go to Manitoba, but, when I arrived at Montreal, people, for whom I got letters, strongly advised me to try Ontario first. When I arrived in Ontario, I made Toronto, the capital, my headquarters, and from thence I went over a good part of the province, looking for land. I found good and bad also dear and good, and I think here I have got land cheap and also good. Of the good land I saw plenty west of Toronto, near London—Hamilton, Woodstock, etc. The land there, however, is about $100 an acre, including buildings. This part of the country, which by looking at an atlas you will see is situated in the Georgian Bay and on the direct route to Manitoba via Prince Arthur's Landing, has both good and bad land: the good, a clay loam on limestone bottom, and the bad swampy land, which, however, could be made good by drainage, and stony, rocky land, very expensive to make fit for the plough—the value, price being from $30 to $50 per acre. It is a newer country than about Toronto and London, &c., but has a good future before it, and the markets Owen Sound and Meaford are rising towns.

All sorts of grain are grown here—wheat, oats, barley, peas and Indian corn. Cattle, sheep, horses &c. do well, and there is a good market for them; but the pasture is poorer than in England, as the climate is much drier. The great want there is drainage. The climate is nearly as hot here in summer as Ceylon, but somehow I don't feel it as much. I have found no difficulty in working in the open all day. The winter is very severe: we registered one day 16° below zero. However, with the exception of a few stormy days, the cold is not unpleasant, as the air is so dry, and the sun shines brightly. Last winter is said to have been the most severe one experienced for a long time, and the spring, of which there was little, and even the summer have been very unseasonable and very wet; so much so that the winter wheat has rusted badly. Other grains however, such as oats and peas, are very fine, and we have had a splendid crop of hay. Snow commenced to fall about the 7th November, and was general about the middle of the month; and it did not quite disappear till about the end of April, and even after that we had a good deal of snow. The country is prosperous, but there is not much money in it, farmers having as a rule started without money —and almost everything is bought on credit, except grain and cattle. Agricultural implements are sold on one to three years' credit. The farmers are or try to be nice and obliging, but they are sharp, and most of them—shame to them!—take advantage of new comers. They are hard working and pushing people.

Fruit here does splendidly. There is an orchard at nearly every house, of apples principally, plums, pears, peaches, cherries, etc., and all the small fruits strawberries, raspberries, etc., grow wild and in profusion, also grapes do well.* I have here an orchard of about 4½ acres, and last year there were about 800 bushels of apples this year the crop of apples is small, but plums large. The trees are rarely pruned; consequently, one year there is an over-abundance and the following year a scarcity of fruit. Apples are worth about 50c, and plums about $1 per bushel of 60 lb. By the way, a dollar is now worth about 4s 2d, and, of course, there are 100c. in the dollar. I brought over with me a few hundred pounds of Windsor Forest tea. At first I found difficulty in selling on, but I did sell all except what I kept for my own use, and I got other 600 lb. of Loolcondera and Rookwood tea, which I am now selling. It is rather difficult to get a market for a quantity, and to get the cash; still, the consumption must increase, and it is greatly appreciated by those who have used it. But the teas drunk here are generally green (Japans), vile stuff, and costing only about 20c. per lb.; and, of course, where money is scarce, people think twice before trying an expensive (at least what they think expensive) tea. Still I am getting more, but my capital is so small that I must get paid for what I have sold before I get more. I shall be glad to correspond with anyone in Ceylon who is anxious to get a new market for his tea. Tea is drunk at breakfast, dinner and supper, the only meals taken; so that, if Ceylon tea was consumed here, the demand would be large. No kind of strong drink is kept in any house here, though the quantity imbibed, when farmers go to town, is pretty considerable. So, good tea, such as Ceylon, would be a great blessing to Canadians. I am now busy with my harvest, and have not time to give you more at present; but I shall write again, and so give you more particulars of the country, Manitoba, etc. In the meantime, if any Ceylon man wants information on any point or points, I shall be glad to write him direct.—Yours truly, JOHN STRONACH.

[Mr. Stronach will be well remembered in planting circles, especially in Dimbula, where he spent so many years as a coffee and cinchona planter.—ED.]

* In hothouses, of course.—ED.

THE PREPARATION OF CACAO BEANS.

We are indebted to Mr. Prestoe, Government Botanist of Trinidad, for a copy of a communication which he has addressed to the *Trinidad Chronicle* on the subject of the curing of cacao beans. Mr. Prestoe is good enough to bear valuable testimony to the merits of the *Tropical Agriculturist*, while he pays the Ceylon planters the high compliment of showing that in the new pursuit of cacao culture and preparation they have improved upon the methods in use in the West India Colony which is specially associated with cacao, —Trinidad. We reprint the communication, which sets forth with clearness and emphasis the benefit of following up the fermentation of cacao beans in their mucilage by clean washing and sun-drying. In cacao as in tea culture our planters seem likely to take a oremost, if not the first place in the world.

To the Director of the Trinidad Chronicle.

Dear Sir,—I cannot tell to what extent the *Tropical Agriculturist* is read here in Trinidad, I fancy, however only to a very limited extent—probably not more than half a dozen copies being received in the Island. This uncertainty on my part must be my excuse, in a measure for troubling you for the favour of space for a few words anent one of the many subjects that go to make up its contents, and meanwhile allow me in view of promoting the agricultural interests in Trinidad to offer my testimony to the really valuable character of this monthly, and which is perfectly unique.

The paper is published by the Messrs. Ferguson of Colombo, Ceylon, who are best known as Editors of the *Ceylon Observer* and *Directory*. It is a book of about 50 leaves, full to overflowing with most interesting and instructive matter, culled from publications in all parts of the world, besides its own original articles and correspondence and which treat on every possible subject with which a tropical agriculturist, especially a resident proprietor, is likely to be interested in; a striking feature of the correspondence being narratives of the writers' experiences with these subjects or what they know of the experience of others—all with the object of effecting improvement in the agriculture and aiding in the general wealth of their colony.

The special value of this monthly, more particularly as relates to Ceylon lies in its character as a means—and a powerful one—by the general information it affords for initiating and promoting the cultivation of new or little known products on the principle of dealing with as great a variety of subjects as the conditions presented in the colony may permit, in preference to concentrating all effort and attention to the development of one or two products for which the conditions of the country may be *best* suited.

So far and so successfully has its influence operated in Ceylon (as well as India) that today we see—not as here the principal exports consist of only one or two subjects, but of a dozen or more.

Some of these besides the leading ones are on such elastic bases that on a leading export showing signs of falling-off one year, some product of lesser importance is made to double its output in a single year—as seen at present in respect of Cinchona Bark, Tea and Cacao—three striking examples which a perusal of this excellent "Tropical Agriculture" will afford ample information of.

The first two we cannot of course do here—for want of elevation—so that notice of their cultivation would be waste of time—but what of Cacao? With this subject there is an extraordinary increase of output—in the course of three years the export having developed from a few pounds obtained from a few neglected trees in the jungle, and which a happy thought had brought to light by clearing and pruning, to the present considerable export of 101,800 lb. and which, besides, in the London market—by the beauty of its sample is the envy of both buyers and sellers, and has accordingly settled down to a leading position in the market at 105s—abreast of the best from Trinidad.

Of course there is no reason why the very best Trinidad Cocoa should not be better than it now is: or that the present Trinidad seconds and thirds and even fourths (if such can still be cacao) should not be equal or very nearly equal to the present Trinidad best, and thus leave the Ceylon cacao at least a shade behind.

In order to obtain this desirable position it will be necessary—simultaneously with the adoption of a methodical plan for sampling our cacao into about five sets (of varieties)—to fallow the system of Ceylon growers: what this is I venture to subjoin an extract from the *Tropical Agriculturist* to show.

From this it will be seen that—as I have previously advocated as indispensable, under a rational method of preparing cacao for the market, and for realizing the full value of the produce—the *Ceylon planters wash their Cacao.* Here, however, and elsewhere in the West, it is affirmed that to wash cacao is to spoil it both in the operation which breaks the skin, and in its after state: or that it costs too much to be practicable even when the sample is *improved.*

But these objections arise only from a want of appreciation of the requirements in the operation and—probably—carelessness in conducting it, if even such had been tried. Previous impression of the effects on the beans of the common practice of amassing, sweating, rubbing, drying (which is simply encasing the beans in their mucilaginous covering decomposed and dried with a considerable addition of foreign matter) must for a long time stand as an obstacle in the way of the creole planter understanding a perfectly clean pale cinnamon brown light bean with easy fracture, as the right sort of sample.

It may be questioned what led the Ceylon planters to wash their cacao—for we may conclude they got no advice from their friends in the West to wash it.

For the answer we may reflect that the Ceylon cacao has been dealt with under the immediate supervision and manipulation guided by the high intelligence of—for the most part—English and Scotch gentlemen resident proprietors or managers. They were suddenly aroused to the necessity of appropriating to the utmost anything in the way of cacao, and a few old trees neglected for years were at all once made recipients of their most tender regard and attention. The trees were bearing profusely, so that cocoa had to be "cured" at once. Old papers and notes on the subject were hunted up, and cacao was found to be cured by being either "sun-dried" or "sweated" and dried, so the sun-drying process being the simplest was started; but then, there was so much mucilage, and after the first day had become so uninviting in appearance that with their feeling of respect for everything clean, they concluded that their cacao was not going to be the right sort of thing for the English market—(though this was the first new cacao they had ever seen)—even if it could be dried, so they decided to *wash* it—for as one told me they could do nothing else with it—but the addition of water so greatly increased the mucilage as to leave it impracticable and besides the skin of the beans broke in the washing and thus the whole thing was thrown away—as actually happened in more than one instance. Further on it was desired to try what "sweating" would do, accordingly beans were put to sweat under the discomfort of wide diversity of opinion as to the period necessary for the "sweating." But being put to sweat, in the course of a few days the mass prosented a disgusting appearance of rottenness that washing was again tried as one way of getting out of the fright: this time with very different results. The sweating had decomposed the mucilaginous covering of the beans, and light washing left them clean and as pleasing in appearance as new copper coins. Put at once in the sun, they dried in a surprizingly short time, and soon the result of the prized Ceylon Cacao of sweet mild flavour, cinnamon colour and free 'break,' was attained.

Before all this however a civilized practice in respect of fruit gathering was followed:—viz

Only the ripe pods were gathered, and thus the beans were uniformly affected in the sweating and drying and came out a uniform sample.

The process herein followed successfully was therefore briefly this:—

Only ripe pods dealt with; the beans amassed to sweat (being turned once or twice) then carefully washed and put in the sun to dry.

It may here be remarked that the beans being sufficiently sweated to admit of being washed readily, and yet not sufficiently sweated to have fully expanded their cotyledons—i. e. the parts which become nibs—or to have reduced their acridity—can be returned for further sweating after the washing.

The drying being effected immediately after the washing or second sweating, mildewing and discoloration therefrom would never occur, and of course the labour of "rubbing" would be avoided. Necessity for prompt drying renders washing indispensable, for washed beans dry in one-third the time of beans covered with the decomposed mucilage; and as during the wet months artificial means for drying cacao as employed with Tea is a great desideratum of the time—a point which it is my chief object in addressing you now to draw attention to, it should not be overlooked that drying by artificial means will not be practicable or unwashed beans—except for re-drying damp cocoa, cured in the old manner.

It would be well for the cocoa interest generally if in view of the November and December rains a practical consideration were to be given to this point at once.

It should never be lost sight of that cocoa beans in bulk—not larger than the usual quantity of a "crook" basket or sack and if kept from the air by such a covering as an ordinary sack—will keep fresh and sound for 3 to 5 days—except as to the mucilage which will waste somewhat—as is desirable. Beans might therefore be brought in from all but the most remote parts to be carefully washed and dried at central towns or villages—with great pecuniary advantage both to grower and dealer.—I am &c.,

H. PRESTOE,
Govt. Botanist.

St. Ann's, 30th June 1883.

Extract from Tropical Agriculturist.

"LOW COUNTRY PRODUCTS."

("NOTES BY A PLANTER ON HIS TRAVELS.")

"CURING THE BEANS" (*CACAO*).

A cooly picks two bushels of cocoa beans per diem, and as five bushels wet=1 cwt the cost is only about 87c a cwt for picking as compared with R2 to R3 for Liberian coffee. The pods are first cut from the tree, a small piece of stem being left on the tree, and the cooly takes one in each hand and with a knock breaks them both in halves, and then with one draw of his fingers dexterously strips all the beans off the centre pulp. The pods are then thrown round the trees and act as manure, while the beans are removed to the fermenting cisterns. It takes from 5 to 9 days to properly ferment the cocoa, and it is then ready for washing. It is trampled first, as in coffee, with the feet, and then is removed in baskets and carefully handwashed, as washing with the "matapalagei" damages the beans. I have no doubt that ere long some means less expensive will be found for washing, and the Clerihew will be much improved on too.

After washing, the cocoa is laid on mats to dry as coffee is, if the weather is suitable; and at times it is advisable to give it a rub over with small pieces of sack or cloth, which improves the appearance of the beans, and facilitates drying in this showery weather.

The difference in well cured and badly cured cocoa amounts to at least R20 per cent, and the prices obtained for it as in tea, will depend in a much greater measure on the careful attention of the superintendent to the curing, than in the case of Coffee Arabica, and the good man will have a better chance of coming 'to the fore' than in days of old with coffee.

TEA-DRIERS.

Our readers will remember that Mr. Owen, in his address to the Maskeliya Planters' Association, spoke in high terms of the Gibbs and Barry tea drier. We are now glad to be able to present the following detailed description of this funnel machine, which we find in the *Indigo Planters' Gazette*. The machine, it would seem, requires only three coolies to work it, and it is claimed for it that it renders burning impossible. The objections are the high first cost (against which is to be placed the saving in trays, which in other machinery wear out) and the fact that coke or charcoal must be used as the heat-generating material. The fumes of coal and the smoke from wood would ruin the tea, the heat being driven through the funnel by fanners.

In these days of competition, when every device is absolutely necessary in the way of economy to make tea pay, and when many contrivances, dodges, or by whatever name one may choose to call them, are unknown to many planters, we consider it the duty of every one interested in tea, to enlighten the Planting community on any topic which may tend to reduction of expenses. The Gibbs and Barry Tea Dryer in this connection deserves our notice. In doing so we are influenced by no partisanship for this machine, for we have heard as many speak well of it as the opposite, and every tea planter is aware how some think the "*Sirocco*" perfection; some say, nothing like the "*Kinmond*," and others say, give us the "*Jackson*"; perhaps the only machine regarding which the opinion of the planter is unanimous being the "*Typhoon*." We propose taking up and dealing with the properties of these different dryers, leaving intending purchasers to judge for themselves which is the best.

The Gibbs and Barry machine is then a coke dryer, and no other fuel can be used except, say, charcoal, of which, we fancy, it would consume too much for the quantity of tea turned out to make it a paying thing. In the machine there are no trays to get out of order. It is a long cylinder which revolves slowly, and the heated air from the coke is driven into the cylinder or tunnel by a fan placed over the furnace, the latter composed entirely of brickwork, so that there is no chance of complaints of burning out, &c., such as was heard of regarding the false sides of the "*Sirocco*," but which is, we believe, now remedied—an ingenious but simple arrangement of air-holes enabling the operator to raise or lower the temperature at will. The necessary heat having been obtained after the fire is lighted, the hot-air duct is opened and the heated air is blown right through the tunnel. The prepared leaf is fed into the cylinder at one end and is discharged at the other, either crisp tea, or ¾ths fired, or ½ fired, this being accomplished by raising or lowering the cylinder. This is a point most decidedly in its favor, as it does away with all chance of burning. All the tea is found to receive the same amount of heat and come out fired equally, the revolving of the cylinder making the turning of the leaf automatic, and the tea all passes through at the same speed; but over and above this a long felt want is here supplied for withering leaf, as the temperature of the tea-house can be raised in wet weather by simply setting the machine in motion and opening the hot-air duct and blowing the heated air into the house. In many factories at the present time the old and antiquated choolah has been kept up, not to fire the tea but simply to wither the leaf in cold wet weather, thus entailing a considerable expense, the presence of the choolah rendering the building useless for packing or other purposes. The quantity the machine is capable of turning out is, we believe, about 2 to 2½ maunds *pucca* tea, so that, worked 12 hours, we may say 25 to 30 maunds. We prefer to calculate the outturn per hour, as some people's days are longer than others. In some factories we believe it is found to be most economical to pass through the whole of the day's leaf pretty rapidly, half firing it as it were, and then fully cooking it over the old choolah; and in this we have heard of as much as 220 maunds of green leaf being passed through. The object of this is, we understand, to impart the same freshness to all the tea which is obtained by the rapid stoppage of the fermentation, and which takes place as soon as the tea is put into the cylinder, as the heat is exceedingly high. The danger of burning the tea too is reduced to a minimum, and many a sleepless night spared the planter, for he knows that if the leaf is put in at one end it must come out at the other at the same speed, and having received the same treatment and not dependent upon a sleepy coolie to turn it. The fuel required is by some considered a disadvantage, but in this machine the drawback is not so great as in some others that only burn coke, as before the heat reaches the cylinder, any coal gas that might be generated—the result of bad coke—is completely destroyed, and the quality of the coke is not so highly an essential as in some others, where the heat is applied direct. There are numbers of small improvements which, we think, might be added, but they are only minor ones, and we have no doubt the patentees will by-and-bye, when the machine becomes more common, be induced to add these. There is little or no wear and tear on any of the parts, so that the machine would be a lasting investment; and once erected would cost little to keep in thorough working order. There is no annual repairing of trays, and the number of coolies required to work it make it very economical. One man is required to feed and another to take away the tea as it falls out at the other end. These with a boy to stoke are all that is needful for the successful working of the dryer. The quantity of fuel to the maund of tea turned out is trifling, so that, so far as economy goes, it has everything in its favor except prime cost, which, we have no doubt, could be lowered if the sale increases.

On a future occasion we propose to notice the Sirocco and Kinmond's both wood and coal burners.

The Sirocco and Kinmond's.

In writing in our last issue of the Gibbs and Barry Dryer, we mentioned that we purposed taking up the *Sirocco* and the "Kinmond's," and we now proceed to do so. In dealing with these a good many points have to be taken into consideration, which had not to be regarded in the Gibbs and Barry, and we would purpose taking these and dividing them into what may be called the pros and cons, or the advantages and disadvantages. First we ought to preface our remarks about these two dryers by stating, that we are writing of them as of one, although they are not exactly the same, because the principle is the same to all intents and purposes, as both machines profess to use any fuel, coal or wood. The only existing difference, so far as we know, being that in the Kinmond's dryer a fan is required to create the draught, whilst the *Sirocco's* action in this respect is automatic, as the funnel answers the purpose of a chimney to carry off the smoke, and at the same time create a draught. Thus one advantage is scored over the "Kinmond" and "Gibbs and Barry" as no motive power is required, and the *Sirocco* once erected contains all the elements of action within itself. Both the "Kinmond" and the "*Sirocco*" are composed entirely of iron, so that there is no danger of fire; but we have heard serious complaints of the false sides of the latter burning. We understand, however, that this defect has been remedied lately by substituting fire brick plates instead of cast iron, which apparently will not resist for any length of time the high temperature that it is necessary to keep up to get the best results out of the *Sirocco*. The *Kinmond* we have complained of as blowing out the fine tea and burning some of it, but the quantity so burned is said not to be serious, at least so an experienced Manager assured us. We understand too, that the motive power required is not great, but still necessitates the engine * being worked after the rolling is done.

* In Ceylon, generally, merely the water-wheel.—Ed.

The quantity of fuel consumed in both machines practical planters assure us is very much more than the prospectus would lead one to believe, and we are assured that it is nearly double, except in fine weather, and that the fuel must be of the very best kind, but this is but a trifling thing with machines that burn any fuel, and would not, we think, act as a deterrent to any purchaser. The quantity of tea turned out epr diem is a most important item, and we are assured that it is only under exceptional circumstances that the Sirocco will turn out over 20 maunds of green leaf in an ordinary day, and that the "Kinmond" fails in this respect too. From Assam the reports of the Kinmond are good and encouraging, but the Cachar planters as a rule do not approve of them, and prefer the *Sirocco*, even although they compleain of the quantity turned out for the cost. One undoubted advantage the *Sirocco* possesses over most other machines, is the recognized flavor of Siroccoed teas, and that there must be something in it there can be no doubt, as it is recognised by the Trade. We may then take the advantages of the Sirocco as fine flavor imparted to the tea, being constructed of iron there is no risk of fire, and no motive power being required to work it; and its disadvantages, high cost compared to quantity turned out, necessitating a large staff of men to fire and turn the tea, great consumption of fuel and wear and tear of trays. In the Kinmond the advantages are, that it gets through a larger quantity of tea per diem, but has the same disadvantages as the Sirocco. If the patentees of these two machines could be induced to lay their heads together and construct a machine out of two, which had all the advantages of the Gibbs and Barry, without any of its disadvantages, then we should say we had got the machine of the period. We do not see why the hot air which generates from the Sirocco should not be blown into a tunnel the same as is used in the Gibbs and Barry, and which does away with all the wear and tear of trays, cost of wire netting, &c., the question only remains to be proved, whether this would impart an equally good aroma with what is now turned out from the Sirocco.* In these days of economy and advancement, the drying of tea at a cheap rate is becoming one of the most important items of expenditure. Rolling has been brought to a good pitch of perfection, but we are still a long way off what may be done in the way of drying. What is wanted is a combination of all the best machines, at such a rate that tea properties can afford to go in for it. At present we know of many small properties that are prevented from going in for machinery, especially dryers, simply and solely on account of their prices. In treating only of Kinmond, Gibbs and Barry and the Sirocco dryers, we consider that we have embraced all those that are principally used. We do know that one or two others exist, but in treating of the above we consider we have taken up all that, so far as we can learn, are of any use in large factories. The Typhoons are a thing of the past; Bicknell's we have never seen in Assam or Cachar and there may be one or two more small ones. Jackson's we have heard spoken of, but consider that in dealing with the Sirocco we have dealt with it.* We trust within a few years to be able to report upon a wiser and better one than any yet out, and as we said before, possessing all these good properties without the bad.

CACAO CULTIVATION IN CEYLON.

We cannot do more than call attention to the very full and thoroughly practical paper prepared by a well-known planter on the subject of cacao cultivation in Ceylon which will be found below. The estimates for cacao are even more encouraging than those of Mr. Hay for a tea plantation. But the writer points out how limited is the extent of really first-class land adapted to the cultivation of cacao. For those fortunate enough to possess blocks with the needful depth of good soil, the shelter and the climate, the present paper cannot fail to be appreciated as a valuable guide to the operations required to open up a successful plantation.

* We should like to hear Mr. Owen's opinion on this point.—ED.

CACAO CULTIVATION IN CEYLON.

ESTIMATES AND REMARKS.

(*By a Practical Planter.*)

Estimate for opening and bringing a Cocoa Estate of 200 acres into bearing, including cost of land.

Probable cost of 200 acres of land at R25 ...		R5,000

1ST YEAR from January to 30th June of following year.

Felling and clearing 200 acres at R15 ...		R3,000
Nurseries: clearing sites	40	
80,000 baskets at R5·50	440	
5,000 cocoa pods at R55	275	
Filling baskets and sowing seed ...	250	
Erecting pandals for shade	120	
Watering and attending	125	
		1,250
Lining at R1 per acre	200	
Holing: 300 holes per acre 12 by 12 feet apart, 2 feet deep by 18 inches wide (20 per man)	1,200	
Filling in 75 holes per man	300	
Planting, supplying and shading at R3·25...	650	
		2,350
Weeding for 16 months at R1 ...		3,200
Roads: 10 miles with inside drain at R1·50...		1,500
Drains: every half-chain apart R10 per acre		2,000
Tools		500
Buildings: temporary lines	200	
Permanent lines	300	
Bungalow, outhouses and furniture ...	500	
		1,000
Contingencies: medicines and hospital charges	400	
Survey...	200	
Stationery, postages, etc.	50	
Chetty's commission on cash	100	
		750
Superintendence and allowances	3,000	
Conductor for 6 months	250	
		3,250
		R18,800

2ND YEAR from 1st July to 30th June.

Nurseries and supplying	R350
Weeding at R1	2,400
Roads: upkeep and culverts	400
Drains upkeep	200
Pruning and singling	100
Staking at R4	800
Buildings: bungalow and furniture ...	3,000
Contingencies	500
Superintendence and allowances	3,000
	R10,750

3RD YEAR from 1st July to 30th June.

Nurseries and supplying		R150
Weeding at R1		2,400
Roads: upkeep and widening out 3 miles into cart road width 10 feet ...		800
Drains upkeep		200
Pruning and suckering		300
Staking, retying, etc...		100
Building: temporary curing-house with stores and fan	500	
Permanent set of lines	700	
		1,200
Gathering, curing and dispatch of 200 cwt. at R6		1,200
Contingencies, including watchers ...		900
Superintendence and allowances ...		3,000
		R10,250

* Jackson's is professedly an improvement on the Sirocco. The main principle is the same.—ED.

4TH YEAR from 1st July to 30th June

Weeding at R1		R2,400
Pruning and suckering		400
Roads upkeep		400
Drains upkeep		200
Buildings, permanent, cleribew, engines, etc.		5,000
Gathering, curing and dispatch of 600 cwt. cocoa at R4		2,400
Contingencies		900
Superintendence and allowances...	...3,500	
Conductor	500	
		4,000
		R15,700

5TH YEAR from 1st July to 30th June.

Weeding at R1		R2,400
Pruning and suckering		400
Roads upkeep		400
Drains upkeep		250
Gathering, curing and dispatch of 1,000 cwt. cocoa at R3·50		3,500
Building upkeep		200
Contingencies		900
Superintendence and allowances ...	...3,500	
Conductor	500	
		4,000
		R12,050

Interest on Expenditure.

5 years' interest on cost of land at R8 per cent on...	...R5,000	R2,000
5 years' interest on 1st year's expenditure at R8 per cent on	...18,800	7,520
4 years' interest on 2nd year's expenditure at R8 per cent on	...10,750	3,440
3 years' interest on 3rd year's expenditure at R8 per cent on	...10,250	2,460
2 years' interest on 4th year's expenditure at R8 per cent on	...15,700	2,512
1 year's interest on 5th year's expenditure at R8 per cent on	...12,050	964
	R72,550	R18,896
Add interest	...18,896	
Expenditure for 5 years ...	R91,446	
Less 1,800 cwt. cocoa sold at R45	...81,000	
Debt on estate at end of 5th year	R10,416	
Add for purchase of other 50 acres at R25...	1,250	
	R11,696	
The expenditure each year after this, allowing R3,000 for manuring would be about ...		16,500
Against which put proceeds of sale of 1,000 cwt. cocoa at R45		45,000
Year's profit		R28,500
Value of estate at 5 years old with only 5 cwt. per acre—this is at the rate of 5 years' purchase—	...R140,000	

As a few remarks on each heading of expenditure in the above estimate will make it more intelligible, I shall endeavour to give this with the aid of information received from friends of larger experience than myself, on many points connected with the cultivation of cocoa. This product being still in its infancy in Ceylon, no authoritative statement can be made as to the best way of cultivating it; but such knowledge as we have has been gained by experience, and can, therefore, be relied on.

The cocoa plant has been in the island for many years (perhaps over 30 years), but till within the last six it was not systematically cultivated. When our attention was drawn to this as a profitable cultivation, we were most fortunate in having at our doors a variety—perhaps the very best we could possibly have had—that has proved, by the vigor of its growth, its fruitfulness, and the range of elevation—from sea level to over 2,000 feet—at which it will grow and yield probably, that it is well adapted to our climate; and the prices realized in the European markets leave nothing to be desired. There are over a dozen other varieties of cocoa in the country, but, till we hear more about them, I would advise our sticking to what we know to be a prime favourite with buyers.

New estates opened were, until recently, planted under the shade of the forest, all the smaller timber being cut out and the larger trees left. This was found in about the second year of growth to be hurtful to the plants, tending to draw them up lanky and weakly. The jungle had, therefore, to be cut down carefully at considerable expense, and where shade has been left, it has been and is still being gradually thinned out. I believe the general opinion now is that direct shade is not good for cocoa, though it remains to be proved whether light and chequered shade is not beneficial.

Land.—The very best land that can be got should be secured for cocoa; the plant is a deep feeder, and to thrive well must have a good subsoil. Dumbara, parts of Matale and Kurunegala have the best soils in Ceylon for its growth—dark friable chocolate of great depth; the vigor of the trees in such soils shows how they revel in it. But, alas! where are we to get soil of this description in any of the forests that are still remaining. Many of the chena lands in the lowcountry have very fine soil yet (the surface only has been skimmed), but the native titles are very defective; and if one does venture, and purchases small lot after small lot till he gets a fair-sized block, the difficulties and delays in the way of getting a "title of quiet possession" from the Government are most vexatious and almost insurmountable. We must therefore be contented with what we can get, and that is generally inferior soil. Light soil with a good deep subsoil is to be preferred to one with a rich surface soil but hard impenetrable subsoil. Very steep land is to be avoided, but moderately steep suits very well: rich flats are the best. I have only estimated R25 per acre for purchase of land, but, in a few years, when capital returns to the country, and there is a demand for land for cocoa, I fancy it will not be got for double that figure. I have made an error in opening the whole of the 200 acres in the block; to admit of opening 200 acres, the block should have other 50 as a reserve. Even supposing that every acre was available that is suited for planting, it would be still necessary to leave belts as protection against wind, as, however well cocoa will do without shade, it will not tolerate wind. On no account should land be felled in a locality known to be windy; and after the estate is opened, belts of suitable trees for shelter should be thickly planted in all exposed situations.

Nurseries.—For making these, flat land near water should be chosen, and they should be in 3 or 4 different spots if possible, as this makes the carriage easier when planting out. Pandals of light jungle sticks and covered with small leafy branches must be put up, high enough to admit of a man walking underneath without stooping. The surface soil should then be scraped into heaps, and the baskets filled with this, well pressed down with the knuckles, but not patted as the coolie is so fond of doing; the baskets being filled place them 6 deep in a row and to any distance the space will allow in length; they must be placed perfectly upright, and to keep them in that position a "varachchi" tied to a few pegs driven into the ground on either side of the beds will do. If earth is filled into the spaces between the baskets, at about every 10 or 12 rows across the beds, it will be an advantage. This must be carefully seen to, for, if the coolie is left to himself (and kanganies and conductors are often not one whit better), the baskets are sure to be placed at every conceivable angle but the right one. The baskets being in position, just put one seed in each about one inch below the surface, the *broad* end downwards—some prefer to germinate the seed before sowing—after sowing well water. Any seed that does not grow in a fortnight should be replaced by a fresh one, and this should be done till there is not a vacancy. Owing to the greater and more rapid evaporation, the outside rows of trees suffer; to prevent this, heap earth against the baskets. The plants should be watered once daily, and, in very dry weather, twice. I have allowed for enough plants to plant the clearing, and do the first supplying. I have never tried planting at stake, but believe it is sometimes very successful. Should the season, however, be a dry one, the clearing is sure to be very patchy, and I hardly think the risk worth the money saved. Some planters aver that they dare not use baskets, as the white ants would be sure to attack them and destroy the plants: this is not my experience, except on a very small scale, but, where it is unfortunately so, planting must be done at stake, or plants raised in beds, the seed being sown 4 inches apart each way and removed by Scowen's transplanter and Davidson's envelopes. This work should be *very* carefully done, the plants not allowed to remain over 3 months in the nurseries, else the taproots will grow too long, and, in withdrawing the transplanter, the plant, instead of coming out with the soil, will be drawn through it, and all its roots disturbed: such a plant will stand a poor chance in any weather. The transplanter should be frequently dipped in a bucket of water, as it makes the work easier, and the envelopes should be wetted and drawn through ashes; if this is not done the earth adheres to the envelope and the labor of transplanting in many instances is lost. The shade over plants, whether in baskets or in beds, should after two months be gradually removed to harden the plants. At three months from sowing the seed, the plants are ready for planting out in the clearing. Baskets for raising plants can be got at Kalutara, delivered at the railway station, for from R4 to R4·50 per 1,000, and another rupee should land them on the estate.

Lining.—All distances from 9 by 9 to 13 by 13 feet have been tried, and I believe that most are now agreed that 12 by 12 is the best; this is, of course, for our ordinary red variety: the pale green, white, and purple kinds would want 16 by 16 at least.

Holing.—Some prefer wide and deep holes—wider and deeper than I have estimated for,—others prefer narrow and deep. The large holes are more expensive and possibly for the first two years the plants thrive better; with large holes staking is a necessity, whereas with narrow ones it may not be needed. It is well-known that for two years cocoa plants make hardly any lateral roots, sending down only a long tap; during heavy rains, the soil in a wide hole gets very sappy, and the plant having no hold is blown over by the least puff of wind. On the other hand, in the narrow hole, the few laterals the plant does make have holding ground at once, and they are thus stayed.

Planting.—This work should be done in the rains, and the earlier in the monsoon the better. One coolie will carry out and plant from 100 to 150 plants either in baskets or transplanter envelopes, according to the distance from the nursery and steepness of land. On hillsides, the baskets should be buried 2 inches below the lower lip of the hole, so that, in the event of any soil being washed away, the roots of the plants will not be exposed; the earth should be well trampled and the hole filled flush with the surface, to prevent water lodging and rotting the plant.

Shading should be done the same day as the planting, or the following morning, and tree-branches the leaves of which will stick on for 3 or 4 months should only be used; the best for this purpose are "Mora" and "Kebella." The cost of shading will depend greatly on the facility there is for procuring the proper shade stuffs, and, unless abundant near at hand, enough trees should be left when felling to give branches for shading, and cut down afterwards. In some parts of the lowcountry, the leaves of the "Madu" palm are used; they are like fronds of the tree-fern, and answer admirably. I do not think it is necessary to cover the plant up entirely as is usually done; in my opinion, it is injurious, shuts out sun and light, and keeps hot air confined; and if the shade is attacked by white ants the plant is bound to go, it cannot escape. The plan I prefer is as follows:—Chop your shade stuff into about 20-inch lengths, stick it upright at about 9 inches from the plant, *so that no leaves of the plant touch it*; run them along north and south for about 15 inches thus:—

E
N ————————*S*
O
N ————————*S*
W

This will protect the plant from both morning and evening sun, which is really all that is needed, and will also prevent the too rapid drying up of the soil; should white ants attack it, the plant escapes.

Supplying.—The first supplying should be done in the early north-east rains, and twice more in the following year, by which time nothing further should be needed.

Weeding.—This is a very important work, and it is very desirable that the clearing should be kept clean from the commencement. If the growth of weeds is great, weed once in three weeks till they are got under. It is quite possible that after a year or more the work can be done for 75c per acre, but do not resort to this till you are quite certain the rupee is excessive. I need hardly say, permit no scraper or mamoty weeding!

Roading and Draining.—These works should, if possible, be done before a lining peg is put in or a hole cut—work is facilitated and after damage prevented, as well as a good deal of vexation and bad temper. The gradients of both roads and drains in the lowcountry should never be steeper than 1 in 15, and for roads intended to be afterwards converted into cart-roads 1 in 25, and less if practicable. Roads should be cut 4 feet in the solid, with a foot deep and wide drain at the back of it: drains should be 18×18 inches. The cost of these works will depend much on the nature and lie of the land: if at all steep, what has been estimated will be spent; if flat, a large saving may be expected.

Tools.—As a large force of labour will have to be employed to get through the work in proper time: the estimate for these will not be too much. See that you buy nothing but good articles!

Buildings: Lines.—20 rooms, roof and walls of cadjans or talipots, can be erected at a cost of R10 a room, site included—which will be watertight and comfortable and last for all the time they are wanted; they can be run up in a few days—a great consideration, and there is no risk of the coolies catching illness from wet mud-walls and damp floors. A line of this sort should accommodate 100 laborers. A good deep drain should be cut *all round* the line to keep the floors dry. A permanent set of rooms can be built at leisure, to serve for those coolies who will remain after the planting is finished. It may seem that the accomodation provided is insufficient for the large force that would have to be employed; but if it be borne in mind, that, in the lowcountry, much of the work would be done by Sinhalese, on contract or day-work, and who would live in the neighbouring villages, it will, I think, be found ample.

Pruning and Suckering.—In the first year, all doubles must be cut away, leaving only one stem. At two years the plant divides, usually into three branches or forks, and then begins to make a head. All cross wood within the centre, and all shoots on the main branches, within one foot of the stem, should be cut out clean; this tends to strengthen the main branches, and prevents crowding when the trees grow older. Twice a year, a month before blossoming seasons, say in May and December, all cross and useless wood should be cut out, so as to let in *side light*: the crown above should not be touched, as I am inclined to think strong sun, direct upon the young blossom, is injurious. Some planters prune away all drooping branches; this no doubt improves the appearance of the trees, and, where grown under sufficient shade, I quite approve of the practice. In the open, however, they should not be touched, as they serve to protect the trunk from the sun, and this encourage the setting of blossom along it. All suckers should be *cut* away once a month, and on no account should they be pulled off.

Gathering and Curing.—The pods when ripe assume a slightly yellowish hue. They should be cut off with a knife close to the pod, leaving the stalk by which it was attached adhering to the tree. If cut off close to the branch, the eyes, on which the future blossoms depend, would be destroyed. The pods are heaped on the nearest road, and, as the husk is very brittle, a slight blow with a light wooden mallet splits it, when the seeds are extracted and put into baskets and carried to the store to be cured. This is done by laying the seeds in a heap, on a platform of reepers and coir matting, and covering it with bags or a tarpaulin. The heap is well turned every two days to ensure equal fermentation, and, on the eighth or ninth day, according to fermentation, it is washed in several waters, till quite clean and free from all mucilage. If the weather is fine, it is then spread on mats to dry; if not it is at once put into the clerihew; three days' sun, and less I believe in the drying-house, will dry it thoroughly, and it is then fit to dispatch. Should the moisture not be dried off the beans the day they are washed, they will, during the night, contract mould, which depreciates them in value.

Permanent Buildings.—A *bungalow* should be begun and finished in the second year: the rooms should be wide and lofty and well-ventilated, with a verandah coming low down all round, and in malarious districts it should have one upstair-room as a sleeping apartment: The *store* site should be chosen on a flat, open to the sun all day, and near water. It is built on Clerihew's plan, and should have a steam-engine to work the fan; where there is water, a wheel can be employed, but in the lowcountry few estates have sufficient for this. Opinions differ as to when the store should be ready. One gentleman says:—"I should have my store and machinery up by the time the cocoa is 3½ years old." Another says:—"I would begin to erect permanent stores at the end of the 4th year." I am inclined to agree with the latter.

Superintendence.—This in the first season is allowed for 18 months, as by far the heaviest part of his work will be in the first 6 months, from January to June; he must be on the spot to give out and supervise felling contracts, and, immediately after the burn, which should not be later than end of February, begin nurseries, erect lines, etc. A conductor is allowed for six months; after that, till the estate begins to crop, no conductor is needed.

Yield of Crop: Estate when in Full Bearing.—I have estimated 1 cwt. per acre for the third year, 3 cwt. for the fourth, and 5 cwt. for the fifth, and they are reasonable. I have figures before me showing that over the amounts quoted have been picked. With trees planted 12 by 12 ft. 10 pods per tree yields 1 cwt., and, as there are two crops in a year, only 25 pods in each season per tree is required to give 5 cwt. per acre. I cannot ascertain when cocoa is supposed to be in full bearing; but opinions seem to point to 10 years, and a yield of 6 cwt.

Manuring.—With our poor soils, cocoa must be manured, if we wish to get good crops and keep our trees in good vigor. The fifth year is not too soon to begin this. A gentleman writes me:—"I have manured some four years old cocoa with great advantage, and, when it can be done cheaply, I do not think that age too young it put 2 cwt. an acre on my cocoa at an expenditure of R22 per acre." If results as good as this were always to follow, I should say four years old was not too young to begin.

Fencing.—This is an emit I have not allowed for, but it is one that should appear in every lowcountry estimate. A belt of sapan ten feet wide, the seeds planted 18 inches apart, will, in four years, make an impenetrable fence. At three years old the stems should be *half-cut* through at three feet high and bent horizontally; thus laid, they will continue to grow and send up numbers of suckers. A fence made from sticks of the burnt-off clearing can be put up at the rate of about R2·50 per acre, which will keep out cattle, and, with a few repairs, will last 18 months. When the fence is completed, sow thickly along it on the inside the seeds of the tree-cotton, and, as they grow, thin them out to 18 inches apart. In 18 months you will have a live fence that, with two rows of "varachchis" tied across at a very small expenditure, will keep out all cattle especially if you give notice in the villages that the owners of all cattle caught in the estate *without a cross pole* round their necks will be fined heavily. I am sure from my experience of lowcountry life that there is more ill-feeling bred between estate-managers and villagers through cattle trespass, than from all other causes combined, and, if this could avoided there would be very little stealing from estates. This is my experience.

Enemies of the Cocoa Tree.—Of these, there are only two that we know at present, and neither is very serious. On of individual trees scattered over the estate, the pods are seen to be spotted black, and, according to the virulence of the attack, the pods are either stunted in growth or killed—trees attacked one year may be quite free of it the next. Those most competent to judge say it is due to an insect. I am watching it carefully, but have not yet succeeded in discovering this insect, and I have my doubts about it; yet the way that only a tree here and there is attacked looks very much as if it were. The other enemy I believe to be a *fungus*, though this has also to be established; it attacks the young tips of the branches, destroying them, and often the branch itself for a foot or two back. The tree, however, almost immediately throws out fresh shoots, and, in a month's time, it would be not known that anything had been wrong. I have occasionally seen a second attack follow. This disease is more common when the trees are young, and rare I believe as they grow older.—W. JARDINE.

THE INDIARUBBER TREE is doing well in the Northern Territory of Australia. It is likely that the product will soon become an article of export.—*Planter and Farmer.*

CEYLON PLANTERS IN NORTHERN INDIA: THE OTHER SIDE.—A former Ceylon planter, now on a tea estate in Assam, writes to a friend in Ceylon as follows:—"There is no doubt Mr. ——— knows of plenty of men (bachelors) who are willing to clear out of Ceylon. The sooner they do so and come out here the better for their chances of ever being able to return to England with anything in their pockets. Salaries are very good out here. It seems a common thing for men of 3 and 4 years' standing to draw their R300 to R400 a month, and men with Ceylon experiences have a great pull over men straight out from England. Messrs. Findlay Muir & Co. [? Calcutta] are the best men to apply to, as they are buying up estates and going in for jungle very extensively, and are hard up for men, but a 3 years' agreement must be signed —nothing is done out here without a stamped agreement: not that they keep you to the salaries mentioned, as should one get on well, the agreement may be cut every year and a better one given. Things are carried on very differently by Calcutta, to the measly way Colombo agents treat one."

TRIAL OF PATENT MACHINERY FOR PREPARING TEA.—Yesterday Messrs. John Greig & Co., engineers and millwrights, exhibited in operation at their works in Regent Road, Edinburgh, a new invention in machinery for preparing tea for shipment. The machines are to be sent to the International Exhibition to be held at Calcutta in December next. There are four machines used in the process—namely, a cyclone withering and drying machine, a cutting machine, a sifting machine, and a link and lever rolling machine. The first-named is in the form of a drum, into which the leaves are placed to be dried. It revolves rapidly, and has four fans in the centre. Heat is generated by a globulose pipe tea drying stove. This stove is open at the side to allow air to get into the pipes, and on their being heated at the top a draught is immediately created. A cast-iron box or air chamber, in which there are four trays, is the tea drier, but the pipes go through the top and draw off the heated air again to supply the cyclone machine. It is claimed that by the system adopted the withering and drying process is carried on equally without firing the tea. Cabbage leaves were used yesterday by way of experiment, and a quantity having been dried thoroughly in about six minutes were removed to the cutting machine, which cuts the leaves into small square pieces of suitable length to roll up for the market, and very greatly diminishes the waste from broken tea and dust. A quantity of leaves were next put into a bag, and taken to the rolling machine. The machine, it is claimed, is much less intricate than any previously used. By means of a roller, with an indented surface, revolving in the centre of the machine, and acted upon by a lever, the bag is made to pass round with the cylinder. A clever lever arrangement provides for a heavy or light pressure being applied according to the nature of the leaf. Another apparatus, called a self-delivering, horizontal, circular-motion sifting machine, is stated to be entirely new in construction. Four sieves are placed on the machine while in motion. The top sieve retains the red leaf which is too old for use; in the second, the Souchong, or cheapest tea to be had here, is retained; while the third holds the Pekoe-Souchong, and the fourth the pure Pekoe. The dust from the tea falls below the machine. Such machinery, it is submitted, would save manual labour, and in foggy climates, such as Assam, where the leaves are often wasted through exposure, would render the tea-grower independent of variations in the weather. Mr. Greig has effected a number of minor improvements in the construction of the machines. In the drying machine, for example, the oil used is liable to get upon the tea and spoil the flavour, and to do away with the use of oil the heated pipe is made to run in asbestos plumbago packing. The whole cost of the apparatus is about £175. Several gentlemen engaged in the tea trade in India expressed themselves as highly pleased with the experiments.—*Scotsman*, Sept. 20th.

Correspondence.

To the Editor of the Ceylon Observer.

LONDON DOCK CHARGES ON TEA.

London, 20th September 1883.

SIR,—In your issue of 7th August you analyze an account sales of 128 half-chests tea and open up sundry large and important questions on the burthens tea has to bear, such as export duty, the profits of middle-men, British import duty, &c., but especially London docks charges.

It may be of interest to you and your readers to have particulars of the London dockcharges in greater detail than could appear in an account sales. I will confine my remarks to them.

The charges vary with the size of the chests that have to be handled and on the work they require; on such a parcel as you allude to they would be somewhat as follows:—

Management rate 7 at 2s 7d, 121 at 2s 1d	£13	10	2
Bulking, taring, refilling and weighing 7 at 1s 11d, 121 at 1s 5d	9	4	10
Rent for 16 weeks (commuted to 11) ...	2	18	8
25 weight notes at $2\frac{1}{2}$d	0	5	3
	25	18	11
Less discount 35 per cent	9	1	7
	£16	17	4
Paid for warrant stamps 6s 3d, Customs re-weighing 5s 8d	0	11	11
	£17	9	3

The "Management Rate" comprizes:—Landing and wharfage at the docks where the steamers arrive and discharge (now always down the river), conveyance under bond to up-town warehouses, housing in the warehouses, sorting, examining for damage, weighing, furnishing landing accounts and warrants, coopering, laying down for inspection, sampling, putting on show for public sale and attendance while on show, nailing up, repiling and delivery by land.

Considering the work done and the time covered, the rates are not more than fairly remunerative. The keen competition that there always is between the various docks and wharfs will prevent overcharge on any staple article. Some of the holders of dock stock stoutly maintain that these rates do not pay, and some that the entire discount must be abolished before they are really remunerative. But competition will probably keep charges on tea on a scale much as they are now, for some time at all events.

Bulking is the cause of the charges on Ceylon tea figuring for such a large amount at present, but the operation is not performed except on the written request of the importer or selling broker after inspection of the tea.

If Indian and Ceylon teas were sent over of regular quality so as to render bulking on this side unnecessary, and the chests of even weight so that average tares could be got as in the case of China tea, there would be no need for the process and the docks charges would be 35 per cent less. This should not be beyond the powers of Ceylon men.—Yours very obediently, HANDFORD.

THE LONDON DOCK CHARGES ON TEA.

A home correspondent writes:—Referring to our conversation the other day regarding the London charges on Indian and Ceylon tea, I have written to two parties on the subject and the following is the substance of the replies received:—

From Messrs. Layton & Co., 17, Mincing Lane.

"We have the pleasure to enclose a *pro forma* account sales for an invoice of tea shewing the total London charges. Provided the teas have been *carefully* bulked at the Garden, the tares being even (which is essential), the bulking operations here might be dispensed with, as is already the case with a few of the Indian Companies, thus reducing the dock rates by one-third."

E. E.

London, March 1883. (Signed) LAYTON & CO.

From H. R. Rutherford, Meadowbank, Polmont.

"The charges amounting to 20 per cent made in London on Ceylon tea is indeed blackmail, and those who have been called on to pay at this rate must have fallen into bad hands. The charges, including freight, on our shipments come to about 12 per cent on the sale amount. We hope in the course of time to get this reduced."

With regard to taring and bulking, a remark or two may not be out of place. When a parcel of tea is offered for sale, let it be a dozen chests or 500, if all of the same description, quality, value, mark, from the same garden, and by the same ship, it is essential to its selling to the best advantage that the tare allowed should be the same for the whole. This can only be secured by care at packing, when it ought to be ascertained that the packages are all alike in weight. Should there be any irregularity when tested by the customs officers the result simply is that a greater number of boxes are emptied (if not all) than would otherwise be necessary, so that the property suffers and charges are multiplied. It is also desirable, that, in addition to being of the same weight, the packages should be of the same capacity, so that the gross may vary as little as possible. In these respects, the Chinese are very careful, and I have taken the weight of hundreds of packages at one time which hardly varied more than an ounce or two and did not differ at all in tare.

Bulking is adopted to save after dispute between buyer and seller, as tea is always sold by sample taken from a few packages out of the parcel. Except for this, the process is useless, and it is always detrimental, as the tea, with every care, gets much broken in returning it to the package. It is therefore clearly the interest of the planter to bulk his tea in his own premises before packing, and to do this carefully and conscientiously so that every chest of the same mark shall be exactly the same as every other chest of the same parcel. Were this done by all the Indian and Ceylon planters, and care taken to have as few trifling shades of quality as possible, the expensive and troublesome process of bulking in the home bonded warehouses would immediately be abandoned, and a considerable percentage would drop from the charges.

PRACTICAL TEA CULTIVATION.

Windblownridge Estate, 6th Oct. 1883.

DEAR MR. EDITOR,—Whilst so much correspondence as to treatment of tea is going on, perhaps you may have noticed that not one out of our three public tea-men have touched on the following point in their addresses :—After pruning, either from leaving too fine wood or from raw cold winds, the tea trees throw out their new shoots, containing only two and sometimes three leaves in both instances, the end one being bangy, and then the shoot or flush seems to stop. Would you kindly tell me with your experience if one leaf should be plucked and then the new flush be allowed to grow some six inches or so before again plucking, or should the bangy be left ? and in that case, the trees being insufficiently clothed with foliage, would they with their rising sap push forth the bangy flush, or would it remain stationary ?—Yours truly, BEGINNER.

THE GERMINATION OF TEA SEED.

12th October 1883.

DEAR SIR,—As great quantities of Indian tea seed will be shortly imported to the island, any method of securing a large proportion of germed seeds will perhaps be appreciated. The one described below gives good results, if carefully tried. On opening the imported cases germed seeds are often found, and, if far advanced in growth, careful treatment is required in separating them from the mass of entangled rootlets, and special attention in putting them down in the beds to secure a straight taproot. The soil of the beds for these should be a little stiff and firm, or the result will be seedlings and plants with long and slender tap roots of an inconvenient length to plant out. The ungermed seeds in the case should be simply aired in an open room or shed for a few hours before being put into the germing beds. In making these beds, select an open dry and flat plot of ground where the soil is firm, or, if not, it should be well stamped and hardened ; measure out a strip of 3 feet in width by 10 feet or more in length. Remove the soil within this space to a depth of 8 to 10 inches, taking care that the sides of the shallow pit or sunk beds are perpendicular and well battened to prevent them sliding or falling in. See that the bottom of the pit is level and hard. Then sprinkle a layer quarter; an inch thick of old lime (coral lime is the best),* and then a layer of fine dry grass or straw or mana (stalkless). Then place a layer of two inches of the compost prepared as per direction below, then alternately a layer of seeds and an inch of compost, the last layer being of the latter and at least two inches in thickness. The seeds should be laid close, but not touching each other. Water the whole, sufficiently to damp but not to drench the bed.

Put up over the bed a light low shed with a double roof or covering—portable one preferable. Drain two feet off the bed on all sides to carry off in wet weather the wash from the roof and to prevent the bed being flushed or made excessively damp. At the end of the first week, cover the bed in the evenings with damp mats or gunnies, after watering the beds slightly if it is needed. Remove the gunnies or mats every morning. The heat emanating from the soil at night is peculiarly necessary to secure successful germination of all seeds, and the soil should be damp but friable. The best mixture or compost for the beds is made up of one of old (or, if new, well washed) coir refuse 3 baskets; of *friable* soil (or, in lieu, stiff soil and mould mixed) 2 baskets; clean sand, not too fine, 1 basket. Where the coir refuse cannot be got, then use fine paddy husk, or *old* sawdust. After the third week, gently remove a strip of the compost and seeds along the width of the bed, taking care not to disturb the lime and straw-covering over the lime. Then proceed with small sticks to loosen gently the mass, picking out the germed seeds. These should at once be put in shaded beds timely prepared. The ungermed seeds must be removed and replaced as before. The process of removing can be repeated weekly in dry weather and every day in wet weather till the eighth week, when the balance of ungermed seed can be tested in the following way. Put these into tub a of water for half-an-hour, and those that sink can be tried again, being allowed to remain for about two weeks or more in the germing bed. By the use of a portable roof, in case of very wet weather especially in high elevations, the beds can be occassionally exposed to the sun. W. PROWETT FERDINANDS.

* I read an extract in a recent number of your journal advising the use of lime to germinate seeds—probably by *mixing* it with soil is meant. If so, the quantity used must be very, very small, and that of very old lime. I would not, however, run the risk of losing seed by mixing it with soil or compost for seed. The use of it as advised by me is to generate heat, and keep off sour damp, also as a partial preventitive against wire and other earth worms coming up and disturbing and sometimes injuring the compost and seed.

CEARA RUBBER EXPERIMENTS.

Peradeniya, 13th Oct., 1883.

DEAR SIR,—Kindly give in an early issue my most emphatic denial that the sample sent to you was manufactured stuff from Europe. It is pure Ceará rubber taken from trees on Peradeniya estate and treated by a new process. If I have got so near the manufactured article as to deceive the savants of Colombo, I am pleased with the result. I have taken your "tip" about the smoking process, but have improved upon it, and that was the first sample. Another experiment was made yesterday with the same process, with, I think, even better results.—Your faithfully,

H. A. GILLIAT.

COFFEE FUNGUS: MESSRS. STORCK AND SCHROTTKY AND THEIR CARBOLIC CURE.

Claverton, Dikoya, 13th Oct. 1883.

DEAR SIR,—I see by your paper of the 10th instant, that Mr. Storck "begs to differ" with the gentlemen who signed the report on the carbolic experiments on Claverton, and I therefore venture to offer a few comments on his letter which may or may not throw light on the matter, according as people are disposed to consider the carbolic treatment seriously or to regard it as moonshine. When Mr. Storck cavils at our statement that "the apparent results of the experiments must still be very much matter of opinion," he appears to overlook the fact that the report was the work of a committee. On the files of the Association are five more or less lengthy reports from individual members of that committee differing very widely on more than one point, and I think, if Mr. Storck had had the task set him, which was given me, of compounding these different views, that he too would have arrived at the conclusion that the results of the experiments were very much a matter of opinion.

The one point, however, on which we were all unanimous was, that, as a practical cure to be recommended to the struggling planter, the *Schrottky-cum-Storck* system fell short of our requirements. As this opinion was arrived at on very various grounds, I venture to give my own reasons for endorsing it. I may say, to start with, that I have perfect faith in the dusting process of Mr. Schrottky as a means of destroying the disease-spores in their atmospheric stage, and that, given favourable weather, I believe that it does this so effectually as to stamp out the disease for a very considerable period. The inability of the *fungus* to again make head in the treated coffee, as compared with other parts of the estate, was still most clearly evidenced in this season's pruning, or six months after the experiments had been concluded, but whether the evaporation of the acid from coconut-shells had had at all the same effect as the original dusting I more than doubt. The staving-off of the most severe attack of leaf-disease last season must at any rate be credited to the dusting, and, if the evaporization process which supplemented it kept off leaf-disease also, it is equally certain that nothing was lost by its discontinuance. Having commenced the treatment with no faith whatever in the dusting, but some hopes from the evaporization, I arrived ultimately at a conclusion the exact converse of my expectations and, indeed, of all that Mr. Schrottky had himself led me to anticipate. Had his other experiments been as fortunate as regards weather, or possibly some unknown luck in hitting off the atmosphere at the right period, which seems to have attended them here, or had he had as much patience as he has had pluck in initiating, he might by this time have proved his case much more effectually than I, who have not the same interest in the matter, can pretend to do.

Mr. Storck is much more near the truth than he thinks when he asks "What do the planters of Ceylon really want—*magic*?" That happens to be precisely what they *do* want, since nothing short of the immediate restoration of coffee can save their drooping fortunes, and, as Mr. Storck shows, it is not in nature that the effects of a disease that has been preying on coffee for a number of years should be shaken off in a single season. The experiment on Claverton convinced me, and I am not alone in the opinion, that carbolic acid will cure leaf-disease, and, in subscribing to the views of the Committee generally, I did so, not because I doubted this, but because I doubt if coffee is worth the cure. The history of its cultivation here and elsewhere has proved abundantly how difficult it has always been to restore to vigour fields of coffee that have once really gone back. Who shall say after how many years of keeping the pest under, after how many rupees spent per acre in manuring and pruning, may we expect our best fields to return to their old form?

Those who first began searching for a cure for leaf-disease did not count on this lost ground to be made up, and it is only by watching such experiments as those here that a distinction can reliably be drawn between the fall of immature leaf from inherent weakness (the result no doubt of a continuance of disease) and that produced by the sporing of leaf-disease itself. Such a distinction it is very difficult for any not working on the spot to admit, the only outward and visible sign to outsiders being the fact that *leaf has fallen*. I am quite satisfied of two things, (1) that dusting with carbolic can be made to stamp out sporing disease for a very considerable period, and (2) that the *fungus* itself is principally local. This conclusion I have arrived at, from carefully watching the coffee since the commencement of the experiment. A very severe attack of sporing leaf-disease, which set in generally in May 1882, completely failed to make a sign in the treated coffee, and that, too, over patches that had always been most susceptible to it. The line of demarkation between the treated and untreated coffee became at once most distinct and could not in my opinion be attributed to *pruning* alone for the following reasons. A cropping face of coffee, through which Mr. Schrottky's boundary line ran, was, shortly after the outbreak of the disease in June, completely smothered with blotches of sporing *fungus* to within a tree or two of the boundary, while, at the same distance below, the *fungus* was simply not to be seen, and no coffee could have possibly looked finer.

The previous year, 1881, the whole of this face, treated and untreated alike, had been worse diseased than any part of the estate, and, having borne but little that year and been manured and knife-handled in September, the pruning in this instance was far too light to lay claim to any such result. Unfortunately, the committee had only inspected the 100 acres a week or so before this became apparent and could not again be brought together. But, again, although pruning undoubtedly reduces the spread of the *fungus* to an enormous extent by taking off the wood most susceptible to it, it has by no means succeeded here in preserving the leaves left on from attack, nor in preventing such vigorous young wood, as was subsequently produced, from developing the spores badly at an early stage. Yet these have been the results actually attained on the *treated* acreage. In support again of my belief that it is local, I would remind you of the many years the *fungus* took to establish itself in these upper districts after much of the finest coffee lower down had been destroyed. I think, however, you will admit with us, that the Dikoya report went quite as far in approval of the carbolic treatment as under the circumstances of the country was justifiable, and that our views of practical cure coincided much more with the feeling and wants of planters than Mr. Storck's do. Indeed, his explanations and criticisms only prove how little he can do for us. The preservation of the staple industry of the island has passed imperceptibly beyond the power and the purses of the planting community, and, as it is the part of a non-paternal Government to deplore rather than remedy the falling revenue, it is idle for Mr. Storck to look for any profitable result for his enterprize here. He ought to know by this time that the Ceylon public has long ceased to interest itself in his vaporizations or "evaporization" either.—Yours truly,

E. H. SKRINE.

P. S.—Permit me to correct the impression conveyed in your letter of 18th inst., that Mr. Schrottky personally supervized his experiments here. He never paid me more than one brief visit, to arrange about sending up his powders. Since this, I have neither seen nor heard anything of him, though from the expressions he let fall then I inferred that he had spent a good deal of private capital in the interests of Ceylon and in return thought that he was getting more kicks than halfpence. E. H. S.

[In saying that Mr. Schrottky had the opportunity of personally watching his experiments, we had those in Dumbara specially in view.—Ed.]

ABANDONED ESTATES *VS.* JUNGLE FOR TEA.

Colombo, 15th Oct. 1883.

Sir,—I find some one advertizing in your columns for an abandoned coffee estate with the view of converting it into a tea plantation. Now, I would strongly advise this person, before committing himself to such a purchase, to travel down to Galle and examine for himself the thousands of acres of Crown land, within a radius of 10 miles from the town, available for planting purposes, at the upset price of R10 per acre. The land is hilly rather than mountainous, and is well-wooded, and roaded to a certain extent. Plenty of labour can be had from the neighbouring villages; the climate is healthy for Europeans, and suitable for tea and other products; and its close proximity to the town of Galle gives one the command of supplies, as well as an occasional run into town on business or pleasure.

Anyone wishing to judge for himself should visit Mr. Simon Perera's Liberian coffee estate of 75 acres in bearing, situated just 4 miles from town, where the trees are loaded with fruit and must yield at least one ton per acre. Here tea and cocoa have also been tried on a small scale and with success. Then, there is the Citrus estate which was sold for a few hundred pounds, and the present proprietors of it will not part with it for as many thousands, since they tried *tea* cultivation on it and saw its results.

Travelling to and from Galle is now *very cheap*, and the Government Agent there will no doubt be ready to give every information required about Crown land available for sale.—Yours truly, X. X.

CONTAGIOUS DISEASES IN PLANTS.

DEAR SIR,—Mr. G. F. Halliley has thrown out a challenge to the world in your issue of 2nd instant, on the subject of contagious diseases in plants, and, if you will permit me, I shall point out some apparent errors in his argument. He first alludes to smut, mildew and rust, as being one and the same thing. Now, smut is caused by a *fungus* called *Uredo segetum*, mildew by another called *Puccinia graminis*, and rust by a third *Trichobasis rubigo vera*. These three are fairly confined to wheats and grasses. But there are other forms of *fungi* like smut peculiar to other species of plant, life, such as varieties of *Ustilago*, *Tilletia*, *&c.*, and other mildews having their own special prey, different varieties of *Puccinia*, *Cystopus*, *Erysiphe*, &c., which are only too numerous.

Balfour and Brown, both authors of manuals of botany, state that diseases which are due to parasitic *fungi* are propagated by contagion. The mould that appears on boots is *Aspergillus glaucus* and sometimes a *Penicillium*. These two are of the *Hyphomycetes* order, whilst the others mentioned above that attack plant life are of the *Coniomycetes* order.

Next, as to the probability of all other plants and trees on an estate getting *Hemileia vastatrix* if it was contagious. The human race and the different orders of animals have their special contagious diseases, though occasionally we hear of one order of mammalia contracting a disease from another.

The same holds good with plants. Different orders have different diseases, and occasionally we hear of the detection of one order transmitting a disease to another. That the difference between orders of plants is as great as that which exists between orders of animals may be deduced by the difficulty, indeed almost impossibility, to produce true hybrids in the proper sense of the term.—Yours faithfully, SPORE.

BEES AND LEAF-DISEASE.

SIR,—Now, as regards bees, it 's many a day since I saw one; and if tea is to be cultivated high and low, above and below the coffee zone of elevation, the part of the country where they are most wanted will soon be *entirely* cleared of them. This, undoubtedly, is a misfortune for coffee, and it is difficult to see how it can be avoided, unless planters take the Bishop's advice to his poor parishoners—to "*keep bees, keep bees.*" A planter was saying, the other day, he remembered hearing dozens of swarms in a day rush like a high-wind over his head many a day, years ago in Badulla, and *that after* the leaf-disease had fixed itself on the Madulsima coffee. It 's in vain to look for the cause or origin of leaf-disease in any of these things. Neither absence of bees, extended cultivation, deterioration of seed, manure, nor any other *guess* that has been made, had anything to do with its advent. It appeared first on young (three-year-old) vigorous coffee, in a new district where there was, *at the time*, far more standing forest than coffee fields: in fact, the estates were merely small clearings in vast tracts of surrounding forests, full of bees then, and for some years after.* Not only was the coffee in isolated patches, but the district itself was severed from all other districts by miles of country not under any sort of cultivation. The disease revelled for a whole year in that place, *before it found its way into the part of the country where the conditions were different.* This disposes of the question of its origin. Its attacks have been singularly benign, and it is a question whether it ever directly killed a single tree. Indirectly to its operation must be attributed most if not all our troubles—there can be no doubt. The leaves fell just when the trees wanted them most; the vigor of the roots then gave way; and Mr. Grub, who had always existed before, found in this to him new condition of the roots a more digestible food, upon which he at once fastened, fattened and throve. They came funk on the part of the planter, and funk on the part of the capitalist; new products and neglected cultivation followed, and it 's a matter of surprise that the coffee on a vast number of estates is alive at all. At present the condition of the roots is the most alarming symptom, and that not from grub so much as from "incipient defunction" in response to the condition of the parts above ground. As long as it is a scientific truth that bees are good and necessary fertilizers, so long must their absence from our blossoming fields be deplored. Other insects and the wind and self-fertilization effect wonders, as witness the many patches of heavy-bearing trees in the almost entire absence of bees; still their re-entry on the scene, in their old myriads, would be a great blessing. Assuredly, the *cause* of our troubles is *above* ground: the *effect* unfortunately (which becomes a new and more alarming cause) is now *below* ground. Where the roots have died back, it is useless manuring between every four trees, or where the roots cannot now reach it, which is the case chiefly in neglected coffee. It gives one the blues to read the report of the Dimbula Committee, and I question if its publicity will do any good. It only serves to show there is no mystery, in coffee cultivation, and and by its contradictions, to prove that each must find out for himself what is best for is *pakkam.*

AN OLD COFFEE STUMP.

* *N. B.*—ED.

THOMPSON'S PATENT TEA ROLLING MACHINE: THE "CHALLENGE"—is advertised in the *Indian Tea Gazette*, and there is a heading for "prices in Calcutta," but, although Messrs. J. Binning & Co., as agents, are prepared to register orders, no prices are given. There are many testimonials, one of which we quote: —"The facility with which your small machine makes up with a good twist about 12 seers of very ordinary leaf in 20 minutes, with only two men to work it, leads me to believe that you have hit on what will probably turn out to be the best principle for a rolling machine that has yet been brought out. I fully expect your machine to be a success,—one great recommendation being its low price.—H. W. CRAIGIE, *Manager*, Gielle Tea Company, Limited."—Not only are no prices given, but the testimonials are undated.

ANY PLOUGH which enables the Indian agriculturist to more readily twist the cow's tail possesses obvious advantages, and we therefore observe without surprise, from a Note Mr. E. C. Buck publishes, that the Kaisar or Swedish single-stilt being far ahead of its rivals in this respect has come into very general use. What the cow thinks must of course be mere matter of conjecture; but we fancy that in Burma where Hodge treats his cattle to the gentler guidance of rope-reins or a long bamboo that animal has rather a pull over the ox of British India. The Behea sugar-mill is also spoken of by Mr. Buck as *the* great success of agricultural Bengal where its use is now widespread and well established; while in Bombay a light winnower for cleaning corn and pulses is gladly taken by the natives on loan. In Bombay however we have no doubt the native would cheerfully accept anything at all on these terms from a plough to a piano; but whether he is a punctual restorer of goods lent is not set forth by Mr. Buck.—*Pioneer*, October 1st.

INDIA:—CROP AND WEATHER REPORT.

FOR THE WEEK ENDING THE 9TH OCTOBER 1883.

General Remarks.—Rain in fair quantity fell during the past week throughout the Madras Presidency and Mysore, which has revived the dry crops; but more is still needed in some parts. In the Bombay Presidency excessive rain has caused injury in three districts of the Deccan, while in others more rain would be beneficial. In Guzerat the crops are in good condition, but in Sind the river continues low. Some damage has also been done by heavy rain in Berar, but prospects there and in Hyderabad remain favourable. Good rain has fallen in Marwar, and lighter showers in other parts of Rajputana and the Central India States. The crops in both Rajputana and Central India promise fair, but rain is needed in Ulwar.

In Burma and Assam rice prospects are on the whole good, though in the former province the deficient rainfall of the season has injured the crop in three districts. Floods have also caused some destruction.

In Bengal, the Central Provinces, North-Western Provinces and Oudh, and the Punjab there has been little or no rain during the week under report, and the late rice crop of Bengal is in a precarious state.

Harvesting of the kharif is going on in most parts of India, and ploughing and sowing for the rabi are also in general progress, though retarded in Bengal and Northern India by the early cessation of the rains. The outturn of the kharif is not yet known, but will probably be below average, especially in North-Western India.

The condition of cattle has improved, but mild cattle-disease still prevails.

Except for prevalence of autumnal fever the public health is fair.

Prices show a tendency to rise in Bengal owing to the unseasonable weather. Elsewhere they are either stationary or falling.

Madras.—Prospects good.

Assam (Sylhet.)—State and prospect of crops good. Public health also good.

Mysore and Coorg.—Rain has fallen generally all over the Provinces. Standing crops improved. Prospects favourable. Public health good. No material change in prices.

"LONDON TEA COMPANIES."

Under this heading, Mr. Ernest Tye of 14, St. Mary Axe, London, has published a table, arranged in order of area of cultivation, giving the results of the working of the principal Indian (though he calls them London) Tea Companies during 1882. We reprint the table in the next column, and meantime we indicate a few of the chief results. There are fifteen Companies detailed, with a total capital of £1,823,273; the total area cultivated being 32,667 acres; total crop 10,088,083 lb.; average cost of tea 1s per lb.; average value 1s 1d; average dividend 3½ per cent. No fewer than five Companies with a total capital of £847,863, yielded no dividend to their shareholders for the past year; these are the Land Motgage Bank, Upper and Lower Assam Companies, Mungledye and Luckimpore Companies. But to counterbalance these, we have 8, 9 and 10 per cent dividends, respectively, from the Jorehaut, Brahmaputra and the "Assam" Companies. The Borelli Company also yielded 8 per cent; while two more earned 6, two earned 5, and two earned 2 per cent. The lowest cost of tea was "tenpence" for the Dejoo and Borelli Companies—the former, however, only giving 2 per cent dividend. The highest average price obtained was for the "Scottish Assam" Company's teas is 3¾d, but these cost 1s 3d and the dividend was only 2 per cent. The highest average yield of tea was 534 lb. per acre from 1,466 acres of the Doom Dooma Company making 783,154 lb. costing 10¼d, selling at 1s (averages), the dividend being 5 per cent on a capital of £113,500. These figures will give Ceylon tea planters some idea the working of the great Indian Tea Companies. We feel sure that a better and steadier return is to be got for capital invested in tea in Ceylon.

LONDON TEA COMPANIES

(Arranged in order of Area of Cultivation).

RESULTS OF WORKING IN 1882.

Name.	Capital Paid up. £	Acreage of Cultivation.	Crop of 1882. lb.	Cost of Tea per lb. s. d.	Value of Tea per lb. s. d.	Dividend on 1882 Crop.
Assan Company	187,160	7,435	2,349,000	1 0 7/16	1 1 7/16	10 per cent.

14th September, 1883. ERNEST TYE, 14 St. Mary Axe, E.C.

* N.B.—These five Companies, with a total capital of £847,863, return no dividend to their Shareholders for the past year.

RUBBER IN HAPUTALE.—Mr. Westland is good enough to inform us:—I have resumed tapping for rubber. When at Rosebury last week, I saw four cakes weighing ½ lb. each of wet rubber; when they are dry, shall send them to you for inspections. I have ordered a cutter and cups from Gilliat and shall let you know result. Meantime, Wall's pricker is being used, and the wound heals up very quickly We have much yet to learn about rubber before freely ventilating our experiences. [But the ventilation helps other experimenters, and in the multitude of operators there is safety.—ED.]

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From LEWIS & PEAT's London Price Current, September 27th, 1883.)

IMPORTED FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White ...	Slightly softish to good hard bright ...	£7 a £8 10s
Yellow ...	Do. drossy & dark ditto...	£5 a £5 15s

MR. HAY ON TEA CULTIVATION AND MANUFACTURE IN CEYLON.

Mr. Owen complained (metaphorically) that Mr. Armstrong had stolen his thunder (just as the ancients stole the best sayings of the moderns); and Mr. Hay represented his predecessors as having exhausted the lightning. The latest lecturer on tea, however, has given us what Goethe desiderated :—"More light." Light is the emblem not merely of knowledge but of cheerfulness, and it is pleasant to hear Mr. Hay's refrain :—"I could not have believed, when I entered this island five years ago, that tea would have made such gigantic strides, in spite of hard times and want of cash." That was the burden of his song to the planters of Dimbula, while amongst the inspiriting notes were such utterances as those which dwelt on the greatly superior advantages of Ceylon over India in a climate which renders proper fermentation almost always a very easy, instead of a very difficult, operation. Even of our heaviest rainfall Mr. Hay makes light, a different tune to that which our good friend Mr. Baker, of the Assam Company, sang when he visited us some ten years back and told us "in mournful numbers" that positive and negative reasons seemed to be against the success of tea in Ceylon: too much moisture and no winter. With well-built and well-furnished tea-houses we can remedy rain and a moist atmosphere; while by judicious and well-timed pruning we can make our own winter, if we find our tea bushes need rest from perennial flushing. Mr. Hay's opinions, founded on actual observation, confirm those of Mr. Armstrong: from tea estates with such steep features as are common in Dimbula, an average yield of 400 lb. per acre may fairly be expected, to be increased indefinitely by high cultivation and manuring. Mr. Halliley must not waken the mountain echoes with a song of triumph as if Mr. Hay had described weeds as beneficial. What he has sai just amounts to this :—"Keep your tea perfectly free from weeds *if you can*; but if labour is scarce and dear and it becomes a question between gathering flush and removing weeds from between the rows of tea bushes let weeds alone for a convenient season and gather the flush." We have always, in the discussion of this question, insisted on the fact of the superior soil of the Indian plantations rendering the simultaneous growth of tea and weeds possible, and Mr. Hay's evident belief that what can be done in India is possible in Ceylon is the greatest possible compliment he could pay to our soil. On Abbotsford, to which Mr. Hay several times referred, the experiment of growing both weeds and tea on the same land has not, as yet, been tried, and we confess we should be sorry to see it tried except on a small experimental scale. It does not seem, however, as if the weeding process need be so careful or so costly in the case of tea as in that of coffee: we mean that it may answer to fork weeds between the rows periodically *into the soil*, instead of incessantly removing them from the soil by the hand. We notice that Colonel Money, with his life-long experience, insists on clean weeding as strongly as he mistakenly does on flat land and an unhealthy climate as essential to successful tea culture. When Col. Money has had the opportunity of seeing the mountain plantations of Ceylon (lat. 7° north, instead of 27° to 32°), he will revise his opinions as to high altitudes and steep (we do not speak of precipitous) features; but we do not suppose anything in Ceylon would render him more tolerant of weeds than he now is. As regards indigenous Assam tea growing well in Dimbula, although not flushing readily, our experience is, that, while first-class hybrid seed obtained from the Assam Company resulted in flourishing plants, indigenous seed, twice obtained at three times the cost of the hybrid, made comparatively slow and unsatisfactory growth. On the other hand, the statement made by one of the speakers at the meeting as to the tendency of the China kind, after a few flushes, to become "bhanji," takes us by surprize. To this day the China plant is that cultivated on the vast majority of the Darjiling hill plantations, the teas of which top the market. We have never before heard this special tendency to "bhanjiness" advanced against the China kinds as grown in India, though we *have* heard of yield considerably less in quantity than that obtained from good jat Assam hybrid. Mr. Hay having had Darjiling experience may be able to say if in that district the special tendency of China tea to become *hard* was a received doctrine? There can be no question, however, that best quality Assam hybrid is the best to cultivate on the higher estates in Ceylon, although "indigenous" may be preferable at altitudes from 2,500 feet downwards.

We have no doubt the very adverse opinion given by Mr. Hay of Jackson's drier (30 per cent less work than the Sirocco with an expenditure of fuel 50 per cent greater!) will attract the immediate attention of Messrs. John Walker & Co., the local agents for Mr. Jackson, and of Mr. Jackson himself. In our own case Jackson's drier was recommended to us as superior to Davidson's Sirocco, and there can be no question that at Abbotsford it has done very good work. At what comparative expenditure of wood fuel is a question to which our attention has not been directed, but we have no doubt that now, Mr. A. M. Ferguson, junior, will send full details for publication. We should be glad also to hear from any other planters who have Jackson's drier in use. The fuel question will, of course, become increasingly important as dead and living timber on estates disappears.

It will be seen that in the case of locally grown tea seed Mr. Hay prefers that from bushes specially devoted to seed-bearing.

For planting in coffee 5 by 3 is no doubt a good distance for tea.

The alternative put to Mr. Hay about deciding, at the end of 18 months, to uproot coffee, if tea is to be finally adopted as the permanent cultivation, will be a sore one to many planters, and men like Mr. James Sinclair, who cannot understand why planters in Dimbula should take to planting tea, will look on the uprooters of coffee as insane. Coffee may and we hope will revive, but we can only say, in view of painful experience, we wish we had listened to the late Botanical Director Thwaites, when, at Nuwara Eliya, in 1870, he advised us personally to avoid coffee and plant tea. We all made light of the fungus in those days. But what its effects have been is forcibly proved by the fact that Mr. Wm. Smith of Mattakelly, who did more, perhaps, than any other planter, in liberally manuring coffee, should be the mover of the resolution fixing on *Hemileia vastatrix* as the main cause of the failure of coffee crops. The fact has long seemed to us so obvious, while we have quite recognized in addition the evil effects of grub and abnormal seasons, that we only wonder 7 should be found to vote against 8 on the subject. What Mr. Wm. Smith said about the immunity of tea on patanas from grub is the more striking in view of the frequent destruction by grub of cinchonas planted on pataunas. An enormous advantage of elevated estates in Ceylon is the slight extent to which young tea plants suffer from insect plagues, such as grubs, crickets, &c. The great—to us the conclusive—advantage of nurseries over planting or sowing "at stake" is the ease with which the young plants can be protected from grubs or rats when they do appear. The first nurseries put down on Abbotsford, now 9 years ago, were to some extent attacked by grubs, but even where plants were nipped off at their junction with the surface of the bed they soon sprang up again and ultimately became strong plants. Planting at stake at high elevations with abundant rainfall, in Ceylon, is a safer process than in most parts of India. But nurseries, which must in any case be adopted to provide supplies, are, in our opinion, decidedly preferable. Tea bushes occasionally die off, mainly from the poisonous roots of a forest tree, a symplocos, but we cannot recollect noticing one destroyed by grub.

Mr. Hay is so strong on the value of abundance of light for tea-houses, that it occurs to us to suggest whether conservatory glass, ground so as to moderate the light rays (and we suppose the heat rays also), might not, with advantage, be imported and used for tea-houses? A modified "Clerihew" seems to have found favour, but, as we understand the matter, tea leaves in withering require only gentle warmth and not the strong current of hot air forced through thick layers of damp coffee by Clerihew's original invention? The great improvement recently has been the enormous multiplication of horizontal space by means of layers of movable shelves. A combination of Clerihew and conservatory may probably be a still further improvement, care being taken to modify the heat; unless indeed Greig's withering machine is a success. We have no doubt a good many decisions as to machinery will be arrived at by planters and engineers who witness experiments at the Calcutta Exhibition. Liberal manuring ultimately will increase the yield of tea without by any means injuring its flavour, and this opens up a new prospect of really paying traffic to the section of the Uva railway when completed only to Nanuoya. We are confident that Sir Arthur Gordon will not be long in the island until he is convinced (by the representations of Sir John Douglas, as well as facts and figures supplied by planters and railway officers), that what with shooks of boxes and sheets of lead, with tons of manure and rice for coolies up and bulky boxes of tea down there will be traffic which will enable the railway so to answer the question "Will it pay?" as to leave no excuse for delay in pushing forward the work to Uva, the capability of which splendid district to grow tea profitably is, in our opinion, beyond question. Even Mr. James Sinclair will ere long acknowledge that tea has revived confidence in and the prosperity of the great Ceylon planting enterprize.

While the greater design of railway extension into Uva remains unfulfilled, we should think the Government might satisfy the demand that Diagama at the top of Dimbula, as well as Bogawantalawa, should be "connected with Horton Plains by road. We suppose "bridle road" is meant?

We take it that most planters will agree with Mr. Hay that it is desirable to have good holes made for tea, although in specially pervious soil dibbling with an alavanga may answer. In every respect tea plants will bear much rougher treatment in the climate of Ceylon than in that of Continental India.

What Mr. Hay says as to the superiority of large sized seeds agrees with experience in regard to "pedigree wheat" &c., but some readers will be surprized to learn that the sizes of seeds differ so much that a maund of 80 lb. weight may vary in number of seeds from 10,000 to 55,000. We suppose that, as a rule, of the 10,000 seeds, two-thirds would become plants: of the 55,000 about one-half. A fair average, it appears is 25,000 seeds (not plants) to a maund. Mr. Hay speaks of 43,000 plants from 2 maunds of freshly picked and planted seed, or 21,500 per maund. It seems to follow that only in very exceptional cases can more than 15,000 plants per maund be expected from imported seeds.

There is no fear of too much rainfall from our atmosphere, and we believe there is equally little fear of injury to tea plants from such an amount of limestone as is diffused in any hill soil in Ceylon. Tea was at an early stage in the enterprize grown beneath the limestone cliffs of Meddecumbera.

Mr. Hughes of Gallebodde, it will be seen, agrees with Messrs. Armstrong and Owen as to the large saving by machinery.

There is much else in Mr. Hay's remarks, especially his warning against overclose plucking, well worthy of attention, which we are sure they will receive.

Ceylon planters are fortunate in the virtual commencement of the enterprize to have available the accumulated experiences obtained in India and to be assured that circumstances of soil and climate as well as labour supplies and means of communication are so eminently favorable.

TEA CULTIVATION IN CEYLON.

A correspondent writes:—Though the Tea Essays contain much of interest and value, the abstract results were made public by you as long ago as November 1879, when you published some figures sent you. I think the memorandum appeared on 26th November. It was signed 'S.' I remember it with interest, because, though it might be much expanded, the statement still holds good." We repeat the statement referred to as of general interest just now. It will become our duty by-and-bye to select from our old files of the *Observer* such practical papers as ought to have a place in the *Tropical Agriculturist*, where they can at any time be readily referred to. "S."'s valuable notes were written at a time when "cinchona" was all the rage in Ceylon:—

The following remarks are offered by one who has had an interest in tea for nearly three years, and who has had opportunities of observing tea cultivation in India.

There can be no question that in the normal state of the tea market, tea cultivation pays most handsomely where the conditions are favourable for obtaining a good yield and for working economically. That these statements may not be considered too broad let it be understood that a good yield is 400lb. (5 maunds) per acre and that economical working is to grow this quantity for R50 per annum, and to pluck it, dry it, pack and deliver it on boardship at Colombo for 27½ cents per lb.

(N. B.—High cultivation such as manuring is not provided for. This of course must be made to pay for itself in additional yield, which no doubt it will where the cost of transport is not prohibitive.)

On this scale 400lb. of tea costs R160 or 40 cents per lb. delivered on boardship. Recent London account sales of Ceylon teas have shown the charges (with freight at 45s.) to be within 8 cents per lb. Let us allow 10 cents. The tea has then cost 50 cents per lb. delivered to the buyer, who in the present state of the market pays about 1s 4d sterling for it. At the exchange of 1s 9d per rupee (allowing for the 10 cents charges payable in sterling) this is worth 75 cents, which leaves a profit to the grower of 25 cents per lb. or R100 per acre. The estate may be supposed to have cost R300 per acre to bring into full bearing and we have the handsome return of 33 per cent on the capital.

The figures upon which the above calculations are based have been carefully computed either from the usual Indian tasks being worked out in Ceylon money or from known local rates, and if of sufficient public interest, any detail can be explained or verified. Superintendence at R15 per acre is provided, so if the planter manages his own estate he gets that as income as well.

The value of 1s 4d per lb in London is warranted by actual valuation and sales. An unsorted sample grown in the neighbourhood of Kitoolgalla and Yattiantotte (Yacdessa district) made by a native on R20 per month, the superintendent having no previous experience, was valued at 1s 3¾d. Windsor Forest Pekoe Souchong recently sold at 1s 4d. Two or three years ago such teas would have been well worth 1s 10d to 2s, and should the market recover, as it seems very probable it may, good estates will be worth R1,200 an acre.

The yield of 400 lb, owing to the youth of the enterprise, has not been so widely verified by the present writer as to render this calculation *perfectly* satisfactory, but planters may judge for themselves what may be done when they know that double and more than double that yield is often procured in India under favourable conditions (Some of our readers may probably have definite information as to yield per acre which we should be very glad to know). From observations which are now being made, there is reason to believe that the trees on an acre of coffee shed considerably more than 400 lb of dried leaf per annum, in addition to their yield of crop and husk.

The following table, which is calculated upon the basis above described, may be found useful: viz.,

A yield	of	300 lb.	per	acre	gives	R62·50	profit	per acre.
,,	,,	350	,,	,,	,,	,, 81·25	,,	,,

Colombo, 21st Nov. 1879. S.

With reference to the above notes, the figures given for cost of production and manufacture,—viz., 12½c per lb. to grow the tea, 27½c to pluck manufacture and ship it, and 10c to deliver it to London buyers,—though no more than *safe* at that time, may be modified under present conditions, in consequence of labour now being cheaper (it was then reckoned at 40c. per man) and weeding contracts lower, also because manufacture is better understood.

It is not too much to say now, that, with good management, a favourable situation for transport, and a yield of 400 lb. per acre, such a yield may be grown for 10c and manufactured and put on board ship at Colombo for even 20c or 22½c more, and so laid down in London for 40c or 42½c per lb. This, however, is not to be attained without effort. There must be skill, knowledge, diligence and prosperity. It may be fairly doubted whether it has yet been achieved with a garden of any considerable extent, but it is believed that it may be done.

Perhaps, for an ordinary Ceylon garden, with its vacancies (speaking of the tea now in bearing), 45c will be nearer the practical result than 40c, but this is simply to allow 12 per cent for waste and unforeseen contingencies. Be it understood, we are speaking merely of the work and upkeep. There is no provision here for plant, or renewals, or interest on capital and such necessary things.

As to *vacancies*, doubtless the older gardens have many, but now that the enterprise is well launched, this most important particular is sure to have attention, and people will not be content to cultivate a tenth or more of their fields yielding no return.

One word as to *machinery*. It is not a necessity, and it should therefore not be reckoned as "plant," as some recent authorities on tea have been understood to reckon it. In the writer's opinion, it should not be employed unless the saving in labour or fuel will pay for it in three years, or say in the time which it may be expected to endure. This is a very simple guide, and will be found correct, whereas if the contrary view is acted upon, and a third or so of the cost of machinery is not charged annually to manufacture, the apparent cost of works is misleading.

The foregoing calculations are for hand labour throughout, but there will be no great difference if machinery is used and duly charged to current expenditure. At the same time, machinery is often a great convenience and may save night-work, and, where labour cannot be concentrated in the required numbers (as in Assam), and when fuel is short it allows of a larger acreage being opened than would otherwise be practicable. Such gardens work at a disadvantage in this particular.

To construct now a similar table of returns to that attached to the notes of 1879, let us take gross average value at 1s 3d per lb., exchange at 1s 8d per rupee, cost of growing the tea at R30 per acre, and other expenses 35c per lb. then

A yield of	300	lb. gives	R 80	gross profit	per	acre
,,	350	,,	100	,,		,,
,,	400	,,	120	,,		,,
,,	450	,,	140	,,		,,
,,	500	,,	160	,,		,,

and so on, every additional 50 lb. yield increasing the profits by R20 per acre.

For every penny improvement on 1s 3d in the selling average, add R5 per 100 lb. yield. Thus, a yield of 400 lb. with selling average 1s 6d, returns R180 gross profit per acre, instead of R120 as above.

It will be seen that the assumed average is a penny per lb. lower, but the exchange is a penny per rupee more favourable now than in 1879. S.

Colombo, 22nd Oct. 1883.

TEA AND COFFEE IN DIMBULA.

(*Proceedings of the Dimbula Planters' Association.*)

16th October 1883.

The CHAIRMAN introduced Mr. C. A. Hay to the meeting, to whom they were much indebted for attending and undertaking to give them further information on tea cultivation.

Samples of tea manufactured on Abbotsford, Lonmay and Mayfield were tasted, the samples from the first-mentioned estate being pronounced the best.

Mr. HAY then read as follows:—

Mr. Chairman and Gentlemen,—I have much pleasure in attending this meeting today, and will try to answer the questions you have placed before me, with regard to the cultivation of tea in Dimbula.

The first is:—

I.—What class of tea is best suited to this district which ranges from 3,000 to 6,000 elevation; and is seed from Ceylon estates or Indian preferable?

In my opinion the very highest class of Assam hybrid is the best for all elevations in Ceylon, and I think it would be a mistake to plant pure indigenous, as the climate of Dimbula is not steamy enough. Of course, it would grow as well, but I am afraid it would not flush as quick as the hybrid plant. Locally-grown seed has done quite as well as Indian when planted on good soil but there is no doubt that when seed from trees that have been giving heavy crops for some years is put in poor soil it becomes in appearance very low class. If Indian seed can be guaranteed and it arrives in good order, I would prefer it myself to the locally-grown.

II.—What distance apart should tea be planted and what is the best means of adjusting your distance to coffee 5' × 6'?

Having seen some very nice-looking young tea growing on Ritnagheria estate, I have come to the conclusion that 5×3 would be a very good distance. By planting thus the lines of coffee would not be interfered with. On poor soil, I think closer planting would be better, 4×3 or 4×4, but, on really rich land, I would advocate the planting as far apart as 5×4, as there is no doubt that they would not be very long in filling up the space, judging from the way the bushes on Abbotsford are growing.

III.—Do you consider that coffee injures the growing tea and can they be grown together without prejudice to one or the other?

Up to the 18th month I consider it rather an advantage to have the coffee as a shade to the young tea and a protection from wind, but as soon as the first pruning is done it must be decided which is to be the principal product. If the tea, then out with the coffee. If the coffee should happen to have some 5 cwt. an acre then the tea can be pruned down and left, but I don't fancy any gentleman with coffee which looks like giving a heavy crop will wish to plant up with tea.

IV. —What is the best way of planting in cultivated land—holing-dibbling, forking, or otherwise? Kindly give the cost of the operation you recommend.

I would strongly recommend the digging of good holes 15" deep and 9" broad, There are many who consider it quite sufficient to fork up the soil as they say it is not necessary to hole when new top soil is not to be put in. By the forking system it is impossible to tell whether the plant's future home is free from stones, or whether there is not a nice big rock a few inches from the surface. Now by holing, as you are all aware, it can be at once seen whether the work is done carefully or not I must say I have seen plants doing very well indeed and they had only been put in with an alavanga. Still, I do not believe in it. When your holes have been carefully cut, filled in, and the plants planted you have the satisfaction of knowing that the best has been done.

Holing.

The cost of cutting pegs and lining is ...	R5·00
Holing @ 100 per man 2,904 5 × 3 = 10-15	12·50
4 × 3 = 12-60	
Filling in 250 holes per cooly...	5·00
Planting 300 per cooly fair amount ...	4 25
	R26·75

Of course this varies a little according to plants per acre. Then there is the price of seed and other R20 per maund for making nurseries. However it may be managed at a lower rate.

V.—What is your opinion of planting at stake, with sprouted seed and with unsprouted seed?

I have only tried it once myself in this country on steep land, and am sorry to say it was only partially successful. The seeds were all germinated and carefully put in holed land well drained, but soon after having some severe rain I found great quantities exposed. I do not see however why it should not be carried out with success, if the ground is staked as is done in India, the stakes being driven well in with a mallet so as to insure their remaining firm for at least 6 months. The holes are then cut on the lower side close to but allowing sufficient space (an inch or so) for the stake to hold. On being filled in the seed or seeds can be put in directly behind the stake about 4 or 5 inches off. At each stake the same thing being done the measurement is exact, and the lines perfectly straight. The distance at which the seed is put in is known, and the stake being secure there is no necessity for the weeders to scrape off the tops of the young plants. I think that unless on very flat land plants are much better than seed at stake.

VI.—Do you consider a large growth of weeds injurious to the plants, and, is monthly weeding best or periodical forking? I can speak from experience as to their actually doing no harm to the tea bushes. I have seen young estates in India, opened out, planted, and, for the first year and more nothing done except keeping the weeds clear from the young plants, all up and across the lines being high in weeds If labor could be spared this was occasionally cut down with a sickle. On old estates I have had to wander up and down lines after pluckers up to my knees in grass and weeds, yet the tea flushed well. I believe our Indian Hamic is much the same as whiteweed, except that it grows high without flowering. This is or was plentiful in the Darjiling district and Dôars, yet I have seen no harm done by it growing amongst the tea. If it is from a pecuniary point impossible to keep tea perfectly clean; try and keep round the stem clear and the bush will flush quite as well. I am no advocate for letting weeds grow, and consider it best and cheapest to keep the estate perfectly clean. Of course if at the height of the plucking season labor is scarce and one cannot borrow, by all means let the weeds look out for themselves rather than lose the leaf. An occasional forking without manure I consider very benefical, and in India it was always considered by doing this that the flush was brought on quicker. I am sure no reasonable being would try to make his weeds grow.

VII.—What do you recommend with regard to plucking?

I have already written my ideas upon this subject but will be happy to read them over again. (*Vide Observer*, Oct. 4th, 1883).

VIII.—What do you think will be the cost of planting coffee land with tea and bringing it into bearing?

The same amount as for forest land, less cost of land and some other items: this I have already made an estimate for and it has been published, (*vide Observer* 4th Oct. 1883.)

Nurseries.—1. Is it best to germinate seed before getting into nurseries?

It is not necessary. Make your beds near a strean or where water can be easily carried, and do not put manure. It is much better that the plant should go into richer soil, if possible, than the nursery. I need not attempt to describe the process of making beds. All I can say is, the beds being made and the seed ready at hand, put as much as will be required for a day's planting into a large tub and float off all the light seed. Plant the heavy seed about 4 inches below the lines and 1 to 1½ inch in the rows, enough to allow a fork to be put down behind each row at time of transplanting. The light seed can then be put broadcast on beds by itself and thus economize space and save expense in making beds for seed that may not be good.

2. Should beds be shaded, and, if so, in what way?

A little fern shade is all that is required. At some times of the year it is not necessary. I have seen very good shade made with lemon or mana grass put on thick at first, and, when the seed showed signs of coming above ground it was thinned down and allowed to remain and decay. To save it from being blown or washed away, a piece of coir was stretched along each side of the bed and pegged down with sticks at intervals.

3. In transplanting from the nurseries, is it best to prune the taproot or not?

It is preferable to leave it alone. Take the plant out of the nursery as carefully as possible, and see that the hole is deep enough to receive it. Of course, if this tap-root is very long, it must be cut. By only digging the nursery beds lightly long tap roots are avoided. In the plains of India, plants won't stand root pruning as they have not time to recover, but here in Ceylon they don't appear to mind rough treatment. I believe I make no rash statement when I say that I have heard that a great quantity of the plants put into Windsor Forest were about 18 months old and had both their branches cut down and their taproots pruned, and all did well.

5. What sized plants are best for planting in coffee fields, in a clearing, and what for supplying?

For my own part, I like a good strong healthy plant of about 6 to 8 inches with not too much green growth, unless it is going under the shade of coffee. A well-hardened plant, red wood to the top, stands best in the open, and, if planting at an unseasonable time with no allowance for shade, I think a small 2-or 3-leaved one stands the heat best.

6. How many plants should a maund of seed give?

Locally-grown seed, freshly picked and planted, has turned out 43,000 plants from two maunds. Seed varies and runs as high as 55,000 and as low as 10,000, the latter being very large. On an average I have found about 25,0 0 go to the maund. I can only speak from my own knowledge, not having had time to enquire elsewhere. I have planted an equal number of seeds from a maund containing 55,000 and one containing 12,000, and the plants from the 12,000 to the maund came up best and were the strongest.

Yield.—What will be the probable yield per acre of tea planted in coffee land at 3,000, 4,000, 5,000 and 6,000 feet, up to six years old?

Judging from the way in which the bushes on Abbotsford estate are flushing at an elevation of 5,600 and from my own personal experience after growing on Windsor Forest in abandoned coffee land, I see no reason to doubt that an average yield of 400 lb. will be got throughout the district, if the general quality of the bushes is good. Of course, in the lower valleys, and on some of the highly manured lands, much more will be got, but, judiciously worked, 400 lb. per acre will be very remunerative.

2.—What will be the probable yield of exposed fields of land previously worked as coffee, and, if steep, will they in your opinion be profitable as tea fields?

Where the land is exposed, the bushes can be planted closer, and the pruning carried out immediately after the burst of the S. W. is over or I should say when the S. W. is *well over*. Unless the weather is persistently raw, cold and misty, and the wind very fierce, the flush is no retarded very much, and, when the bushes are well-grown in their third or fourth year, they seem to stand the wind remarkably well, from the nature and aspect of the land. So the pruning can be carried out facing the N. E. first and S. W. last. I have not noticed in my wanderings through your district any land too steep, if the parts pointed out to me by Mr. Talbot are the steepest. There need be no fear of planting up such land and working it profitably. On very steep land, I consider it a mistake to plant tea, as the coolies are so constantly going over the ground about three times a month all the year round. The soil, if cultivated, is in danger of all being pushed into the drains, and worst of all, in moving about from tree to tree, the women tear down the branches by catching hold of them, to save themselves from falling.

3.—What rainfall is requisite for successful tea cultivation?

I do not think that there is any danger of this being too little in this district, and, from all I have seen, there is not too much. I did not feel any great inconvenience from the 230 to 250 inches which fell on Windsor Forest, and I don't suppose you suffer from more than that amount up here. For my own part, I would like the first drop to fall as the last basket of leaf was weighed in, and before the last tomtom had been beat in the morning, then throughout the day hot steamy atmosphere.

4.—Will soils with limestone grow tea and give a good yield?

This I cannot answer, and must leave it to someone else. I know that lime in nursery beds is death to tea seed and young plants. Why it should be I cannot say, but this is quite different to limestone in the soil.

Cost of Production.—So much has been written by Mr. Armstrong, and in such an able way, that I need not say anything upon cost o manufacturingby hand *versus* machinery, except with regard to plucking. I consider an average of 16 lb. per cooly throughout the year as much as one can expect at all events, until the labor force of the country has became more accustomed to this work. I am informed by Mr. Hughes of Gallebodde that a saving of $5\frac{1}{2}$ cents per lb. is effected in this way. *Handwork rolling* at 36 lb. per man ... ... 4c. per lb. tea.

Watching and withering at R10 per month on say 25,000 lb. tea is	... $\frac{1}{2}$	,, ,,
Drying, cost of charcoal and labour	$2\frac{1}{2}$	,, ,,
	7c.	,, ,,
Machine rolling, withering, cutting firewood (firewood being close)	... $1\frac{1}{2}$	,, ,,
Saving...	... $5\frac{1}{2}$c	,, ,,

In spite of drying by machinery, I think it necessary to have a small supply of charcoal handy in case of anything going wrong. Certainly the Jackson's and Siroccos do not soon get out of order. Still, it is best being prepared. Charcoal is also useful for getting up heat for withering in parts of the store not influenced by the heat of the drier and for soldering tho linings of chests.

III.—What are the relative quantities per 100 lb. of tea, of wood, coke and coal for firing?

Very much depends, in drying tea over charcoal, where your furnaces are built, how the charcoal burns in them, and the quality of the charcoal. I find that it generally takes from 1 to $1\frac{1}{2}$ lb. of charcoal to dry 1 lb. tea, and for drying and redrying before packing on an average 2 lb., so that it takes say 8 lb. of wood to a pound of tea, hand manufacture. A Jackson drier (of which I am sorry I can say nothing favorable) will dry 400 lb. tea with one yard firewood of 5 cents to the yard or 560 lb. A little over 1 lb. wood to a pound tea, not counting wood, used for redrying which is very little. With regard to the Sirocco, I can say that it does infinitely better work: it does 20 per cent more than Jackson's at 50 per cent less cost. Mr. Hogg of Imboolpitiya estate writes 21st July this year:—"The Sirocco burns 2 lb. firewood to 1 lb. manufactured tea and does 35 lb. per hour." Best of all machines however is Kinmond's drier, one of which (No. 2) is equal to 4 Sirocco machines. For coal and coke, I know nothing about.

IV. In this district do you foresee any difficulty as to withering so as to make the best class of teas?

Not, if the factories are properly built. I would have nothing to do with weather-boarding. Keep your heat in and your cold out if you have boarding; plaster inside. I would even go the length of plastering the upper withering loft boarding. Have plenty of light and don't spare glass. Light always helps on withering. If the sun shines in too strongly have a cloth to put over. Have your windows so that they can open if required; have plenty withering space, so that in wet weather the leaves can be laid quite thin; it is the wet weather one has to think about in Ceylon not the dry. When withering has to be forced and there is no sun, the space above the drying machine is best.

With regard to manufacture, I can hardly make any remarks: so much has been already written. All I can say is, see that the women pluck good leaf. Try and protect it as much as possible on the field from rain, and, each time that they put a fresh lot of leaf in their baskets see that they turn the whole lot up from the bottom. This insures its not getting heated. If the fields are far removed from the factory, I would recommend the putting up of one or two small thatched receiving-houses, where the baskets could be placed, and where forenoon weighing in might be carried out. Bring the leaf to the factory as dry as you can; it withers so much better and will always make better tea than wet sodden leaf. Every tea-house being so different, it is only long experience that ets one know in what part to put first: however, if the leaf is very wet it can be put for a short time where it is very warm, constantly being turned, then, placed on the trays, will wither better than being placed there at first.

Rolling.—Some people are believers in light rolling, as the tea is not so much broken and the tip remains uncoloured from the expressed juice. I myself believe in hard rolling, lightly at first, until the leaf begins to take a twist; the pressure can then be put on and the rolling continued until the whole roll clings together, and if there is any juice it comes out. When half rolled the broken tea can be taken out through a No. 4, or 3 which is best. What falls through is set aside to ferment, separate from that which remains on the sieve, either on bamboo trays or on a table. By this system a much better and more even fermentation is got in the fine broken tea. In the process of rolling by hand, all coarse leaves should be picked out: if by machinery, after the roll comes out. Do not throw this away; give it a sifting to detach any finer leaf clinging to it; roll it again and dry it. It can always be sold.

Fermentation.—After rolling, place the "roll" on a table about 6 inches deep, covering over the whole with a cloth or blanket. It is not always necessary to cover as the fermentation goes on very well without anything. Still it keeps all dust from falling on it. The roll should be turned over repeatedly every 30 minutes until ready to go on the drying trays. No exact rule can be laid down for fermenting leaf, and it is simply absurd saying "with the thermometer at 80 ferment so long and at 90 so long." Some kinds of leaf might lie a year and never take a color, and others color under the rollers' very hands. After pruning, with the first flush, it is almost impossible to get any color whatever, as there is only a thin watery fluid. Towards April and May you may have to fire off these rolls almost at one time. The leaf towards the afternoon always ferments best. Use your eyes and nose; try, if possible, to get a nice copper-color, and a good fresh smell: if you can't get that, get as near as possible. Better have slightly underfermented leaf than a nasty dull dark brown leaf, the liquor from which is thin and poor. To an experienced eye it is very easy to tell, as the leaf is being rolled, whether the fermentation will be good or bad. We have a great pull over India in being able nearly the whole twelve months to get good fermentations, and, towards what we call the end of our season, June (though there is no end), our fermentations are at the very best. I can look back upon many a hard struggle to get leaf to ferment in India, and I am convinced it is owing to our getting such good color here that our tea sells so well.

Drying by Charcoal.—In the early morning, before the rollers come, the fires should all be cleaned out and the fresh charcoal put in ready for lighting. On some estates a grating is used in each furnace to place the lighted charcoal which is taken from one kept for supplying them. This grating is not necessary if the charcoal is well made. Simply pour so much into a furnace, and let it lie on the bottom, which must be made wider than the ones with grating. Then, when the first roll is finished and placed for fermentation, light all the furnaces required, and, when there is a light surface and no black pieces, sprinkle over with wood-ash to deaden the glow and place the tray on the top. One man can look after 5 trays, and he should keep constantly taking them off and turning the leaf, so that the small broken leaf and dust which dries first may fall through and remain on the table. When leaf is half-fired, it can be sieved through a No. 8. This allows the bigger leaves to dry quickly. By rights, the man drying should simply dry and not touch the tea at all, except to turn it, as his other trays are in danger of burning, whilst engaged in this work. No Indian cooly would do this, as he uses fires so hot that his whole time is taken up in taking off and putting on his trays. The brisker the fire the quicker fermentation is checked, and the better and brisker the dried tea. Leaf dried over a dull cool fire is never good. It is better if possible to give one man only 4 trays. Don't put too much leaf in each, and use light fires. Let a sample of each man's make be put aside and tasted the next morning, then you will find out who dries carefully and who does not. Every day's make should be tasted before putting away for sifting. A man need not be an accomplished tea-taster to do this. At first all he has to do is to see that there are no black leaves in the cup after infusing the liquor, and that the outturn of leaf is of a bright color. If the tea is burnt, an eye can be kept on the man who dried it; if it is only high-fired, it can be kept until there is a large amount of tea ready for dispatching, and introduced into it without any danger of damaging the sale. If tea is very badly burnt, it must not be mixed in with any other. Only gross carelessness can cause this, and the man who spoiled the tea should be made to pay for it. Let strict attention be paid to the drying, and assist the man in every way, and do not let him quit his work without having taken away all his trays off the fire or being relieved. Of course, with machinery there is not so much danger.

Every tea planter who carries on work by hand should be conversant with the way to roll, so that he can at once show any beginner, and not have to call the tea-house conductor. The process appears very simple, but it is not so quickly picked up as one might imagine.

Each day's charcoal should be weighed and put on the board opposite green leaf and tea made, so that it can at once be seen how much it has taken to turn out the dried tea.

Sifting.—There is no particular rule for doing this. Some men use Nos. 14, 9, 8 and 7, others use 10, 9 and 8. It all depends on the size of tea you are going to sift. One week a No. 9 is used for getting out the pekoe; next week, with a finer tea, No. 10 may be best suited; it is only experience that teaches one what best to do. The tea of the previous day should be sifted the next, divided into its different classes, and at 4 o'clock put away in the bins. I find women are the steadiest and most careful workers. Get the same ones each day, and have a spare one or two, so that on Monday or Saturday, when one is sure to be sick or in the lines, another may take her place. When enough has been sifted for packing, re-dry carefully. See that your linings are well soldered and free from any soldering fluid, and pack as hot as you can. A very good way to insure the quantity in the chest being equally divided is to take the quarter of the amount,—say 80 lb. pekoe is being packed then 20 lb. is the quarter. This is weighed, and, being placed in the box, is pressed down until it is in a quarter of the space of the chest. This is ascertained by taking the depth of the box, and, having divided it into 4, cut marks on a stick, and the first mark will be up level with the top, when the first 20 lb. is put in. By weighing the whole 80 lb. and then pouring in an unknown quantity, the tea at the bottom may be very loose, and at the top heavy pressure may be required. Always solder up what has been packed the same day, and make the carpenter nail down the lid and hoops. Then all that remains is to mark the name and numbers.

Mr. Chairman and gentlemen, before concluding, there is one thing I should like to say: that is to warn you against close-plucking, a fault which I fear has to a great extent been aggravated by the jealousy which appears to exist between planters in this island as to average prices brought by their teas in London. From what I have seen on a few estates that I have passed through, I am afraid there is some chance of their proprietors finding in the future that average prices have been too high. When a man plants up a clearing with tea he should look upon it as an investment to give him a fair income for the remainder of his life-time. Plucking the bushes on the top and all round directly tip and one leaf appears will not conduce to this result, although returns for the first few years may be good. My advice is—aim chiefly at making a bush with a large plucking surface, and lay down as a golden rule that for the first few flushings after pruning you leave on every shoot plucked *two* leaves untouched and, later on, always one.

I could not have believed, when I entered this island 5 years ago, that tea would have made such gigantic strides, in spite of hard times and want of cash. All I hope is that many more acres may be added to the amount already in bearing, and that we may go on and prosper. C. A. HAY.

Blackwater, Oct. 12th, 1883.

Mr. HAY said he would be glad to answer any questions any gentleman would like to ask.

Mr. WICKHAM asked if a tea-house 100 ft. × 20 ft. allowed for in the estimate was sufficiently large for an estate of 200 acres giving the yield anticipated. The tea-houses he had seen in gardens in Darjiling were much larger, and he instanced one house as 300 ft. long. He also considered Mr. Hay's estimate for freight in machinery, 30 per cent, was not sufficiently high, his experience being that 70 per cent should be allowed.

In reply, Mr. HAY stated that he considered the dimensions given for a store large enough. He knew the store in Darjiling referred to by Mr. Wickham, but a large portion of that store was never used, and it was unnecessarily large. With regard to charges for freight his figures had been obtained from a reliable source.

Mr. FERGUSON confirmed Mr. Hay's statement as regards requisite store-room. The tea-house at Abbotsford for 110 acres measured 30 × 60, and in that all manufacturing processes were carried on, and he could easily wither 2 000 lb. of leaf.

Mr. SINCLAIR, who appeared somewhat sceptical about the permanency of tea, asked if the anticipated yield of 400 lb. per acre would be maintained without manure and other members asked questions of the same tenor.

In reply, Mr. HAY stated, from what he had seen of the soil in the district and from the amount of manure, applied to coffee, he might safely predict a yield of 400 lb. per acre for 6 years at least, and looked upon tea as a permanency.

Mr. A. CAMPBELL asked if the flavour of the manufactured tea was likely to deteriorate as the bushes grow old and whether manure affected the flavour of the tea as well as the yield of leaf.

Mr. HAY replied that the flavour would not deteriorate; manure would not affect the flavour though it certainly would the yield.

Mr. SMITH suggested the use of Clerihew stores as being suitable for tea.—Mr. Hay said he had seen plans of buildings of somewhat similar arrangement, though never seen them in use and doubtless they would be most suitable for tea business.

Mr, A, CAMPBELL asked if planting 3×3 was not more advisable than 5×5 or 4×4, by keeping the bushes well-pruned, they would not interfere with one another and they would have their plucking surface nearer the roots?

Mr. HAY considered, if the trees would cover the ground, 5×5 was a good distance; but, if they were planted 3×3, quicker returns would be obtained, and if after a time the bushes were found too close, the alternate ones could be removed. There was no object in having them too large, in which case they could not be properly plucked.

Mr. FERGUSON, referring to the growth of tea in high lands, stated that there was a tree on Abbotsford 25 feet *in diameter*, and wished to bear testimony to the goodness of Assam hybrid over China bushes; the latter flushed well for a time, after pruning, but in a very short time gave up flushing and went bangy.

The CHAIRMAN thanked Mr. Hay for the exhaustive manner he had replied to the questions put to him, and a cordial vote of thanks was accorded him.

The report of Sub-Committee on manuring and pruning was then read.

Proposed by Mr. HUMPHREYS seconded by Mr. WICKHAM and carried that the report be adopted.

The clause in the report which states that managers of estates in the neighbourhood of the Wallahas attributed the falling-off of crops to the ravages of grub gave rise to discussion.

Mr. ELPHINSTONE was strongly of opinion that grub was the cause of our crops falling short, which was only to be remedied by collecting the grub and manuring, and gave statistics of crops picked from Logie and Belgravia, where the grub had been persistently collected.

Mr. SINCLAIR held similar views. The grub not only ate the roots of the coffee, but also the manure, and therefore the results of manure were not equal to what they were previous to the days of grub and this state of things would continue unless grubs were collected and the coffee properly cultivated. He had collected no less than 140,000 grub from 25 acres, during a short period. He did not understand why people in the Lindula district should desire to plant tea, and proposed the following resolution, seconded by Mr. ELPHINSTONE:—"That grub and want of cultivation are the main causes of the sudden falling-off of crops in the Lindula district."

Mr. W. SMITH was strongly opposed to the idea of grub being the cause of crops falling-off. He had spent as much money and trouble over grubbing as any member of the district and had also manured highly. The falling-off of crops was not confined to Lindula only, but the whole export from estates and native gardens was seriously affected and must be attributed to leaf-disease, and he no longer believed in the manuring and cultivating of coffee, and, if the resolution were passed it would be most misleading.

Mr. LAWRANCE agreed with Mr. Smith in so far that leaf-disease and not grub was the cause of short crops, but much regretted what Mr. Smith had urged with reference to the uselessness of manuring and cultivating of coffee in this district. His estate, Balmoral, continued to give good crops by the aid of manure every third year, and he never had collected the grub.

Mr. SINCLAIR again urged the want of cultivation and the grub as the principal causes and also the planting of cinchona among the coffee, &c. &c.

After further discussion Mr. SMITH proposed, and Mr LAWRANCE seconded, the following amendment:—"That leaf-disease is the main cause of the failure of coffee crops in Dimbula and Lindula during the past 4 years." For the amendment 8, for the resolution 7 amendment carried.

In connection with grub not attacking tea, Mr. SMITH stated, he had searched for grub amongst tea planted on patana land without finding one, whilst the patana in close proximity was crammed with grub.

C. J. SCOTT, Honry. Secretary.

TEA MANUFACTURE BY HAND AND BY MACHINERY.

The outcome of the controversy which has arisen on the comparative cost of making tea by hand and by machinery seems to be, that, circumstances being fairly equal, 5 cents represents as nearly as possible the money saving per lb of tea by the adoption of such machinery as is yet in use. Our correspondent "Adam's Peak," it will be observed, while giving a lower figure for the saving per lb. on 400 lb. of tea, acknowledges that the ratio of saving is likely to increase with the quantity made where machinery is employed, while a cooly cannot roll more than 40 lb. of leaf. Against the saving of 5 cents on every pound of tea made must, of course, be placed the capital cost of machinery (in excess of the appliances used in hand manufacture) and interest on the money until the outlay is paid off. But, excellent as hand-made tea often is, there can be no question that the strong arguments in favour of machinery are founded on the *uniformly* good quality of the tea it turns out. Charcoal is not a necessity, unless for furnaces kept as a reserve in case of accident to the machinery, or for refiring; and, above and beyond all, night work, with its dangerous and demoralizing effects, can be dispensed with. Coolies employed at night may underfire or burn the tea, and possibly set fire to the tea-house. The watching and the charcoal fumes cannot but be deleterious to the health of the European superintendent and the tea-makers, and we suppose the latter are generally paid extra for night work. With extended tea cultivation in Ceylon, labour might become scarce and go up seriously in price, were a cooly always required, for instance, to roll every 40 lb. of green leaf gathered. Machinery will enable an estate to be worked with a considerably less labour force generally, and especially with a less proportion of what may be called skilled labour, in the persons of experienced and careful tea rollers. The machinery will get neither sulky nor sleepy, neither lazy nor disobedient, and such ailments as it is liable to are genuine and soon cured. To be able to dispense with charcoal in favour of wood fuel, and in the many cases of tea taking the place of coffee where timber is scarce or non-existent, to substitute coal and coke, are great advantages. When the railway is open to Dikoya and Nanuoya, and ultimately to Uva (not to speak of branches into the lower districts), coal and coke can reach woodless estates at fairly moderate rates,—the railways, no doubt, carrying such substances at charges not much higher than those for manure. It really comes to this,—that, if tea cultivation progress as we hope in Ceylon, no money and no efforts would be sufficient to secure the labour force which would be needed at one man for every 40 lb. of green leaf rolled, with coolies employed in proportion in firing, sifting and sorting. Even, therefore, if there were no direct saving effected by the use of machinery, if its only merits were that with ordinary fuel it will turn out tea uniformly good, resort to rollers, driers, sifters, and such other labour-saving appliances as have been or may be invented, would be a necessity. But besides the more uniformly better tea—from more even rolling, brisker firing and, probably, from less handling in the sifting process—there is certainly a saving of 5 cents per lb. on the items which admit of comparison: rolling, firing, sifting and refiring. Our correspondent "Proprietor" has gone very carefully into the question of preparation by hand, and we believe his figures of $6\frac{1}{4}$ cents per lb. for rolling and firing are as near the truth as can be. Planters who show similar figures say "it could be done for LESS," so that a *saving* of 7 or even $6\frac{1}{2}$ cents seems impossible. But 5 cents saving per lb., added to the other many advantages we have glanced at, seems decisive in favour of machinery. It remains that the most perfect machinery should be obtained at moderate prices. The present selling prices of some machines are almost prohibitory. Comparison at the Calcutta Exhibition and resulting competition will, no doubt, bring about the best possible results for planters in Ceylon as well as India.

Since writing the above the further notes from "S." have reached us (page 383) and in them the novel ground is taken up that machinery should be as good as "written off" (out of the saving over hand work?) in three years; but surely this is far too short a period, the tear and wear and interest on cost of machinery cannot require a writing-off of capital outlay in so short a period?

ONE OF THE BEST PAYING SUGAR ESTATES IN DEMERARA the "De Kinderen and Boods's Rust," has just been disposed of by tender. There were three offers: that of Mr. Quintin Hogg ranging from 30,000*l*., with 50*l*. above any other bidder, up to 50,000*l*., terms 20,000*l*. cash, balance in four months at 6 per cent; Mr. Evans, one $170,000 cash; Sanbach, Tinne & Co. offered 25*l*. over other bidders up to 32,000*l*., terms cash. The property thus fell to Mr. Quintin Hogg for $170,240 (35,466*l*. sterling). The yearly crop of the estate has been about 1,050 hhds., but it is estimated that the crop on the ground is 1,200 hhds. Thus we have the value of a first-class vacuum pan sugar estate at 30*l*. per hhd., or the actual crop on the ground. The gross value of that crop, including all expenses for tillage and reaping, may be put at 25*l*. per hhd. Thus the estate has fetched 5*l*. per hhd. over gross value of the crop on the ground. We understand that two independent planters have valued the estate at 32,000*l*., so that it is evident that the realised price is a fair one between buyer and seller.—*Colonies and India*, Sept. 21.

JAK TREES BEARING AT FIFTEEN MONTHS. Such is the statement in a notice in the *Queenslander* of the Rockhampton Botanic Gardens:—It has been the practice of Mr. Edgar to bring in a regular supply of rich manure to ensure the development of the plants under his care, and many a valuable nanny goat has contributed its quota to the growth of vegetable life within this enclosure—so much so that it has sometimes jocularly called the Rockhampton goat cemetry. The very thing which under less practical management would have hastened a failure has been made, by the judicious application of fertilisers, to forward the end intended. Sand well and scientifically cultivated can be made to accelerate vegetable growth of most kinds, and the history of many of the trees and shrubs in this garden is neither more nor less an illustration of remarkable precocity. As one instance of this, it may be mentioned that soon after it was started seeds of *Artocarpus integrifolia* (jackfruit) were procured from India and sown in the open borders, where they were to remain. The ground was deeply trenched and well manured for their reception, and the result was that within eighteen months of the seeds being sown the young trees were from 15 feet to 18 feet high, and carrying fruit. Sand naturally encourages the multiplication of roots, and if it is kept well enriched the superabundance of fibrous roots it occasions helps on a certain precocity, as in this instance. For propagating purposes, and for bringing things on rapidly, sand is very good, and plants started in it are admirably adapted for transplanting into other soils; hence it is highly prized by nurserymen, florists, and market gardeners. But for a botanic garden, in which trees and shrubs are required to be permanent, it is not so desirable a soil.

DR. TRIMEN'S REPORT ON THE CINCHONA PLANTATIONS OF THE NILGIRIS.

In the earlier half of this year, Dr. Trimen visited the Nilgiri Cinchona Plantations, prior to their being placed under the charge of his old friend, Mr. Lawson, of Oxford. Besides Mr. Lawson, he had the advantage of the company of Dr. Bidie, Major Campbell Walker, Mr. Gass and Mr. Lorne Campbell. Dr. Trimen was well prepared for the task of reporting on the plantations, scientifically and economically, from his thorough knowledge of botany generally, his special study of the cinchonas at the British Museum and elsewhere in Europe, besides the facilities he had enjoyed in Ceylon, and finally from his mastery of the various blue-books and detached reports by Messrs. McIvor, Broughton and others, besides the general literature of the subject. The result is an elaborate report, in which most of the disputed questions on the botany of the species and varieties cultivated in India are thoroughly examined and most of them, we should think, settled. Dr. Trimen believes as little as ever in Mr. Cross and his "Pátá de Gallinazo," and as strongly as ever contends for the hybrid origin of the robust forms of cinchona which have appeared on plantations and received the varying appellations, besides that contended for by Mr. Cross, of pubescens, lanosa, magnifolia, &c. To the apparently strong argument that plants of the forms about which controversy has raged existed amongst the oldest trees on Naduvatam, he opposed the facts revealed by the records, that quite a number of the original trees were cut down, the vacancies from this cause as well as from "dying out" being supplied by plants from locally produced seed, some of the plants from such seed being inevitably hybrids, judging from all experience in India and Ceylon, where different species are attributed with every reach of each other. Talking of "dying out," it is now evident that even on the best Nilgiri plantations the losses from this cause have been very heavy, while whole plantations, such as Hooker's and Wood's at Pykara, have suffered so much that, their abandonment is recommended. The tale has been much the same on the Nilgiris and in British Sikkim as in Ceylon, and also in Java, although in the latter case to a far lesser extent. The cinchonas seem to be just as capricious as to soil and climate, as they are variable in form and "sporting" in character, to the disturbance of the equanimity of grave and reverend professors of botany and experts in bark. Dr. Trimen is no more afraid of breaking a lance with Col. Beddome and Dr. Bidie than of shrinking from a contest with the champion quinologist, Mr. Howard, and we generally feel that the spoils of victory are his. But there are certainly some things in his report which puzzle us. Knowing as we do that it was from the Nilgiri gardens that Mr. McIvor sent to seed from which the Yarrow and St. Andrews Ledgers were grown in Ceylon, we are amazed to be told that Dr. Trimen saw no trace of undoubted Ledgeriana during his examination. He was told of a few plants, but he could not identify them by the foliage. More astonishing still, considering that it was amongst the Dodabetta *C. officinalis* trees Mr. Broughton noticed the numerous diversities of forms of which he wrote so graphically to Mr. Howard, is it, to be told that the one impression created on Dr. Trimen's mind by a view of the Dodabetta trees was their complete uniformity of character! Apart from the fact that the eye of the botanist does not rest on diversities of foliage, so much as on characteristics of flowers and fruits, the solution of the difficulty, probably, is that trees like human beings, however much addicted to sport in their youth become steady and settled in maturity. Some of the veteran *officinalis* trees of Dodabetta must now be close on a score of years in the field. Dr. Trimen, while he does not fail to magnify his own profession by rejoicing that the South of India Cinchona Plantations are now placed under the care of a competent botanist, is keenly alive to the importance of a continuance of the researches which were cut short by the unfortunate resignation and disappearance of Mr. Broughton, the late Quinologist, of the results of whose analyses and reports Dr. Trimen justly holds a high estimate. Dr. Trimen is at pains to trace the chronological introduction of the various cinchonas existing on the Nilgiris. Of *C. succirubra*, the most successful kind though not the best in quality, seeds of plants were obtained in February and April 1861, over 22 years ago. In December of 1861, Dr. Anderson brought seed of *C. lancifolia* from Java. The grey barks were also introduce in 1861, and so was the poor sort, *C. Pahudiana*, from Java. In February and March 1862 seeds of *C. officinalis* were obtained, and in April of the same year a plant of the best variety from Mr. Howard. It was 1865 before the calisayas were introduced, including Mr. Money's share of Ledger's seed. Some other forms of calisaya were added in 1866 and 1867. *C. Pitayo* or *C. Pitayensis* arrived in 1869. In 1880, came the soft and hard Carthagena or Columbian barks, of which Mr. Howard seems to hope well. In March 1883, seeds of a calisaya stated to be the "verde" and "morada" of Bolivia were introduced, from which numerous seedlings have been raised. Of all these, only *succirubra* and *officinalis* have been as yet assured successes on the Nilgiris. For Ledgeriana, Dr. Trimen recommends a new plantation at an altitude of between 3,500 and 4,000 feet. That altitude on the slopes of the Nilgiris generally means fever. And this reminds us that not only are the succirubras at Naduvatam at a very high altitude (quite 6,000 feet, some of them) but that this high altitude is in latitude 11° north on a continent, against our insular 7° from the equator. If only there is free soil and shelter, we do not see why Ledgerianas should not flourish at 5,000 feet in Ceylon. Mr. Markham wrote a book to prove the wrong done to the Countess Chinchon, by the spelling "cinchona," and had influence enough with the Indian Government to secure the plants being called "chinchonas" in official reports. But Dr. Trimen pleads for uniformity, and states he is not aware of one living botanist (rather hard on Mr. Markham) who writes the name otherwise than cinchona. Our readers are, of course, aware that Linnæus originated "cinchona" by a slip in writing, but it is useless for Mr. Markham or other purists to fight against not only the popular but the botanic custom. In view of Dr. Trimen's true statement as to the extent to which trees from seeds and even from cuttings are influenced by surrounding circumstances, and the importance of growing "pedigree" cinchonas, by selection according to analysis, we trust a chemist will speedily be at work with Mr. Lawson on the Nilgiris. The *Ceylon Observer* has ever consistently advocated the retention by the Madras Government of their plantations for the purpose of obtaining and distributing such valuable information as the reports of McIvor and Broughton contained. The former had his weaknesses and the latter his faults of temper, but cinchona growers owe much to their memory for the facts they ascertained and communicated.

REPORT ON THE CINCHONA PLANTATIONS OF THE NILGIRIS.

Peradeniya, 30th June 1883.

From Dr. H. TRIMEN,
Director, Royal Botanical Gardens, Ceylon,
To the SECRETARY TO GOVERNMENT,
Revenue Department.

SIR,—I have the honor to forward to you my report on the Cinchona Plantations of the Nilgiris, which I have divided into two portions.

PART I.—BOTANICAL OBSERVATIONS.

1.—In accordance with the invitation conveyed to me on 10th April that I would "inspect and report upon the Botanical problems presented by the Nilgiri Cinchona Plantations," I proceeded, with the sanction of this Government, to Madras, and reached Ootacamund on May 5th. During the succeeding fortnight I investigated the plantations at Dodabetta, Naduvatam and the Pykara river. Throughout the examination I was so fortunate as to have the Company of Dr. Bidie—who has an intimate knowledge of the plantations—and of my old friend, Mr. Lawson, who has lately been appointed Superintendent of them;* at Naduvatam we were joined by Major Campbell Walker, Conservator of Forests; Mr. Gass, Deputy Conservator of Forests, under whose charge the plantations actually were; and Mr. Lorne Campbell, a member of the Cinchona Committee of 1878.

2. *Previous Preparation.*—In addition to a somewhat critical study of *cinchona* made during my connection with the British Museum, and the facilities I have since enjoyed in Ceylon from an acquaintance with the cultivated kinds, I may add that during a visit home last year, I took the opportunity of renewing my acquaintance with the dried collections, both at Kew and the British Museum. At the former establishment, I paid special attention to the original specimens sent home from the Andes by Spruce and Cross and to Colonel Beddome's and Mr. Bidie's recently received series from these plantations; whilst at the Museum I re-examined chiefly the original type-specimens of Pavon, and a fine numbered set collected in the Nilgiri plantations themselves by the late Mr. McIvor in 1873, and presented by the Secretary of State for India.

3. *Botany of Cinchona in General.*—So many persons have reported upon the botany of the trees under review that they possess quite a small literature of their own, and it might be supposed that the subject was thoroughly exhausted. In past times Mr. Markham, the late Mr. McIvor, and especially Mr. Howard, and more recently Colonel Beddome, Mr. Cross, and Dr. Bidie have paid particular attention to the troublesome questions connected with the nomenclature of the several kinds. With regard to some of these writers, I trust I am in no way forgetful of the many and great services that they have rendered to the cinchona enterprise when I feel bound to say that from the botanical point of view, I think it is much to be regretted that circumstances should have thrown this very difficult genus into the hands of those who have had so little of the requisite training and experience in systematic botany for dealing with it effectively. It ought indeed to be generally understood, that however eminent a writer may be as a quinologist, a traveller, or a gardener, if he can see important botanical characters in the height of a tree, the chemical constitution of its bark, or the colour of its leaves, he is *ipso facto* disqualified to pronounce on questions of classification. A number of published names have, however, been defined by nothing more than some such botanically trifling or variable distinctions, and should not be recognized until properly characterized. There is nothing about the genus *cinchona* in its botanical aspects to warrant it being treated on any principles different from those which the systematist is ordinarily accustomed to employ: for authors who know little of those principles or have had no experience in the application of them to other groups of plants to attempt to arrange the forms of so involved and complicated a genus as this, can only lead to failure and confusion.

It may be said that botanists themselves disagree largely on such points: their differences, however, appear greater than they really are. There is rarely any serious disageement as to the relative value of characters, though there is much as to the *grade* which the individuals or groups defined by them should occupy. Thus a group which one naturalist will consider as a single species with several varieties will be four or five species to another; or a small set of allied species or a single isolated one may be regarded as a distinct genus by one botanist, and be relegated to some larger one by another. Such differences there must always be, for they represent the more or less synthetical or analytical bent of individual minds, but naturalists have long left off discussions over such matters, which, indeed, since the general recognition of affinity by descent, have lost entirely the significance they once had.

We possess, however, arrangements of the whole known species of *cinchona*—worked out simultaneously but quite independently—at the hands of two eminent botanists both familar with South America and the wild trees, the late M. Weddell of Paris and M. Triana of New Granada,* and it is to these works and especially to that of M. Triana that we have to go in the endeavour to find sound views as to the limits of the species (which are nearly all of extreme variability) and their correct nomenclature. Unfortunately in neither treatise are descriptions given; I venture to think that had M. Triana attempted to accurately define his thirty-six species he would have considerably reduced their number. Too many are still little more than varieties of *barks* distinguishable by the collectors or by merchants, and do not represent *plants* with such a combination of anatomical characteristics as is necessary to constitute a recognizable species.

4. *The kinds in cultivation in the Nilgiris.*—The now well-known story of the successive importation of different sorts of cinchona from South America to the Nilgiris is told in official detail in the five blue-books (issued from 1863 to 1877) so far as to the middle of 1875, and has been briefly summarized in Major Campbell Walker's excellent report of 1878. It is much to be regretted that the late Superintendent's reports are so meagre in detail as to render it impossible from them, to trace with any minuteness the history of the kinds which thus came under his charge. The latest to which I have access is dated 31st July 1875† and professes to give the botanical names and numbers of the plants of each "species" then cultivated. I need say nothing here about the *numbers* given; they have been since shown to be exaggerated to an almost incredible extent; but as to the *names*, the twelve kinds given were no doubt generally at that time distinguished in the plantations.

1. C. succirubra ...	...	Red bark.
2. C. Calisaya.		
Do. var. frutex	...	Yellow bark.
Do. var. vera	...	do.
3. C. officinalis.		
Do. var. Condaminea..		Original Loxa bark.
Do. var. Bonplandiana		Select Crown bark.
Do. var. crispa	...	Fine Crown bark.
4. C. lancifolia ...	...	Pitayo bark.
5. C. nitida ...	...	Genuine grey bark.
6. C. species without name	...	Fine grey bark.
7. C. micrantha ...	...	Grey bark.
8. C. peruviana ...	...	Finest grey bark.
9. C. Pahudiana.		
10. C. lanceolata-leaved variety of C. officinalis.		
11. C. Pitayo. Raised from imported seed.		
12. Do. Plants brought out by Dr. Simpson.		

The nomenclature of the first nine kinds dates from Mr. McIvor's first report, 31st May 1862, but some changes had been made since that date. At that time "C. officinalis" was collectively called "C. condaminea" and the three varieties were respectively "var. Uritusinga," "var. Chahuarguera" and "var. Crespilla." No. 4 was then said to afford 'Crown bark' (not Pitayo bark) and No. 9 at first went under the name of "C. lucumæfolia" of the Dutch.

* At the time of my visit, Mr. Lawson had not been actually placed in charge.

* H. A. Weddell, Notes sur les Quinquinas; in Ann. des Sc. Nat., Botanique, ser. 5, XI, page 346, and XII, page 24 (1869). J. Triana, Nouvelles Etudes sur les Quinquinas, Paris, 1870 [1872].

† Blue Book V, page 189.

Nos. 9 and 10 first appear in the returns for July 1869. No. 10 was the tree observed by Mr. Broughton in 1868 to be so rich in quinine, and provisionally called by him* "var. lanceolata," which name was in 1872 altered, in accordance with Weddell's nomenclature, to "var. angustifolia." The last, No. 12, was added in January 1871.

As a correct chronology is important it will be well to give, for easy consultation, the sources and date of reception of these various kinds which composed the plantations of July 1875.

1. C. succirubra...Seeds, South America, Spruce ... ...February 1861.
   Do. ...Plants, „ Cross...April „
2. C. Calisaya ... „ „ „ ... „ „
   Do. ...Plants, Java (originally collected in South America by Hasskarl in 1854), T. Anderson ... ...December „
   Do. ...Seeds, South America, Markham ... ... „ 1865.
   Do. ...Seeds, Mr. Money (? Including "C. Ledgeriana) ... „ „
   Do. ...Plants, Kew (originally from seeds collected in South America by Weddell) "Josephiana, glabra." ... „ 1866.
   Do. Plant, J. E. Howard, "superior variety." ... ... „ 1867.
3. C. officinalis...Seeds, South America, Cross ... ...February and March 1862.
   Do. ...Plant, J. E. Howard (from seed collected by Don Riofrio in South America). "Uritusinga." ... ...April „
4. C. lancifolia ...Plants, Java (seeds originally collected in South America by Karsten) T. Anderson ... ...December 1861
5. C. nitida ...
6. C. species without name ...
7. micrantha ...
8. C. peruviana... } Seeds, South America, Pritchett ... ...January „
9. C. Pahudiana...Plants, Java (originally collected in South America by Hasskarl in 1854), T. Anderson ... ...December „
10. Found among progeny of No. 3.
11. C. Pitayo. [C. pitayensis.]...Seeds, South America, Cross ... ... 1869.
12. ——— ...Plants, brought from England by Dr. Simpson ... „ 1870.

Probably seeds or plants of "C. Ledgeriana" from the Government Plantation in Java were received in 1872—1875 or thereabout, but I find no record of their reception. Since the date of that report the principal new sorts that have been brought into the plantations are the New Granadan (Columbian) Bark-trees. Mr. Cross arrived at Ootacamund on 8th October 1880 with three plants of "Santa Fe" (Soft Columbian) and six of "Carthegena" (Hard Columbian) which he had himself collected in South America. Quite recently, in March 1883, seed of varieties of "Calisaya" stated to be the "verde" and "morada" of Bolivia have been purchased from a London firm and numerous seedlings have been raised.

5. *The Hybrids, "pubescens" and "magnifolia."*—Mr. McIvor died in June 1876, and up to the arrival of Mr. Cross as above noted, the names in the list given above were generally recognised and used. In addition, however to these, the two names at the head of this paragraph were also commonly employed to designate trees which it was believed resulted from the crossing of "C. officinalis" and "C. succirubra." These were first brought prominently into notice by Mr. Broughton in 1869;* Mr. McIvor, in his report for 1869-70, also remarks on the readiness with which hybridization occurs and states that some "very interesting hybrid varieties" had been raised from seed. The name "pubescens" dates from 1872 when it was bestowed as a varietal (hybrid) name by Mr. Howard† on a plant, the bark of which afforded him a very high percentage of alkaloids; that of "magnifolia" seems to have arisen from a faulty identification of the leaves with the plate of "C. magnifolia," Pav. in Howard's "Illustrations"‡ by Mr. McIvor. The hybrid nature of these plants remained unquestioned, and their rapid increase led Mr. Howard to write in 1876:§ "it seems difficult now to obtain seed from Ootacamund that is not hybridized." Dr. Bidie also in 1878‖ was much struck with the strong tendency of the species to cross and says of the "hybrid called 'C. pubescens'" that "specimens submitted to Dr. King and myself...... show that it is a hybrid with a strong strain of the 'officinalis' family, and apparently a cross between 'C. officinalis' and 'C. succirubra.'"

Similar experience was recorded as early as 1870 from Sikkim, Ceylon and Java, and up to the end of 1880 there was a general consensus of opinion as to the probable origin of the plants.

6. *Mr. Cross's and Colonel Beddome's opinions.*—In January 1881, Mr. Cross sent in a report on the plantations, which was printed in the following June. Early in the same year, the plantations having been transferred to the Forest Department, the Conservator, Colonel Beddome, was directed to inspect and report upon them. The valuable notes he prepared in June, together with further observations by himself and by Mr. Cross in August, were printed in September, and as the botanical points now in dispute have mainly arisen on the opinions expressed in these documents, it is necessary to give them particular attention. This is especially due to Colonel Beddome, who has a well-merited reputation as a skilful field botanist: as Mr. Cross was the original collector of most of the kinds, and familiar with them in the wild state in their native localities, he would also seem to have claims to a hearing.

The principal point insisted on by the latter in his report refers to the hybrid form called "pubescens." This, he says, is really a "narrow-leaved variety of red bark" and was called "Pata de Gallinazo" by the bark-collectors in South America. He could not see in it "a particle of the characteristics" of "C. officinalis," and he observes that the trees may be found at Naduvatam "not unfrequently among the first-planted trees there." He further informed Colonel Beddome that he himself sent *seeds* of this "Pata de Gallinazo" to the Nilgiris at the same time as "succirubra," but not separate from that species; in a letter to Colonel Beddome, however, dated 10th August 1881,¶ he gives a very different account of the mode of its introduction, in which he states that he obtained *plants* in the bottom of a ravine on Chimborazo to fill up one of the packages of "succirubra," and that his companions, two lads, the sons of a bark-collector, identified them at once as Pata de Gallinazo. He also calls it "a new and undescribed species."

All this was absolutely new to everybody; for not a hint of anything of the sort is to be met with in any of the voluminous reports or papers referring to the collection of the Bark-trees for India. Colonel Beddome, however, was quite convinced of the accuracy of Mr. Cross's recollections, and supported his assertions. He, too, could see in the plants none of the characteristics of a hybrid, and considered that they had evidently been in the plantations from their commencement.

Cross afterwards restricted his previous remarks to "magnifolia" only, and said that "pubescens" was a different species from "Pata de Gallinazo;" after some

‡ Tab. 13. This represents a member of a different genus, and is now "Cascarilla magnifolia," Wedd.

§ Quinol. Ind. Plant., p. 84.

‖ Appendix to Rep. of Cinch. Committee, pp. 42-45.

¶ Enclosure in No. 422.

[illegible] consideration, he pronounced that "pubescens" was the real "C. succirubra" and that the plant, hitherto known under that name, was not that species but "C. micrantha," or some other grey bark! Colonel Beddome, however, could recognize varieties only of a single species in "magnifolia" and "pubescens," but this, he thought, quite distinct from both "C. succirubra" and "C. officinalis."

With regard to the supposed numerous varieties of "C. officinalis," neither Colonel Beddome nor Mr. Cross could trace them out. The former speaks somewhat doubtfully as to the nature of what passes as "Uritusinga" on Dodabetta, of which he believes there are about 1,000 there and about 12 at Naduvatam. As to "C. calisaya," he could distinguish four varieties, ordinary "Calisaya," "Ledgeriana," "anglica" and "javanica."

A paragraph (45) is devoted by Colonel Beddome to an "unknown species" with very rough corky bark and leaves hairy on both sides, of which five trees were found on Dodabetta. Mr. Cross at once pronounced this to be "the celebrated "C. crispa" of the Loxa mountains, a packet of the seed of which we collected when collecting the "officinalis;" he added that it gives a very valuable bark and that he sent the seed to Mr. McIvor who told him that it never germinated.

Mr. Cross sent home thirty samples of bark for analysis by Messrs Howard. In his remarks upon No. 18 ("Pata de Gallinazo") Mr. J. E. Howard—who also fully accepted Mr. Cross's statements—says* that it is "C. coccinea" of Pavon,† and not red bark at all. In abandoning his former view of the hybrid nature of "pubescens," Mr. Howard merely says it is one of the "cognate species to 'succirubra.'"‡

Colonel Beddome collected and dried good typical specimens of the 18 different kinds of "Cinchona" he could recognize, and these were forwarded to Kew with the object especially of the "Pata" (No. 2), "pubescens" (No. 3) and the "unknown species" (No. 18) being there identified.

7. *My own views and those of the Kew botanists.*—In September of the same year, I had the pleasure of receiving Colonel Beddome during his short visit to Ceylon. He found on the estates here abundance of Cross's "Pata," and some of the Nilgiri "pubescens." In his report to Government, dated 3rd October (No. 167), by some strange misapprehension, he quoted me as supporting his views as to the nature of these trees. They had, of course, been long familiar to me, but I had always carefully avoided committing myself to a definite opinion about them, though strongly leaning towards the view of their hybrid origin. I therefore found it necessary to state my position, which I did in a letter to the *Ceylon Observer* newspaper, 27th November 1881. I may here be permitted to quote the conclusion of this communication. The name "robusta" which I proposed to adopt was, Colonel Beddome informed me, in use on some estates in South India; it is now commonly employed in Ceylon for the trees in question.

"I also desire to say a few words as to the name which this cinchona should bear. It is, I think, much to be regretted that the name "Pata de Gallinazo" should have been brought out of its obscurity by Mr. Cross and adopted (even provisionally) by Colonel Beddome. This is a mere bark-collector's name and is used in different parts of the Andean chain for at least six different kinds of barks. That which has the best claim to it (as having been first published and more often used) is the best sort of grey bark collected by Pritchett in Huanuco and referred to *C. peruviana* or *C. micrantha* * * * [illegible] of course, the case that the name is also used for the "Cascarilla serrana," or Hill Red Bark, which Dr. Spruce obtained on Chimborazo at 8,500 to 9,000 feet, and with which Mr. Cross (who accompanied Dr. Spruce as gardener) now identifies the plant under discussion. * * * * * *

"It is to be hoped that the copious dried specimens sent home by Colonel Beddome for comparison with types in the London Herbaria may clear up the matter; but this cannot be very confidently expected. Meanwhile, I would recommend the suppression of the Spanish name of "Pata de Gallinazo" for our "hybrid." If the tree has been duly described and named, we shall, of course, get the proper appellation in time. If not or till then—since the names "pubescens," "magnifolia," "villosa," and others are all, for various reasons, unavailable—we cannot, I think, do better than adopt that already coming into use in Southern India, *robusta*, which is a very appropriate one. By using this, we do not commit ourselves to any views as to the origin of the plant, whether on the plantations of the Nilgiris, or the higher slopes of Chimborazo."

Colonel Beddome's specimens were duly examined by the Kew botanists. Mr. Dyer in his letter upon them (in No. 382, 24th January 1882) agrees that "*magnifolia*" and "*pubescens*" are practically one and the same plant. As to "Pata de Gallinazo," he points out that Mr. Spruce has described this and the closely allied "Cuchicara" in his report (Blue Book I, pages 116, 117), that his specimens are in the Kew herbarium, and that "although there is some resemblance in the foliage it may be said with some certainty that the Nilgiri '*magnifolia*' is not the 'Pata de Gallinazo' of Chimboraza." It is further remarked that Spruce's specimens have been referred by that botanist and by Howard to *C. erythrantha*, Pav., and that "this identification is probably correct;" also that Mr. Triana considers both these specimens and *C. erythrantha*, Pav., as belonging to the species *C. pubescens*, Vahl. It is decided that "the most probable account that can be given of the forms '*pubescens*' and '*magnifolia*' is that they are hybrids between *succirubra* and *officinalis*."

With reference to the "unknown species" (No. 18) no opinion is expressed; as the specimens collected by Mr. Cross were in private hands, no comparison could be made.*

8. *Dr. Bidie's Reports.*—Meanwhile Dr. Bidie had been requested by Government to enquire into Mr. Cross's assertions, and to collect a good series of all the Naduvatum cinchonas and their barks. In his letter (No. 199), dated 3rd March 1882, he summarily disposes of the notion that any mistake had been made as to the plant known as *C. succirubra*. He also shows that "*pubescens*" is not as Cross maintained, *C. succirubra*, but suggests that it will probably be found, on comparison, to be "identical with Spruce's pubescent 'Cuchicara' of Llalla," above referred to. As to the "*magnifolia*" Dr. Bidie considers Mr. Cross's identification with "Pata de Gallinazo" "will probably prove correct." For both these opinions his basis is Spruce's brief description above noticed. In a further letter (No. 284), dated 29th March, written after perusal of the remarks of the Kew botanists, Dr. Bidie still supports the above contentions, on the grounds of (*a*) the occurrence of the plants in the oldest plots of the Nilgiri plantations, (*b*) the probability of the truth of Cross's positive statement, (*c*) the improbability of two hybrids so similar to Spruce's two plants arising spontaneously, (*d*) the want of any tendency to depart from type, and (*e*) the fragmentary character of Spruce's specimens (as gathered from his narrative) rendering the comparison possibly fallacious. Sir J. Hooker in reply (letters, dated 13th June, 7th July and 3rd August) can see nothing in these observations to cause him to alter the views previously expressed that "the plant called '*magnifolia*' is not the 'Pata de Gallinazo' collected by Spruce; neither is the plant called '*pubescens*' the 'Cuchicara' of the same traveller." The discussion of these questions is continued at page 8 of this report, paragraphs 19 to 22.]

A collection of well-selected and dried specimens of 38 different forms was made by Dr. Bidie (with an accompanying series of the barks from the same trees) and forwarded to Kew where I had the opportunity of examining them

* Enclosure in No. 267, (July 1881).

† This was Spruce's determination of the real "Pata" of Chimborazo (see Weddell, "Notes" l. c. page 30).

‡ Pharmaceutical Journal, October 1881, page [illegible].

Colonel Beddome's report (page 8) contains the extraordinary assertion (derived from Mr. Cross) that [illegible] their appearance, bark and leaves—the lower and [illegible] —in his paper in the "Journal of the Linnean Society," iv., page 155. Indeed, it is Mr Cross's [illegible] in this matter, that is the novelty.

* On the identification of this plant see paragraph 16 of this report.

in July last.* The trees supplying these have been permanently labelled with the same numbers as the barks and specimens, so that they can be readily referred to at any time. The examination of Dr. Bidie's collection led to the following remark by Sir Jos. Hooker in his letter of 3rd August: "Crossing has evidently gone on so extensively that no one but a botanist accustomed to the *facies* of living cinchona plants could pronounce an opinion upon the mixture of forms with any authority or without the risk of adding to the confusion of nomenclature."

I now proceed to the observations I have to make on the botanical characteristics and names of the trees inspected by me in the Nilgiri plantations.

9. *C. succirubra*, Pav.—In regard to red bark, I can very confidently endorse the opinions expressed by all the botanists who have examined the matter, that the well-known tree which forms the bulk of Naduvatam is the true *C. succirubra*, Pav. I have examined Pavon's own specimens in the British Museum which precisely correspond with the ordinary red bark of India, Ceylon and Jamaica. This has the leaves generally more or less pubescent or puberulent beneath, as is the case with Pavon's specimens; and Mr. Howard is mistaken in saying† that the common plant in India is perfectly smooth. Dr. Spruce's description at p. 101 of his octavo report of 1861 is very good.

I must, however, allow that I found *succirubra* in Naduvatam a more variable type as to the foliage than I am accustomed to in Ceylon. Among the large trees in the original plots are to be noticed, besides the ordinary kind with leaves glabrous above and pubescent beneath, not a few which have leaves at least when mature altogether smooth; some again are persistently hairy on both surfaces. There were also a few trees with remarkably narrow leaves attenuated at the base. As a rule, the leaves are less bullate and smaller than in Ceylon, but it must be remembered that Naduvatam is a somewhat higher elevation than this species is usually grown at here. I have no doubt that some of the leaves from the Naduvatam red bark would be called "*pubescens*" in Ceylon, and I am also convinced that this is partly due to many plants and seeds of this kind having been actually sent out from the Naduvatam plantation under the latter name.

A few miserable and scarcely recognizable little trees were all I saw of *succirubra* on Dodabetta.

10. *C. Calisaya*, Wedd.—I have little to say about the plants included under this name represented in the Nilgiris.‡ There are patches both on Dodabetta and Naduvatam, but neither contain any well-grown trees. As may be seen from the list in paragraph 4, they are of various origins. A plot on the east slope of Dodabetta low down planted in 1865 (said to be from Mr. Money's seed) presents the extraordinary mixture of varieties that one is accustomed to in seed from Java. The bulk are the varieties known as "*javanica*" and "*vera*" in Ceylon, but there are also a few trees of *succirubra* and *micrantha* and two or three of what I am accustomed to consider a hybrid between *calisaya and officinalis* and occasionally met with in Ceylon plantations. Among them, too, the superintendent, Narrainsawmy, pointed out two or three which he said Mr. Moens in his visit in 1880, had pronounced to be *C. ledgeriana*, but these were not in flower, and I am not able to distinguish this species with certainty from foliage alone.

At Naduvatam, as would be expected from its locality, the *Calisaya* varieties are rather better in growth, but even here they are gradually dying out. Dr. Bidie selected no less than fifteen sorts for his dried collection which exhibit a wide range in size and shape of leaf, size and colour of flower and form of the seed-capsule. A large and broad-leaved form is that which grows most vigorously. I saw nothing like *C. Ledgeriana* among them. As might be expected, a fair number of the very broad-leaved large-flowered hybrid with *C. succirubra*, *C. anglica*, How.,* were to be seen in Naduvatam.

11. *C. officinalis*, L. *(C. condaminea*, Humb. & Bonpl.—Dodabetta plantations are almost entirely composed of this species which grows there to perfection; there are also a large number of Naduvatam. In common with other botanists who have been recently over the plots I failed to detect many marked varieties; indeed what particularly struck me was the remarkable uniformity of type prevailing throughout the vast expanse of the Dodabetta;† no greater variety was to be seen than in a plantation of oaks, elms or poplars. If it be desired to distinguish by names the differences in the width of the leaves it would appear that the broadest represent *C. uritusinga*, Pav., and the narrowest the true *C. crispa*, Taf.: the intermediate ones being the vars. *Bonplandiana*, How., and *Angustifolia*, Wedd. I am unable to separate these, which completely pass into one another, I had expected to find here something more distinctive as *Uritusinga*. Two varieties bear the plantation name of "*Angustifolia*" and are distinguished as "No. I" and "No. 2"; the latter has by no means a narrow leaf. One of these represents apparently Mr. Broughton's plant (No. 10 of the list in paragraph 4.)‡ A vigorous propagation was going on by seed of another form, which was called "*crispa*" by McIvor and Beddome, on what grounds I am not aware. This form has rather acuminate leaves and very large flowers, and is remarkable for the development of a very thick corky outer bark. I saw but one plant, but there are said to be seven or eight in Dodabetta. I also detected two plants of *officinalis* (both broad-leaved) distinctly pubescent beneath.

12. *C. lancifolia*, Mutis.—Though this has been in cultivation from the very commencement of the plantations, very little has been heard of it; and recently it has quite dropped out of notice, being no longer included in the annual lists. The few existing trees are the survivors of the numerous descendants of a single plant which was alone saved out of six brought from Java in 1861. The two or three that I saw were in the lower part of Dodabetta near the Jalap Garden. I was at first inclined to treat them as another form of *officinalis*, but a closer examination has since shown me their distinctness, if not as a species at least as a well-marked variety. The habit and leaves are certainly very like an ordinary *officinalis*, but the calyx shows a marked contraction above the tube, and its free part is sub-campanulate and spreading with rather large triangular segments; the disk is very thick and prominent, and the corolla large, dark lake and with a broad tube; the large calyx is persistent and crowns the oblong-ovoid capsule. The different calyx seems to separate it from all forms of *officinalis*§ A figure, reduced from the magnificent plate of Karsten's Columbian Flora, will be found in Markham's "Cinchona Species of New Granada," page 53, where is also reprinted a full description. The cultivation of this species is maintained in the Java Government plantations.

13. *C. micrantha*, R.& P. *and its allies*.—The Grey Barks require no particular notice here. However important a place they may have once occupied in the plantations, they are now

* The dried specimens have been transferred to the herbarium here at Peradeniya. Dr. Bidie has since prepared and transmitted to the Pharmaceutical Society's Museum in London a still larger series, but with the same nomenclature.

† Pharmaceutical Journal, October 1881. Nor do I think he is correct in stating that bark of "Pata," of "pubescens," or of "Cuchicara," is sent home from India or Ceylon under the name of "red bark"; though, no doubt, *succirubra* bark may have been sent as "hybrid pubescens."

‡ I notice that in the most recent enumeration of the trees (31st March 1882) no estimate of the number of *calisaya* is attempted, the space being left blank.

* Well figured by Howard in his "Quinology," t. 10. He raised it from seed sent from the Nilgiris by Mr. Broughton and taken from an ordinary *calisaya* which had doubtless been crossed by neighbouring *succirubra*.

† McIvor in 1869 says (Report, para. 9) that from the three original kinds of crown bark, at least seven distinct varieties had been raised. He is said afterwards to have distinguished as many as twenty-two sorts. Mr. Broughton mentions as many as twenty.

‡ It appears, however, that Broughton's original tree is no longer in existence.

§ True *C. Chahuarguera*, R. & P. (not of Howard, which is merely narrow-leaved *officinalis*), is closely allied or intermediate; and *C. macrocalyx*. Pav. (as figured in Wedd., Hist. Quinq. t. bis., fig. A) must also be very near *C. lancifolia*.

practically extinct.* Isolated specimens can be found on Dodabetta, Naduvatam and Wood plantations, the last survivors of their race. They have died out rapidly: in 1878, close upon 800 trees of *micrantha* were counted on Wood plantation, I saw but one moribund specimen. It is, therefore unnecessary to make any remarks on their botanical characters; which is somewhat fortunate as these species are very obscure as to their nature and affinities.

14. *C. carabayensis*, Wedd.—(*C. Pahudiana*, How.) Several healthy trees of this pretty but useless species are still growing in the earliest-planted plots at Dodabetta. Its characteristics are quite well-known and its interest to Quinologists chiefly historic. Dr. Bidie includes a specimen (No.. 36) from Naduvatam in his series.

15. *C. pitayensis*, Wedd.—Of this remarkable species there are some 45 or 50 trees in a clump near "the Jail" at Dodabetta. They are very striking from their habit being so unlike all the other cultivated species; indeed they rather suggest at first a Lauraceous tree or a *Symplocos* than a Cinchona. The species is but little known to botanists, but Howard has given an excellent figure in his "Quinology" t. 12.† The branches curve strongly downwards for most of their length and then turn upwards suddenly at their ends; here the leaves are crowded, which are stiff, thick and polished, and stand erect with their pointed ends upwards. The trees were past flowering at the time of my visit, and I was unable to examine the corolla, so remarkable for being hairy within; but the young fruit was characteristic enough, crowned with the persistent long, almost setaceous calyx-segments. I was glad to see that some propagation of this species was being undertaken; it appears to have been singularly neglected. It is true we read in the reports of the late Superintendent of 500 planted out in 1872 at Dodabetta and 400 at Hooker plantation, and of no less than 4,386 put out in 1874 at the latter, ‡ but not one of these, I believe, now exists. The tree affords true Pitayo bark; three different varieties were collected by Mr. Cross, and I noticed among the trees some varying slightly from the rest in having shorter and broader leaves.

16. *C. Humboldtiana*, Lamb.—I was enabled to name Colonel Beddome's unknown species, the "celebrated *C. crispa*" of Mr. Cross (see paragraph 6), from my examination of the material in the London herbaria. The original specimens of this species were collected by Pavon; they are in the British Museum and labelled by him "C. sp. nova de Jaen de Loxa en Quito." The sheets are named by Lambert *C. Humboldtiana*, a name which he published in his "Illustrations of the genus Cinchona" in 1821, where, however, his description does not perfectly agree with his specimens. What I consider to be the same species was also collected by Spruce in August 1856, "in Monte Campana prope Tarapoto, Peruviæ orientalis" and is numbered 4832 in that traveller's extensive series of dried specimens. Though Mr. Cross's determination of it as "*C. crispa*" may be disregarded, yet that he may have collected the seed is evident from the fact that one of the three dried specimens § he brought back with him is this very species. This is ticketed as follows:—"No. 3, *C. species*. In deep ravines on the Sierra de Campana and Koritroche. This species of cinchona grows on steep banks of ravines in rather moist situations it is frequently found in the mountains of Samora which lie eastward from Loxa and is sometimes collected by the wild Indians which traverse that tract of country. This tree grows from 50—60 feet in height, Oct. 18, 1861, R. C." It is of this specimen that Mr. Markham writes:* "Bark and leaves of *C. lucumæfolio* of Pavon, from Zamora. This is the 'Cascarilla de hoja do lucma' of the natives." He adds, "Mr. Cross made no attempt to collect the seeds as this species is comparatively worthless;" but be that as it may, the plant has clearly reached the Nilgiris.

Colonel Beddome was by no means the first to notice this at Dodabetta.† Specimens are included in the series made up by Mr. McIvor ‡ for the India Office in 1873 (see Blue Book V., page 91) where they are numbered 24 and called merely "Corky bark." I have examined them in the British Museum duplicate set.

C. Mutisii, Lamb., appears to differ only in the leaves being smooth above, and probably ought to be combined with the present species. To this is to be referred the figure of *C. microphylla* in Howard's "Illustrations." t. 17, fig. 1, which plate is a fair representation of the Dodabetta plant with the exception of the slight difference above mentioned. Howard's plate of *C. villosa* (Ill. t. 6) is referred to *C. Humboldtiana* by Triana (and "*C. villosa*, Pav. M.S.S." is certainly quoted by Lambert), but cannot represent that species.

This plant is clearly a near ally of *C. carabayensis* (*Pahudiana*) and is probably equally valueless; it differs in its smaller calyx, much less conspicuous in fruit, its less hairy capsule, and its smaller thicker leaves which are rounded at the base instead of tapering, and stiffly hairy above as well as beneath even when fully grown; when dried, their margins are strongly recurved. The large development of cork at Dodabetta is probably an accidental circumstance

17. *Santa Fé Bark*.—The two surviving plants of this valuable cinchona are both at Dodabetta, one planted out in the lower part of the North-east side, the other still in a pot in the propagating house. They are now $2\frac{1}{2}$ years old, and that planted out is about three feet high only. The few leaves they possess are peculiar and appear to indicate a species quite unknown to me. The figure (fortunately not coloured) in Howard's "Quinology" t. 14 is a very g od representation of them. Both Weddell and Triana place the "Calisaya of Santa Fe" under *C. lancifolia*;§ and in default of further material for comparison, here it must remain for the present.

18. *Carthagena Bark*.—There are seven plants of this permanently put out at Dodabetta and two at Naduvatam; the latter are the more healthy and the larger is about four feet high. Numerous cuttings are in the propagating houses. There is also a fine plant in Sim's Park at Coonoor.

Of the name of this handsome species I am quite ignorant; it has possibly never yet been defined or named. The leaves of seedlings and young plants are useless for comparisons, being frequently very different from those of adult trees; in these plants they resemble those of *micrantha* more than any other species. The "Hard Carthagena bark" is usually referred to *C. cordifolia*, Mutis, a variable species with a very wide distribution in South America. Mr. Howard has suggested an affinity with *C. purpurea*, R. & P.. which, to judge from the description and his plate (Illustrations t. 11) seems to be probable.

19. *C. robusta*.—In paragraph 5, I have given a sketch of the opinion which prevailed as to the plants I include under the above name up to the year 1880; and in portions

---

* The plantations were, however, still credited with the possession of 1874 plants on 31st March 1882 (see report 1881-82).

† The figures of *C. corymbosa* and *C. Trianae* (both referred to *C. pitayensis* by Triana) as reproduced from Karsten in Markham's "Cinchona Species of New Granada" very little resemble the Dodabetta trees as to foliage.

‡ Report for 1873-74, paragraph 3. The plantation books ought to give some details as to the precise plots where these were planted.

§ These specimens, formerly in the possession of Mr. Markham, were presented by him to Kew Herbarium, February 1882, where I had the pleasure of examining them.

* "Peruvian Bark," p. 238, footnote. I have examined the type specimens of *C. lucumæfolia*, Pav.. from Loxa; which is a totally different plant with narrow and perfectly smooth leaves.

† Mr. Howard, in a notice of Colonel Beddome's report (Pharmaceutical Journal, October 1881, page 354), says the plant should be *C. decurrentifolia*, Pav.

‡ It is doubtless the plant alluded to by Mr. McIvor in his report for 1869-70 (paragraph 5). "Among our Crown barks we have this year discovered a very interesting and apparently a new species with soft downy leaves and rough corky bark, but deficient in alkaloid. This plant was raised from the original seeds introduced by Mr. Cross through Mr. Markham, and must have been gathered by accident" (Blue Book V, page 6).

§ I am unable here to refer to Mr. Howard's paper in the Bull. Soc. Bot. France, Vol, XXII, on. *C. lancifolia* var. *oblonga*, referring to this plant.

of paragraphs 6, 7 and 8 are detailed the successive views of Mr. Cross, Colonel Beddome, myself, Dr Bidie, and the Kew authorities. I entered on the examination of the Nilgiri trees with no strongly settled opinion as to their nature, though my Ceylon experience had more and more inclined me to look upon them as hybrid forms rather than as one or more autonomous species.

I found the forms presented to be just those so common in Ceylon plantations. Generally robust well-grown trees, larger, hardier and healthier than either the *officinalis* or *succirubra* among which they were scattered and often flourishing where neither of them can thrive. Botanically, there was the same range of variety, the extreme form in one direction, with its dark green smooth shining leaves, closely approaching some of the large-leafed forms of *C. officinalis*, and that in the other direction with its larger paler thinner leaves more or less pubescent beneath, so close to the hairy form of *C. succirubra* as to be often with difficulty distinguished from it. Between these, as regards color and pubescence, were many intermediates, though undoubtedly, with a little ingenuity, the whole can be thrown into the two groups. There are not many on Dodabetta (where are no *succirubra*), and these are nearly all of the glabrous sort, but on Naduvatam they are much more numerous, and in parts both there and at Hooker plantation they stand out conspicuously above the more or less sickly and stunted kinds round them.

As the chief of the test-points as to origin was the alleged occurrence of a few "in the oldest plots" at Naduvatum, I particularly examined several. They are certainly growing in plot No. 1, planted in 1862, and are of both the glabrous and pubescent kinds.* They are also undoubtedly old trees, but that they form really a part of the 1862 *planting* cannot, I think, be affirmed with certainty. From the look alone I do not think it possible to say whether a given tree be twenty years old or sixteen; it is therefore necessary, in the present case, to see whether there are any grounds for supposing that the *robusta* trees may have been supplies put in to fill up vacancies in the original planting. With one tree this appeared to be the case, as it was clearly out of the line, but in two others there was certainly nothing in the surroundings to suggest that they were not part of the same planting as those around them. But the question is of such importance that it requires further examination.

C. succirubra first flowered in 1863,† but I have no evidence that *C. officinalis* did so before 1865. In that year, however, both species ripened seed, and in the next the majority of the young plants were being raised from seed.‡ We have it on Mr. McIvor's authority that "in 1866 a number of hybrid seedlings were produced" and that "the selected varieties were planted here and there in every way, soil, exposure and elevation available."§ In the same year, 1866, six hundred of the original trees, planted out in August and September 1862, were cut down for their bark;‖ and though nothing is said as to the filling up of the gaps thus caused, this was certainly done, as is evident from the regularity of the existing plots. It is most likely to have been effected with the new seedlings: two or three years later, Mr. McIvor expressly states that "all the supplies are plants raised from seed."¶ What therefore more probable than that some of these "hybrid seedlings," which were planted "in every way available" should find their way into the 1862 plantations along with the other supplies in 1866-67.

One of the trees pointed out to me in this 1862 plot was one of those hybrids denounced by Mr. Broughton (31st July 1871) as "combining the bad qualities of both their parents."** Now, he could scarcely have called

‡ McIvor, Reports, 1864-65 and 1865-66, para. 4.

§ *Id.*, Report, 2nd August 1875. Mr. McIvor believed these to be the result of his experiments in artificial cross-fertilization; it may be so, but it is perhaps more probable that they arose naturally. In either case they appeared.

‖ McIvor, Report for 1866-67, para. 2. This important fact seems to have been overlooked by subsequent writers.

¶ McIvor, Report, 1869-70.

** This particular tree is a glabrous *robusta* with the leaf more elongated than usual. Colonel Beddome considered it "glabrous *pubescens*."

this tree a hybrid if he had not good grounds for believing that it was no part of the original 1862 plantation in which it grew; indeed he states definitively (13th February 1873) that the hybrids "appear only among seedlings, *there being none among the original trees*."* I may add that in this same "1862" plot there are several trees of *Calisaya*, which cannot be any part of the first planting.

A search through the late Superintendent's papers and the plantation records might very probably give much information as to this and other historical matters. He has stated that he always reckoned 30 per cent of every year's planting as failures to be subsequently filled by supplies, a fact which the recent compilers of statistics of the plots seem to have scarcely fully realized.

These remarks may be considered a sufficient answer to the first of Dr. Bidie's arguments (see para. 8.) I will now proceed to discuss the remainder of them.

20. *Mr. Cross's credibility.*—Dr. Bidie thinks Mr. Cross's positive statement that he sent plants of "Pata de Gallinazo" to India to be probably true. To my mind I must say that "probability" points rather the other way. Dr. Bidie has himself remarked on the "little reliance" that can be placed on that traveller's memory, and indeed we have abundant evidence of its treacherous character. It has made him give two different accounts of this very matter, caused him to forget well-known facts and make unfounded statements about Dr. Spruce, hopelessly confused him over the distinctions between *succirubra* and *micrantha*, and supplied him with a totally erroneous name for the plant "No. 3" of his own collection, now shown to be *C. Humboldtiana*. His reminiscences indeed seem singularly confused, and I do not consider it necessary to further allude to them.

21. *Alleged stability of type.*—Another point urged by Dr. Bidie (*d*) in favor of the autonomous nature of this plant is, as he thinks, the want of a decided tendency, "as in the case of hybrids," to vary more than is usual in other undoubted species of *cinchona*. I need scarcely remind Dr. Bidie that cultivated plants supply us with abundant examples of known hybrids as permanent as most species; but as regards "C. robusta" our experience in Ceylon is very different. It is notorious that the seed is most uncertain, and it is well known that Mr. McIvor would not trust it. On his visit to Ceylon in 1875-76 he gave seed of his best "*pubescens*" to several careful planters here; the result in one case was 10 per cent like the parent, and the remainder varieties of *succirubra* and *officinalis*; and this has been the so general experience here that I am indeed surprised to read of a different state of things in the Nilgiris. In Darjiling, Dr. King states that "about half" the plants from seed come up "officinalis."† Colonel Beddome could not deny these facts, but tried to explain them by careless collection of seed, but I know of cases where this source of fallacy was most carefully guarded against with no difference in the result. Colonel Beddome himself must at the last have had doubts, for he allows that it is better to grow the plant from cuttings.‡ It is indeed this reversion to apparently parent forms that is one of the chief reasons for regarding *robusta* as a hybrid.

But we have more direct testimony of it origin. I am assured by planters of credit that they have grown both glabrous and pubescent *robusta* from seed of ordinary *officinalis*, and that it is by no means unfrequent for seedlings of them to appear in seed-beds on estates where no trees but *officinalis* and *succirubra* occur. I have myself seen seedlings of *robusta* self-sown where there are no parent trees of the sort whence they could have been derived: and at one time I was inclined to regard it merely as a variety of *officinalis*. There are, I think, grounds for believing that *succirubra* generally supplies the pollen and is therefore the male parent, both in the case of *robusta* (succirubra × officinalis) and *anglica* (succirubra × calisaya). I do not attach any importance to bark-chemistry alone as a botanical character, but it may be noticed, as bearing on the derivation of these trees, that the analyses of their barks (though very variable) combines as a rule the characteristics of both Red and Crown barks.

* Letter to Howard, printed in his "Quinology" p. 113. The italics are my own.

† In his Report of the Bengal Cinchona Cultivation for 1881-82 Dr. King distinguishes "six distinct forms" of these *robusta* hybrids.

‡ Beddome, Report on visit to the Sikkim Plantations.

22. "*Pata de Gallinazo*" and "*Cuchicara*" *Barks*—*C. erythrantha*, Pav.—The two remaining arguments (c and e) advanced by Dr. Bidie become of less importance in face of what has now been stated. The specimens of "Cuchicara" and "Pata de Gallinazo" collected by Spruce* are no doubt imperfect ones; they have, however, proved sufficient for one of the most careful of botanists, M. Triana, to identify them with "C. erythrantha," Pav.,† to which Messrs. Spruce and Howard had also, with doubt, referred them. The flowers of the more pubescent specimen of the "Cuchicara" are described by Spruce on his ticket as "deep brick red," a tint I have never seen in any cinchona flower in the East. The leaves of all his three specimens are more or less pubescent. Dr. Bidie rather begs the question when he argues that the fact of the imperfection of these specimens is in favor of the Nilgiri plants being the same, and then proceeds to remark what an "extraordinary coincidence" it would be that two hybrids approaching so closely these wild South American plants should arise in the Nilgiris. It is not admitted that these *robusta* forms *do* approach Spruce's specimens very closely; on the contrary such eminent botanists as Sir J. Hooker, Prof. Oliver, and Mr. Thiselton Dyer express themselves strongly to the contrary effect. The wider tube of the corolla in the "Cuchicara," the color of the flower, and the flat-topped character of the inflorescence are good distinctions from all the forms of *robusta*.‡

On a review of the whole question then I am of opinion that the additional evidence derived from an inspection of these forms of Cinchona in the Nilgiri plantations does not by any means prove the improbability—still less the impossibility—of their being, as so long believed, hybrids of local origin between *officinalis* and *succirubra*, which opinion is, on the contrary, supported by a large number of facts of observation and warrantable inference.

23. *Uniformity desirable.*—In conclusion I wish to add a plea for uniformity in nomenclature. It is very much to be desired that the same plants should bear the same names in India and Ceylon and elsewhere, and that obsolete, incorrect, or duplicate names should be abandoned. No less than three different Cinchonas are called "*c... a*" at Dodabetta: it is rightly applied but to one, and that is so ill-defined that the name might well be dropped altogether. The various denominations bestowed on the hybrids may be entirely dispensed with as incorrect or misleading; *magnifolia*, pata, cuchicara, *pubescens*, *villosa*, &c. The glabrous and pubescent forms are now allowed on all hands to be of similar nature, and a single name is sufficient. Those who are convinced of their hybrid character may use the descriptive title *succirubro-officinalis*, or the shorter name *robusta*, whilst those who still think them an autonomous species of South America are bound to call them *C. erythrantha*. Of course I am not speaking of barks; planters and merchants may give these what names they require, *in the vernacular*, but with these names the botanist, as a systematist, has nothing to do.

The only other remark I have to make is to suggest whether the time has not now arrived when the Madras Government might adopt the spelling of this genus of plants followed by scientific men. So far as I am aware, there is not one living botanist who writes it in any other way than *Cinchona*. The matter is a purely technical one; systematists have long ago decided on the rules governing such cases of nomenclature, and the present one is not to be regarded as a subject for discussion. Were it permitted to amend the Latin genera which do not happen to agree precisely in spelling with the names (it may be Russian, Hungarian, or Japanese) of the persons whom they are intended to commemorate, many besides *Cinchona* would have to be altered. But it is not so permitted.

PART II.—PRACTICAL SUGGESTIONS.

24. I have now concluded the remarks I have to make with regard to the botany of the cinchona plantations, the subject upon which I was requested to report. But I have reason to believe that some observations upon the principles which ought, in my opinion, to regulate the future management of this fine State property will be acceptable to the Government. I take it for granted that the recent appointment of Mr. Lawson, of Oxford, to the office of Superintendent is evidence of a desire to maintain the plantations in a high state of efficiency.

25. *Management for past six years.*—It is to be feared that on the whole, during the last few years, the conduct of the estates has not been altogether satisfactory. They have been managed too much with a view to revenue, and without that constant care and oversight which was (at any rate for many years) bestowed by the late Superintendent. I consider that both the plantations and the trees have been overworked. Though many trees which have been frequently barked on Naduvatam and Hooker still appear healthy and cannot be said to have been much hindered in growth, yet, owing to the very imperfect renewal of bark —only in short strips or patches—it is now difficult to get any good samples or to practise the shaving method. I think that very many more trees should have been left untouched; we have yet to learn the effect of removing the bark upon the longevity of the trees and the real life-history of cinchona in the East. The recent supplies or renewals do not appear to have been very successful, the number of failures being very large.* No vigorous attempts towards increasing the specially valuable sorts or the recent introductions have been made; even the Pitayo barks—obtained at such cost and trouble, and specially recommended in 1878 by Government for further cultivation—remain little more than curiosities, and no effort to propagate the valuable Santa Fé has been made since Mr. Cross' departure.† Selection by cuttings or seed from the best of known analyzed trees (by which system, steadily persisted in, the Dutch in Java have so largely increased the value of their bark) has not been practised, nor is propagation of the delicate sorts by grafting on more hardy varieties carried on. I know from experience that seed has not always been carefully collected, and that there has been a good deal of confusion between "*pubescens*" and *succirubra*.

26. *Necessity for a good propagator.*—Under a new *régime* we may expect to see attention paid to these things as well as to experiments in artifical hybridization‡ and its results, the effects on longevity and health of the processes of stripping and shaving respectively, &c. I venture, however, to suggest that, if the assistance of a skilful propagator be necessary, such an addition to the staff of the Superintendent may be made.

27. *A scientific culture the object for the future.*—Progress in knowledge and improvement in practice, and not gain, should be the main objects of Government in the management of their plantations. I do not forget that the ultimate end of the enterprise is the production of a cheap and efficient febrifuge for India and the East. But this great purpose will be in no way retarded by the course recommended; on the contrary, as all that adds to our knowledge of bark-cultivation will lead to the increase of private plantations and their successful and profitable culture, it must be forwarded and hastened. The subject is somewhat complicated by various other considerations; but probably the final realization of that grand and beneficent scheme is more likely to be immediately effected by private enterprise in Europe

* It should be remembered that these were collected in 1859, before Dr. Spruce was employed by the Indian Government or Mr. Cross was engaged.

† *C. erythrantha* is figured in Howard, Illust. t. 12. It is considered the same as *C. pubescens*, Vahl. by Triana. The descriptions (but not the figures) in the same work of the following are also referred by M. Triana to *C. pubescens*, Vahl.; *C. coccinea*, How.; *C. Pallida*, How.; *C. subcordata*, Pav.; and *C. suberosa*, Pav.

‡ I may add with advantage that in my careful search through the public herbaria of London I did not find any Cinchona from South America agreeing with either of the leading forms of *robusta*.

* In the three official years 1878—81 no less than 33,407 red barks have died upon Hooker Estate alone (Beddome's Report, Appendix B); and I understand that the mortality of crown barks put in since has reached as much as 80 per cent.

† *C. lancifolia* (in paragraph 14) should also be propagated. The latest analyses of this in Java (Moens' Report, 20th February 1883) show total alkaloids varying from 4·6 to 7·2 per cent., of which quinine is from 1·1 to 2·0. Though less valuable than *officinalis*, this species is rather better than the majority of the Java *Calisaya*.

‡ This subject was specially insisted upon in the Report of the Cinchona Commission of 1878.

or in India itself than by any Government manufacture of alkaloids. Humanity will be equally benefited in the one case as the other. For the present this subject, however, may be allowed to rest.* Meanwhile the Government possesses a very valuable property, which, worked without stinting the expenses necessary for the highest experimental cultivation, cannot fail to return a profit for many years to come. More than twenty years ago the Home Government very justly remarked (Despatch, Secretary of State, Jan. 1863) that the Cinchona experiment could not be regarded as a mere money speculation, "nor are the commercial advantages that may be derived from it to be considered as other than a secondary consideration, though of course a return for the outlay and the spread of Cinchona cultivation by private enterprise are very desirable in themselves." How little, when these words were penned, could the present financial success have been imagined, and with how much more force do they now come, when even the outlay itself has been more than repaid, and a large and enterprising class of private growers of bark is in existence.

28. *Necessity of a Quinologist.*—The recent appointment is a step forward, but for any satisfactory progress to be made the chemist as well as the experimental physiologist and botanist is a necessity. For it must be remembered that it is *alkaloids* we want to grow, not bark only, and the cultural Superintendent is likely to be able to give us little accurate information about them. Further, the chemist must be on the spot, among the trees constantly, and always in readiness to work in unison with the Superintendent as one man at jointly-planned investigations. I desire to press this strongly, as the vast importance of constant analyses does not appear to have been realized by the members of the Commission of 1878, nor at first by Colonel Beddome.†

The Madras Goverment in supplying this deficiency will, in fact, be merely taking up again the work which was unfortunately dropped some eight years ago on the sudden resignation and disappearance of Mr. Broughton. The value of this chemist's researches is unquestioned, and his results are constantly quoted and acted upon. But his work was left quite unfinished, and it is to be feared that he got but scant assistance from the late Superintendent. He worked, too, a good deal in the dark as to the names and nature of the trees, which were then very unsettled. Since his time this has been changed, and chemists have also given us a great mass of facts as to the chemical composition of the barks of all the cultivated kinds, the main characteristics and general relative value of which in the market are now quite well understood. But there are many questions of the greatest value to cultivators still pressing for solution. The range of difference in the proportions and quantities of the alkaloids in barks from trees of *identical botanical type* is very large, and the same is true of the plants raised from seed of a single tree. We know nothing of the causes of these *individual* differences. There is even variation in analysis of bark raised from cuttings of one and the same tree; yet it has been shown‡ that the stock has no influence on the alkaloids in grafted shoots. It is thus clear that in the production of alkaloids the inherited nature of the trees is largely influenced by certain surrounding conditions, and these it is most important we should discover. The apparently good results which Mr. Broughton obtained from experimental manuring have never yet been corroborated or disproved. Even the cause of the increase of alkaloids in renewed bark is but little understood, and we probably are unable to avail ourselves of the fact to the full extent. The influence of age on alkaloidal composition in the various species is only guessed at from experience, but no series of analyses of selected trees at frequent intervals from the commencement of their lives onwards is available. These are samples of the investigations which only an analyst resident on the spot and working with the Superintendent can hope to decide.

29. *Position of the Government of Madras.*—All such researches however can only be properly carried on in a Government establishment, where the officers can devote themselves in a spirit of pure research to a work which must, of necessity, be spread over many years. And I will add that it is to the Government of Madras that all who are interested in cinchona in any of its various aspects necessarily look to take the lead. No other Government, in fact, will be likely to its undertake it. In Bengal, the production of febrifuge at present engages the whole attention of the staff, whilst here, in Ceylon, the Goverument possesses no plantations and is in no position to expend public money without an immediate return. It is true that from Mr. Moens in Java we have learnt much, but even there the object has never been revenue, and we ought not, and need not, to be dependent upon what a foreign Government may please to make public. On the other hand it was Madras that was formerly in the front position. At the pioneer of cinchona-growing in India it proved thas the best barks could be grown there, and initiated a great industry. This it did as an experiment and with a judicious liberality at immense cost. The excellent system followed has, from fortuitous circumstances, come to an end; under the very favorable present conditions, one cannot but expect to see it revived.

30. *Selection by Analysis.*—To go into any details of cultivation would be out of place here, but I may express the conviction that, in the present state of our knowledge, the most promising direction for the improvement of the trees as alkaloid-yielders is *selection based on analysis.* This is to be effected by the isolation of trees with high analysis, precautions to prevent cross-fertilization, care in collecting seed, analysis of a selection of the resulting plants, destruction of all that do not reach the standard of their parent, again, isolation of the best trees, and so on for several generations. The same principle may be more readily applied to grafts and cuttings. It is clear that in such a cultivation it is the chemist who regulates the procedure: plants which his analyses condemn are ruthlessly destroyed, those which answer his test are preserved to become the parents of improved successors.

31. *Changes required.*—The desirability of a plantation at a lower elevation and with a more equable rainfall has been already recognized by Government (G. O., No. 1,280, 29th August 1881). Neither *C. Ledgeriana* nor any of the varieties of *C. Calisaya* (of which there is good reason to believe there are some valuable sorts not yet in cultivation) succeed on the existing estates.* A site should be selected at about 3,500—4,000 feet in sheltered forest land. In some estates in such situations in Ceylon *C. Ledgeriana* is doing very well, and has more than equalled the Java trees in alkaloidal yield.

On the other hand the utility of keeping up the Hooker and Wood plantations might be again considered. They have been obviously much neglected, and I see no advantage to be derived from their maintenance beyond the profit from bark sales.

32. *Arrangement of Records and Publication of Results.*—The only other suggestion I have to offer is perhaps scarcely required. It is that all the records, papers, notes, and orders connected with the Government plantations be brought together and properly arranged and classified, so as to be readily available for reference. There must be much in Mr. McIvor's papers supplementary to his rather meagre annual reports, and probably Mr. Broughton's notes would repay perusal. At all events the history of the plantations cannot be followed without ready access to all the records. For the future, Government should take care that accurate note is kept of all work done in the plantation plots (as to deaths, supplies, renewals, and harvesting operations) as well as in the experimental houses and nurseries and in the laboratory. I will conclude by expressing the opinion that all results should be made promptly available to the public in annual reports, which also ought to be easily obtainable.

I have the honour to be, Sir, your most obedient servant,

HENRY TRIMEN, M.B.

* It has been thoroughly discussed in the Report of the Cinchona Commission of 1878, pp. 2—11, and with their opinions on the matter I generally agree.

† The latter however, after his visit to Ceylon, completely changed his views, and has expressed the opinion that the analyst is "all important." This opinion has been commended by Government to the Secretary of State (G. O., No. 1,513, 13th October 1881).

‡ Report for first quarter of 1883 of the Java Cinchona Enterprise.

* The *Calisaya*-forms hitherto introduced make very bad growth and are short-lived. They are also mostly poor quinine-yielders. Of the fifteen barks of this kind selected by Dr. Bidie for analysis, only two afforded over 3 per cent. of that alkaloid (one, No. 14, gave 5·55), whilst one (No. 21) gave only a trace, and all showed a strong tendency to develop the least desirable of the alkaloids—cinchonine (as much as 4·10 in No. 17). Some may be tried at the lower elevation, but experience in Ceylon is not favorable to their cultivation.

AGRICULTURAL STATISTICS IN INDIA AND CEYLON.

Mr. Buck, who was Commissioner for India at the Melbourne International Exhibition, and who is now Secretary to the Government of India in the Revenue and Agricultural Department, seems determined that a body of really reliable agricultural statistics for the Indian Empire shall be obtained, and, at his instance, a Conference of officers representing the various local Governments is to be held in Calcutta for the settlement of important subjects connected with the end in view, a programme of which will be prepared in Mr. Buck's office. Mr. Buck, with rare consideration, has fixed the third week in December for the meeting, with the belief that the meetings of the Conference can be concluded in a week The officers deputed from Madras, Bombay, the. North-west Provinces, the Punjaub, the Central Provinces, Burma, &c., would thus have tho opportunity of spending their Christmas holidays in examining the various objects at the Exhibition which will be then open, with pleasure and profit to themselves and with ultimate advantage to the Governments they will represent. From Madras, Mr. Wilson, the Director of Revenue Settlement and Agriculture, is to be deputed, and it has struck us that it might be well if the Ceylon Government asked that of India to allow an officer from this colony to attend the proposed Conference for the purpose of making himself acquainted with and reporting on the system proposed for adoption in India, whereby reliable statistics of agriculture are to be collected, classified and published. We should have named the Auditor-General as the fitting deputy from Ceylon, but for the fact that a member of the Executive cannot be spared so soon after the arrival of a new Governor and during the bringing forward of the estimates of revenue and expenditure in Sir Arthur Gordon's first Session of the Legislative Council. Under these circumstances, if the idea were entertained, the choice might fall on a member (the senior) of the Grain Tax Commission. By the time that Commission has completed its labours, we suppose a nearer approximat on than at present will be possible, as regards the acreage of land in cultivation under the various grain crops and the yields per acre of lands cultivated each year, distinguishing cases where two crops per annum are reaped from those where there is only one sowing season and one harvest. But agricultural statistics include cattle of all descriptions, ploughs and thrashing implements and floors, quantities of water used in irrigation, as also root and fruit crop , &c. At present, nothing beyond rough guesses can be made at the statistics of strictly native agriculture. Thanks to the European planters and others who have aided the compilers of *Ferguson's Ceylon Handbook*, the statistics of plantations, coffee, cinchona, tea, cacao, rubber, &c., are very closely correct; while the figures for such native or semi-native cultures as coconuts, cinnamon and lemongrass are pretty near the mark. But when we deal with the purely native cultivations of rice, dry grains, roots, fruits other than coconuts, &c., we enter the region of vagueness. This ought not to be the case. From the Customs Accounts we know exactly how many bushels of grain (an enormous quantity) are annually imported from the teeming granaries of the Indian deltas and the swamps of Pegu; and we are in the habit of indulging in the *guess* that the grain locally grown may bear the proportion of two-thirds of the entire consumption against one-third imported. But there is no real certainty as to the proportion locally grown, any more than as to the average rates of yield per acre in different districts, lowland and upland, "under" tanks or irrigated by streams led over terraces. In his report on the forests of Ceylon, Mr. Vincent describes the returns of dry grain obtained from chena land (forest felled and burnt) by figures which seem to us incredible. We know not the value of the evidence he went on, but all such points ought to be set officially at rest. To understand the condition of the vast proportion of the natives of Ceylon who live by grain growing and agriculture generally and apply remedies where needed fairly accurate information as to the average returns yielded to enterprize and labour is necessary, but such fairly accurate information is not now available. Our new ruler is sure to ask for the figures which represent the standard of material comfort and well-being in which the sons of the soil live, but he must, like previous Governors, be contented with mere approximations of rather a hazy character, until a proper and effectual system of obtaining agricultural statistics is elaborated and enforced. The time for such a reform, we submit, has come, and it seems possible that much benefit might accrue to Ceylon from the presence of a well-informed and receptive-minded officer at the Conference to be held in Calcutta in December of officers from all parts of India, whose attention has specially been directed to the best means of obtaining, classifying, aggregating, and reasoning from agricultural statistics. From conversation and discussion with them, the representative of Ceylon could not but learn much which would be of great value applied to the circumstances of the colony in a more or less modified form.

PLANTERS AND LABOURERS IN FIJI.

The correspondent, "A. R.W.," who writes to us (see page 410), from Forest Creek estate in Taviuni, Fiji, is anxious to remove certain unfavourable impressions which he supposes were produced by the letter we published some time ago from "A. J. S.," both as to the realtions between planters and labourers and as to the conditions under which coffee can be grown successfully and free from such diseases as black leaf and *Hemileia vastatrix*. "A. R. W." adduces the case of his own estate to show that coffee flourishes far above 1,000 feet elevation, producing fruit plentifully and almost free from the presence of the leaf fungus. As we read we cannot help remembering how confident Ceylon planters were for the first half-dozen years after the appearance of the fungus, that the pest was temporary in its character and that, like the previous visitation of coccus, it would disappear entirely or hide itself in a few corners, leaving the coffee trees none the worse. Admitting all the exceptional circumstances of soil and climate in favour of the group of islands in the Pacific, we can rather wish than fully hope that our sad experience of gradual and then rapid decadence may not be repeated in "Far Fiji." The planters there have the advantage of us that they can turn to sugar, as well as tea, cinchona and other products, if coffee fails them. Where the planters in the Pacific are at a serious disadvantage is in regard to a reliable labour supply. They complain that Sir Arthur Gordon's native policy of accepting taxation in kind has de-prived them of labourers with benefit only to the native chiefs who hold the ordinary cultivators in a species of bondage. Such

Fijians as do labour on plantations do not seem to find favour as compared with natives imported from other islands of the South Seas,—what the Queenslanders call Kanakas. But the abuses and the risks connected with the recruiting of such labour has produced so strong and widespread a spirit of opposition to what is denounced as a species of slave-traffic, that this source cannot long be relied on. Some coolies from India had been introduced and legislation had been passed to secure regular supplies of Asiatic labourers. But the planters of Fiji do not seem to take kindly to Ramaswamy, and if the two classes cannot get on together, then we cannot but fear for the extension and even the permanence of European planting enterprize in Fiji. Seeing how entirely the interests of the planting enterprize are dependent on a sufficiency of labour, no members of the community should be more desirous than good, honest humane planters, that the black sheep of their community, who treat natives with wanton cruelty, should be stringently dealt with. Our correspondent "A. J. S." related some striking cases of offences by planters and the signal punishment of the wrong-doers; but the last idea conveyed to our mind or entertained by us was that the treatment of a supposed malingerer by a series of mustard plasters while the tortured wretch was tied up in a sack was the deed of a *ci-devant* Ceylon planter employed by another ex Ceylon planter. "A. J. S." is mentioned to make up the trio and leave the impression that for anything discreditable to the body of planters in Fiji, men are responsible who were formerly in Ceylon and accustomed to deal with labourers who came to the Ceylon plantations flying from famine! Is this a true bill? Planters in Ceylon as well as in Fiji will dispute the correctness of the details. The series of views sent us by our present correspondent might pass for views of a Ceylon coffee estate but for the semi-negro features and curly hair of the Kanaka labourers. They are, no doubt, strong little fellows, but we cannot but adhere to the conviction that if, in Fiji and the tropical portions of Australia agricultural enterprize is to prosper, dependence must ultimately be placed on the obtaining of plentiful and regular supplies of Indian cooly labour.

With reference to "A. J. S."—a planter formerly well-known and much respected in Ceylon, we feel it due to him to quote what the present correspondent says in an explanatory note:—

"I have to add in fairness to 'A. J. S.' that when he actually wanted to advocate was not to be allowed to thrash or be cruel to boys but to be allowed to work them without cruelty. It is obvious that if the natural authority of the intelligent planter is stultified by the Government, removing his authority under the impression that the removal strengthens the influence of the Government, while it actually weakens the Government, there is nothing left to the planter but the employment of brute force. It is futile at this time of day to advocate being allowed to place a finger on a labourer."

On which we have to remark that the less brute force is resorted to the better. But certainly planters are often sorely tempted *not* to let patience have her perfect work; for instance when a surprise visit reveals a gang sleeping while they expect to be paid as if working. All who fight the battle of life, however, have need of patient forbearance as well as of persevering hard work, in order to ensure success. A large proportion of Tamil coolies are but over-grown children with deficient moral sense and needing to be taught the first principles of rectitude. As far as the government and the administration of justice go, they are as well protected here as in Fiji; but rightly administered by sensible men, the law does not leave the planters' rights unprotected or justify the conclusion too common amongst young magistrates, that in all cases coming before a court the planter must necessarily be considered the offender.

KOSLANDA IN UVA (CEYLON) AS A SCENE OF TEA CULTIVATION.

So long as coffee continues to yield fair returns in Haputale and other portions of Uva, of course it will be the part of wisdom to cherish and nourish the old staple. But in Uva, as in other districts of the mountain and hill regions of Ceylon, tea is attracting attention; and we have the strongest possible belief that by resort to proper modes and seasons of pruning the plant can be profitably grown over most portions of the Principality. Tea, it is true, will flourish in climates where the rainfall verges on 300 inches per annum, but it also grows and yields well where the annual rainfall is considerably below 100 inches. In some parts of Assam, tea is grown with a rainfall of only 70 inches. When, therefore, our correspondent who writes from Koslanda, (see page 410), in the south-eastern corner of Haputale, asks whether a rainfall of over 90 inches, well distributed, will not suit tea, we can have no hesitation in answering in the affirmative. Altitude makes all the difference in the world, for the beautiful but deadly "terai" which stretches away to the salt-lagoons of Hambantota is, next to the country inland from Mannar, about the most arid and deadly region in Ceylon. When the road which runs in almost a straight line from the foot of the hills near Rosebury to the town and harbour (?) of Saltopolis was in course of construction, a gang of coolies equal to a score were attacked by malarious fever at noon of one day and were all dead by 2 p. m. of the day following. This case and similar ones, apart from the impossibility of converting Hambantota into a safe harbour at a cost which can be looked at, or of making it a healthy town by means of "all the king's money and all the king's men," form conclusive answers to advocates of the seductive but utterly wild scheme of a railway from Hambantota to Uva. If the object of those who asked for this unattainable phantom, born of mirage, had been to weaken their own cause by a division of forces, when the real, substantial, feasible railway was sanctioned to within 25 miles of their beautiful and conveniently central Pass of Haputale, that object could not have been better served, unless indeed by the coarse and senseless abuse poured upon those who consistently adhered to the complete scheme of a railway into Uva through country as salubrious as it is fair and fertile. Even if the coffee of Uva ceases to be what it once was, we firmly believe that the success of tea will more than justify the local Government in keeping faith with the planters by completing the Uva extension into Uva. When the fulfilment of a distinct and sacred pledge is explicitly and finally refused, then will it be time enough to ask us to advocate the formation of a line where the physical obstacles may be slight, but which would involve holocausts of human victims to the fever demon. But we hold our confidence that Sir Arthur Gordon will not long be Governor of Ceylon until he presses on Her Majesty's Government the sanction of the remaining section of the true Uva railway, along every mile of which the climate is perfect, the scenery a combination of the grand and beautiful, while nature is waiting for the the operations of enterprise and industry on a soil which will reward both. Apart from extension of the planting enterprise proper, it is impossible to say how much grain and root and fruit cultivation, with the rearing of stock, may be developed in the magnificent valleys of Uva when it is joined by the iron bands of the railway to the metropolis of the island, the harbour of which is the constant resort of the ships and the people of all the nations. Holding such convictions, we are grateful to the Koslanda planter who has supplied us with rainfall returns indicative of a perfect tea climate. He has sent us complete figures for the five years ended 1882, as follows:—

Years.	*Inches.*
1878	95·35
1879	96·22
1880	93·53
1881	98·04
1882	81·63.

The average is almost exactly 93 inches, which average 1883 is expected to exceed, the fall to 29th Oct. having been 82·26 inches. Our correspondent has also supplied the monthly figures which show the distribution of the rainfall over the year, of special importance with reference to tea cultivation and we submit very satisfactory. Having deduced the averages from the table sent to us, we find that in 6 years the rainfall in January varied from 2·69 inches and 6 rainy days to 12·04 inches and 14 days: the averages being 6·64 inches and 11 days. In February the range was from ·20 to 10·61 inches and 1 to 13 rainy days: the averages being 4·30 and 6 respectively March ranged from 2·31 to 20·42 inches and 5 to 21 days; the averages being 6 inches and 10 days. In April the rainfall varied from 3·96 to 20·01 inches and the rainy days from 10 to 18: the averages being 12·13 inches and 15 days. May gave a range of 4·59 to 13·10 inches and 10 to 23 days: the averages being 6 inche and 13 days. June varied from ·23 to 3·28 inches ans 3 to 8 days: the averages being 1·20 inches and 5 days. July ranged from ·15 to 11·75 inches and 1 to 16 days: the averages for this month being 4·58 inches and 10 days. August varied from 1·54 to 6·35 inches and 9 to 13 days. The averages were: inches 4·21; rainy days 11. In September the range was 1·45 inch to 7·43, and from 4 to 13 rainy days. The averages were 4·35 inches and 9 days. We now come to averages for only five years. October varied from 7·49 to 19·20 inches and 14 to 22 days, with averages of 13 inches and 15 days. November is by far the rainiest month, having varied from 10·42 inches to 20·80 and 12 to 20 days. The averages are 17 inches and 17 rainy days. December gave a range of 8·66 to 17·35 inches and 12 to 22 days: the averages being 12·60 inches and 18 days. At Koslanda, therefore, the average annual rainfall is from 92 to 93 inches falling on 140 days; the monthly variations being from 1·20 inch and 5 days in June to 17 inches and 17 days in November. The bulk of the rain falls in the three concluding months of the year, which will probably be the pruning season in this district as well as in Uva generally. Rainfall in the spring of the year is not of such consequence in Ceylon, where our only winter is a winter of rainfall, but about one third of the total rainfall occurs between 1st Jan. and 30th April. There is a genial climate with warm air from the lowlands all the time, and it will be seen that our correspondent describes the rain as falling chiefly at night. Nothing could be more promising for tea cultivation and railway extension.

AUSTRALIAN TREES ON THE NILGIRIS.

When the mysterious disease appeared which spotted and withered the leaves and cankered the stems of the *eucalypti* in Dimbula and the neighbouring districts, we felt inclined to attribute the affection to high altitude as well as to the excessive moisture and cold wind of the south-west monsoon of 1882. But from the facts recorded in a report with which we have been favoured by the Madras Government on "Measurement of the Growth of Australian Trees on the Nilgiris," we are compelled entirely to abandon this idea. The higher the elevation at which the blue gums are grown on the Nilgiris—and plantations exist at 7,550 feet above sea-level—the more the trees have flourished and the more rapid has been the rate of increment. On the Nilgiris the soil is probably more suitable, and, although the wind can blow with any possible horse-power on the Utakamand plateau, the rainfall generally is not much more than one-half that which falls on the region between Nuwara Eliya and Adam's Peak, while there are longer intervals of dry weather. Frosts occur on the Nilgiris, of which we know nothing in Ceylon, but the *eucalypti* and *acacias* of Australia have to endure pretty severe frost in their native habitat. The terrible south-west monsoon of 1882 did, however, injuriously affect the plantations exposed to its influence, the foliage at least suffering as in Ceylon, although in the report before us we see no mention of stem mortification. We quote as follows:—

During the past unusually violent monsoon there is no doubt, however, that some of the plantations to the west of Ootacamund have suffered severely. Large portions of the Governor's shola group of Eucalypt plantations have had their foliage nipped and scathed as if fire or frost had passed over them. The acre-increment for the present year in these plantations cannot but be lowered and the trees must suffer in health. The past severe monsoon has in no marked way affected the plantations to the east of the Dodabetta range. I have nowhere observed that peculiar action of the monsoon by which the young foliage of the blue-gum is withered, shrivelled and killed.

This action is not analogous to a wintering or fall of the leaf: it is the young foliage and tender shoots at the top of the trees which are attacked first. Probably, in ordinary years, or always where the situation is sheltered, in the cooler and damper climate of the west side of the Dodabetta range, the Ootacamund plantations (other circumstances being equal) have a higher acre-increment than the plantations near Coonoor and Wellington. Where the effect of the monsoon is most to be considered in the Ootacamund plantations is, when we come to compare the stock on the total area with that on the sample area. In plantations in exposed situations to the west of Ootacamund, the stock is in places deficient and irregular; here and there are areas where planting has been a failure. In the Coonoor plantations the stock is generally more regular and more equal throughout to that on the sample area. Doubtless the question of planting shelter bands of dense growing trees to the windward of plantations in exposed tracts will receive attention. The blue-gum with its tender branches and scanty foliage is itself singularly unfitted for planting as a barrier against wind. A dense band of *Acacia melanoxylon* would be more serviceable in this respect. The following trees are of rapid growth at Ootacamund as may be noticed in the case of the fine specimens of them in the Government gardens, and they appear well fitted for planting as barriers against the wind and for forest purposes generally:—

Frenela rhomboidea or oyster-bay pine,* seeds and reproduces itself readily from seed. There is a thicket of self-sown seedlings of these trees near Bishopsdown.

* Stated to be an important forest tree in the colony of South Australia—*vide* Conservator's 1st Annual Report, "Indian Forester," 1880.

Pinus insignis, probably the fastest-growing conifer on the Nilgiris.

Cupressus torulosa reproduces itself from self-sown seedlings.

They are all of a dense sturdy habit of growth and appear to be sufficiently hardy for planting on a large scale. It thus appears that the blue gum, instead of being a good shelter-tree, requires itself to be sheltered. *Pinus insignis*, we may say, is largely grown around Melbourne, but the growth of all the pines and arecarias is, so far as we know, much slower than that of the Australian *eucalypts* and *acacias*. It is quite true that the *eucalypts*, though tolerant of long droughts attain their extreme growth in such moist mountain regions as those around Fernshaw and in Gippsland - but Australia knows nothing of what Ceylon endured in the south-west monsoon period of 1882, when, during ninety days, the rainless days did not exceed nine. The great benefit anticipated from growing blue gums lay in the belief that in the tenth year of their age, the trees would yield hard timber suitable specially for railway-sleepers. Young trees have been known to grow 20 feet or over in a year, and, although the rate of upward growth slackens when the trees have to increase laterally as well as perpendicularly, we have felt justified by the known growth of individual trees to reckon an *average* increment of height equal to 10 feet per annum; so that, at ten years of age, a blue gum should be 100 feet high, and 150 feet in its fifteenth year. The measurements taken by Mr. Deputy Conservator of Forests, D. E. Hutchins, justifies the estimate up to the tenth year, trees having been measured up to 115 feet in their tenth year, equal to 10½ inches per annum: but after this period lateral growth evidently makes more demand on the tree, for the tallest tree measured *in the plantations* gave only 136 feet, and the plantation was stated to be 19 years old. It is quite possible, however, that isolated trees in favourable situations may attain the height mentioned by the late Mr. McIvor, 150 feet in fifteen years. The annual rate of growth for the case of the 136 feet high tree is about 7 feet, with 3 inches per annum for girth. A tree a foot lower gave 45 feet girth at 5 feet from the ground, whence the Forester deduced an ideal cylinder of 151·06, so calculating the cubic contents from 10 feet sections of the stem at 66·66 feet. The cubic contents of the top and branches being taken at 2·94 feet, we get 69·60 feet as the cubic contents of one tree 19 years old. Under the column for remarks we find "Branch-wood 66 lb. per cubic foot, twigs and leaves one head load = ½ cubic foot." Another remark is to the following effect:—

Weight of wood of *Eucalyptus globulus* dry = 44 lb., or with bark 40 lb.

Loss of weight on driage is 40 per cent., therefore 66 lb. of fresh cut branch-wood = 1 cubic foot. A head-load of fresh twigs and leaves is taken as weighing 20 lb., when dry = ½ a cubic foot.

As showing the effects of abundance of light and air, we may state that a tree grown on the margin of the plantation containing the tallest tree, though only 104 feet high, had such a girth at 5 feet from the ground of 64 feet (nearly 3¼ inches p. a.) the result being that the cubic contents of this grand tree came up to 96·28 feet. It was nearly isolated and had a tapering trunk with many branches. The tall trees at Fernshaw (the tallest though not the stoutest trees in the world) grow so closely together, that the stems, which resemble the pipes of a giant organ, are branchless, except close to their tops. The number of trees crowded together tends, no doubt, to induce perpendicular growth, each tree pushing up to reach air and light. If trees symmetrical in lateral as well as perpendicular growth are wanted, of course space in good proportion must be afforded, the trees thickly planted at first, being gradually thinned out, as is thinning being deemed preferable to coppicing.

		Cubic feet.
The average cubic contents of 16 trees were	...	28·726
" 5 "	...	40·764
" 20 "	...	34·836
Aggregate	..	104·326
Mean average	...	34·775

for blue gum trees 19 years old.

Acacia melanoxylon (the black wattle, blackwood, and also, curiously enough, the lightwood of Australia, which is spared for its valuable timber when every other tree is ringed and burnt) does not grow so rapidly as the blue gum, the tallest tree measured in a plantation 25 years old being 117 feet in height. But it had a girth at 5 feet of 66 inches, the result being that the cubic contents reached 135·69 feet, a quantity of much superior timber far in excess of any of the gum-trees. Of 13 trees measured on the 25-year old plantation, the averages were 42·076 inches girth, 90·766 feet height—cubic contents of trees 55·966 feet. A remark is made to the effect that

A cubic foot of freshly-cut old branch-wood of *Acacia melanoxylon* with bark weighs 48 lb.

A head-load of twigs and leaves is taken as equal to ½ a cubic foot.

The acacias, however, does not seem to receive justice when grown with gums, which speedily overtop them.

Of trees 10 years old, grown under such circumstances, the highest was 58 feet, the greatest girth 18 inches, and the greatest cubic contents 5·872 feet; the averages of 10 trees being 13·9 inches girth, 47·1 height, and 2·9816 feet cubic contents. The individual increment of the trees is indicated at ·266 cubic feet per annum. The specific gravity of these trees is thus shown:—

Specific gravity of Acacia Melanoxylon.

Girth in inches.	Length of Billet in feet.	Cubic contents in feet.	Weight of Billet in lb.	Weight per cubic foot.	Remarks.
12	10	·79	43	54·1	Middle Section.
14	10	1·08	64	59·2	Section from base of tree.
10	12	·66	29	43·9	Top Section.

This is a tree divided into three sections, each of which was carefully weighed; in the top section the proportion of bark is much larger, and the specific gravity consequently less than in the others; and in the second section it is less than in that taken from the base. Weight of dry heart-wood (Gamble) is only 36 lb. For the factor of the Norwood trees the weight of the green wood is taken as 50 lb. per cubic foot.

Of 508 ten-year-old *Eucalyptus globulus* trees measured, the averages were:—Girth 23·301 inches; height 84·866 feet; cubic contents 16·416 feet. Experiments showed that the weight of a cubic foot of freshly cut *Eucalyptus globulus* is 72 feet. One cubic foot of young *Acacia melanoxylon*, wood green, and with bark, weighs on an average 47 lb.

Mr. Hutchins' Report embodies, at the commencement, a summary of notes by General Morgan, one of the oldest residents in the great South of India Sanitarium, regarding the first introduction of Australian trees to the Ootacamund plateau. The summary is as follows:—

Some trees of *Eucalyptus globulus* were planted as early as 1843 by General (then Captain) Cotton at Gayton-park and Woodcot in Ootacamund. The first planting on a large scale was done by General Morgan in 1856. In 1857, Blue-gum plants were sold at the Government gardens at the rate of 12 annas each. The first Government Blue-gum plantation was made in 1862 under the orders of Sir William Denison, then Governor of Madras. There was a large Blue-gum tree at Gaytou-park which, till the head was broken off by the wind, was one of the sights of Ootacamund; it has now a girth of 14 feet and a bole 100 feet high. General Morgan has some Blue-gums near his house. "The Retreat," now twenty-three years old, with a height of 140 feet and a girth of 7½ feet. In 1868, General Morgan cut down a tree at Tudor Hall which at eight years gave a yearly increment of 3 cubic feet of wood. General Morgan can speak from experience of the powerful draining action of the Blue-gum tree. He has seen ponds and streams on the Nilgiris dried up locally, after the planting of this tree near them. There are no trees on the hills sufficiently old to thoroughly test the value of Blue-gum wood for building purposes. In 1862, General Morgan tried several varieties of Eucalypts; the valuable Jarrah failed as it has failed uniformly in Southern India. *Eucalyptus rostrata*, the Red-gum of Sydney, succeeded, as did also *Eucalyptus amygdalina*, which in Australia grows to such a gigantic size. General Morgan recommends planting 6' × 6', and thinning at eight years or before; he considers that the growth of *Eucalyptus globulus* is about twice that of teak, and teak about twice that of the European oak. *Acacia melanoxylon* and *Acacia dealbata* were introduced on the Nilgiris a few years before 1845, coming probably at first from the Cape. General Morgan remembers *Acacia melanoxylon* as a rare plant in 1851 from the circumstance that in that year some plants were stolen from General Watson's grounds, and found afterwards in a priest's garden. Last year General Morgan felled an *Acacia melanoxylon* that had been planted before 1845, and was therefore about thirty-eight years of age. It furnished sufficient planks to board a room 24' × 15'. Some other trees forty years of age have each produced 50 cubic feet of timber.

General Morgan's account of the cubic contents of both the blue gum and the black wattle is certainly favourable. *Eucalyptus amygdalina* is the tree which surpasses all others in height, although the great Californian trees excel it in girth. Although General Morgan speaks of the red gum as a success, no measurements of any trees of this species are given. We have stated those of *Eucalyptus globulus* or blue gum, and *Acacia melanoxylon* or Australian black-wood The only other tree mentioned is *Eucalyptus obliqua*, or stringy-bark gum. Iron-bark is not mentioned any more than the tree which promises so well in Ceylon, *Grevillea robusta*. Mr. Hutchins states :—

A small clump of 11 stringy-bark trees growing outside the sample area gave, as will be seen from a table appended and individual-increment of 1·64 cubic feet. These figures show a growth rather better than that of the blue-gum, but were a large number of stringy-barks available for measurement, it is certain that the difference would be in favour of the blue-gum, though probably not so much as it is usually supposed to be.

The oldest plantation of blue gums is at Arambi

At an elevation of 7,460 feet; 1¾ miles from Ootacamund; area 58 acres: planted in 1863-64 and 1865 by the Jungle Conservancy Department, at 6' × 6' from basket-pots; the oldest portion where the sample area was taken is on shola land. Arambi is the oldest of the Eucalypt plantations, leaving out of consideration those where they are a few Eucalypt standards over Acacia coppice. Originally planted 6' × 6'-it contains now (in the sample area) 498 trees per acre.

This plantation was thinned once, and is stated to have required further thinning for some years back. The thinnings are sold in Ootacamund for firewood. Mr. Hutchins believes in thinning down to 200 trees per acre, in order to secure the best possible annual increment per tree and per acre :—

Arambi plantation is of beautifully regular growth, with clean stems 110 and 120 feet up to the first branches. Many of these tall trees however have a head of foliage represented by ¼ or ⅓ of a head-load of green twigs and 30 or 40 lb. of branch-wood. Tree No. 10 of the Factor trees, for instance, had only 15 lb. of branch-wood and one-tenth of a head-load of twigs, and this tree was 63 feet in height. The yearly Individual-increment at *Arambi* is only about half that of *Norwood* when it might be expected to be double; thus the Individual-increment of *Norwood* or of *Balia* (aged 10), is double that of *Bathri* (aged 5 years), the trees in these three plantations being well spaced and showing a progressive development. The mean Individual-increment at *Arambi*, ·953 cubic foot, is not ¼ that of the *Marlimund* standards which have 4·187 cubic feet. A severe but gradual thinning down to about 200 to the acre seems advisable. The sample area, has an elevation of 7,460 feet, a westerly aspect, and a garadient of about 1 in 6: it is at the bottom of the oldest portion of the plantation.

Premising that *Acacia dealbata* is the wattle which grows into such dense groves by sending up plants from the roots, that it is deemed a nuisance in Nuwara Eliya, but especially in Ootacamund, but which ought to be valuable for fuel for tea plantations, if confined to convenient limits. We quote what Mr. Hutchins says of the Brookland plantation where the two *acacias* and the blue gum were grown together :—

About 10 acres, situated near the head of the Sígúr ghât, in an exposed locality: ascertained by Colonel Beddome to have been planted about 1862. It consisted originally of *Acacia dealbata* (Wattle), *Acacia melanoxylon* and a few *Eucalyptus globulus*. The original owner, a missionary, sold it to some natives who cut over the Acacia, leaving the Eucalypts as standards. The assessment being in arrears the plantation was put up to auction and bought in by the Forest Department in 1875 or 1876. Since then the Wattle coppice has been cut twice. The rapid growth of the Wattle after being cut is noticed in the Nilgiri Forest Administration Report for 1876. The *Acacia melanoxylon* was cut, and failed to coppice. The Eucalypt standards, fully exposed to the south-west monsoon, have assumed a sturdy, branching and gnarled form, different to the usual appearance of a Eucalypt in this country. Of unusually large girth at the base, they taper rapidly to a point. For the trunks alone the "Reducing-factor" (the fraction which expresses the form of the tree) would be about ·30, but the low spreading heads give a very large weight of branch-wood, which raises the factor to ·39, thus approaching what it would be in High-timber plantation trees. Turning to the table of Individual-increments, it will be seen that the Individual-increment from these Eucalypt standards is as much as 4·32 cubic feet per annum. As has been noticed, in the closely-grown plantation trees at *Arambi*, at about the same age, this figure is barely 1 cubic foot (·9534 cubic foot). An attempt was made to get an increment per acre from *Brooklands* plantation by measuring the spread of the branches. This gave 100 trees, or 8,636 cubic feet per acre, or an increment per acre per annum of 431·8 cubic feet = (at 40 lb. per cubic foot) 7·71 tons. Now this figure corresponds, within a fraction of a ton, with the acre-increment, (without allowing for thinnings, in both cases) obtained from trees grown under exactly opposite conditions at *Arambi*. Turning to the table of Individual-increments (page 23), we see that a *Brooklands* tree is making wood at a rate nearly five times as fast as a tree of the same age in *Arambi*. Looking again at the measurements of the branch spread of the *Brooklands* trees we have the result, that 100 trees at *Brooklands* give nearly the same acre-increment as 500 trees at *Arambi*. It would be assumed theoretically that 2 acres of ground completely covered with foliage of the same species would have the same increment, although the number of trees per acre varied. This appears to be true for *Eucalyptus globulus* within the wide limits of 100 trees per acre and 500 trees per acre. But apart from figures an examination of the two plantations would indicate the same deduction. A tree makes wood other conditions being equal, in proportion to the leafy surface. The *Brooklands* Eucalypt standards have large hady heads: the *Arambi* trees have deplorably scanty heads. The *Arambi* trees have beautifully symmetrical growths, but are deficient in head and leafy surface. The *Brooklands* trees have comparatively shapeless trunks, but five times the leafy surface and five times the individual growth of the *Arambi* trees.

Intermediate in form between these two extremes are the Eucalypt standards at *Marlimund* plantation. With shapely trunks and ample heads, these trees leave nothing to be desired in their appearance, and though older than either *Brooklands* or *Arambi*, the *Marlimund* Eucalypts must have a high acre-increment. Nine and a half tons have been obtained from the standing stocking now on the ground, and this figure, it must be remembered, is merely that calculated from the space (obtained by survey) which the trees now occupy, leaving out of account the previous heavy thinnings, which cannot be estimated and of which no record has been kept.

On the Marlimund plantation, at 7,500 feet high, but in a sheltered situation on good soil, with sub-soil moisture from a swamp, the gradient being about 1 in 5, the black-wood trees were felled because they had suffered so much from *loranthus*. Here, as at Brooklands, the black wattle failed to reshoot, so that it seems settled that this tree will not coppice, which the blue gum does readily. In the case of forests, however, as in plantations of cinchona, the best mode seems to be to plant closely, and, then (if the trees do not die out), to thin periodically by uprooting the trees. Regarding *Eucalyptus globulus* planted on Norwood plantation 9×9, it is reported that the stems were more or less crooked from being planted too far apart. As they grew up, however, they recovered the erect position, and now leave nothing to be desired, the number of trees to the acre being 416, instead of 537 originally.

At the present moment, the increment of the growing stock is 12·4 tons per acre per annum, or, in other words, over a ton an acre of dry wood per month.

Some trees failed and about 60 trees per acre were thinned out under the personal superintendence of the Duke of Buckingham. This plantation is taken to prove that *Acacia melanoxylon* will grow under a covert where *Eucalyptus globulus* would not. We quote as follows regarding the Ralia plantation of mixed Australian woods, from which our readers will see that *Eucalyptus calophyl a* is to be avoided in ordering seeds :—

In June 1876, Colonel Beddome writes with regard to *Ralia* plantation : " Sixty acres planted in 1872, 9' × 9' with *Eucalyptus globulus* and *Acacia melanoxylon*, in alternate broad strips. The growths of the *Eucalyptus* is not straight, having been planted too far apart: this plantation may be treated as a coppice fuel plantation and felled over every five or six years." Again in 1881 : " This plantation is now fit for the axe, and as soon as increased sales are obtained for firewood it will be carefully cut down and the stools trimmed to ensure good coppice; the present growth is not straight enough for timber."

The intermixture of two kinds of trees in this plantation—Eucalyptus with a light shade, and *Acacia melanoxylon* with a dense shade—is interestieg. Under the latter, there is a nearly clean soil: under the gum trees there is the usual undergrowth of *Rubus* and succulent plants. Fire entered the plantation and did some damage three years ago; and here it may be remarked that had the *Acacia melanoxylon* been planted in a band entirely round the plantation,it would probably have constituted an efficient bar to the entrance of fire. A permanent fire-line, composed of a band of any species of tree throwing a dense shade, would seem to be desirable generally round plantations of blue-gum or other Eucalypts. *Acacia melanoxylon* would, in addition, be some barrier against the wind. *Acacia decurrens* or *Acacia pycnantha* throw a good shade and afford valuable tanning barks. These species can be seen apparently thriving at the Government Gardens, Ooty, but there is some doubt whether they are hardly enough for planting on a large scale.

An interesting feature in the *Ralia* plantation is the fair show of stringy barks, *Eucalypatus obliqua*. Some of these are of very good girth (after allowing for the thick bark), but both here and at *Arambi*, where there are a few trees, the average height rarely equals that of the *Eucalyptus globulus*. In the same band with the Stringy-barks there are some trees of *Eucalyptus calophylla* presenting a meagre appearance similar to those of the same age in *Norwood* plantation.

In regard to the Old Forest plantation of 200 acres blue gums, it is stated :—

As at *Norwood*, the general conclusion to be drawn from the growth at ten years from planting 9'×9' is, that the forebodings of a bad growth from planting at this distance are not borne out by later experience. The cost of planting 9'×9' is about one-half that of planting 6'×6', and, though a plantation planted 9'×9' may, for some years, look patchy and uneven (as is, in fact, the case with all but the best natural reproduction), at ten years or as soon as the plantation has closed overhead, there will be no less in the acre-increment and a far better individual-increment for the planting done 9'×9'. Writing a year ago, Colonel Beddome says : "This plantation looks remarkably well. It is now being cut down for fuel-supply. The stools have been carefully trimmed and have thrown up good coppice." The coppice growth at this plantation Mr. Dickinson thought was remarkable: the portion stated to have been cut over four years ago looks to me double that age.

And now comes the notice of Black Bridge plantation, from which the conclusion seems deducible that even 6,000 feet in South India is too low an elevation for the Australian blue gums :—

This is, of the Eucalypt plantations measured, that at the lowest elevation. The sample area had an elevation of 6,025 feet: the elevation of the plantation generally is not above that of Coonoor church, or only 5,954 feet. The growth in this plantation, whether from differences in soil, elevation, or rainfall, is markedly inferior to that at *Lathri*. They were both planted in the years of drought—1876 and 1877. There appeared to me in this plantation to be symptoms of that tendency to struggle—to send up long thin stems bearing only a tuft of the early sessile leaves—which is noticable in the Blue-gum as it approaches its lower limit of elevation in the latitude of Southern India.

Bleak House plantation was

Composed mainly of *Acacia melanoxylon* with *Acacia dealbata* (Wattle) in parts, and a few Blue-gums and Casuarinas. Colonel Beddome writes in 1876 : "About 235 acres ; 150 of this was planted nearly twenty years ago chiefly with *Acacia melanoxylon* ; this must stand for High-timber, but requires a good deal of thinning : there is some *Acacia dealbata* which has mostly been felled over for fuel, and it must regularly be cut over for this purpose on its attaining sufficient size. Seventy-five acres are young, having been planted during the last few years, and are composed almost entirely of *Acacia dealbata* (the Wattle), and must be treated as a coppice fuel plantation." In his report, dated 1878, Colonel Beddome says that " 150 acres were planted about 1856-57 at 4' × 4' and 75 acres between 1864 and 1873 at 6' × 6'. All the Wattle has been cut out for fuel. and the *Acacia melanoxylon* has been thinned, all the trees suffering from parasites being taken out. The growth here is very poor for its age and this plantation proves how very inferior the *Acacia melanoxylon* is to *Eucalyptus globulus* either as timber or firewood : the older portions were originally planted too close, and for many years little or no attention was paid to thinning: but besides this nearly all the Melanoxylon trees suffer terribly from the loranth parasite, which soon renders them sickly and retards their growth, and unless they are cut down they eventually die; the largest tree that I could find was only 5' 8" in circumference at 6 feet from the ground, which is very poor growth for twenty-one or twenty-two years, compared to Eucalyptus. The average girth in the older portion of this plantation, taken from the measurement of 30 trees as they came, is 2' 11". It is no use attempting to keep this plantation for timber, as the trees will continue to suffer from parasites and must be felled when badly attacked; it should therefore all come down short, and when cleared must be replanted with *Eucalyptus globulus*." Again, in a report written last year : " A portion of this contains the oldest and largest *Acacia melanoxylon* trees we have on the hills, but unfortunately they are so subject to attacks of the parasite (Loranthus) that I fear eventually the whole plantation will have to be cut down. As this site is a suitable one for a plantation it should be re-planted with Blue-gum when cleared."

But Mr. Hutchins has a very different tale to tell :—

At the present date the *Acacia melanoxylon* in this plantation presents a far more encouraging appearance than when the above was written. There are now but few trees suffering from loranths: three attacked and three dead out of 289 trees in the sample area, or 2·07 per cent. As a show of timber there is nothing finer on the hills than the straight clean stems of these beautiful Acacias, crowned with their ample heads of foliage. Felled, the timber shows a rich black heartwood occasionally mottled brown, equal to the description of the tree as it occurs in Australia where it is used for furniture, ornamental panelling and the variety of uses to which a light tough ornamental wood can be put. The advantage of *Acacia melanoxylon* wood is that while very dark and often richly marked and while tough and close in the grain, it is at the same time light weighing when dry only from 36 lb. (young Nilgiri wood) to 44 lb. (Australia) per cubic foot. The heartwood appears as a black streak when the tree is under ten years old, as at *Norwood*, and in large old trees there is comparatively little waste from the whitewood. Rings can be traced in the whitewood, but in the heartwood, as is sometimes the case with other trees, they become indistinct. On account of the fine shade afforded by Acacias, the soil under them is free from the tangled undergrowth which characterises the Eucalypt plantations; there is a fair show of humus under the *Acacia melanoxylon* tree and usually some natural reproduction. In the *Bleak-house* plantation the trees from self-sown seedlings are numerous enough and large enough to require a table apart. A gully near the sample area, but not eluded in it, had a very fair show of self-sown seedlings of all ages. Left quite alone, this plantation would possibly resolve itself into a few scattered trees, and into sholas of *Acacia melanoxylon* filling up the hollows and ravines. Natural reproduction of *Acacia melanoxylon* from seed and root shoots may be observed in many situations near Ootacamund and Coonoor; the tree is not intolerant of shade like the Eucalypts, and seems well fitted for sowings and plantings impoverished sholas, or wherever the natural forest is worked systematically for its improvement or for a revenue. It may be mentioned here that nowhere in the Eucalypt plantations is there any evidence of natural reproduction from seedlings, while natural reproduction from coppice shoots is equally at fault in the Melanoxylon plantations.

The elevation of this plantation was that of most parts of Nuwara Eliya Plain, 6,384 feet. It seems clear that if *Acacia melanoxylon* were kept clear of the *loranthus* parasite it would be a valuable timber for our uplands. It would probably flourish on the patanas which stretch away from Nuwara Eliya into Uva. What we miss from this report are the results of experiments with the Australian trees, which

At present, are used exclusively for firewood, for which purpose the stem, branches and twigs are all sold.

After giving a table of acre increments, Mr. Hutchins states:—

What appears established beyond a doubt from this table of acre-increments is that *a Blue-gum plantation, whether planted 6' × 6' or 9' × 9', will, if fully stocked, at 10 years show a growth of 12 tones per acre per annum.* The *Bathri* figure indicates that the Acre-increment may reach 12 tons as early as 5 years in the case of a plantation planted 6' × 6'. *Black-bridge* however, the next in point of age, weather owing to a poorer soil or a lower elevation, has an acre-increment of a little under 7 tons at 6 years. The next plantation on the list, *Old Forest*, is one of the best on the hills. Its acre-increment of just under 12 tons at 9 years is from a piece of planting *not above the average* in appearance, and selected, as has been explained, because it was free from unrecorded thinnings. It may be asserted positively that the whole of the 200 acres of the *Old Forest* plantation is now making wood at a rate of not less than 12 tons per acre per annum.

Norwood plantation, the next on the list, has the highest acre-increment obtained, namely, 13·4 tons. Of this figure just under a ton comes from thinnings. It may be, to some extent, to careful thinning that this plantation owes its high increments. The next plantation, *Ralia*, planted at the same distance 9' × 9', and at practically the same elevation, has within a very small fraction the same acre-increment as *Norwood*, if we subtract the thinnings at *Norwood*. The figures of standing stock per acre, as has been mentioned, show a close correspondence, *Norwood* having 6,829 cubic feet per acre of actual stock now on the ground, while *Ralia* has 6,960 cubic feet.

Again:—

The acre-increment of *Acacia melanoxylon* at ten years is one-half that of *Eucalyptus globulus* at the same age; and there is reason to believe that afterwards the Melanoxylon acre-increment rises slowly while the blue-gum acre-increment remains stationary, or possibly declines gradually.

ACRE-INCREMENT OF ACACIA DEALBATA OR WATTLE.

A quarter of an acre of Wattle coppice 4 years old at *Bleak-house* plantation was felled clean, the firewood weighed, and the area which was irregular surveyed with a plane table. The figure obtained, 8·154 tons, it must be remembered, represents green-wood trees and leaves, and to be compared with other acre-increments which refer to dry wood it must be reduced to about 3 tons. All coppice (and Wattle is no exception to the rule) grows very rapidly at first, but after a few years its acre-increment is exceeded by that of high forest. It is probable that the acre-increment from Wattle coppice never rises beyond 3 tons per annum, and that at ten years it is about ¼ that of the blue-gum.

Close planting is defended as resisting wind, but 9 × 9 cost only one-half 6 × 6, and the trees grow better. To quote again:—

In the large Government Casuarina plantations in Mysore, the planting is now done uniformly 9' × 9'; it was formerly done 15' × 15'. On account of the difficulty in keeping down the grass and the slower growth of Casuarina as compared with blue-gum, even closer planting than 9' × 9' would be advisable there, if it could be done economically. Planting 6' × 6' would be considered extravagant.

The *Eucalyptus globulus* is a tree which appears on the Nilgiris to require plenty of light. It is the same in the temperate climate of Australia where the Eucalypt forests are described by Darwin as strikinly sparse and open. At low elevations in South India the blue-gum appears to be less intolerant of shade.

As proving the value of thinning so as to give space and light:

Bathri, which is not too crowded for a young plantation, has an average growth of 10 feet per year up to five years, and likewise *Norwood* of 8½ feet per year up to ten years. General Morgan considers that during the time that the *Eucalyptus globulus* grows rapidly in height the average is about 8 feet per year. It may be concluded, therefore, that in those plantations which, owing to a neglect of thinning, are now suffering from overcrowding, not only has there been a direct loss, as has been seen, in the production of wood per acre, but the individual trees, so far from having been drawn up and put into a good shape for timber, have suffered in their growth to an extent that *their average height is now less than if they had been grown less crowded.* It is possible that the inequalities in growth observable in the Blue-gum plantations on the Nilgiris may be due in part to changed conditions, Australian seed being exclusively used; but in any case the value of thinning as a means of getting rid of trees of poor growth remains. The fact of the natural forests of Gum trees being strikingly sparse and open has been already noticed.

We have devoted so much space to this subject, because the question of fast-growing timber trees for fuel, tea chests and building purposes has become an urgent one, now that so large a number of old coffee estates from which timber has utterly disappeared are being converted into tea plantations. If the timber proved suitable—and there can be no question as to fuel and but little doubt as to general purposes—the Australian trees, especially the blue gums, have beyond all others the great merit of rapid growth. Up to the tenth year, when the trees will yield useful timber, the *Eucalyptus globulus* grows in India at the average rate of about 8 feet per annum in height and about 3 inches in girth. It is quite possible, indeed, that, in favourable circumstances in Ceylon, the average perpendicular growth for ten years may reach an average for the whole period of ten inches per annum, the girth at 5 feet from the ground being about 3 feet. Experience on the Nilgiris seems to prove that the higher the altitude, up to 7,500 feet, at which the blue gums are grown, the better they flourish. The trees are not handsome, except in their youthful stage; in cultivated soil they become surface-feeders, and are liable to be blown down by storms of wind and we now know that they suffer in specially wet seasons from a leaf-disease and from canker of the stems. If shelter-belts are required, the gums do not seem to be the best trees to choose. Planted amongst coffee, the blue gums do injury, not only by abstracting fertilizing properties from the soil, but by pouring down a black gum, which spreads round their root-stems. The blue gum, if grown, therefore, should not, we think, be planted amongst coffee or tea, but in isolated groves. The red gum, *Eucalyptus rostrata*, produces a far better timber, but neither in India nor in Ceylon has it flourished like the blue gum, and, when it has grown, it has too, often adopted the habit of sending up forked stems which renders it liable to split and so allow admittance to moisture which injures it. In Nuwara Eliya as in Ootacamund and Coonoor, the Australian "blackwood," *Acacia melanoxylon*, grows a much handsomer tree than the blue gum. It grows a slim pyramid of dense foliage, so that at a distance it might be mistaken for a cypress. It is slower growing than the blue gum, but its timber is superior. Unfortunately, its dense foliage and rough bark affords lodgment for the insidious parasites, the *loranthi*, well-known from their honeysuckle like blossoms, varying from yellow to ruby red. The glutinous seeds of the *loranthus* are carried by birds; fixed on a branch or stem, and spread their feeding rootlets over the bark, sucking the life juices of their host. They are specially conspicuous on casuarina trees; but we have seen jak, mango and other valuable cultivated trees exhausted to death by the parasites, because no trouble was taken to remove the latter. In most cases a crooked knife at the end of a long bamboo would suffice to clear affected trees. Had the corrective of Mr. Hutchins' Report not appeared, *Acacia melanoxylon* would have stood condemned on the dicta of Col. Beddome, quoted by Mr. Gamble in his very valuable Manual of Indian Timbers. But if only a little trouble is taken to rid the blackwood acacia of the *loranthus*, it is a valuable tree to grow for its black heartwood, which it produces under a white-wood outer covering, just like the ebony tree. *Acacia dealbata* is inferior altogether as a timber tree, but, from its habit of sending up a perfect grove of stems, it might be worth cultivating for small firewood and for its bark. The bark of all the wattles is good for tanning purposes. We do not think that to grow them for bark alone would pay, but bark as a subsidiary product to timber and fuel would help. The parasites do not attack either this wattle or the blue gums. *Grevillea robusta* which promises so well in Ceylon, and, the timber of which, being valued in Australia for staves of tallow casks, ought to be good for tea chests, does not seem to have established itself to any large extent in India, although we recollect seeing some small specimens near the church at Ootacamund. This tree is, however, included in Gamble's Manual and thus noticed:—

Grevillea robusta has a rough bark, 3-16ths inch thick. Wood hard, light reddish brown, sapwood greyish white. Pores moderate-sized, scanty, in concentric patches of white tissue. These concentric patches are interrupted by the medullary rays and bend outward where they meet the rays, so that the concentric bands have a wavy outline. Medullary rays broad and very broad, very prominent on a radial section, shewing a beautiful silver grain. The heartwood seems durable, but the sapwood decays quickly. It would be a handsome furniture wood.

We also quote what Gamble says respecting the Australian *acacias*, only reminding our readers, that Hutchins has most emphatically reversed Col. Beddome's adverse verdict on the Australian blackwood:—

A. dealbata, Link.; Benth. Fl. Austr. ii. 415; Brandis 180. The Silver Wattle.

A tree spreading rapidly by numerous root-suckers. The wood is moderately hard, light brown, but warps considerably. Pores small, often in short liner groups. Medullary rays short, fine and moderately broad, well marked on a radial section.

Indigenous in New South Wales, Victoria and Tasmania. Introduced on the Nilgiris, and now naturalised since 1840.

The wood is extensively used in Australia for timber and the bark for tanning. It has being tried in plantations in the hills of the Punjab, North-Western Provinces and Sikkim. Our specimen was cut from a tree 11 years old and 46 feet high, and was about 12 inches in diameter. Colonel Beddome, in his report on the Nilgiri plantations of April 1878 said that this Wattle grows very readily from the stool, but comes up in a dense mass of small twig-like stems, so that it can only be depended on for very small firewood.

A. melanoxylon, R. Br.; Benth. Fl. Austr. ii. 415.; Brandis 180. Australian Blackwood.

A large tree with hard and durable wood; heartwood dark brown and beautifully mottled, soft, shining, even-grained; pores mostly oval, moderate-sized and divided into compartments conspicuously marked on a vertical section. Medullary rays short and fine.

New South Wales, Victoria, Tasmania and South Australia. Introduced on the Nilgiris since 1840 and now completely naturalised. Also being grown in the hills of the Punjab, Kumaun and Sikkim.

With regard to its rate of growth, Colonel Beddome, in his report of April 1878 on the Nilgiri plantations says that in the Bleakhouse plantation, Wellington, the average girth of the trees in the portion which is 21 to 22 years old, taken from the measurement of 30 trees as they came, was 35 inches at 6 feet from the ground (about 4 rings per inch of radius), the girth of some of the largest trees being 56, 55, 50, 46 and 44 inches. Our specimen was cut from a tree 20 years old and 90 feet high; it gave a plank 2 feet broad. The wood seems to be regarded on the Nilgiris as very inferior to that of *Eucalyptus Globulus*, either for timber or firewood; its growth is much slower and it is attacked by species of *Loranthus*, which parasites in time kill the tree. It does not coppice well, unless cut very young.

Weight, according to Mr. Newbery (Timbers of Victoria, 1877), 41 to 48 lb. per cubic foot; our specimen gives 36 lb.

It is used in Australia for cabinet work, coach-building, railway carriages and agricultural impliments; on the Nilgiris chiefly for firewood. Its bark is used for tanning.

Besides *A. melanoxylon* and *A. dealbata*, there are several other species of Wattle some of which are cultivated in India. *A. decurrens*, Willd., the "Common" or "Black" Wattle, is a small or medium-sized tree; larger in most localities. According to Mr. Newbery, the wood weighs 45 to 48 lb. per cubic foot. It is being grown in several places in India. *A. pycnantha*, Bth., the "Golden" or "Broad-leaf" Wattle, is the most valuable species for tanner's bark and gum. Its wood weighs 51·5 lb. per cubic foot. *A. homalophylla*, A. Cunn., is the Myallwood, a small tree with a hard, dark wood with the scent of violets.

Wattles grow in almost any soil, but their growth is best is loose sandy places or where the surface has been broken for agricultural or ther purposes. It is well, before sowing the seed, to soak it for a short time in warm water; this moistens the outer shell and induces more speedy germination. The seeds generally germinate in from 7 to 10 days, and are apt to damp off if too carelessly watered. Our readers will notice the distinction, which, we fear, we have not always observed, between the Australian "blackwood," *Acacia melanoxylon*, and the *black wattle*, *Acacia decurrens*, the latter an inferior tree for timber purposes, though no doubt valuable for firewood and tanning bark. To make our quotations complete, we take over what Gamble states respecting the eucalypts:—

Eucalyptus, L'Her. Numerous species of this genus of trees have been introduced into India from Australia, where they have the general name of "Gum trees;" but their success has been very variable. *E. Globulus*, Labt here described, and *E. Obliqua*, L'Her., have been almost completely naturalised on the Nilgiris. The latter species is known by the name of "Stringy bark," and in Victoria, South Australia and Tasmania is an immense tree, reaching occasionally to 300 feet in height, with a girth of 100 feet (Brandis, 231). It has also been tried at Changa Manga, but has failed at Lucknow. At Lucknow, however, the cultivation of *E. saligna*, Smith, "The white or grey gum" of New South Wales, has succeeded well in the Wingfield Park, and that of *E. rostrata*, Schlect in the Horticultural Gardens. At Changa Manga plantation several species have been found to grow well, and at Abbottabad *E. Globulus*, Lab. *E. Stuartiana*, F. Müll., *E. tereticornis*, Sm., *E. viminalis*, Lab., and *E. leucoxylon*, F. Müll, have succeeded admirably. The seeds of numerous other species have been sown at different places in the plains and valleys of the Punjab, as well as at the Botanic Gardens at Saharanpur, the Horticultural Gardens at Lahore and Lucknow, and many places in the Central Provinces, Berar and Central India; and there is no doubt that when it has been determined which species are most suited to the very different climates and soils of the various parts of India, the cultivation of the species of Eucalyptus which possess so many valuable properties, such as their quick growth, useful timber, and the numerous products to be obtained from their leaves and bark, their cultivation should be encouraged and their growth fostered.

I. E. Globulus. Labillardière; Brandis 231. The blue gum. Vern. *Kurpoora maram*, Madras.

A lofty tree with fibrous deciduous outer bark. In Australia the wood is brown, hard, tough, durable. The wood of a tree grown on the Nilgiris, 18 years old and 95 feet high, is grey, with darker streaks and moderately hard. Pores moderate-sized, round, frequently arranged in groups or in radial or oblique lines. Medullary rays fine, very numerous, the intervals between the rays smaller than the diameter of the pores. Pores marked on a longitudinal section, and medullary rays visible as narrow bands on a radial section.

Gregarious in Victoria and the south of Tasmania. Introduced on the Nilgiris, and now completely naturalised.

Of the *Eucalyptus Globulus* several successful plantations have been established on the Nilgiri Hills. There are 22 plantations in all, but some of them are exclusively of "Wattles" or Australian *Acacia*; others contain only a small proportion of *Eucalyptus*, while others have not been successful owing to bad locality or others reasons.

The growth of Eucalyptus is sometimes very fast. Captain Campbell Walker in his paper on the "Plantations and Firewood Reserves in the Madras Presidency," read at the Forest Conference of 1875, says that the growth is often 1 foot per month during the first few years; and Colonel Beddome in his Report of July 1878 says that a *Eucalyptus* tree 12 years old, recently felled at Ootacamund, gave 144 cubic feet, which amounts to 1 foot per month, which is the same as was stated by Captain Campbell Walker.

The seeds of *Eucalyptus* are usually very small, those of *E. Globulus* being perhaps the largest of the species usually tried in India; the seed, is good, germinates well usually, and the plants at once begin to grow fast, but they are very tender of transplanting, so that that operation has to be very carefully done. On the subject of the transplanting of Eucalyptus, the following memorandum was drawn up by Colonel H. R. Morgan, Deputy Conservator of Forests Madras:—

"The seed, which should be procured in January or February, should be placed in beds in rows 6 inches apart. When the plants are 6 inches high, they should be taken up and placed 6 inches apart in beds; the roots should be shortened to 4 inches. When 3 feet in height, the plants are taken up with a ball of earth round their roots, moss is bound tightly round the ball and the plants are left in beds well earthed up about the roots, and watered till the young rootlets show through. They may then be put out. April is the best month for planting, as the plants are then able to make strong roots before the monsoon. When moss is not available, bamboo pots may be used, taking care to keep the large end of the joint for the top of the pot; the hole at the bottom to be plugged with grass. The plants should be placed in the pots when 8 inches in height, and left till they are 2 feet high and the roots show through; then thrust the roots through, and the plant comes out with a ball of earth attached to the roots. Pits should be 18 inches cube."

Weight, Mr. Newbery's "Descriptive Catalogue of the Specimens in the Museum at Melbourne, illustrating the economic woods of Victoria," gives 44 lb. on an average; our specimen gave 43 lb. The weight and value of P., calculated from the average of the six experiments given at page 203 of Laslett's "Timber and Timber Trees," were W=64 and P=534. Wood strong and tenacious, durable, extensively used in Australia for beams, railway sleepers, piers and bridges; also for ship building. The wood from the Nilgiri plantations has scarcely been used except for firewood or charcoal. The leaves give an essential oil used in medicine, and paper has been made of the bark.

The slow and poor growth of the blue gum at Darjiling we should feel inclined to attribute as much to latitude and winter cold as to damp. In Dimbula and similar districts, the growth of the blue gums is as rapid as could be wished for, perpendicularly and laterally; but the disease which has developed recently is probably the effect of damp. Whether salt-storms had anything to do with the "mortification" of the stems is a question on which more light is required. There are a few well-grown blue gums in Colombo, and some flourishing young trees, brought as plants from the Kalutara district, we believe, in the garden of Mr. F. Reid. Between these plants at sea-level and some which are growing at 7,000 feet on Horton's Plain, there is a wide range of climate.

OFFCIAL REPORT ON PERAK (PLANTING) FOR 1882.

Planting.—The experimental garden at the Government Hill near Gapis, and that at Larut, were both continued during the year, the former at a cost of \$10,723·68 and the latter at \$3,374·04.

In these gardens Coffee, Tea, Cinchona, various kinds of India rubber, many fruit trees and plants of all descriptions are cultivated with success. Those at Gapis consist of three separate gardens at various elevations up to 3,500 feet, with a nursery at Kwala Kangsa, and all the reports I received of them are favourable, but I am rarely able to visit them. Great inconvenience and loss has been incurred by the impossibility of procuring Indian coolies or other labour at proper seasons, so that it has happened that large portions containing valuable plants have been destroyed by weeds. With the exception of Ipecacuanha, everything which has been planted was flourishing, tea and Liberian coffee promising to give most successful results.

The Rinderpest destroyed thirty-six out of forty-two cattle on the Government Farm at Kwala Kangsa in about ten days, and it has been very fatal in many parts of the State.

A great part of the land in Kitau is divided into small holdings and used for paddi planting by Malays. Copies of the surveys as recorded in the office maps, are attached to the leases, but of those, 408 only had been issued to the end of last year, of 885 which had been prepared in the Survey Office.

In addition to the land cultivated for paddi about 11,059 acres, for the most part unserveyed at the date of these returns, have been taken up by the enterprizing Chinese merchants of Penang, on which 4,114 coolies were employed in sugar planting and the enterprize having proved profitable, a European Company from Shanghai is opening a large estate in the southern part of the district.

No new estates were opened by Europeans during the year, but those at Slim are reported to be brilliantly successful as regards Liberian coffee, while the Government Gardens and that of Mr. Schutze at Gapis prove the suitability of the climate and soil for Cinchona and Arabian Coffee; the leaf-disease occasionally attacks both Liberian and Arabian Coffee, but on the former it has no perceptible deleterious influence, while Arabian Coffee soon throws it off.

The difficulty of labour, which is now, by the efforts of His Excellency, in fair course of speedy solution by free immigration from India, has been a great drawback. The Government Gardens contain nurseries of the finest strains of cinchona sufficient for 200 acres of ground, and tea of the best Assam kinds for a large garden, but nothing can be done for want of labour, the coolies refusing to work the rate of 35 cents a day, which has been freely offered by Mr. Schutze and the Government Superintendent.

All kinds of India-rubber succeed admirably, and seeds and plants of "Hevea Braziliensis" have been distributed to Java and Singapore, to Ceylon and to India, and supplies will be forwarded on application to any person or institution which will take care of these valuable plants.—*Straits Times.*

"GENUINE MOCHA."

TO THE EDITOR OF THE LONDON "GLOBE."

SIR,—One cannot but agree with the severe comments in your yesterday's article under the above title on the mean frauds of coffee adulteration. To get only 20 per cent. of the commodity asked and paid for, shows, indeed, a lamentable want of commercial honesty. But is not the public itself, in a large measure, to blame in this matter? If the consumer is really desirous of knowing when and how much coffee he is buying, why cannot he ask for that article pure and simple, and if chicory is, in his mind, essential to the composition of a good cup of coffee, do likewise with that. But if this be too much trouble, and he prefers, or, anyway, persists in purchasing fanciful concoctions paraded as "French coffee," his eyes are opened wide enough to the fact that he is buying a mixture of chicory and coffee in proportions only defined by the degree of the vendor's cupidity for profit. By placing himself in such a tempting position, he directly courts the pleasure of being cheated. It is largely to be regretted (and most painfully so by those connected with the coffee trade, as I unfortunately am), that these deceptive compounds should have obtained such a hold upon the public taste for many reasons; not the least being the extensive field for imposition it lays open to the dishonest trader. But, putting aside special considerations, it is distressing to see a beneficial and enjoyable beverage like coffee vulgarised by its universal association with a root characterised only by its medicinal qualities, and with nothing in its favour but its comparative cheapness. Nor can the consumption of "French mixtures" be pardoned on the score of economy, for whereas 10d. is paid for these innutritious compounds, good genuine coffee is obtainable at 1s per lb., and should the demand arise in these times of fierce competition, it would soon be supplied at 11d per lb. None, I fancy, are so afflicted with penny wisdom as to advocate the drinking of an undesirable article such as chicory, in place of one double the price, for the saving of 1d. or 2d per lb.—Trusting you will do me the favour of inserting these few lines, I remain, yours truly, COFFEE.

London, September 27th.

[In the instances referred to in our Note of the Day the vendors were punished for selling the adulterated stuff as "coffee" pure and unmixed.—ED. THE GLOBE.]

THE FLORA OF QUEENSLAND.*

This volume by the Colonial Botanist, Mr. Bailey, printed at the expense of the Government, and issued from their printing office, does equal credit to the author and the printer.

No volume specially descriptive of a complete colonial flora by a colonial botanist has previously appeared, and the liberality of the Queensland Government in disbursing the necessary expense is much to be commended, as the local demand would not be at all sufficient to repay an author for the labour and cost of publication. Baron Mueller, the Victorian Government Botanist, has indeed published almost innumerable botanical memoirs, profusely illustrated, at the expense of that Government; but these extend over the whole Australian flora, and though most valuable contributions to the better knowledge of a very difficult subject, and largely used by Mr. Bentham in his excellent "Flora Australiensis," are rather intended for persons already more or less acquainted with the subject, and who have surmounted the preliminary difficulties of that copious yet indispensable nomenclature, which is the main deterrent to many who would gladly know something of the most delightful of all pursuits, and which is a scoff and by-word to illiterate people of all ranks.

Mr. Bailey has duly, as far as in him lay, disposed of this difficulty by giving the derivation of most of the generic and specific names, where possible: for some are altogether untraceable and insoluble, as the original authors were not careful to record their meaning, and they were not Latin or Greek compounds. An explanation on the words employed in describing the physiological or morphological structure of plants is also subjoined, and will obviate these preliminary difficulties with the help of a little perseverance. These descriptions of species and genera are clear and definite, with as little use of technical language as possible; they are sometimes too short perhaps, but brevity was indispensable in keeping the size of the volume within bounds.

The medicinal properties of such members of the Queensland flora, as are certainly known to possess any, and there are several of great power, are duly recorded, but more experience is required to justify the admission of others into a colonial pharmacopœia; credulity on this head is almost universal among unprofessional people and any amateur who has successfully administered a native prescription on an emergency is ready at all times to indorse its infallibility. Mr. Bailey has of course followed the systems of classification used by our most reputed botanists—Lindley, De Candolle, Bentham—and has in so serious a matter attempted no innovation of his own, while he has paid, as he was bound to do, due acknowledgment to the unremitting labours of Baron Mueller, who has done so much to illustrate Australian phytology, and whose name is better known in Europe than that of any other Australian, whatever may be his local importance. Nay, our late able Colonial Secretary will be transmitted to a late posterity in that his name has been given to one of the finest of our native lilies—*Doryanthes Palmeri*—while fifty years hence it will be forgotten that he was the ablest of Colonial Secretaries, and the most autocratic of Republicans.

Mr Bailey has duly explained the abbreviations he has been compelled to use in the interest of brevity. Mr. Bailey has done good service to the intelligent youth of both sexes in thus providing a ready and comparatively inexpensive means of obtaining some knowledge of our very extensive and somewhat difficult provincial flora; and is justified in believing that his name will long be remembered in association with this excellent model—the first in its kind—of a complete local flora, if such a word can be fairly applied to the immense province of Queensland, long after most of his contemporaries are forgotten.

Let us repeat that too much praise can scarcely be given to the Government Printing Establishment for the production of the volume, excellent as it is in typography, punctuation, and orthography—the latter but scant praise in printing ordinary books, but less to be expected where innumerable Greek and Latin compound words necessarily are employed, with which ordinary compositors cannot be familiar.—*Queenslander*, Aug. 18th.

* "Queensland Flora," by F. M. Bailey, F. L. S. &c. issued from the Government Press, July, 1883.

COL. MONEY ON TEA MANUFACTURE AND MACHINERY.—No. 1.

The preface to the first edition of Col. Money's Prize Essay on Tea Cultivation was dated November 1870, and stated that the Essay embodied the results of eleven years' previous experience. The fourth edition, published in July this year, contains, therefore, the mature conclusions of a full quarter of a century of experience of the cultivation and manufacture of tea, in such widely separated and differing portions of India as Darjiling, Chittagong, the Nilgiris and the Dooars. Had Col. Money paid a visit to Ceylon, before this latest edition of his work was issued (and it is strange he did not, considering the ties which bind him to this island), he would have received information and seen for himself a state of things which might have led him to revise some of his opinions and deal more fully than he has done with one of the youngest but not the least promising of the tea countries of the world. When Col. Money commenced his career as a tea planter, the idea that Ceylon, already the third coffee country in the world, should threaten even the supremacy of Darjiling, Assam and Cachar, as a producer of tea, would have seemed as preposterous as the assertion, that ere long tea would be rolled, fired, and largely sifted by machinery and without the use of charcoal as a fuel. To Col. Money Indian tea planters are largely indebted for the simplification of the manufacturing processes, and the discovery that the copper pans which the Chinese had used for many centuries, and to which they still adhere as tenaciously as they do to ancestral traditions generally, are in reality superfluous. But time and experience were necessary to convince him and other early planters, that hand-rolling could be completely superseded by machinery, and that the detergent fumes as well as the clear, intense heat of charcoal were not necessary to the outturn of the best tea. Writing of the final firing before packing, Col. Money states :—

Though I know many planters think the fumes of charcoal necessary and beneficial for the last drying, I do not. I have tried both sun and charcoal, and no difference was perceptible. The former costs nothing, is more commodious, and I always apply it when possible. The sun cannot burn the Teas ; the charcoal, if the heat is too great, may.

Whether you use sun or charcoal, put the Tea hot into the boxes. The only object of the final drying is to drive off the moisture, which the Tea will certainly, in a more or less degree, have imbibed since its manufacture. Even the large zinc-lined bins which should be fitted up in all Tea stores, and in which the Tea is placed after manufacture, will not prevent entirely damp, so in all cases a final drying is necessary.

We believe that few tea manufacturers now resort to sun heat, excepting perhaps the makers of green tea in the north-west Himalayan districts. We should like to know, however, the extent to which if at all sun-heat is utilized by tea manufacturers in Ceylon. Col. Money states :—

Sunning between the fermenting and firing processes has no effect whatever on the liquor or the out-turn, but it makes the Tea rather blacker, and as it drives off much of the moisture in the roll, the firing process after it is shorter and does not consume so much charcoal. What little effect therefore it has is good (for if not continued too long, it does not make the Tea too black) and it is economical. I therefore decided on retaining it.

At the end of the seaon, however, sunning has more than the above effect. It then makes the Tea "Chubby" in form, of a reddish colour, and improves the strength of the liquor.

Col. Money in the new edition of his book, after "Manufacture," adds "Mechanical Contrivances." He leans to excess rather than deficiency in the withering process ; and as to rolling, the result of his experience is that "in all but the point of pekoe tips, hard-rolling is better." No doubt the thorough breaking up of the leaf cells brings out the strength of the tea, provided the juices be reabsorbed and the process of "fermentation" well-performed so as to avoid equally "rasping" pungency and "fusionless" liquor. Col. Money, adhering to the Indian tradition of a good tea for mixing purposes, still retains the following paragraph :—

The Liquor. In taste this should be strong, rasping, and pungent, with, in the case of Pekoes, a "Pekoe flavour." There are other words used in the trade to particularise certain tastes, but the words themselves would teach nothing. Tea tasting cannot be learnt from books. *If* the liquor is well flavoured, as a rule, the darker it is in the cup the better. But to judge of Teas by the colour of the liquor alone is impossible, for some high-class Teas have naturally a very pale liquor.

In India largely, and in Ceylon wholly, teas are now, made to be used on their own merits and not as fortifiers of weak China stuff. We do not suppose that the table described in the following paragraph has yet reached Ceylon ?—

An ingenious planter, a Mr. McMeekin, in Cachar, invented a rolling table with the object of separating the said leaves. It is constructed of battens, and while rolling the leaf on it, many of the small leaves fall through. The said table is now well known in Cachar, and is in use in several gardens. I have tried it and find that in a great measure it answers its object, but the objection to it is that the leaf *must* be rolled lightly, and lightly-rolled leaf, as observed, does not make strong Tea.

The Pekoe tips may be, in a great measure, preserved by rolling *all* the leaf lightly on a common table. But then again the Tea is weak, and the plan will not give so many Pekoe tips as McMeekin's table.

In short, in the present state of our knowledge except by the hand process (a tedious and expensive one for separating the leaf), strong Teas and Pekoe tips are incompatible.

The difficulty is just where it was, and will so remain until dealers give up asking for Pekoe tips (not a likely thing), or till a machine is invented to separate quickly and cheaply the two said small leaves from the others *after* they have been all picked together. That such a machine is possible I am certain, and the inventor would confer a boon on the Tea interest far beyond the inventor of any other machine, for all the other processes can be done by hand without much expense, this cannot.

Col. Money then goes on to notice such machines and contrivances as he knows of for cheapening the manufacture of tea Kinmond's rolling-machine he originally considered the best, although he did not believe in any machine entirely superseding hand-rolling until he had seen Jackson's which finishes the rolling. The different conditions in India and Ceylon are strikingly apparent in the fact, that Col. Money, while speaking of manual, animal, wind and steam power applied to machinery, does not mention water, which is available for the vast majority of our Ceylon tea estates. Col. Money mentions, without having snee it, a rolling-machine invented by a Mr. Gibbon and a good deal used in Cachar. Col. Money wrote :—

I only know of one other tea rolling-machine, which is Nelson's. It does not profess to do more than *prepare* the green leaf for rolling, which, as stated above, is, I think, all that any machine will ever do. I have never seen it working, but it appears simple, being nothing more than a mangle. The leaf is placed in bags, and then compressed under rollers attached to a box, weighted with stones. The prospectus states, it will prepare 80 lb. green leaf in fifteen minutes and that one man can then finish as much of such prepared leaf in three minutes as would occupy him twelve minutes if the same had not been prepared. I see nothing unlikely in this. The machine, though inferior to Kinmond's in its arrangement, *ought* to be cheap enough to bring it within the reach of all.

Unfortunately it is not. It is advertised at R300, with a yearly royalty of R50 the first year and 20 after. The royalty should be dropped, and the machine sold for R150, which would give the inventor a good profit.

We quote again :—

I have already spoken of one of McMeekin's inventions. His chest-of-drawers for firing Tea is, I think, superior to his batten table. It is now so well known, and in such general use, that I shall describe it very shortly. It is nothing more than a low chest-of-drawers, or trays fitted in a frame one above the other, the bottom of each tray being fine iron wire, so that the heat of the charcoal, in the masonry receptacle over which it is placed, ascends through all the drawers and thus dries or fires a large quantity of "roll" at the same time. By the old plan, a single wicker sieve was inserted inside a bamboo frame called a "dhole," which was placed over a charcoal fire made in a hole in the ground. On the sieve the roll was placed, and all the heat, after passing through this *one* sieve, was wasted. Mr. McMeekin's diea was to economise this heat by passing it through several drawers.

Most planters use these drawers, and there is no doubt in the space saved, and the economy of heat : it is a great step in advance over the old barbarous method, where not only was the heat wasted after passing through *one* sieve, but a great deal was lost through the basket work of the "dhole" itself,

Still I do not advocate four, still less five drawers one above the other. I think the steam ascending from the lower drawers must, more or less, injure the roll in the upper ones. I confine myself to two, and even then in the top tray leave a small circular space vacant by which the steam from the lower drawer can escape. I utilize the heat that escapes, partially, by placing "dhallas" in tiers above, with roll in them. These are supported by iron rods let into the wall, and are useful not only for partly drying the roll, but also for withering leaf when there is no sun.

It would thus appear that Mr. McMeekin had anticipated the main principles of the siroccos and driers now in use. Col. Money finally noticed an advertisement respecting Jackson's sifting machine, and said its larger size than those previously in use might be in its favour. A machine for sifting and fanning tea at the same time, Col. Money had used, but it did not sort the teas with any nicety, and, although it fanned the tea well, that process might be done by much cheeper appliances. A Jackson's Sifter is doing very good work on Abbotsford. Space and light, Col. Money truly says, are the great wants for withering leaf in wet weather. Col. Money believed in tea-houses made of iron and glass, and, when the 3rd edition of his book was passing through the press he was sending out glass for a tea-house. He has not, in the fourth edition, related the result, but we can have no doubt it was good. Colonel Money correctly states :—

One and the principal reason why Indian Tea is stronger than Chinese is that in India the sap or juice is generally retained, while in China it is, strange to say, purposely wasted !

But Mr. Sillar in England, Mr. Everard in Melbourne, and others whose interests were specially wrapped up in China tea, indulged in the most vehement and senseless denunciations of Indian tea, as awfully unwholesome, just because the juice containing the strength of the tea was not thrown away ! After describing the various operations in tea manufacture, Colonel Money wrote :—

All the above operations should be carefully conducted, but I believe the secret of good Tea consists simply in, *first*, stopping the fermentation at the right moment; and, *secondly*, in commencing to drive off the moisture immediately after.

In this article we have dealt only with Col. Money's incidental allusions to tea machinery in his chapter on the "Cultivation and Manufacture of Tea," but in the fourth edition there is a chapter of no fewer than 47 pages devoted to "Tea Machinery," to which we shall advert in a further article. Meantime, we may say that Col. Money pronounces as strongly in favour of Kinmond's drier as he previously did for Jackson's roller. Kinmond's drier we have not seen, but our experience of Jackson's is very favourable, although we are not yet able to say what the consumption of fuel in proportion to work done is, as compared with Davidson's sirocco and Kinmond's drier.

A COSTLY ORCHID.—Some rare orchids were sold on Wednesday in Mr. Stevenson's Rooms, Covent-garden. Three hundred specimens were put up for auction of every variety of the established, semi-established, and imported orchid. For one specimen of New Acrides in flower, which was brought home about two years ago, and had eight or nine growths, and spikes two feet long and some 30 flowers, 235 guineas were realized. This is believed to be the highest-price ever obtained at an auction for a single plant, the nearest approach to it having been realised last April for a plant of "Cattleya Trianae Osmanii," for which 215 guineas were given.—*Globe*, Sept. 21st.

TEA AT HIGH ALTITUDES.—The following is from a "Travelling Correspondent" of the Ceylon "Times" :—

"It is curious to note how, on the introduction of any new plant or product, its supposed zone is limited and contracted by those who at the time are looked upon as authorities on the subject. This has been the case with coffee, cinchona, cocoa, and cardamoms in turn, and now we are only just trying to realize that what was looked upon as infallible with regard to the supposed limits of the profitable cultivation of tea is erroneous. The adventurous ones, who commenced to plant the shrub up to 2,000 feet scoffed and laughed at for their folly, whilst the very few, who bolder even than the rest, attempted its cultivation as high up as 4,000 or 5,000 feet., were pitied as lunatics whose doings would bring their own punishment. We have now learned our mistake. The laugh and scoff if any is all on the other side. The more one reflects on such a theme the greater is his astonishment. How comes it that we were not able without prejudice to apply the same conditions, which the smallest enquiry would how satisfied us obtained in the various tea districts of India, to our own case? From sea-level up to considerably over 5,000 feet, the hardy shrub flourishes in India and is profitably grown between these extremes, with much the same temperature as exists with us here, and has been for years previously. Yet we in Ceylon would not believe but that the nearer sea-level was kept to the better, and this view is even now not yet altogether exploded."

Correspondence.

To the Editor of the Ceylon Observer.

NEWS FROM FAR FIJI.

Forest Creek, Taviuni, 7th Sept. 1883.

DEAR SIR,—In the July number of your most valuable compendium of contemporary planting information appears a letter from "A. J. S." and I claim room for refutation of and remarks on certain statements contained in your correspondent's letter on the ground that I too shall communicate information.

First: From statements such as *e. g.* "We are suffering from black leaf" and "Coffee at lower elevations than 1,000 feet escapes to a great extent," you infer that "for coffee curiously enough the climate of Taviuni at least seems to be too wet even at 1,000 feet above sea-level." In refutation, I have to remark that this estate is at an elevation of from 1,000 feet to 1,600 feet, that it has never suffered from "black leaf" or "black rot." Twice I have seen "black leaf" on this plantation: once in a nursery where the plants had been allowed to grow in one mass to about two feet or two feet and a half high. By wholesale stumping of the bed affected, the disease disappeared. The second time it appeared on one or two trees at the boundary of the estate. On opening out the trees affected, the disease disappeared. And Liberian coffee at 1,300 ft. is growing magnificently.

Secondly: With regard to leaf-disease it may be observed that the same conditions which produce a very heavy crop and immunity from black rot on this plantation may protect it from any injurious attack of leaf-disease. Sometime ago Mr. Parr, who takes an enlightened and broad-hearted interest in the prosperity of Fiji, whose coffee estate was sacrificed, and who suffered spoliation in an endeavour to eradicate leaf-disease, wrote asking me to allow Mr. Storck to practise on 20 acres of Forest Creek, promising me enhanced crops. An excerpt from my reply appeared in the *Tropical Agriculturist* that I should not wish to see the trees bear more heavily than they do, and a month or two afterwards my overseer could not find a leaf affected with the disease to show the Wesleyan minister who wanted to see what the *Hemileia vastatrix* was like.

Thirdly: With regard to the inference you have been led to draw that "the best coffee crops are to be found below 1,000 feet altitude, which is not true of Ceylon or of Jamaica," I should remark that any conditions in Fiji that are found different from the conditions imposed in other countries will be found to owe their origin to the work of man, not to Providence. No doubt coffee planted at a low elevation may show a spurt for a year or two, but the permanent estate as in other countries will be the one planted at a high elevation. I enclose four *cartes-de-visite*, and, at a glance, you will observe that this estate is backed by lofty hills attaining an elevation of 4,000 feet which form a natural breakwind from the prevailing S. E. winds; whereas the estate of which "A. J. S." speaks as if it represented Fiji is situated on a level plain or undulating plateau on one end of the island, without the slightest natural protection, and coffee on such situations has never done any good in Ceylon. The soil too on the estate referred to is a stiff reddish clayey soil, while that on the slope of the mountains is a loose chocolate soil with dark mould. But for the conditions imposed by man, this estate would warrant the whole hillside for a stretch of some fifteen miles by a depth say of two miles and a half to be opened up for coffee estates, when my mill (I confess to being an interested party) would be a valuable investment instead of as now a heavy drag on my own estate. It would be few single estates in Ceylon that could support a mill costing some three thousand pounds with the help of the charges of curing about twenty tons of coffee in all for others.

Lastly: I wish to refer to the matter of the stringency of the labour laws in Fiji, and the deprecation of any sympathy with the cruel planter drawn from you. One would be in great error in referring from the statement of "A. J. S." that the Fiji planter desires not the liberty but the license of putting four mustard plasters on a labourer, and tying the man in a sackup to the waist for less than three months' imprisonment with hard labour. Had the act been performed on a Polynesian, apart altogether from the effect on the policy of the Government, who are over-willing to sacrifice the ninety-and-nine righteous planters if one wicked planter be found, irreparable injury would have been done to the planters who desire to recruit labourers. The Polynesian comes from a home blessed with favourable conditions of existence, and as a rule is anxious to return to his home at the completion of his service, if even for a short stay, and then come back to Fiji. From a glance at one of the pictures showing eighty Polynesians, you will observe their strong physique, and they are no less capable of attaining speedily the rights of a civilized man in virtue of their intelligence and development of ideas, simply because they don't learn reading, writing (and arithmetic?) In this severe climate of an elevated estate, with an average of eighty men, I have not had a death for more than a year, and not a single case of sickness for six months. The act, however, was performed on a Fijian whose animal nature has been systematically developed at the expense of his human nature. I could enlarge indefinitely on the point, were it not that I have communicated my views in length almost extending to a volume to the Government, but I shall content myself with saying that the policy of the Government in looking to order as an end in itself and not as a means of attaining to liberty even by the oppression and the enslaving of and the hardening of bonds of tyranny on the white man extenuated to some extent the offence of the peculiar method adopted of stopping shamming ill. The instance chosen is chosen very injudiciously and comes with some authority from "A. J. S.," he having done certain work for the Government and the proprietor of the estate from which he writes being a member of the Legislative Council, and unfortunately it so happens that (1) "A. J. S.," (2) the party who performed the act, and (3) the proprietor of the estate on which the act was performed are all Ceylon men who learned their ideas in working coolies who come to Ceylon in many instances to escape starvation, whereas the Fijian and the Polynesian are permitted to go into the service of the white man, as a means of their mutual further development and civilization.—Faithfully yours, A. R. W.

TEA IN KOSLANDA: RUBBER AND CINCHONA.

DEAR SIR,—I beg to send you the rainfall here for over five years. Now that tea is being grown successfully in nearly every district, I do not see why it should not turn out a paying product in this. Our rainfall may be considerably smaller than about Dimbula and Dikoya but I think it is better distributed. Our rain falls chiefly in the shape of afternoon showers or during the night, so would no interfere with plucking the leaf; there are also often a day or two of dry weather between the showers, so that the trees have ample time to take all possible benefit of every shower; if the tea trees were to produce flushes of leaf as rapidly as the coffee here produces wood, I think there need be little fear of its success.

Have you ever observed that there are two sorts of Ceara rubbers, one a stunted, bushy useless thing which seeds when only about 12 months old, the other and better sort, is not inclined to produce branches or seed until well-matured.

In going through a cinchona field of mine the other day I was grieved to see so many of the trees dying out, but on going about through them I was surprised to find a tree here and there apparently quite healthy, although the others around them were dead. On examining them I found they were trees I had left for seed and had not lopped them like the others; they were scattered about because I had left a tree here and there at different elevations to watch the result in seeding. Observing this made me think that the system of lopping off the lower branches may have something to do with the excessive mortality amongst our cinchonas now compared with what used to die before this system became so general: no doubt it is necessary to lop to a certain extent when the trees are growing amongst good coffee, but there is no need to carry it so far as some do and leave only a tuft of leaves on the top of the tree; the system altogether must surely be against nature and must be very trying to young trees; of course nothing can be done to save trees that have been planted in unsuitable soil, but something might be done to save them from over-lopping and over-barking.—Yours faithfully, G.

MARAGOGIPE COFFEE.

London, 21st Sept. 1883.

DEAR SIR,—I am sending you out a small sample of the new coffee called "Maragogipe" coffee. I also enclose you the particulars, such as I have collected respecting it; and I may say that I have been five months trying to get a supply of the seed, and have succeeded in getting a small quantity, which has been dispersed amongst planters this week.

I have sent samples to all the botanical gardens, including Dr. Trimen's, so that it will be unnecessary for the Kew authorities to distribute this seed at the expense of the British taxpayer, as I am offering it to any planter who chooses to purchase it. This is a better plan than sending out plants at 2s to 4s each.—Yours faithfully, THOS. CHRISTY.

MARAGOGIPE COFFEE.—A new coffee called "Maragogipe," has lately been discovered in Brazil, and a Commission was formed to investigate the qualities of the coffee and also of the plant, and they decided entirely in its favour. Not only does it produce a larger crop, but the coffee berry is much larger, and possesses a very silky-looking smooth surface, with high quality flavour. It stands well on the high lands, and the first planters that have adopted it in Brazil are so delighted with the results, that they are cutting down their splendid coffee trees of the old variety of coffee, and planting this new "Maragogipe" variety. I hear from a gentleman who has just returned from visiting many of the coffee estates in Brazil, that in all directions he found the planters speaking in the highest terms of this new variety of coffee, and he has kindly placed at my disposal a leaf of the plant, to show the size to which it grows, so on the back I have had traced the outline of an ordinary Caffea Arabica leaf, and the leaf of the new Maragogipe, kindly lent me by Von Glehn, of London, and this is what he writes me about it:—"The Maragogipe coffee tree which I have seen growing in Brazil, on the plantations of Mr. Francisco Clemente Pinto, has a much larger leaf than the ordinary coffee tree. It grows with extraordinary vigour, and trees three to four years old were already eight to ten feet high, and full of fruit. The tree seems to come into full bearing much sooner than the ordinary coffee, and the bean is very much larger. Altogether the weight of coffee per acre must be very much more when land is planted with Maragogipe than with the ordinary coffee tree." Having heard of the discovery of this plant in the early part of the year, I sent for a supply of seed and have succeeded at last in getting placed at my disposal a few quarts of seed for distribution.—THOS. CHRISTY. On the 23rd January, the Minister of Agriculture dispatched the following official note to the President of the Province, in relation to the propagation of the new species of coffee lately discovered:—"The species of coffee called 'Maragogipe,' which according to information in this Department of State was discovered in your Province by Crisogno José Fernandes, has found great favour among the planters of Rio de Janeiro, and the merchants who have examined it in this market, and in various countries of Europe, all agreeing that in size of berry, aroma and taste it is one of the species most recommendable. With a purpose, therefore, of propagating its cultivation, Your Excellency is hereby authorized to acquire, on account of this Department, and to remit 500 kilogrammes of this fruit, in a condition suitable for the plantation. Also, I recommend that Your Excellency order the extension of the cultivation existing there to be verified, and the results which it has produced, as well as under what conditions can be obtained the greatest quantity of seeds, having in consideration the vigour of the plant, the time of harvest, the price, and the guarantees of origin and quality."

NEW CEYLON: PROGRESS OF THE PLANTING ENTERPRIZE.

Sandakan, 22nd Sept. 1883.

DEAR SIR,—You will be glad to hear matters are going along all right here, the town of Sandakan itself increasing in size daily, while buildings of a more permanent nature than those formerly constructed are being erected.

Planting matters in the Bay are progressing slowly but surely the tobacco planted as an experiment being most encouraging. Sugar, however, will be, I fancy, one of the principal products grown in this Bay, but at present proprietors are confining themselves to nurseries of it. The rush of Chinamen to this country has subsided, the speculators mostly having returned to China. I should, however, like to see more of the planting class of that race; doubtless, these will now soon follow their brethren in trade.

Sandakan is built on the steep side of a hill, and there is a scheme in hand which promises to be settled in a few weeks or so to reclaim a great portion of the seashore.

The Government offices, which will be finished in the course of a month or so, will be the finest building in the territory, and then a church and a club are to commenced.

Kudat is going slowly but surely ahead, and I think it has a very prosperous future before it.

Silam, which was an experimental station, has fully performed its duty; the natives in that locality were formerly the greatest pirates in North Borneo, but now they are reformed, clothed, and in their right minds.

The experimental garden is nearly finished, although I hope to see additions made to it annually. Of all the products planted, cinchona is the only product that has not been successful, but then I was never very sanguine of its answering at sea-level. Liberian coffee just a year old has begun to blossom. *Coffea Arabica* appears to do best in the open; ditto cocoa. The remaining products planted and which are doing well are tea, cinnamon, cloves, nutmegs, sugar (20 varieties), cardamoms (2 varieties), citronella-grass, sugar palm, African palm, vanilla, jute, sago, *Coffea Arabica* (3 varieties), gambier, pepper and indigo. What is most encouraging is there is no disease of any kind on any of the products being grown.

I presume you have seen our *Government Gazette*. It does not come out very regularly, but is, nevertheless, well compiled and reflects great credit on the editor.

Two gentlemen, representing the Australian Borneo Company, have been prospecting for land, and have, I believe, taken up 100,000 acres. They are, or were when last I was with them, loud in their praises of the Borneo climate; the only damper to their feelings appeared to be the leeches. Sugar is the principal product they intend planting.

I have just returned from a trip to our south-eastern boundary, at which place the Governor hoisted the Company's flag. This boundary is disputed by the Dutch authorities, it having been granted to them by a native chief; but we maintain the country did not belong to the chief, so he could not give it.

The noise of the eruption in the Strait of Sunda was plainly heard all over Borneo: the natives inland who murdered poor Witti were under the impression, when they heard the noise, that we were coming to attack them from the east and west coast, and bolted away from their villages.

H. M. S. "Magpie" has been here some time surveying our coast, and now leaves for the Straits of Sunda.

Surveyors are very busy, and will be so for some time to come. Messrs. Garland & Co. have extensive contracts, which are being rapidly carried out by Mr. Abrahamson. More Government surveyors are, I believe, on their way from Ceylon, although I should have thought we had nearly cleared you out.

Mr. Wait has proceeded to Silam to take up the appointment of medical officer at that station.

On dit an ex Ceylon planter now in the Straits is coming here to commence operations on a large grant of land; if such is the case, I *cottam*plate handing my pen over to him.—Yours faithfully,

L. B. VON DONOP.

AN ENEMY OF CARDAMOMS.

Gampola, 12th Oct. 1883.

DEAR SIR,—Some time back, I saw a letter in the *Observer* about a poochie that gets inside cardamom pods and eats the seeds, but your correspondent had not been able to find any of them. I now send you one in the pod as it was found.—Yours faithfully,

CARDAMOMS.

[Enclosed was a small caterpillar, which arrived too much decayed to identify. Wire-worms have also been found in cardamom pods.—ED.]

CHARACTER OF THE COFFEE FLOWER.

15th October 1883.

DEAR SIR,—I have not by any means overlooked the fact that a healthy coffee blossom is a perfect flower, as a flower is said to be perfect or complete when it consists of four distinct portions, two of which are non-essential, whilst the other two are indispensable, viz., calyx and corolla, and stamens and pistil; but I must dissent to Mr. Halliley's assertion that perfect flowers are also cleistogamic. There are about sixty known genera that produce flowers of this class, about half of which also produce ordinary flowers, and cleistogamous flowers are confined chiefly, and perhaps exclusively, to herbaceous plants. That coffee blossom has on several occasions set without the flower having expanded cannot be denied, but this apparent anomaly can be explained by pollen having been deposited on the stigma whilst the anthers brushed past in the act of falling with the withered corolla. I do not think Mr. Halliley has any grounds for saying that a weakly child will turn out a strong healthy man if properly matured: if he had used the word *might* instead of *will* it would have been better, for, if the weakness be constitutional the probability is against the development of strength. Lastly, both Blue Mountain and Liberian coffees were exotics, and were introduced at a time when the atmosphere was simply overladen with disease spores, and the wonder to my mind would be the exemption of a new unacclimatized plant from the liability of infection with a disease so prevalent amongst members of its own genera. The larger variety was no doubt enabled to withstand it longer by reason of its greater robustness, and thicker integument of its foliage. If the new varieties could have been kept free from contamination until they were acclimatized, I believe their introduction would have been attended with success.—Yours faithfully,

SWADDY.

KOTAGHERRY TEA:, "POUCHIE FLUSHES" AND THE REMEDY.

Kandy, Oct. 15th 1883.

DEAR SIR,—In "S. W. H."'s letter headed "Kotagherry Tea," which you took over from the *Indigo Planters' Gazette*, in your issue of the 12th instant, he complains of the small out-turn of crop, caused partly by the long continuance of the "pouchie flushes." He puts the question:—"Do the planters in Assam suffer from the same complaint,—a small worm which sous (?) up the young flush and utterly destroys it for plucking?" What is meant I think must be, a small worm which *sews* up the young leaves of the flush, and no doubt the mistake lays with that annoying imp, the printers' d——l.

The worm referred to must be the larva of one or more species of *Tortricidæ* (Leach), leaf-rolling moths, and it would be of importance to know, if the Ceylon tea planters are suffering, or are likely to suffer to any extent, from the ravages of these little pests. You are, doubtless, familiar with the habits of these knowing insects, which roll up the leaves of plants with their silken threads, and thus form for themselves a house or tent of security, and on a portion of which they feed, until they assume the pupa stage of their existence. Just examine your rose-bushes any morning, and you will likely find them at work. Catch hold of one of the rolled-up leaves, and the cunning little occupant will remain perfectly quiet until you begin to break into his house, when out he jumps, and drops to the ground like a shot, or remains suspended in the air by his almost invisible silken thread.

In my little tottam I have no tea, and I never thought of examining tea bushes for the leaf-rollers yet. I have suffered from their ravages, though to no great extent, and have principally in the case of the *Okro* and other members of the *Hibiscus* family, the Rose and the Capsicum. I have, however, long known the cure for these pests. It is simple, and attended with *no* expense. No sulphur and lime—not even carbolic acid—is wanted. It is *nature's antidote*, the best and most efficacious in all such cases.

You know the nimble little Tailor bird well,—he's not shy. In the early morning, you can hear the ring of his metallic note all over your garden-compound. Watch him for a little, and you will see him, and perhaps Mrs. Tailor and the little Tailors, flirting their tails with delight, and examining every leaf of the roses and other shrubs. The *leaf-roller is at work*! See the little warbler how he squints in, first at one end of the rolled-up leaf, then at the other; but poochie is not to be thus caught! Up hops little snips on the stalk of the leaf, and, with a dig of his long sharp bill, sends it straight into the middle of the house of the leaf-roller, which bolts, and *is bolted* instantly!

The tailor bird is but one of the many feathered enemies of the leaf-rollers and other destructive larvæ. All the other warblers, thrushes, robins, bush-creepers and fly-catchers, destroy vast numbers of them, and are first-class gardeners. Even the cheeky sparrow, though dead-nuts on seeds and lettuces, does a deal more good than harm.

In my own garden, I suffered seriously from the larvæ of the *Lepidoptera*, until I managed in various ways to encourage the settlement in the neighbourhood of several families of warblers, ant-thrushes and bush-creepers. Now the wretched varments do me comparatively little damage, being devoured almost as soon as they put in an appearance. I assure you it is very pleasing, to watch the little birds examining leaf after leaf, and I wage constant war against all their natural enemies. Long before old Sol has dispelled the dewy mists of morning, and while the sparkling dew-drops still cling to the drooping fronds of the graceful weeping bamboo, my little feathered friends are hard at work, and devour the caterpillars by the hundred, ere their morning meal is ended. When we consider for a moment hte extraordinary speedy powers of digestion possessed by insectivorous birds and the rapidity with which they feed, we can foam some faint idea of the vast amount of insect-life destroyed in a few short hours, by even a single family of these useful little creatures.

It would appear from "S. W. H."'s letter referred to, that these pests, the leaf-rolling moths, must be doing serious injury, at certain seasons, to the tea gardens in some parts of India. Should they show up here in such numbers as to be equally injurious (which Heaven forbid), I believe that the best agents of destruction to be found will be our *insectivorous birds*.

[We have more than once referred to a minute leaf-rolling moth as the most serious tea pest we have yet observed at work. Red spider and "mosquito blight" (*Helopeltis Antonii*) exist, but they have have not hitherto done extensive mischief. The moth referred to appears perhaps once in a year, and then vanishes. The moths, which we believe to be the parents of the poochies, are nocturnal; creamy white in colour, and not larger than the little finger-nail of a man. The most marked and marvellous characteristic of the *larvæ* is the rapidity with which they pass through all the changes from grub to winged insect. We have seen a flush leaf perfectly healthy on the morning of one day, and rolled-up, black, dry and cindery the next. When we *have* found the insects there has been no obvious web, only a little worm in a damp envelope, making no attempt to escape and not having any apparent power of throwing out a thread to descend by. As to the remedy of insectivorous birds, a most marked characteristic of Ceylon plantations, especially at high altitudes, is the paucity or utter absence of bird life. Birds seldom appear even to feed on cinchona seed, and we do not know how they are to be attracted.—A proof of this letter having gone to A. W. with our note at the end, he writes:—"I observed your interesting foot-note as to the paucity of insectivorous birds, and in fact birds of all sorts, in our coffee districts. Just so. I quite agree with you; there is a deplorable want of bird life in these old favorite districts, where scarcely a remnant of forest or cover of any sort is left. But this is an *unnatural* state of things, and there would be no lack of birds if they only had suitable cover and favorite breeding haunts. For example in and around Nuwara Eliya there are abundance of them; and warblers, bush-creepers, ant-thrushes and blackbirds can be seen in every hedge-row, and it would be much to the advantage of the owners' *kale yairds* if these useful birds and their habits were studied more. Another serious question will arise in these districts which are but one expanse of coffee,—where is the fuel and charcoal to come from for drying the new and destined to be the staple product—*tea!* May the experience of the past and present impress upon planters the folly of clearing away large expanses of natural forest without leaving intervals of cover, and thus banishing from their estates the most valuable enemies to insect life, which Nature has provided."—ED.]

COST OF COAL FUEL FOR TEA IN MASKELIYA.

Maskeliya, 16th Oct. 1883.

DEAR SIR,—Mr. Gray was quite right about the cost of coal. Coal can be got in Colombo for R20 a ton, and, when the railway is opened to Dikoya, the cost of bringing it up to Hatton will probably be 12·60 a ton; add 12·20 for other charges, cart-hire, &c., and we have it in Maskeliya for R44·80, or 2 cents a lb. The Sirocco advertisement states that No. 1 dries from 20 to 25 maunds of green leaf per day of 10 hours, with 6 to 8 maunds of dry wood or 2/2 to 5/2 maunds of coal fuel. This clearly shows that 1 lb. of coal does dry 2 lb. of tea. Mr. Owen's reply to the Chairman's question was surely a rash one, as he must know that the estates with a reserve of jungle on them are few and far between. We are told that Maskeliya, Dikoya and Dimbula are admirably suited for the growth of tea, and I am surprized that this fuel question has not been mooted before. Mr. Gray deserves our thanks for bringing the question to light. How did those in the old districts, Pussellawa for instance, propose drying their tea, where they have not even firewood for their coolies?—Yours faithfully, R. L.

THE SCANDALOUS EXACTIONS ON, AND DEDUCTIONS FROM, TEA SENT FOR SALE IN THE LONDON MARKET.

SIR,—For the information of my brother tea planters, I beg to say that 6 breaks of my tea amounting to 27,469 lb. were shipped to London: of this only 26,749 lb. were accounted for as sold, the balance 720 lb. being lost to me. The explanation given is, that 398 lb. went as trade allowance of 1 lb. per parcel, and 322 lb. *was lost in weighing!* I look upon this as *scandalous robbery*, and the sooner some motion is made about it the better! The home charges for freight, insurance, brokerage, sale charges, dock charges and agents' commission amount to a little under 2d per lb.: this does NOT include agents' commission and other charges paid at Colombo. I look upon it that with all these deductions tea planting *will not* make our fortunes! What are we to do?—Yours faithfully,

A CEYLON TEA PLANTER.

MR. ARMSTRONG ON "BANGY" BUD AND TEA MANUFACTURE.

Rookwood, Deltota, 17th October 1883.

DEAR SIR,—"Beginner" will find I do recommend the plucking of "bangy" in my paper, under the head of plucking, last paragraph, even if its single leaf is hard and has to be thrown away.

If it is plucked, a healthy shoot is nearly always thrown out from the next eye; if not, the twig remains the same till the end of the season, to be pruned off. I have some very windy ridges, but I have not noticed that wind causes "bangy." Causes, as far as I can see, are:—Heavy pruning with the sudden and rapid growth ensuing, giving a small percentage; young whippy laterals not cut far enough back in pruning often grow "bangy"; dry, hot weather after pruning; poverty of soil; and low jat.

I think Mr. Owen's explanation in your issue of the 15th and a more careful perusal of the cost of hand-vs. manufacture by machinery will satisfy "the gentleman of high authority"—he has been too hasty. For hand manufacture I have, as with machine, given the *outside* rates, and I am at present working my machinery at one cooly less than I showed.

With regard to lining for tea among coffee, I see no difficulty in it. If the coffee is *very* thick, and land much broken, cut the lining rope into lengths of about 40 feet or so, and fasten them together by a hook and eye (made out of pieces of old wire shoot, a ring and hook); the rope can then be worked any length, and *always on the ground*, the coffee lines guiding us when we have short ropes, and instead of hauling the rope unhook the lengths and pass them along the ground. The objection to Mr. Northmore's method is that coffee is seldom square lined throughout, and his lines would run diagonally across the hill, an objection if the land is at all steep.—I am, yours truly,

C. SPEARMAN ARMSTRONG.

PREPARATION OF TEA BY HAND AND BY MACHINERY.

Maskeliya, 19th October 1883.

DEAR SIR,—Mr. Owen's explanation (page 365) of the "*mistake your informant has fallen into*" may be "*quite plain*" to Mr. Owen himself, but I fear his readers are scarcely so fortunate. Mr. Owen's figures as to hand-manufacture are so ludicrously incorrect, that I can only suppose the printer's devil has been "fooling around" with Mr. Owen's manuscript. The cost of rolling by hand is under 4 cents, not 6·5, and sorting ·36 per lb. not 4 cents.

The only way I see of arriving at the truth is to take the cost of a full day's work of the machinery, and compare it with the cost of making an equal amount of tea by hand. I will take 400 lb. tea, as this enables me to use some of Mr. Armstrong's figures. An experience of some five years' tea-making by hand enables me to guarantee my figures for that mode of manufacture, but, in the case of machinery, I court information and correction. I have, of course, only taken into account those operations in which machinery can be employed. It is of no use to confuse the matter with tea-lead, packing, &c., which have nothing to do with the question.

Machinery.	
1 engine-driver per day	R1
4 coolies at 36c.	1·44
Sorting machine 1 cooly	·36
Firing 3 coolies	1·08
Refiring ditto	1·08
Firewood for engine 3 cubic yards at 45c. ?	1·35
	R6·31
Profit on machine work	18·67
	R24·98

Hand labor.	
Rolling, withering and firing 1 cooly to every 30 lb leaf 53 men at 36c	R19·08
Charcoal firing and refiring say $5\frac{1}{4}$ cwt. at 85c. per cwt.	4·46
Sorting 100 lb. ℘ man 4 coolies	1·44
	R24·98
Total cost of manufacturing 1,600 lb leaf or 400lb. tea by hand.	

Profit on machine work 18·67 or about 4·67 ℘ lb on 400 lb. tea.

In the figures for hand manufacture, I have given liberal allowance of labor. A cooly rolls 40 lb. leaf, the extra men are for firing, withering, &c. As explained, I have not used machinery myself and have had to collect figures from various sources. Perhaps my good friend, Mr. Armstrong, will correct them. It is to be remembered that the more tea you make by machinery the cheaper the work becomes. This is scarcely the case with hand manufacture. You may save a man or two in firing or withering, perhaps, but you will always require a rolling cooly to every 40 lb. leaf, if you want your work properly done.—Yours truly, ADAM'S PEAK.

[This letter was written before Mr. Armstrong's explanation was published. It is clear that all who have used machinery extensively are satisfied of two things: first, the work is better done, and, second, at considerably less cost.—ED.]

23rd October 1883.

DEAR SIR,—Though a great deal of light has been shed of late on the subject of tea, it does not strike me that it has been made clear what the exact saving should be, by the use of rolling and drying machinery.

Mr. Armstrong puts it down at $6\frac{1}{2}$ cents per lb., but his jungle lies close to the tea factory, and he says he makes his coolies frequently carry a load of firewood when returning from work. This is probably the reason why he is able to put down his machine

rolling at	0·41 cents
and his firing at	0·25 ,,
Total...	R0·66

while Mr. Hay, in his latest paper, quotes $1\frac{1}{2}$ cent for the same things, and adds "firewood being close." But firewood is close on very few estates, and the cost of cutting and transporting it to the factory, should always be taken into account.

Mr. Owen, in his paper read at Maskeliya, gave the saving at 7 cents per lb, and in a later communication he modified it to $6\frac{1}{2}$ cents. In saying "sorting &c costs 4 cents" he must include packing boxes, lead, etc., which ought to be left out. Refiring is sometimes done by hand, even when there is drying machinery.

What Mr. Hay gives is not his own experience, but information given him. We must accept it, however, as substantially agreeing with his own lengthened experience of hand and machine work, at Windsor Forest. He puts the saving down at $5\frac{1}{2}$ cents.

It now remains that one of the superintendents trained by the late Mr. Cameron should come forward, and give the result of his experience in regard to the saving made by machinery. It is well-known that on the estates he visited not only were fine teas turned out but the cost of manufacture was exceedingly low. The tea was then made by hand, but, on several of them machinery is now in us and it would be interesting to know what the saving is found to be there.

My calculation of the saving by the use of rolling and drying machinery I give below, but, not having used machinery myself, I take Mr. Hay's figures for it:—

One coolie rolls 40 lb. of leaf=10 lb. of tea, and taking the average checkroll rate at 35 cents, rolling cost	$3\frac{1}{2}$ c. per lb.
One coolie fires 80 lb. of leaf—20 lb. of tea, which at same rate costs	$1\frac{3}{4}$,,
Charcoal costs	1 ,,
Total	$6\frac{1}{4}$c. ℘ lb.
Mr. Hay gives as cost of machine-work	$1\frac{1}{2}$,,
which would show a saving of	$4\frac{3}{4}$c. ℘ lb.

But when it is taken into account that charcoal on some estates costs *less* than 1 cent per lb. of tea, and hand-rolling and firing less than the figures given above, owing to the checkroll rate often being less than 35 cents, it will be seen that hand-rolling and firing, with cost of charcoal included, may sometimes amount to less than $6\frac{1}{4}$ cents; while, on the other hand, if firewood has to be transported some distance (often by coolies) machine-work must cost more than $1\frac{1}{2}$ cent. In the above remarks "sorting" (which, by hand, usually costs 1 cent per lb.) is omitted, as there are very few sorting-machines yet erected in Ceylon.
PROPRIETOR.

A DEFENCE OF SELF-SOWN SEEDLINGS, &c.

DEAR SIR,—Will you ask "L. B. Y. L." why he neglected to do, as he recommends others to do?

Does he think that folks who are aware of the following *facts* can coincide with what he puts forward as the cause of our trouble?

1. That the coffee first to go out in the Maskeliya district, and I may say the worst in it, was planted from nurseries of selected seed from a Ramboda estate, *then* as a rule topping the market at home with the highest prices.

2. That the finest sheet of coffee in the same district (I may say none better in Ceylon now to look at) was mostly planted with self-sown seedlings from Glencairn estate, and that, too, after another man had picked several hundred thousands to put into nurseries, so small were they.

3. "L. B. Y. L." will admit all village stumps are self-sown, I presume.

4. Look at the magnificent fields of coffee in Haputale, where fully one-half of the old coffee was all village stumps from every village in Uva, and the same holds good too of Udapussellawa and Maturata, and it was from the villages of the two latter districts the greatest complaints used to be made of the stumps having black hearts.

I remember Mr. T. once saying he "would rather have a clearing of his in Haputale remain unplanted a year than use Maturata village stumps," and I believe it did so.

These are *facts* that speak for themselves.

A self-sown seedling is just as good as any nursery plant, provided it gets the same treatment, is take up carefully and planted out carefully. You can damage them easily enough, when allowed to grow too old and roughly pulled out of the hard soil; unless the tap root be quite straight, it will split and naturally become unhealthy. If, assisted with a fork or crowbar, properly pruned and put out, for hardiness and general *quality* no nursery plant will equal it. No: "L. B. Y. L." you are out of it when you blame these causes as the source of the present unhealthy condition of our coffee tree.

Cinchona.—I know not the cause of your death.

Tea.—I must learn more of it ere I speak. I have tried a good many, but I did not always find the largest seed the best.

We are making a big leap now. But, remember, THE MORE YOU LOOK THE LESS YOU LIKE IT.

INDIAN *VERSUS* CEYLON TEA SEED.

Dimbula, 22nd October 1883.

DEAR SIR.—Mr. Hay is quite right in advising planters to plant *Indian seed*. Every Assam planter I have asked ridiculed the idea of the advantage of country seed. Not only is it inferior jât, but in 99 cases out of 100 the seed sold is *unripe*, and many of the resulting plants miserable abortions. I planted both kinds in my nurseries last year. The INDIAN SEED plants (Amluckie Tea Co.'s), containing 19,000 seeds to the maund, were ready to plant out in June, and *have* all been planted, while the country-grown seed plants are still struggling for existence in the nurseries.—Yours truly, PLANTER.

[There can be no question as to the advantage of obtaining the best possible seed; and carefully gathered, ripe-seed of superior jât from India, well packed and rapidly transmitted and put into the ground, ought to give such first-rate results as our correspondent obtained from the Amluckie Co.'s seed which he advertises in the best possible manner. But if Ceylon-grown seed from best Indian jât ought not to be used in Ceylon, in the first generation, does it not logically follow that Assam-grown seed from trees of perhaps the fourth generation ought long ago to have been abandoned for growing in Assam? Probably the solution of the difficulty would be an exchange of seed; although no doubt Assam planters would laugh consumedly at the idea of Ceylon sending *them* tea seed. For those who would palm off bad jât seed for good, or supply unripe seed, we have only words of condemnation; but there is good jât tea in Ceylon, the property of planters who, if poor, are honest. We see no occasion, therefore, for so sweeping a condemnation of Ceylon seed, unfortunate (the reverse of Am—luckie) as our correspondent's experience seems to have been. We have no personal interest in the matter of the sale of Ceylon-grown seed, for numerous applications for seed from Abbotsford have been uniformly refused. All that the 7 to 9 year old seed-bearers from Assam Company seed can produce is used to extend cultivation on the estate. So much is this the case, that, for a low-country place, we have had to purchase first Indian tea seed and then locally grown. We quite agree that the very best Indian tea seed is better, just because it comes from a different soil and climate. We only protest against the sweeping condemnation of local seed, even if grown from the best Indian jât. Since the above was written we have seen letters from the late Mr. Cameron ordering first 100 maunds and then 25 of seed locally grown on bushes, the result of good jât seed from India. He also expressed his opinion as to small-sized seeds thus:—"I have tried the seed and find it very good, 90 per cent of it sound. It is no drawback at all to seed, to be mixed with small, for, as a rule, small seeds come up as well as large, and often make better plants. It is a well-known fact that some very small seed is often got from pure indigenous tea trees.' It is an equally well-known fact, we believe, that inferior China plants often produce very large seeds. The point, however, is that Mr. Cameron, who certainly knew something about tea cultivation, had no hesitation in recommending Ceylon-grown tea seed to his constituents.—ED.]

CACAO AND COCONUT CULTIVATION.

Kalugala, Kegalla, 22nd Oct. 1883.

DEAR SIRS,—Seeing the valuable contribution in your paper, "Cacao Cultivation in Ceylon," it reminds me that some five years ago I planted as an experiment in a coconut garden in the low-country some cacao plants—quincunxed with the coconuts. Revisiting the spot some little time ago, I found the plants had grown into strong and healthy trees, and were crowded with fruit

Again, passing lately along the road from Doloshage to Kegalla, I was shown some cacao trees in a coconut garden planted exactly in the same way, and which were to all appearances flourishing and bearing well.

In neither instance, I learned, had the cacao trees received any extra attention, and had never been manured. The soils in both gardens were an ordinary red loam.

I mention these facts in the hope that those possessing coconut estates and gardens, with suitable soils, would be induced to go in (experimentally at least) for the cultivation of cacao amongst their coconuts.

The cacao, being a deep feeder, requires a free and fairly good soil, and, receiving shelter and checkered shade from the coconuts, would, in my opinion, have all that it needs.—I am, yours faithfully,

G. W. F. SAULIERE.

POOR OLD "KING COFFEE" IN HIS OWN DEFENCE.

23rd October 1883.

DEAR SIR,—You don't know perhaps that I also was at the Dimbula planters' meeting, not in my shroud as some planters in Dikoya, notably Mr. Skrine, would put me, but in my kingly robes was I there. I had firm hopes that Messrs. Elphinstone, Sinclair and Lawrance would have defended me, but even these could not agree as to my ailments. So, I now whisper to you, and leave you to make it known to all planters (*a*) that I am the medium through which Providence punishes the planters; (*b*) that leaf-disease and grub are the main causes of the failure of coffee crops in Dimbula and Lindula during the past four years, aggravated in many instances by no manuring, no pruning, or insufficient pruning, and no application of disinfectant. To those who bow to Providence and wish to give me fair treatment, I would strongly recommend (1) to give me a liberal supply of sweet (not fungoid) manures, to prune me better and earlier, and to scatter disinfectants all around me which will counteract leaf-disease; (2) to burn the patanas as early as possible, dig holes, or trenches, and mix manure with soil, put in hole and cover well, then scatter wood-ash and lime over the top, by which means you will destroy a lot of grub, and prevent the beetle to come into your coffee, their food near the surface (poonac, bones and small rootlets) being covered over with soil, wood-ash and lime; (3) as I cannot stand cinchona at all, but do not mind tea, you must take out your cinchona, or I cannot live; and (4) give me also some air-holes, to allow my feeders to get fresh air and to let bad gas out. If the planters will follow this my advice in Lindula and Dimbula, which is a climate I like, I will prove to them that I will be able to tlive any of their new loves and pay them handsome profits. Capitalist, trust me yet; treat me well, and I will repay you.—Yours on the watch,

KING COFFEE.

THE NEW COFFEE.

25th October 1883.

DEAR SIR,—I have just seen in your issue of the 23rd instant Mr. Christy's letter about the Maragogipe coffee. Can you let us know whether seed of this apparently highly valuable variety are to be obtained in the island, and, if so, to whom we should apply? If it is really such a paragon as described, we should lose no time in obtaining a supply, though it will require a very determined planter to follow the example of the Brazilians, and cut out his splendid (?) trees of the old variety to make room for the new.—Yours truly, EARLY BIRD.

[We believe Messrs. Bosanquet & Co. are Mr. Christy's agents; but, after the mode in which Liberian coffee and Blue Mountain coffee have been attacked with leaf-disease, there is not much encouragement to try new kinds of coffee.—ED.]

LARGE TEA BUSH IN DIKOYA.

Bogawantalawa, 26th Oct. 1883.

DEAR SIR,—The following particulars relating to a tea bush on this estate may be of interest to some of your readers who contemplate cultivating tea at high altitudes. Age of bush, 6 or 7 years; species, Assam hybrid, with dark shiny leaf; girth of stem 6 inches above ground and below the junction of the branches 2 ft. 1 in.; diameter of bush about 8 ft. from the ground, 18 ft. 6 in.; height 19 feet. This bush has never been touched with a knife. Does this beat the bush on Abbotsford which I have heard spoken of?—Yours faithfully, THOS. FARR.

[The Abbotsford giant when last measured showed a diameter of 25 feet, the circumference being about 75 and the height about 22.—ED.]

INDIAN *VS.* CEYLON TEA SEED.

Glenannie, Kegalla, 26th Oct. 1883.

DEAR SIR,—"Planter," in his letter "Indian *vs.* Ceylon Tea Seed," evidently overlooks the fact that his Amluckio seed went through the process of germination during its transmission from Assam, and very naturally the resulting plants were ready sooner than those grown from the Ceylon seed, presuming, of course, that the latter was planted at the same time and ungerminated.

I quite endorse his statements that tea seed obtained locally is often insufficiently matured; and I find that the resulting plants show every variety of jat, proving that care had not been observed, by those growing seed for sale, to allow only those bushes to run to seed which are of an undoubtedly good jat. As everyone knows, previous to the present demand for seeds of good jat, estates, with perhaps few exceptions, had been planted with unselected tea plants.—I am, yours faithfully,

G. W. F. SAULIÈRE.

THE COMMENCEMENT OF LEAF-DISEASE.

DEAR SIR,—The ideas of "an old coffee-stump" who can scarcely manage to keep branches and leaves together, cannot, in themselves, be of any intrinsic value, except in so far as they report the condition and progress of himself and his fellows. But the talk which I sometimes overhear and make notes of is by our masters, who, to judge by their voice and action, hold pretty tenaciously to their opinions, and mean what they say.

Just now, that old familiar sound—the music of the pulpers—is heard every day, only there are not so many verses in it as there used to be. It is sooner ended; and, for my own shuck part, I quite envy the vigor of the neighbouring trees from which I see the coolies carrying loads and loads of ripe coffee to the pulping-house every day. But my turn will come "next year": there, I have blurted it right out this time, but I feel it is true, and that makes me bold.

So much for myself. As regards a subject I reported in my last, I heard the same durai talk further as follows:—"Your morning contemporary has noticed my assertion that leaf-disease had its origin in Madulsima. Not in order to deny that historical fact, but to submit that it is 'open to question,' or to 'cavil,' as he puts it. Well, until some evidence of facts is forthcoming of much more value than the hazy 'fancies' and opinions of men suddenly overcome by surprise and disaster, would-be wiseacres who believed they knew everything concerning coffee from 'insidious defunction' to the lightning strides of leaf-disease, which gave them no time to think, shall I agree that 'cavilling' is the better word. What are the facts? Here is a highly prolific thing—something between a vegetable and an animal—with seed-spores far lighter, more numerous and more insidious than the seeds of the goat-weed, finds a plant for the leaves of which it has the greatest possible affinity—in structure and composition being so completely all that it needs for its habitation and diffusing by every wind that blows—that once on this side of the huge barrier, the Nuwara Eliya range, it spreads over our coffee fields like wild-fire. And yet, we are asked to believe that these spores had been lingering for years about coffee, here a bit and there a bit, unable to make up its own mind, or apparently to be aware of its own nature! And all this on the strength of mere fanciful recollections, concerning which, if put on their Bible-oaths, these old planters would not swear. But what would be the good if they did? The unerring operations of Nature are surely more to be relied upon than their vague imaginings. The disease appeared first in large patches on Galloola and Doomoo Oovahkelle and Verella Patana estates, but nevertheless so apparently within a measurable compass, that Mr. Donald Reid hoped to check its progress by employing coolies to pluck off and remove the affected leaves. In this, of course, he was unsuccessful, as the wind, and the vigorous and virulent tenacity of the thing itself, took care to defeat his efforts. It at once extended its *area* with the resistless energy of a tidal wave. True, individual trees only suffered in patches severely—generally, far less than half the leaves on fine large trees were affected—but coffee in those days was vigorous, from roots whose ramifications occupied every inch of the soil; but this very vigor only favored the diffusion of the pest, by keeping it provided with so large an area of leaves upon which to deposit itself. Let that eminent naturalist, Mr. William Ferguson, say if in common-sense it is reasonable, or if in nature it is possible, to believe that a *fungus* of such vigorous vitality, having *once* found conditions so favorable to its functions and fertility (as afforded it in the wide expanse of Ceylon coffee fields) would go fooling about, year after year, appearing here on a leaf and there on a leaf, and then disappearing, as these 'recollections' of some old planters would have us believe? I think it quite *possible* that its appearance was *simultaneous* in other districts than Madulsima, but, as a fact, I do not believe it was so, because, while it was troubling the minds of the Madulsima planters (and, be it noted, their minds only), I took a tour through all the other Uva districts, and scrutinized the then splendid coffee-fields, estate after estate, without being able to find a single affected leaf!"

Pooh! I'm glad he's done; for, if there had been much more of it I am afraid my few remaining leaves would have dropped off in my excitement and efforts to hear and record it all. Besides, after all, what's the good? Coffee is "doomed," so what does it matter? Nobody cares anything about the past, the present or the future of coffee, now-a-days that tea is filling everybody's head. But you can just tell "*leetle tea plant*" not to be so cocky, because it's just possible that coffee won't "go" at its bidding; and, also, that it's just possible, that, if grub and its other afflictions will go away, then, a lot of little and big tea plants will be pulled up again, and be ignominously removed from its nobler presence. At all events, so thinks

AN OLD COFFEE-STUMP.

TEA MANUFACTURE AND "CRITICS."

DEAR SIR,—In a recent issue of your paper a correspondent signing himself "Adam's Peak" states that Mr. Owen's figures for hand-manufacture are "ludicrously incorrect," and complains plaintively of his want of power to understand them. I have referred to the remarks in question, and find that Mr. Owen, quoting Mr. Armstrong's figures in a brief form, gives rolling, &c., 6·5; sorting, &c., 4: total for hand manufacture 10·5. Perhaps, "Adam's Peak"'s friends may be able to explain his inability to grasp a simple statement, but, when he credits your general readers with no better developed mental power than his own, he is surely presumptuous. I am one who has taken a great interest in this and all other subjects relating to tea, but I cannot see that captious criticism either adds to our knowledge or to our confidence in the *facts* your correspondent brings forward in a letter which is a very marked contrast to the one signed "Proprietor" which follows it.—Yours truly, D.

INDIAN *VS.* CEYLON TEA SEED.

No. I.

27th Oct. 1883.

DEAR SIR,—Your correspondent "Planter" (page 415) seems to been have singularly unfortunate in his Ceylon tea seednurseries and veryl ucky in his Indian seed ones. If the Ceylon seed which "Planter" bought was palpably unripe, why did he accept it? If the seed in question looked ripe, withstood the floating test, and any seed opened had a fully developed kernel within, I do not understand how such seed could be pronounced unripe or fail to germinate, if put in beds within a reasonable time after delivery. As to seed of inferior jât being sold in Ceylon, no one should buy seed where trees are inferior or where they do not know the superintendent has cut down the inferior trees to prevent them bearing seed, as has been already done on numbers of estates. Your footnote justly condemns so sweeping a statement against Ceylon tea seed in general. For one nursery (as in "Planter" 's case) a failure with Ceylon seed, how many hundreds of nurseries have been perfect successes? Apologizing for space taken, I remain, yours truly,

CEYLON TEA SEED.

No. II.

Central Province, 28th October 1883.

DEAR SIR,—I am not as a rule anxious to rush into print, but really such a sweeping assertion as "Planter" 's (page 415) cannot be allowed to go unchallenged.

How does "Planter" arrive at the conclusion that in 99 cases out of a hundred Ceylon-grown tea seed is sold *unripe?* Surely a man with an infinitesimal amount of commonsense could easily tell ripe from unripe tea seed and so reject the latter. I have had a considerable quantity of locally-grown tea seed through my hands, and my experience of it is most favourable; of course, I saw that the seed was *ripe* and of a good jât.

To write as "Planter" does at this time of day in Ceylon is simply ABSURD.

P. S.—Let a few more, who have as I have had, successful nurseries from locally-grown seed, send you their opinions. Indian seed may be good and all that "Planter" says of it, but that's no reason to condemn Ceylon-grown, *ripe* and from trees of mature age and good jât.

No. III.

27th Oct. 1883.

DEAR SIR,—I note (on page 415) a letter signed "Planter" that 99 per cent of Ceylon grown seed sold is "unripe." I am sure you will not allow this rash and mendacious assertion to pass uncontradicted. I would ask your correspondent whether he is foolish enough to purchase white or red coloured seed; if not, how can he possibly tell ripe from unripe seed? I should have thought it incredible that any market could be found for unripe seed, so easy it is of detection! "Planter" has apparently some subtle method of his own, for distinguishing ripe and unripe seed. I have no wish to ask him to divulge his secret. When your correspondent states that all local seed is of inferior jât, he displays the same brilliant knowledge and the same startling untruth, that he exhibits in asserting that 99 per cent of the seed sold is unripe!—Yours faithfully, N. B.

No. IV.

27th October 1883.

DEAR SIR,—Can your Dimbula correspondent (page 415) "Planter," tell us how to distinguish unripe tea seed from ripe? I have no means of judging other than by colour and weight; but these tests cannot be conclusive, or, if so, in the 99 cases out of 100 where locally-grown unripe seed is sold, there are an equal number of cases of

CAVEAT EMPTOR.

No. V.

27th October 1883.

DEAR SIR,—After your footnote to "Planter" 's letter (page 415) it may seem unnecessary to notice his views about imported *versus* locally-grown seed.

However, a *fact*, which I can adduce from my personal knowledge, may cause him to considerably modify his views on the subject.

Mariawatte estate was planted by Mr. Pilkington in 1879, and I believe that it will give from six to seven hundred pounds of made tea this present year ending 31st December. Now, I believe, I am within the mark when I say that not more than one-third of the bushes on Mariawatte are from imported seed.

Does not "Planter" go a "leetle" too far when he says that in 99 cases out of 100 the seed sold locally is *unripe!*

Is it necessary that seed to produce good healthy trees should be *fully* ripe? Let "Planter" listen to what Burbidge (no mean authority) says on the subject:—

"If seeds are to be sown as soon as they are gathered it is as well to observe that the germ or embryo of the seed is fully capable of perfect germintoion long before the seed has arrived at that perfect state of ripeness or maturity, which is necessary to insure its keeping properties."

I do not see that Mr. Hay specially advocated Indian seed. What Mr. Hay did say on the subject of Ceylon and Indian seed is as follows, viz.:—"Locally-grown seed has done quite as well as Indian, when planted on good soil, but there is no doubt that when seed from trees that have been giving heavy crops for some years is put in poor soil it becomes in appearance very low class. If Indian seed can be guaranteed and it arrives in good order, I would prefer it myself to the locally-grown."

Mr. Hay says "If." Ah! there is great virtue in an "if."

Now, I will give "Planter" the reverse of this picture. I know two cases of neighbours getting Indian seed and its proving a failure. In one case eleven (11) maunds turned out only about forty thousand plants, and in the other case less than five per cent of the seed came up. Of course there is good seed as well as bad sent out of India, and I know of a neighbour who got at least fifteen thousand seeds per maund to germinate from Indian seed. You can always examine locally-grown seed on arrival, and if it is bad return it. But you cannot do so with Indian seed. "It 's a far cry to Loch Awe."

I hope you will excuse the length this letter has run to, but "Planter" ought not to make such sweeping statements as "99 cases out of 100."

His statement that every Assam planter he had met ridiculed the idea of the advantage of country seed sounds very much as if Bass had ridiculed the idea of anyone drinking Allsopp's ale.—Yours faithfully,

ORION.

TEA AND FIG TREES: QUERIES ANSWERED.

DEAR SIR,—When was the tea plant introduced to Ceylon? In a late issue of the *Observer*, a correspondent staes that the tea plant was introduced to Ceylon in 1841, but the plant was here when Moon's Catalogue was published in 1824, and perhaps one hundred years before then, though there is no record of the fact. It is most likely that William Kerr, the first English gardener appointed by Government, and who came here from China in 1811, brought tea plants with him to Ceylon. I have seen tea plants growing in various parts of Ceylon since 1839. [Tennent mentions that the Dutch attempted the cultivation of tea in Ceylon. See our "Planting and Agricultural Review" prefixed to *Directory* of 1876-8.—ED.]

3rd: Would the introduction of the Moreton Bay fig tree be a great accession to Ceylon?

In your issue of this date you quote a paragraph from the *Queenslander* in praise of the Moreton Bay fig, *Ficus macrophylla*, and its mode of cultivations, and you add at the and that this Moreton Bay fig would be a great accession to Ceylon. We have from 20 to 30 indigenous fig-trees in Ceylon and several foreigners, including the bo-tree, the oldest historical tree in the world, and nearly everyone of them are as remarkable for their mode of growth as the Moreton Bay fig-tree. Are not most of them the great destroyers of old buildings, dagobas, temples, forts, walls, and even hewers of rocks, should w and why introduce more of our enemies to crumble our ancient temples into ruins!—Yours,

W. F.

THE CACAO PLANTS AMONGST COCONUT PALMS.

Kalutara, 27th October 1883.

DEAR SIR,—Referring to a letter signed G. F. Saulière, (page 415) giving such a plausible account of cacao flourishing betwe n the rows and under the shade of coconuts, would that gentl man be good enough to mention the name of the estates where these are to be seen? I, for one, shall put myself to the trouble and expense of going and seeing it; for it seems hardly credible when taken into consideration that more than one proprietor of coconut property has most carefully tried the experiment even with the aid of manure, but without success. We all know that the coconut palm spreads its roots like a network all over the ground between the rows, so that any other plant, more especially a delicate plant like the cacao, has no chance of existence. Now to this perhaps G. F. Saulière would say: how is it that we often find fruit-trees growing and bearing under and alongside the coconut? My answer is that the fruit trees must have been planted simultaneously with the coconuts, and when the soil was new, and in this case, too, it is not often, or rather not in every instance, that success is gained. We often find mango, jack and other fruit-bearing trees planted between the rows of the coconuts and doing well near habitations, and that is owing to no other reason than that they are attended to by being kept clear of weeds and indirectly manured by the daily sweeping which takes place.

The only way that I partly succeeded in my attempt to grow the cacao plant underneath the shade and between the rows of the coconut palm was by cutting trenches 1 × 1½ ft. in depth all round, at a distance of 2½ to 3 feet from the stem of the cacao plant, and with the aid of manure in shallow holes all round the stem. The trenches have always to be kept clean, for, with the accumulation of dirt and soil by wash, the coconut roots will be found to make their way through this, to the manure applied, with amazing rapidity, and thus check the growth of the cacao plant.—I am, dear sir, yours faithfully,

A NATIVE PROPRIETOR.

MR. JAMES SINCLAIR ON COFFEE, TEA AND CINCHONA.

27th Oct. 1883.

DEAR SIR,—Although my views regarding the future of our infant industry may be of small import to you or your readers, I trust you will allow me space in an early issue, in correction of a wrong impression which my remarks at the last Dimbula meeting seem to have given rise to. He would be a pessimist indeed who could resist being impressed favorably with the prospects held out by those who have recently spoken on the subject of tea, most of them being gentlemen who evidently know what they are talking about. My observations had reference only to a portion of the Lindula section of the Dimbula district, and, had a full report of what I did say reached you, it would have been seen that I indicated, without naming all the estates, the particular locality in which I considered it would be impolitic to plant tea.

I think, sir, that you agree with me that much good coffee has been rendered non-paying for some years back through another product having been planted out amongst it, which, alas, has proved in itself such a broken reed; and it was for the purpose of bringing this to recollection that I directed attention to the fact, and not that I do not believe in tea where coffee has ceased to pay.

I think I am right in stating that the gentlemen who have spoken and written on the subject, and who are competent to express an opinion from experience in both products, with one voice advise taking care of good coffee, as tea will never give the return that the former does even at 4 cwt. per acre.

I consider that tea is a perfect godsend to those whose estates are played out for coffee (of course depending much on in what respect they are played out), to those who planted coffee where it has proved a failure and to those whose fortunes have not been secured by cinchona; but I maintain that it would be very imprudent to rush tea into coffee estates which have during the whole currency of leaf-disease given most satisfactory returns, but owing to recent severe attacks of an additional but remediable pest have become unremunerative temporarily. The Scotch housewife's aphorism in regard to servants is very *apropos*, "better the ill kail than the guid unkail," which being translated for the benefit of the Sassenech runs "better to be served by a bad servant whom you you know than a good one you do not know."

Bearing in mind the result of the previous planter's resuscitator, for the planting of which precisely the same arguments now being brought forward in support of tea were used, aye, even down to results from actual experience—"an acre realized so and so." a large tree was to be seen on an estate in some low district, ditto on a high estate, and so on—I cannot help thinking that we are apt to overlook contingencies which are bound to crop up as we proceed, and which will assuredly take off a good deal of the gilt.

For instance, can we expect immunity from all pests are prices likely to keep up, and last but far from least, is this degree of permanency of tea over its elder brother to be a reality? My question to Mr. Hay as to cultivation was for the purpose of getting some idea as to the latter, as I consider that in the event of cultivation other than pruning and gathering on such hill slopes as ours being necessary, permanency may be dismissed from our minds as an impossibility.

Most people, however, will be satisfied with such returns as we are promised, even if they amount to 20 per cent for as many years on invested capital!

I cannot let Mr. Smith's remarks at our meeting pass unnoticed, and with your permission I propose saying something when I can get a little spare time.—Faithfully yours, JAMES SINCLAIR.

LONDON CHARGES ON TEA.

30th October 1883.

SIR,—A Ceylon tea planter (page 413) raises the question of London charges and "exactions" on tea. He has not, I think, made out a very strong case for himself as things are. It has always been the custom to allow one pound per parcel to the buyer, and, as a fact, 1½ per cent. wastage is not excessive in re-measurement, especially when, as is often the case with Ceylon manufacture, the teas are "dirty." * It is quite true, as was stated by your London correspondent, that the dealers have lately burnt their fingers over the long prices realized by our teas, and two mails ago I myself heard of one large firm who were taking 3d less than they paid for a break of Loolecondura tea; there is no doubt, in my mind, that Ceylon teas will become low-priced, comparatively, if they are not *kept well in hand.* The public have taken kindly to them, and are willing to pay long prices, but, as soon as ever an appreciable quantity is upon the market the buyers will keep the game in their own hand; with a demand, they can sell at once at say 1d advance to the retailer, who will, as usual, make the real profit out of the public. No one has a right to complain. Let us see how the grower can get the benefit of this retail profit. We know that many Indian tea companies opened direct agencies in London for sale of their produce, and that most of them have proved unremunerative. The reason for this is, I take it, that the public can buy as much Assam tea as it likes from any grocer's shop in the kingdom. With us in Ceylon it is different: we can, at present, only put a limited quantity of tea upon the market, a quantity which, as I have said, we can keep well in hand. It behoves us to keep up our prices *now*, and to get them well established for the big lots that we shall be shipping a few years hence. The market will not help us, and I believe the only way is to place our teas directly in the hands of retailers. (Five or six large houses, such as Ridgeway's, would take the whole of our present supply.) If the large growers would agree to do this, the dealers would be nowhere, and the public would be obliged to get their Ceylon teas from the duly-authorized agencies thoughout Great Britain, &c. By an arrangement that can be entered into, the planter can draw upon the retailer, up to 50 cents per pound f. o. b.; the retailer for say 15 per cent commission must sell under the account sales, and by this means the average to the grower could hardly be less than 1s 7½d net. I can prove that which I write. You are quite at liberty to give my name to any enquirer. A.

[The scheme could be rendered possible only by unanimity, which is unattainable.—ED.]

MR. HALLILEY AND MR. HOLLOWAY.

SIR,—Between the two gentlemen mentioned above, Ceylon coffee planters have a bad time of it. By their own account they both know how to regenerate coffee and planters. Yet planters *will not* be regenerated by their methods. Mr. Halliley confines himself to propounding theories (or rather hypotheses) while Mr. Holloway takes refuge in vague generalities that no fellow can correr.

* We have seen no such statement in English reports. —ED.

When Mr. Halliley can say: "Come and see, here are two similar portions of the estate, one part worked on my system and one part on the old-fashioned system; here is the acreage of the two portions, here is the expenditure, here the details of work done for 3 or 4 seasons consecutively, here are the crops, and *here are the profits* (this *N. B.*!): judge ye for yourselves"—then the planters *may* be regenerated, but not till then. Unfortunately (? fortunately), very few planters are in a position to make any attempt at a system so opposed to ordinary principles of agriculture.

Mr. Holloway is not much better. He has every advantage to start with—good soil, generally sheltered, and the best climate for coffee—the fundamental elements of success. From these very *particular* conditions he goes on to prescribe, *generally*, a system of cultivation. Mr. Holloway deserves praise to a certain extent for being able to make his place pay at present (even under favorable conditions), but beyond this I see no merit. High cultivation or a special line of cultivation is not a panacea for all the ills coffee is heir to. What suits Mr. Holloway's soil and climate may not suit the next estate. Bees will not make a coffee crop, nor will the want of them seriously diminish the effects of a good blossom. If Mr. Holloway can get a good blossom in favorable weather, he won't break his heart because there are no bees. On a low bush like coffee, ants and many other (some very small) insects appear to be far more active than bees.

Mr. Holloway goes on to mention some estates which he says have "splendid crops." I have not seen them, and, I am inclined to think, neither have the superintendents! At anyrate they are not gathered yet. And I could name at least two estates in Kelebokka which have been very highly cultivated under a first-class manager for several years, but which have "gone back" as badly as any others.

In conclusion, let Mr. Holloway publish the acreage he weeds* and cultivates, the expenditure thereon, and a few details of the works, and, finally, the total crops, say for 4 years back. From that, I think, we shall manage to calculate the profits! I freely admit that I am sceptical of the results.—Yours truly, M.

HAND AND MACHINERY MADE TEA.

Maskeliya, 1st Nov. 1883.

DEAR SIR,—Does your correspondent "D" (page 417) dispute my figures for the hand-manufacture of tea? If so, and he can tell me on what grounds he does so, I shall be glad to hear from him. If, however, he only desires to make remarks on my intellectual shortcomings, why then, sir, "this discussion," as you sometimes have to observe, "must now cease." But I will willingly admit that "D" will have some right to make such remarks if he can show us how to save 7¾c out of 6½c this being an arithmetical feat which I cannot hope to rival. But there is no use in pursuing the subject. Everyone conversant with the hand-manufacture of tea, who has lately approached the subject, gives figures varying only from 6½c to 7c per lb. for the three operations in which machinery is available. The statement that 7¾c can be saved is, therefore, evidently erroneous, the difference appearing to be from 4¾c to 5c. per lb.

It makes no difference whence Mr. Owen took his figures: he published them and is responsible for them. If Mr. Armstrong made the original error, he may well be pardoned for it, in consideration of his having written what I take leave to consider the best essay on planting matters which has appeared for 17 years past.—Yours truly, ADAM'S PEAK.

* And the acreage he does *not* weed, acting on the principles he advocates.—ED.

SHADE TREES FOR COFFEE.

Coombewood, Lindula, 3rd November 1883.

DEAR SIR,—Mr. James Sinclair may spare his breath and leave off trying to persuade people that coffee if well-manured will pay; at least, his writing and talking will not convince others, but, if he can by manuring show on Bearwell regular crops of from 3 to 5 cwt. per acre, he may succeed. Seeing is believing. Planters are too sceptical nowadays to be convinced by argument: a thing to be believed must be seen. Notwithstanding leaf-disease and grub, I still think sheltered coffee with deep-rooting trees through it 20 to 30 feet apart will pay handsomely—but estates as at present circumstanced will not pay, no matter how liberally treated in the way of manure.

Perfect shelter and open subsoil, with suitable manure, is, in my opinion, the sole condition under which coffee may be grown at a profit.—Yours faithfully,

SINCLAIR'S NEIGHBOUR.

ASSAM AND CEYLON TEA SEED.

Dimbula, 3rd Nov. 1883.

DEAR SIR,—When writing you (page 415) my views on Ceylon grown and imported seed, I quite anticipated the storm of indignation that would be raised and was prepared for it. In spite of all your correspondents, I still stick to my opinion that the tea seed sold in Ceylon is in nearly every case unripe, and that we are ruining our future prospects by planting up thousands of acres with seed of a bad jât. You remarked that the late Mr. Cameron recommended country-grown seed. He did so, but only after he found he could not procure Indian seed. Of the many orders he booked for the latter, not one I believe was executed. He went in for country seed, having no alternative, and it was in the interests of his employers to sell as much as he could. It is all very well for planters having seed to sell, to sneer at Assam planter's opinions and attributing to them selfish motives.* You will, at any rate, give them the credit of "practising what they preach." In the large tracts now being opened up in the Dooars, all the seed is imported from Assam, although they could get seed off old tea in the immediate vicinity. In Chittagong, the new extensions there are all planted with Assam seed; and in Assam itself, only the very best jâts are planted, the price being from R75 per maund for hybrid to R150 for indigenous. The latest authority I asked was a well-known tea broker in London, formerly a tea planter himself. I showed him tea bushes here grown from seed from a well-known garden in Assam (the seed from which has never been sold under R75). I asked: "Would you plant out seed from these bushes?" His answer was: "Certainly not, *but I would sell it!*" Your correspondents ask how I arrive at the conclusion that so much of the seed sold in Ceylon is so bad. I do so just from what I have seen on gardens from the elevation of Abbotsford to Awisawella. For obvious reasons I cannot give names.† Your correspondents will admit that, unlike Assam, where the seed ripens nearly all at once, the tea bushes here go on flowering nearly all the year round, similar to the coffee in Uva, and that the seed is in all stages of ripeness, necessitating the very greatest care in selecting the ripe seeds. In my travels I have seen the whole crop of an estate clean swept off and distributed to the buyers. A ripe tea seed should not only have a full-developed kernel, but the brown skin should also adhere to it. This is a most important point in testing tea seed, and many planters even gifted with a good deal of commonsense overlook it. I commend it to your correspondent "Absurd"'s consideration. Another correspondent asks why I did not return my seed when I found it unripe. I unfortunately paid for it before delivery, and I knew I had no chance of seeing my money again. A fellow planter, however, in Dikoya, who fully agreed with me in the disappointing results of locally-grown seed, informed me he got seed to replace what he had purchased on complaining of its being unripe. This seed, I think, was from Orwell estate and prominently advertized in your paper. Now that I have named it, will the superintendent or proprietors of this estate favor us with answers to the following questions?:—1. What acreage of tea in bearing is there on Orwell? 2. How many maunds of tea seed have been sold as Orwell seed within the last 12 months? 3. How many maunds planted in Orwell or same owners' nurseries? 4. How many maunds have been given to make up for bad seed and the cause of the seed turning out bad? I think the sum total, if given, will rather open your eyes. Bear in mind, the lower the jât the heavier the yield, and *vice versa*.

In conclusion: "None are so blind as those who won't see." If planters will persist in rushing into tea in the way they are doing, let them: there will be a great awakening soon.—Yours faithfully,

PLANTER.

* No selfish motives, of course, actuate those who are interested in the sale of Assam seed. Like the lawyers about the appeals, they are actuated, as our correspondent of course is, by the purest motives of benevolence. These are the things that make one shed tears, as the editor said when he received a present of onions—ED.

† This is rich, after having specially named Abbotsford: since we last wrote, we have learned that Ceylon tea seed has been taken to Darjiling.—ED.

THE PRICE OF TEAKWOOD, particularly Burmah teak has risen very much within the past year or two. Logs that could be purchased at R60 or R70 per ton, now cost R140, and it will soon be a question of finding some other timber as a substitute for it. Australia bids fair to supply this, and India will soon be compelled to draw on this colony for her timber supply. An enterprizing firm in Madras has imported a consignment, and a Madras paper hears that Government intend to give the timber a trial. A wood that will not decay rapidly on immersion in water, is wanted, and an experiment is, we learn, to be made in the construction of a lock on the Buckingham Canal with this timber. If it should answer, it would soon become a very important item in the imports of the Madras Presidency, as it now is procurable at about a third of the cost of teak, and competition in the trade will no doubt reduce it still further.—*Madras Athenæum.*

DARJEELING.—The last day of September saw the end of the Dam Dim tea factory, as it was burnt to the ground on Sunday night; at the time the fire broke out there were about 200 maunds of tea in the factory, and it was all lost. I do not know if this was covered by insurance or not. Anyhow the loss of the factory is a very serious one just now, as it will be impossible to rig up a jury one by the close of the manufacturing season, and the nearest factory is nine miles off, so that making any more tea this season is out of the question. Talking about tea reminds me that the crop will be even less this year than was anticipated two months ago. "Mosquito blight" has broken out anew and with renewed virulence, the result being that planters are at their wits ends in some parts of the district to find leaf to pluck. On the other hand, prices have been very good all round and probably loss of quantity will be fairly well balanced by gain in prices. I saw the results of a London sale the other day, and the prices were not only over valuation but remarkably good into the bargain.—*Indigo Planters' Gazette*, Oct. 9.

TEA GARDEN SKETCHES.

The Sirdarin—or woman sirdar, owes her position to the fact of her possessing the longest tongue of any one on the estate, (bar none). When the women require a slanging for plucking badly, no one can make such an impression on them as this gifted female.

She walks amongst her sex, jingling her bangles, with an air of superiority which is not to be denied.

She seems to understand the languages (which are many) and the peculiarities (which are more) of all the people in the lines, and she often lets the men have a bit of her mind when they interfere with her department in any way.

She is one of the oldest coolies on the estate, and is thoroughly versed in all the intricate manipulations allotted to her sex, both in the tea-house and on the garden. On the whole she is a useful institution.—B. C.—*Indian Tea Gazette.*

ARTIFICIAL PROPAGATION OF OYSTERS.

SIR,—I have received from Professor Baird, United States Commissioner of Fisheries, a telegram which I am sure will be of great interest to European fish-culturists, and which I, therefore, take pleasure in making public through the colums of the *Field*.

It is to the effect that Mr. John A. Ryder, embryologist of the Fish Commission, who has for two or three years been engaged in investigations upon the oyster, has finally succeeded in successfully propagating this mollusk by artifical means. On the 4th of September there were in the ponds of the Fish Commission at Stockton, Maryland, an immense number of young oysters, three-quarters of an inch in diameter, which had been hatched from artificially impregnated eggs forty-six days before. There was abundant natural food for the young oysters in the pond, and they were multiplying rapidly.

I need not say more than that this success marks another epoch in the history of "fish culture."—G. BROWN GOODE, Fisheries Exhibition, South Kensington.—*Field.*

SUPERPHOSPHATE OF LIME AND RUST IN SUGAR-CANES.

The following letter from Mr. James McHenley, Analytical Chemist, will be read with interest:—

The sopherphosphate of lime made from bones, or from the waste products resulting from the manufacture of animal charcoal, is not alone a valuable fertiliser but an antidote to the "rust" disease in sugar-cane. A number of years since, when on the Zunderbunds of the Hooghly River in India, the rust had for several seasons destroyed the cane crop: two philosophers from Europe came to investigate the cause, and for this purpose began at the effect, but failed to find the cause. They discovered animalculæ on the leaves of the cane, but were unable to say whether they were the cause of the rust or the product of the rust, and so the matter ended—the planters being left as much in the dark as ever. Not being a philosopher, but a humble analyst, I set to work to analyse the sound and unsound canes, and found the rusted canes to be deficient in sulphur and phosphorous, and therefore recommended the application of the superphosphate of lime, which had the desired effect—the rust disappearing wherever applied. Some five years ago, when I came to Mackay, I made a lot of superphosphate of lime at the Foulden Plantation, which was applied to some rusted black Java cane, the result of which was marvellous. The rust disappeared: a heavy crop of cane, rich in sugar, was the result. Five hundredweight to the acre was the quantity used.—JAS. MCHENLEY.—*Queensland Planter and Farmer.*
[Has superphosphate of lime been observed to have any special effect on coffee leaf disease beyond invigorating the trees.—ED.]

THE PARAGUAY TEA TREE.

The superintendent of gardens and grounds attached to the United States Department of Agriculture mentions in his last report that the department has recently had numerous inquiries regarding the feasibility of growing in the United States a plant similar to the *Ilex paraguayensis*, or Paraguay tea tree, from which the leaves are stripped and used in infusion as an article of food under the name of *maté*, and gives the following description of the cultivation of the tree, and the method employed in the preparation of this article. In rich soils the tree will attain a height of from seventy to ninety feet; it is said to be confined to mountain slopes, never appearing on table lands nor the broad plains which skirt the river beds, while it is plentiful in all the moist valleys that branch out of the extensive chain of mountains that divide the waters of the Parana and Paraguay rivers. For the preparation of *maté* proper the leaves are dried, or roasted in cast-iron pans, set in brick-work and heated by fires underneath; when the leaves are sufficiently heated, they are pounded in stamping mills worked by water or steam power until reduced to powder, and then packed in bags by means of presses. There are three qualities or sorts of yerba known in the South American markets. The best is said to be prepared from the young leaves when they are about half expanded from the bud, called *caa-cuys*; the second consists of the full-grown leaves, carefully picked and separated from twigs, and frequently the midrib and veins of the leaves are removed; this is called *caa-mira*; the third is the *caa-guaza* or *Yerra de Palos*, made from older leaves, carelessly broken up with the small branches and leaf-stalks, all of which undergo the roasting and pounding process together. The leaves are also collected and dried in a similar manner to that adopted in the preparation of Chinese tea. This is called *maté* in leaf, and is prepared for use by infusion, and taken with milk and sugar in the same same way as ordinary tea. *Maté* in powder is also prepared by infusion, by putting into a small vessel about an ounce of the powder, and pouring boiling water over it; as the fine dust does not fall to the bottom, but remains suspended in the water, the *maté* is taken by means of a sucker, that is, a tube terminating in a small hollow ball pierced with very fine holes. *Maté* contains theine, the same active principle as tea and coffee, but is not possessed of their volatile and empyreumatic oils; it contains less essential oil, more resin than coffee, but less than is found in tea. Chemical analyses show that it contains nearly double the quantity of theine that the same weight of grains of coffee contains, and about the same quantity as tea leaves. The Brazilians recommend *maté* as a nourishing, warm, aromatic, stimulating, and very cheap beverage, its extreme cheapness being a guarantee of its genuineness, as it is not worth adulterating.—*Journal of the Society of Arts.*

INHERENT AND ACQUIRED FERTILITY.

All our ideas as to the comparative value of manure from cake and corn have been disarranged, and our faith shaken, by the last report of the Woburn experiments, from which it appears that Indian corn produced manure which was, weight for weight, quite as effective as that from the consumption of cake. If this is confirmed by further investigation, it would suggest that the table of values requires revision, and valuers will do well to watch closely the results of the Woburn experiments. They will also have to remember that imported fertility, either through foods consumed or manures applied, only adds to the floating capital, and can be nearly all removed by two or three corn crops. The durability of artificial and highly soluble manures is even less; and no doubt practical men will consider that the reaping of a corn crop reduces greatly, if it does not altogether annihilate, tho claim.

As regard the manuring value of purchased grain, until we have very strong and confirmed evidence to the contrary, valuers must assume a much lower scale than for cake; and this is brone out by general experience. Everyone knows the marked benefit which follows the use of cake; on grass land; and we venture to think that no practical and observant farmer would argue that a similar weight of any grain crop, including beans, would have as great an effect.

If soils under cultivation, and especially during the process of bare fallowing, are liable to lose some of the floating capital by the washing through the soil of nitrates, &c., so is land laid down to grass capable of accumulating organic nitrogen, as the following table, which shows the amount of nitrogen per cent in the first nine inches of dry soil in several fields at Rothamsted, will certainly prove:—

		Nitrogen per cent.
1.	Root crops grown continuously by mineral manure	0·0934
2.	Wheat crops „ „ „	0·1000
3.	Ordinary arable laid just land to pasture	0·1235
4	Pasture laid down in 1872	0·1509
5.	„ „ 1863	0·1740
6.	„ „ 1858	0·2048
7.	„ „ 1838	0·1949
8.	Very old pasture, age unknown	0·2466

These figures are very instructive. If we multiply the four decimal figures by 2½, we shall have approximately the number of pounds per acre of nitrogen in the first nine inches of soil. In cases Nos. 1 and 2 we see the effect of a succession of exhausting crops in depriving the soil of nitrogen. Equally do we see that the laying down land to grass is a recuperative business. The organic matter increases chiefly by root growth. The treatment has apparently little to do with this result. Field No. 6, we are told, has been mown every year, and dressed each year with purchased dung or artificial manures—the two alternating. On No. 5 field stock has been fed with decorticated cotton cake, and no hay has been taken for eighteen years; whereas the analysis of No. 8 was made after twenty unmanured crops of hay had been removed. It is therefore evident that if we get a thick close sward, the soil will be enriched year by year, and therefore the tenant who has laid down such grass is entitled to compensation, but only to the extent of this accumulated nitrogen, which would all be taken out by three or four crops.

There will, especially at first, be great difficulty in arriving at just conclusisns as to value of an improvement to an incoming tenant, because there will not, as a rule, be reliable evidence as to the condition of the farm at the time of leaving, as compared with that on entry. Valuers must be guided to a large extent by the nature of the work done, the period at which it was done, and the probable duration of effect upon the particular class of land. Eventually, the particulars to be given in the award will be an important guide as to the state of the land on entry. The public are once again indebted to Sir J. B. Lawes for valuable information which will help them to distinguish between inherent and acquired fertility.—*Field.*

CULTIVATION OF THE BEAN.

(*Faba vulgaris*, Mœnch.)

This vegetable is an annual, and one of the oldest cultivated plants we possess. Some uncertainty exists as to its native habitat, however it is generally supposed to be a native of Persia. There are two distinct classes cultivated in gardens, viz., the long pod and broad Windsor. The pods of the former are from 5 to 9 inches long, and contain from four to six medium-sized beans. Those of the latter are from 3 to 6 inches long and much broader than the long pod, and generally contain three flat large-sized beans. There are numerous varieties detailed in European nurserymen's catalogues, however all are referable to either of these two classes. The long podded varieties are the most prolific, and succeed best in this country. They acclimatize without any perceptible deterioration in quality, and should therefore be always grown in preference to the broad Windsor sorts.

In the Plains, beans come in use about the middle or end of February, and continue in season until the end of April. They should be sown in succession from the middle of September to the end of October. Two sowings are sufficient for ordinary requirements, but when it is desired to have them in season for as long a period as possible, three sowings should be made at intervals of a fortnight between. They succeed best in a deep, rich, and somewhat heavy loam. Where the soil is light and sandy, heavy meanuring must be resorted to in order to meet with success. I find the following to be a good and economical mode of preparing the ground. Dig trenches 1 foot deep and 18 inches wide, at distances of 3 feet apart for long podded, and 2½ feet for broad Windsor sorts. Half fill the trenches with old rich manure, and dig or fork it into the subsoil at the bottom of the trench. Then fill up the trenches with the surface soil and also give it a liberal supply of manure. The trenches will now form low ridges owing to the manure and looseness of the soil. They should next be pressed with the feet, and if the soil is still above the surrounding level, part of it should be drawn to each side, leaving a space 18 inches wide down the whole length of the rows. The soil drawn away may be left along both edges of the latter for the purpose of facilitating the retention of water when irrigating. The seeds should be inserted 2 inches below the surface, in double or single lines in each row at 6 inches apart and the same distance between the lines when two are sown. The double line is preferable to the single one for the following reasons. If the seeds are imported many of them fail to come up, and the resulting vacant spaces, besides being a waste of ground, give the plot an untidy appearance. In a double row, vacant spaces, as a rule, are not so numerous, besides the plants are much benefited by the support and protection they afford each other during storms.

The germinative power of the seeds is much increased by being soaked in warm water for six or eight hours before sowing. Care, however, must be taken that they are not again dried up by being inserted in hot and dry ground. When the latter is in the state mentioned, water should be given immediately after sowing, and the ground kept damp by subsequent waterings until the seedlings appear above ground. During their progress, water should be freely given, the ground kept free of weeds, and the soil frequently sttired between the plants. When the flowers begin to appear, a slight earthing up around the neck of the plants is beneficial. When the stems are well covered with flowers or when about 1½ or 2 feet high, the point of every shoot should be nipped out. If this is not done they will continue to grow and flower without forming any pods. As already mentioned the long pod acclimatizes readily. When seeds for future use are desired, they should be collected from the pods lowest down on the stems, as these are invariably the largest and best developed. The bean is not subject to disease or to the attacks of insects when cultivated on the plains.

On the Hills—autumn sowings come in use in May, and by successive spring sowings beans can be kept in season until August and September. A small sowing should be made in October or November for the early crop of the following spring. Those for the main crops should be sown in succession from the beginning of March to the end of May, at intervals of a fortnight between. The mode of cultivation is the same as described for the Plains, and need not again be detailed. The plants are sometimes attacked by a species of Aphis or green fly. The best remedy is frequent syringings with soap and tobacco water.—W. G.—*Indian Forester.*

TEA: TIMBERS FOR BOXES AND OTHER PURPOSES.

(*Continued.*)

Uriam, or Joki, as it seems called in Cachar, I see, has had its botanical name changed since I made out my list some years ago, and is now *Bishoffia Javanica.* This tree, of which the Assam Rajas used sometimes to have their coffins made in above times, seems to grow almost equally well in high or low land, and is common on the flats near rivers; Assamese were, I am told, not allowed to cut it formerly. It attains a girth of some 6 or 8 feet, but the bole or shaft is not generally so long as the preceding trees, and runs 30 to 40 feet. It has a large and dense crown of rather dark foliage; the stem is seldom so straight as in the Sopas. The bark outside is very dark brown and rough, remarkably free from stains and lichens; the inner bark is thick, fleshy, and pink, exuding red sap. The leaf is in 3 distinct lobes, like a bramble, but larger, and dyes a yellow color; the seeds are in large open clusters of dark berries, the size of large peas, eaten by monkies and natives.

The young leaf-shoots have a good reputation as a febrifuge, and are extremely bitter. Properly this wood has no distinct heart, strongly marked in conspicuous contrast with the sap wood. It more generally gets denser and darker towards the centre gradually. When wet it is a deep red, and when dry is of a dull purple, pretty hard and heavy, though it will float. It is a more common tree than Nahor or Sopa, and useful for posts, planks, canoes, &c., but too heavy for boxes, which need a *strong light wood,* that is also tough.

Gahora, the Dalo Ujah of Cachar, and *Premna speciosa* of botanists, is a useful tree for posts. It is peculiar in several respects; the stem is so very rarely straight, and is so generally deeply grooved, that it is seldom sawn. When young, the central whip-like shoot seems particularly subject to curvature by creepers. The branches also are frequently broken off by storms, and hence the growth is very crooked; now and then a straight piece can be got pretty long if grown in forest. There is no ture heart wood, but when old the centre changes from yellow to brown. In any stage it lasts fairly well, partly due to its keeping wet; small posts of young trees often last 4 or 5 years until dry; old and large trees will go 10 and 12 or more. It is a fairly good tree to secure for the posts of lines, as it is pretty common, and will outlast thatch or walls, which is more than so many others will do. Large old Gahoras are good for bridge posts, as they go so long in water. The bark is pale drab color or whity brown and thin, with a flaky surface; the true bark is not shed apparently, and hence it is a great favourite with orchids of several kinds. The leaf is 4 to 5 inches by 2, pointed and serrated. The wood is yellow, and splits readily.

Toi Angoli Jamok, or Jamu, one of the *Eugenia*, is on the list, but it is seldom large and straight; when it is, and the young wood removed, it lasts fairly; small trees of it are good for posts of lines.

Bor Jamok or Jamon, *Eugenia lancifolia*, is often a large tree, 6 or 8 feet in girth and 30 feet in the bole. The heart of it lasts pretty well, but not more than half as long as Nahor, Gondri, or Ajar.

Sonaru, or Bandolat, *Cassia Jistula*, is a fine wood for posts and other purposes, but in the plains is not common; near the hills it is more frequently seen,* and is larger, though never a very large tree. The girth 4 to 6 feet, and 40 feet stem; the bark is grey, and the seed, a long rod-like pod, a foot or 18 long, x 1 in. thick. The blossom, however, is the most conspicuous feature. a huge panicle of brilliant pale yellow, pea-shaped flowers, not unlike Laburnum, but ten times the size. The heart wood is *heavy and dark*, *most durable*, but unfortunately the tree is rare, and not large. It grows readily from seed. Planted alternately with Nahor and Ajar, it helps to form a fine avenue.

Amsia is another wood almost equally good and equally rare in the plains. The heart when young is bright greenish yellow, and in a variety called Amsilika, the heart is often a brilliant orange; both last long, and in the hills Amsia is often used, and runs to a large size; the wood dark neutral green. It is so seldom seen in the plains that it is hardly worth recording as an available wood.

So far this has been only a list of timbers most useful for bridge and bungalow posts. In giving lists of trees, it is better to have some system, or a work of this kind is almost useless for reference. This first group therefore has been taken because the need for good wood for posts is so common, and the timbers are few, they are easily picked out; no doubt the list will be increased as our experience of the trees extends, and your readers can well understand that it is not given to any single person to know everything. Many trees are almost peculiar to certain localities, and well known perhaps to but few. The next group of trees for many reasons had better be confined to those useful for general purposes, and will include many of great size; a subsequent list to be devoted to box timbers and one for charcoal woods. A list founded on botanical basis would be of less value to a planter than one founded on *uses*.

In this, 2nd series of timbers large and small that are good woods, and yet not fit to put in list No. 1, I had best place them in alphabetical order as far as possible; and I may here mention that since these notes were begun, the importance of the question of good and bad box woods has considerably increased.

The three samples of wood alluded to by Mr. Gamble, were kindly forwarded to me by Mr. Mann, our Conservator of Forests. It is not easy to verify a tree from a sample 2" square and ¼" thick (more especially if neither bark nor leaf can be seen.) The sample No. 3, that has the bad reputation, and the lead attached to it as a white film, like paint, may be, as far as I can see, either mango, or wild mango, Moj-Poreng or Gondri, (Gondserai); these are all extremely alike, and if the wood had a strong aromatic smell when first sampled, I should say it was Gondri, and may tell you that I have had samples of mango and Goundserai made and lead attached, closely, between, and shall report the result as time goes on, or the moment I see anything to report. Ere closing this notice to-day, I may tell your readers what—no doubt many know—that there is far less danger from a dry seasoned wood, than one wet or half dry, especially when heated in the hold of a ship. The quantity of moisture in a wet tea box, or one of unseasoned wood, is also far more than most planters or agents would suppose, and in some cases it is exactly half the weight of the box. I append a case where a Simolwood tea box was weighed just as it was made up, and the same when quite dry —in 30 days.

Nov.	6th	at	30	lb.	Nov.	15th	at	17	lb.

This should show those who insist on even tares, the utter impossibility of getting them unless the woods are quite dry; and in the height of the season the planter is often between two stools, contractors suddenly failed to supply boxes [or died], and agents screaming for tea. The moral is, that boxes should be laid in *several months* ere they are required.—S. E. P.—*Indian Tea Gazette.*

THE CENTRAL STATES OF COLOMBIA.

The last number of the Proceedings of the Royal Geographical Society contained some notes upon these little-known regions by Mr. Whiting, and the following abstract of the more important portions will, we are confident, be read with general interest:—

A great deal of information has been published respecting the lower Atrato, particularly in connection with the projected inter-oceanic canals. The upper portions of this great valley, with their relatively healthy climate and fertile lands, are accessible by steamer from the Atlantic Ocean, and can also be easily placed in communication with the interior and more populated parts of Colombia. The river Atrato at Quibdó is 250 yards wide and 12 feet deep in ordinary seasons, and small steamers can go up to Lloró. The greater part of the land in the basin of the Atrato from Quibdó upwards may be said to be simply hilly, not mountainous, and generally adapted for agriculture. There are few clearings, and the virgin forest which covers the greater portion abounds in valuable produce. The course of the upper Atrato was first surveyed by me, and it had been previously believed that the river took a more direct course from the cordillera down to the main valley. The detour made by the river accounts for the relatively open and unbroken country through which it runs. The higher portions of the valley at an elevation of 4,000 and 5,000 feet above the sea are very healthy, and here considerable areas of open prairie land are to be met with.

Every description of tropical produce may be cultivated, as the mean temperature ranges from 60° to 80°. Caoutchouc of the best quality abounds in the warmer parts, and the ivory nut is very abundant. Promising copper lodes exist near Quibdó and coal is met with in several places. The Atrato itself and all the tributary streams are rich in alluvial gold, which is of very high standard.

Although the scanty population of these regions detracts from their present value, there can be no doubt that they will at no very distant day attract attention. As the works upon the Panama Canal advance, so the inhabitable and productive lands in its vicinity will become valuable. For the Atrato valley, with its rich alluviums, contrasts favour-

* In Ceylon it is chiefly found in the dry hot plains of the eastern portion of the island. It would be much more common in Colombo, were it not for the inveterate destructiveness of the natives, who strip the stem of its bark for medicinal purposes.—ED.

* Or a reduction of very nearly one-half the original weight in one month.—ED.

ably with all the region north of it as far as Costa Rica. It is easy of access from the Atlantic, and will without doubt be called upon to serve as the great source of the food supply for the isthmus and the traffic induced by the canal.

The western frontier of the state of Antioquia, marked by the western chain of the Andes, is only 60 miles distant from Quibdó. On entering Antioquia one sees at once that it is from here that the colonists of the upper Atrato will come. This comparatively small state has a population of 400,000, of which three-fourths are whites and one-fourth mulattoes. It is a mountainous country, and its inhabitants are hardy, active, and industrious, being principally descended from emigrants from the north of Spain. The neat, clean villages and towns, and the evidence of industry shown in the extraordinary cultivation of the rugged country, strike the traveller most favourably. At present there is a tract barely transitable for mules opened through the forest between Quibdó, on the Atrato, and the town of Bolivar, which is the first of any importance on the Antioqueñan frontier. The country, however, over the whole of this distance, does not present any difficulties to the construction of a good road or even of a railroad, as the western cordillera which here divides the states of Antioquia and Cauca is uncommonly low, the height above the level of the sea being only 6,850 feet. As the country progresses in civilization and commercial importance, attention will no doubt be given to this route as a means of communication between the interior and the Atlantic coast, and it is probable that political considerations only, arising from the fact of the road having to traverse the territories of two States in which the customs tariffs and other laws are not entirely in accord, have prevented this route from being selected as the preferable one for opening up the communications referred to. A scheme has been already sketched out by Mr. Francisco Javier Cisneros, C. E., for a railroad which, traversing the whole of the valley of the Patia and that of the river Cauca, would communicate with the Atrato via Quibdó. As the first of these rivers debouches on the Pacific coast, and the Atrato on the Atlantic, an inter-oceanic communication would thus be formed which would afford facilities for the whole of the interior trade of the country to be carried on with the ports on either ocean.

At the present time the Atrato valley has a population of 40,000, of which one-fourth are whites, and three-fourths half-caste negroes. The white population are principally engaged in importing such few articles as are necessary for clothing and general purposes amongst this very plain living people, and they purchase the gold which is obtained by the negro washers at a consideralbe profit, and export it to pay for the articles which they import. The negroes occupy themselves in the collection of caoutchouc, ivory-nuts, sarsaparilla, and a few other natural products, and also in gold-washing on a small scale, principally by streaming. Their wants are few, thay use little or no clothing, and their food consists principally of bananas, fish, and game.

The varied climate of the Patia valley, and its extreme fertility, enable it to show an extensive list of natural and cultivated vegetable produce. That comparatively delicate tree, the cacao, flourishes near El Castigo, and the vanilla, a peculiarly sensitive orchid, grow wild in the greatest luxuriance, affording pods of the finest quality. Near El Castigo there is a district in which the quality of the soil and the special climate permit of the cultivation of tobacco which rivals that of Havana. The coffee produced on the higher lands, say from 4,000 to 6,000 feet above the sea, is of fine quality. Rare balsamic resins, such as Tacamahaco and Maria balsam, are found in the lower valley. Caoutchouc is abundant. Amongst the trees peculiar to the special climate possessed by the Patia, various dye-woods are notable, among them a valuable species of brazilwood, first identified by Professor Oliver from specimens sent home by me.

So far the most valuable product which has been exported from this region, and from the mountains at the head of the Cauca valley, where the celebrated Pitayo locality is situated, is the cinchona bark, but unfortunately the tree is rapidly becoming extinct. No supervision is exercised by the government nor by the owners of the forests themselves over the labourers who are engaged in the collection of the bark, and not only are the trees cut down, but even the roots are dug up, and thus every chance of resuscitation is destroyed. Cinchona trees may, after being cut down, be induced to send out saplings again if properly treated It seems strange that, considering the facility with which any amount of land may be acquired in these districts, no effort has ever been made to cultivate the cinchona in its natural habitat, whilst we see the great interest which has been taken, and the enormous sums which have been spent, in endeavouring to do so in other parts of the world. I believe that a company has been occupied in this near Bogota, but it is the only instance I know of in the country. Some cinchona bark is still sold in this country under the name of *Pitayó*, but as a matter of fact not an ounce of bark exists in the whole of that district, the trees having been completely destroyed. The cacao trees planted near El Castigo by a wealthy Spanish slaveowner, at the beginning of this century, cover an area of nearly 100 acres, and now present quite the appearance of a forest, many of the trees being upwards of 120 feet high. They still bear fruit from their bases upwards, and the great *Erithynas*, which were originally planted to form the shade for the cacao, have long since died off, their fallen trunks lying amongst the surviving cacao trees. Near this plantation my men obtained from a young tree growing in the woods 25 lb. weight of dry cacao beans of very superior quality. The monkeys are very fond of the pods, and naturally have scattered the seeds through the surrounding forest; and although it is well known that the cacao tree generally degenerates when left without cultivation, this is not found to be the case in this district. Near the Minama Strait, a length of upwards of half a mile on a precipitous hillside is covered with a forest of Guayabo arrayanes—a Eugenia—in which the trees are literally overburdened with the vanilla orchid, whose long creeping roots hang down from the branches, and positively offer an obstacle to one's passage through the woods. The perfume from this forest on a fine day scents the valley for a considerable distance.—*Planters' Gazette.*

PLANTAIN CULTIVATION FOR INDIA.

CLIMATE.

The real climate for plantain is the one which has moderate cold and heat; and which has the atmospheric air loaded with moisture,—in other words, *humid climate.* In such a climate plantain will grow, shoot and fruit very freely; and mature its fruit altogether well. Much cold helps to retard and make imperfect the processes of *involution* and *evolution*, thereby stunting the growth of stem, leaves, and fruit: and partially or wholly, according to the degree of cold, withholding the maturity of the fruit. On the other hand, much heat, by the rapid exhalation of moisture, so greatly exhausts the plant that it has scarcely strength left to grow, consequently gets perfectly scorched of the leaves and outer layers of the stem-sheathes. In illustration of this subject I might here add, in many parts of India, such as Northe West Provinces, Oudh, and the Punjab, most parts of these provinces, where the summer season is fearfully hot, I have observed the plaintain so severely suffer during the season that during the rains, so to speak, it has to commence life afresh; and when the winter sets in, growth being imperfect, it has no power to muster sufficient strength to send out fruit-spikes: after the winter it has again to embrace the summer season which, as said above, serves only to destroy it,—thus, I have seen plantain growing and suffering, again growing and again suffering for a number of years, and never, or very imperfectly fruiting, which fruit never fully developing and ripening, but getting either scorched (if in the summer) or stunted (if in the winter).

TIME OF PLANTING.

The best and most inexpensive season for planting plantain is when the rains have thoroughly set in, *i.e.*, from the end of June to end of August. This applies to drier parts of India, such as N.-W. Provinces, Oudh, the Punjab, Central Provinces, &c., but in Bengal, Assam, and British Burmah, in addition to these two or two-and-a-half months, February to April will be equally suitable to plantain planting. Being altogether a succulent plant, having much water in its composition, the rainy season has peculiar advantages for the growth of this plant, which no other season, in Upper Western India, in particular, can supply. In Lucknow and Sitapore, both Oudh districts, I have planted plantain in all parts of the year, and grown it successfully but by resorting to the costly means of artificial irrigation. I would, therefore, in point of economy and on chemico-physiological grounds, recommend the rainy season to be the best for planting in places wanting in the natural advantages of humidity in the soil of Bengal, Assam, and British Burmah.

GEOGRAPHICAL DISTRIBUTION.

Plants of the N. O. *musaceæ* are natives of various parts of the world; but all of them, on close examination, will be found to flourish under the same physical conditions of the atmospheric air and soil. The following is the natural geographical distributive scheme of all important cultivated edible species of the plantain and banana order as established by the researches of Professor Baron F. von Mueller, K.C.M.G., M.D., Ph.D., F.R.S. The wording and arrangement are my own; but the subject-matter (from *a.* to *g.*) partly belongs to this distinguished naturalist and doctor, and partly to various eminent botanical authorities of older times.

(*a.*) *Musa Cavendishii.*—Native of China; has been translated to the South Sea Islands, where it is now extensively grown. *M. Cavendishii* has been found to succeed in Madeira and Florida (artificial).

(*b.*) *Musa paradisiaca.*—India is the native habitat of this most extensively cultivated species, which is said to have one hundred varieties.

(*c.*) *Musa sapientum.*—Insular India, extending to the Indian Archipelagoes.

(*d.*) *Musa troglodytarum.*—Older botanists mention its nativity to be in India. Baron Müeller, however, has ascertained it, in addition to India, to be indigenous to the Fiji and other Islands of the Pacific Ocean.

(*e.*) *Musa simiarum.*—Indigenous to Malacca as far as the Sunda Islands. This plantain, with its varieties, fifty in number, are also to be found in the Indian Archipelagoes.

(*f.*) *Musa Livingstonia.*—Native of African mountains of Sofala, Mozambique, and the Niger regions.

(*g.*) *Musa ensete.*—This plantain, the most magnificent of the order, is a native of the mountains of Sofala to Abyssinia in North Africa. I may add it is unknown in India to tho masses of the people, existing perhaps in the Botanical gardens. Very eligible for introduction in India. The edible part of this plant is the inner stema.

(*h.*) *Musa corniculata.*—Native of Insular India.

SOILS.

Loamy soil of the *calcareous order*, of the species having more *humus* and *less lime.*

COMPOSITION OF SOIL.

Clay	40	parts.
Lime	3	,,
Humus	5	,,
Sand	52	,,
	100	,,

Plantain will grow in any soil, even in the most *sandy*. In such a soil, in the Lucknow Agri-Horticultural Gardens, many species and varieties of plantain are growing; but are productive of bad results, since they neither fruit well nor are the fruits so palatable and nutritious as those of Lower Bengal, Burmah, China and other places. Plantain requires good percentage of *clay* and *humus* in the soil without which, as a plantain grower, I can, from personal observations, testify that it is useless to cultivate this plant; especially where quality as well as quantity of the fruit are objects points undeniably every cultivator do and should aim at. Much *lime* in the soil is bad for plantain; in moderate quantity, it is highly beneficial. This I say from my failing to obtain fruit from plants grown on highly *calcareous soil*, in which slender stem and stunted appearance (sure signs of not fruiting) of plants of three years' standing, were the results. During these three years they never fruited; had, therefore, to be rooted up. But in soil having less lime, more *humus*, good percentage of *clay* and sufficient *sand* to keep the soil loose and friable, I have in six months calculated from the time of planting, succeeded to grow off shoots two feet high of the tall varieties into almost full-grown size, measuring twelve feet high to the apex of the leaf, ready to throw out fruit-spike by the end of the rainy season. The off-shoots were planted in February, and the above height acquired by the end of July.

CHEMISTRY OF THE PLANTAIN PLANT.

The centennial composition of the plantain plant in a green or fresh undried state will appear from the following table, being the mean of 7 analyses:—

	Water.	Organic Matter other than water.	Inorganic matter or ash.	Total.
Leaves ...	80·15	15·90	3·95	100
Stem	81·5	14·95	3·55	100
Fruit, including rind...	75·58	21·17	3·25	100
Total ...	237·23	52·02	10·75	300

Centennial chemical composition of the inorganic or ash portion, being mean of 7 analyses:—

	Leaves.	Stem.	Fruit including rind.
Oxide of Iron		1·00	1·86
Oxide of potassium	20·59	18·30	20·15
Chloride of potassium	15·43	14·43	10·52
Chloride of sodium...	7·58	5·25	3·75
Oxide of calcium	10·97	11·25	15·26
Oxide of magnesium	2·66	3·28	4·75
Phosphoric acid ...	2·95	8·52	25·96
Carbonic acid ...	7·27	5·07	2·05
Sulphuric acid ...	1·76	1·52	5·15
Oxide of silicon ...	25·54	25·15	7·65
Waste, *i e*, earthy matter, or oxide of aluminum...	5·25	6·23	2·90
Total ...	100·00	100·00	100·00

The foregoing tables should be taken as approximate data of the chemical constituents of all species and varieties of the plantain plant. The tables have been constructed from analyses of seven different edible varieties of plantain in general cultivation in Bengal, and from thero disseminated in other parts of India.

The organic principles of the plantain fruit are starch in abundance, and protein compounds, hence, the fruit is nitrogenous and excellent food. The pith of the stem and root bulb contain starch. These principles exists in different proportions in the same plant, and in different species and varieties, cultivation and fertilixing matters in the soil having also much influence in augmenting or lessening them.

PARTITIONING, TRENCHING, AND MANURING OF SOIL.

The soil, measuring 660' × 66', or one acre, should be partitioned off breadthwise in 3 partitions by 2 water channels, allowing 2' for each water channel; and having trenches 4' each wide with intervening space of 6' from border of trench to trench:—thus, we will have 660÷(6' intervening space from trench + 4' width of each trench)=66 trenches in each partition and (66' 66'÷(2' space occupied by one water channel + 2' space for the other water channel=16 —6"=length of each trench, or length of each trench. These trenches, 330 in number, 26—8 long and 4' broad each, should be marked and prepared, two months before the planting time by digging 3' deep, one foot of earth of which should be thrown on two side-spaces on both sides of each trench. This finished, suitable manure or compost should be thrown in the trenches, thoroughly incorporated with the soil, and irrigated with liquid manure, if available, or with water. The irrigation is required for inducing physical changes in the soil by which the manure and soil are rendered eminently fit as plant-food ingredients. It might be ommited if natural irrigation by the fall of rain be available, otherwise it is indispensable.

UTILIZATION OF BLANK SPACES.

In the first and subsequent years of plantain planting much space is available, both in the trenches and in the space intervening them, which certainly can be utlized in various ways, for raising of seedlings and cuttings of various kinds requiring sheltered positions, and for placing pots, &c., containing *stocks* for budding, inarching, and grafting.

SELECTIONS OF OFF-SHOOTS, PLANTING, AND THE NUMBER REQUIRED FOR PLANTING AN ACRE.

The best size of off-shoots for planting is 2' up to the apex of the highest leaf calculated from above the bulb. Smaller plants do not succeed so well being so very tender, and larger ones suffer from transplantations, owing to the delay of springing out of fresh roots without which the plant cannot establish itself, also for the rapid and great exhalation of water from the stem and leaves.

Young plantain plants should be planted one foot deep, in the middle of the trench, preceded by a hoeing of the soil if possible, six feet apart from plant to plant in the same trench, and immediately irrigated. But it would be very desirable to so time the planting time, as to fall on rainy day or days, and at the time when it is fast raining; as the planting at this time would ensure economy and remarkably facilitate the establishment and growth of the plants.

From what I have said in this and previous headings it will appear there are 4 plants in each trench, and as there are 330 such trenches in the acre, the number of plants per acre will be 330 × 4=1,320 plants, each of which eventually growing into a group of from 6 to 15 plants of various sizes.

IRRIGATION.

Where natural advantage of humidity of the soil does not exist, irrigation for plantain is very important. In such places the soil (trenches only), in which plantain plants are growing, requires to be constantly flooded with water by artificial means, in the summer and winter; and during the rains also if the falls of rain be at long intervals and scanty. When, however, the fruit-spikes have been sent out, total withdrawal, or in moderate quantity according to the nature of the soil and condition of the season, of irrigation should be made, to allow the sap to concentrate for the formation of new substances for the fruit, to be again applied when the fruits have established themselvse on the spike.

AFTER-CULTURE.

This consits in the elimination of weeds from the trenches, hoeing round the plants, not less than six inches deep, and mannring once a year during the rainy weather.

TRANSPLANTATION.

Every third year plantain plants require to be rooted up, the root-bulbs deprived of the stems, separated, and only the healthy off-shoots or young plants planted out in the same trench which has been well hoed and manured. By doing this fresh vigour is imparted to the young plants which had to struggle for existence between the intermining net-work of root of old plants, ripened, fruited and removed.

HARVESTING AND STORING OF FRUIT-SPIKE.

When one or two fruits on the spike have ripened, the spike should be removed from the plant, and the plant, also. The fruit-spike should be stored *i.e.*, hung from the ceilings, in a warm air-tight room, to allow all the fruits to ripen.

YIELD.

The yield of plaintain plant is very various owing to various causes. Again, two varieties or species not producing alike in the number, size, and quality of its fruit. The minimum, per spike or plant, is 80 fruits, and the maximum 500 fruits, of various sizes.—O. L. Bryce, Agri-Analytical Chemist, Late Supdt. Agri-Hortl. Socy. of Oudh Gardens.—*Indian Agriculturist.*

Amount of Water in Irrigation.—In India and Ceylon, water not only is wasted but worse than wasted in rice culture. By the application of too much water the soil gets water-logged and the crops suffer. We quote a paragraph from a paper by Mr. P. O'Meara, M. Inst. C.E.:—"It was laid down as a rule that the duty of water in irrigation must vary with the character and condition of the soil, the amount of rainfall, the temperature, evaporation, &c. Details are given to ascertain the amounts of water and length of time required to moisten different soils in the Cache La Poudre Valley. The condition of some of the older farms was held to indicate that the quantity of water required for beneficial irrigation became gradually less year by year after a few years from the commencement."

AGRICULTURAL AND PLANTING ITEMS.

(*From the Queensland "Planter and Farmer".*)

The plant cane on the Grove Ranch Plantation in Hawaii is said to be yielding an average of five tons and a half per acre on the whole crop. We should like to learn the varieties planted.

It is said that common salt is a certain cure for white ants. A contemporary mentions a selector who entirely destroyed these pests by a liberal application. It should be easy enough to test this on either buildings or fences.

A very novel and interesting industry has been started in the South Seas by an American firm—the drying and preservation of local grown fruit. The process used is called the Alden process, of which we have no details. The firm has fifty acres or more of bananas under cultivation, and intend also to buy from outside planters. The bananas are first thrown into boiling syrup, and then subjected to the drying process, the sugar crystallising upon the fruit and imparting a delicious flavor. If this plan of utilising this most nutritive and wholesome of fruits could be introduced into Queensland, thousands of acres might be grown for export, and the industry become most lucrative. [And why not in Ceylon.—Ed.]

The *Planters' Monthly* of Honolulu continues to increase in interest. Its articles are eminently practical, and are evidently the outcome of much experience on the part of its contributors. From its June issue we learn that the Hilo Planters' Association have stopped talking about introducing the mungoose, and have gone to work. The sum of $1,100 has been subscribed among them, to send a man for mungooses. If the mungoose will accomplish what is claimed for it in the way of exterminating rats, this, it thinks, will be a good investment. One planter estimates his loss from rats last season at £2,000.

The Chinese, among others, are going in for breeding polled cattle. Recently a consignment of Aberdeen polled cattle and Ayrshire cows were exported from Greenock. The polled cattle, together with some other breeding stock, are intended for the Kiai-Ping breeding farm, Tin Sin, extending, it is said, to about 100,000 acres, and owned by Mr. Tong-King-Sing, an enterprising merchant and cattle-breeder in the north of China. The Ayrshires, together with some dairy shorthorns from the Southeast Farm, Leighton Buzzard, are for the Shanghai Dairy Company,

So far the present season appears to be most favorable in all the Australian colonies. The accounts from New South Wales as to the sugar and other crops is satisfactory. In Victoria the weather continues favorable, and good reports are arriving from all quarters' wheat sowing having been concluded in a satisfactory manner. The temperature having risen, pastures are improving, and dairy produce is becoming more plentiful. Lambing is also proceeding satisfactorily. Evidence is to hand that an increased area of land in the northern districts is being sown with wheat. Reports from South Australia are also cheering in character. A contemporary states that "from all the centres of population throughout the colony the news is uniform in character, all reports agreeing that the present season is, so far, the best that we have had for years, and that the rainfall during the month is greater than has been experienced for a similar period since 1875."

The following extract from an article on the "Agricultural Outlook in England," from the pen of that well-known farmer, Mr. C. S. Read, will be read with interest:—"The records of Rothamsted show that the climate of England is certainly altering. During the past forty years each succeeding decade gives a larger rainfall, so that of the last ten years is the heaviest recorded by Sir John B. Lawes. But what strikes the farmer of the present day more even than the increased rainfall are the long spells of wet and of dry weather which prevail. There may be weeks and months with nothing but rain, and then a sharp drought sets in of long continuance, which hardly ever passes away without some electric disturbance. There is a total absence of that mild, balmy, growing weather which was considered one of the most pleasing features of our English climate. Last year, after a dry spring, the summer was made up of a few hot days and a thunder-storm, followed by a prolonged period of cold wet weather." [So that the weather in England and Ceylon is much alike: abnormal and ungenial?—Ed.]

SOUTH AFRICAN PRODUCTS.—Kilwanga needs a word of special mention, it is such an important article of consumption in the Congo *menu*. The root of the manioc, or cassada, a very ancient introduction from Brazil, is taken and pounded into a fine white pulp. This is left to soak for about twenty-four hours in running water (possibly to rid the substance of a certain acrid poison attributed to the root), and is then allowed to ferment. When worked up into a consistence of stiff dough it is divided into portions, and each portion is wrapped up in a large green leaf until wanted for cooking. Kilwanga tastes and looks like sour dough, but it is highly nutritive. The best way of eating it is to cut it into very thin slices, and eat these fried in butter, or, if butter be not procurable, in ground-nut oil, easily extracted from the *Arachis hypagea.* Perhaps a simple recipe for doing so might interest intending African travellers who are reading these pages. Take a bushel of ripe ground-nut that have previously been dried in the sun, pound them to a pulp, and put them in a cauldron of boiling water. The oil will rise to the surface, and can easily be skimmed off and put apart into a vessel. The residue is excellent fattening food for fowls, and the oil itself is almost indistinguishable from the best olive in taste. Indeed, most of the olive oil we use in Europe *is* nothing but the oil of ground-nuts, which are exported largely from West African ports to Marseilles to be there manufactured and flavoured into various salad oils christened by different names. This oil of ground-nuts is excellent as a kitchen grease and as a lamp-oil. I will even give you another recipe in which this substance may be advantageously employed. Take a quantity of sugar-canes, some nine or ten sticks, peel them, cut them up into small cubes, and mash these to a pulp, straining off the abundant liquor into a large pot. Put this over the fire to boil, and at the end of an hour and a half you will rejoice to find the sweet syrup liquor reduced to a considerable quantity of gluey barley sugar. If this does not sufficiently gladden the heart, and you crave for something yet more toothsome, mix a certain quantity of this thick sugar with ground-nut oil; further, blanche some ground-nuts and scatter them freely in the mess. This compound, if carefully cooked for about ten minutes, will produce the most ravishing African Toffee! Little shifts and expedients like these serve considerably to lighten the explorer's lot, and to render palatable many forms of native food. We are here following the great trade route from Stanley Pool to the coast, and the sides of the way are strewn with the top leaves of pineapples, which, when the fruit is eaten, are thrown away, and, taking root in the rich red soil at the side of the path, serve to spread this plant along the whole route between Lutetè and Stanley Pool, in some places, especially in the dank, moist ravines, forming an almost impenetrable hedge on each side of the narrow path. The inhabitants come to these narrow valleys, and fill their long wicker baskets with the beautiful golden fruit which forms now so large a part of their diet. In one village we came to there was a perfect orgie of pine-apples going on. The people were too indolent and careless even to sell them, and one lady, with whom from pure habit I was disputing the price of her basketful, said in a languid way to Faraji, "Here, take them; as he does not want to pay, he can have them for nothing." The dogs, the cats, the pigs, the goats, the fowls, and the children, all lived on pine-apples. The very people had a golden tinge about them, as if from the absorption of such quantities of mellow fruit, and the fowls I brought here had a flavour that was quite unaccountable save for this theory of an exclusive pineapple diet. Here it was impossible to resist halting; we arrived about eight in the morning, and for two whole hours we sat and ate pine-apple. A few brass rods paid for the entire feast, and the generous natives moreover brought us a heaped-up basketful to carry on our journey. However burdened the men might be, this was an extra load they never refused.—*From Mr. H. Johnston's Visit to the Congo, in the "Graphic."*

CARRIER RAVENS.—At Coblenz lately experiments were made with young ravens with a view of replacing carrier-pigeons by them. The ravens are not so subject to being attacked and destroyed by birds of prey. The ravens were sent from Coblenz to a small place on the Moselle near Treves, a distance of about forty miles. The experiments proved eminently successful.—*Nature.*

RICE AND COFFEE MILLS.—There are eighty-one mills and plantations on the Sandwich Islands—both rice and coffee huskers are obtainable; the first in Louisiana, and the other in Ceylon.—*Sugar Planter.*

SUGAR.—From the *Townsville Herald* we learn that the first sugar from the Burdekin was brought to Townsville by the Star of Hope. It consisted of about twenty-five tons, the result of the first crushing at the new mill on Airdmillan plantation, and its quality shows that with proper crushing and refining appliances, the Burdekin can produce a sugar equal to any manufacture in the world.—*Planter and Farmer.*

BUDDING MANGOES.—Mr. Shann, of the Bowen Botanical Reserve gives the *P. D. Times* the following valuable information on this subject:—Mangoes budded in September take very freely, the sap is well up and the bark parts freely from the old wood. Previous to budding, a lean young shoot should be chosen from the variety to be budded, pinch out the top of the shoot while the young leaves are red, so as to throw all the strength into the wished-for buds; by the time the bark and the leaves of the young shoot begin to assume a green colour plump buds have formed, which should then be inserted in the ordinary way of T budding upon the stock intended for them. In a month or five weeks the bud will begin to push, the tying should be slackened to keep it from cutting through the bark and preventing the flow of the sap.—*Planter and Farmer.*

THE TARO PLANT.—A colonial paper states that the taro plant, which constitute the principal article of diet amongst the natives of many of the South Sea islands, has been cultivated for years on many of the sugar plantations of Queensland for the use of kanakas. It has not come into general consumption a nongst the white population, although it is said to be a very healthy vegetable, equal, if not superior, to the sweet potato. It has recently been introduced into some of the Southern States of America, where it is not only relished as a vegetable, but has been found a most excellent food for horses and cattle. The taro grows to greater perfection in the island of Tanna than in any of the other islands, on account of the great depth and freeness of soil in that island. The natives cultivate it, like the yams, on the tops of mounds of finely-pulverised earth. When grown on land cultivated by the plough, it is usual to plant it on the tops of large drills prepared by hilling up together three or four furrows. A very good starch and a very fair arrowroot are made from the bulb. It can only be cultivated with success, however, on fine alluvial soil such as is to be found along the barks of rivers.—*Journal of Horticulture.*

A NEW VINE DISEASE IN FRANCE.—Her Majesty's Vice-Consul at La Rochelle says that to the various diseases to which the vine is subject, must be added the *Ponospora viticola*, or mildew, which has been undoubtedly introduced by vines from America. For a long time, the vineyards in certain parts of the United States have been ravaged by this disease, but it appears to have been totally unknown in France prior to 1878. From an account given by a chemist who has been engaged in making researches on the subject, it appears that the mildew is a species of fungus which attacks the under side of the leaves, turning them brown and dry until they eventually fall off, and spreads according to the dampness of the atmosphere. The stems, deprived of their foliage, can no longer nourish the grapes, which shrink up before ripening. The spore of these species of fungus germinate in one night in a drop of water, consequently, when the air is dry, and there is no rain or dew on the leaves, the malady makes no progress, while proximity to the sea, and a misty humid condition of the air, favour its development. Later in the season, it forms another spore in the tissue of the leaf, which propagates the disease for the following year; it is, therefore, important to collect and burn all dead leaves after the vegetation of the vine has ceased. It is easily distinguishable from the *oidium*, as it produces a distinct and clearly defined spot like a burn on the leaf; the fungus is thicker, and of a whiter colour, and has no smell; the mildew also does not form a boss on the upper side of the leaf corresponding to the spot attached underneath, as is the case with the *erinium.* The mildew has already caused considerable damage in the south-west of France and Algeria, and it appears to be rapidly spreading.—*Journal of the Society of Arts.*

A CORRESPONDENT of a southern paper asserts that a small proportion of kerosene thoroughly shaken up with the castor oil is even better than the latter lubricant alone for greasing waggon axles and other similar bearings being less liable to gum.—*Planter and Farmer.*

NAGESAR WOOD (*Mesua ferrea*) has dark red heartwood, extremely hard. It has been found to answer for sleepers equally well with Pynkado, but the cost of cutting the hard wood, its weight, and the freight from the Tenasserim forests to Calicutta prevent its being much used, as the total cost is scarcely covered by the price (R5) per broad gauge sleeper. It is used for building, for bridges, gunstocks, and tool handles; but its more general use is prevented by its great hardness, weight, and the difficulty of working it.—*Indian Forester.*

THE LIFE OF TIMBER.—The ordinary life of unprotected timber structures is not more than twelve or fifteen years. Timber exposed to moisture in the presence of air, especially if in a warm place, or to alternate wetting and drying, will decay rapidly. Sap and moisture retained in timber, by painting or closing in the sticks before they are seasoned through, will cause decay of a very insidious kind, as it works in the interior, leaving an apparently sound exterior or skin, which is the layer that had an opportunity to season. Paint on unseasoned timber is, therefore, more hurtful than serviceable. Large sticks of timber dry so slowly that, before they are seasoned throughout, decay may begin, and hence pieces of small scantling are preferable to large ones. Dampneess and a lack of ventilation combined will hasten decay. The best seasoned timber will not withstand the effects of exposure to the weather for much over twenty-five years.—*Lumber World.*

EAST INDIAN FURNITURE WOODS.—Toon Wood (*Cedrela Toona*) is light, soft, and red, and has no heartwood. It is not eaten by white ants; it is highly valued and universally used for furniture of all kinds, and is also employed for door panels and carving. From Burmah it is exported under the name of "Moulmein Cedar," and as such is known in the English market. It there fetches about R65 per ton, the cost of cutting and delivery being R44, according to Major Seaton. In North-West India it is used for furniture, carvings, and other purposes. In Bengal and Assam it is the chief wood for making tea-boxes, but is getting scarce on account of the heavy demand. The Bhutias use it for shingles and for wood carving; they also hollow it out for rice pounders. It is, or rather used to be—for very large trees are now rather scarce—hollowed out for dugout canoes in Bengal and Assam. In Bengal, Assam, and Burmah it grows to a very large size, trees 20 feet girth, with a height of 80 to 100 feet of clear stem, being not uncommon in forests which have been only little worked like those in Dumsong and in some parts of the Chittagong Hill Tracts.—*Indian Forester.*

INSECTICIDES: GOOD FOR GRUB.—With reference to phylloxera on vines in a place near Manchester, the editor of the *Journal of Horticulture* writes:—As we remarked a few weeks ago, a nobleman's gardener saturated a phylloxera-infested border with ammoniacal liquor from gas-works in almost the full expectation that it would kill the Vines. It did not kill them, but killed the phylloxera, and the Vines have since borne many fine crops of Grapes. This liquor, we may remark, should be diluted with from four to six times its volume with water. We are not aware that petroleum has yet been tried as a remedy against the phylloxera, and we think it worth trying. It may be fairly mixed in soapsuds in which a little soda is dissolved. An ounce of oil dissolved in a gallon of water has been applied to Onions, Lettuces, and Kidney Beans without injury to the plants, but resulting in the death of all insects with which it came in contact. On page 332 of our issue of April 28th, 1881, Mr. Witherspoon enforces the value of hellebore as an insecticide, and suggests that it be tried on phylloxera-infested Vines, firmly believing it would prove effectual, as he observes that "in soil saturated with hellebore no insect can live, and yet plants are not injured." The method of using it is to dissolve 2 oz. of the powder in a gallon of water, but first mixing a small portion in a little hot water to the consistency of cream, then adding the quantity of cold water required. This is worth trying, as also doubtless will be several other preparations that will suggest themselves to those specially interested in the matter.

RUBBER.—An esteemed correspondent writes to us:—"The Nagas in this portion of the Naga Hills (above Amgourie tea garden), are getting a good deal of rubber from a woody vine. The vine climbs trees and grows to three or four inches in diameter. When the seed-pods are ripe, they burst open, and a light flimsy material comes forth, and is wafted about by the winds. It is this fact that gives to the vine its Naga name *Apungmange.* The botanical name I do not know. The vine is common in the forest jungle of these hills, and the Nagas say it is in the forests at the base of the hills, but not as abundant as in the hill forests. The juice in the green state and when dried has every appearance of that from the rubber tree. It might be well for Government to ascertain how abundant this forest vine is in the plains and other hill districts of India: also to give a thorough test of the value of the rubber from this vine.—*Indian Agriculturist.*

MAGNESIA is seldom used in practical agriculture as a manure, and the effects following its use in scientific experiments seem to indicate that in ordinary soils the fact that it is an essential plant food may be ignored, as almost all soils contain enough of it. That it is essential may be regarded as proved, for plants grown in calcined sand from which it was excluded and everything else supplied, failed, and from the fact that it is never absent from ordinary plants, more especially their seeds. Though constantly present in plants, it is not so to the same extent as lime, potash, soda, or phosphates. In the ash of ordinary garden vegetables it is only occasionally above 10 per cent, and is often as low as 1. It is removed from the soil to the extent of one-eighth of the amount of potash in an ordinary rotation of kitchen garden crops. Many ornamental plants, however, remove it in large quantities comparatively. According to Ivison Macadam of Edinburgh, it is sometimes present in the ash of certain Fuchsias to the extent 16 per cent, and in Ficus elastica to 11. In greenhouse mould, which before being used contained 0·248 of magnesia, only 0·182 remained after use. In fruits it is not largely present; in Grapes there are nine grains of potash present for every one of magnesia. In the ash of white Mustard 11 per cent of magnesia occurs and only 9 of potash.—*Journal of Horticulture.*

CINCHONA BARK FROM JAVA.—According to a report by Mr. Consul Cameron, the crop of bark from the Dutch Government cinchona plantations in Java is increasing year by year, that for 1882 amounting to 230,000 Amsterdam pounds (17½ ounces nearly) against 165,000 pounds in 1881. Experiments made last year to ascertain the percentage of alkaloid contained in the bark from young Ledgeriana trees raised from seed produced by plants grown in the island showed that the bark from a plant four years old, when bearing the true type of the mother stem, yields 9 to 11·75 per cent of quinine, being an improvement on the parent trees. There were at the end of the year 3,305,200 cinchona trees in the Government nurseries and plantations, of which 820,700 were young Ledgeriana trees in the nurseries, and 604,900 older ones in the plantations. The exports of bark from the private plantations in Java during 1882 was 181,354 Amsterdam pounds, a quantity that is likely soon to be considerably increased.—*Pharmaceutical Journal.*

TEA-BULKING.—Our remarks we hope will be taken in the spirit in which they are meant, for we believe that the planter is not so much to blame in many instances as the appliances he has at his command. For instance, in how many factories will a good air-tight, or rather weather-tight, tea-house be found? In very many more than half theestates in existence, the tea is manufactured in a *kutcha* house, the atmosphere of which, on a wet day, is loaded with moisture, except when the actual fires are burning, and fires in many instances have given way to siroccos, &c., so that it is only in a very limited space, close to the drying appliances that the air is at all dry and free of moisture, and yet in those houses the planter is expected not only to bulk his tea, but to keep it there until there is sufficient to make a break, and the larger these are, now-a-days the better the broker likes them, for is it not being continually dinned into the planters' ears, that small breaks are a mistake. This latter of course makes bad worse, for it takes some time for ordinary gardens to get enough together to make a break.—*Indigo Planters' Gazette.* [In the generally damp climate of Ceylon, it is probable that a furnace and hot air pipes would be valuable in preserving a dry temperature in tea-houses.—ED.]

COL. MONEY ON TEA MACHINERY.

Col. Money commences with a notice of ploughing and hoeing machinery, which may ultimately be found of use in some of the lower and flatter estates in Ceylon. In Assam so much of the land is flat that we do not wonder at frequent suggestions to supersede expensive cooly labour by ploughs and harrows, even the use of the steam plough being recommended. The tea plants would require to be very far apart in the rows, however, to escape damage from the animals used for traction, and the steam plough could only be used, so as to pay, in the preparation of very large expanses for planting. Col. Mooney's remark on ploughing is :—

If animal power is used, it must be a single bullock alone. How to harness a single bullock to the plough is the question. A collar with a hinge below, which allows it to open at top, may be put on from below, and then the sides fastened together at the top. But I advise another plan, which I have seen most successfully practised in Austria. The traces, joining together, and thus becoming one behind the bullock, are fastened to the horns, and tightly connected with a leather pad across the animal's forehead The bullock thus pulls by his head, and I am sur he can pull in no more efficient or easier way to himself. Bullocks in pairs, or singly, are thus harnessed for plough work in Austria, and I have seen single animals dragging ploughs of much greater weight and power than we should require in our tea gardens.

Given a proper plough, and I feel sure a large strong bullock thus harnessed would be successful.

But he adds :—

Cultivation with ploughs of any kind can never be feasible except on flat land.

He notices "planting-pots" made of clay, cow-dung and cut straw, by means of which the seedling "does not know it has been transplanted." He next mentions, with qualified approval, Jebben's transplanter. Happily, in our climate, "planting weather" can generally be relied on sufficiently long-continued to enable planters to dispense with all such aids. But we have many inventions in Ceylon for the purpose, amongst which we may mention the combination of Davidson's transplanter and Scowen's cups to keep the root-earth firm; but for cheapness and simplicity what can excel Mr Owen's method of wrapping the uplifted plants in funnels of old newspapers, the paper being left on, as the moisture soon decomposes it? Proceeding to notice "tea-manufacturing machinery," Col. Money safely asserts that no plucking machine can be invented, but that

A good withering machine (it must be on a large scale) might, I think, be easily invented; there is none at present. Why do none of the inventors of other tea machinery try to succeed in this?

We recently quoted a description of a machine such as is desiderated by Col. Money, invented by Messrs. Greig & Co. of Edinburgh, the efficiency of which remains to be proved. Then, as to *sorting green leaf*, Col. Money writes :—

This is sometimes attempted in a rough way by the use of sieves of different meshes. To separate the fine from the coarse leaf, and in some cases to eliminate the Pekoe tips, is the object. A machine by John, Greig and Co., of Edinburgh, professes to do the latter. I have never seen it, but I doubt any machine abstracting the Pekoe tips alone. A machine which would however, separate the fine from the coarse leaf previous to rolling is, I think, quite feasible, and it would conduce much to good tea. This, again, is an opening for inventors.

Of *rolling*, Col. Money states :—

This is perhaps the most important of all processes in Tea manufacture. The object of it is to break the cells in the Tea and liberate the sap (fermentation could not take place otherwise), and further to give a tight roll or twist to the leaf. Formerly this was always done by hand (it is so done in China, I believe, to this day), but the process was lengthy, expensive and dirty. I might perhaps add inefficient, for doubtless machine-rolled tea is better done (better in appearance, better in liquor) than hand-rolled.

Col. Money then proceeds to deal in detail with the rolling-machines of Jackson, Kinmond, Haworth, Lyle, Greig and Thompson—all he had heard of. Jackson, it seems, invented five machines, and, of the Cross-action and Excelsior rollers, the Essayist speaks in terms of unqualified approval. He adds :—

His last invention (if I mistake not) is the Rotary Tea Roller, which is on quite a different principle to the others. It consists of an elongated revolving barrel or cylinder, with a polygonal *internal* surface, and a roller with a fluted *external* surface, mounted within the said barrel its whole length. These revolve in opposite directions (the roller the quicker) and the leaf is rolled in the annulus between. It is not yet known what the success of this last invention will be.

This is what he says of Kinmond :—

Kinmond invented the first tea roller (see page 117) many years ago. Many improvements resulted, eventually, in his "Improved Double Action Tea Roller," which is a very good machine and has given satisfaction to the many who have used it. From all I have heard and seen, however, I doubt if, take it all in all, it is equal to Jackson's Cross Action Excelsior. Kinmond, some two years ago, invented a "Centrifugal Roller." It was made in two sizes. The smaller seems to have done well, not so the larger; one of the latter on the Phoolbarry garden (in which I am interested) has proved a failure. But Mr. Kinmond has quite lately materially altered the said Centrifugal machines, and is confident that they *will* do well. He is now leaving for India with one, and anticipates good results.

Tea machinery is still so much in its infancy that the best machines are likely to be improved upon, and perhaps superseded by others, but as things are now, I think, though some do not agree with me, that Jackson has carried off the palm in rollers.

Col. Money then quotes a letter from the *Tea Gazette*, the writer of which states :—

For *coarse* leaf, Jackson's "Excelsior" is a splendid machine. I should say a factory could not want two better machines than one of Kinmond's "Patent Double Action" and one of Jackson's "Excelsior" Rollers—the former for *fine*, the latter for *coarse* leaf.

But, as far as we understand the matter, the pressure in the working of Jackson's rollers can be regulated to suit coarse or fine leaf, if our planters ever pluck coarse leaf. Regarding Kinmond's Compound Action Centrifugal Roller the complaint was that it not only heated the tea but cut 5 per cent of the leaf into mincemeat. Then comes a notice of Haworth's roller, in the case of which the tea leaves operated on are enclosed in bags. That probably is the reason why the leaf is not so well twisted as in the case of that prepared in Jackson's. Mr. Owen, who has had the advantage of us in having seen tea rolled in bags, spoke well of Haworth's machine; and the result of comparisons instituted was that, although Jackson's roller gave the tea best in appearance, Haworth's gave superior liquor, and the tea prepared in the latter was, for this reason, valued a little higher in Calcutta than the tea done in Jackson's roller. Col. Money thinks that Haorth'sw roller has not received the attention it deserves. Of Greig's roller, Col Money can only give the description supplied by the manufacturer. This we recently quoted. Finally, as regards rollers, we have a notice of Thompson's Challenge Roller, to this effect :—

This (quite lately invented) though given last is likely, by all I hear, to stand well among rollers. I have no drawing or description of it, but *why* I think well of it is that a Tea engineer, Mr. Ansell, of Kurseong, who thoroughly understands tea machinery, thinks so highly of the machine that he has recommended its purchase by the Phoolbarry Tea Company. I have every faith in Mr. Ansell's judgment, and feel confident therefore the machine must be a good one. One feature and advantage claimed for it is, "free contact of the leaf throughout the roll with the outer air."

Subsequently, it is stated that it is claimed for this machine that by its use

"Balling" of the leaf is avoided.

The tips are kept quite bright.

Heating prevented.

Simplicity of "feed" and "discharge."

One attendant, a minimum of motive power, and low priced.

A good twist attained.

Simplicity in the machine, and ease of transport and erection.

We suppose, the use of hard wood for the rollers obviates the objection offered by Col. Money that the wood absorbs the sap, and, unless it is washed very clean, the old sap might contaminate the new leaf. The use of porcelain and opaque coarse glass is recommended, but we suspect both would be apt to crack and break in use. There is, doubtless, much truth in what was stated in a letter to the *Tea Gazette* :—

1. All "genuses" of machines are equally good.

2. There are hardly two "species" of the same genus which give similar results.

3. Changing the "fixings" of a machine makes all the difference in the world.

Ergo a good mechanic will have a good machine whether he patronize Jackson, Kinmond, Haworth, or any other inventor.

I think with your correspondent "A Voice from Assam" that the machine that gives the roll quickly, and in a continuous supply, is the best.

I would defy any man to prove that any *inventor* has it "all his own way," for I certainly have not found it so in my experience.

For the fermenting process no machine can be used, but it seems Mr. J. Fleming of the Phoolbarry Garden invented a series of shelves at varying heights from the floor, so as to "regulate the fermentation, inasmuch as the higher the shelf the warmer the air, and warmth hastens the process."

Col Money devotes much space, but not more than the importance of the subject demands, to drying or firing tea and the machines which have been invented for the purpose. As regards his own share in this reform, he writes :—

For many years charcoal only was used to fire Tea, and it was an established belief that *the fumes* given out by the said charcoal had some chemical effect on the Tea—in fact, that good Tea could not be made without it. When, twelve years ago, I published the First Edition of this Essay, I had begun to doubt the soundness of the above belief, and four years later I had thoroughly satisfied myself of its fallacy. It was not, however, till 1877-78 that I devised *a means* of firing Teas without charcoal. The invention was well received, and thought well of. At all events, it *proved* what I had long urged—viz., that any heat, if contact with the smoke was avoided, would dry Tea. My invention was a very crude one, and quickly superseded by [illegible] more perfect [illegible] I have the satisfaction of [illegible] that on this head I have done much to perfect Tea manufacture, and that the conviction I had attained to in 1874 is now general and practised throughout India.

Robertson's Typhoon, which it was said could be erected for R300 and which could dry 1 maund of tea with ½ maund of firewood, that is to say only ½ lb. firewood per lb. of dried tea, made good tea, and was well spoken of, but it seems to have gone out of sight. The next machine mentioned is Allen's tea drying apparatus, the advantages claimed for which were,

1. Quick drying. 2. Coke can be used as a drying agent, 10 seers to one maund of Tea. 3. Only manual labour required. 4. Not necessary to turn the Tea. 5. Perfect control over temperature.

Col. Money is of opinion that this drier is well suited for small gardens, which cannot afford steam motive power ; but cost is not indicated. Davidson's Sirocco is then mentioned as a machine of which hundreds have been sold, and which is so well known and appreciated in Ceylon that a detailed notice is not necessary. A letter is quoted from the *Indian Tea Gazette*, complaining of the iron portions of the machine being burnt away, a defect which we believe has been cured. Gibbs and Barry's tea drier, of which Mr. Owen wrote so favourably and which dispenses with trays, the tea being carried round and forward in a cylinder, is then briefly noticed. We are not aware that any specimen of this machine has reached Ceylon ? Next comes a notice of Mr. Charles Shand's steam drier, of which full accounts are quoted from our columns. Col. Money says that steam for drying tea is not quite a new idea, as he saw an apparatus to use it in Cachar years ago. We are rather surprized that Col. Money does not see the applicability of the principle of this machine, whether hot water or steam is used, to the artificial withering of tea leaves in wet weather. Mr. Shand himself claimed that his machine was especially adapted for re-drying tea before packing, this operation being carried on at a low temperature (?) and requiring a good deal of care. Col. Money left Kinmond's and Jackson's driers, respectively, to the last ; and he as unhesitatingly now gives the palm to Kinmond as he awarded it to Jackson in the case of the roller. Besides the drier in which trays are used, it seems Mr. Jackson brought out a trayless machine in which the tea once fed in, required no more attention until it was discharged dry, the tea being steadily but slowly kept in motion. Can any reader say if this competitor with Gibbs and Barry's machine has been a success? In Kinmond's drier, Col. Money fully believes The principle differs from Jackson's in that a fan working at 600 revolutions per minute forces hot air through the tea on the trays, a *separate* blast of hot air being forced through the tea on each tray. Col. Money rather strains the English language by declaring that with recent improvements, the machine is "very perfect." It ought to be, for the prices for the various sizes are

No. 1 Dryer, capable of drying one maund of pucka Tea per hour, £150; No. 2 Dryer, capable of drying two maunds of pucka Tea per hour, £220; No. 3 Dryer, capable of drying three maunds of pucka Tea per hour, £300. These prices are f.o.b. in London.

So that, consequently, when erected on an estate in the hills over 100 miles from Colombo, the cost would be increased by about one-third, or say £200, £300, and £400. No wonder though Col. Money should complain that the prices are too high, suggesting that with advantage both to inventor and planters they might be reduced. Mr. Kinmond states :—

This is the only Tea-drying machine which can keep pace with the largest rolling machines. It is made in three sizes. The capacity of the smallest or No. 1 Dryer is one maund of pucka Tea per hour. The capacity of No. 2 Dryer is two maunds per hour, and that of No. 3 Dryer is three maunds per hour. The consumption of fuel is less than one maund of wood fuel to one maund of pucka Tea dried.

One of the great advantages of this Tea Dryer is the facility it gives for *final firing* before packing. The enhanced price of Tea which has been dried and finally fired in this Dryer is well shewn in the high average of 1s 6d. per lb., which the Scottish Assam Company's Teas have fetched this season. See letters annexed from their superintendent in Assam, Mr. Cruickshanks, and their secretary in Edinburgh, Mr. Moffat.

When *final* firing Tea with the Dryer, it is found convenient to place a fine gauze cover over the top trays in each compartment, to prevent any of the Tea dust being carried away with the hot air which passes through the Tea.

In order to get the maximum quantity of work from the Dryer, the trays must be spread with rolled leaf twice as thick as that used when Tea is dried over charcoal, where there is no forced current of air, and after the Tea has been *half-dried*, then the Tea on *two* trays should be spread on *one* tray, and the drying finished. In the Dryers now in course of construction, the trays have been made one-half deeper, so that the half-dried Tea on *three* trays should be finished in *one* tray. The out-turn of the machine is greatly diminished when the foregoing method is not observed; and owing to its non-observance, many of the Dryers in use have never been worked to their greatest capacity.

The Dryer should be lined outside with one thickness of bricks—they are the cheapest and best non-conductors of heat—inferior or badly-burned bricks may be used. Both ends of the Dryer should be lined, and both sides and elbows as high as the trays. The top may either have a lining of bricks, or four inches thick of sand or clay. When the Dryer is lined round with bricks, it not only greatly reduces the consumption of fuel, but by preventing the radiation of heat, it enables the men to increase the outturn of pucka Tea.

The Dryer is extremely simple and compact—the No. 2 size occupies a space of about 7 feet long and 3 feet wide. The fan of this Dryer requires about half a horse-power to drive it.

The fan should be driven at a speed of 500 revolutions per minute. The pulley on the fan spindle is 7½ inches diameter and 4 inches wide.

Col. Money gives the preference to No. 3. the machine which dries 3 maunds (240 lb.) per hour, and which erected on an estate in Ceylon would certainly cost not much under R4,500. This is a serious expenditure to face, but on large plantations it will probably pay. Col. Money quotes a letter which he wrote to the *Tea Gazette* apropos of Kinmond's machine and the necessity of making good teas at a small cost.

This latter, I hold, both as regards quality and economy, *can* only be attained by the use of machinery; and thus, what is the best kind of rolling machine, the best description of dryer, equaliser, and sifting apparatus, is an all-important point.

What is the "equalizer" to which Col. Money refers? A machine to cut or break tea to one size? He goes on to state that it is now generally admitted that tea prepared in driers is superior to that prepared over charcoal, while the saving of time is enormous:—

If there is one thing certain in Tea manufacture, it is that speed is necessary. Charcoal drying took on an average 45 minutes; Tea is fired in the best Dryers in eight minutes. In respect of speed, Kinmond's Dryer (which is the one I advocate) is certainly unequalled.

The saving of time, by the use of Kinmond's drier instead of the old mode of charcoal drying, is thus 37 minutes out of 45.

When, as in large factories, 30 or 40 maunds of Tea have to be made daily, it is evident that, *cæteris paribus*, the machine which will do most in a given time and given space must be the best. In these respects also Kinmond's Dryer stands well, for the small size (No. 1) will do one maund, and the larger size (No. 2) will turn out two maunds per hour. In other words, in a working day of 12 hours (and I allow no more, for I do not believe in night work) 12 and 24 maunds daily are the capacities of the two sizes. Considering that the said two sizes, with necessary stokehole, tsibles, &c., occupy respectively not more than 200 and 260 square feet of space in a factory, the satisfactory results, in both the above respects are unquestionable.

Tea made at night, both because the colour of it in its different stages cannot be well seen (let the light be what it will), and also because superintendence cannot then be so close, is never so good as day-made Tea. This is *why* I do not believe in night work; and it is also a very important extra reason why machinery (which by its speed enables all the necessary Tea to be made by daylight) will prove such a great and lasting advantage.

When Kinmond's Dryer was first constructed, it was proposed to work it at 300 degrees. Later experience has proved 260 degrees is better and sufficient; but of course more time is thus taken, and with the old sizes one and two maunds per hour could not be turned out at the lower temperature. The machines are now made one-fifth larger to obviate this.

The fan is worked at 600 revolutions per minute, and this is found to be the best speed.

Several alterations, and important ones, have been made since the first machines were constructed, but I will mention them shortly, for they will only be understood by those who know the Dryer—1. The trays now take out alternately both sides. 2. The fine Tea or dhole trays take out independently. 3. Outside bearings are supplied to the fan shaft or spindle: thus the lubricating oil cannot now run down into the fan casing. 4. The chimney is moved forward, and thus heats a large amount of air and reduces fuel. After the necessary temperature has once been obtained, one maund of wood will fire one maund of Tea. This is an outside estimate.

We may notice that 12 maunds and 24 respectively are the equivalents of 960 lb. and 1,920 lb. We agree with Col. Money as to the great desirability of avoiding night work. Withering in damp weather is the difficulty. If night work becomes absolutely necessary, it may be possible to generate brilliant electric light by the motive power applied to the machinery. In Col. Money's own case the teas averaged an increase of 2 annas per lb. after the supercession of charcoal drying in favour of Kinmond's drier. Talking of using these machines to aid withering, which he deprecates, Col. Money says:—

A machine fitted for that work has yet to be invented, unless Baker's Wet Leaf Dryer, of which I have heard good accounts, but have not seen, would answer.

Mr. Baker is the gentleman connected with the Assam Company who visited Ceylon in 1874 and we understood that his invention was intended merely to aid the withering process by expelling moisture from the leaves gathered in wet weather. We have seen no references to its successful working. We are told that Mr Kinmond has quite lately invented a coke-burning drier, ¼ maund of coke to 1 of tea; 2¼ to 2½ maunds tea per hour; one half lighter than wood burning drier; requires no foundation of any kind; price £180 f. o b. in England say about £220 in Ceylon. Considering the work it does, 180 lb. to 200 lb. per hour, Mr. Kinmond's claims for this drier the merit of being the cheapest in the market. Can any reader speak of it from experience? In 1881, Col. Money wrote an article for the Calcutta *Statesman* in which he remarked that there was no market for tea seed now Times are altered since 1881, the demand for Ceylon being large. The Assam Company, therefore, may again declare big dividends, as Col. Money says they previously did, largely from sales of seed. From this article we make some quotations:—

It says not a little for the enterprise and the inventive genius of the Anglo-Saxon race that, while in China the manufacture of Tea dates back many centuries, and yet all the Tea is still made by hand, we in India, who have only planted Tea some forty years, have invented machines and use them today for each and every operation in manufacture. It is but as yesterday that we imported Chinamen to teach us the *modus operandi*. We now know far more than they do on the subject, and verily the pupil has beaten his master.

Col. Money talks of "Lyle, the inventor of the

Sirocco" (?). In the article a detail connected with Kinmond's machine is mentioned which we had not noticed previously :—

Another peculiarity in the machine is, that the same air is used again and again, being re-dried and re-heated each time. By this two advantages are obtained : (1) fuel is saved, it is easier to heat air which still retains caloric than fresh air ; (2) the aroma of tea is very volatile, and when hot air, which dries it, passes away, some of the essence and strength of the tea goes with it. But here the same air being used again and again, the volatile essence (how much who can say ?) is returned to the tea. It is reasonable to suppose that this will increase the value of the tea; indeed, we know it did so materially in one garden last season.

A letter is then quoted, in which cost of charcoal drying over "choolahs" and that by machine are contrasted, thus :—

1*st.*—*Charcoal firing and its merits.*—Except for those who persist that the fumes of charcoal are necessary to make good tea, I can see no merit whatever in charcoal drying' either in cost, quality, rapidity, saving of labour, or anything else, over machine-dried tea.

COST PER MAUND TEA OF TEA DRIED OVER CHOOLAHS BY CHARCOAL.

		R.	A.	P.
Charcoal at 8 annas per maund, $1\frac{1}{2}$ maunds	=	0	12	0
1 Battiwallah at annas 4-6, kutcha firing	=	0	4	6
Do. pucka firing, say.. ...	=	0	0	6
Cost of firing by charcoal		R1	1	0

N.B.—Notice the labour staff required for three months in the year to make charcoal; the immense space (and heat) taken up by choolahs; cost of timber used for charcoal ; the number of trays, gauze, iron, &c., &c., required ; the masonry and carpenter's work always more or less out of repair ; loss of small tea falling through trays, &c., &c.

Now let us take

COST OF MACHINE-DRIED TEA PER MAUND.

		R.	A.	P.
1st. Those machines which dry by coke, say cost of coke	=	0	8	0
3 men at annas 4-6 per 5 maunds tea=about		0	2	8
Cost of drying per maund tea for a machine, drying by coke 5 maunds in 10 hours...		0	10	8

I now give an estimate of cost of 1 maund tea dried by a machine of similar capabilities, but drying with any sort of fuel—coal, wood, grass, bamboo, &c., say 2 maunds of firewood at 6 pie per maund=1 anna per 1 maund tea.

N.B.—Price of firewood at 3 pie per maund should be nearer the mark.

3 men's pay, annas 4-6 for 5 maunds in 10 hours—annas 2-8 per maund. The analysis of the above comes to this—

		R.	A.	P.
Charcoal drying	=	1	1	0
Coke "	=	1	10	8*
Wood fire "	=	0	3	8

We read of machines drying with any fuel, and doing double the tea of what I have estimated above, and how people can still stick to charcoal beats me.

Col. Money then comes to sifting machines, and he writes :—

In the body of this Essay (page 122) I say, "I do not believe in any present or future machine for sifting tea." I did not then ; that was in the early days of tea ; but I was wrong. A sifting machine, on the large scale on which tea is now made, is essential for every garden.

Jackson's Sifter.—I have seen this, and heard it well spoken of, but I have no experience of it.

Greig's Sifter.—This I have not seen, but from the drawing I have I should doubt if it would sift enough per day for a large garden.

Fridham's Sifter.—This is quite a new thing. I know nothing of it.

The fact is, the manager at Phoolbarry and I have been so thoroughly satisfied with the Sifter we use there (Ansell's) could conceive nothing better, and I have not therefore looked into the matter of Sifters.

In January, 1881, I sent an article to the *Tea Gazette* describing *Ansell's Sifter*, and as I thought then I think now. I believe it is by far the best tea sifter yet invented. Many are the testimonials, too, in its favour. The price, £80, is too high ; but the manufacturers (Ransomes, Head and Jeffries, of Ipswich) advice me they propose reducing it to £70. Even that, I think, is too much ; but there can be no question the use of it effects a great saving in a factory.

Col. Money forgot that a "green leaf drying apparatus" has not yet been invented, or, at least, adopted, when he wrote :—

An Indian Tea factory, well set up with machinery—that is to say with a green-leaf drying apparatus, rolling machines, Tea dryers, equalisers, and sifting and sorting machines, all driven by an engine of 15-horse power—offers a wonderful contrast to a Chinese Tea factory where all is handwork.

But is there an equalizer driven by machinery ? Col. Money describes Ansell's machine as "the best tea sifting *and fanning* machine extant," although we understood him previously to object to a combination of fanning and sifting. The description is as follows :—

Its length is 19 feet, its breadth 5 feet. The tea, in bulk, is delivered through a hopper from an upper floor, on what I will call the A end of the machine, to distinguish it from the other end, which I will name B. The principle of all other sifters (except Jackson's), as far as I know, is, that the succeeding trays of differing wire-mesh are arranged one below the other, the slope all being the same way, that is—from A to B. This plan is objectionable in the following way: if the Tea has been well rolled and clings together, a good deal of the fine teas that are in the mass or bulk often passes some distance down perhaps over half the tray or wire-mesh length before falling through. If they do so, and the object is to sift out any particular class on the next succeeding tray, there is only half the length of mesh left to traverse to effect the object, instead of the whole length of the tray. This is obviated in practice by pushing the teas continually back up the inclined tray; but this is done at the expense of extra labour and making the teas dusty and grey.

The above objection is obviated in Ansell's machine. It consists of 4 slopes, but each of these incline downwards, alternately, different ways—*viz.*, No. 1 (the upper), from A to B; No. 2, from B to A; No. 3, from A to B; No. 4, from B to A, and below the mesh of each slope is a carrying tin tray, sloping the same way, which carries all the tea which falls through each mesh down to *the head* of the succeeding slope, while in each case the tea which will *not* pass through the mesh is delivered separately. The above arrangement, however, does *not* hold with the upper or No. 1 slope. This consists of two wire trays or meshes, with the carrying tray below the lower one. Such of the bulk as will not pass through the upper tray is delivered on the head of No. 2 slope, at the B end of the machine. What passes through the upper tray, but will not pass through the lower, is delivered by a side shoot at the B end of the machine, and is "No. 1 Pekoe." What passes through both sieves on to the carrying tray is also delivered by an opposite side shoot from the B end of the machine, and is "Broken Pekoe." Between Nos. 1 and 2 slopes is an air chamber, which, as the bulk left on the upper sieve of No. 1 slope falls on the head of No. 2 (a blast being sent through it by a fan at the A end of the machine), drives out of the said falling bulk all red leaf, stalks, fannings, &c.

No. 2 slope receives the bulk at the B end of the machine, after the red leaf and fannings are taken out as stated above, and what will not pass through the mesh is delivered at the back of the A end of the machine, and is "Congou ;" while what does fall through the mesh into the carrying tray below it (which is still bulk, consisting of "Pekoe," "Pekoe Souchong," and "Souchong" mixed) is delivered at the A end of the machine on to the head of No. 3 slope.

What will not pass through the mesh of No. 3 slope is delivered at the B end of the machine in front, and is "Souchong ;" while what does pass through the mesh of No. 3 slope on to the carrying tray below (still bulk, consist-

* I should be glad to be set right if I have not rightly calculated the price of coke.—(*Writer of the letter.*)

ing of "Pekoe" and "Pekoe Souchong") is delivered on to the head of No. 4 slope at the B end of the machine.

No. 4 slope has no carrying tray: it would be useless. What will not pass through the mesh is delivered at the A end of the machine, and is "Pekoe Souchong;" while what does pass through the mesh falls on the floor of the factory and is the remaining "Pekoe," that is, "Pekoe No. 2.

The sorting is so far finished, and the results are the following teas, placed round the machine thus:—"Pekoe No. 1," at the left side of B end; "Broken Pekoe," at the right side of B end; "Red Leaf and Fannings," some distance in front of B end; "Souchong," also in front of B end, but nearer to the machine; "Congou," at back of A end; "Pekoe Souchong," also at back of A end, but nearer the machine; "Pekoe No. 2," on the floor below the machine.

With teas thus minutely sorted, all possible requirements are provided for, and the planter can, by mixing or otherwise, make any number of classes he may choose.

It will be observed that "Pekoe" is taken out twice, resulting in "Nos. 1 and 2 Pekoe." These differ slightly, but are better mixed together. "Why take them out separately," some exclaim, "to mix them together again?" But there are three very good reasons: firstly, the "Pekoe" is taken out at the commencement, previous to fanning, to prevent the small broken pekoe tips being blown out in that process; secondly, the "1st Pekoe" being taken out thus early, its appearance is not injured by passing over a large amount of sieve-mesh area; and thirdly, *all* the "Pekoe" is thus extracted, which it could not be, as far as I can see, by any other process.

From all kinds detailed above, I make only four—viz., "Pekoe," "Broken Pekoe," "Pekoe Souchong," and "Broken Tea;" but others can do as they will.*

The machine is of course driven by steam.† The movement of all the trace is a backward and forward one of 3 inches longitudinal semi-circular motion, the latter movement being imparted by the steel spring hangers. Only a small amount of power is required to drive the machine, viz., under half horse.

I must here conclude my description.

Now as to the amount of work the machine will do. I speak from actual experience when I state what follows:—

It will sift and fan seven maunds of tea per hour. The only hand labour required to supplement it is a few (a very few) women to pick out any foreign substances out of the "congou."

At our garden in Western Dooars. 1,260 maunds of tea were made in 1880, and all sifted by this machine, the hand labour besides being only 44 women during the whole season. or about one-fifth of a woman per day.

The machine requires only two men to work it continually, and one boy to feed it from the upper floor.

I can think of no possible objection to this machine, or even of any possible improvement. I believe, in the case of a 300-acre garden with a decent amount of produce, the machine, in its saving of hand labour, pay for itself in one year, whilst the teas are much improved in appearance by its use, and fetch higher prices.

The machine seems certainly very efficient, doing 5,600 lb. of tea in ten hours. Jackson's sifter divides the tea into only four sizes and has no fan attached. The sifter, like the roller, can, of course, be moved by water power in Ceylon. Amongst the testimonies in favour of Ansell's sifter is a letter quoted from the *Ceylon Observer*, as follows:—

A correspondent writes from London to the *Ceylon Observer* as follows:—Ansell's Patent Tea Sorter seems to be an article which will later be much used in Ceylon. In a memo. before me there is an extract from Messrs. George Williamson & Co., who say:—"The manager of our Majilighur Garden writes:—'I have now had sufficient experience of Ansell's Sifter to be able to report very favourably upon it. It does its work thoroughly and cleanly, and, owing to the comparatively small space it occupies, little or no loss occurs even of the finest dust. Sixteen maunds in nine hours is what I find to be about its capabilities, and four boys do all the work connected with it. It has effected a great saving in the tea-house this year, and has quite done away with hand-sieving, except equalizing the broken pekoe and broken tea—a very trivial operation.'"

* I advise only these four kinds. When the trader becomes more sensible, three or even two would be better, but as it is now four are necessary.

† With a driving belt from the engine shafting.

We now come to the final operation of packing. Col. Money writes strongly in favour of the handsome tin-boxes made by Messrs. Harvey Brothers & Tylor, which surely would have been universally adopted did Col. Money's statement still hold true that tea sent home in them averaged 8d per lb. in excess of teas packed in the ordinary manner! There can be no doubt they are very nice looking and would be appreciated in America. But the price of a box to hold 20 lb. of tea is about 2s 6d. For little more, than this a timber box to hold 100 lb., with lead, nails, &c., complete can be purchased. We fear, therefore, that cost is an insuperable objection. There is also the difficulty of packing for carriage. Col. Money finally quotes from the *Observer* a communication respecting hoop-iron for wooden tea-boxes, which we may repeat.—

The *Ceylon Observer* says:—"The planters should note the following (writes to us a London firm)—From quotations lying before us the prices of 22 gauge iron hooping are as follows:—½ in., 165s per ton; ⅝ in., 110s per ton, ¾ in., 70s.; ⅞ in., 60s.; 1 in., 50s. Thus by using one inch hooping, less than one-third the price is paid. The narrower the hooping, the more difficult is it to manufacture."

Col. Money adds "It is also not so strong."

AGRICULTURAL EDUCATION IN CEYLON.

It is not so very long ago since English operatives smashed machinery and burnt the mills in which labour-saving engines were employed, on the plea that the machines were taking the bread out of their mouths. Neither they nor *The Times* office printers, from whom the late Mr. Walter had to carefully conceal his efforts to perfect a printing machine, were educated enough to know that they could not possibly put back the hands of time, and that the ultimate effects of machinery, besides doing the work of millions of hands, would be to provide fresh and varied employment for human beings as virtual directors of labour instead of being themselves slavish toilers and moilers: doing the maximum of work with the minimum of results. The masses of the natives of Ceylon are still much in the same dark mental condition. It is well-known that the late Mr. de Soysa, after having promised to provide capital for a railway to Moratuwa, refused to go on, in consequence of an appeal to him as a patriotic Sinhalese by the native cart-drivers. They said:—"The English have ruined many of us by making railways in the hills. Are you going to join them and complete the work of ruin by helping to make railways in the lowcountry?" It is amusing, however, to learn that the native cultivators are likely to oppose the introduction of improved ploughs on the same ground. The occasion for this fresh development of crass stupidity arose from Mr. Green, the Director of Public Instruction, having got over some of the light iron ploughs from Saidapet, some Swedish and some Nawab.

Mr. Green tried one of the Swedish ploughs in the compound of Uplands, where he lives, and it did very well. Two natives (well dressed) came in and looked on: one said:—"Yes, the plough works better and quicker than anything we can do with our ploughs, but it will ruin the country. First the Government bring in the railway and ruin the poor carters; now they bring iron ploughs and take the bread out of the mouths of the poor cultivators!"

Mr. Green has, however, proposed to the Government Agent of Kurunegala, a ploughing match between one of the new ploughs and any native ploughs that may enter the lists at the next Kurunegala Fair, thinking correctly, that it will be a good plan for showing them to the people.

We hope the new ploughs will be successful, and, by enabling the cultivators to double the produce of their lands, show them that not ruin but profit follows the introduction and use of improved manufacturing and locomotive machinery and agricultural implements. If the ploughs are a great success, they will give increased employment to ploughmen, because, not only will existing cultivated lands be ploughed more frequently and more deeply, but large tracts of fresh land will be brought into cultivation.

Since writing the above, our attention has been called to a characteristic paragraph in the local "Times," in which the writer, after showing how natives in towns —he might have added carpenters and masons and other artizans with contractors, dealers in rice, etc., not necessarily resident in towns—have been benefitted by British rule and British capital and enterprize, goes on to say :—

We wish we could speak as cheerily of the agricultural population. The advent of the British in Ceylon has unhappily done but little for them, and that little not of the happiest, for their headmen have, in too many instances, adopted the worst features of our civilization, and when their leaders fail them their course cannot be towards improvement. We have, it is true, given them roads, hospitals, schools, and, in some places, irrigation works, but it may be doubted if in these things they have a compensation for the propagation of arrack shops, petty courts, additional taxation, and other things. If we have given with one hand we have taken with the other, and the tale that is told by old men in agricultural districts is not one that is pleasant to hear. They tell us that in the olden time there was less money but more food for the people, and certainly less crime, as witness the huge jails that have cost the country so much during the last twenty years.

In a matter like this, we should think judgment would be formed, not merely on what ignorant pleasants say but on what intelligent observers know to be, the fact. From the first days of British rule in Ceylona Minutes of Government and the proceedings of a long series of agricultural societies show that strenuous efforts were made to improve agriculture and the condition of the farming and peasantry classes. It was in their interest chiefly that compulsory labour was abolished, only the British went too far and found it necessary to retrace their steps in favour of rules for the restoration and upkeep of irrigation works and the formation of thoroughfares. In favour of the agricultural population, Government abandoned its share of all products excepting grain, and at this moment measures are in progress to render the collection of the grain tithes as light as any tax can possibly be. We have given the country roads and railways and improved river, backwater and canal navigation, which have cheapened to the agricultural classes the commodities they had to purchase, such as salt saltfish, cotton, cloth and household requisites, while those means of communication and the presence of coolies on estates have enhanced the value of the grain, straw, vegetables, fruits and "native coffee" which the cultivators had to sell. Is all this nothing? Then, as the above writer admits, we have given them "hospitals, schools, and in some places irrigation works" What he ought to have said is, that, besides the immense benefits derived from hospitals and schools by the people of Ceylon, the British Government have gone far ahead of what native enterprize and industry are prepared to follow in the restoration of irrigation works. There, at Kantbalai and so many other places are the tanks, the precious water stored and the fertile soil "under the tanks" waiting to be awakened into laughing fertility. The hour has come, but where are the men? Vegetating on badly tilled or worn-out ancestral fields, without the courage to go ahead and better themselves, but ready enough to aver "the former times were better than these" and that their depressed condition is all the fault of the British Government which has scattered "petty courts" over the land. If Police Courts and Courts of Requests are referred to, all we can say is that for a European to recognize their greater numerical existence as a grievance is about as curious a phenomenon as the recent green colour of the sky at sunset. In the reports of the Parliamentary Committee which followed the so-called rebellion of 1848, no point of reform was more insisted on than such additions to the Civil Service as would render any of the inhabitants of Ceylon unable henceforth to say, what many then said, that in the whole course of their existence they had never seen or come in contact with a member of the ruling race. Can the British Government wash the Ethiopian white? They cannot, and, therefore, in accordance with the policy recommended after 1848, as many educated white men as possible were scattered over the land. Have none of them striven to improve the condition of the agricultural classes by introducing superior products, such as Carolina rice, and also improved appliances, such as fanners? We think we heard of such things and of the opposition of dead, passive native conservatism. The people do not know much of the Proverbs of Solomon, but they evidently have an equivalent one to that which deprecates meddling with those who are given to change. Being orientals, too, it is only natural that they should not consider any amount of better government or social benefits, equivalents for "additional taxation and other things." If the condition of the native agriculturists of Ceylon is depressed, it is most unfair to throw the whole blame on Government. European agriculturists in Ceylon are in a depressed condition, although all that enterprize, skill and industry could do, they did. Native agriculture has to some extent sympathized with the cognate European pursuit. But can the writer we refer to say of native agriculturists what we have said of the Europeans? When the native husbandmen have done all that enterprize, skill and industry can accomplish, then will be the time to give them all our sympathy and throw all the blame on Government.

RUBBER-HARVESTING EXPERIMENTS IN CEYLON.

The cakes of rubber sent to us by Mr. Westland from Lower Haputale (see his letter page 450)—are not so satisfactory in appearance as others sent to us and are pronounced by an expert not quite so good as Madagascar or Borneo rubber, and, though clear, the rubber is sticky and has not sufficient elasticity; it is difficult to give a quotation, but probably these cakes would be worth as much as Assam rubber, say 2s a lb., or at most 2s 6d. Ceará rubber, in the opinion of this gentleman, is the only kind worth cultivating now.

The eighteen cakes sent by Mr. Westland weigh no more than 2½ lb, and, if each cake took a cooly half-a-day to collect, it is clear that the harvesting will not pay! The 18 cakes at outside are worth only R3, putting exchange against all other charges from the gatherer's hands to the London market;

while nine days' labour of a cooly must be R3·50 and even if of a "podian" (a boy) R2·25. We have no doubt, however, that with trees more advanced in years and further experience in harvesting, the return and quality of the rubber will be more satisfactory. Meantime, experimentalists should carefully peruse the mass of useful information collected in the little work on "Indiarubber" published at this office.

SUGAR-PLANTING: CEYLON PLANTERS IN NORTHERN QUEENSLAND.

The following extracts of a letter, from one of a trio of Ceylon planters who recently went to try their fortunes in Queensland, will be of interest to our readers:—

Seaforth Estate, Lower Burdekin, *via* Bowen, Queensland, 20th August 1883.

The Burdekin is to be a very favorite district, and large acreages are being opened up. What strikes one from Ceylon is the fearless way in which capital is being laid out, compared with our reduced expenditure of late years. The sugar plant is in full operation, crushing in Airdmillan. We are just getting ready for the plant to arrive here in the course of ten days, and Mr. Young expects his within a couple of months. Meantime Airdmillan is the only factory in working order on the Burdekin. They have somewhat over 1,200 acres under cane there, while there are 600 acres here and the same breadth at Kalamia. Mr. Macmillan has several mills of tramway and a locomotive at work—while the Seaforth line joins that of Airdmillan and the first 100 acres of cane are being sent by rail to the Factory at the latter. It seems almost idcredible the amount of work that has been done on some large properties during these past two years. I must say the prospect fully warrants the iberal expenditure. The appearance of the young fields of cane is simply magnificent and the yield per acre and density of juice is beyond expectation at Airdmillan.* I hear of further extension and probably a second factory there. The two great immediate wants are railway communication and a steady supply of coloured labour: you know the latter is a burning question. It seems to be the general impression that the stand against Indian labour cannot hold much longer. The sugar industry is getting too strong for its wants to be ignored. The working classes need be under no apprehension of the cooly pushing them out of the field. There is much skilled labour for which the Indian cooly is totally unfit, while on the other hand their importation would lead to the opening out of large tracts of fertile country, thus at the same time offering employment to really good European labour—but of all these questions you have a much more intimate knowledge than I can pretend to as yet.

There is no question but that Queensland has very great resources which only want a secure supply of labour to attract capital to their developement.

Both myself and my two friends like the colony and the work very much. There is a contrast to Ceylon in very many ways, but I think it is more the less pleasant. If one has any energy, this is certainly the country to develop it—and it is equally *not* the country for the helpless young man.

* We "assisted" at an experiment, when 11 per cent was shown.—ED.

TEA ROLLERS.

[After writing the article which appears on page 429 on Tea Machinery, we noticed the following account of rollers in the *Indigo Planters' Gazette*, in which Mr. Lyle is mentioned.—ED.]

In a former issue we took up the subject of Dryers, and we now propose to give Rolling Machines a few words. The best known of these are Jackson's Excelsior, the Cross-Action, Kinmond's Centrifugal, Haworth's Bag Roller, Nelson's Bag Roller, Lyle's modification of Haworth, and Thompson's Challenge, comparatively new and unknown in Assam and Cachar. Opinions of planters are bound to vary, and a little partisanship is sure to exist where there are so many machines to pick and choose from, but to judge from the numbers used on different factories is probably the fairest test. Jackson's rollers stand out prominently, possibly Haworth's and Lyle's modification come next, these may be counted as one, and then Kinmond's follows. The opinions of experienced planters would seem to point to Jackson's Excelsior as the coming machine, and there can be no doubt to look at it, it has more engineering talent displayed in its manufacture than any of the others. Its simplicity, too, strikes any one as a strong recommendation. We do hear that it rolls fine leaf, but this is what all rolling machines do, and although some of them make a little better work than others of coarse leaf, yet the results with coarse leaf are not up to one's expectations. The Excelsior is a comparatively new machine, and until last year very little was known of it; but we have never heard any one say anything worse of it than what we have stated above about fine leaf. The Cross-Action is an old favorite, and seems to do excellent work with both classes of leaf, and some prefer it to the Excelsior. The quantity these two machines turn out *per diem* is about the same, and in writing about them are influenced by no partisanship, but are merely expressing the opinions of planters whose judgment and experience entitle them to be heard. So far then the "Excelsior" and the "Cross-Action" give about the same results, unless of course very coarse leaf is plucked, in which case Lyle's modification of Haworth's would appear to have the advantage. It is absurd in planters to expect a rolling machine to roll all classes of leaf and get good results, because the pressure required to bring the coarse leaf into shape, destroys the fine young succulent pekoe tips; but if leaf is plucked separately, the best results may be obtained by using perhaps two different rollers, one for coarse and one for fine. From what we have heard of Lyle's machine, we should be inclined to think that its strong point lay in manipulating coarse leaf. The ingenious method of gaining pressure suggests the idea that whatever goes in might, if required, be reduced to a pulp. Of course there is the drawback that the leaf has to be put into bags to be rolled, and there is the continual wear and tear of bags, but this we do not fancy amounts to much. Of Haworth's machine we have heard much the same accounts, except that in its case again crops up the question of fine and coarse leaf, and that it rolls fine leaf better than coarse. Of Nelson's rolling machine the accounts that have reached us are not very encouraging. It is complained of as taking up too much space, and as not giving very good results. We understand the Patentee made some alteration in the driving gear, placing it under the machine so as to save space but that it was not a success. However, we believe that he is bringing out a new machine to roll without the use of the bags, and which will take up a small space, so that no doubt, if it is a success, it will increase in public estimation. Kinmond's machine according to the verdict in the case, Kinmond *vs.* Jackson, was the original that gave Jackson all his ideas from which, from time to time, he has improved upon until the Excelsior and Cross-Action have been evolved. In order to keep pace with his rival, Mr. Kinmond has kept altering his table until he arrived at the Centrifugal, which is, we believe, the latest improvement, or at least thought to be so. As far as we can learn the Centrifugal has not been the success predicted, more especially the large-sized one. The small size with fine leaf, so far as we can learn, gives fairly good results, but planters complain of the large size. The chief complaint we have heard has been that it tumbles and bruises the leaf, instead of rolling it, and that too much leaf is put into one charge, and in consequence gets very much heated; besides, when discharged from the machine, the cold air it meets gives a check to fermentation, and in consequence deteriorates the quality in cup. Of the small one we have heard very good accounts indeed, with the one saving clause that it must be *fine* leaf; but as we said before, this is an essential in almost all the machines. Of Thompson's Challenge we know nothing, the testimonials attached to the prospectus read well, and the price of results are good; these should be an attraction. In summing up our evidence these two points must strike the reader as the opinions of the planters, namely, that most of the machines will only roll *fine* leaf well, with the one exception of Lyle's, which would appear to roll coarse leaf best, so that, where a factory can afford it, the best policy would be to pick out one of the many others to choose from, and also Lyle's, provided the coarse leaf can be plucked separately. It is no fault of any of the machines that fine and coarse cannot be manipulated together. It must be apparent to any one, even who knows nothing of tea manufacture, that a coarse leaf must require more rolling and crushing than a fine sort succulept leaf, and that the latter must lose by overdoing. We believe it costs more to pluck separately, but we should suppose the increased value for the tea would more than compensate for the extra price paid for plucking. We therefore say pluck and manufacture separately. [But surely the two descriptions of leaf can be separated in the store and rolled separately?—ED.]

TEA.

SEASON, 1883.

The anxious question which is now revolving in many a shareholder's brain is, are we to get a dividend or not this year? So far the season has been an unusual one, and we cannot say a favorable one. It began with a severe drought and was followed by a flood in May, and then successions of sunshine and drought until it culminated in August and September with a mild flood again. This refers principally to Cachar and Sylhet although other parts of the Province have suffered from the excessive rainfall and attendant cold weather, yet we do not think, from what we have seen in the daily prints, that it has assumed the characters of a flood in any but those two districts. In looking at the *Assam Gazette*, however, it can be seen at a glance that the rainfall has been more than ordinary and the weather cold and bleak, causing a great deal of sickness amongst the coolies and retarding flushes, in fact not only retarding them, but rendering them less succulent than usual, and consequently injuring the freshness and pungency of the liquors. A prominent feature this year at the public sales has been the comparative neglect of Cachar Teas, and to some extent Sylhet as well, and we wonder if this is to be accounted for by any other reason than what he have seen the brokers putting forward? The flushes this year have been more than ordinarily heavy when they did come, and in consequence the planters could not manipulate them properly, or was it due to atmospheric changes? We are inclined to think that both have something to do with the matter. Owing to the cold weather which accompanied many of the periods of raintall this year, the leaf became especially leathery and consequently required a harder roll than usual, and we imagine that this was just what planters were unable to give it owing to the excessive quantity which came into the factories to be manipulated, for we are informed on good and reliable authority that in some of the heavy flushes this year some planters had just double the quantity they had ever been known to work off in one day. Then we must take into consideration that withering, a most important item to be taken into consideration, was carried on under most trying circumstances, and in a great measure artificially, owing to the low temperature that prevailed, and to this probably as much as the large quantity to manufacture is, we think, due the deterioration in quality complained of in Cachar and Sylhet Teas. The fag ends of large flushes, if we may so term them, have come out very slowly, and in consequence have lost a great deal of their succulence, hence the rolling cannot be carried to such a pitch of perfection, and the heavy pressure required to be put on to break up the cells naturally destroyed the appearance of the tea and although there may be no coarse plucking, still gave a larger proportion of low class brokee than under ordinary circumstances might be expected from the same class of leaf, provided it was young and succulent. We do not consider that the fault lies with the planters, and we are glad to note this year that Brokers themselves do not lay it at their door. This is a step in the right direction. But to return to the question with which we started, are shareholders to get a dividend this year? We answer in the affirmative, with this reservation, provided that care and economy are component parts of the management both locally and in Calcutta. Last year a good many gardens and a few companies, not always the most favourably placed, paid fair dividends with tea fully an anna lower so that even with a little deficit in quantity we do not see why the dividend this year should not be better, as five rupees per maund advance in price represents per acre, at a low estimate, 15 rupees, that is to say 3 maunds per acre. Now most gardens do not carry more than 500 rupees per acre capital, so that a rise of one anna per lb. means a dividend of, on an average, 3 per cent. In coming to the conclusion that the profit this year should be more than last, we do not think that we are taking an over-sanguine view of the matter at all, even taking into consideration that the quantity may be a little less. Taking the whole of the crop of Indian Tea. we do not think, it it will be less, but we are speaking individually of gardens, for what the old gardens fail to make, will be fully represented by young ones coming into yield for the first time, and by extensions made in connection with old estates. We therefore think that the Shareholder may safely look forward to a dividend this year, more especially if he pocketed one last year, for we do not anticipate any collapse in the market such as took place last year, although we do not anticipate any greater rise in values.—*Indigo Planters' Gazette*, Oct. 26th.

ECONOMICAL USE OF MANGROVE BARK.—The *Straits Government Gazette* announces that whereas Frank Gumm Bernard, a trader of Singapore, has filed in the Colonial Secretary's office a specification of an invention entitled "an invention for manufacturing Cutch from Mongoor or Mangrove bark," His Excellency the Governor in Council has, under his hand and the public seal of the Colony, granted to the said Frank Gumm Bernard the exclusive privilege of making, selling and using the said invention for the term of fourteen years from this date. The specfication may be seen at the Colonial Secretary's office, on payment of the usual fee.

THE OOTACAMUND GARDENS.—Mr. Lawson, the Director of Government Parks and Gardens, has drawn the attention of Government to the great improvement which would be made in the general appearance of the Ootacamund gardens were the lawns properly levelled and thereafter regularly mown. Government having coincided with the Director's views the levelling will be carried out, and an indent is to be made on England for the necessary mowing machines. They have also approved of another of the Director's propositions, that an experimental kitchen garden be started, where those vegetables which have not hitherto been found to thrive on the Nilgiris might be given a fair trial. An extended system of meteorological observations is also to be organized, an indent being made on England for the necessary instruments. The Director further recommends that, for the information of those who might feel interested in the subject, the meteorological results might be daily placarded in some prominent place at the gardens, such as the entrance gates.—*Madras Times*.

CAN COFFEE BE GROWN IN SINGAPORE?

One of the most noticeable features in the history of these Settlements during the last ten years, dating, in fact, from the arrival of Sir Andrew Clarke amongst us, and the inauguration by him of new ideas as to the position and duties of Government towards the Settlements, and more especially towards the Native States on the Western slope of the Peninsula, has been the development of planting enterprize in the Straits. The misfortunes of Ceylon in its coffee industry aided in this development by sending abroad a number of Ceylon planters in search of "fresh fields and pastures new". How far, from a mercantile point of view, planters have been successful, it is impossible to say, and is a matter of considerable doubt. Tapioca planting has been a great success, of which we have a striking instance in our midst in the Chasseriau estate, due entirely to the energy, perseverance and skill of its proprietor. Yet this success has not been unchequered by misfortune, and is now materially modified by the great fall in the price of tapioca. The Chasseriau estate, moreover, is about the only instance that is generally known as a success. How other planters have succeeded is not known, and their reticence on the subject is remarkable. Some years ago large blocks of land were taken up in Johore for coffee and tea planting, and we know that a Planters' Association exists in the territory, yet what their experiences have been so far can only be conjectured. Yet it is a question of considerable importance whether tea and coffee can be grown in the Straits. Both have been tried in Singapore. Tea is, we are afraid, very doubtful, but coffee may succeed. Our enterprizing townsman, Syed Mohamed Alsagoff, Esq., for example, has, it is said, a small but flourishing coffee plantation at Bukit Tungal, in Thomson Road. Mr. Chasseriau has about 60 acres on his estate planted with Liberian coffee, and asserts with French energy that he is going in ten years to revolutionize planting enterprize on the island by showing how coffee can be planted with success and with great profit, and we can only hope that he is right, not only for his own sake, but for the sake of planting enterprize generally in the Straits.—*Straits Times*, 27th Oct.

PRUNING FRUIT TREES.

The principal use of pruning is to preserve the symmetry of the trees, though in closely planted orchards it is necessary to prune to keep the trees within bounds. Pruning for either of these reasons is easily accomplished, but there are other reasons for pruning which only the man of experience and scientific acquirements can properly understand. Supposing an ordinary pruner was sent into an orchard to prune, his endeavour would be to carry out either or both of the abovenamed purposes, and he would therefore probably prune the hardest those trees that had made the most wood, and leave unpruned or lightly pruned those that had made little or no wood; while the man of experience would be likely to act in a directly opposite manner; he would be aware that the trees making the most growth were the least fruitful, while the others had probably borne more than they could bring to a first class condition. His object, therefore, would be to reduce the bearing propensity or power of the latter, and by the same means increase their power of growth; while in regard to the former he would endeavour to check their exuberant growth, and induce them to become more fruitful. The over-prolific trees he would prune hard, thinning out a large proportion of the fruit-bearing spurs, by which means the supply of sap the roots were able to send up the following spring would be less divided, and each remaining bud would receive a larger share than it would have done had the whole of the buds been allowed to remain and claim their share. The result would be that each bud, having received an extra supply of sap, would make stronger growth and more foliage than before; the leaves, by reacting upon the roots, would cause a great extension, and so the vigour of the tree would be increased; the enlarged number of roots sending up a constantly increasing supply, both shoots and fruit would benefit thereby. That such results would be obtained may be seen whenever a tree, whether aged, decepit or young, is headed down; the superabundance of nourishment, finding a limited demand, becomes used up in the formation of wood of vastly increased strength, while any fruit there may happen to be is proportionately enlarged. In this climate the fruits of cooler countries are forced, as it were, by the, to them, unnatural amount of heat and light, into a condition of precocity, which, if not checked, must necessarily end in weakness; the endeavour should therefore be to counteract the tendency to precociousness and maintain the tree in a well-balanced condition, producing no more fruit than it can bring to full maturity, and a due proportion of wood for the maintenance of that condition—a suitable and properly cultivated soil, with due supplies of manure, being, of course, understood. The difficulty of attaining the desired result is sometimes greater in the case of an over-luxuriant, and therefore partially or quite barren tree, than in the opposite case, especially when it happens to have an unlimited root run. Trees in such a condition not unfrequently continue to receive the usual amount of pruning year after year, thus producing such an exuberance of sap that blossom buds cannot be formed, except on a few weak and pinched spurs, and increase so slowly in number that it requires many years before the tree is brought into a full-bearing condition; whereas, if such a tree is left altogether unpruned, it would certainly become fruitful either the next or the following year. The aim, then, should be to maintain a fair balance between the production of wood and fruit, and if the nature of the variety to be operated upon is known, a scientific pruner can soon establish, and afterwards maintain his trees in that condition, by checking over-luxuriance, and encouraging the formation of fruit buds, or the contrary, as may be necessary. Much good may, in many cases, be effected in checking over-luxuriance by summer pruning, for if the young growth of the most vigorous tree is continually stopped, its vigour will presently be reduced, and even its health may be impaired, if the process is carried to an extreme. Summer pruning is generally neglected, partly from ignorance of its good effects, and partly because orchardists have little leisure at that season. It is, however, of great value, especially in the formation of useless wood that has to be cut away at the end of the season, and increasing the strength of that which has to remain.—*Leader*.

THE NORTHERN TERRITORY OF AUSTRALIA.

Our correspondents write hopefully of the revived prospects of the Northern Territory in view of the passage of the Palmerston and Pine Creek Railway Bill. The pastoral and agricultural industries are growing in importance, and mining operations are still successfully conducted, though want of water through an exceptionally dry season has somewhat retarded them.

We learn from Captain Green, of the China mail steamer "Tannadice," that his vessel brought to Port Darwin on her last trip from Hongkong a buffalo bull, three cows, and a calf, sent by the Indian Government to the South Australian Government, and consigned to the Acting Government Resident at the Northern Territory. The cattle were in charge of three "ghee" makers, hailing from Cawnpore, and their purpose in proceeding to the Northern Territory is to introduce there the "ghee"-making industry, which the leader of the party tried with slight success in Victoria some time ago. "Ghee" is a kind of butter in great request in India amongst the natives, but it is said to be not a great favourite with Europeans. Whatever the ultimate prospects of the industry in our northern country may be, its inauguration was satisfactory enough, as the cattle were landed in capital condition, and the keepers were in good health.

The Government are making early and active exertions to carry out the construction of the railway works recently authorized in the Northern Territory. —*South Australian Register.*

PLANTING PROSPECTS IN NEW GUINEA.

The *Argus* special correspondent, Captain Armit, in his latest letter, dated Wabadam, July 27th, has the following:—Entered the village of Wabadam, of which Boiori is the chief. Time, half-past 12 a. m.; 1,550 feet above sea-level. The rain stopped about 4, and gave us a chance to shoot and collect fungi, ferns, and plants. I inspected the gardens, and was astonished at the luxuriance of the crops. Cane 16 feet high, Bourbon ribbon, and I believe Scott's cane or Otaheite, a small yellow sort; bananas in full bearing the large bunches tied up in leaves; bread-fruit trees (Artocarpus incisa) 50 feet high, and plantations of small trees of all sizes; taro, whappa, a very large leaved species of arum, yams, sweet potatoes, tobacco, pumpkin—all were growing here in profusion. The tillage also is superior to anything of the kind I have yet seen in the island. The weeds are kept down, and the soil well and deeply worked. In clearing the land the graceful palms have been spared, and add an element of beauty to the scene as they raise their graceful fronds 70 feet to 100 feet above the plantations. The country to the south of Wabadam is open forest with isolated hills and ridges strewn over its surface. The natives do not cultivate these flats. The soil is too hard, and would require heavy labour before it could be utilized. The scrub soil, on the contrary, is always moist and loose. It is easily worked after the scrub has been cleared, and remains light and friable. The people of this country have no conception of the capabilities of the soil. They grow more than they want, and this suffices. Were these lands in the hands of European planters we should soon be astonished at their productiveness. Sugar, coffee, arrowroot, cinchona, cocoa, ginger, vanilla, rice (mountain), and a host of fruit trees could be admirably grown here. Ceylon has been almost ruined by the coffee leaf-disease (hemilia vastatrix), and many planters have been inquiring in Queensland for land suitable for coffee growing. Here they will find not only land of the best quality, but also labour at their very doors. If these people are kindly and honestly treated they will work, and work willingly and well for the Britauiata, as they call us. But England must take the utmost care that, in purchasing the land, the present proprietors receive a fair value for it. If, after a few years, they find out that they have been swindled, there will be serious trouble. They will soon obtain firearms and learn how to use them. Then they will not prove contemptible foes, especially as they have quite sense enough to join together and make common cause. I do not desire to dishearten intending settlers, but everyone should know what the people are like, and that in coming to New Guinea they will find an agricultural race, owning the soil and perfectly aware that they do own it—not a race of unfortunates like the Australians, who, after having been robbed of their land, were left to perish of starvation or ruthlessly shot down for daring to hunt over their own soil. The country to the north of Wabadam is all ridgy, scrub country, rising gradually into Mount Lawes, to the N. W., and extending to the flanks of Mount O'Bree, 20 miles distant E. N. E.—every inch of it magnificent land. At a distance of three-quarters of a mile, and bearing N. by E. ½ E., stands the village of Ottowano, 25 inhabitants. The people of both villages belong to the Tabouri and Sogere tribes, who live together on the territory of the former. This is a good omen for the future settlement of the island. A few years ago these two tribes were deadly enemies.

I saw no breccia today, the rock being all trap. Palms are very numerous and graceful. Bread-fruit and okari trees abound everywhere. Fungi especially are to be found in the native gardens on the fallen and decaying timber. The edible fungus I found in company with Professor Denton, as well as a host of other most interesting forms. The former is eaten in New Zealand and also in China, to which country it is exported. It belongs to the genus Ileodictyon. Altogether, I do not repent staying here this afternoon, as besides fungi I obtained several fine crotons, all growing in the village.

I shot the smallest parrot today that I have ever seen. It was not more than two inches-and-a-half in length, of a beautiful green, excepting the upper tail, coverts, and lower portion of back, which were of bright scarlet. Belford tells me there is yet a smaller one in this country, and common. Raspberries are common here, but very insipid. Mr. Denton found a strawberry in the scrub, and—ate it! He also picked up an acorn. It is very much larger than our English acorn, and not so long. Wild pigs are very fond of them, and the ground under the trees is rooted up in every direction.

Cycads are very abundant throughout the country I have seen. The Papuans macerate the nuts in running water for three days—using a net bag for the purpose—and then pound them up into a sort of damper or cake, which they bake in a stone oven. This bread is very good and clean, very different from the disgusting compound made by the natives of Northern Queensland. Belford sowed a few Chili seeds here in the hope of obtaining a few ripe fruit some day. I notice that the native names for the different birds resemble the bird's call as nearly as possible. They will imitate this so cleverly that even the bird is deceived, and can often be brought close up to the gun.

INDIAN GOLD MINING, AND ITS PROSPECTS.;*

QUARTZ OUTCROPS OF TRAVANCORE.

(*Continued from page* 44.)

In order to trace more completely the comparison between the lithology of the auriferous zone of the Wynaad and those districts of Travancore which I visited, I shall once more direct attention to what I have quoted from the commissioners' report of 1832 (Art. II., M. J., p. 518)—"that the superstructure consist of sand and gravel, below which are large nodules of quartz and gneiss." Now, in many parts of Travancore, where the soft gneissic rock occurs, there are beds of quartz sometimes 2ft., 3ft., or even 6ft. in thickness, having interspersed throughout their mass here and there crystals of felspar, in a state of decomposition. Further, these beds having been for a considerable period of time exposed to atmospheric influences, as well as tolerated aqueous solutions, have had the more easily decomposable portions of their walls—which consisted principally of felspathic and ferruginous compounds—washed away by the periodical monsoon rains, leaving crevices which have afterwards become filled up by the earthy materials resulting from the decomposition of the gneissic rock in which they are embedded. Such beds occur on Ballamore, Kildonan, and Ballochbuie estates. One of the Ballochbuie beds I caused to be opened to a depth of from 4 to 5 feet, and had some of what appeared to be the purest and most compact part of

* By J. Macdonald Cameron, Fel. Inst. Chem., F. C. S, &c. tao Assistant Chemical Laboratories, Royal School of Mines.

the quartz bed blasted. This revealed a beautiful thin vein of mundic from 1 to 2 in. in width, and alongside of its quartz matrix a vein of iron ore about 1 ft. in thickness, largely impregnated with crystals of the arsenical mineral. Some of what appeared to be the purest specimens of it, as well as the quartz matrix in which it was found embedded, were assayed in my laboratory, and showed appreciable quantities of gold.

What may be the lithological composition of the highest of the Travancore Ghauts I cannot precisely say, as my instructions kept me quite within the spurs, but the most elevated of those rock masses which I examined are most certainly a very quartzose form of gneiss, and at this rock and its homologues—quartz rock, mica-schist, and clay-slates—most usually accompany the older igneous rocks, I have come to the conclusion that the highest and more barren peaks of Travancore, like those of the Wynaad and Neilgiri ranges, are probably granitic. Gneiss rock then in its several varieties may be said to be the rock *par excellence* of Travancore. In the southern portion of Assamboo district, in the neighbourhood of Retreat, Little Valley, Glenmore, Glenbeg, Corriemony, Seafield, Ballamore, and Hillside estates, and along what is locally known as the Great Valley, we have the more compact and quartzitic variety largely studded with the common garnet, and less of the quartzose form; but from the Great Valley northwards along the district road to Agustier, Glenelg, Bon Accord, and Oaklands estates, and further through Merchiston, Ballochbuie, Strathmore, and Glenista onwards to Invernettie estate in the Kulratti district, those two leading varieties of gneiss rock alternately predominate. Occasionally, however, there are found the other rocks of the metamorphic series—mica-schist and clay-slate. On the opposite side of the great gorge, travelling from Oaklands bungalow to that of the estate conductor at Kildona, there is a most remarkable instance of sudden transition from the quartzose form of gneiss to the fine grained and light yellowish fissile and quartzitic variety which so much resembles hard compact sandstone. As the ravine is entered there is a bold escarpment of the quartzose variety several hundred feet in height, with an almost horizontal dip, which rapidly increases until as the quartzose characteristics are lost, and the bungalow is approached, the beds become almost vertical.

The mica-schist group, I did not find largely represented, but it crops out in some of its varieties, such as chlorite and hornblendic schists to a greater or lesser degree at Auldbar and at certain points along the district road between the latter place and Invernettie estate. On the left front of the superintendent's bungalow at Auldbar there are interesting outcrops of this group. As might be expected in a country where the metamorphic system of rocks is so well represented as in Travancore, the minerals which usually accompany it would also be present in a corresponding degree. Thus talc, hornblende, chlorite, and actynolite, and several varieties of felspar may be met with in almost any portion of the country from Invernettie in the north to Mahendrigherry in the southern portion of Assamboo district; but what struck me most was the size, beauty, and variety of colour of the felspars; some of them passing from the dull yellow of the orthoclasic variety to the pale green of talc. Indeed were it not for the softness of the latter mineralsome of the Travancore felspars might readily be mistaken for it, especially in cases where the outlines of the felspathic crystals are not very clearly defined. Magnetic oxide of iron is not only present in abundance in the metamorphic rocks of Travancore, but it may be seen to even a greater extent in the coffee soils on the mountain slopes, as well as in the soils of the low country and along the road sides after a shower of rain. In walking along the sea-shore at Colachel, and watching the waves of the Indian Ocean break upon their sandy beach, I was much struck with the very great quantity of this mineral, which in wreath-like masses became exposed to view as the waters of each spent wave receded to their briney source. Graphite or plumbago, which is one of the most valuable minerals belonging to the metamorphic system I have also met with. In the low country in the neighbourhood of Trevandrum, the capital, I am informed that there are very satisfactory and extensive beds of this substance, and samples alleged to have been taken from some of these beds I have had submitted to analysis in my laboratory, and found them to be of first-rate quality, as indeed their appearance indicated.

Having now briefly noticed the geological and mineralogical characteristics of the Wynaad and Neilgiri districts, and so far compared them with those of Travancore, I shall proceed to notice the quartz outcrops of the latter country so far as my survey of it enables me. What I have quoted from the several reports already mentioned shows that the greater portion of the rocks of the Wynaad, Neilgiri, and Travancore districts of India belong to the metamorphic system, and when it is considered that this system embraces the gneiss, quartz-rock, mica-schist, and clay-slate groups, and that I have shown in the preceding articles that the former group greatly abounds, and the two latter to perhaps only a small extent in Travancore, it might reasonably be expected as a consequence that somewhere in that country the quartz rock group, as well as quartz veins, would be found. As previously noticed such actually is the case.

Retreat Estate.—First then in Assamboo district, at the northern extremity of Retreat estate, which belongs to Mr. G. Thornhill, and above that point where the main river which forms its western boundary is joined by one of its principal tributaries, there have been laid bare by the rapid river currents which obtain during the southwest monsoon period, several masses of syenitic rock along with beds of a reddish brown ironstone of apparently poor quality. Nearly at right angles to the direction of the river course there intersects the upper masses of syenitic rock, a band of quartz about 7 ft. wide, and which at its sides is impregnated with large crystals of felspar; these crystals increase in quantity as the quartz mass loses itself in the syenitic matrix. Its strike is N.W. and S.E., and it narrows to a width of about 2 ft. as it loses itself in the jungle, which is on the western side of the river. It has been traced for a distance of about 10 yards, and its dip, as far as I could ascertain, is nearly vertical, the felspathic constituents which, as already noticed, are largely present in that portion which is exposed in the river bed become fewer or disappear entirely at the point where it enters the jungle. Were it not for this fac it might be mistaken for a vein of graphic granite. About 15 yards below this point, or near the junction of the tributary with the main stream, there is another outcrop of quartz from 1 ft. to 2 ft. in width running through what appears to be the same syenitic rock, striking in N. W. direction, and having like the one already noticed an almost vertical dip. A few yards below the junction of the two streams there intrudes another vein of pure quartz about 1 ft. to 2 ft. in width, striking N. W. and S.E., and throwing out a branch or leader of nearly similar dimensions, which takes an east and west direction, and has also a nearly vertical dip; and a little above this again another vein is exposed for a distance of about 12ft. running east and west and having a bluish-pink colour. The first and second of these quartz outcrops where blasted to a depth of 12in., and selected samples roasted and treated with mercury at Colachel, when small quantities of gold were found in them. Several of the remaining pieces of quartz, by no means the best, were taken home by me and submitted to assay in my laboratory, when they were found to yield quantities of gold varying from 1 dwt. and 1 dwt. 8 grs. to 2 dwts. per ton. Besides this I ought to mention that I came across a chip from one of these quartz outcrops that showed very minute specs of tree gold.

With the exception of the first mentioned of the several outcrops of quartz on this estate all the others appear to be true reefs or veins, and although their width is not so great as the majority of those now being worked in the Wynaad, it has yet to be proved that they would not be found to increase in size were they traced further downwards or in the direction of their dip. It has besides occurred to me that possibly—nay, even probably—they would be found to be leaders to a much larger vein in their vicinity, though the time and the means at my command prevented my making excavations of a nature which would tend to show the truth or fallacy of this opinion. I may mention that the rocks associated with these quartz outcrops have not that distinctly fissile or even stratified appearance which is possessed by the different members of the several groups of the metamorphic series, nor where the lines of stratification can be defined do the quartz veins, except in one instance, run parallel with them. Further, the quantity of gold obtained per ton, though small, is no evidence that were the examination pursued to a greater depth more satisfactory results would not be obtained, and when it is remembered that these quartz outcrops have been exposed to the denuding action of the river during an untold number of monsoons and that the atmosphere has been performing its work of degradation for an equally long period of time, we need not wonder that at a depth of 1 ft. from the surface the samples of quartz obtained failed to yield a greater quantity of gold than 2 dwts. per ton.

Ballamore Estate.—Leaving Retreat estate and passing north-wards the next outcrop of quartz which I met with is on the estate of Mr. P. Grant, at Ballamore, where it showed itself in the soft quartzose gneiss at the side of the road which passes through a coffee field to the north-east of the bungalow. From the great depth of soil which covers the under-lying rock its strike is difficult to determine. It appears, however, to run in a N. W. and S. E. direction, and dips to the S. W. at a considerable angle. It is distinctly bedded, and its leading characteristics have been already alluded to in this article when noticing the quartz beds of Kildonan and Ballochbuie estate. Mr. D. C. C. Grant, the present superintendent of the estate, had it excavated to the depth of a few feet, and took a quantity of quartz from it, but the crystalline structure, as well as the general character of the contents of this bed, were not promising.

Auldbar Estate.—In treating of the lithological characteristics of the Travancore I noticed that on Auldbar estate the gneissic group was well represented with here and there outcrops of mica-schist. This would suggest that the quartz-rock group which usually comes in between these two would also be present somewhere in this neighbourhood. So far as my examination went I found only one small outcrop, nor is there any vein quartz in these portions of the estate which I was enabled to examine. The outcrop of quartz to which I allude is exposed in a ravine which passes through the 23-acre field to the left of the bungalow, and which I have designated No. 3 ravine. It is about 9 in. wide, runs parallel to the lines of stratification of the gneiss rock, and loses itself in the coffee soil on each side the ravine. In none of the other ravines are there any outcrops of quartz but there is no reason whatever to suppose that it may not be found in those portions of the jungle bordering the estate which I am unable to examine, and up along the great valley through which the Auldbar River passes. *Chemical and Metallurgical Laboratories, Lime-street, E. C.—Mining Journal.*

THE PEERMAAD COFFEE DISTRICT.

A correspondent writes:—The following short account of a visit paid to the Peermaad Coffee District, Travancore, may be interesting to some of your readers. The coffee districts in Travancore are divided into South, Central, and North. Peermaad is the northern district, though there is one still further north, which principally belongs to the North Travancore Co. There are two routes by which Peermaad can be reached from Madras, or the West Coast: one *via* Erode and Ammanachenoor by rail. and thence by cart or transit, *via* Perreacollum to Gudalur, at the foot of the Peermaad Ghat. The ghat up is a short one, but is seldom kept in good order, and though carts do go up it, the intending traveller is advised to secure a pony for the journey from Gudalur. The other route is by rail to Shoranoor, and thence by cart or muncheel to Trichoor, from whence it is easy to reach Cochin by water. From Cochin it is a night's boat journey to Cottayam, and a cart road connects Peermaad with Cottayam. This is perhaps the better route, and certainly the more comfortable, while it has the advantage of taking the traveller through two such interesting places as Cochin and Cottayam; the former town so well-known for its Jewish colony, and the quaint look of its old houses, and the latter for its beautiful scenery, and being the head-quarters of the Syrian Church and the C. M. Society's Travancore Mission. Cottayam has a Planter's Club and a Traveller's bungalow, and is also the head-quarters of several native officials. Carts are easily secured from this to the foot of the Peermaad Ghat (thirty-three miles), and the journey is easily made in a night to the village of Mundekyam. The country was formerly a wild one, through which the road passes, and at one time swarmed with wild animals. but beyond jungle fowl I was informed nothing could be seen since the road had been opened. At the Mundekyam resthouse, a good view is obtained of the Peermaad plateau, and soon after passing the fine girder bridge spanning the Mundekyam river the ascent of the ghat begins. The trace has been well carried out. without a single traverse, to the top of the plateau, a distance of twelve miles. About a third of the way up, I noticed the remains of a deserted coffee estate, and for some miles there were the traces of several abandoned native estates. I passed. however, two fine properties before making the last rise to the plateau. Immediately after passing the last estate, a fine water-fall attracts one's attention, and a very pretty ride through heavy forest finishes the ascent. The Hope Estate was the first to come in sight, and was opened in 1861. It is, with its neighbouring estate (Woodlands) opened at the same time. still flourishing. though both properties have long since passed out of the hands of the original holders. A range of hills beyond the Woodlands divides the district in two. Six estates are situated to the north of the range (known as the Tambies) and make the Perreatora group, and about a dozen properties make the Peermaad group to the south of the range. Another group of, I believe, eight estates scattered in the valley of the Perryar make a still further division of the district. The estates everywhere in the three divisions appeared well kept. The soil looked light, and in parts gravelly and quartzy, in the Peermaad and Perreatora groups, and manuring had to be resorted to at an early age of the estates. As each estate was usually surrounded by good pasture land, the expense of keeping cattle was not very great, and manuring could be done at a cheaper outlay, than in other Indian coffee districts. As far as I could learn 500 tons was the most the three divisions had sent down to the coast in one season. The Perryar estates seemed more favored as to soil, and from the elevation and less rainfall, appeared better suited for coffee. While the average elevation of the Perryar group is about 2,500 feet, the other two divisions are at least 1,000 feet higher, and more exposed, and the average rainfall is about 150 inches, against 250 inches on the higher estates, but while Perryar is considered feverish, the higher estates are comparatively healthy, Planters, as in Ceylon, have not till lately paid attention to any other cultivation but coffee, but as coffee has not proved quite the steady paying investment it once promised, attention to other products, such as cinchona and tea, is being given, and one very fine tea property in the Perreatora group proves how well this product will do. Cinchona is still on its early trial, and I believe some estates were to be planted up between the rows of coffee with two or three varieties of it. The Perryar struck me as suited for cocoa. The tea estates I have mentioned is situated in a windy exposed part of the district, where coffee had partially failed, and yet was doing well, and had yielded, I was told by the owner, as much as 300 lb. of prepared leaf in the year, and yet better results were hoped for. Both on account of rainfall and soil, tea appeared better suited for the upper hills than coffee, which, after the prevailing high monsoon and east winds, I was informed looked often hopelessly "shuck," and often did not recover from battling with the winds in time for giving crop. Cardamoms seemed to grow well everywhere in the district, but owing to it being a Travancore monopoly, planters were nearly debarred from cultivating it. In the first place I was informed the cardamom crop had to be given up to an agent of the Travancore Government, and the planter received one-third of its market value. In the second place, the payment was seldom punctual, and planters were frequently not paid in full for mouths after the crop was weighed to the agent. The consequence is, the cardamoms growing in the belts and reserves of an estate were neglected, and what might under fairer treatment prove a help to estate-owners is scarcely looked on as a means of income. No doubt a proper representation to the Travancore authorities would secure better terms for the planters. Labour appeared plentiful and good on the estates I visited, and the cooly lines and buildings appeared to be all that the cooly could desire. Both sides of the hills furnish the labour used, and Tamil mixed with Telugu might be heard one minute, and the next Malayalam. Planters preferred the Tamils. The rate, I was given to understand, averaged about 4½ annas, out of which the cooly had to pay for his provisions received from the estate store. Estate products mostly went down the western ghat and were shipped from either Quilon, Alleppey or Cochin, but provisions mostly came up from the plains of Madura. The cattle on the estates seemed to me of poor breeds. On only two estates did I notice any well-bred cattle. I was told the monsoon was too severe for them to thrive, and that only West coast cattle or cross-breds could stand the heavy rains; that indeed cattle did not increase, the births not even keeping up with deaths, and that only by frequent purchases could herds be kept up to their full strength. Some estates were trying pigs and buffaloes, and for manure there is little doubt these animals are better than cattle. Most of the land in the district has been taken up from the Travancore Government. The land is first put up to auction and sold to the highest bidder, the original applicant very often being kept out of the purchase by competition. At the last sale of lands, as much as R70 an acre, I believe, was paid. This arrangement is hard on those who have at great expense and trouble selected a piece of forest, and some consideration and preference should in fairness be given to prospectors. For five years no tax is levied; after that grace, which is supposed to allow the planters to get a portion into cultivation, twelve annas an acre is charged per annum on both cultivated land and forest. A duty of, I believe, a rupee a cwt. is further charged, and taking the average crops of the district at three cwt. an acre the planter does not get off under (with interest on original purchase) four to five rupees an acre; a very high rate when what planters pay in other districts is considered. The Peermaad planters, however, have some *quid pro quo* for the highest rate they pay by having good roads all over the district, and there was scarcely an estate I visited that could not be reached by cart. I believe the last sale of land was in 1873, and since then no grant have been given, and it is the present intention of the Travancore Government to dispose of no more forest land. Perhaps it is a wise decision, as in one of the mosts flourishing district in the Province estates have in some cases been abandoned, and the Government is loser to the extent of the land tax, while the land probably never returns to forest again. At one time game was plentiful on the Peermaad hills, and the early pioneer must have a famous time of it among the sambur, bison and ibex but at the time of my visit there was little to shoot, though the reserve jungles looked likely fiends of game. Though it seemed to me the palmy paying days of the coffee were over in the district, the plucky efforts to introduce other products must, if successful, make it safer for planters, who have hitherto depended on but one product which, owing to leaf disease and other causes, was unrealiable. I trust the most sanguine expectation of my friends will be realized.—*Madras Mail.*

TEA is the most important manufacture in Chittagong and the Chittagong Hill Tracts. According to the administration report of the division for the year 1882-83, the number of gardens was 29, and the quantity of tea exported 1,030,927lb., against 810,390lb. in the previous year. Two rice mills have also been established at Chittagong, and appear to be doing a good business.—*Friend of India*

TEA IN THE MORAWAK KORALE, CEYLON.—We learn from a gentleman who recently visited this district for the first time, that nothing could be finer than the sheets of tea cultivation on Anningkanda, Campden Hill and some other places. On Campden Hill, the machinery was doing splendid work, a Kinmond's roller getting through the daily plucking (equal to 360 lb. of made tea) by an early hour. A great deal more tea will be planted in the district, and poor Le Cocq's grand coffee-store on Craven, with its fine water-wheel, will yet do good service as a tea-house. Alas ! for the change since '72, when we found Le Cocq erecting his machinery and the hill-sides a busy scene of coffee cultivation with encouraging prospects. The biggest coffee crop ever gathered in the district was by Capt. Bayley from Clesenberg, and, as that was equal to 6 cwt. an acre all over, it was very good and very profitable; but it did not last. In tea, Morawaka is likely to have a different history, we trust.

TOBACCO IN BURMA.—We heard a good deal some two years ago, of the steps taken in British Burmah to develope tobacco cultivation there. One Deputy Commissioner visited the hills, where the Karens are said to grow the finest description of the weed but to fail miserably in curing it according to Western tastes. He smoked a good deal on his trip, drew his travelling allowances we presume, and wrote a *couleur de rose* report on all he had seen. A plantation was started near Rangoon, and people were to be induced to bring there all the leaf they could grow, to be cured on the American plan. Instructions were to be given moreover, to ensure the best varieties only being cultivated. It was thought that as the steam rice mills had encouraged the cultivation of paddy, by purchasing for cash all that agriculturists or boatmen would bring to their mills, so a factory or plantation prepared to purchase whatever leaf was brought to it for cash, would largely stimulate the planting of tobacco. Has the project failed, that we hear so little about tobacco in Burmah at present? The local press is silent on the subject, and good Burmah cigars are as difficult to get as they ever were. The public both in and outside of Burmah would be glad to hear something of the results of its experiments in tobacco cultivation and curing, of which we were led to expect so mucht. What has been the result of the experiments and whan money have they cost? The wisest and cheapest plan in the end might be to offer a handsome premium for the first shipment of really marketable tobacco or cheroots, as has been done in Australia and New Zealand with other produce. The result of such bonuses in the colonies has been to establish several important new industries. We are not saying that the attempt of the Local Government has failed, but we should like to know something of the results of the experiments made.—*Friend of India.*

PLANTING IN THE TRINCOMALEE DISTRICT: TOBACCO AND CACAO.—Mr. H. H. Master writes from Lowlands:—"Thank you for sending me the 'Tobacco Leaf.' I see the paper speaks of a near future for Sumatra tobacco, especially as wrappers: I hope indeed it may be so. Sumatra tobacco has as yet done us but little good down here, generally from bad curing and not being planted out at the proper time, too late or too early making all the difference in the crop and season for curing. I am trying 8 acres this year, and hope with knowledge of previous mistakes made to succeed. I am glad to see in the *Observer* of the 25th Mr. Saulière speaks well of planting cacao between cocoonuts, as I am doing the same here and was uncertain whether the plan would answer, taking into consideration the space over which coconut tree roots spread."

UPPER MASKELIYA, CEYLON.—A light clear morning, after a spell of heavy wet, and the unmistakable keen and crisp feel of north-east weather. On such a day as this the climate of the Maskeliya hills is second to none in the world, the Blue Mountains of Jamaica and of Mr. Morris not excepted. I have been reading of the account of the Portrush (Co. Antrim) Railway, and it has set me thinking that we have in this district water enough to store electricity for the whole world. A single wire stretched from a 40 feet fall will generate force equal to a 26 horse-power steam engine. Let those whom it may concern make a note of this. (I wonder if science will ever use the tide of the sea as her motive power, at once as never failing and powerful as it is invincible.) Coffee is looking better again, and, with a dry season, we ought to do better next year than this. Not saying much perhaps, but all we ask for is crop enough to pay expenditure and enable us to plant up tea. Picking is merely a walk over now-a-days. Ah! for the brave and halcyon days of old Matale when the coolies could only get over five trees each per diem!—but then coffee stuck at 60s. Cannot you engage professor S. Baldwin as your special prophet, to prophecy to us on the coffee market? At present, for instance, it is surely a rising one, yet I hear of sales being made at R9 for the incoming crop. Now this is hardly good enough. As to cinchona, if its true value is only sixpence per unit, how is it the price of quinine keeps up as it does? Surely there is a "ring," and it is enough to make the planter anathemize the Milan Co., Pelletier, Howard, and all the many Jews and Gentiles employed in the manufacture of the sulphate, with a vengeance. About the most valuable large lot of bark ever exported left Maskeliya lately; its analysis averaged over 9 per cent, and its price just over 30c! A fearful snare this product has been altogether. This is the very year your worthy correspondent was to have retired with his little patrimony increased ten-fold. His little patrimony is buried and gone as effectually as are his hopes and his paper calculations. I see you are very hot on *tea*. Personally I would rather sell it than grow it. They tell me that one advantage is you can abandon it with impunity and re-open again; well, but you can't do this with R250 debt per acre upon your place, and who has n't got as much? As to prices, do you think that this good run on Ceylon teas will last, because I don't; and it is better for men to face the fact that their yield up here will be more probably 300 than 400 pounds per acre—except on unusually good land—and their average price will be 60c, rather than 75c, as at present; in fact, those that can make R35 per acre profit will do well. All I maintain is that we have no right to base calculations upon prices that have run up in a most unprecedented manner, and which are more absolutely ruled by supply than is the case with any other staple; and we shall do well to remember that tea is a terrible cosmopolitan, and will grow anywhere and everywhere. Let us enter upon this new venture with all hope and determination to do our best, but without rushing or vaunting it; then, we can say that these latter years have not taught us the hard lesson of adversity in vain.

CINNAMON IN ANCIENT TIMES.—Dr. Carl Schumann's 'Kritische Untersuchungen über die Zimtländer,' published as a supplement to Petermann's *Mitteilungen*, is a most erudite contribution to the history of geography and of commerce. The author carefully examines the notices on cinnamon and cassia to be found in the writings of the ancients and of the Arabs, and critically examines these by the light of modern research. The ancient Egyptians procured their cinnamon from Punt, which is identified with the "Regio innamomifera," or the modern Somali land. But neither cinnamon nor cassia was a product of this region, nor are they now, and this point is amply proved and illustrated by a consideration of the geographical distribution of the Lauraceæ. The *khisit* of the inscriptions in the temple of Der al Bahari is correctly translated "cinnamon" or "cassia"; the latter word and the *gizi* of Galen and the *kezi'ah* of the Hebrews are derived from it; but it is itself a corruption of *kei-shi*, the Chinese name for cassia. The author concludes from this that China supplied the ancient world with most of, if not all, its cinnamon, but did so through traders settled in the ports of Arabia or of the Somali coast. China maintained her monopoly until the discovery of cinnamon on the island of Ceylon. Ibn Batuta is credited with having first mentioned this island as a cinnamon region, for the Sayalân of Kazwini and Yakut is not Ceylon, as supposed by Col. Yule and others, but Râmi or Sumatra.—London *Athenæum*, Oct. 26.

THE CINCHONA LEDGERIANA CONTROVERSY.—Mr. Howard has written the following reply to Dr. Trimen in the *Planters' Gazette*:—Sir,—I have seen the letter of my friend, Dr. Trimen, which I think may render good service in bringing out the contrast between the *red-tapeism* of "taxonomic and descriptive botany," (in which he thinks me ill-informed) and such *practical* information as I am able to supply. I have only just received the paper, and cannot be expected to reply to all that Dr. Trimen says, still less to admit that my "term *Ledgeriana* was not intended as the name of a variety or form of cinchona, that in fact it *did not apply to a plant or tree at all*, but was meant to include all the bark of a certain rich quality grown in Java from Mr. Ledger's bag of seeds." The truth is that I thought the quality and the physical characteristic of the bark *pointed to a new sort*, which my friend, Dr. Weddell, defined as a variety of *his Calisaya*, and of course I must "abide by this *diagnosis*." It does not at all follow that I think it complete. This sort of *barktree* (to speak generally) Dr. Trimen describes after faulty specimens (as I think) as a *new species*. I cannot enter on the question of the correctness of the plates. Compared with Mr. Moens' recently published work—still more with the herbarium he was good enough to give me, I find them, as I have said, *faulty*; but, be that as it may, I think it of great importance to the planter to know that all the forms which produce such a good result in Java are simply *good Calisaya*, and esteemed as such in their native country. That there is *no new species*, simply a variety, distinguished by generally white flowers, &c., but that the seeds of *best Calisaya* imported by Mr. Christy will, in all probability, produce *exactly the same forms as those from Mr. Ledger's celebrated bag*, without the trouble of going in search of some fancied *new species*. Dr. Trimen counsels me to cease to "tackle questions of technical scientific botany, for dealing with which I am so little qualified." I ought to be grateful for this advice, though I apprehend my errors in this line are not more conspicuous than that of a Professor who describes for the benefit of cinchona planters a cinchona without any analysis of the bark which it produces, or means of recognizing the same "in commerce."—Yours truly, JOHN ELIOT HOWARD.

P.S.—Will Dr. Trimen help my ignorance by informing me what constitutes *a true species*?

SIROCCOS AND THEIR WORKS.—Mr. Davis of Strathellie estate, writes as follows :—"I see the *Indigo Planters' Gazette*, quoted by you on the 18th, states that siroccos required a large number of men to work them; but, though I have two working constantly, I never have more than two men attending: one to place the leaf on trays and stoke, the other to attend to the drying tea (and with four siroccos, I believe, three men are sufficient). I find one turns out tea at the rate of 3 lb. in 4½ minutes, being 20 per cent more than the *Indigo Planters' Gazette* states. I have had one erected nearly two years, and have worked it ten days at a stretch several times, but have never had to renew a tray, only the false sides, which were then made of iron, and the diaphragm plates, which can be done in a few hours. For fuel my coolies each bring a piece of wood to the muster ground, near the store, so I only have the cost of cutting—about a cooly a day." We are much obliged for the information, and the obligation will be increased if Mr. Davis will add the quantity by weight and cubic measurement of the fuel consumed for each pound of tea prepared by the sirocco. We have asked for similar particulars in regard to a Jackson's improved drier, and we wish to compare the results for the benefit of the tea-planting community. Fuel is still plentiful and cheap on many estates, but the question of the quantity needed by driers will, with the lapse of time, increase in importance.

CACAO IN CEYLON.—The following is what Bennett, in his "Ceylon and its Capabilities," says on the subject :—

The soil is also admirably adapted to the growth of the hitherto much neglected chocolate-nut tree (*Theobroma Cacao*, L.), which, in the course of a few years, might rank as a staple of the island. I have had [Bennett was here from 1807 to 1827.—ED. C. O.] very fine specimens of the fruit in my own garden, from trees planted by the late Jacobus Burnand, Esq., a Dutch gentleman, whose name is deservedly remembered at Ceylon with respect and regard; for he was distinguished, both by his zeal for the welfare of the island, through the introduction of the culture of valuable exotics from the Malay peninsula, and the Dutch islands of Java, Banda, and Amboyna, and by his botanical acquirements. The nuts were equal to the finest I had seen at Penang and Malacca, or in the West Indies, and in no degree inferior, either in size or nutritious properties, to the best productions of South America. This tree requires shade; and, for that purpose, plantations of banana and plantain trees, which are of rapid growth, might be formed in parallel lines, leaving spaces of ten or twelve feet between each, for the reception of the chocolate plants. I am well aware of the objections likely to be opposed to my suggestions upon this subject, arising upon a *prima facie* view of it, from the comparatively slow return for the outlay, owing to the great difference of time between the produce of the chocolate tree and that of the coffee bush attaining maturity: but it should be taken into consideration, that here "the steed does *not* starve, whilst the grass grows;" for, independently of the annual value of the fruit* of the banana and plantain trees, which is in general request by the natives of all classes, the medicinal usefulness of the leaves, which also afford excellent fodder for cattle, and the several mechanical purposes to which the fibrous stalks may be applied, as already described; indigo, ginger, turmeric, cardamoms, cassada, arrow-root, maize, Guinea grass, and the Principal grains, after rice, to which the native farmer turns his attention, particularly those called—Gingillie (*Sessamum orientale*, L.), Mun and Mung, a species of *Phaseolus*, Meneri (*Millium Zeylanicum, minus*), Korakan (*Cynosurus Coracanus*, L.), Badhaamu, a species of *Dolichos*; and a few others, known by the native names of Mutches, Cadecourie, Cambanpullo, Warego, Swamy, Tinnéswamy, Pannéswamy, and, although the last, not the least in value, for its domestic purposes, dholl and horse gram, might be planted and sown, by way of under crop, without injury to the chocolate plants. To these might be added, an extensive cultivation of the black pepper vine; for, notwithstanding the soil is well adapted to its growth, the island is still dependent upon Malabar for supplies of this spice, which is indispensable for the preservation of cinnamon bark during the homeward-bound voyage.

Surely, this is a speculation worthy of the attention of British capitalists; indeed, but a moderate capital would be required, to bring very large tracts of ground into a profitable state of cultivation; and if a few zealous individuals would but determine to adopt this system of agriculture, and give it a fair trial, it would establish the truth of my assertions, that the returns from the under crops would be as rapid as the most sanguine could have anticipated, and be ultimately increased by an abundant harvest of the chocolate nut.

* Mandrakes of Scripture, *Duda'im* of the Hebrews. Gen. xxx, 14.

COCONUT CONFECTION seems to be of some importance in the United States, judging from an advertisement we find in the *American Grocer*, which states :—

No Grocer can afford to sell second-class or short weight Cocoanut. The Metropolitan Crystallized Cocoanut is decidedly the best preparation of Cocoanut in the market, and as we handle from seven to ten millions of Cocoanuts a year, we claim to be the largest importers and operators in Cocoanuts in the United States, and can afford to sell a pure full weight article, (16 oz. to the pound) in bulk, or in fancy decorated tin canisters, at prices quoted. Bellevue Medical College, New York. Messrs. Herron and Spencer, City.—Having witnessed in detail your process for preparing the Metropolitan Crystallized Cocoanut, from the removal of the shell through the various operations to its final dessication, and having examined the appetizing product, I am able to testify to its freedom from injurious chemicals, to its purity and wholesomeness.—R. OGDEN DOREMUS, M.D., Prof. Chemistry & Toxicology.

Fancy one firm handling ten millions of coconuts in one year. Has coconut kernel ever been candied in Ceylon?

RUBBER EXPERIMENTS.—Mr. Wall writes:—"I send a small sample of rubber in a new form, and I think it is better than the cakes, though these are in many ways very convenient. The daily cake shows the fluctuations of the collections, as it is made from the same trees always. I find, however, that, on cutting them in two, there are holes containing liquid in them. So I dry it in strings now". Mr. Wall adds :—"I should like to stick to the cakes for many reasons, if possible, but I apprehend that the ball-rubber would be purer and more valuable. I think it will be a tight fit, in any case, to make rubber *pay*. So I have not regarded the *spirit* dodge with any interest except experimentally. In all *my* experiments, the coagulation is only too rapid. I don't want to hasten that part of the process. The only thing is to *exclude* the impurity and avoid its forming blow-holes in the cakes. I am satisfied incisions will never do. Some I made three months ago are not closed up yet They were ¼ inch or less wide when I made them, and have become great gashes ¾ inch wide and only partially renewed over." On reference to an "expert," the report is :—"It is good average quality, and buyers do not care whether they get it in ball or cake, so long as both are big and IN QUANTITIES. The labor of balling must be costly, much greater than clapping flake on flake to make cakes." A further report runs :—"I return you the rubber sample. It is valued by a practical Singapore buyer at 4s per lb. as against Para at 4s 6d But my friend tells me that it would not, he thinks pay to prepare so cleanly for the buyers make their bids after allowing for a certain percentage of bark, sand, gravel, &c.,—in some cases, the dirt in the rubber comes up to 40 per cent."

SULPHATE OF QUINIA.—The French Secretary of War requires sulphate of quinine to stand the following tests:—

1. It must be white, uniform and in crystals.
2. Calcined in a platinum crucible it must leave a residue not larger than 1-400.
3. Heated to 212° F. it must not lose more than 12 per cent water.
4. It must dissolve completely in 50 parts of water at 212° F. The solution must be perfectly clear, and alkaline to red litmus paper.
5. It must dissolve completely in 80 parts of 85 per cent alcohol at 60° F.
6. It must dissolve completely in cold acidulated water.
7. It must not contain either quinidine, salicine or other extraneous matter.
8. Its composition must be:—

Quinine...	...	...	...	76·25
Sulphuric acid	...	...	...	9·42
Water set free at 212° F. ...			...	12·00
Water remaining at 212° F ...			...	2·33

9. Not more than 2 per cent of cinchona are allowed.—*Union Pharmaceutique* 1883.

AN INGENIOUS METHOD OF GROWING TREES is thus described in a notice in this *Queenslander* of the Rockhampton Botanic Gardens:—One of the last attempts to utilise the space in these outer grounds, and to turn its choice spots to the best account, consists in planting the two sides of a moist and treeless valley with *Ficus macrophylla*, our native fig. The object in view when doing this was to create a shade suitable for planting this naturally moist locality with ferns and such plants as love shade and moisture. The *modus operandi* employed in attempting to accomplish it is sufficiently novel to be of general interest and at the same time instructive to those who may wish to do something similar. Mr. Edgar first procured a sufficient quantity of hollow logs, a foot or more in diameter, and about 5ft. high. These he placed in position, erect on one end, wherever he intended a fig-tree to grow. He then filled up the centre with suitable soil, and in the top of each planted a seedling fig, finishing the work by nailing a few short laths or slats on the log to run up above the tree on all sides, to protect it from animals. This as will be seen is in imitation of nature. The fig mentioned invariably commences its career as a parasite, through birds dropping the seeds in some hollow of a tree where it germinates and pushes into growth, and from which it eventually pushes out roots which strike into the earth at the foot of the tree it started on, these eventually becoming the trunk of the fig. Mr. Edgar very truthfully observes that this fig naturally tends to branch low from the ground, which unfits it for a general shade tree unless its nature is to some extent altered. This is at once accomplished by the expedient mentioned. The seedling being in the first instance 5ft. or so from the ground, gives it that much of a stem, and with a little help besides it can be extended quite as high as is required, so the usefulness of the expedient is at once to that extent apparent. The seedlings thus planted soon send roots down into the ground, either through the hollow of the log or on the outside, and if left to themselves afterwards will quickly hide the log upon which they started by throwing down roots all round, which will eventually spread and cover the log and form the trunks of the trees. The principle here described has been largely adopted by Mr. Edgar in planting some of the Rockhampton reserves parks, and apparently with good effect, and it has been noticed at this length here because it is a practice sufficiently worthy and economical to be largely imitated by the general public. One thing that will tend to commend it largely to all who wish to create shade upon their lands for the use of cattle is that no fences need be made at the first and kept in order afterwards, as the logs are all the protection needed when the laths or slats mentioned above are carefully nailed to the log on its upper end to form a circle around the growing tree from 20in. to 2ft. higher than the stump itself. For shade purposes possibly nothing could be found to suit this colony better than the fig in question." This Moreton Bay fig and the *Ficus Bengomini* of Java would be a great accession to Ceylon.

GAS LIME IN THE GARDEN.—H. H. Allen, of Mo., writes that an application of gas-house lime upon cabbage plant, tomatoes, sweet potatoes, etc., killed them. Of course it did. It is very poisonous to plants, and even fatal to them in small quantities. It contains valuable manurial substances, notably ammonia, in combination with sulphur or some acid of sulphur, and sulphate of lime, besides more or less slaked lime. The sulphur compounds, except sulphuric acid (which is innocent, nay, valuable, when combined with the lime), are all poisonous to plants, but exposure to the air causes them all to become harmless. It is best to apply gas lime upon the surface of the ground in winter, and thus give it thorough exposure to the weather for several months. There will not be much ammonia left in it, but the lime and the sulphate of lime, equivalent to land plaster, will be of value, especially on clayey or loamy soils rich in vegetable matter. —*American Agriculturist.*

ABOUT FELDSPAR.—James Rideout, Macon Co., N.C., asks us if Feldspar is used as a fertilizer. Feldspar, in a state of decomposition, occurs in his lolity, and he has observed that where the blocks have been thrown out, the vegetation around them is very rank. His soil needs a fertilizer; it costs too much to bring lime, and, though he does not say so, he evidently intended to ask if he could use Feldspar instead. There are several kinds of Feldspar differing greatly in composition. The most common Feldspar a silicate of potash and alumina; another has soda in place of potash, and others still have lime in combination with soda. It will be seen from this that Feldspar is a term for a very variable mineral. Some of its forms readily decompose and make a very fertile soil. Our correspondent must be governed by local conditions. If he has decomposing feldspathic rock at hand, and it can be distributed upon his soil at a small outlay, it may pay him to use it as a fertilizer. It is doubtful if any form of Feldspar can be available commercially, as the same elements may be had in a much cheaper form.—*American Agriculturist.*

ACACIAS AND ACACIA-LIKE PLANTS, such as abound in the north and east of Ceylon, are thus noticed by Mr. Vincent in a letter to the *Indian Forester*:—The road northwards from Sidhout passes first over a low pass in the Lankamalai hills, which here have a fine growth of Red Sanders above and thickets of acacias below. The chief of these last was the *A. Sundra*, which very closely resembles the well-known khair (*A. Catechu*) of Northern India indeed, so closely, that it would be not easy were the two mixed together, to say which was which. Talking of acacias, one of the difficulties in South Indian forestry is to say which is which of the many species there are of Acacias and Acacia-like trees. The common blue-stemmed *Albizzi amara* is only recognizable from an Acacia by its want of thorns; *Prosopis spicigera* by its larger leaflets, and *Dichrostachys cinerea* by its twisted pods and flowers of two colours pink and yellow The white bark of *Acacia leucophlaa* is its chief characteristic, and there is another species near it with purple and yellow flowers and sweet scent, which probably is *Acacia tomentosa*. Other and better known species are *Acacia arabica*, the sweet scented *A. Farnesiana* grown in villages, the climbing *A. Intsia* and *A. Pennata* and the *A. Sundra* and *A. Latronum* already alluded to. Then there is the *Acacia planifrons*, which is only indigenous in southern districts like Tinnevelly, but is often planted in the north as on the slopes of the old forts of Gooty and Bellary. Let the pods be gone and the flowers not yet opened, and perhaps besides let the tree be considerably grazed or lopped, and it is most difficult to say at once to which of the species mentioned a given plant belongs. These thorny plants and the allied *Mimosa* make it exceedingly difficult to get through the scrub forests, especially when the thorns of the acacias are aided by those of the *Canthium*, *Zizyphus* (*Enopliar*, *Carissa Carandas*, *Toddalia*, and other bearers of similar defensive weapons. The Mimosa is not that of Northern India, our well-known and detested *M. rubicaulis*, but the allied *M. hamata*, chiefly recognizable by the curved prickles on its jointed pod.

Correspondence.

To the Editor of the Ceylon Observer.

COFFEE AND ORANGE TREES AND CARDAMOMS.

Munzerabad, 24th Oct. 1883.

Dear Sir,—At page 229 of *Tropical Agriculturist*, the following under the heading of "Treatment of Plants," appears :—"The coffee tree resembles the orange tree which suffers materially if its surface rootlets are cut by the hoe."* Excuse an inexperienced coffee-planter for asking is this so? The custom on this estate, and I may say my neighbours do the same, is to dig round the coffee tree to the depth of six inches or more, and, of course, we must cut away roots and rootlets; yet, to my uneducated eye, the coffee appears to be flourishing and gives good crops, especially one estate nearly, if not quite, forty years old.

I would like to remark, that it has been found after long experience that the cardamoms in this part of the country do better with any dry leaves that are near at hand placed round the stools and allowed to remain there, until first-picking every year, so that the racemes come stronger and longer, and, consequently, more fruit is the result. Of course, Ceylon, with its different climate, probably needs a different way.—I remain, yours faithfully,

LOONIE.

* The statement was not made editorially.—Ed.

CACAO PLANTS AND COCONUT PALMS GROWING TOGETHER.

Kalugalla, Kegalla, 3rd Nov. 1883.

Dear Sir,—The garden in which I was shown cacao growing amongst coconuts and bearing well is about half-a-mile from Kegalla, and owned I believe by Mr. Andree, the Minor roads' officer. The appearance of the cacao trees in this garden would, I am sure, if visited by "A Native Proprietor," convince him of the possibility of growing cacao amongst coconuts, provided of course, as I maintained in my letter, the soil and climate was favourable to its cultivation as evidently in this instance it is.

Because "A Native Proprietor" has not apparently been very successful in growing cacao amongst *his* coconuts that is no reason why cacao should not be successfully grown amongst coconuts in other soils and in other localities. Would "A Native Proprietor" be surprized to hear that I have seen coconut trees in bearing growing amongst cultivated coffee in the Matale district, and the coffee under them looking anything but "shuck" and yet coffee is a surface whereas cacao is a deep feeder?

Fruit-trees which attain a great size, such as jack, mango, etc., planted amongst coconuts already planted sufficiently close together are along with the coconut-sure to suffer injury from over-crowding; but this no argument against cacao (red-fruited variety), which for many years will not obtain any size, and which can be if necessary kept down by pruning, growing in localities where it takes kindly to the soil and climate. I do not agree with "A Native Proprietor"'s opinion, that to ensure success fruit-trees (I presume he means when planted as they should be where there is room for them to grow in) should be planted simultaneously with the coconuts, although it would, perhaps be better to do so.

It would be interesting to know the kind of soil "A Native Proprietor" has planted his cacao in, the variety of cacao, and whether planted quincunxed with his coconuts or closer.

The Kalutara district, as far as I am aware, is not noted for a free soil of good quality; on the contrary, I believe, the sub-soil there is inclined to be hard and gravelly. If this is the case in "A Native Proprietor"'s property, I am afraid his cacao will not be a success, although perhaps his coconuts may.

Cutting a trench round his cacao plants, and so close to their stems, would have the effect of draining off moisture, and this may have effected the health of the plants; or perhaps, the holes in which the cacao were planted were not (prior to planting) dug sufficiently deep and wide.

I would not manure the cacaos until after they had thrown out lateral roots (which they scarcely do until they are about two years old), and then not close to their stems.

There is no need to lay down any hard and fast rules as to where cacao will grow and where it will not. All that a person can do, if he thinks he has suitable soil, is to try, not once, but repeatedly, and not confine his experiments to only one portion of his property. Many persons fail at first from want of experience and from an insufficient knowledge of the requirements of cacao plants. All that one requires to begin with are a few cacao pods and some bamboo pots (split into halves before using) or baskets. Plant your plants when well-grown in holes, cut deep and wide, quincunxed with the coconuts. It will, I think, be of advantage to fill the holes with a prepared soil just sufficiently rich to encourage the plants to make a good start.

Many plants will perhaps have to be sacrificed before success is attained, for, even on estates with virgin soils and favoured with all the conditions necessary for successful cacao culture, this plant has proved very fickle; and all that one can do is to persevere until he wins success.—Yours faithfully,

G. W. F. SAULIÈRE.

[Of all the cultivated plants we know, cacao seems the most impatient of wind. We saw, recently, a fine, flourishing tree growing on the leaside of a rock, so as to be protected from the south-west monsoon winds. It had borne 200 pods. Its congeners in the open had their foliage blown to tatters with every wind-storm and were miserable objects. For cacao to grow amidst coconuts, the latter must be very young or very far apart, and the soil must be exceptionally good.—Ed.]

FOREIGN ORNAMENTAL TREES.

Royal Bot. Gardens, Peradeniya, 6th Nov. 1883.

Sir,—*Apropos* of an editorial note in your columns yesterday, it may interest you to know that the Botanic Gardens contain trees both of *Ficus macrophylla*, the Moreton Bay fig, a native of New South Wales as well as Queensland, and of *F. Benjamina*, which grows wild in Assam, Burma, Western India and Queensland. I quite agree with you in your estimate of the highly ornamental character of both these species: the latter is especially desirable, and one large tree of it here is much admired. It is this fig which is known in Jamaica as "the Ceylon willow"! (mentioned in Mr. Morris's Report for 1881-2, p. 16), as I was able to determine from specimens lately sent me from that colony. This, by the way, is a good and instructive example of the usefulness and accuracy usual in "English names" of foreign plants.

With regard to the *Dammara* avenue, near Buitenzorg, this is scarcely likely to have been formed of *D. australis*. The magnificent Kauri pine of New Zealand could not, I think, flourish in Java at so low an elevation. The trees were more probably the *D. alba* (*D. orientalis*) of the Malay Archipelago, the source of white Dammara resin; or the Queensland kauri, *D. robusta.* Both these trees are also to be seen at Peradeniya. Of the latter, a magnificent specimen, over 80 feet high and as straight as an areca palm, is very conspicuous: *D. australis*, it has not been attempted to introduce here as yet.—I am, sir, yours faithfully, HENRY TRIMEN.

[We are glad to receive this information, and we trust that erelong plants of the two figs of such opposite habits, but each so handsome, may be issued from the Royal Botanic Gardens for the adornment of the streets and roads of our principal towns. It is interesting to know that Ficus Benjamina (we stand corrected about the termination) is not confined to Java and the Straits, but is indigenous in Burma, Assam and Western India. To show how local some plants are, we need merely state, that in several hundreds of miles of travel in Queensland, we never encountered, except in the Brisbane Botanic and Acclimatization Gardens, any specimens of *Araucaria Bidwillii, Grevillea robusta*, or the Moreton Bay fig. If we saw *Ficus Benjamina*, the specimens must have been too inconspicuous to attract our attention. On the banks of rivers in tropical Queensland we could almost fancy ourselves back in Ceylon, so common were *Hibiscus tiliaceus* and other familiar forms. But Dr. Trimen, naturally enough, emphasizes by a note of admiration the fact that a tree foreign to Ceylon, and not yet known beyond the bounds of the comprehensive collection in the Peradeniya gardens should, in Jamaica, be called the "Ceylon willow." We thought the bo-tree was indicated, and we were puzzled to see any resemblance to a willow. But the Waringi fig does resemble the weeping willow in its drooping habit, and, apart from avenues, a tree or two of this graceful fig would add as much attractiveness to the neighbourhood of houses in Colombo, as the weeping willow does in and around Melbourne. We were so struck with the beauty of this fig in Australia that we got Dr. Treub to let us have a plant, and it is now growing at Mr. Wm. Ferguson's residence in Colombo. We believe Dr. Treub told us it would grow readily from cuttings. ED.]

INDIGENOUS ASSAM TEA AT NAWALAPITIYA, CEYLON.

Nawalapitiya, 6th Nov. 1883.

DEAR SIR,—I enclose two large tea leaves. The tree is only 17 months old—no manure was used when planting. It is just close to a water-stream, and I suppose it is a true indigenous tea tree. I shall be happy to hear your remarks on same.—Yours obediently, J. P. ABRAHAM.

[All we can say is that the leaves are truly magnificent: $8\frac{1}{4}$ inches long by $3\frac{1}{4}$ bread in the middle. The largest we ever noticed on a first-class hybrid at Abbotsford was $10\frac{1}{2}$ inches in length The colour is a much darker green than that which usually distinguishes hybrid, and probably the plant is, as Mr. Abraham surmises, indigenous Assam. Proximity to the stream, no doubt, increased the luxuriance of the growth.—ED.]

AN ENEMY OF THE TEA TREE.

7th November 1883.

DEAR SIR,—I send you in a match-box a couple of poochies which I found on a tea bush. Have you ever seen the like of them before, and do you know what they are?—Yours truly, J. ARTHUR.

[The poochie is the larva of [illegible] *graciosa* See Nietner's "Enemies of the Coffee Tree," page 11, No. 1 —ED.]

MR. HOLLOWAY'S CULTIVATION OF COFFEE IN CEYLON.

Maria, 7th November 1883.

DEAR SIR,—(1) *Soil.*—It is well-known that I take credit for getting crops from Maria, because nearly all visiting agents and old planters, even Mr. Hughes, the chemist, thought no coffee would thrive on such land much less pay handsomeprofits and growing all products.

(2) *Shelter.*—Part of the estate is exposed to the north east wind, and the other to the south-west: so much for being sheltered. I had many shade trees, branches brought down by the wind.

(3) *Climate.*—There are at least 12 estates near me with same climate.

(4) *Cultivation.*—Expenditure has not exceeded R100 per acre, including planting cacao throughout the coffee, tea and cinchona along roads, pepper and vanilla on trees, making three good hackery roads through estate from the high road, and buildings.

(5) *Crops.*—Mausakele and Madulkele have good crops in Kelebokka, and Silvakauda, Mausakanda and Kandanuwara in Matale East, I believe.

(6) *Weeds.*—I have stated before when I intend to apply manure in holes I do not weed for one or two months prior to applying the manure. I will then scrape surface soil, weeds and all rubbish on the ground with manure and disinfectants well mixed into the hole, which makes the best and cheapest food for coffee, $\frac{1}{3}$rd of estate each year or thereabouts.

(7) *Sceptical* "M." had better come and see; I can give him all particulars, and will no doubt make a convert of him as I have of many others, for "seeing is believing." He can see sandy, gravelly and good loamy soil; yet coffee in all soils doing well. He can inspect the adjoining estates: One of my neighbours cultivates as I do, and gets good crops on R100 per acre expenditure. There are two estates working on from £4 to £6 per acre: he will see the difference in appearance, and I can prove the difference in crop.

(8) *Different Soils.*—I strongly advocate district V. A.'s or managers, because soil and climate vary so much in Ceylon: it requires a man to be in a district for some time; he must learn the wants of coffee or other products by the appearances of the leaves and trees, be willing and able to supply those wants at once. Faith is wanted. I have as much faith in Arabian coffee now as I ever had. There has been coffee planted where tea would thrive better, and coffee trees did not bear. Plant up tea or any other product in such land at once.

(9) *King Coffee.*—4 to 5 cwt. per acre of coffee on an expenditure of R100 per acre pays well with cacao and croton extra; what pays better?

While leaf disease hangs about we must use disinfectants and extra manure—wood ashes and country lime are the safest disinfectant, scattered over the coffee, over the ground, mixed with the soil and other manures and are a manure as well. I mean good country lime containing a great deal of magnesia, the coarser the more lasting. All my cattle-manure as daily removed from the cattle-shed is sprinkled over with unslaked lime. My cacao pods are much larger than on adjoining estates. Tea seems to throw out good flushes, and some tea made here has been pronounced very good and of a good aroma by a gentleman who makes good tea. My tea tree is now 25 feet 3 inches high. My cocoa trees among coffee and tea along roads received lime same as coffee.

Our Government is certainly much to blame for not having made the railway up to Haputale years ago and enabled planters to get up manures so much cheaper and quicker than they can by carts. The question should not have been "Will it pay?" but a far-seeing Governor should have known that without cheap transport for manures our lands would get so impoverished eventually that nothing would grow at a profit on them; but with cheap manure while soil is still in fair order our crops would here increased. On Maria estate I have proved what can be done even with poor soil and old coffee when properly cultivated, and I know there are many planters who would gladly follow out my system but cannot, as transport by cart for manures is too expensive. I trust our new Governor as soon as he comes out will at once take the railway to Haputale into his consideration. He being an energetic far seeing man, I am positive he can come to onlyone conclusion: this railway must be made as quick as possible.

You remember in 1866 I was the first who strongly urged District Associations; this was pooh-poohed at the time by our big folks, but, eventually, I saw it carried out, and now District Associations are doing more good for planters than the parent. I now urge on each Colombo firm to appoint a good practical planter in each district to supervise their interest; then let one of their firm or their V. A., who should have an interest in the firm (not separate interests of his own), come round every six months, take time to go over the estates carefully, go over all matters with the district V. A., and no doubt a more careful cultivation,—no throwing away of money on unprofitable work or products,—and better profit will be the result. It is the field that wants the best supervision; accounts are only secondary. Too much has been made of elaborate reports and accounts lately.—Yours truly,

J. HOLLOWAY.

THE TEA PLANT IN CEYLON.

Dear Sir,—In reference to W. F.'s query "when was the teaplant introduced into Ceylon?" the following extract from Percival's History of Ceylon (1805) is in point (p. 330):—"But it is not sugar alone, that Ceylon seems destined to afford to the general use of the western world, the *tea* plant has also been discovered, native in the forests of the island. It grows spontaneously in the neighbourhood of Trincomalee and other northern parts of Ceylon. General Champagné informed me that the soldiers of the garrison frequently use it. They cut the branches and twigs and hang them in the sun to dry; they then take off the leaves and put them into a vessel or kettle to boil, to extract the juice which has all the properties of that of the China tea leaf. Several of my friends have assured me that the tea was looked upon as far from being bad, considering the little preparation it underwent. The soldiers of the 80th made use of it in this manner, on being informed of its virtues and qualities by the 72nd regiment whom they relieved. I have in my possession a letter from an officer of the 80th regiment in which he states that he had found the real teaplant in the woods of Ceylon of a quality, equal to any that ever grew in China, and that it was in his power to point out to Government the means of cultivating it in a proper manner. The vast advantages to be derived from the cultivation of the teaplant in our own dominions, ought at least to prompt a speedy and vigorous experiment on the subject."

Cordiner (1807) says:—"The real tea tree is not indigenous in Ceylon, but the island produces several species of that genus one of which, (used by the natives) is contained in General Macdowall's grounds at Colombo but none of the plants have grown large nor have any of them, produced flowers or berries. Reports have been circulated announcing the discovery of the real plant in the woods but specimens of the shrub have never been produced to determine the credibility due to the assertion. The China tea tree, however, might be easily imported and there can be little doubt that it would in time, prove a source of wealth to the island."—Yours,

SPERMOLOGOS.

INDIAN AND CEYLON TEA SEED: No. I.

Sir,—"Planter," the advocate of Assam-grown seed, would seem to imply, that, while every Assam planter is a most conscientious and intelligent person incapable of picking or selling unripe seed, 99 per cent of Ceylon tea planters are foolish and immoral who do not know ripe from unripe and who do not hesitate to sell rubbish as good seed. As a fact, seed picked perfectly ripe in Assam is more likely to reach Ceylon rotten and defective than if it were picked the least bit unripe to ripen on the way.

Assam seed at R75 per maund in Assam will only give some 12,000 plants to a maund, costing fully R10 per 1,000 when ready to put out, whereas Ceylon seed will give some 20,000 plants, possibly costing from R4 to R5 per 1,000 when ready for planting. Again, the process of taking out bushes of inferior type seems to go on as much on estates planted entirely from Indian seed as it does on those grown from Ceylon seed.

Purchasers of Ceylon seed can go and see for themselves the trees from which their seed comes. If they buy Indian seed, they to a certain extent buy a pig in a poke. Human nature is the same as regards integrity in Assam as in Ceylon, I opine.

Will planters prefer going to the expense of R10 per 1,000 for Assam plants, or R5 for CEYLON PLANTS?

No. II.

November 9th, 1883.

Dear Sir,—Personally, I so far agree with "Planter" that I would prefer planting up with seed imported from Assam or Darjiling simply for the reason given by you in your footnote to "Planter" 's first letter, viz., the advantage to be derived from a change of seed, and I would advise others to plant imported seed also, *if* (and here lies the difficulty) they can depend on getting seed of a *good* jât delivered on their estates in a *sound* condition. Is it not probable that now the people in India find a "rush" from Ceylon. They may pick tea seed off places which have been abandoned partly because of having been planted with poor class trees and partly from unsuitable soil. But "Planter" will tell us that Assam planters or proprietors are incapable of doing any wrong: but he can't deny that it was in India that the tea seed was parboiled in the early days.*

I will give another short extract from "Cultivated Plants" by F. W. Burbidge: at page 3 he writes:—"The seeds of cultivated plants are rarely allowed to remain on the plants until they are perfectly ripe." There is a wide distinction between perfect or fully ripe and merely ripe seed.—Yours faithfully,

ORION.

P.S.—Has "Planter" succeeded in selling that seed which a "well-known tea broker in London" advised him to part with? I wonder if that was the seed which was "sweeped" off and distributed to buyers!

TEA PREPARATION: THE PRICE OF COKE AND COAL TO PLANTERS.

Maskeliya, 10th Nov. 1883.

Dear Sir,—Can you find out for us, what can coke be landed at from England, per ton, including *all* charges? Later on, coke or coal must be used for manufacturing tea on some estates. Coke, of course, would be the cleanest and brightest, and last not least give out more heat than coal. *Leaf-disease is going away*, but when it will take its departure is very hard to say.—Yours &c.,

CHEER UP.

[As the most convenient referee we sent our correspondent's inquiry to the Manager of the Gas Works,

* Is this a true bill? "Can such things be?"—Ed.

and Mr. Monk is good enough to reply as follows:—"English Foundry coke costs R50 to R55, and is not suitable for a stove except there is a strong draught or blast to make it burn well. Gas coke is delivered at Colombo station (and bags lent free for a fortnight, if returned to the Gas Works free of charge) at R18·75 per ton, and the carriage to Nawalapitiya is R14·70 for one ton, R29·40 for two tons or any quantity up to four tons for the R29·40, so that it is much cheaper to get a four ton lot; a special quotation would be given for latter for a trial. The Gas Works coke is best for stoves, only requiring a wood kindling and fair draught, and broken small for use. Coal costs R20 to R30 at Colombo station, and as per bargain about lending, hire, or purchase of bags." It will be observed that four tons gas coke can be delivered at Nawalapitiya for R26·10 per ton. We suppose it can be delivered at Hatton 9 or 10 months hence by rail for R30, so that the tea planters in that quarter can then give it a fair trial, if indeed they, as well as others, do not begin at once.—ED.]

CROTON SEEDS AS A MARKETABLE PRODUCT.

W. P., 12th November 1883.

DEAR SIR,—Would one of your commerical readers in the Fort kindly answer at any rate *some* of the following queries anent croton seeds?

1. Is there demand for it in small quantities (down to 5 lb. or so), and, if so, what price is obtainable?
2. Is it necessary to cure the seeds in any way; or is it marketable in the husk, merely dried in the sun?
3. Is it necessary to pack the seeds carefully so as to exclude damp &c?

Any other information will be thankfully received by

YAKKO.

[Our correspondent will find information in last volume of the *Tropical Agriculturist* regarding croton seeds. Mr. Holloway says the seeds must be dried, shelled, and dried again in the sun: this is all the preparation required. The seeds can be picked in bags. 50s a cwt. has been offered at home for Ceylon croton seeds.—ED.]

CEYLON TEA: GOOD ADVICE FROM MESSRS. W. H. THOMPSON & Co. ABOUT PLUCKING.

Kandaloya, 13th Nov. 1883.

DEAR SIR,—Perhaps the following extract from a letter just received from the Messrs. Thompson, London, may prove of interest to your readers, treating about the vexed question of plucking as it does:—"Your teas, as all have done this season, show a marked improvement on the produce of former years and are quite free from faults. We cannot advise you to make any change in your system of manufacture, seeing what excellent results in this case have been produced. Yours are now fully up to the average standard of Ceylon teas, and only fall short by the special strength of *Loolecondura*, the rich malty liquor of *Gallebodde* and the fine flavour of *Rookwood*. These gardens, with one or two others, show better results and higher prices, due, perhaps, to exceptionally favourable soil, position and class of plant, but you have no reason to be dissatisfied with your teas. *Plucking*.—Many, we think, err in allowing too long an interval between the different pluckings, thus letting the leaf grow too large; where labour will permit it is found better to go over the bushes oftener, taking a finer leaf which will give a higher grade without in the long run reducing quantity."

Them's my sentiments as to plucking.—Yours faithfully,

JAMES WIGHT.

CEYLON *VS.* INDIAN TEA SEED: PRACTICAL EXPERIENCE OF A VALUABLE KIND.

13th November 1883.

DEAR SIR,—After reading "Planter's" sweeping remarks on Assam and Ceylon tea seed in your issue of the 6th instant, the following returns from locally grown seed may not be uninteresting. 39½ maunds of seed were purchased, about 10 of which came from Mr. Howie then on New Forest, and the remainder from Mr. Armstrong of Rookwood. From this seed, one million one hundred and eight-three thousand plants (1,183,000) have been planted out, and there are still a few thousands in the nurseries. Nearly all the plants were put out before the end of January last, and their growth and regularity are most satisfactory. Now for Indian tea seed, seed specially selected by a planter who went over to India for that purpose: out of nine maunds supposed to be delivered in good order, 51,200 plants have been put out; there may be a couple of thousand small ones left in the beds. So far as "jât" goes the local seed carries the palm. My own opinion is, when local seed of known quality can be procured for original planting, don't hesitate in availing yourself of it, and, if possible, arrange to get seed of a good jât from India to supply with.*

H.

BOILING TEA SEED.

14th November 1883.

DEAR SIR,—In reply to your query about boiling tea seed in the old days in India I send you a verbatim extract of two paragraphs from the "Tea Cyclopædia." I had to borrow the book from a neighbour to take the extracts, else I would have sent you the book itself.—Yours faithfully, ———

Extracts from "The Origin and Future Prospects of Tea in India," by Samuel Baildon, author of "Tea in Assam":—

"It is a subject for regret, and one which cannot be denied, that the crash in tea was in a measure due to the dishonest practices of sundry 'tea concern promoters.' Estates were sold at many times their value, false representations were made as to existing arrears, and the actual state of affairs generally discovered too late. Men to manage gardens were recruited from anywhere; ordinary seamen and captains, professional men, others who had failed in everything else, all—nearly all of them—as gnorant regarding the industry they were entering as could have been the case; gardens were made in places where tea was the last thing to plant; extravagance was indulged into the fullest extent: and so the end came."

"I have been informed of a case where a few small estates were amalgamated and sold to a Company in London, and the 'promoter,' finding people red-hot to invest in tea, considered it a good time for making a private harvest, and in the particulars of the three estates he included and actually sold a 100-acre garden which had no existence, writing to his representative by next mail to buy seed at any price, clear and scrape something near 100 acres and plant the seed, *as it had been sold*."

"Sundry mercantile men in Calcutta were convicted of boiling the tea-seed after it was sold, to prevent its germination, and to retard the success of the purchasers who were embarking in tea. Another practice, when it became known that tea did not usually yield until three years old, was to reckon the year (or thereabout) which the seed had taken to mature from the blossom in the parent bush, so that when it was planted the garden was one year old.'"

The above extracts have been copied from "The Tea Cyclopædia."

[We have both books, but we regard the boiled seed statement as an outrageous fiction.—ED.]

* As nearly as possible 30,000 plants to the maund.—ED.

WHAT WE KNOW AND WHAT WE WANT TO KNOW ABOUT CEARÁ RUBBER.

SIR,—We know a good deal about experiments on a few individual trees, but we want to know something about results on a larger and more business like scale. Mr. Gilliat is last in the field, and gives us interesting information, but, like his predecessors who who have written on rubber, he relates results of a few trees only, and they do not add much to our previous knowledge.

We know that the tree will probably be short-lived. So say botanists, and its very rapid growth favours the idea.* If, therefore, we are to make any profit out of it, we ought to begin at once to learn how that is to be done.

We know, that, whether the tree be young or old, wounds made for the purpose of extracting its milk soon stop bleeding; and therefore a very little milk can be obtained from any wound, however it may have been made; nor can we obtain much milk at any one time, however many wounds we make. Trees subjected to the severest treatment, in order to ascertain the utmost yield of milk procurable, have proved, by their insufficient yield, that we must depend for any renumerative result on frequent tappings. We know, in fact, that we must be content to take a little at a time, and to take it often. What we want to know is how much we may take, and how often.

In the first place, therefore, we must devise a method of tapping, which may be often repeated without material injury to the tree or the bark. Every kind of incision that has hitherto been tried, whether vertical, horizontal, or arrow-shaped, has proved, sooner or later, to seriously injure the bark. It is true that the cuts or slits sometimes heal pretty quickly, but they are often a long time in closing, and produce serious scars. Some slits made several months ago on trees a year old are gaping yet. Although renewed bark has formed, it does not close over the wounds, which are now three times as wide as when they were first made, owing to the rapid growth of the trees. Perhaps, Mr. Gilliat's method may succeed better, but that remains to be seen. Meantime, it is satisfactory to know that a row of punctures will yield as much milk as a vertical slit or incision of the same length, whether such incision be made down to the cambium or be a mere shaving down to the lacteals. Punctures heal quickly, without material injury to tree or bark, and may be repeated at very short intervals. Trees have been thus tapped *daily* for several weeks without their showing any difference as compared with untapped trees in adjacent lines. Even when incisions heal completely, the renewed bark, especially in old trees, is very rough and intractable. For some time it yields very little milk, as compared with original bark, and is always rough and uneven. The methods of tapping by incisions seem, therefore, to be a needless as well as an injurious mutilation of the trees.

My first prickers were intended to *tear* the bark a little, in order to produce a wound that would not close too quickly, but that is a mistake. A rough wound bleeds no longer than a smooth one; and a deep one, down to the cambium, yields no more milk than a shallower one that reaches the lacteals. The prickers are now being made with a guard to prevent the spurs going too deep, and are made to produce a *clean* wound instead of a rough.

The quantity of milk procurable from different trees of the same age, at the same day and hour, and from the same tree on different days, varies very much. This has been ascertained, but we ought to know the cause or causes of this variation, so as to adapt our proceeding accordingly. The factors of the variation are probably the hour of the day, the state of the weather, the condition of the tree, whether in flower, fruit, or flush, and the time of the year. The part which each of these factors plays remains to be ascertained, and can only be found by persevering and systematic experiment. Occasional or casual trials are of no avail whatever for this purpose. The milk drawn in the early morning is generally thin and watery, and becomes thicker as the day advances. After 10 o'clock, it sometimes becomes too viscid, but in the evening it again flows more freely. As a rule, milk may be drawn at all hours of the day, but it remains to be seen whether it would be better to discontinue the extraction during the heat of the day. The quantity of milk drawn, so far as it depends on the operator, is regulated, of course, by the length of the vertical row of punctures. Hitherto, a double row of 4 to 5 feet in length, on one side of a tree of about 5 inches in diameter, has been found to yield about 15 grains of dry rubber per tree. The daily collection of a cooly is *about* half a pound, and will probably be increased by improved appliances and with larger trees. We want to know more about this; but, should it be found that trees will bear such extraction for 240 days in the year, the cultivation would be profitable, and there is reason to hope for such a result.

The curing of rubber seems to be a tedious business. My first collections were made in tins and each day's collection formed a cake at the bottom of the tin. The milk coagulates so quickly that the cake, though soft, can be removed from the tin when the cooly returns from the field, but afterwards it dries and hardens slowly. Pressure causes a quantity of liquid to exude, and even when the cakes are hard they contain holes, like those in Parmesan cheese, full of liquid. Late experiments have been made with an apparatus which forms the rubber into strings, and these, when wound into a ball, look very pure and business-like, but even these balls, when cut in two, disclose some slight remains of liquid impurity. Probably Mr. Christy's suggestion of the use of a cheap spirit might assist in eliminating this mucilaginous matter; but spirit is costly, and there does not seem to be much room for extra expenditure in the process. The cake rubber was valued at 2s 6d per lb. and the balls I think at 4s.

The foregoing is very imperfect, and shows rather what we want to know than what we have already learnt. Still, it is as far as I have got, and perhaps some of your correspondents can advance in a step or two further? W.

[It must not be forgotten that most of the experiments yet made in Ceylon have been made on immature trees. As the trees grow older, it seems reasonable to expect if not more juice from a certain surface yet a juice far less watery—almost pure gum, in fact.—ED.]

* The great longevity in the face of rapid growth of the 500 feet high eucalypti at Fernshaw in Victoria is the exception to the rule.—ED.

THE EDINBURGH INTERNATIONAL FORESTRY EXHIBITION.

DEAR SIRS,—I have pleasure in forwarding you the enclosed list of patrons and prospectus of the "International Forestry Exhibition" that is to be held in Edinburgh next year. I am busy collecting, and intend forwarding as complete a list of Ceylon forest produce as I can possibly gather together. I shall arrange a catalogue of all the exhibits, which will include a copy of your new *Directory* and Vincent's report. Anyone willing to assist me will receive my best thanks. This proposed exhibition has been started by the Scottish Arboricultural Society, under the full expectation that it may lead to a school of Forestry being established in Edinburgh.—I am dear sirs, yours faithfully, J. ALEXANDER.

[The Queen is Patroness of the proposed Exhibition, and it is to be supported by the leading societies and individuals in Scotland. We give the prospectus and classification below, and we trust Ceylon will make a good show of forestry products on this occasion.—Ed]

INTERNATIONAL FORESTRY EXHIBITION, EDINBURGH, 1884:—PROSPECTUS AND CLASSIFICATION.

Class I.—Practical Forestry.—1. Implements, tools etc., used in forestry, draining, enclosing, etc.; surveying-instruments, chains, dendrometers, etc. 2. Models of foresters' huts, charcoal kilns, timber slips, sluices, dams, weirs. 3. Plans of river embankments, rafts, and appliances for floating timber. 4. Models and machinery for transporting timber and transplanting trees. 5. Saw-mills—wood-working and pulp machinery of every description, in motion or otherwise. 6. Fencing materials.

Class II.—Forest Produce, Raw and Manufactured.—1. Collections of timber specimens and ornamental woods: *a.* Indigenous or naturalised. *b.* Exotic. 2. Woods used for ordnance—as gun carriages, etc. 3. Woods used for railway purposes, natural and prepared. 4. Wood pavements. 5. Cooperage—tubs, barrels, etc. 6. Wood carving and turnery, with tools used. 7. Basket and wicker work. 8. Fancy woodwork, including bog oak, veneers, parqueterie, stained and coloured woods, etc. 9. Wood engraving. 10. Bamboos, canes, reeds, and manufactures therefrom. 11. Tanning substances—barks and extracts. 12. Dyeing substances—woods, roots, flowers, etc 13. Barks, including cork. 14. Fibres and fibrous substances. 15. Materials for paper manufacture. 16. Gums, resins, and gum elastics. 17. Wood oils and varnishes—including lac of sorts. 18. Drugs, foods, spices. 19. Charcoal for gunpowder, tinder, etc. 20. Peat and its products. 21. Cones, seeds, and fruits of trees and shrubs.

Class III.—Scientific Forestry.—1. Botanical specimens of forest flora. 2. Microscopic sections of woods. 3. Parasites—Fungi and lichens injurious to trees. 4. Forest fauna injurious to woods. 5. Entomology.—Useful and noxious insects, and damage produced—as pine beetles, weevils, etc., coffee borers, white ants, moths, carpenter bees, locusts, etc., with specimens, as far as possible, illustrative of the specific damage done by them. 6. Preservative processes applied to timber. 7. Geological specimens and diagrams illustrating the different formations adapted to the growth of trees. 8. Fossil plants—collections illustrative of the trees of coal measures, etc. 9 Trees found in bogs—oak, fir, etc.

Class IV.—Ornamental Forestry.—Growing specimens of rare and ornamental trees and naturalised species—in tubs or otherwise. Rustic work—arbours, bridges, seats, etc.

Class V.—Illustrative Forestry.—Paintings, photographs, and drawings of remarkable and historical trees—Foliage and scenery. Delineations of trees in their native countries, or of recent and important introductions. Illustrations or photographs showing effects of blight accident, or any abnormal condition, including those of parasitical plants. Sketches of work and operations in the forests. N.B.—Special attention is invited to this class.

Class VI.—Forest Literature and History.—1. Reports of forest schools—forest periodicals and other publications—manuals and almanacs—treatises on measuring and valuing woods forest floras of different countries—treatises on fixation of dunes, and on ancient or extinct forests. 2. (*a.*) Working plans of forests, and plantations of estates, valuations, surveys, etc. (*b.*) Maps charts, etc., illustrative of the geographical distribution of forest trees, and their altitude. N. B. Special attention is invited to section 2.

Class VII.—Essays and Reports.—Essays and reports on specific subjects, for which premiums are offered as per separate schedule.

Class VIII.—Loan Collections.

Class IX.—Miscellaneous.

RUBBER: THE CULTIVATION AND THE HARVESTING OF THE PRODUCT IN CEYLON.

Golconda, Haputale, 16th Nov. 1883.

Dear Sir,—By today's tappal I send for your inspection 18 cakes of rubber from Rosebury estate; each cake may be considered half-day's work of a cooly. The smaller cakes represent the collection from trees from 12 to 18 months old, and were on day of collection almost as large as the others from trees 2½ to 3 years. The milk from young trees is therefore of a very inferior quality, and for this it is scarcely worth running the risk of bringing valuable trees to premature decay. "W." has stated that the tree will probably be short-lived, but a too early tapping is not calculated to lengthen its life.

If rubber does not fall much in price in the London market, the rubber cultivation will pay handsomely, as the milk from the older trees is as rich in comparison with the younger, as richly-fed cattle milk is to poor skimmed.

From early morning till about noon, the trees yield most, and after that tapping should cease for the day, as it is not worth injuring the bark of the tree for all the yield of milk.

We have yet much to learn, but in our anxiety after practical knowledge we should avoid the danger of weakening trees by tapping too soon.—Yours faithfully, J. W.

BLACKENED COFFEE LEAVES.

Dear Sir,—The cause of the black disease being neither insects nor fungi, I must, of necessity, conclude that it is from within. But *H. V.* and *B. D.* are closely allied, as you will see by the enclosed, so that both are external and both caused by the unhealthy state of the formation fluid.

In Orr's Circle of the Sciences, "Organic Nature," vol. ii, page 173, is the following:—"Fungi, moulds, morels, mildews, blight and puff-balls grow for the most part upon decaying matter." (He might have said all.)

Then why should our coffee be an exception to this general rule? Organic nature works by general laws (see the fern period and the present), not by hops and jumps, and my belief is that all and every species of fungi are all an evolution from decaying matter.—Yours faithfully, J. HAWKE.

[Mr. Hawke generalizes widely from the occurrence of spots on coffee leaves similar to those on gum-leaves, which are of atmospheric or of chemical origin. Both this and *Hemileia vastatrix*, a distinct *external* fungus, are due to the unhealthy state of "the formation fluid"! Then all fungi are evolved from decaying matter. Mr. Hawke evidently means that the leaf fungus is not the cause but only the effect of decay which had set up in our coffee. All the evidence is against him. Decay has its own special fungi, but *H. V.* is not one of them. It came and saw and conquered not decaying but eminently flourishing and well-cared-for vegetation.—Ed.]

TEA SEED AND RESULTING PLANTS.

20th November 1883.

Dear Sir,—Would your correspondent "H." (page 448) give us the distance of carriage and tell us how the 19½ maunds of Rookwood tea seed were packed? 30,000 *plant*s raised from a maund of seed is exceptionally good, I should think, and does credit to the grower. Seed freshly gathered with little or no carriage does generally do well and what is "H."'s reason for advising Indian tea seed, just inferior, for supplies at a cost, without nurseries, of R17 odd per 1,000 as experienced in his own case, 9 maunds only giving 51,200 or 5,688, per maund? "H."'s letter shows one ought to buy from a known tea and a *careful* manager.—Yours, D.

VEGETABLE PHYSIOLOGY, AND COFFEE PLANTING: SCIENCE REQUIRED TO GET GOOD CROPS.

DEAR SIR,—If coffee planters, in general, were more familiar with the science of vegetable physiology, and had a knowledge of the organization and the vital functions of the coffee tree, and were able to tell the requirements of the shrub, and what was necessary for the formation of leafage and flower, and how the elements necessary for their increase be assimilated so as to enable plants to absorb the required nutriment, I am certain that it [Coffee ?—ED. C. O.] would reproduce crops that would startle even the *merchants* out of their shells.

If vegetation is to be treated, as if it was inorganic matter, it 's but natural that it will be inanimate, its vitality gone, and therefore yield nothing.

Numbers pooh-pooh science, as being unnecessary for agricultural purposes—saying that commonsense and experience are sufficient—but science, is indispensable for bringing vegetation to perfection, and, added to experience, any ailment that vegetable vitality suffers from, might be cured.*

Having made these remarks, I think it well to explain how plants derive their food.

The food of plants is partly deduced from the soil, and to some degree from the air, but it is requisite that whatever plants require, must either be reduced to a liquid, or gaseous state, before it can be taken up by the organs of nutrition. Now there are four elements which constitute a plant, viz:—carbon, oxygem, hydrogen and nitrogen:

By this several questions arise, as to the best way of supplying coffee shrubs with what they require, and this can only be taught, by the study of vegetable physiology and chemistry.†—Yours faithfully, ARISTO.

QUININE FROM TAR.

Edinburgh, 30th October 1883.

DEAR SIR,—Annexed is a quotation from *Chambers's Journal* of October 27th, from which you will see, that cinchona will soon be abandoned, if the quotation should *prove correct ?* Perhaps you might favor us with your opinion.—Yours truly,

P. D. MILLIE.

QUININE FROM GAS-TAR.

"A long series of experiments carried on by Professor Fisher, an eminent chemist of Munich, has resulted in the discovery of a white powder, in the residuum of gas-tar, which contains all the medical properties of quinine, added to the advantage that it assimilates more easily with the digestive organs than quinine itself. It has been proved to be wonderfully efficacious, in subduing fever, ice being unnecessary.

"One great advantage of this discovery will be the cheap rate at which it can be sold, by which means it would be brought within the reach of these poor people who require quinine but who find it difficult to purchase such an expensive drug."

[Tar has yielded sweet perfumes and beautiful dyes, but we certainly do not believe in its adding a perfect substitute for quinine.—ED.]

* Indeed! The highest science of our time, however, has failed to cure the potato and coffee fungi or the vine insect. We quite believe in the benefits of science: but before many of the "ailments of vegetable vitality" it is perfectly helpless, and candidly confesses the fact.—ED.

† This learned correspondent ought at once to take out a patent for his wonderful discovery. We hope he will use science practically so as to make coffee "reproduce" crops fit to startle merchants out of their shells.—ED.

INDIA CROP AND WEATHER REPORT.

FOR THE WEEK ENDING THE 6TH NOV. 1883.

General Remarks.—There has been heavy rain during the past week in the coast districts of the Madras Presidency which has inundated the crops in parts, but general prospects continue good in Madras and Mysore. Rain has also fallen throughout Deccan and Southern Mahratta Country, doing slight injury to standing crops in several districts. Great scarcity of water prevails in Kurachee, and locusts are destructive in three districts of the Deccan. Rain is needed in Ulwar, otherwise the report from Central India and Rajputana are favourable.

No rain fell in Assam and very little in Burma, and more is wanted in both for the rice crop, but general prospects are good.

Slight and partial showers have occurred in the Central and Southern parts of Bengal, which have done some good, but, except in the Eastern districts and Cooch Behar and Jalpaiguri, the greater part of the rice crop on high lands has been already destroyed, and the crops on low lands are in a critical condition. Rabi sowings are also seriously impeded. In the Central Provinces the outlook continues favourable, although some injury has been caused to cotton and linseed by cloudy weather. In the North-Western Provinces and Oudh and Punjab prospects are fair, but rain is much needed for the rabi in both Provinces.

Harvesting of the kharif is still in progress in most provinces, and the outturn has generally proved to be under the average. Rabis owings are also progressing and promise fairly well, except in Bengal.

Cholera in a sporadic form exists in Madras and parts of Northern India, and fever is prevalent, otherwise the public health is fair.

Prices continue to rise in Bengal.

Madras.—General prospects good.

British Burma.—Public health good. No increase of cattle-disease. Rainfall for the week and up to date very deficient compared with last year. Crops on the low-lying lands progressing favourably. The later paddy and the crops on high lands suffering in parts from want of rain. On the whole the outlook appears more favourable than was reported last week. Price of paddy keeps steady.

Assam (Gauhati.)—Weather seasonable. Mornings and nights cool and foggy. Rain much needed for rice crop Land being ploughed for mustard. Public health fair.

Mysore and Coorg.—Rain has fallen generally throughout the province; Kolah, 5·46; Chickmagalur, 2·82. Standing crops in good condition. Agricultural operations in fair progress. Prospects satisfactory. Prices stationary. Public health good.—*Pioneer.*

RUBBER CULTIVATION: MR. GILLIAT'S EXPERIMENT.—In my first experiment on September 11th, I tapped only 3 trees, age about 3 to 3½ years old, 4 cuts each tree, and the result was average ⅛ of an oz. of dry rubber per tree. The same trees were tapped again on the 18th September, result just over ⅓ of an ounce per tree, and I have no doubt I can tap 25 times a year without injury to the tree. I have one tree, near my bungalow which was tapped 6 times in the month (only 14 months old) and which gave 1 1-16th oz. I shall tap it again this month, as it shows no signs of exhaustion, and will let you know the results. If "W." first removes all the bark off the trees before commencing to tap, I am at a loss to know how a cooly can do 300 trees a day, as, with my knife, where there is no removal of bark necessary, I now consider 100 trees a day good work. Dr. Trimen and myself, on Tuesday last, examined the trees that have been experimented upon, and he expressed himself thoroughly pleased with the way in which the cut had closed, *many* of them quite healed up; and he thought that, in another two or three months, they might be re-cut. I believe now that the best way to treat the milk after collection is to place it in a sort of tray, with an even, uniform heat under it by means of small lamps or jets with kerosine oil. I have such a lamp, with 14 small burners, with a tray on the top of it, and, in heating a bottle and a half of milk, I found I did not use more than about 5 cents worth of kerosine oil. The heat seems to drive off all the impurities of the rubber, and to leave it comparatively dry and white. H. A. GILLIAT. Peradeniya, Nov. 11th, 1883.—Local "Times."

PLANTING IN THE LOW COUNTRY NEAR HENARATGODA.

16th Nov. 1883.

It will indicate the sort of weather we have been having when I say that I put down a tea nursery on the 6th ult. and have not since found it necessary to give an artificial watering: there has not in the six weeks been thirty hours without rain. As regards the amount of rain, I had occasion some time ago to dig a pit eight feet square and three feet deep into which, I directed the surface drainage, of somewhat less than 1,000 feet; on two occasions that pit was filled to overflowing. The weather has been such that the labour has been much interfered with, and weeds have gone so ahead that I had to suspend every other operation, and set all hands weeding.

The coffee is beginning to ripen. *Hemileia* has been hard on many individual coffee trees, but the attack has not hitherto been so general as last year; but on this occasion it is mostly the largest and finest trees that it has selected for destruction.

I planted out half an acre of cardamoms on the 16th of last month, and there are few if any failures. I have since sown as much seed as ought to give me all the plants I will require for a ten-acre field. I am satisfied that seedlings will be more economical than bulbs at R40 per 1,000, and from recent observation I believe that the gain in time, by using the latter, will not be great. From seed sown only six months ago, I have seen vigorous plants of eighteen inches high.

I have recently planted out 150 cloves as an experiment, and their appearance is encouraging, where the plants were well-grown and healthy to begin with, but unfortunately some of the plants had been injured by water in the seed-bed.

I have continued to plant out pepper, as I could get suitable slips. They attach themselves readily to the surface of the rocks, wherever there is scurf of vegetable matter, but very reluctantly to a bare washed surface. The most advanced plants are twelve feet high and well branched. As my progress in extending this cultivation is not so rapid as I could wish and the price of slips at the Government garden absurdly high, so I propose, as soon as I can get ripe seed, to put down a nursery. It will take many thousands of plants to give all the rocks on the place a chance of becoming useful; and I have planted about 500 *imbul plants*, along the roads with the ultimate view of attaching a pepper plant to each, but even for their own produce, I am credibly informed, there is an inexhaustible market in Australia. [And now in Britain.—ED.]

The continued wet weather has been very injurious to the cacao: thousands of pods, of all sizes, have rotted on the trees before coming to maturity. I am afraid I must admit the new cacao field as a failure: fully one-half of the plants are gone, and of those that remain more than one-half are not promising. I have given the best parts of the soil another chance by putting down fresh seed, but I will plant up the land with cardamoms as soon as the plants are ready.

Some of the tea is growing very well in the field, but it hangs back on parts that have very promising soil; and all over the growth is very unequal, and the failures numerous. The nursery has now been six weeks down. The most advanced plants are four to five inches. I have still no certainty as to the percentage of plants for seed I am likely to get: less than one-half has yet germinated; some of the ungerminated seeds still appear perfectly sound, but as many are evidently done for. None of the very small seeds have germinated, and most of the other certain failures have a light brown colour, which, I fancy, is indicative of their having been gathered while insufficiently ripe. I cannot measure the injury done by the seed having fermented and contracted considerable heat in the bags before it reached me, but this is a matter that buyers should attend to, and return all seed that has heated. I know not who suggested wet moss as packing for fresh tea seed, but I know that it will rather promote than retard fermentation. I would not insist on powdered charcoal, but dry sand, or, where that is not at hand, common earth, dried, pounded, and sifted, will answer as well, and effectually prevent fermentation.

I have not lately been making any experiments in the harvesting of rubber, but I have several projects which I will test, at a convenient season. That was a rather remarkable advice given by the rubber expert the other day, but I hope it will not be followed by the Ceylon planters, whose honour and reputation are concerned in the character of their produce. It may be true, that the buyers of rubber discount as much as forty per cent for foreign matter in the samples with which the markets are now supplied, but they will not long continue that practice with parcels absolutely pure. I would have my brother planters take all the pains they can to supply an article unmixed with any foreign substance whatsoever, and trust it to find its value in the market on its own merits. There can be no gain in sending earth and gravel half round the world, and the certain recovery of the forty per cent discount for dirt will cover all extra cost.

ALL ABOUT TEA.

(*By a K. C. B. on Tea-totum.*)

Tea is a bush, and good tea needs no *bush*. Now this is a thing no fellah can understand. A man who gets a good flush is soon flush of *money* and has nothing *owin'*. No tea planter should be without a T square, or he is sure to get mixed, which is quite an art by itself and does not matter to anyone but a *merchant*. Be sure you buy high-bred tea, as low varieties ain't no sort of use.

Germinated tea seed is very good; but some say China is the best, at any rate there is much to learn upon this point. Ask for *tips*.

When you begin to gather leaf da(i)ly, then you must look out; and do not 'fire' your tea too much, if you know anything about 'vetinary' surgery you will soon see the mistake of this, and when you make, or all take, tea do not have any more iron in the water than you can help. Solder the water a little and it will be a soft liquor. Never drawer tea too long, unless you are sure the 'being in the wood' a long time will not make it fusty. Tea may be tippy, but this can only be ensured by having pekoe and not broken. Souchong is not a China tea, and congou does not come from Africa. Brick tea is not made of London clay, but is much used upon steppes.

Indian tea is not black like Indian ink or Asiatics, but is quite green like coffee until withered. Persons in training should not drink much tea even if tee-totallers as they may get a regular 'tannin' when it comes to the time for the struggle.

A maundering sort of person should never be about a tea-house, and it requires a man of small bulk to get off a good break. A break-down in any way will give one a severe dance, and an accident to your *Sirocco* will fill you with a disgust. A maund of seed is a measure, but half-measures will spoil your seed. Some people ferment their tea too long, and then it is not as sweet as *Hay* which is a 'sine-qua.' The Ceylon people have great *hope* in tea, and in their pilgrimage about Adam's Peak in search of land have made their progress as well established as *Bunyan's*. However, I will not teas(e) you with further details, and will conclude with one word of advice, and that is to triumph te(a)duce!

DESTROYING THE PHYLLOXERA.—It is not necessary to destroy Vines in order to get rid of the phylloxera. Carbon bisulphide and sulpho-carbonate of potassium have been, and continue to be, very extensively and successfully used in vineyards where the phylloxera has appeared. Carbon bisulphide is used where water is scarce. There are two objections to its use—it is explosive, and it checks the Vine to which it is applied. Sulpho-carbonate of potassium is used where water is plentiful; it destroys the phylloxera without checking the Vines, and it acts as a manure. For 1 square yard of soil the application should be 1⅓ oz. dissolved in 5 gallons of water; this mixture should be poured on gradually, so that it may sink evenly into the soil. For this country sulpho-carbonate of potassium has been manufactured wholesale by Messrs. Wm. Bailey & Son of Wolverhampton.—G. T., Oporto.—*Journal of Horticulture.* If the remedy were effective on a large scale, we should not continue to here of the destruction of vineyards in France and other countries.—ED.

THE CINCHONA CALISAYA (OR LEDGERIANA) DISCUSSION.

Mr. J. E. Howard, F. R. S., has favoured us with a letter on this topic by last mail, in which he deprecates our having introduced the personal element into the discussion. What we did was to express our amazement that first Sir J. D. Hooker should have been supposed capable of figuring a pseudo-micrantha as a calisaya and then Dr. Trimen of having committed the same mistake when figuring and describing a Ledgeriana. We expressed the opinion which we still hold, that neither botanist was capable of an error which would have been so gross and discreditable. We insert a communication from Dr. Trimen, and we quote as follows from Mr. Howard's letter :—

"When I say that this great authority (Hooker) has never seen my plants nor been brought into the discussion at all (so far as my knowledge extends) you will see that your remarks as to my asserting that 'such men as Hooker and Trimen were capable of mistaking a bastard grey bark for the very prince of the yellow barks' are irrelevant.* I regret being compelled to differ from Mr. Moens, but find that he is disposed like a true man of science to discuss all these matters in a friendly spirit. Dr. Trimen has more reason to complain of me, as I have called in question his botanical skill, and I do not wonder that he wishes me to withdraw from the field; but if all my independent critisim is to be crushed, what will become of the success of the great enterprize in which we are all so much interested?

"The opportunities afforded by the existence of Government Gardens in Ceylon and elsewhere for the assistance of the planters are very great, but the amount rendered has so far not been equal to expectation. Take the question so much agitated of the hybridism or otherwise of forms of cinchona, a most important one because *real* hybrids are unstable. All this might have been settled long ago by actual experiment. I am reading just now the works of Darwin and Müller on the fertilization of plants. What a vast amount of information do I find there on the *perfecting* of seeds, of which your readers, whilst paying so largely for seeds from Java, are probably wholly uninformed?

"I freely admit that Dr. Trimen is right that I am *no botanist*; but I am a botanical explorer, as far as my means and opportunities extend, and I continue to study the development of my plants from the Yarrow seeds and those from Bolivia, which I showed to Dr. Trimen in their early stage. I remarked that they were as like as six to half-a-dozen. This character on the whole they still retain. But it is otherwise with a flourshing plant from seed sent by Mr. Gammie from Darjeeling to Kew and thence to me. This *far away* surpasses in power of growth and richness of foliage all the others, and I could easily understand that it might form one of the supereminent *Tata* trees. It is not the under surface, but the *whole leaf* which according to Mr. Ledger turns *rojo* or scarlet and gives a character of resemblance to the *succirubra*. Of course this exisits in degree in other species as in the C. officinalis, but no one would fail to see the difference.

"Mr. Gammie's plant has *not* the bronzed character of the tips which prevades all the others. I believe it, nevertheless, to be the *same* essentially, and that, probably, it is the form described by your Java correspondent found under ledgeriana trees and combining the vigorous growth of the *succirubra* with the product of *ledgeriana*. How important than to propagate this? and I believe it is all from the same parent trees when *rightly fertilized*. Darwin obtained from the 6th *self-fertilized* (!) generation of Ipomœa *a single plant* which he named the *hero* which transmitted the peculiar colour of its flowers, as well as its *increased tallness and a high degree of self-fertility*, to its children, grandchildren and great-grandchildren (see Darwin's 'The Effects' &c., p. 349). This was a true *Tata* ('father') plant in its way.

"*P.S.*—The distance from the Rio Beni, in the neighbourhood of which Ledger's seed was procured, to Chimborazo, the centre of the Red bark district, is more than 1,100 miles. See the map."

* Most decidedly Mr. Howard represented Sir J. D. Hooker as figuring a Micrantha calisayoides as Calisaya josephiana.—ED.

DR. TRIMEN AND MR. HOWARD.

Royal Botanic Gardens, Peradeniya, 21st Nov. 1883.

SIR,—I have addressed the subjoined communication to the Editor of the *Pharmaceutical Journal* in reply to the letter of Mr. J. E. Howard on "Cinchona Ledgeriana" published in that periodical.

As sufficient time has now elapsed for my paper to have reached its destination, I forward you a copy for publication, should you think the subject still possesses an interest for your readers.

But, if my communication be too long or too technical for the columns of a daily newspaper, it will doubtless find a suitable place in the more permanent pages of the *Tropical Agriculturist*, where so much material bearing on the subject has been already brought together.—I am, sir, yours faithfully, HENRY TRIMEN.

THE BOTANY OF CINCHONA LEDGERIANA.

BY HENRY TRIMEN, M. B., F. L. S.

To the Editor of the Pharmaceutical Journal.

On the 3rd May, Mr. J. E. Howard read a paper on this subject before the Linnean Society, and within the four months following he has found it necessary to publish two additional papers *(a)* to endeavour to explain successive changes in his opinions. These changes have resulted from "new light" obtained in instalments from different sources and of varying brilliancy :—the specimens and letters of Mr. T. N. Christie of Ceylon, the visit of Mr. Ledger to England, and the publication of Mr. Moens' "Kina Cultuur in Azië." Now at length the first paper is published, *(b)* considerably shorn of whatever importance it may have originally had, but this also has an "addendum," undated but apparently written in August. It may be regretted by some Fellows of the Society that the author did not refrain from printing views which he had so modified since he expressed them. I presume at all events that in endeavouring to ascertain what really are Mr. Howard's present ideas on the nature of C. Ledgeriana (no easy task), I shall be right to take the statements and suggestions contained in the paper latest in date, that, namely, which, under the rather sarcastic heading of a "brief note," he contributed to your columns. To assist the exegesis I shall, however, have to avail myself of the earlier papers also.

When in September 1881 I prepared the description of C. Ledgeriana, Moens MS. which was printed in my Journal *(c)* for November, the only published botanical information was Weddell's definition in Howard's "Quinology."*(d)* It does not appear whether Weddell saw any specimens, or whether he drew up his diagnosis merely from Fitch's three fine drawings made from dried plants from the Java plantations: he allows that the characters he gives are "not weighty ones," and indeed these plates would not be sufficient alone for discriminating Ledger-

(c) *Journ. Bot.* xix, pp. 321-325.

(d) *Quin. Ind. Plant.* p. 85.

iana from Calisaya. (*e*) The plant thus remained as very probably merely one of the pseudo-varieties of the bark dealers which might not possess any botanical characters sufficiently definite to be able to be distinguished in the field or in the herbarium. In Java no doubt they knew better even then, but that was the state of information prevailing in England and India when I came to Ceylon at the beginning of 1880; and to the frequent and urgent requests of the growers of bark-trees to say whether such were "Ledgeriana" or not, I found it impossible to give any positive answer.

Mr. Moens visited Ceylon in September 1880, and it is to him that I am indebted for having first pointed out to me that the plant had good definite characters. These were familiar to him in Java as distinguishing all the best and most marked trees which had come from Ledger's seed(*f*): and, so soon as I was satisfied that they held good in Ceylon, I lost no time in making them public. My description was based on the examination and comparison of numerous fresh specimens; and it was an additional proof of the correctness of the name, that the plants yielding them have all without exception been traced back to Ledger's seed.

In making (after consultation with Mr. Moens) Weddell's variety into a *species*, I expressed some compunction for adding yet another specific name to this already overburdened genus, but I gave what I thought good reasons for the course followed; and I may now add that further experience has justified it. (*g*) Mr. Moens' own description has now appeared; (*h*) it is much fuller than mine, but differs in no other respect from it.

Yet Mr. Howard asserts in his two earlier papers that my plant is not "Ledgeriana" but a variety of C. micrantha! It is true that in his most recent paper he acknowledges he "may be mistaken" in this extraordinary determination; in making it one can only suppose that he could not have read my description with any care; but, looking only at the figures accompanying it and remembering a former error of his own, (*i*) at once accused me of a similar blunder. But having supplied a full definition I must be judged by that rather than the plates accompanying it. I expressed in the paper my regret that I should be forced to figure so poor and ill-grown a specimen, but it was the best I could get at the time; and the tree, apart from its stunted growth, was considered by Mr. Moens as a very characteristic example of the species.

Mr. Howard further has matched these figures of mine with one published in August 1873 in the "Bot. Magazine" (tab. 6,052) under the name C. Calisaya, var Josephiana, Wedd. This figure was made from a plant which flowered in Mr. Howard's conservatory in 1872, having been received from Kew. In the text accompanying the plate Dr. (now Sir) J. D. Hooker tells us that the plants were brought from South America by Pearce in 1866, and that several wardian cases of them were sent to India in that year. He also says that it seems to be "intermediate between calisaya and micrantha," but that Mr. Howard, after first thinking it var. calisayoides of the latter species, afterwards agreed with Dr. Weddell in calling it Josephiana Mr. Howard now says, "I should myself have preferred calling it C. micrantha, var calisayoides." but it is remarkable that in 1876 when he himself published another figure (Quin. Ind. Plant. t. 9.) of identically the same plant in his green-house, he should still give it the name of Josephiana, var. glabra. Nor in the accompanying text (p. 86) does he say a single word about it being more properly a variety of micrantha. Both these plates show a plant with large erect white flowers and clavate buds; and what resemblance Mr. Howard can have seen between them and the figures accompanying my paper I fail to understand. No wonder Mr. Ledger "rejected" this plant. Mr. Howard does not tell us why he prefers to put it under micrantha; so far as the leaves go, it seems more rightly put under Josephiana, where I see Mr. Moens also places it.(*j*) Ripe fruit would help to determine this point.

Of the other (or the same?) recorded intermediates between Calisaya and micrantha extremely little is known.(*k*) Of the one called C. Calisaya, var pallida, Wedd., no description or figure has been published; of the other, called C. micrantha var calisayoides, a very brief diagnosis by Weddell is all that we have. They are allowed to approach one another extremely closely in foliage, and the bark of each seems to have been called "calisaya blanca," but I have no means of determining whether they be identical.

The next point Mr. Howard remarks upon is that no analysis of the bark of the tree figured by me was given, and appears to think this a serious omission. Can he mention any other genus of plants where it is necessary to give such an analysis in describing a new species; and, if not, why should it be required in Cinchona? However important it may be in other respects, I attach no value to chemical composition as defining species or varieties. We know indeed from experience that out of 10 trees with the characters Mr. Moens and I have pointed out probably 9 will yield a large, though variable, percentage of quinine almost unmixed with the other alkaloids; but the other one may be as poor as an ordinary Calisaya. It is true that the bark of the actual tree figured was never analyzed, but it was one of a row of several all of precisely the same botanical type, and the analysis of the bark of some of these *has* been published by Mr. Agar the proprietor.(*l*) The analysis, as it happens, was made by Mr. Howard himself "who pronounced it to be Ledgeriana bark."

Now, as to the magnificent pictures illustrating or forming the basis of Weddell's diagnosis of var. Ledgeriana, they are no doubt fine examples of Fitch's work, and one cannot but admire the skill which can produce such restorations from the dried mummies in a herbarium. But it is risky work, and the botanist is but too familiar with the want of that sort of accuracy which he particularly needs, so often to be seen in the work of even the best botanical artists. In these plates none of the characteristics of the flower of Ledgeriana are accurately shown so as to be beyond dispute; the points missed are just such as would be likely to escape an artist unless his attention were drawn to them, and they were not then known to Mr. Howard himself. Nor has the artist caught the *facies* or habit of the plant any better than the details (as may very well be seen by comparison with the phototypes illustrating Mr. Moens' "Kina Cultuur"), whilst the gaudy and inaccurate colouring makes them still less like reality.

It is necessary to say thus much about these plates because Mr. Howard seems to regard them as so accurate as to justify him in speaking of them as though they superseded type-specimens of the plants themselves. This appears when we endeavour to ascertain what, after all, he considers his var. Ledgeriana to really be botanically. It is, he says, to be restricted to "the 'Rojo' bark of Ledger," which is "one form of Dr. Weddell's second division of C. Calisaya;" (*m*) further, it is Howard's "form A (plate IV) exclusive of B and C" (plates V and

(*e*) Mr. Howard himself candidly avowed that, to him, Ledgeriana's character was stamped "by its great productiveness in pure quinine" (l. c.); Dr. Weddell did *not*, however, include this in his definition.

(*f*) It is perfectly wellknown that this seed was not all the same. There were some very bad trees of quite another type among those from the original sowing.

(*g*) The dignity of "species" varies considerably in different genera, their characters being inevitably lighter in such very natural genera as Cinchona. In fact C. Ledgeriana is pretty much on a level with most of the other accepted species in the genus.

(*h*) *Kina Cultuur in Azie*, pp. 75-77.

(*i*) See his paper in *Journ. Linn. Soc.* p. 319.

(*j*) *Kina Cultuur*, p. 84.

(*k*) This little is to be found in the introduction to Howard's "*Illustrations*," p. v. and Weddell's "Notes" in *Ann. Sc. Nat.*, ser. 5. xi. 361, and xii. 51 and 57. Triana (*Nour. Et.* pp. 62, 75) puts both under micrantha.

(*l*) *Ceylon Observer*, 24th June 1883. They gave 7 per cent pure quinine and only a trace of other alkaloids, being then 4½ years old from planting out.

(*m*) That is, of an amplification by Howard of C. Calisaya var microcarpa, Wedd., described in *Ann. Sc. Nat.*, l. c. p. 54, with the vernacular names of "Calisaya Zamba" and "Zambita."

VI) and therefore only in part the var. Ledgeriana of Weddell and the C. Ledgeriana of Moens. In fact it is a *picture* (plate IV) merely, selected it would seem by Mr. Ledger as the most like what he remembers or supposes these "Rojo" trees to be: that is all. This plate represents a robust plant with large erect flowers!

But Mr. Howard's restricted "Ledgeriana" is still further narrrowed down. Plate IV. happens to have been made from a short-styled plant, and it chances that Weddell's diagnosis was also drawn up from one. Mr. Howard prefers with the natives to call this form "macho," and really believes that it is *male* in some more especial manner than the long-styled form, which the untutored Indians and he term "hembra" or female. It seems scarcely credible that he can seriously propose to restrict his *var.* Ledgeriana to the short-styled state, but he distinctly says that "it is exclusively the *macho* form." Mr. Howard has been led to the *reductio ad absurdum* of giving a definite botanical name to a mere sexual condition probably incapable of self-fertilization, simply on the faith of Mr. Ledger's opinion as to plate IV. The latter gentleman (or rather his native servant) was also much struck with the *colour* of another plate (tab. X.) representing the hybrid "C. anglica." This reminded him of the colour of the "rojo" and Mr. Howard at once jumps to the conclusion that the two are "very nearly related"; but as this plate X. happens to be drawn for a long-styled form, or is very decidedly "hembra" as Mr. Howard puts it, it "cannot come under Weddell's diagnosis."

We may, however, feel, very certain that Dr. Weddell, in 1875, when he drew up the definition in question was not intentionally creating a variety on what was then well known to be a merely physiological condition; to support the position that he did so, Mr. Howard quotes remarks written by that excellent botanist in 1849 when the nature and relationships of dimorphic flowers (so frequent in *Rubiaceæ*) were not properly understood: it is noteworthy that in 1869 Dr. Weddell had deliberately dropped the bark-cutters' term "macho," which he then no doubt saw to be misleading.

One sees with regret throughout all these communications of Mr. Howard a very remarkable neglect, or an intentional defiance of the accepted rules of botanical nomenclature. For instance, he makes the astounding remark that "it belongs to Mr. Ledger and to him alone to define what is the true Ledgeriana." Why? on what possible grounds? Mr. Howard has said a little before, and fairly enough, that "the privilege of naming a plant belongs to the botanist who first observes and properly describes it"; this may pass, but how in the world can it apply to Mr. Ledger?

In conclusion, a few words as to the Ceylon cinchonas spoken of by Mr. Howard. He has committed himself to the following identifications:—(1) The plant figured by me = C. micrantha, *var.* calisayoides (probably); (2) Mr. Christie's specimens (St. Andrew's Estate) = C. calisaya, var. microcarpa but probably hybridized with "C. officialis); (3) Mr. Laurie's (Yarrow estate) = C. calisaya, *var* "Ledgeriana." Now, I am familiar with all these. They are all from the same small quantity of seed and were raised in the same nursery beds at the same time; and I can state positively that they are *all botanically identical.* Further, they are also identical with what is and always has been known as "Ledgeriana" in Java; and, as "Ledgeriana" (species or variety) was founded on the plants in Java and has never yet been applied to any wild South American tree, the Ceylon plant must of course bear the same name. I regret the quantity of ink shed over so simple a matter.

Peradeniya, Ceylon, 29th October 1883.

INSECT ENEMY OF ORANGE CULTIVATION IN BRITISH GUIANA.

Downing Street, Jth September, 1883.

Ceylon No. 307. Sir,—I have the honor to transmit to you herewith a copy of a report by Mr. R. McLachlan, F. R. S., upon an insect which has attacked the orange plantations of British Guiana.

As scale insects infest many kinds of plant in Ceylon, the information contained in this report may be found of use in the colony.—I have &c., (Signed). DERBY.

Lieut.-Governor Sir JOHN DOUGLAS, K.C.M.G., etc., etc.

MR. MCLACHLAN TO SIR J. HOOKER.

Westview, Clarendon Road, Lewisham, London, S. E., 23rd Aug. 1883.

To Sir J. D. HOOKER, K. C. S. I. F. R. S., etc., etc. Director of Royal Gardens, Kew.

Dear Sir Joseph,—I have the honor to report on certain portions of branches of orange from British Guiana forwarded through the Colonial Office which are greatly infested with a "scale insect" or "coccus."

The insect in question belongs to the (genus) of coccida termed Diaspis and as it did not appear to accord with any previously described species of that (genus) I forwarded it to my friend Dr. Victor Signoret of Paris, who has made the systematic classification of coccida his special duty. He is of opinion that it is undescribed, and has recently, I believe, bestowed upon it the name "Diaspis durantie."

Three samples of portions of branches were submitted to me labelled respectively "orange" Bhal (?) and "lime": of these the orange appears to be the least affected and the "lime" the most, but in all cases the scales are so thickly placed as to nearly obscure the bark. The same species of "scale" infests all three, but at first sight there appear to be two different kinds, one large and dark in colour the other much smaller and whitish. The larger "scales" are those of the female insect, the smaller those of the male.

The life history of scale insects may be briefly stated as follows:—

The eggs (which are very numerous) are deposited by the female under the scale she has secreted and under which she herself lives for the greater part of her life. These eggs soon hatch (the time varing according to the temperature) and the young larvæ wander forth. This period of activity is of very short duration probably never more than a day or two and at its end the larvæ settle down on some portion of the plant affected and commence secreting the "scales" under which the female lives for the whole of her remaining existence and the male until it is ready to assume the perfect state in which it is a very minute whitish two-winged insect (but in many species of Coccida, the male is unknown and the generative condition known as "parthenogenesis" probably obtains). In hot climates, such as British Guiana, it is probable there may be three or four generations in each year, but this can only be determined by local observation. It is of importance that the short period of activity immediately after emergence from the egg should be borne in mind, for it is possible that at this period the insect can be more readily atttacked by remedial measures.

Remedies may be mainly sought under two categories "mechanical" and "insecticides," and in connection with these I would earnestly advise those interested in orange culture in British Guiana to consult the report of the entomologist of the United States Department of Agriculture for the the year 1880, by J. Henry Comstock (1881), and the report of the entomologist from the annual report of the same department for the year 1881, by Charles V. Riley (1882), both issued from the Government Printing Office at Washington. Both may be consulted with advantage, and the more so as the two authors did not work in concert, and their ideas are not always identical in the means proposed. In Professor Riley's report he has been aided by the practical experience of Mr. H. S. Hubbard, who devoted himself especially to the subject. In the Southern United States the attacks of "scale" on oranges has become of national importance and experience there, and in British Guiana should be nearly identical, although the particular species of scale insect injurious in the British Colony does not appear, to have been observed in the States.

Of mechanical measures, one of the most important is that of brushing the parts of the trees infested with a brush sufficiently strong to remove and destroy the scales without injuring the bark. It must rest with orange planters in the districts affected to consider how far this can be successfully done, in which the height of the trees and the comparative freedom from scale of the leaves and fruit must be taken into consideration, cutting back or lopping and burning the affected portions of the tree might also be tried, though this naturally checks the supply of fruit until new wood is produced, stimulating by powerful manures so as to enable the trees to out grow as it were the attacks of the insect, has also been recommended, but it is possible that this may tend to an over-production of young wood and leaves, and a diminished supply of fruit. Finally, there is the radical remedy of stamping out by destroying all the infested trees and beginning again. This might occasion ruin or severe loss to poor planters, and would probably require a Governmental subsidy to the parties affected for a considerable time. In connection with this it is desirable, whether the planters should not ask themselves if the trees have become naturally in an unhealthy condition, and the soil exhausted through continuous growing of the same trees on the same ground. It appears to me possible that rotation of crops may be as necessary in the case of cultivated trees or shrubs as it has been proved to be with cereals and herbaceous plants, and in this point I think the American reports before alluded to, are not sufficiently explicit.

The number of insecticides that have been tried is very great. Some of them have proved impracticable owing to their destroying both the plants and the insects, others again have proved only partially successful or have been very difficult of application or too expensive. It seems then that those to be seriously considered are very few. To be effective they should consist of solutions of such a nature that can be applied by means of a force pump so as to reach every part.

Whale-oil-soap in a solution of one pound of soap to one gallon of water is reported to have killed all the insects, but only few of the eggs; it must be applied hot, as it solidifies in cooling, and it is recommended that the operation be repeated several times at short intervals.

The most effective of all insecticides is termed Kerosine Emulsion, the formula for the preparation of which is here given :—

Pure kerosine, 1 gallon.
Condensed milk, $1\frac{1}{2}$ pints.
Water ... ... 3 pints.

Mix the milk and the water before adding the oil and churn until the whole solidifies and forms a "butter." In applying this preparation the kerosine "butter" should be diluted with from 12 to 16 times its quantity of water and then be applied immediately, for, if it is allowed to stand, the "butter" rises to the surface and the solution is imperfect. The results of experiments with this are stated by Mr. Hubbard to have been satisfactory and he gives it the preference over all other insecticides. It should be remembered that it is possible (I might say certain) the insects can be more readily combatted by insecticides during the very short period in which they are active, just after emergence from the egg (attention has been directed to this already in this Report) local observation only can define this short period.

No remedial measures can be of much value unless as the result of concerted action. The care of one planter may be utterly neutralized by the neglect of another, his neighbour. Therefore it is desirable that if after the trial of any special remedial measures favourable results have been obtained, the application of such a remedy should be made compulsory universally and not be left to individual discretion.

Insect 'pests" are (with few exceptions) endemic and epidemic in the same locality. They are always present and so long as they continue endemic and limited in their numbers the injury sustained is but small and may even in certain cases become an actual benefit by checking over production. It is when the epidemic condition shews itself that the real injury is inflicted. The epidemic condition may be only transitory or it may prevail to such an extent as to destroy or permanently damage the plants.

It is therefore desirable to keep up a healthy condition and if in spite of this the plants still shew themselves liable to destructive attacks it is more than ever necessary to enquire whether their constitution has not been deteriorated by long continued cultivation on the same spot without rotation.—I have &c.,

(Signed) ROBERT McLACHLAN.

THE SIZE OF THE BREAKS OF INDIAN TEA.

(To the Editor of the *Home and Colonial Mail.*)

SIR,—For some time the Indian Tea Districts' Association have been occupied in a praiseworthy attempt to effect an arrangement with the Wholesale Tea Dealers' Association and the Customs' authorities, by which a new system might be instituted for weighing teas in the chests, with the view to avoid turning out the contents in the manner now adopted in the large storing warehouses in London. The Association deserve credit for their effort, but is not the movement premature?

Old planters assert that the decline in quality of our Indian Teas arises from the objectionable system of binning the daily out-turn until sufficient is collected to complete fair-sized breaks. When tea is packed immediately after final firing, the aroma is retained, but when it has to lie in the bins for a day or two the aroma, if not entirely destroyed, is at any rate partly lost. It is reasonable to assume that tea with a good "nose" is worth 2d per lb. more than tea with very little aroma, but, to be on the safe side, let us say the difference is only a penny—and even at that reduced rate we find a loss of 8s per 96 lb. chest, to say nothing of the cost of extra labour employed under the binning system, and the loss of valuable space in the tea house.

The buyers in the Lane demand large-sized breaks, and are not satisfied on a busy day to find minimum lots of even twenty chests. How many factories in India are capable of turning out sufficient tea daily to complete even twenty chest breaks without binning? On the assumption the average assortment consists of Broken Pekoe, Pekoe, Pekoe Souchong, Souchong, and Broken Tea, it would require 100 chests daily to make five breaks of each twenty chests. How many gardens average anything like that quantity?

Many planters have taken immense pains to second the effort of the Home Association, and after having incurred endless trouble and worry in their efforts to bulk on the factory, find that, on arrival at home, the teas have to be re-bulked to suit the trade.

My tip to brother planters is, pack at once after final firing, and thereby make sure of aroma. Store the packages until a good size break is collected. The tea on arrival at home will then open out with a fine nose, and it is then the duty of the agency firm to see that the warehouse keepers employ proper means for rapid bulking.

PLANTER.

THE COCOA PLUM.—Those persons who visit Florida can, if they are interested in such matters, make the acquaintance of a number of wild fruits. Among these is the Cocoa Plum, of which some speak in high praise. The Cocoa Plum is *Chrysobalanus Icaco* (the generic name meaning "golden acorn"); the genus is now placed in a sub-order of the Rose Family, and differs from *Prunus*, the common Plum in points only of interest to the botanist. It is a shrub from six to twelve feet high, producing white flowers, the arrangement of which, as well as the shape of the leaves, and an outline of the fruit, will be seen in the engraving. It is very common in all of the West India islands, and in Florida it is confined to the southern portion of the State. The fruit, in size and general apearance, is much like a common plum, but is remarkably variable in color, some being white, others yellow, while it is not rare to find specimens with red or purple fruit. The pulp is sweet, and though a little austere at first, most persons become very fond of the fruit. In Jamaica and others of the West Indies, a conserve prepared from the pulp is an important article of domestic trade. The kernel yields an oil on expression. The leaves and roots are astringent and employed as local remedies.—*American Agriculturist.*

FIBRE AND FIBROUS MATERIALS:

CHINA (RHEEA) GRASS; ALOE AND OTHER FIBRES.

(*Continued from page* 949, Vol. II, 1882-3.)

Recurring to the consideration of the Favier patent machine for rhea fibre, we must mention that we should like to see an experiment tried with rhea shoots, which Dr. Trimen can supply, in Smith's patent machine which Messrs. John Walker & Co. got out some time ago. It is somewhat surprising that the French inventor has not claimed the Indian reward of £5.000 if his machine is so great a success; but it is suggested that he may not have wanted to part with his patent, being under the wrong impression that the Indian Government made that a condition. At the same time it is evident that FAVIER'S PATENT has proved a success in Europe, and, according to the following report in the "Journal of the Society of Arts" it is likely to be a turning-point in the industrial history of China grass fibre :—

During the year 1882, a development took place of the interest attaching to the cultivation and use, in manufactures, of China grass, and, with repect to the supply of the raw material it has been estimated that the progress achieved in 1882 was as much as had been done in that direction during the whole of the fifteen years immediately preceding.

According to a detailed statement, published by the *Central Blatt fur Textil-Industrie*, the principal feature of the year was the extension of cultivation in Europe, the bulk of the supply having been received, previously to 1882, from China and the adjacent islands.

China grass has recently acquired a position of considerably augmented importance as an industrial product. The sudden advance of a textile substance, in the estimation of the manufacturing public, is not without precedent. Flax and cotton had, it is remarked, a long period of quiet utilisation before they became such important articles as they now are. The discoveries which gave an unexpected impetus to their employment for industrial purposes were, it is stated, Witney's machine for treating cotton in the raw state, and the flax-spinning machine of Philippe de Girard. In the same way China grass owes its present greatly increased favour to the Favier system of treating the fibre; the introduction of this process having been, in fact, a turning point in its industrial history.

In Italy, M. D'Humières has been for several years making experiments in its culture, and he has recently published the fact that, with suitable arrangements, a profit of 33 per cent. may be made by the grower. Larger plantations have now been organised in that country. Portugal has already planted a million roots; and Spain has also taken important steps in the matter. The plantations in Algiers and Egypt have, it would seem, been materially increased. In Java companies have been formed to promote the culture; and it is stated that in various French colonies, as well as in America, steps will shortly be taken to introduce it. France seems, however, to have taken the lead in the new movement, and during 1882, several million roots were imported for planting. In the southern departments, fields of China grass are constantly becoming more frequent. Favier's patent is owned, it is stated, by a company entitled, La Ramie Française, which is located at Avignon, and has established nurseries in the departments of Vaucluse, Var, Bouches-du-Rhone, Gard, &c., occupying about seventy-five acres. This company intends to sell plants to the agriculturists, and to arrange for the purchase of the yield. It will also carry on, for its own account, the preparation of the fibre and will be, therefore, able to offer it to the spinners ready for them to operate upon it.

The spinning of China grass is being developed upon a scale proportionate to its extended cultivation. Before the year 1880, it is stated that there were only two establishments in Europe where China grass was spun, and it would seem that these could only obtain their supplies from the London market. It is remarked that the establishments referred to have, since then, materially extended the scope of their operations. Six others are said to be now in working order, and, doubtless, others are in contemplation.

In France, many trials have been made as to the employment of China grass in various branches of textile manufacture, and from the successful results, it would seem that an important consumption of the article is assured. Its introduction in the trimming, hosiery, and cloth branches has been well received. Some further modifications in the spinning of the yarn and lower range of prices would, it is said, place China grass in a prominent position as a textile material. The Ramie Française Company exhibited last year (at the Avignon Industrial Exhibition, and at the Colonial Exhibition, at the Palais d'Industrie in Paris) specimens of dress goods, cloths, and other materials, either entirely made of China grass, or into which it entered as a component part.

It is remarked, in conclusion, that the cause of the leading position held by cotton is the low price of articles made from it. A serious competition is not to be looked for, it is considered, on the part of flax, but it is suggested that China grass, if its price is reduced, may be found for certain purposes an important rival of cotton.

We are surprised to find that no reference is made in the above summary to the facts that Sir Titus Salt, many years ago, mixed China grass with alpaca wool in his manufactures and that in Bradford wollen manufactories the substance is used to a considerable extent.

From M. Favier's French, pamphlet placed at our disposal by Mr. Kay-Shuttleworth, we translate and quote as follows* :—

In August 1881, the machine was publicly tested at Avignon. Near it were arranged specimens of the brilliant materials and remarkable ropes of all kinds and *texture* which by their fineness and resemblance to silk attracted the admiration of the *filateurs* present. M. Favier believes he has discovered the right principle on which the separation of the fibre from the wood and epidermis should be carried out.

He began by introducing some dry stalks of China grass into the mouth of the machine. One rotatory movement had scarcely been given to the machine when at the opposite extremity the stalk came out instantaneously the stalk cleaned and transformed into an open bast, having the same length as the stalk and looking as if it had been combed, so well was the parallelism of the fibres preserved. There was a *total* removal of the epidermis, a great strength of resistance in the fibres, and no threads were broken. One might seek in vain among the débris that fell from the body of the machine for any particle of wasted fibre. There was nothing as waste but the wood and the bark which can both be utilized for their fertilizing properties.

Ropes made of this fibre are much stronger than hemp and also have the advantage of being lighter and having a smaller diameter.

The *China* grass, which is reputed the best, can never be used in its primitive state, as it must always first be deprived of its gumminess; it would, therefore, says M. Favier, be desirable to use a fibre that can be worked in its raw state without any preparatory process.

The maximum length of stalk attained in the south of France is 2 metres or yards.

The following particulars will show the rapidity with which the machine works or what is done in one minute:

Medium Stalks—rather small.—Fifteen are introduced into the mouth in this short space of time. They issue giving 28 *grammes* (1 oz.) of fibre. This represents in the hour 68 by 12=1,680 gr. (3 lb. 5 oz); in 12 hours—1,680 by 12 =20,160 (20 kilograms) (44 lb.).

Large Stalks. In one minute, with 12 stalks, we obtain 50 gr. of fibre, which makes in the hour 3,000 gr. (6⅝ lb.), in 12 hours 36 kilos. (78 lb.). These numbers multiplied by 2, the minimum number of mouths to a machine, give for the small stalks 40 kilo. (88 lb.) per day; for the larger ones 72 kilo. (158⅜ lb.) per day. Say a daily aver-

* Since this was in type, Mr. Shaw-Kennedy has sent us a pamphlet in English, a translation of M. Favier's.—ED.

a[illegible] of [illegible] kilo. (123½ lb.) The net produce is reckoned thus: 12 stalks weigh 165 grammes. They yield 38 gr. of fibre. It comes then to [illegible], say 23 per cent net.

The expense of the manipulation he calculates as follows.—

2 girls are required to cut the heads and tails of the cane before introducing it, at 75 c. (7½d)...		1·50 fr.
2 women	one to introduce the stalks	... 1·50 „
	one to receive the fibre	... 1·50 „
	Total	... 4·50 „
		= 7s 7d

To this must be added about 2½d per kilo. for general expenses. The cost of the machine would be about 4,000 francs or £160. It might be considerably reduced and would cost less, and again it might be possible to increase the force to three mouths.

M. de Courtois has been cultivating the grass successfully for 12 years near Arles. He notices that the *white* grass is more hardy than the green variety and grows more easily in that country. The plant requires a light soil and watering. But M. Favier says that, in spite of certain advantages attaching to the white variety, he prefers the green, as it yields more fibre and of a much finer quality. The manufacturers present at the trial meeting valued the fibre of the white kind at 2½d per kilo. less than the green kind.

M. [illegible] of Florensac, who had also cultivated both, said that the white kind (nivea) grew certainly, at first, more freely, but it soon stopped. The green on the other hand attained afterwards a much greater development and was of much superior quality.

In 1880 there was a competition at Saharanpore, as the English Government had made most brilliant offers to inventors of machines for cleaning China grass fibres. But M. Favier would not compete, as he wished to preserve for France the benefit of the monopoly as long as his patents lasted.

It will be observed that *dried* stalks yield 25 per cent of fibre. But surely freshly cut stalks can be operated on, and we should like to know the proportion of clean fibre to weight of moist stalk. Green aloes yield only about 3½ per cent.

As respects the local supply and growth of the rheea, Mr. Kay Shuttleworth, in private notes written to us since his return, says :—

About ramie (China grass)—I saw some specimens of it growing freely at Peradeniya, the variety there being *Urtica nivea*, which I also saw in cultivation in Italy. On the Rambodda Pass I saw another variety, which grows here also, and which I am sending for classification to Dr. Trimen.

I want to compare the unbleached material of M. d'Humières' manufacture with the local and *very* general "gambahe," a common shrub at every elevation from the sea to Nuwara Eliya, in every ravine and also on rocks, &c. "Gambahe" is the Sinhalese name. It seems to be of the same family and of the same habits, but the leaf is long and narrow instead of oval, [illegible] also grey underneath. A special point in the China grass is that the first crop may be expected within 5 months at the outside from the time of planting the cuttings, and that the fibre is 20 [illegible] of the dry stalks. The leaves also are a favorite food for sheep (among other uses here), and are suggested as fodder in the case of the Urtica proper by the growers in Italy. The manufacturers use the refuse for fuel, but it is also said to be suitable for paper—with also the leaves. Is the gambahe identical with the Nilgiri nettle? *M[illegible]* seems to be of the same family. The *Urtica nivea* is growing freely at Peradeniya and Hakgala: at the latter only a few cuttings, at the former it is almost [illegible].

The plant referred to as the "gambahe," of which some bark and fibre were enclosed, is supposed by Mr. W. Ferguson to be the "[illegible]" of the Sinhalese (morocarpus mulberry-leaved longifolia) and we may as well quote what is said of the "Urticeæ" in the [illegible]

[illegible] ACEÆ.

"Laportea crenulata. [illegible] Urtica stimulans Moon Cat. p. 62. *Maussa*, Sing. I mention this plant simply to attract attention to its fearfully virulent properties; Dr. Hooker in his Himalayan Journals gives very interesting facts connected with the effects of the stings of this plant on himself and others. Two coffee estates in Ceylon, at least, are named *Maussakelly*, after this plant.

"Bœhmeria malabarica." Wedd. "Urtica aquatica." Moon Cat. 62. *Mahaliya-hal*, S. A small tree, the bark of which is used for fishing lines by the natives.

"Morocarpus longifolius." Blume, 261. Urtica verrucosa, Moon. *Gass-dool*, S., bark used like the above.

The following paper of instructions respecting the rheea was published some time ago by the Government of India :—

Instructions relative to the cultivation and preparation of the Fibre of Chinese grass cloth (Boehmeria nivea).

I.—On the cultivation and preparation of Rheea Fibre, or China Grass. Communicated by Dr. D. J. Macgowan to Vol. vi. part iv., of the Journal of the Agri-Horticultural Society of India.

Planting the Seeds.—In China, this takes place in May. Great care is first taken in the selection of seeds, and in the preparation of the soil. The seed should be gathered on the appearance of frost: those produced from a recent root are the best. After being dried, they are stowed away in a basket or jar mixed with sand or dry earth, others say moist earth. The jar is then covered with straw to protect the seeds from the cold, as, if exposed to its influence, they yield an imperfect plant. Before planting, the seeds are tested by immersion in water, those which float are to be rejected, those at the bottom to be planted. A loose dry soil is to be selected, if near a canal or rivulet it is preferable. The ground is to be well ploughed or broken finely, manured and then divided into beds about eight yards long and one wide; the beds are to be raked and afterwards made compact with a hoe. After this it is watered and left for a night; on the following day raking up and pressing down is repeated. The beds being smooth, two or three table spoonsful of seed are mixed with a bowl of earth and sown broadcast over half-a-dozen beds, then they are swept with a broom to cover the seeds. In some places, the seeds are first made to sprout, and then planted in drills, which are carefully filled up. Just before the blades appear, a framework is to be constructed over the beds, on which mats should be spread to protect them from the heat of June and July. The matting must be kept moist by day, and removed at night that the blades may receive the dew of heaven. The beds are to be constantly weeded. When the plant is about two inches high, the framework and matting may be removed. When three inches high, it should be transplanted, having been well watered the night before; the blades should be taken up separately with a portion of earth and planted in a field, far removed from mulberry trees, about four inches apart. It may form a border to the cerealia and vegetables, protecting them from the depredations of domestic animals, which all avoid the "*ma*." In dry weather, the field is to be watered every three or four days until the second decade, when it may be watered every fifth day.

In November and December, manure it with horse or buffaloe dung, earth, straw, or any rubbish, a foot or more thick, to protect it from cold. In March, rake it away and expose the plant, watering it in dry weather, and using rubbish of any kind for manure. A caution is given never to use swine's dung, as it is "saltish" and hurtful to the "*ma*." In the third or fourth year, some say in the second, the plant may be cut and used.

Planting the Roots.—The roots are to be cut in pieces of three or four fingers' length, and are to be planted in May, half a yard apart, and watered every three or four days. On the appearance of the blades, use the hoe and water them; they will be mature for cutting in the second year. In the course of ten years the roots become unfruitful, the shoots may then be cut off, and, if enveloped in earth and covered with matting, can be transplanted in places thirty or forty inches distant. The ground should be well prepared with manure, and freely manured afterwards, the manure being half water. Here, as before, the plants should be hoed from time to time. In many cases, fresh earth, pulverized bricks, ashes, &c., are used for manure. Some years the husbandman has his crop injured by worms, he needs, therefore, to seek for and destroy them as they appear by picking them off. It not unfrequently happens that the crop is in some places remarkably small, and sometimes the produce is very great without assignable cause.

Cutting the Ma.—It yields three crops every year. The first cutting takes place in June. Care is to be taken not to cut the young shoots, keep therefore an inch from the ground. In a month or two the shoots are seven or eight feet high, when the second cutting takes place—do not cut the original stem. During the latter part of September, or in October, the last cutting is performed. from which the finest cloth is made, the first being inferior, coarse, and hard. After each cutting, the plant is to be covered with manure and watered, but not day by day unless it be cloudy. At Canton, the plant is pulled up by the roots every year. from which it is evident that it differs widely from the "*Ma*" just described.

Peeling the "Ma."—On being cut, the leaves are carefully taken off with a bamboo knife, by women and children, generally on the spot. It is then taken to the house, and soaked in water for an hour, unless it is already wet by recent showers; in cold weather the water should be tepid. After this the plant is broken in the middle, by which the fibrous portion is loosened, and raised from the stalk; into the interstice thus made the operator, generally a woman or child, thrusts the finger nails, and separates the fibre from the centre to one extremity, and then to the other. The steeping process is very easy. It appears to be difficult to remove the fibres from Canton "*Ma*," as it is soaked in water for more than forty-eight hours before peeling, which is done by men. They first cut off the roots, and then, separating the fibre from the stalk, strip it off by drawing it over a pin fixed in a plank. In either process half of the fibre is taken off at one stroke. The next process is scraping the hemp, to facilitate which the fibre is first soaked in water. The knife or scraper is about two inches long; its back is inserted in a handle of twice its length. This rude implement is held in the left hand; its edge, which is dull, is raised a line above the index finger. Strips of hemp are then drawn over the blade from within outwards, and being pressed upon by the thumb, the pilous portion of one surface and the mucilaginous part of the other are thus taken off. The hemp then "rolls up like boiled tendon." After being wiped dry, it is exposed to the sun for a day, and then assorted, the whitest being selected for fine cloth.

Bleaching and Dividing.—A partial bleaching is effected on the fibres before they undergo further division, sometimes by boiling and at others by pounding on a plank with a mallet. These are in some places repeated. After being dried in the sun, an important operation then succeeds by women and children, to whom is entrusted the tedious process of splitting the fibres, which they do with their finger nails. Expert hands are able to carry this division very far. When this process has been preceded by hackling, the shreds are finer and softer. The threads are formed into balls, and subjected to frequent soakings and washings. The ashes of the mulberry leaf are recommended to be put into the water with the hemp, others use lime for a whole night. Some simply expose it to dew and sun. In rainy and cloudy weather it should be exposed to a current of air in the house: moisture darkens it. The threads are now ready for splicing, the work of women and children, the labours of the agriculturist being concluded when the threads are rolled into balls, after being sized or stiffened with rice-water. Before the thread is ready for the weaver, the balls are steamed over the vapour of boiling water in a closed oven. They are then spread out to dry. The subsequent stages, until the cloth is removed from the loom, includes nothing which interests, or at least instructs artizans in the west.

II.—ON THE RHEEAS, OR NETTLE GRASSES, OF ASSAM. By Major F. S. Hannay. From Vol. VII, Part I, of the "Journal of the Agri-Horticultural Society of India."

Cutting and Removing the Fibre from the Stalks.—The stalks are considered fit for cutting when they have become of a brown colour for about six inches above the roots. To cut them the Doom seizes the leaves at the upper end with his left hand, and, passing the right hand down to the root, strips off the leaves, and cuts the stalk close to the ground. The stalks are made up into bundles, and the scraping-off the outer bark commences at the same time, or this operation is deferred until the whole crop of the plot has been cut. The scraping-off of the fibre from each stalk is a very tedious operation, and is performed with a blunt-edged knife; all that is left is the fibre and the woody part of the stalk, which are exposed to a hot sun for two or three days to dry. The third morning after having been exposed to the dew for several hours, the fibre is drawn off. This is done by breaking the woody stalk right through towards the thicker end, and then separating the fibre therefrom, drawing it off slowly towards the small end, some care being required in giving the same a peculiar twist, so as to draw off as much as possible. Having finished with the smaller end, what remains on the thicker end of the stalk is pulled off in the same manner It will be seen that this is a very clumsy way of extracting the fibre, and, as far as I can judge, one-fifth of the fibre still remains in the stalk, which may be taken off however, at a second breaking; but the Dooms are not particular, so long as they get what they require. The hanks of the fibre are then separately twisted at the upper end, and tied up in bundles of long hanks of about one seer in weight, if to be kept for sale. As the fibre, however thus extracted, is quite ready for the purpose of net-making, little or nothing more is done than to open out and prepare the threads for spinning, which is done first by drawing the single hanks several times with a blunt-edged slip of bamboo, held in the right hand. This softens and strengthens the fibres, and they are more easily opened out to the required fineness with the fingers and thumb-nails and then made up into small hanks ready for the spinning process, the first stage of which is performed by the women, with the common *takoo*, or spindle, in general use throughout India, the hanks having been well opened out and spread over the top of a high circular open bamboo frame, set end-ways on the ground. The further operations of spinning the first threads to the requisite thickness, and the weaving of the same, is performed by the men.

We may add from the *Dictionary of Economic Plants* :—

"*Grass Cloth*, a name given to the woven fibre of *Bœhmeria nivea*, a perennial of the Nettle family (Urticaceæ), native of China. It sends up numerous rod-like stems 4 to 6 feet high, having heart-shaped leaves silvery-white on the under surface. The stems contain a quantity of fine fibre, which is now imported in considerable quantity from China and India, and woven into the fine linen-like cloth known as China grass cloth. It is now extensively cultivated in Jamaica, as also in the Southern United States; and the British Government have lately been much interested in its cultivation in such of the colonies as are favourable to its growth. There is, however, some difficulty in separating the fibre from the bark and wood, which has led the Government of India to offer a reward of £5000 for the best mode of overcoming the above difficulty. The plant grows freely in this country, but in severe winters the roots are liable to be injured; it might, however, be profitably cultivated in Cornwall and the western counties. The fibre in Assam called Rhea is the produce of this species. Puya Fibre (*Bohmeria* [illegible]) is a plant similar to the preceding in habit of growth, but has longer leaves. It is extensively cultivated in Upper India: the fibre is used for making ropes and sail-cloths."

An even more elaborate account of the cultivation and preparation of China grass has been lately published in the *Indische Mercuur* from which we quote the following as to the range of this most common of Eastern plants :—

Name: Lat. Bœhmeria nivea (URTICA NIVEA, U. TENACISSIMA); Dutch. *Rama*; Fr. *Ortie de Chine*; Germ. *Chinagras*; Assam, *Rhea*; Malay, *Rama*; Sumatra *Caloe*; Japan *Tsjo Kasoe*; China, *Tchou ma Chu*.—Exogen: shrub, 5-8ft. The range of this plant is very wide, especially if we admit the identity of several locally distinguished species or varieties. As a native it occurs abundantly in China, Japan, the Philippines, Java, Sumatra, and the Eastern Archipelago generally; in Siam, Burma, Singapore, and Penang; as well as in Assam, Nepal, and in some parts of the Lower Provinces of Bengal, as Rungpore and Dinagepore. Its natural limits appear to be about 36° N. lat. in Corea and Japan, and between 9° and

10° S. lat., in the Molucca. Under cultivation it has been proved to flourish in almost every part of India; and it has been successfully introduced into many foreign countries. It thrives in Natal, where an indigenous variety attains a height of 24 ft., in Mauritius, in Algeria especially near Relizane, and in the plain of the Habra, in the province of Oran, its cultivation has been attended with great success; the island of Corsica offers similar prospects; S. France, especially the Departments of Vaucluse and Alpes Maritimes, is now producing large quantities of the plant; in the Channel Islands, and even in Great Britain, it does not refuse to grow, though its culture probably could not be made profitable; the alluvial and upland soils of the S. W. States of America are well suited to the plant, and its culture is being successfully carried on in Louisiana and California; it is grown in Martinique, Jamaica, and Trinidad; it has been naturalized in Mexico; finally it is recommended for culture in the rich and warmest forest valleys of Victoria, where irrigation can be applied; in the open ground, it suffers from the night frosts, which, however, do not prevent fresh shoots being sent up during the hot season. An allied variety B. *calophleba*, recently discovered in Lord Howe's Island, deserves attention and investigation.

The instructions to cultivators in the paper quoted above are very much the same as those already given, but clearly rheea grass is regarded as an "exhausting" crop, requiring careful manuring. It differs from all allied textile plants by being perennial and it is said to improve under successive crops. If all the refuse after exhausting the fibre were returned to the soil, the quantity of manure would not need to be much. It grows from cuttings or suckers as readily as a willow, and, loving a great deal of moisture, ought to suit Ceylon. In Java, however, the first experiments failed because the rice instead of the coffee land was chosen for the cultivation.

There are no data by which to estimate the cost of cultivation in Ceylon, but no doubt the same experience applies here as in India, and on the opposite continent, where the one trouble was the cost of extraction and preparation of the fibre. Now, if M. Favier has solved this point, we trust he will, waiving the further honour of France have entered an appearance at the special trials to be made in connection with the Calcutta Exhibition as notified in the following official paper just published:—

NOTICE.

It is intended to allow experimental trials in the extraction of fibres of all kinds to be made at Calcutta during the ensuing rains in connection with the International Exhibition to be opened next December.

2. Stems and other fibrous portions of fibre-bearing plants or trees, and, as far as possible, motive power, will be provided by Government for the use of intending exhibitors.

3. Machines or appliances should arrive in Calcutta about the 15th July or 1st August at latest.

4. Persons desiring to perform experimental trials should have their names registered at the Office of the Revenue and Agricultural Department of the Government of India not later than the 30th June next, and should state on what fibrous plants they wish to experiment, and to what extent, in order that arrangements may be made for providing sufficient quantities of material to be operated on.

5. A list of plants suggested for trial is appended.

6. These experimental trials will be open to the public and are likely to afford a favorable opportunity for inventors who may wish to make known their machines or processes, or to take out patents.

7. Any inquiries or communications relating to the contemplated trials should be addressed to the Exhibition Branch, Revenue and Agricultural Department, Government of India.

Scientific Names.	English names.	Vernacular names.	Remarks.
Abelmoschus esculentus	Okro	Bhindi	Found all over India.
,, ficulneus	Wild Okro	Ban Dheuras	Bengal, South India.
,, moschatus	Musk Mallow	Musk Daná	do do
Abroma augustum	...	Ulat Kambal	Bengal, South India.
Agave Americana	Aloe Fibre	Hathi-chingar	All over India.
,, vivipara	...	...	—
Ananasa sativa	Pine-apple	Anánas	Bengal, South India.
Anona reticulata	Netted custard apple, bulls-heart	Nona	Bengal, Burma, South India.
Bœhmeria nivea and varieties	Rhea	Poi	Assam, Tarai, &c.
Bauhinia racemosa	...	Bakl	Forests all over India
,, scandens	.	Bakl mahwal	
,, vahlii	...	Maholi	
Butea frondosa	...	Palâs, Dhak	All over India.
,, superba	...	...	Himalayan forests.
Calotropis gigantea	... Mudár	Madar ak, yercum	... All over India.
Cannabis indica	Hemp	Bhang	... Kumaon, Northern Bengal
Careya arborea...		Kumbi	.. Forests.
Cocos nucifera	Cocoanut	Nárikel	... Bengal, Burma, South India.
Corchorus olitorius	. Jute	Pát	... Bengal.
Crotolaria juncea	Sunn	San	... North-Western Provinces and Bengal.
Grewia elastica	...	Dhamin	... Himalaya and south India forests.
Hardwickia binata ...	...	Acha	... South India.
Helictres isora...	...	Murorphali	Central India
Hibicus cannabinis ...	...	Patsar	... North-Western Provinces.
Hibiscus Rosa-sinensis ..	...	Jaba	... Bengal.
Linum usitatissimum	... Flax	Alsi	... North-Western Provinces and Oudh.
Marsdenia tenacissima ...	...	Babal Ják	.. Central India.
Musa paradisiaca	Plantain	Kala	.. Bengal, Burma and South India.
Sanseviera zeylanica	... Lily fibre	Marul	... Bengal, South India.
Urtica heterophylla	... Nilgiri nettle		South India.
Yucca gloriosa ...	Yucca fibre		Ditto.

Referring to the official list given above, it is strange, to say the least, that the green-leaved aloe, Foureroya gigantea, has been omitted from the list, more particularly as a series of experiments made very lately by Mr. H. G. Turner, acting Collector of Vizagapatam (who called on us *en route* to Europe, to express his interest in the *Tropical Agriculturist* as a most valuable periodical for India as well as Ceylon) go to show that fibre from the green is far better than that from the ash-coloured aloe (*Agave americana*). We quote as follows:—

Read.—The following from H. G. Turner, Esq., Acting Collector of Vizagapatam, to the Secretary to the Board of Revenue, dated 22nd December 1882, No. 1331:—Adverting to Board's proceedings, No. 2106, dated 2nd September 1882, I have the honor to forward herewith copy of a letter addressed by me to Mr. Elseworthy, the agent to Messrs. Arbuthnot & Co., at Bimlipatam:

	R.	A.	P.
Cost of preparing 950 lb. of *Agave Americana*...	21	1	0
Bandy hire from Vavilivalsa to Vizianagrum...	4	0	0
Do from Vizianagrum to Chittivalsa ...	1	12	0
Cost of 100 lb. of *Foureroya Gigantea* ...	5	0	6
Do cooly hire from Anantapur to Vizagapatam ...	1	10	
Vizagapatam to Chittivalsa ...	1	5	0
Total ...	34	15	6

Letter from H.G. Turner, Esq., Acting Collector of Vizagapatam, to the agent to Messrs. Arbuthnot & Co., Bimlipatam, dated Vizianagram, 11th December 1882.

With reference to your letter, dated Bimlipatam, 7th October 1882, I have the honour to forward herewith 950 lb. of aloe fibre for a special report as to its market-value in London, the cost of pressing, packing, insurance freight, brokerage and any other charges which it may be found necessary to incur in connection with its transmission to London.

2. This fibre is extracted from a plant which I take to be the *Agave Americana*, an aloe with an ash-colored leaf.

3. This fibre is harsh, and prepared roughly by a native process which consists in steeping, washing on stones and dry-

ing; therefore I am prepared to hear that it is of inferior value. But I want to know whether the stuff possesses quality which might be brought forth by a better process, and I shall be glad of distinct information on this point.

4. This fibre is inferior in quality to that extracted from the *Fourcroya Gigantea*, a green-leaved aloe. I am about to send you 100 lb. of this last article, which I take to be the same stuff as is now being exported from Mauritius; and if you can procure distinct information for me as to its identity with the Mauritius fibre, I shall be much obliged to you.

5. I shall send you shortly 500 lb. of the Sagar nar (*Sanseviera Zeylanica*) for transmission to London.

Read—The following letter from Messrs. Arbuthnot & Co., Madras, to the Secretary to the Board of Revenue, dated Madras, 29th August 1882:—With reference to the Board's proceedings, No. 4730, of the 23rd June, and our reply of the 30th, we have the honor to subjoin copy of a report received by us from our correspondents on the sample of fibre *Sanseviera Zeylanica* forwarded to them. If the sample fairly represents the average quality of fibre which could be obtained, it would appear to be encouraging. In continuation of our letter of the 30th June, referred to above, we would suggest that the Collector of Vizagapatam should place himself in communication with our agent at Bimlipatam, forwarding him enough of the fibre to be pressed into a bale at our Jute Factory. From it we could calculate the cost of baling, shipping, &c., and form an estimate of the cost of freight.

London, 29th July 1882.—Report and valuation of Overland Sample of Fibre on account of Messrs. Arbuthnot & Co.:—Good fibre, well cleaned, good color, but rather short. There is a little roughness, but is mostly soft and would be a very useful fibre if a steady supply could be depended on. Value about £20. Discount 2½ per cent.

Resolution dated 2nd September 1882, No. 2203.—Communicated to the Collector of Vizagapatam. He is requested to arrange for the supply to Messrs. Arbuthnot & Co., agent fibres of sufficient for one bale.

The official list of fibre yielding plants includes many which have been attracting a good deal of attention of late and the report of experts on the results of the trials at the Calcutta Exhibition, will be looked for with interest. Meantime, however, if M. d'Humieres has made the cultivation and preparation of fibre pay in North Italy, we may be asked why not go to work at once in Ceylon. It would certainly be worth while cultivating an acre systematically and testing the crop of raw material taken off, and perhaps when this was reported to M. d'Humieres with the conditions of this colony, as regards climate, cheap labour and facilities of transport, he or M. Favier might be tempted to establish a factory here and buy raw produce.

There can be no doubt as to the great interest at present taken in the fibre as in other latent resources of India. District officers vie with the Presidency Governors in their enquiries and reports, and nearly every week lately, an official paper of some kind on the subject has been issued in Madras. Here is a specimen:—

READ—the following letter from Messrs. Hinde & Co., to the collector of Malabar, dated Calicut, 17th January 1883, and endorsement by W. Logan, Esq., Collector of Malabar, dated Calicut, 26th January 1883:—

Referring to your letter of the 17th November last we beg to hand you, herewith, six copies of a pamphlet giving a brief description of Ekman's process for preparing cellulose, fibres, &c., and specification of the patent.

2. We have ordered from London an experimental boiler and all the necessary apparatus, chemicals, &c., for preparing paper pulp and preparing fibres, and we hope to have the machinery set up and at work before May next.

The board's resolution with enclosures and a copy of the pamphlet enclosed will be communicated to the Government of India with reference to their letter, No. 15 F. and S., dated 6th March 1882, and Messrs. Hinde & Co. will be requested to favor Government with a report as to the practical working of Ekman's machines after trial

Again as to PLANTAIN FIBRE, which, we fear, can never be extracted so as to pay, Mr. P. Guard, of Cherambadi, has reported to the Madras Government, as follows:—

"Captain Cox has been in England for the last two years and I, as his Manager and Attorney, opened your communication to him. I can inform you, however, that he has quite failed in extracting the fibre from the musa textiles by machinery, and that the process by hand, although simple, is so expensive as to render this method prohibitive.

The Natal planters have also of late taken a good deal of interest in the cultivation of fibrous plant, and one of them has been interviewing the veteran Mr. P. L. Simmonds who certainly ought to be an authority on the commercial aspect of the subject, which, after all, in its "will it pay?" form, is the most important. The result of the interview is given as follows in the *Natal Mercury*:—

Report of a committee appointed to enquire as to the cultivation and preparation of fibres and their suitability to this colony.

Mr. Chairman and gentlemen,—Your Committee, for obvious reasons, have thought it best to confine their enquiries to those fibres which have a more or less known commercial value, and therefore selected the *Sansiviera*, indigenous; the *Phormium Tenax*, exotic; *Rhœa*, exotic, hemp, exotic, but almost naturalised; and aloe (as it is commonly called here), two varieties. Eventually, it will be seen that it is to the last we should, at present, chiefly direct our attention, and therefore the others may be disposed of first.

An application, through the public prints, for information, brought no reply. The Committee, however, have had the papers of M. E. de Chazal before them, and received much valuable information from Dr. Sutherland, who has made numerous experiments, and given much time and thought to the subject. They have also received some valuable communications from Mr. W. Peace, covering information from Mr. P. L. Simmonds, whose authority on this and similar subjects is well-known.

Replies, on the subject of machinery, have been received from Mr. Deakin of Messrs. Deakin and Cradock; and also from Mr. Hillman (of Messrs. Pontifex and Wood).

With respect to *Sansiviera*, Dr. Sutherland says it is not practically available, as the yield per acre is not sufficient, and no machinery has been adapted for it. Mr. Simmonds says "the *Sansiviera* requires technical skill in its preparation to such an extent that it is a (commercial) success, nowhere." We need not, therefore, further consider it here, though the quality of its fibre is known to be of a high class.

As to *Phormium Tenax*, the information obtained is a little better, but not very encouraging on the whole. Dr. Sutherland says that it yields about 10 per cent. of fibre; that he has a quantity growing, and that it grows very luxuriantly; matures in about a year, and can be cut twice a year afterwards; that it is worth about £30 per ton, and that he calculates the profits at about £10 per acre on an average. On the other hand, he had written to two brothers (McWilliam) formerly of Natal, respecting it; but they replied, that though in New Zealand it grew wild in certain districts, and the produce was obtained from a radius of fifteen miles, enough could not be got to keep the factory established there supplied. Dr. Forbes Royle is very minute in his description of this plant in his work, "The Fibrous Plants of India," published, however, nearly thirty years ago. He estimates the yield at about 16 cwt. per acre, and states its strength to be twice that of flax, and half as strong again as hemp. Thirty years ago a large factory for this fibre was built at Grimsby, in Yorkshire, and nearly a century back (1798) it was introduced and cultivated in the south of Ireland; but in spite of every sort of encouragement given by the Imperial Government it does not seem to have made any great progress. At St. Helena more recently it succeeded better, but has been at length abandoned. One of the members of your Committee who visited St. Helena made many enquiries as to this; and considers that the reason which caused it to be a failure there would not apply here. Captain Young, however, of the *Grantully Castle*, who was supplied with rope made there of it, says that it is of no use for running gear, as it swells so considerably with even light wet that it jams in the blocks. Mr. Simmonds says that though it is now cultivated very largely, the money realised scarcely pays for the cost of production.

Mr. Simmonds says you may dismiss the idea of *Sansiviera* and *Phormium Tenax* being cultivated successfully in Natal, restricting the term to the commercial sense of the word. The *Sansiviera* requires technical skill in its preparation to such an extent that it is a (commercial) success nowhere, and the New Zealand flax is already cultivated very largely, while the money realized scarcely pays for the cost of production. As regards the *Agave*, Mr. Simmonds speaks very differently, and would decidedly encourage attention to the subject as to machinery for its preparation. English makers have yet to begin: the French people are more conversant with the matter, and have probably made some of the machines now in use in the Mauritius. Mr. S. says your most practical course is to obtain in Mauritius all the information sought, and this sums up in one sentence the only conclusion to be arrived at in England. Mr. Simmonds says the cultivation of the *Agave* and preparation of the fibre offers one of the most promising fields for enterprize that can be named at present, but considers the fibre made from China grass would be the most valuable if a machine could only be invented for separating the skin or bark from the stem, differing from other fibres. That made from China grass is obtained from the skin or bark, which has to be peeled off while the stem is fresh cut, or afterwards it can only be done after the stem has been softened by water. No machine has yet been invented that will do this work properly. Mr. Simmonds confirmed what I have heard several times lately, that there is a great want of material for paper-making; so much so that sawdust from Sweden and Norway is now being converted into a pulp by chemical process for the purpose of being mixed with other material for paper. Even megass from sugar estates, after being dried and bleached, if obtainable in large quantities, will be worth here about £8 per ton. The wild pineapple and many other plants are capable of being converted into pulp, bleached, and used for paper-making. I was not aware that Manilla fibre is produced largely from the wild banana and plaintain until Mr. Simmonds told me so; there are proper machines for expelling the sap (rollers, &c. in use in the Philippine Islands.

Rhea fibre, or China grass, has been already tried here, and so far as growth is concerned is everything that could be wished; but no machinery has yet been made to prepare it successfully, though lately a Mr. Cautwell has published a process which seems to overcome certain difficulties. Still your Committee think that the knowledge of this subject is, at present too imperfect to warrant its being tried here for at all events some time to come.

Hemp and jute. These plants deserve more than a passing notice. There can be no doubt, according to Dr. Sutherland that both these plants can be grown successfully. But the jute has a woody stem, from which the bark has to be removed by a somewhat tedious process. Then its cheapness in India would probably make its production here a doubtful success. Hemp grows luxuriantly, but is specially liable to be ruined by storms; a violent wind or rain storm would lay and spoil it. It is diœcious, that is one of those plants that are male and female on different plants; and each variety requires to be differently treated, unless the seed be sacrificed. It has one objection, however, which is by no means slight; unless the steeping, or retting, is done by chemical process, it is highly poisonous, both in its liquid form and from its noxious gases. It is true that one member of your Committee asserts, from his personal knowledge, that it merely requires drying, and that retting is unnecessary; but we cannot find any printed authority for such a plan. Some books do, indeed, mention it, but only to condemn it; and if retting is a necessity, your Committee think it would be unwise to run the risk of recommending its cultivation, unless it be accompanied by legislation, to control its preparation. At the same time, it has the distinct advantage of an unlimited market, which would recommend it to many. There are many native plants akin to these which your Committee do not notice, as its members conceive the Association did not so much wish to have attention called to new plants as to those which, being already known, have a distinct commercial value.

We now come to the different varieties of Aloe, as they are popularly called, though the only two your Committee wish to notice are the *Agave Americana*, or Blue Aloe, and the *Fourcroya Gigantea*, or Green Aloe. The habit of calling all these "aloes" has led to a supposition among some people that the commercial drug and the fibre come from the same plant, which is erroneous, so far as the plants under notice are concerned. The pamphlet by M. Evenor de Chazal, and the translation by his brother, will be fresh in the minds of the members of the Association, and your Committee, therefore, think it unnecessary to further allude to them here; and, as they also quote from Dr. Forbes Royle's book, no reference is made to that work. Your Committee will only allude to the communication from Dr. Sutherland, under date 29th July, 1882, where he mentions the great success which attends on the cultivation especially of the *Fourcroya*. It has an objection in (according to him) requiring six years to mature (this is somewhat modified by Mr. Blamey's experience at Milkwood Kraal, alluded to further on); but the leaves will then be 6 to 10 ft. long. A full crop, he says, will yield probably 75 tons per acre of leaves, fresh as cut; the yield of fibre is 2 per cent., giving thus 1½ tons of fibre per acre, worth about £40 per ton or £60 per acre. It is not suitable for cultivation where the frost is severe or long continued. Yet the circumstance of growing it in such a situation led Dr. Sutherland to an inference which may hereafter be valuable. He noticed that the frost caused the leaves to droop for about half their length, or until the thick part was reached; and in a very short space of time this portion of the leaf completely rotted, as he describes it, like a bad pumpkin. He conceived this to be due to the juices bursting the cell-walls of tissue, when, of course, the substance would quickly decay. As the fibre and cell walls are composed of the same material, no chemical could be used to destroy one without affecting the other; yet if such a process could be discovered a great impetus would be given to the cultivation of the *Fourcroya* by greatly increasing the quantity of fibre, a large proportion of which is lost by any preparation by machinery. The action of the frost gave Dr. Sutherland a hint, which he only lacks opportunity to put to a practical commercial test. He conceived the idea of imitating the action of the frost in bursting the cell walls of the plant, and accomplished this by submitting the leaves to a pressure of 60 lb. of steam. The result was partly successful, the only objection being that the process slightly discoloured the fibre, which is naturally of a pure white. At present this is not of so much consequence, as the fibre is said to be largely used for adulterating Italian hemp, and the extra quantity may compensate for the loss in colour; but when proper experiments are made probably the discoloration will be avoided, or decolorization effected by some bleaching process. We find that fibre from this plant has been for some time, and is now, exported from various countries, presumably at a profit. One thing is certain. The fibre, in all cases, is prepared by machinery more or less rude and primitive. Even M. de Chazal says of the process now in vogue in Mauritius "c'est brutal;" and there can be little doubt that if this fibre can be produced at a profit with the present rough appliances, which do not extract the half of it, it will eventually prove one of the most reliable crops we can produce. Mr. R. Blamey, of Milkwood Kraal, has given some practical information to the Committee, and exhibits specimens of rope and cord made from *Fourcroya* fibre. He estimates the yield of fibre at the same as Dr. Sutherland, and says that no cord or rope is used on Milkwood Kraal Estate but what is there made from *Fourcroya* fibre. He exhibits (*a*) sample of a leaf, cut and buried in damp sand for a fortnight, and afterwards beaten and washed on a stone; (*b*) sample of rope made by hand, one man doing 40 yards per day (*c*) sample of stout cord, made in same way at 60 yards per day; and (*d*) smaller cord at 120 yards per day. He also says that it takes 6 leaves to make a pound of fibre; but that it matures in 2½ to 3 years. This differs from Dr. Sutherland's account; but probably the latter speaks of the maximum growth while Mr. Blamey does not. From the nature of the information obtained, your Committee can come to but one conclusion; and that is—that the cultivation of the *Fourcroya* should be strongly recommended. In addition to the apparent profitable nature of this enterprize, there are strong reasons for this recommendation. It is always advisable to have the products grown in a country of many varieties, not only on account of climatic variation, but also on account of health. Your Committee believe it will be found, on investigation, that the general health, both of animal and vegetable life, is not nearly so good in those countries where one article only is chiefly grown as in those where crops are various; and the reasons are too obvious to require more than this general allusion. It may be as well here to call attention to this important consideration—the general effect of vicissitudes in the growth of fibre plants is that a diminution in size is accompanied by increased fineness of fibre; the number of fibres remaining constant.

We now come to the preparation of the fibre; and considering that this enterprize is, at present, experimental, your Committee is of opinion, that if planters agree to plant the *Fourcroya*, it is as much as at present they can be expected to do

Your Committee, therefore, think that the preparation should be the work of a company; so that in case of its not answering expectations, no great loss would be sustained by any one individual. Doubtless Dr. Sutherland would assist in developing this enterprize, as his public spirit in such matters is well-known. Fortunately, there will be no difficulty in forming such a company. In order that there may be no delay or hesitation in starting the enterprize, your Committee have been guaranteed by a few gentlemen that the machinery should be forthcoming, if planters will guarantee a moderate but sufficient quantity of leaves, to be delivered at about 8s per ton. As the quantity per acre is stated to be 75 tons, that would yield £30 per acre.

Your Committee, therefore, considers it is justified in strongly recommending planters to put in a certain quantity as soon as possible, as it takes some time to mature, and still longer to propagate. They may be planted as a crop; they may be used as a live fence, which would stop fires, and no cattle would face; and if planted in double rows, one the first year, and the other two years after, an impervious fence could be kept up, at not only no expense, but at a considerable profit.

That was written in December last, and it is very strange that up to that time Mr. Simmonds had not heard of M. Favier's machine, or, if he had, should have ignored it. On the substitutes for fibres, Mr. Simmonds has a couple of paragraphs in an interesting paper on "Useful Shams" contributed by him lately to the *British Trade Journal*, which we may introduce here:—

FIBRES.—When the war with Russia rendered bristles scarce and dear, commerce soon supplied our brushmakers with vegetable substitutes in the shape of kittool fibre and coir fibre from palms, Mexican fibre from the leaves of *Agave sisilana*. Piassava fibre from the leaf-stalks of a South American palm, came in to supply bass-brooms, chimney-sweepers' brushes, and street-sweeping machines. Even split quills have been brought into requisition for brushes, and for white and dyed bristles we are not alone dependent upon the stiff hair of the hog. Another cheap substitute brought into use is that of vegetable down, to replace the costly animal product eider down. These silky downs, clothing the seeds of several plants, such as *Bombax*, *Ceiba*, *Calotropis*, &c, are now largely used for filling coverlets, ladies' quilted petticoats, muffs, and other articles. This vegetable down is 50 per cent cheaper than the feather down. The qualities which recommend it for use are immunity from attacks of moth and vermin, lightness, elasticity and softness, medium warmth, and cheapness.

Not alone in the East and South are fibrous plants attracting attention. In home papers, recently, there was a paper on those of Mexico, from which we quote:—

Anything and everything connected with the supply of fibre whether for textile purposes, cordage, or for paper, is becoming of more interest almost daily. A recently issued report on some fibrous plants of Mexico, with notes on their habits, will therefore be read with interest. * *

This plant—the lechugilla—seems to be that known to botanists as *Bromelia pita*, and, together with the maguey or *Agave Americana*, and the Palma criolla, have attracted much attention both in Mexico and abroad, in the United States and Europe. All the plants grow along the line of the Mexican National Railway, above an altitude of 1,000 feet, and throughout the districts contiguous. They are prolific, growing wild upon the plains and mountain side, between Lampagos and Saltillo, and especially so at Bustamante and the Plaxcala Pass near by, where there is excellent water-power from a stream flowing from a mountain spring, which has a volume of two square yards, with a fall of 200 feet in five miles. They can be gathered at all points along the line, and conveniently transported in vast quantities to an eligible locality for disintegration and shipment. The salubrity of any point on the line of this railway is said to be equal to that of the great health resorts of the world, and all, owing to temperature, altitude and high condition, are far remote from the yellow fever and other infected districts, and well suited for mining operations, manufacturing centres, and populous districts. The lechugilla—the literal translation of which is said to be *small lettuce*, is described as furnishing a coarse and strong fibre from 18 to 24 inches in length, and is used for making sacks, mats, ropes, brushes, &c. It is the textile fibre of commerce, and is exported in increasing quantities from Mexico to the United States and other countries An infusion of the root has strong detergent properties and is extremely valuable for cleansing woollen clothing It is said not to have the effect of displacing colours, but on the contrary, "articles likely to fade may be washed with an infusion of the root in safety." Though it seems that the principal use of this fibre in its native country is for rather coarse purposes, it has been described as of extreme fineness, equal to the best China grass, and capable of being manipulated into the finest fabrics.

The maguey, century plant, or agave, as it is variously called, is described in the report we are considering as being quite as abundant as the lechugilla. The maguey, as is we known, is the *Agave Americana L.* The heart of the plant yields "agua miel," or "wort," and this, when fermented, becomes pulque, an intoxicating liquor in great request by the people. The roasted heart is mescal, and this, when pressed in a mill, yields a liquid by distillation, called vino de mescal. It is a strong spirituous liquid, as clear and colourless as spring water. A juice is extracted from the leaves of the plant by simply wringing them, which is said to be an excellent antiscorbutic, and has been used with most satisfactory results in cases of scrofula. The fibre can be obtained from five to even six feet in length. It is very fine and the Mexicans weave it into fine textures. It is said that shoemakers use it to make their best thread, and the writer of the report says he has seen it "wrought into handsome money bags, ornamental baskets, &c., and then tinted with various colours. So far no machinery has been invented, or at least the Mexican people know of none, suited to break, hackle, and prepare this product. They do it in a cumbrous way by hand."

The following is given as an illustration of the extent of agave plants to be found in a given area. At Santo Ysabel, a station between Lampazos and Bustamante, the railway runs for a distance of about six miles over the land of a certain Don Solome Botello, who distils a great quantity of vino mescal. "To give an idea of the great abundance of maguey growing spontaneously on his land—all without cultivation—it is but necessary to say that 10,000 plants were destroyed in clearing the ground for the right of way. Lately, while making a short excursion across his lands, in company with the general manager and general superintendent of the road, he called our attention to the great loss of maguey leaves in taking the heart of the plants for distillation. For every plant cut 25 great leaves were left strewn to rot upon the ground, or 5,000 leaves to each 200 plants."

The "palma criolla" (*Oreodoxa regia*) is a tall growing palm, often planted in avenues. It is described as being very plentiful. The fibrous leaves are used to thatch the ordinary Mexican hut, or if straw or other material is used for the thatch, it is nearly always tied on by strings formed from the torn leaves after being heated; this string, indeed, constitutes the common twine of the country. The fruit is somewhat similar in appearance to the date, and is sometimes eaten. It is also distilled, and from it a quantity of *aguardiente*, or rum, is made. "There was quite a large distillery of this kind near and northwards from Salinas on the railway. This plant, or tree, has lately excited much attention, as throughout it is of a fibrous growth, trunk, leaves and all, and some are experimenting with it with a view to the manufacture of paper."

From the above it would seem that the grey aloe, *Agave americana*, is utilized in Mexico only for the sake of its alcoholic juice, and that the source of the fibre so largely exported from Mexico is not the large green aloe, *Fourcroya gigantea*, but a dwarf plant not yielding fibres equal in length even to those of the Marul or Neyanda of Ceylon (*Sansevicra zeylanica*) For some months we have bad beside us a translation of M. Chazal's pamphlet on the fibre industry in Mauritius, and how it has been made to pay we cannot understand. The leaves of the green aloe have little more proportion of fibre than plantain-stems. It is probable, after all, that the common aloe (*Agave americana*) will be found the most profitable to work in Ceylon, and, while awaiting the result of practical experiments by Mr. Payne of Handrokande, who has a large supply of the raw material in his properties and is working with a converted pulper, as also the trial of "Smith's machine" imported by Messrs. John Walker & Co., we may give the following Indian official paper of useful information on the subject, published two years ago :—

ALOE FIBRE EXPERIMENTS.

The aloe, vernacular Kiuva, *Agave Americana*, grows freely over most parts of Northern India. It is very hardy, attaining a favorable development under the varying conditions of heat, cold, drought, and moisture; this is particularly noticeable in the lower hills, where the plant grows in places in which it would seem impossible to derive moisture save from rainfall, the scanty vegetation in the Punjab Siwaliks having reduced the hygroscopic power of the soil to almost a minimum. Yet amongst boulders, bare and arid sand, out of clefts in the conglomerate and freestone which "crop out" considerably in these hills, the aloe vegetates with ease. It will also grow in the Kangra Valley and Lower Himalayas up to 4,000 to 5,000 feet above sea level. It is an excellent hedge plant, impenetrable by man or beast, all animals having a wholesome horror of its sharp spear-like points. For fences and enclosures of all kinds, nothing could surpass it, and it is a question whether for railways on this side of India, aloe would not be cheaper than wire fencing, the only drawback being its slow growth, and the time it takes to form a good stiff barrier. As a *natural defensive* element in a system of permanent fortification, aloe would, it is believed, be of great service, especially when planted out at the "foot of the glacis" along the bottom of the ditch, and on the superior and exterior slopes of the parapets. A post or armey, work so environed would be safe from any attempt to carrd it by escalade, the boldest form,—even a *Ghazi*, well primed and let off at high pressure—would think twice before attempting to force his way through a *cheval de frise* composed of *Agave Americana*. The aloe does not suffer like the *Cactus Indicus* from the attacks of the cochineal insect, and, owing to the large amount of sap in the stalks, an aloe hedge could not be ignited or fired by shell, carcass, rocket, &c.; projectiles could only make a clean round hole through the stalks, which would in a great measure mitigate the murderous effect of splinters from shrapnel and shell.

The preparation and use of aloe fibre seems to have been understood in most countries where the plant is met with. Royle relates that in Mexico Humboldt saw a suspension bridge 131' span, the main cables of which were of aloe fibre 4" diameter. In South America, Spain, Southern Italy, Algeria, the inhabitants of these countries turn the fibre of the aloe into various uses, such as cloth, mats, rope, paper, fishing lines, &c. When twisted into rope, aloe fibre possesses great strength, and will compare favorably with "Sanu"—*Crotalaria pencea*. Dr. Royle in his excellent work "The Fibrous Plants of India," says that, in a trial made at Calcutta, a rope of aloe fibre 3" circumference broke with a weight of 2,519 lb. whilst ropes made of "coir," hemp, and jute, similar in every respect, broke with weights of 2,175; 2,269; 2,456 lb. respectively. In an experiment made at Paris with Algerian aloe and hemp, both ropes being of equal dimensions, the former broke under a weight of 2,000 kilogrammes, and the latter with a weight only 400 kilogrammes, 1 kilogramme=2·2046 lb. Dr. Royle also mentions an experiment made at Toulon dockyard, where two ropes, one of hemp and the other of aloe, were tested, after a six months' immersion in sea water. The former only bore a weight of 2,538 lb., whilst the latter *carried* a weight=3,810 lb., showing a clear surplus of strength of 1,272 lb. in favour of the aloe or pita.

On the other hand a trial is quoted, made at Madras Arsenal, where a coil of aloe rope was received at the Arsenal, immersed in a tub of water for 24 hours and then exposed to the open air, and after a few showers of rain, was found to be quite rotten. The same results were obtained after similar trials on various ships in the Royal Navy.

Kahars and water-carriers make rope of this fibre in the Punjab. It stands moisture fairly, and has one great advantage *viz*, that, bulk for bulk, it is lighter than hemp or *Musa textilis*.

During the early part of the year the writer of this paper endeavoured to see if the stalks of plantain, *Musa paradisiaca*, could not be utilised for paper stuff or rope. A certain quantity of plantain fibre was prepared and tried, but it was disappointing to find that it was excessively weak; it would not stand "heckling;" the long, soft, fibre, 36" to 48" long, would snap and tear, even when passed through the teeth of a fine hair comb. Care was taken not to *steep* the fibre at all. The operation was, as follows :—The stalk was cut into lengths of four feet, and divided by two cuts, at right angles to each other passing down the middle of the plant The sheaths of lengths of stalk were passed between the *iron* rollers of a small sugar mill. One kind was quite sufficient. The strips of bark or more strictly speaking sheaths, were next laid on a clean washed board held in the left hand, and the operator, with a blunt piece of flat iron, or the back of a pruning knife, held in the right hand, firmly, though gently scraped off the green pulp and herbaceous matter. The strip was then turned over and scraped on the other side. When perfectly free from pulp and other substances the strips of fibre were shaken and washed rapidly under a jet of water, put up to dry in the wind, and again taken down, slightly damped, and the fibres drawn out After this they were finally dried and ready for packing.

The great drawback to the country plantain fibre is its extreme delicacy and fragile nature, which of course enhances the cost of production. Some specimens were sent down to Calcutta to Messrs. Ahmuty & Co., asking what price the fibre might fetch in the market. Their reply was discouraging, inasmuch as they gave it as their opinion that fibre of the description sent would not realize more than R2-8 to R3 per maund in Calcutta. Supposing that the introduction into Upper India of the *Musa textilis*, or even a plantain yielding a fibre superior to the *Musa sapeculum*, were possible, it may not be unprofitable to ascertain what the fibre would cost, say, landed in Bombay or Kurrachee. There are no means, unfortunately, existing in India by which the cost of production of plantain fibre can be determined, such an industry being unknown, certainly in the Punjab. But assuming (1) the fibre to be good, and (2) that the cost of cultivation is more than covered by the value of the fruit —we have all the stalks and resulting fibre to the good. To make the concern pay, the working establishment would have to stand at not less than the following strength :—

Two men to cut up and slice the stalks; 5 boys to carry the stalks to the mill; 1 pair of bullocks to work the mill; 2 boys to attend and serve the mill, as well as to distribute the fibre to 15 women who would wash, scrape, and clean, each, 10 lb. of fibre per diem.—

∴ 10 × 15 = 150 lb.

Daily working expenses would stand at				R.	A.	P.
1 pair of bullocks				0	8	0
2 men @ 2·5 as...				0	5	0
5 boys @ 1·5 „				0	7	6
15 women @ 2 „				1	14	0
				3	2	6
	R.	A.	P.			
Drying and packing ...	0	4	0			
Freight to Sea Port ...	1	12	0	2	0	0
				5	2	6
Contingencies				0	5	0
				R5	7	

$\therefore \frac{2240}{150} = 14\cdot21$, and $14\cdot21 \times 5.5$ R $= 78\cdot15$ R., or in round numbers £8 per ton. The West Indian fibre has been delivered in England at a price varying from £10 to £11 per ton.

Plantain fibre not proving a success, attention was turned to aloe *Agave Americana*, and, on a grant from the District Fund Committee being received, experiments were commenced with a view to ascertain the cost of production, the value, and quality, of the fibre. The process of preparing and cleaning the fibre was in almost every respect similar to that adopted for plantain. The long leaves were cut off close to the stem, tied in bundles of 50 and 60 each, and brought up to the mill; they were then passed between the rollers, two and two together, and laid down on a trestle table close by. After a certain number of bundles had been thus dealt with, the crushed stalks were taken up again and passed a second time through the mill. The second operation completely expressed the fœtid and unpleasantly odoriferous sap, as well as breaking the outer cuticle of the leaves. This sap blisters and irritates the skin considerably, and will produce a serious inflammation of the eye, should a stray drop chance to find its way into that organ; this had to be guarded against, and until the workmen had anointed their arms, legs, and chests with oil, they never set to work. After having passed through the mill a second time, the stalks were taken up and scraped with a *blunt* knife, to remove as far as possible the green pulp and herbaceous matter, after which the stalks were tied up in convenient size bundles, taken off to the banks of a "toba" (*kutcha*, tank), and buried in wet sand for four or five days. On the fourth day the bundles were taken out, washed in a running stream, lightly beaten with a wooden maul or beater, washed and beaten again, and washed the third time. After the third beating and washing, the fibre was clean and of a dull yellowish color. The bundles were then hung up to dry in the shade, but exposed to the wind; during drying the fibre gained the silky white appearance which in Mexico and South America has gained for it the name of "silk grass." The next process was that of "heckling." Heckles, the writer had none, but was obliged to resort to the local market. Two were consequently made up, but the only contrivance which indigenous *art* was capable of producing, was an instrument bearing a close resemblance to a small garden rake; it was certainly better suited for the purpose of "rippling" flax or hemp, than that of heckling a fine fibre; moreover the temper of the metal teeth was inferior, and in drawing the "strick" or lock through the comb, the teeth gave and bent, causing a great waste of long staple, the geater part being left as tow or codilla. Samples of fibre, twisted rope, and tow, were sent to the Calcutta Chamer of Commerce for a professional opinion. The following extract from the proceedings of the November meeting of the Agricultural and Horticultural Society of India shows what chance the fibre has of succeeding as an article of commerce:—

Mr. W. H. Cogswell, a member of the fibre Committee, gives the following report on the above samples, Mr. S. H. Robinson concurring: "With reference to the samples herewith, alluded to in the foregoing memorandum, I beg to observe that the washed and heckled fibre prepared from the *Agave Americana*, or common aloe, is about the best I have seen, being beautifully clean, and well freed from the bark or outer skin of the plant; of good colour, there being but a very slight tinge of greenish which it is impossible to thoroughly eradicate without extra steeping, or the addition of chemicals, to the injury of the fibre; it is of very great length, and fair strength, and a really good commercial commodity, its value today being about R8 a bazaar maund. The samples unheckled I would value at R1 per maund less. The samples of combings, generally as tow, could be used in this country for paper-making only, its value as such being about R3 per maund; but in England, where spinning machinery can be applied to it, a good yarn might be produced. As a produce for shipment thereto, it is of greater value than being consumed locally for paper-making: for the latter, I am of opinion it is too good and costly, as jute, tow, and such like fabrics, are so cheap and plentiful in this country."

In preparing the fibre there were sundry difficulties to be overcome; the operators were new to the work, they had never seen fibre prepared from aloe before. The sharp points pricked their hands, the fœtid offensive looking juice was found to be a painfully powerful rubefacient. The mill rollers were *iron* and *not wood*. The motive power, instead of a pair of bullocks, consisted of two "Sainis" working at the end of a horizontal lever, and the resistance to be overcome was sometimes considerable, which meant that the two Sainis had to exert considerable muscular force. There were considerable prejudices in the eyes of the Aryan brother, and took time to tone down. Also, it was only experience which shewed the proper amount of "retting" in wet sand and the degree and duration of beating required to finally separate the green pulp from the fibres. The rollers of the mill used in these experiments were vertical. A system of horizontal rollers in an iron framing, worked by belting from overhead gearing, would give better reresults; the shafting to be fitted with a fast and loose pulley, so as to throw the mill out of gear when not required for work.

60

The question of motive power next demands consideration. The motive-power available in India is—bullocks, water, steam, and wind. Bullocks would not be economical for many reasons. Water is not always to be had, except near canals or close under the hills. So that it resolves itself into a matter between steam and wind. Steam means the employment of skilled labour and a plentiful supply of good fuel. In Upper India, coal, any distance from a railway, is too dear to be thought of; wood is seldom to be had under four maunds per rupee, and the only other substance available is grass or straw. In the "Khandi" or submontane tracts there are thousands of acres of land covered with long grass—*Saccharum sara S. spontaneum*, *Andropogon involutum*,—which would serve as excellent fuel in any engine fitted up with a large fire box and one of Messrs. Head and Schemidth's patent straw burning apparatus; 20 lb. to 22 lb. of gross being fully equal, in calorific effect, to 6 lb. of best Welsh or Newcastle coal. One of Messrs. Ransome Sims and Head's* 10 H. P. engines, working at a high rate of expansion, and fitted up with the most recent improvements, would in a working day of 8 hours consume $8 \times 10 \times 22 = 1{,}760$, or in round numbers 1,800 lb. of grass fuel. This grass sells for 16 loads of about 30 seers each, for 1 rupee; the daily consumption of grass would not at this rate exceed two rupees per diem.

With regard to wind power, we have in India a vast natural agent almost wholly unutilized, as there is seldom a day in which we have not wind enough to propel machinery, provided suitable gearing and apparatus be forthcoming. A wind mill having a sail area of 500 square feet, would, under a wind velocity=14·67′, or 10 miles per hour, give a useful effect of about 11 H. P.

By the following Formula, $\text{H. P.} = \frac{A\ V^3}{108000}$

where A=Total sail area.

V=Wind velocity, in feet, per second.

$\text{H. P.} = \frac{500 \times 14\cdot67^3}{1080000} = 14$. Allowing 80 per cent only for useful effect we have 11·20 H. P.

Each such wind machine could work four mills, each mill consisting of a pair of rollers 3′ long, 1, diameter; and the amount of skilled supervision required would be almost *nil*. One boy or man to oil and lubricate the bearings would be ample.

With regard to the yield per acre of an aloe *plantation*, the following were some calculations made:—

One acre would hold 1,000 plants; each plant would give 1·5 lbs. of fibre.

Supposing acreage of plantation, $=1{,}000 \therefore \frac{1000 \times 1000 \times 1\cdot5}{80} =$ 8,750 maunds.

Of this amount 60 per cent would be fibre suitable for yarn, lope, etc., and the remainder, 7,500 maunds, a material fit for tow and paper.

Then—

NOTE.—* It is not overstating the fact by remarking that this eminent firm seem by general excellence of workmanship, durability, and economy in actual performance, to have brought their steam machinery for agricultural purposes as near perfection as possible. They seem to have left most other competitors in this branch of the profession a long way behind.

Cost of production of 11,250 maunds @ 6·5 per maund			R.	73,125
Carriage to sea port of "	"	@ 1·0	"	11,250
Carriage to sea port of 7,500	"	@ 1·0	"	7,500
				R91,875

This would fetch, according to valuation given in a former para, as follows:—

11,250 maunds of long staple at R8	per maund			R90,000
7,500 " tow, etc., at R3	"	...		22,500
		Total	...	1,12,500

According to this, the surplus of receipts over expenditure would equal about R20,000. In this calculation the cost of production has been taken at a maximum, and with suitable appliances this should not exceed R6·25 or 6·0 per maund.

Would cultivation improve the quality and yield of the fibre? Hemp, flax, etc., have been improved in India by judicious cultivation. The yield and quality of cereals depeod on the care bestowed on the plants. Napoleon *pere's* "Edict" prohibiting the import of English sugar etc., into France and other continental countries, however short-sighted a measure in itself, had one result—it compelled the growers of beetroot in France to devote their energics to develope the cultivtion of that plant, and it ended in their raising its percentage of saccharine matter, from 5, to 10 and 11 per cent. With these facts before us, it is not too much to anticipate similar beneficial results in the case of the aloe.

Deboisement and destruction of forests seem to go hand in hand with civilization, in India as well as in other countries, and would seem to be one of the unqualified (?) benefits inseparable from the introduction of British rule. And even if nothing else were to be done to reboise the Lower Himalayas, perhaps long deep zones of aloe, planted along some of the present bare and desolate "Revers" of the Punjab Siwaliks, would do a great deal to check, if not wholly mitigate, the terrible evil which threatens to make certain parts of this glorious province as bare and wild as the Sahara itself.

Before concluding, it might be as well to remark that in Mexico the aloe sap is evaporated, and the residual substance used as soap. Also, further experiments might show that the green sap is capable of heing used as a dye.

Annexed is a memo, showing some trials made with a view to ascertain the breaking strain of aloe rope—

Rope used was 1·5" circumference

			lb.
Trial No. I	It was loaded, and broke with	...	587
" II	" " "	...	890
" III	" " "	...	728

There was a wide difference between each result, and these trials were not accepted as conclusive, on that account. The rope was of three strands, laid up by a "sainsar" or native rope-maker, and twisted by a small English rope twisting machine. After trial No. 1., the rope was carefully examined, and the point of fracture in the three strands was found *not* to be in the same horizontal plane. The portion subjected to strain was cut off and the weight suspended from the other end. On the second trial the fracture of all three strands was simultaneous, and in the same horizontal plane. In Trial No. III., a fresh portion of rope was used, and, as stated before, gave way under a strain of 728 lb. or 9 maunds Again the three strands did oot part simultaneously. According to the best authorities the breaking strain for ordinary rope is expressed by the formula—

$B = C2 \times 2$ (B beiog breaking weight, in tons) which would, with the rope used, give us about 1,000 lb Trial No. II., gave results approximating to this the closest theoretical value.

From a recent report on Mauritius and Manila published by an Australian paper, we quote as follows:—

Next to our main staple of sugar is that of aloe fibre, of which the production for some time past has made much progress here. Our best qualities find a ready sale in the London market for £45 and even £48 per ton. In the neighbouring island of Reunion, or Bourbon, as we still persist in calling it, this industry is making rapid progress, as the following extract from the last annual report of the British cousul there will show:—

"A new industry has quite lately sprung into existence in this colony, the first impulse to which was given by British firms or individuals from the neighbouring island of Mauritius. I refer to the extraction of the fibre from the 'yucca,' known in the West Indies as 'Adam's Needle,' and I believe improperly called an aloe. There are four species of this plant, all of which grow here abundantly without cultivation worthy of the name, the scientific denominatious of which are:—1, *Agave Americana*; 2, *Agave angustifolia*; 3, *Fourcroya gigantea*; 4, *Fourcroya fœtida.* The two last kinds have only hitherto been used for the production of fibre, but it is known that a much finer fibre, although of shorter length, and consequently of less marketable value, can be obtained from the *Agave Angustifolia.* The *Fourcroyœ* are believed to have been introduced into Reunion from Brazil about the middle of last century. The production of this fibre promises to have important results here, judging from the rapid development of this euterprise in Mauritius. At present the fibre plantations and mills are wholly in the hands of Mauritius British subjects; but the Credit Foucier of Reunion and several creoles of the colony are beginning to devote their attention to this profitable undertaking, which they have so long neglected to turn to account, and they are even now only stimulated to this new source of commerce by the example set to them by British enterprise. It is certainly remarkable that the inhabitants of the island do not take advantage of this industry, which can be carried on with so little outlay. The number of mills actually at work is two (others being in course of construction), capable of producing about one ton and a half of fibre per diem, worth in London (for fair average quality) about £38 per ton, or net about £30 per ton. Manilla hemp is worth about £10 above this value per ton. The cost of the production of the aloe fibres here is understood to be about £20 per ton.

A friend resident in Dundee calls our attention to the following paragraph from the *Textile Trade Review*:—

The plant *musaceæ* has recently been found to contain a fibre which, if utilised for textile purposes, for which it is well adapted, would create an industry involving a circulation of millions of pounds. The penguin, and the various species of the pine-apple plants, also appear as eligible candidates for a place in textile manufactures. In France experiments are being made to extend the use of the pineapple fibre, and these have been used more or less successfully in the East Indies, South America, and Africa. The cost of production is—in a country of suitable temperature—exceedingly small, and it only wants working to become a staple industry. The other textile material is the product of an insect, a kind of spider, whose home is on the East Coast of Africa. This foreigner has been discovered by a member of the French Society for Practical Climatisation, and is expected to supersede the silkworm. It manufactures a yellow silk, long, strong and fine; and can produce more weekly than a cocoon of the ordinary silkworm. It is thought that this little labourer would agree well with a change of air, and that Spain or Italy, or even France, would suit its constitution, even better than its native land. It is unfeelingly described as "an exceedingly ugly creature," of about five inches long, and one broad, with legs of six to seven inches long; but, in the largeness of our hearts, if its products contribute to the adornment of ourselves, and add to our comfort, we can, with our usual generosity, freely forgive—even enjoy—its ugliest aspect.

As regards the planters. "Old Colonist" says:—No country in the world could compete with Ceylon in this. 100,000 acres now utterly valueless in the low country might grow this to perfection.

FIBRES AND THEIR PREPARATION:

A NEW INDUSTRY FOR CEYLON.

A new interest has recently been given to the preparation by the comparative success of machinery recently invented for that purpose. On the foregoing pages will be found a great deal of interesting and instructive information on the subject specially applicable to the case of Ceylon, which can supply the raw material in rhea grass, plantains, or aloes, as may be considered most desirable. Amid the experiments in rubber cultivation and preparation, we trust the equally important industry which might be established in fibres will not be forgotten, and, with the aid of the several skilful mechanists in the country, headed by Messrs. John Walker & Co., our planters and others ought not to find much difficulty in arriving at practical results, and in ascertaining whether the proposed industry will stand the "will it pay?" test.

We are indebted to several gentlemen, notably to Messrs. Kay-Shuttleworth and Shaw Kennedy, for sending us pamphlets and papers on the subjects as well as samples of fibres and cloth. Those brought back by Mr. Kay-Shuttleworth on his return from Europe have been seen and admired at our office by a great many persons, and besides all the information we publish today we have, in the shape of correspondence and papers, a good deal more still to dispose of. In the *Society of Arts Journal* for August 21st last, there was a very succinct paper on the fibre plants of India by Mr. J. W. Minchin of Ootacamund for which we must endeavour to find room in the *Tropical Agriculturist*. He speaks of the rhea as being cultivated on many coffee estates in India and Ceylon, but that "it requires rich unexhausted soil." "It grows with the greatest vigour in damp warm climates," so it ought to do well in many districts here, and indeed it is to be found freely growing in the island, especially on the banks of streams. An enquiry is contained in the following letter from a Matale planter which has been lying by us far too long:—

Dear Sir,—Could you or any of your correspondents inform me, whether the Mauritius planters, who, I understand, use the gratteuse for the prepartion of aloe fibre, steep the aloe leaf in any chemicals before putting it through the machine? If so can they give a description of the solution? I have here a gratteuse, and previous experiments with the green leaf are not at all a success. The pulp on a newly cut leaf does not come off to the extent it should do, and without a "steep" of some sort I fail to see how any machine can clean the fibre sufficiently for the market. I think makers of these machines ought to guarantee the successful turnout of clean fibre, as my endeavours to get a good sample from the green leaf has failed in all my experiments. I have not seen a new machine at work—Smith's I think, but as it is a bar stripper on the same principle as the gratteuse. I have not much faith in its success, unless the maker also states the kind of "steep" to be used I would be very glad to have any information about the Mauritius way they clean the fibre from any of your correspondents as anything I have yet observed passing through your paper does not touch upon the main thing wanted, the *proper steep*.

If this were known, I am sure our aloe fibre cultivation would extend.—Yours truly,

ALOE FIBRE SOLUTION.

Now this is just the want—some chemical process in aid of the machine—which, as our latest information from Europe shews, has just been supplied by a distinguished French chemist. Mr. F. Shaw-Kennedy sent us the English translation of M. Favier's pamphlet, and called our attention to the fact that the cultivation of the rhea or Chinese nettle is specially recommended for old coffee estates. But M. Favier, although most successful in the decortication of this nettle or grass, nevertheless failed to deliver the resulting fibre of such uniformly good quality as to constitute a commercially reliable article. This want has been supplied by Professor Frémy, and curiously enough among the fibre samples sent us by Mr. Shaw-Kennedy is one of "Ramie decorticated in a Frémy bath." What the "Frémy bath" is will be learned from the following account which appeared in a recent number of the London *Times*:—

Rhea, which is also known under the name of ramie, is a textile plant which was indigenous to China and India. It is perennial, easy of cultivation, and produces a remarkably strong fibre. The problem of its cultivation has long being solved, for within certain limits rhea can be grown in any climate. India and the British colonies offer unusual facilities, and present vast and appropriate fields for that enterprise, while it can be, and is, grown in most European countries. There have been difficulties in the way of decorticating the stems of this plant, and the Indian Government, in 1869, offered a reward of £5,000 for the best machine for separating the fibre from the stems and bark of rhea in its green or freshly cut state. The offer of £5,000, in 1869, led to only one machine being submitted for trial, although several competitors had entered their names. This machine was that of Mr. Greig, of Edinburgh, but after careful trial by General (then Lieutenant-Colonel) Hyde it was found that it did not fulfil the conditions laid down by the Government, and therefore the full prize of £5,000 was not awarded. In consideration, however, of the inventor having made a *bona-fide* and meritorious attempt to solve the question, he was awarded a donation of £1,500. The Government, in 1881, re-offered the prize of £5,000. Another competition took place, at which several machines were tried, but the trials as before, proved barren of any practical results. The strength of some rhea fibre from Assam experimented was in 1852 by Dr. Forbes Royle, as compared with St. Petersburg hemp, was in the ratio of 280 to 160, while the wild rhea from Assam was as high as 343. But, above and beyond this, rhea has the widest range of possible applications of any fibre.

Last year, however, witnessed the solution of the question of decortication in the green state in a satisfactory manner by M. A. Favier's process, as reported by us at the time. This process consists in subjecting the plant to the action of steam for a period varying from 10 to 25 minutes, according to the length of time the plant had been cut. After steaming, the fibre and its adjuncts were easily stripped from the wood. The importance and value of this invention will be realised, when it is remembered that the plant is cultivated at long distances from the localities where the fibre is prepared for the market. The consequence is that for every hundredweight of fibre, about a ton of woody material has to be transported. Nor is this the only evil, for the gummy matter in which the fibre is embedded becomes drid up during the transport, and the separation of the fibre is thus rendered difficult, and even impossible, inasmuch as some of the fibre is left adhering to the wood. M. Favier's process greatly simplifies the commercial production of the fibre up to a certain point, for, at a very small cost, it gives the manufacturer the whole of the fibre in the plant treated. But it still stops short of what is required, in that it delivers the fibre in ribands, with its cementitious matter and outer skin attached. To remove this, various methods have been tried, but, as far we are aware, without general success—that is to say, the fibre cannot always be obtained of such a uniformly good quality as to constitute a commercially reliable article. Such was the position of the question when, about a year ago, the whole case was submitted to the distinguished French chemist, Professor Fremy, member of the Institute of France, who is well-known for his researches into the nature of fibrous plants, and the question of their preparation for the market. Professor Fremy thoroughly investigated the matter from a chemical point of view, and at length brought it to a successful and, apparently, a practical issue.

One great bar to previous success, would appear to have been the absence of exact knowledge as to the nature of the constituents of that portion of the plant which contains the fibre, or, in other words, the casing or bark surrounding the woody stem of the rhea. As determined by Professor Fremy, this consists of the cutose, or outer skin, within which is the vasculose containing the fibre and other conjoined matter, known as cellulose, between which and the woody stem is the pectose, or g m, which causes the skin or bark, as a whole, fibre included, to adhere to the wood. The Professor, therefore, proceeded to carefully investigate the nature of these various substances, and in the result he found that the vasculose and pectose were soluble in an alkali under certain conditions, and that the cellulose was imsoluble. He therefore dissolves out the cutose, vascutose, and pectose by a very simple process, obtaining the fibre clean, and free from all extraneous adherent matter, ready for the spinner. In order, however, to insure as a result a perfectly uniform and marketable article, the Professor uses various chemicals at the several stages of the process. These, however, are not administered haphazard, or by rule of thumb, as has been the case in some processes bearing in the same direction, and which have consequently failed, in the sense that they have not yet taken their places as commercial sucesses. The Professor, therefore, carefully examines the article which he has to treat, and, according to its nature and the character of its components. he determines the proportions of the various chemicals which he introduces at the several stages. All chance of failure thus appears to be eliminated, and the production of fibre of uniform and reliable quality, removed from the region of doubt into that of certainty. The two processes of M. Favier and M. Frémy have, therefore, been combined, and machinery has been put up in France on a scale sufficiently large to fairly approximate to practical working, and to demonstrate the practicability of the combined inventions.

The process, as carried out, consists in first treating the rhea according to M. Favier's invention. The apparatus employed for this purpose is very simple and inexpensive, consisting merely of a stout deal trough or box, about 8 ft. long, 2 ft. wide, and 1 ft. 8 in. deep. The box has a hinged lid and a false open bottom under which steam is admitted by a perforated pipe, there being an outlet for the condensed water at one end of the box. Into this box the bundles of rhea were placed, the lid closed, steam turned on, and in about twenty minutes it was invariably found that the bark had been sufficiently softened to allow of its being readily and rapidly stripped off by hand, together with the whole of the fibre in what may be called ribands. Thus the process of decoration is effectively accomplished in a few minutes, instead of requiring, as it sometimes does in retting the process, days, and even weeks, and being at the best attended with uncertainty as to results, as also is the case when decortication is effected by machinery. Moreover, the retting process, which is simply steeping the cut plants in water, is a delicate operation, requiring constant watching, to say nothing of its serious inconvenience from a sanitary point of view, on account of the pestilential emanations from the retteries. Decortication by steam having been effected, the work of M. Favier ceases, and the process is carried forward by M. Frémy. The ribands having been produced, the fibre in them has to be freed from the mucilaginous secretions. To this end, after examination in the laboratory, they are laid on metal trays which are placed one above the other in a vertical perforated metal cylinder. When charged, this cylinder is placed within a strong ron cylinder, containing a known quantity of water, to which an alkali is added in certain proportions. Within the cylinder is a steam coil for heating the water. and, steam having been turned on, the temperature is raised to a certain point, when the cylinder is closed and made steam-tight. The process of boiling is continued under pressure until the temperature—and consequently the steam pressure—within the cylinder has attained a high degree. On the completion of this part of the process, which occupies about four hours, and upon which the success of the whole mainly depends, the cementitious matter surrounding the fibre is found to have been transformed into a substance easily dissolved. The fibrous mass is then removed to a centrifugal machine, in which it is quickly deprived of its surplus alkaline moisture, and it is then placed in a weak solution of hydrochloric acid for a short time. It is then transferred to a bath of pure cold water in which it remains for about an hour, and it is subsequently placed for a short time in a weak acid bath, after which it is again washed in cold water, and dried for the market. Such are the processes by which China grass may become a source of profit alike to the cultivator and the spinner, A factory situate at Louviers has been acquired, where there is machinery already erected for preparing the fibre according to the process we have described, at the rate of one ton per day. There is also machinery for spinning the fibre into yarns.

On the whole, the conclusion is that the results of the combined processes, so far as they have gone, are eminently satisfactory, and justify the expectation that a large enterprize in the cultivation and utilisation of China grass is on the eve of being opened up, not only in India and our colonies, but possibly also much nearer home. A writer in the *Planters' Gazette* of 1st November backed up by Mr. Thos. Christy maintains however that

The Ekman process is a long way in advance of the one above described, and theoretically at all events it satisfies all the requirements of the situation. Nay, further, the clean fibres turned out by it are simply magnificent as specimens, but whether they can be actually used as they are by the spinner and weaver still remains an open question, for it has not yet been tried. We say to all appearance this has been accomplished, and it will be put to the test as soon as Mr. Ekman can obtain a sufficient supply of rhea plants. Still it must be understood that there would be no market for the article unless manufacturers were assured of regular and abundant supplies, so as to make it worth while for them to adapt their machinery to the peculiarities of the material.

Mr. Christy writes almost contemptuously of the French inventions :—

The Favier process consists of placing the stems of China grass or other plants having a hard wood barrel or core in a tank composed of wood, or it might be called a box with a pipe underneath leading from a boiler or vessel in which steam can be generated. The action of the steam upon the stems causes the gummy matter to dissolve, and when the stems are taken from the box or steam chest, their skin comes away with the greatest ease, but it leaves the outside brown skin adhering to the fibre; therefore, it is no nearer being a practical result than if some native had stripped the bark off himself. These steam chests are exactly similar to those used in China and also in some parts of India, and I entirely fail to see how any patent could be held for this part of the process.

To have made the process any success worth the notice of financiers they ought to have had over a Death & Elwood machine, which can be purchased for about £30, and which turns out a large quantity of fibre in the twelve hours, because then the sticks could have been taken from the steam chest, and the action of the air acting on one side of the skin or mass of fibre and the water acting on the other side, as in that process, would have, in my opinion, disintegrated the fibre and removed a large quantity of the gummy matter. But we shall not have long to wait for these experiments, as they are being tried here.

One disadvantage in the Favier machine is that fuel, which is always very expensive in India, is a necessity, whereas with the Death & Elwood machine it is quite independent of heat if only water power can be obtained.

There is another point which must not be lost sight of in these trials, and that is the quality of the China grass or any fibre that is looked upon as a staple article. I have shewn in my No. 6, "New Commercial Plants," that certain Asiatic plants grown in Europe only yield poor weak fibre compared with the strong elastic fibre they produce in their native soil; and I believe it will be found that if hemp and flax were treated by the Favier process when the plant is ripe, they would get a better fibre from these plants grown in Europe than they will from the European China grass. This question will also be shortly set at rest by trials now being made by Mr. George Fry, F. L. S., in this country. He proposes to allow the plants to properly ripen, and by treating them by some process other than retting.

But it is pointed out that Mr. Christy has failed to note the fact that the Frémy process is now amalgamated with Favier's, and that the one should not be judged without the other. We may be sure that if the French process is a practical success the inventors will not be long in taking advantage of the best and widest fields available for the utilization of their patents, and therefore through the Government of India—if not at the Calcutta Exhibition—we shall be sure to hear about the processes, if continuously successful ere long.

THE TROPICAL AGRICULTURIST: A REVIEW.

(Communicated.)

21st Nov. 1883.

Volume II of this useful periodical lies before me, and scattered through its 1,008 closely-printed pages s a veritable fund of information. A rapid glance through the copious and well-arranged index informs us that we may "inquire within" for instruction on the following amongst hundreds of other subjects scattered throughout the book, viz.:—Ants, America, Beans, Borneo, Cacao Coffee. Cloves, Canada, China, Dogs, Demerara, Fungi, Fiji, Gingerbeer, Grenada, Hay, Hawaii, Indigo, Italy, Java, Jamaica, Japan, Leeches, Lucknow, Mango, Manitoba, Madagascar, Malacca, Morocco, Nutmegs, Natal, New Guinea, New Products, New Zealand, New Remedies, New York, Oats, Oysters, Oranges, Pigs, Potatoes, Pernambuco, Penang, Quicksands, Quinine, Queensland, Rainfall, Rice Cultivation, Réunion, Russia, Sulphur, Sea-Sickness, Sumatra, St. Helena, Tea. Teneriffe, Vines, Walnuts, Wynaad, Zanzibar. It is not surprizing therefore to find that appreciative notices of the *Tropical Agriculturist* have been received from many quarters of the world, including London, Scotland, East and West Indies, Africa and Australia.

The leading products of our island are discussed in 1,013 articles distributed as follows:—

Coffee (King)	...	362	articles
Cinchona	...	209	,,
Tea (Queen)	...	180	,,
Indiarubber	...	69	,,
Cacao	...	48	,,
Cinnamom (Raja)	...	35	,,
Coconuts (Rani)	...	20	,,

To review the whole volume would occupy too much space, so I confine myself more particularly to the numbers for April, May and June. Page 773 naturally opens "about tea," and informs us that at a recent sale in London 42 chests of Ceylon tea were sold at prices ranging from 1s 7d to 2s per lb. A great future certainly lies before the successful Ceylon tea maker, and, if war should break out between China and France, we may look for better prices still. Mr Bosanquet (p. 778) gives sound advice as to manuring coffee. This is after all a very ancient mode of cultivation. See story of "barren fig tree" written 1850 years ago. Where the coffee trees are not barren there the less they are tampered with the better; but where the soil is naturally bad, or has become exhausted, there the want of *bulky* cattle and other manure, mixed with fertilizers in *extreme cases*, is indicated. Strong artificial manures, if used alone, may give the trees a "spurt," but may speedily be followed by a total collapse. Weeds *must* be removed, Mr. Halliley to the contrary notwithstanding (p. 805). When coffee trees are ready to die of starvation, it would seem to be worse than madness to allow a "carpet of weeds" to hasten the end by absorbing the little good still left in the soil. Weeds are compared to the "governor of a steam-engine." This illustration might be appropriate where the trees are likely to suffer from over richness of the soil, but as in an engine where the supply of steam is deficient the governor is useless, and, even if it acted, would do more harm than good, so on most estates in Ceylon what we want is to husband our strength and all our resources for *proper use*, and not to let any escape. Mr. Halliley wishes us to believe in weeds because "Old Cabragalla" in the days of old gave large crops in spite of the weeds. Most estates gave large crops then—the average exports of coffee for five years ending 1871 was 973,975 cwt. The question is, can old Cabragalla, or old anything else, now be brought to bear heavy crops by spreading over the land a "carpet of weeds"? If so, then we may expect Rakwana and other districts to flourish again; for on all the abandoned estates, weeds are the order of the day. No, Mr. Halliley, if you want "crops," you may "boulder" your estate or you may "stone" it, but you must not "weed" it. Mr. Halliley returns to the charge (p. 864). His remarks on over-pruning are worthy of notice, but what is over—pruning? The object of pruning is two-fold. To revive the tree, and to help it to put forth its powers in the right direction. *Ergo*, all the long whippy branches should be taken off so as to relieve the tree of the necessity of supporting yards and yards of useless wood. The nearer the blossom and fruit to the main stem, the better for both the crop and the tree. The article on New Ceylon by Von Donop (p. 829) is interesting reading, but "Old Ceylon" is not quite played out yet, and those who stick to the old love will find themselves better off in the long run. Cacao curers will study with profit Mr. Shand's able article on p. 848. Lowcountry products are ably discussed on pp. 858-61. The writer speaks of Liberian coffee, cacao, fruit-trees leaf-disease, crops, etc., etc., on Delgolla, Udapolla and Liberian estates. Timber for tea boxes is referred to in an article on p. 881. The advice to plant suitable fast-growing timber trees is sound and worthy of the consideration of all whom it may concern. On p. 885, arrowroot and cassava are spoken of. To those about to plant either of these products we say in the language of *Punch* "Don't." And we tender similar advice to those who may think of emigrating to Manitoba (p. 893). 80 in the shade in Ceylon is preferable to 19 in the sun at Manitoba, especially, to those who have any regard for their noses and ears! Coconut-growing in Queensland (p. 904). It is very questionable whether trees which love a hot moist climate can be cultivated with success in Australia: an attempt on a small scale seems to have been made at Mackay (p. 170). Dr. Trimen's report for 1882 (p. 913) and Mr. Morris' report on Jamaica for same year (p. 939) are interesting and valuable papers.

NIREFONOS.

COFFEE AND NATIVES IN THE NEW HEBRIDES.

The following interesting extracts are from one of "The Vagabond's" letters to the *Argus* dated August 25th from New Hebrides:—

RODD'S ANCHORAGE, August 25th. Mr. Glissan's homestead at Rathmoi is a building eminently adapted to the climate. The thick walls are formed of a concrete of coral line, and the roof is of thatch. A broad cerandah runs round the house. The garden is well vultivated, containing some magnificent specimens of crotons, of which no less than 24 different varieties care found on this island. The walks are of crushed coral. There are trophies of shells, and there is a general care in the surroundings which speaks of a refined feminine taste. There is a beautiful outlook over sea and land. We are received most hospitably, and Mrs. Glissan busies herself in preparing a welcome breakfast, including fragrant coffee grown on the Siveree estate and fried jungle-chicken, young of the domestic fowl run wild in the woods, and shot by the "boys" in the coffee fields. It is very like pheasant in its flavour. Mr. Glissan is an old Queensland pioneer. He has been settled at Siveree for some 12 years, and his opinions are worth having. Conversing on the annexation question, he expresses himself favourable to French rule. It will give the residents here law, order, and protection. He would prefer a connexion with the colonies, but certainly not with Fiji. The statement that "the powers of the High Commissioner will be enlarged," he views with mistrust. His view, as that of every man I have met with in the islands, is, that the powers of the High Commissioner have only been used in a one-sided way, to the annoyance, persecution, and prosecution of British subjects, never to their protection. Mr. Glissan has had trouble with the natives. On one occasion a "mob" of them surrounded his hill plantation of Seaview, with the intention of killing him. As he was on the alert, however, they retired, and murdered and ate one of his labour-boys from another island. A year ago a "bushman" presented a musket at Mrs. Glissan in the garden, with the intention of intimidation and robbery. The "saltwater" men, by whom he is surrounded, and from whom he bought his property, are, however, friendly enough. It is the inland tribes, enemies of the men on the coast, who annoyed him. The trouble is now, however all over. The people round about have nearly all become Christian—over 100 converts having been made by the native preachers since Mr. Macdonald's absence. Mrs. Glissan, as an observant lady would do, has found out a great deal about the feminine natives which would escape a man's notice. Coming here with the usual English idea that the islanders are downtrodden and oppressed, and full of sympathy for them, she has gradually had to alter her opinion. She finds neither truth nor gratitude in them. In none of the dialects is there any word to represent thanks. Mrs. Glissan says that the natives at the neighbouring mission on Muna Island have disgusted her by their want of acknowledgement of the way in which Mrs. Milne has worked amongst them. "They are untruthful, lazy, and ungrateful. The more you do for them, the less they will do for themselves," is the verdict of this English lady, who has been 12 years amongst them. She tells me some curious instances of female native customs on this island. The strangest, perhaps, is that when a girl is betrothed her mother never again looks on the face of the prospective son-in-law; she always avoids him. If by accident they should meet the mother-in-law turns her head and covers her face with her calico wrapping, if she should possess such a thing. I suggest that this custom is one which many an unhappy benedict would hail with pleasure if introduced into civilised life. I believe it would increase the percentage of marriages. We go and view the estate, the flock of goats, the turkeys, the fowls, the ducks and geese. The property consists of 10,000 acres. On the lower flats maize is grown with yams and bananas as food for the native labourers. Mr. Glissan has 70 acres under coffee, and is rapidly clearing and planting the berry. The coffee of the New Hebrides, as I know by what I have drank, is of a very superior quality. It is a good paying crop too, and can be picked here 20 months after planting. The yield, too, in this virgin soil is something enormous. One patch of 13 acres last year brought six tons of coffee. The coffee-fields are at Seaview, 1,000 ft. higher than Rathmoi, and some two to three miles distant. There is a good and easy road, however. It reminds me very much of the ascent to Mr. Adolph Joske's plantation on the Navua River, Fiji. A coffee plantation in full bloom is one of the most beautiful sights in the world, the contrast between the snow-white flowers and the deep green of the leaves on the shrubs on these slopes is worth climbing to Seaview to witness. But more than this rewards my gaze. The blue Pacific is at our feet, dotted with a dozen islands of all sizes. Muna Pell, and Hinchinbrook are beneath us, Mataso is 30 miles off, and near it the Monument, a great rock 500 feet high, home of the seagull, against whose base the waves dash on a girdle of white foam. The three hills of Mai are in the distance, Api looms beyond, and far in the horizon there is a faint cloud, not larger than a man's hand. It is not rain, but the smoke of the great volcano of Ambrym, a pillar by day and night for 60 miles around. In the morning we are off Api, an island about the same size as Sandwich, some 70 miles in circumference. It has more mountainous country, and is thickly wooded, but one misses the verdant terraces of Vaté. Api has a bloody history. The people were and are still cannibals, and many massacres of white people have taken place here. There are three copra stations here belonging to the new Hebrides Company. The missionary and his wife complete the total of six white inhabitants. We sail on towards Ambrym, to the right of the island of Paama and Lopevi, 5,000 ft. high, a smouldering volcano. To the left Malicolo, as yet only inhabited by two white men, but which Captain Macleod says will some day be the head-quarters of trade in these seas. He should know something of it, as so long back as 1874 he established a "station" there. A cloud is above Ambrym from the ever active volcanoes, but the wind is taking the smoke to the east. The night would be dark, as the moon is hidden by clouds, but 3,500 ft. above our heads the crater gives out a steady roseate light beautiful to behold. Not a small affair is this, as the fire appears to extend for miles above the dip in the mountain which forms the bed of the volcano. A grand and magnificent sight, yet so prosaic is man that I can only compare it in my mind to the lights of the blast furnaces in the "Black Country," seen from the heights of Barr Beacon or Bromsgrove Lickey. Yet the delicate tints to be seen here could never be produced from a cupola. We are crowded with visitors in the morning. Captain Petersen of the "Aurora" a worthy Swede, but naturalised Frenchman, who possesses only one hand, having blown off the other with dynamite, is early on board. So, too, is "François" the young trader, whose pile of copra on the beach is protected by the *tricolore*. Two vessels also floating the flag of France, must vex the souls of the worthy missionaries with fears of annexation and inroads of Marist priests, Francois speaks English fairly, and delights to air his knowledge of the language. He has lately taken a wife *Vaca Ambrym*, paying her computed value in pigs. Eight of his relations accompany him on board, as a bodyguard. They are all perfectly nude, the bandages they wear only increasing their nakedness. Their hair is artistically done, some of them having it worked by the aid of oil and fibre into a thousand separate spikes, which stand on end like quills of the fretful porcupine. In the matter of earrings there is a diversity, but he with the Jew's-harp dangling from his lobe is evidently "a blood." The chief has a belt made of cocoa-nut fibre and a piece of yarn knotted round his neck—handy to strangle him by. He has a club, but the rest are unarmed. Pipes are stuck in their hair, tobacco in their armlets, and wax matches in their whiskers Matches, I am told, are as good articles of "trade" as one need have. The laziness of these people is so great that they will use as many as an Australian bushman; they will not move a yard to get a "fire-stick" These savages huddle together and shiver in the slight rain. They follow Francois into the cabin and admire themselves in the glass. The place becomes redolent of "nigger" and cocoa-nut oil.

GROUND PEPPER?

The attention of the trade is being seriously directed to the fact that so-called ground black pepper is being freely offered at prices far below the cost of the lowest whole pepper, which is the more remarkable, as the cost of, and loss in, grinding is at least ½d. per lb. The chief explanation of this remarkable state of things is to be found in the following facts. White and black peppers are both, as is well known, the produce of the same vines, and the difference is simply due to the removal of the outer or darker portion of the corns in the former: white pepper being the same as black but less the dark skin. This envelope, or outer coating, used always to be removed abroad, and by a process which, if it be as is reported, was by no means an agreeable one to reflect upon. Some years back, owing to speculation, white pepper was driven up to famine prices. It was then found that black pepper could be husked here by suitable machinery, and that the resultant white pepper had a preferable colour, when ground, to that which was made abroad. Consequently the process known as "decorticating," that is, of removing the outer husk from black pepper, and of leaving only the central white portion of the corns, has become general here. The question then arose of what was to be done with the large proportion of black husks which were removed by decortication, and it has been solved by simply grinding them up with whole black pepper, and selling the produce as ground black pepper. The white pepper prepared in England by decortication fetches such a high price, that the refuse husks can be sold at an exceedingly low rate, and then mixed off, and used to reduce the selling price of ground Black Pepper far below the original cost of the raw material.

The question whether such a practice is allowable is one of degree, for black pepper has always been ground with its husk, but the mixture, in the process of grinding, of a larger proportion of husk than appertains to the pepper, might be carried on to a point, at which the product might be more rightly termed ground black pepper husks. Still, the practice could scarcely be called adulteration, as the husk has pungent qualities, serviceable for the uses to which pepper is put, and it is not proved that the inside of the grain is more useful than the outside. Indeed, a large number of persons much prefer black to white pepper. It is also to be said in favour of the husks in question, that decortication cannot be well practised with the very lowest qualities of black pepper, so that the husks are from a superior quality of pepper to that which is often ground. Still, allowing all this, there is much to be said on the other side. A wheat miller may with perfect propriety sift his flour into various degrees of whiteness, and offer it as firsts, seconds, and thirds, mixing off a portion of the bran; but if he ground up his bran by some new process so as to make it resemble flour, for which he passed it off, he would be doing something more nearly resembling what has recently been done with pepper. The spice grinder, in the same way, may sort out his pepper into various degrees of fineness or colour, and offer them at proportionate prices. But if he exaggerated the operation, the question would certainly arise whether he would be justified in grinding the husks, and then, by implication, selling them as the produce of the entire peppercorn—for such ground black pepper is certainly supposed to be.

It is well to remember, if any public question arises as to these matters, that the whole consequences would fall, not upon the wholesale dealer, but upon the retail grocers. If the latter offer as pepper, that is, as the produce of the entire corn, a material containing, say, 50 to 80 per cent. of the husks or shells, the fact is sure to be detected by the chemical tests now in vogue, especially as the proportion of dirt always contained in unscreened pepper, even of the fine pepper used for decorticating, is to be found entirely in the husks. The law would find out the misrepresentation, by discovering the differing proportions in the constituents of ground pepper and ground husks, and not improbably arrive at the conclusion that there was adulteration, when, strictly speaking, there was none. It is true that it is not believed that anyone has as yet gone so far, as to grind husks only and call them pepper, but, judging from the prices quoted, a good deal of progress has been made in that direction. Of course, pepper ground whole, as has been said above, must include some husks, and therefore all these points are questions of degree. The grocers, however, run a serious risk in buying very low-priced ground peppers, and considering the small importance of the trivial extra profit, even to those in a large way of business, it is surely to their interest to discourage to the utmost all such departures from an old-established practice. Already not only are husks very freely employed to "reduce" cost, but long pepper, a totally different commodity, is added to the product, to "improve" colour. In fact, owing to the demand caused by its being mixed in this way, long pepper has recently risen about 9s. per cwt. If the grocers wish to avoid another question between them and the analysts, like that of coffee and chicory, or that of mustard and sago flour, or other ingredients they should decline to buy any pepper but that ground from the whole corns; for the gain of the substitution of the one for the other would not be worth considering to any individual retailer. On the other hand, the wholesale spice grinder, if unscrupulous, would have a wide field opened to him by such commodities becoming current in the trade. At the present moment the lowest and dirtiest whole black pepper costs in the market 6¼d. per lb. The cost of grinding, the loss of weight, and putting into barrels, is at least ½d. per lb., so that real pepper cannot be sold, without any profit, under 6¾d. per lb. wholesale. Husks, of which 1,400 bags were disposed of last week at public sale, cost 2⅞d. per lb ready ground for, presumably, the commonest; and about 4⅝d. for the roughly broken husks and pepper. The latter would cost, ground, about 4⅞d per lb., filled into barrels. Mixed half and half with pepper ground from the whole corns, the commonest of the above could be sold with a profit at 5d. per lb. Of course there can be no objection to husks being sold, either wholesale or retail, as "Ground Pepper Husks," since there is nothing that unfits them for similar uses to pepper, and they certainly contain nothing injurious; but the grocers should be careful not to buy or sell them as simply ground pepper.—*Produce Markets' Review.*

REPORT ON THE DUTCH CINCHONA ENTERPRIZE IN JAVA FOR THE 3RD QUARTER 1883.

(*Translated for the "Ceylon Observer."*)

The past quarter was again marked by a severe drought. At the end of August and beginning of September some smart showers of rain fell, which indeed caused a brief intermission in the gathering of bark, but which greatly benefited the plantations, especially the young gardens. The harvesting has been steadily carried on. Advantage was chiefly taken of the intense drought, in the absence of the necessary means for artificial drying of bark, for the drying of old plantations of inferior sorts of cinchona, and especially of those gardens which were getting into a drooping condition. During the past quarter 147,390 Amst. lb. of bark were dispatched to Tjikao. The produce of the harvest of 1883 gathered and dispatched by the end of this quarter therefore reached the important figure of 306,653 Ams. lb. On account of the steadily increasing outturn of cinchona bark from the Government plantations, the amount made available by art. 192 of the budget proved insufficient by a long way. In the month of August the sum fixed by the budget—f39,000—was already entirely used up. Convinced of the productive nature of the expenditure, the needful funds were granted with open hand, for further extension. The increased expenditure upon the cinchona culture is due in a large measure to a more careful system of cultivation, which is being more and more practised, and the great advantages of which have been so apparent the last few years. Undoubtedly, the expenditure will be amply made up in another year by increased production. The supply of labor was more than sufficient. A long drought, which hindered the growth of a second crop, and a small coffee crop were the chief causes of the presence of laborers. The disease caused by the *Helopeltis antonii* decreased greatly during the past quarter. These insects, so destructive to the growth of cinchona, were caught and killed in thousands. At Lembong great damage was done to old gardens by caterpillars. In a very short time very considerable extents of this product were eaten entirely bare. Here also the catching and destroying of the insects appeared to be the only means to adopt. The trees are already beginning to recover from the devastations. In accordance with G. O. No. 23 of 28th June 1883, by which directions were given for the sale of cinchona seed from the Government gardens, on 4th August the first sale was held, of ledgeriana, succirubra and officinalis seed. Very high prices were paid for seed of original Ledger trees. Some persons even paid *f*20 and more per gram. For seed of typical Ledger descendants also high prices were for the most part paid. The produce of the harvest of 1882 was sold at public auction on 13th July last in Amsterdam. On the whole, good prices were obtained, for ledgeriana and officinalis barks as well as for quills of inferior varieties. The highest prices were paid for renewed shavings of old ledgerianas raised from American seed. This renewed three year old bark fetched *f*5·55 per half kilogram, while for shavings of original bark of the some trees *f*5·35 was given. In the nurseries at Tjmjiroean, besides a great number of seedlings, there are about 30,000 grafts and cuttings of the original ledgerianas, more and more sought after, with which the plantations at Tirtasari will be greatly extended during the coming west monsoon.

Van Romunde,
Director Govt. Cinchona Enterprize.

Bandoeng, 9th Oct. 1883.

INDIAN TEA ASSOCIATION.

WEIGHING OF INDIAN TEAS IN BOND.

We have been asked to publish the following letter, addressed to the members of the Tea Association, and its accompaniment, which will be of interest to many of our readers :—

Calcutta, 31st October 1883.

Dear Sirs,—In July last, the General Committee issued a circular containing the new rules for the weighing of Indian Tea in London, but it has since been found desirable to obtain the sanction of H. M.'s Commissioners of Customs to slightly amended rules, which have the support of the trade in London, on condition that they do not come into operation till the 1st January next, and provided that the chests shall be re-weighed at merchants' expense on delivery.

The present orders of the Commissioners of Customs sanctioning the amended rules are as follows :—

The weight of Indian tea for duty may, if desired by the importers, be ascertained under the following regulations :—

1. The packages on arrival to be weighed to ascertain the gross weight of each packages.
2. With each entry, the importer to give an endorsement or statement of the nett contents of each package.
3. To test the accuracy of the endorsement or statement of the nett contents, ten per cent of each break to be turned out and weighed nett, but in no case should less than three chests be turned out.
4. If the variation in weight of the test packages be found to exceed one pound, the whole parcel to be weighed nett.

When the average of the packages weighed nett amounts to so many pounds and a half or more, the half or more will be charged as a full pound. When the fraction is less than a half, it is to be rejected and disregarded.

The new system to come into operation on the 1st January next.

In connection with this new system of weighment, the Indian Tea Districts Association of London has issued the following Memo., the remarks in which are, in the opinion of the General Committee, worthy of very careful consideration. It will be noticed that the two questions of weighing and bulking are essentially distinct, and that it is with the former alone that the Customs will concern itself. If the Teas are not bulked in India, or are found on inspection to be imperfectly bulked, that operation will be performed in London as heretofore, and the chief advantage of the change in the system of weighment will be lost.—Yours faithfully, G. M. Barton, Secretary.

MEMO. EXPLANATORY OF THE NEW SYSTEM OF WEIGHING INDIAN TEAS NETT.

That the present system of weighing and bulking Indian Teas in the London warehouses is highly detrimental to the tea is beyond doubt or question. It is not merely he immediate injury—grave in itself—resulting from the contents of every package being turned out, exposed to the atmosphere, and crushed back into the cases, but the fact that teas so treated coupled with the damage done to the lead linings of the cases, rapidly deteriorate in condition—a point of some importance to retail dealers as well as to growers and importers. The latter are also taxed with the heavy charge of taring every individual package, irrespective of the charge for bulking in London —by no means a light one.

It is with the view of lightening these serious burdens on an industry sorely pressed to maintain its ground, that her Majesty's Treasury and Commissioners of Customs have sanctioned a change in the system of weighing Indian Teas, by the substitution of nett for tare weight. The first economical effect of this change will be a reduction of some 80 per cent in the old charge for taring upon all teas bulked in London, provided they are found by ten per cent of test chests to give within a narrow margin of variation an even average nett weight. When found to exceed the allowed variation, the whole will be weighed nett, and this advantage lost to the importer. Another effect, however, of far greater importance will be the vastly increased facility afforded for bulking in India, by which the cost of that process in London may be avoided as well as the resulting damage to the teas. By dispensing with tare weight, the chief impediment to this reform will be removed. If the difficulty of finding wood suitable for securing an approximately even tare weight in the boxes has been found by the great majority of planters to be almost insuperable, and always costly and uncertain, there can be no real difficulty, or valid excuse for failing in putting into a strong, well-lined, and, so to say, hermetically sealed chest, a given quantity of dry tea (giving say half-a-pound overweight), so that it shall turn out essentially the same weight in the London warehouse—any chests, injured in transit, being put aside and dealt with separately. Occasional variations will no doubt occur under the new system, as under the old; but the growers and importers claim as one of the merits of the new, that such variation will be reduced to a minimum, and that if buyers may, upon an average of all teas bought, receive a barely appreciable fraction less overweight than under the old system, they will still receive all fractions of pounds in addition to the pound draft. They will also secure a more uniform and certain distribution of weight than took place under the old method of taring parcels bulked in India, by which one buyer frequently received a good deal more than his due quantity, and another a good deal less—the inevitable outcome of the variation of several pounds allowed in striking an average tare weight. Under the substitution of nett weight for tare weight in the test packages, not only will the nominal margin of variation be reduced, but the actual one must in practice be still more so; and the buyer having the further protection of having the whole parcel weighed nett when the nominal margin is exceeded, he cannot be prejudiced by the adoption of the new system, whether the teas are bulked in India or London. In fact, it should be clearly kept in view by both importers and buyers that the two questions of weighing and bulking are essentially distinct, and that it is with the former alone that the Customs will concern itself. If the test packages of each break give a correct average nett weight, the parcel will be passed by the Customs. If the teas are not bulked in India, or found, on inspection, to be imperfectly bulked, that operation will be performed in London as heretofore, and the nett weight of each packages, as determined by the Customs weighed into it again. Although in such cases the chief advantage of the change will be lost, the saving in the cost of weighing will remain, with the way paved for the gradual attainment of the main objec—tthat of bulking the teas on the plantations, untrammelled by a disturbing tare-weight, which has hitherto rendered the best efforts of the grower in that direction almost nugatory.

It is not too much to say that the adoption of this change of system—simple and economical in its operation, as it is rational and just in its principle and incidence—will, in not a few instances, turn the scale between the profitable and unprofitable working of tea estates, and a very large proportion of them have in these days of low prices taken their rank in the latter category.—*Friend of India and Statesman.*

PLANTING IN BRITISH BURMAH.

(*From a Ceylon planter.*)

The Model Duke Estate, Tavoy, 3rd Nov. 1883.

I am sending you now Mr. Petley's report on his Toungoo estate. I fancy this will be of more use to Ceylon men than anything else I could write about at present until I make more headway. But for all this I must tell you that I have now in my estate Liberian coffee, Coffea arabica, hybrid tea, indigenous tea, indigenous to Burmah, as I found it growing on my place. I have to thank Captain Butler for the different plants I have now got.

I have been down at Mergui and was received by Captain Butler and Mr. Palmer with the greatest kindness and hospitality. I found Captain Butler killing his coffee with kindness, John Chinaman cutting up and top-dressing just as he would cultivate his much prized vegetables, and trenching the ground, removing all roots, of course going right against the nature of the good old King Coffee. There is something natural in the jungle not being trenched up for coffee that is hard for a planter to explain, and in fact few can explain, and I fear Capt. Butler was rather amused at the clumsy way that I expressed myself; and when I returned today, I took my pen and made things and queries more clear for him, and now he has embraced my ideas with profit and advantage; for he is a most observant man, as I could see by what success he has gained having never seen a coffee nor tea estate in his lifetime. (Mergui.) Liberian coffee very fine: about four acres or more. Tea hybrid very fine, but not pruned; but he had a good sample made by his Chinaman, a good strong flavouring tea. Tobacco very fine spotted leaf and seemed well cured. Coffea arabica not so good; but as I have said before had not a chance, has gone against the nature of the tree and had it planted where he ought to have had his tea planted; bean small but "plump" and firm a great crop of good 6 cwt. per acre, but the trees are feeling the crop and no wonder under the circumstances. Pepper A 1, growing up natural trees; and Capt. Butler knows this cultivation and know hows to treat same more than the writer. Rubber of different kinds growing splendid from shoots and seeds, but, oh, the *ants*, the *white ants*! Vanilla growing first rate, but not bearing yet. Nutmegs in their element, and I got from Capt. Butler 140 nuts which I have now down here and growing first rate: also doorians, mangosteens. I was much pleased with my trip to Mergui, and we anchored and slept opposite Tavoy Island for the night, proceeded next morning for Mergui, reached French Bay and ran opposite King's Island, but it would require the pen of A. M. F. senior to describe this beautiful country.

I am going to send you some seed for "Clarendon" Mr. H—— to sow amongst his coffee: it is a weed here, and the Burmese make coffee out of the seed, and it makes a capital substitute for coffee. I have myself used it: I got some from Dr. Dawson. The Tamil name is *Tayri Vellie* and the botanical name I think *Thorea cassia.*

You can print Mr. Petley's report for the good of my dear old home, Ceylon, and my happy lucky old *friends!* Ceylon, with all thy pests, I love thee still, and always am thinking about thy welfare.

I will write you at greater length, and will always write you now and again, and shall be glad to hear from anyone interested, and I am now ready to select land for anyone who will take *bona fide* steps to cultivate. I have now got liberty from the Chief Commissioner to select near Tavoy, so now I am ready to select lands for coffee, Liberian coffee, Coffea arabica, cacoa, and cinchona, cardamoms grow a weed here: they are the weed in fact. Rubber grows wild, two varieties. "Sapan" in hundreds of tons. Gamboge lots of varieties, pepper nigram in two varieties. Tea indigenous to the country; I took some into Rangoon with me to Mr. Smeaton, our able Director of Agriculture, etc.

I will give you my report on Tavoy waste lands in a short time. I have been very busy indeed: you will find out this before long. I have splendid health, which is my greatest blessing and best friend on this earth. It's now time to trust only to one's own right hand and strong arm only.

REPORT ON THE CULTIVATION OF TEA, COFFEE, AND CINCHONA ON THE KAREN HILLS NORTH-EAST OF TOUNGOO, 1883.

Tea.—This produce has not been increased. Considerable loss occurred since 1880 amongst the shrubs set out, owing to destruction by the mole crickets and other causes as shown in former reports amongst both coffee and tea. Vacancies have been filled up, and the total quantity of shrubs at this date are about 25,000; about half are yielding flushes, and the manufacture of good tea continues, on a small scale, as heretofore. The whole will probably yield next season.

Coffee.—Report of 21st September 1881 shows 3,417 bearing trees, 1,620 nearly bearing, and seedlings 29,638. These latter are coming on well, about one-third bearing maiden crop—in fact all up to two years' growth with a sprinkling more or less. About this number has been kept up by filling in vacancies where the young plants have been killed by crickets, as the bulk of these are past the stage of liability to destruction from crickets now. A considerable increase of crop may be looked for next season Dec. 1884.

The yield of coffee 1882-83 was 4,200 pounds. It should have been more but for loss from attacks on the ripening crop, by birds, civet cats, and other destructive animals. Sample of season 1881-82 sent to the London market has been pronounced really good berry and of fair market value.

Cinchona.—About 1,500 trees (succirubra of 5 to 7 years' growth) have been coppiced and 500 uprooted; the bark prepared and sent to the London market 5,300 pounds dried and well packed. The "quill" and large branch realized 8½d to 1s 6d per pound, a *low* figure but good average and fair rates in the present glutted and very low state of the home market, competing favourably with other red bark. Small branch and "twig" gave dead loss, fetching only 1d per lb. against 4d for similar kinds sent last year, when the market was favourable and the demand greater.

A small lot of 300 pounds having been sent them as a trial shipment. *Branch* fetched 1s 5d to 1s 8d, and "twig" 4d per lb.

On the whole it appears that cinchona can be grown profitably on these hills and with proper care in harvesting the bark in future; rejecting the unpayable small branch and "twig," it is calculated, will prove a fair investment. With this in view all available young plants and shoots have been set out this year, considerably increasing this produce. The coppice stumps are mostly throwing out shoots freely, a piece only of which are kept on each stump for the future tree. The quantity now under cultivation is about 30,000. Trees, plants and shoots are as follows:—

Succirubra.

Young trees 3 to 5 years' growth...	878	
" 2 " ...	700	
" 1 " ...	3,000	8,958
Plants sets out July 1883 ...	2,880	
Coppiced stumps	1,500	
Shoots planted out July and Aug. 1883		14,800

Calisaya.

From 3,780 young plants set out May 1882, 2,880
Less about 900 failures leaves
,, 3,500 ,, set out June 1883
,, 1,200 probable failures leaves... 2,300 } 5,180
1,020
Shoots set out Aug. 1883
Trees and plants... Total...14,138
Shoots... ... ...Total...15,820

The products of the plantation all continue free from disease and the climate is favourable to growth, especially mild during the rainy months. Thermometer 65° to 72° during the 24 hours, the extremes of heat and cold during the day and night being at no time very great as at Toungoo and the plains.

The young plants of cinchona, especially calisaya, are coming on well.

A substantial wooden dwelling-house and a tea-house have been built now on the place.

JAMES PETLEY.

Toungoo, 12th Sept. 1883.

WYNAAD PLANTERS' ASSOCIATION.

From notes of a Committee Meeting held at the Pookote Club, Vythery, on Wednesday, the 7th November 1883, we quote as follows:—

Cinchona.—Read following letter from Captain Cox, Chedington Court, Crewkerne, Somerset.

3rd October 1883. The Secretary, Wynaad Planters' Association.

Dear Sir,—I have delayed answering your letter asking my opinion as to the relative merits of the two modes of harvesting Chinchona bark, viz. (1) stripping (2) shaving in order that I might obtain information on the subject. The tests of the relative merits of the processes are two viz: quantity, and quality.

With regard to the former I am unable to pass an opinion, the trees on my estate are of different ages, also planted at different distances, and in harvsting I have only adopted the shaving process.

Quality judged by Analysis:—Renewed bark on the Neddiwattaum Government plantation where stripping has been regularly carried on, has given analysis as follows:—

	Sulph. of Quinine.	Cinchon-idine.	Chinchon-ine.	
1876	3·80	2·30	1·70	
1877	4·51	1·48	1·83	whether from Ootacamund of Neddnvattam I do not know.
1878				
1879				
1880				
1881				
1882				
1883				

I have been unable to obtain separate analyses for the years but I am informed that the average was about 4 per cent and is now decreasing. In 1879 a sample of bark renewed by the stripping process at Charambady gave—

Sulph. of Quinine	Cinchonidine	Cinchonine
4·70	1·00	1·80

Analyser's remark:—Exceptionally fine. But sample of renewed bark tested.

Of bark renewed by the shaving process my analyses have been as follows:—

	S. of Quin-ine	Cin-chon-idine	Cin-chou-ne.	
1881	4·60	1·20	1·80	Deeply shaved 1 year.
1882	3·05	3·65	1·95	Lightly chiefly 1 year.
1883	8·30	2·36	2·00	Deeply shaved 2 years.

I have communicated with Messrs. Lemain & Co. whose letter to Messrs. Croysdale of Madras you sent me. They have repeated their opinion on the subject but have not given the data on which they found their opinions. The quinine manufacturers and brokers generally are rather in favour of the stripping process for producing the richest bark. They inform me with regard to the shaving process that "random and ignorant" shaving is doing much mischief, that they have received bark very lightly shaved in which the result seems to be that the woody fibre has increased while the cellular tissue in which the alkaloids are formed has proportionately decreased. they consider that in the case of light shaving the Cambium is not reached, and that a proper outpour of cellular tissue does not take place. A satisfactory conclusion as to the relative merits of the two plans can only be arrived at by a careful series of trials. For these trials trees of the same age, say 8 to 10 years old, should be taken, so many acres being treated under each plan, and records carefully kept of 1 Number of lb. of dry renewed bark; stripped, per acre, per annum. 2 Analyses of ditto, to be made each year. 3 No of lb. of dry renewed bark, shaved per acre, per annum. 4 Analyses of ditto to be made each year.

Bark should be "stripped" before the end of the rainy season and the denuded surface at once covered with some substance which will protect it from the sun.

I enclose a plan of a driving house which has been furnished me by Messrs. Gordon & Co., they inform me that they have supplied the iron work for one of these houses to Mr. C. Firwee, Secretary of the Wentworth Estates Company, and that it was sent to Madras. It would be of great benefit to all Cinchona growers if individuals would make known to the Association the results of experiments, also the analyses they have had made of their barks. Quinine barks are valued according to the percentage of Quinine contained so that the cost of an analysis is money well spent.—Yours faithfully,

(Signed) W. T. H. COX.

Resolved that Captain Cox be thanked for the information given which will be circulated to all members of the Association.

A SIMPLE AND INEXPENSIVE TEA-ROLLER.

There are many small tea estates, or estates with only a small portion of the bushes in full bearing, the owners of which would be glad to obtain at a moderate cost, a small roller to be worked by hand labour. Such a machine Mr. Henry Kerr of Kinrara estate, Matale, has invented and patented, and will soon offer for sale. We were much struck with the simplicity and effectiveness apparent in the model shown to us by Mr. Kerr a few weeks ago, and samples of tea rolled by the one machine which has been completed seemed all that could be desired, and were well-reported on by good judges. Today we had the advantage of the opinion of a tea-planter, so experienced as Mr. C. A. Hay, to whom Mr. Kerr showed his model and fully explained the details of working, including the utilization of coffee pulpers if necessary. There were also specimens of tea rolled by the machine, which Mr. Hay pronounced to be very well made, with a good twist, due to the roller, of the principles and action of which he spoke very favourably. Mr. Kerr's great object is to meet the demand for small and inexpensive rollers capable of being worked by two coolies but two connected, of the small rollers can be worked by three coolies, and larger sizes can be constructed for water power or steam. Mr. Kerr has shown us highly favourable opinions expressed regarding his invention and of the quality of the tea rolled by the completed machine, by planters exceedingly well qualified to judge, the gentleman in whose tea house the roller is placed stating that it does its work well. One authority states:—"The two chief things in favour of your machine, are: first, its low cost; and second, the small motive power required to work it." Another states:—"I certainly consider the samples you sent very well rolled, and, if 3 coolies can do 150 lb. per hour with this machine, it will be very useful to proprietors of estates not having water-power, and also small acreages." Still another :—

"Judging from appearance the rolling is simply perfect. I showed a neighbour the tea, who said if the price was R[illegible] to R[illegible] and the results such as the samples showed he would order one at once. I have no doubt that many with a small acreage of tea would only be too glad to get hold of a machine with such evident merits at the price."

And finally :—

"The manufacture of the sample of tea you sent me appears all that could be desired. I think you could not do better than have your machine patented at once: it just the sort of thing wanted in these hard times—a *good article* for *little money*.

Mr. Kerr gives the following general description of his invention :—

My invention consists of one central shaft or arm held at one end by means of a lever or working in a slot forth and back; to the other end of this shaft or arm is attached a box working on hinges that can be thrown back, opening up and from which the rolled tea when completed may be taken; the box end of shaft or arm making an oval, circular motion, this motion being obtained by means of a crank *above* shaft, and about 1-3rd from box end thereof revolving in a circular movement, this motion being obtained from bevel or other wheels set on a shaft or arm at right angles with crank shaft.

The box containing the leaf is supported by means of two iron rods fitted with screws and nuts at both ends in an upright position and the whole held up by a gallows-like frame. The box containing the leaf has attached to it all round brushes which keep any leaf that may come from under box when in the act of rolling swept back under box, each stroke or revolution which it makes. These brushes are set in motion by means of variously arranged levers attached to them and to the stationary parts of the machine and are thereby self acting. The box containing leaf is supported about 3-16ths of an inch from a table or platform having in its centre a depression or hole at the bottom side of which is a door with four pieces of wood attached in the form of a cross thus + which grips hold of the tea, which with the motion given to the box of an oval circle as above described, causes a friction to be given to the leaf and making it to roll into the required form, the table over which the box moves is stationary. The main shaft to which the box is attached in order to give a double action to the machine may be prolonged to an equal distance beyond the retaining lever or slot at the reverse end of box, and to which another box may be attached suspended, having brushes attached and working over another platform or table as above described thus giving a double action to the machine and permitting of double the work done, the same set of bevel wheels, shafting, driving handles or other motive power sufficing for both boxes.

The above arrangements may be attached to existing coffee machinery when there is a circular sieve used and driven by a revolving crank by means of removing sieve and substituting the shaft, boxes, &c., as above described. The boxes are fed by means of removing half the cover and inserting a moveable hopper through which the leaf enters the box, after which the half cover is replaced and fastened down. The box cover is weighted sufficiently to put pressure on the tea to keep it in position at bottom of box and causing it to roll—should the pressure appear to be too great, at any time a lever at top of box is arranged to attach to handle through support at top of box fixed to [illegible] to which is attached a spring balance [illegible] the screw [illegible] put on, how much weight is taken off the pressure caused by top of box weight. This machine may be driven by manual, steam or water power [illegible] for [illegible] required [illegible] small that it places the [illegible] of the machine in the possession of all classes of proprietors.

At the close of [illegible] cal description referring to the drawings, the inventor of this new, simple and cheap roller states :—

I claim for my invention that the machine is cheap, durable and cheaply-worked [illegible] simple and easy propulsion, that the rolled tea is [illegible] removed from it, and that the *self-acting brushes* have not hitherto been adopted or used by any other machine, the main shaft worked by a single crank has also not before been used. Our feeling from what we have seen, and from what practical tea planters state, is that Mr. Kerr's invention will maintain in action the merits he claims for it, and be a decided boon to the rising tea interest of the island.

THE GROWTH OF SUGAR PLANTING IN NORTH EASTERN AUSTRALIA.

Grafton is now one of the best laid out towns in Australia. The streets are at right angles, and all of them two chains wide. On each side there is a row of trees, mostly evergreen. The buildings are good, and the banks and public offices have been built at great expense. There are several hotels, a post and telegraph office, fine court-house, and three banks. The Sydney steamers load and discharge at the town wharf, where there is a steam ferry boat connecting North and South Grafton. But what surprised me most was the immense tracts of sugar cane on both banks of the river—miles upon miles of cane, and numerous mills in full operation. I was always under the impression that sugar cultivation could be carried on only in a tropical climate, but here sugar cane is to be seen in every stage, from the young cane to that fit for cutting—steam droghers and punts carrying the cane to the mills, which were in full operation. The field, in one or two places, were slightly touched by frost, but not to any injurious extent. The cultivation of maize, once the chief product of these rivers, is fast giving way to sugar—the farmer has only to grow it. The proprietors of the mills—chief amongst which is the Sugar Company of Sydney—buy the cane in the fields, send their own men to cut it, and their punts to bring it to the mill, the farmers receiving a stated price per ton. It is calculated that one acre of cane will yield 2 tons of sugar—a splendid return in so low a latitude. I have been informed that the return per acre in the Mackay District is 2¼ tons, and in the Burdekin District, a short distance south of Townsville, 3 tons. There is not an acre of ground open for selection on the banks of the Clarence or Richmond rivers, and in the northern parts of Queensland there is very little available sugar country. It is found to be a very lucrative investment, and capitalists from Victoria and New South Wales have secured all the best of the land south of the Endeavour River. On the Clarence and Richmond rivers good sugar land was realizing 30*l*. per acre, and labourers who cut by contract can make their 8s. and 9s. per day. The sugar industry is becoming one of vast importance, and the product of that material will be one of the chief exports of Northern Australia.—J. C. WHITE, Sydney, Sept. 10, 1883.

RHEA FIBRE :—TWO IMPORTANT DISCOVERIES.

The following is from the *Planters' Gazette* of Nov. 16th :—During the interval that has elapsed since our last issue certain circumstances have occurred, of such magnitude and importance in their bearing upon the utilization of Rhea fibre, that they may without exaggeration be said to take rank as discoveries. One of these has reference to the production of the plant, and the other to the extraction of its fibre, and we had better deal with them in their natural order, though it is obvious that the former would be of comparatively little consequence without the latter.

By the last mail from India the managing director of the Tambracherry Company in London received from the superintendent of one of the company's estates in the Wynaad a [illegible] of long but rather coarse looking fibre, obtained by him from plants which he said were growing wild in the virgin forest forming part of the property under his charge. He did not know the name of the plant, nor whether the fibre had any commercial value, and he asked information on the latter point, as in that event it would be easy to plant up the abandoned coffee fields with it, and also portions of the forest reserves of which the company owns over 5,000 acres. The sample of fibre was submitted to experts here and in Paris, and they have pronounced it to be, without doubt, a species of Rhea (*Conocephalus*, Moens) and we may add that a hank of the fibre, which had undergone boiling under Ekmann's process, has been valued at £70 per ton, but of this we shall speak later on. Now, it is well known that Rhea grew wild in some districts of Upper India, and that it could readily be grown under cultivation almost anywhere in the tropics, provided always there was sufficient moisture in the soil, but it was not hitherto believed to be indigenous to Southern India, and the importance of the discovery lies in the fact that the wild plants will furnish a ready supply of plants for cultivation, as the manager of the Tambracherry estate suggests, that is to say, of course, if such means of extracting the fibre were provided as would render the operation profitable, and this brings us to the second point,

Dr. Forbes Watson, formerly of the India Office, and now of Lime Street Chambers, is well known to have devoted an immense amount of time and attention to the inquiry how Rhea can best be turned to account, and he was the author of a report prepared in 1875 for the India Government, which is still the standard work on the subject. Mr. C. E. Collyer, of 141, Fenchurch Street, is also well known as the leading broker in China grass and other fibres, and these two gentlemen, it will be remembered, were last month invited to attend the trials of the Favier-Frémy process in Paris, because their verdict in its favour would have been generally accepted as conclusive. It is no secret that they have also recently been investigating three other chemical processes, with none of which, however, were they entirely satisfied. But a few days ago it occurred to them to try what the machine patented by Mr. J. Smith, of Mauritius, and manufactured by Messrs. Death and Ellwood, could do with fresh stems of Rhea. The result was a genuine surprise, for by a single operation the machine took the fibrous matter away from the stick-like stems, and also separated it from the outer cuticle, leaving it sufficiently clean and free from gum to be fit for the manufacturer. We do not mean to say that it then presented the appearance of fine wool or silk, such as is attained either by Ekman's or Frémy's process, but, at all events, it was in a thoroughly marketable condition, and better value perhaps than the China grass, which has for many years been imported from China and sold here at from £45 to £50 per ton. So satisfied indeed were these competent authorities with the efficiency of the machine to solve the problem of Rhea treatment, and therefore of its extensive employment in the near future, that we understand arrangements have been made to purchase the patent, and to at once introduce the machine to the notice of the Indian Government and planters.

In the meanwhile a good deal of attention has been attracted to the Favier-Frémy processes, as specimens of the results obtained by them are being exhibited at the offices of Messrs. Brogden & Co., Gresham House, Old Broad Street. It is the intention of the Company which is being formed to establish what one may call central factories conveniently near to the places of production, and there to treat by Frémy's process the "ribbons" of fibrous matter removed from the Rhea stems by Favier's steaming process, whilst this latter will be conducted on the fields themselves. The Company will send its agents, with furnished the Favier apparatus, on to the estate at harvest time, prepared to pay down a fair price for any quantity of "ribbons" that can be supplied, probably about £16 per ton, and it takes 16 tons of stems to make 1 ton of "ribbons."

SOUTH WYNAAD.—Crops are being got in fast, and some of the estates have even arrived at the stripping stage. The coffee (what little there is) this season has ripened with a rush, and the first round of picking has made many a poor planter's heart quake, for the pickers seem to have left nothing behind them, and, as a rule, most men find that they will not get in even half of their estimates. Till lately we have been having most abominable weather for drying, and it was as much as one could do to prevent the coffee from sprouting on the barbacues.—*Madras Mail.*

COCONUT PUDDING.—Get a good sound coconut, and try to get the shell off without breaking the kernel. Remove the brown skin, and grate the nut; add three large tablespoonsful of powdered loaf sugar, and about half-an-ounce of lemon peel. Mix all with milk to the consistency of a thick paste. Line a tin with rich or puff paste; put in your pudding, and bake in not too hot an oven to the colour of a pretty pale brown.—*Natal Mercury.*

GIBBS & BARRY'S TEA DRYER.—Mr. T. C. Owen attracts our attention to a late number of the *Field* in which is "a diagram of Gibbs's ensilage drying machine It is a facsimile of Gibbs & Barey's tea dryer, and is very highly spoken of for fodder as you will see. Many who take the the *Field* in may be interested in the diagram for this reason, and you might extract the description for the benefit of readers."

The description is as follows:—In the annexed engraving, Fig. 1 is a side view of the improved corndrying cylinder. The cylinder, E E, is supported on brick piers, but they may be of iron, or even wood The furnace A, supporting the fan B, may also be of metal. The compound fan, with the air-ducts to the furnace and cylinder, is made of strong wrought-iron. The cylinder and interior fittings are galvanised. D is the hopper into which the grain is fed. Between D and the fan is a chimney, C, for carrying off the smoke when the furnace is first lighted. It has a valve for closing it afterwards. C is the thermometer for showing the temperature of the air. When 18ft. and upwards in length, the cylinder may be made in two lengths, and joined in the centre by a flanged ring. It rotates on four runner wheels, gearing with two turned rings on the cylinder. A large spur wheel surrounds the cylinder, and is driven by a pinion below, which in turn is driven by bevel gear; the fan, being driven by a strap from an engine, gives motion to this bevel-gear shaft. The cylinder is adjusted at any angle by worm-wheel and chain gear, and can be raised or depressed, so as to dry the corn to the exact point required. Nothing can be more simple, more easily adjusted, or less liable to get out of order. The whole of the inner periphery of the cylinder is furnished with cells, as shown at H. The grain, fed in at D, falls into these at the bottom of the cylinder, and as this rotates the grain is lifted up in the cells, discharged each time a little further down, according to the angle at which the cylinder is adjusted. The grain does not fall perpendicularly from the cells above into those below, but is distributed in its fall by the louvres of the hot-air duct, shown at G. These are fixed obliquely in the cylinder, forming an expansion chamber closed at the lower end, so that the hot air from the fan is forced through the louvres, drying the grain as it slides down over the openings, and blowing away all mould, dust, and straw. Those who have examined the different drying cylinders now in use will at once see the superiority of this machine. In all the others the wet grain is not sufficiently scattered, but falls in lumps, or is pressed forward by screws. The cells of Mr. Gibbs's machine, on the other hand, thoroughly scatter the grain so that every berry is separately and equally dried, whilst the louvres have a scouring as well as a drying action. A far higher temperature and stronger blast can be used than in any other known machine; and this accounts for the unusually large yield of 850 tons per week from one cylinder. Coke is generally used as fuel, the hot air being taken directly from the furnace, as in kiln-drying; but the waste heat from any existing furnace can be drawn by the fan through brick flues for even such distances as 50ft. or 100ft., so as to dispense with all fuel cost. This plan has been adopted with these cylinders by Messrs. McDougall Brothers (of Millwall) for some years with complete success. On the other hand, when preferred, the air can be heated by a steam coil, the latter method having been in use with one of Mr. Gibbs's other forms of drying machines at H. M. Royal Gunpowder Works at Waltham Abbey for five or six years.

Correspondence.

To the Editor of the Ceylon Observer.

HIGH AVERAGE PRICE OF MARIAWATTE TEA.

2, Great Tower Street, London, 2nd Nov. 1883.

SIR,—You will no doubt be interested to learn that at our auction sale this week the average price realized for an invoice of 103 packages of tea from the Mariawatte estate was 1s 10½d per lb. This is, we believe, the highest on record.

We enclose catalogue herewith.—We are, sir, yours faithfully, GEO. WHITE & Co.

The Mariawatte Tea Estate.

		s. d.
Mariawatte Ceylon.	38 chests broken pekoe	2 3
"	36 chests pekoe	1 8
"	10 chests broken mixed	1 2½
"	19 boxes pekoe	1 7½

TEA FROM CUTTINGS.

Kabragala, Maturata, 5th Nov. 1883.

DEAR SIR,—Can you or any of your readers tell me whether it would be safe to plant or supply clearings with cuttings from tea bushes of a good ját. I have been told they grow well and form into good bushes but will not stand constant plucking as bushes raised from plants or stumped plants do. Now that there is such a demand for seed, information on the above may prove useful to many SHORT OF PLANTS.

[There can be no question that tea can be grown from cuttings. Some years ago, we saw a nursery of several thousands of cuttings on Oliphant estate, but we do not know their subsequent history. Perhaps some planters can tell about those or others. Our impression from all our reading is that bushes from cuttings are much inferior to those grown from seed. In the index to the Tea Cyclopædia we have looked in vain for "Cutting" or "Graft." The omissions seem significant.—ED.]

A NEW RHEA GRASS: ALLEGED PERFECT SUCCESS IN CLEANING THE FIBRE.

155, Fenchurch Street,
London, E. C., 16th Nov. 1883.

SIR,—No doubt you will ere this have got the information of the imporant discovery that has been made of the *concephalus niveus.* This is a variety of the China grass, and it has been found growing wild in Southern India. Messrs. Hinde & Co. have had over some of the stripped stems which have been treated here in the Death & Ellwood machine and also by the Ekman process. The fibre clean has been valued by the consumers at £70 per ton.

The late trials in Paris for treating the China grass have produced, as I foreshadowed, important results: it was sought by a set of people here to introduce the machines adopted by the French house which exactly compared with the Chinese system of steaming the stems in a box. On the return of Messrs. Forbes Watson & Collyer from Paris they tested the Death & Ellwood machine with its late improvements, and from their report they at once advised the purchase from Mr. Smith of Mauritius, the patentee of his entire rights. The experiments not only showed that the China grass which had been grown in Europe could be treated most successfully and produce the filaments as they are sent from China and India, but also with the same machine could carry the process one step further and produce a magnificent fibre as clean as cotton without knots or knits. This machine with its latest improvements I can say after having studied this question, entirely sets at rest the claim for the award of the Government for any machine that can treat China grass; and having seen the fibre treated by the Ekman process boiled with the chemical, it is something surprising to see how nearly this simple machine with only the action of water has approached the same result. I, therefore, consider that this inventor who has worked to perfect this machine for many years is justly entitled to the Indian Government award, more particularly so when it is considered that this same machine treats with equal result the agave and hemp and all the other fibre-yielding plants that have been tried in it.—I am, sir, yours truly, THOS. CHRISTY.

AN ENEMY OF TEA.

Ambagamuwa, 17th Nov. 1883.

DEAR SIR,—Can you identify the specimens of poocies I send to you under separate cover?

They are from a young tea estate near Nawalapitiya, where these creatures are very active cutting up the young tea plants to form their habitations, which have the appearance of miniature bundles of varatchies.—Yours faithfully, X.

[The poochies are the larvæ of moths of the genus *Psyche*, or of the allied genus *Oiketicus.* The caterpillars of these genera live in a case constructed of pieces of small stick, fragments of leaves &c., lined and kept together with silk spun by the caterpillar.—ED.]

SILK CULTURE IN CEYLON.

Lentran, Haldummulla, 20th Nov. 1883.

DEAR SIR,—To those who like myself wish to give silk culture in Ceylon a fair trial, it may be interesting to know how my experiment in that line has resulted; and I hope it will show how careful one ought to be in procuring eggs from moths, which have been raised from perfectly healthy silkworms. I procured eggs in May last from Father Palla, the greater number of which contained apparently healthy worms. All went well till the time came for producing the silk, when disease showed itself and the worms had only sufficient vitality to spin a very thin covering, and in which they almost all died, only, one cocoon out of some thousands producing an unhealthy moth. I have now got a great number of the Pusean mulberry plants, for which I am indebted to my friend Mr. P. N. Braine, and if you could let me know where to procure a healthy lot of eggs, I am sanguine that, if properly cared for, the result will prove that silk-farming in Ceylon on a larger scale will repay in full measure those who care to try it.

What is the opinion of Dr. Hector, Director of the Geological Survey of New Zealand? Why, that four years' experience had convinced him that an annual yield of £100 sterling per acre would fall greatly short of the result he expected a few years later when his trees had grown older.

What industry more suitable to the apathetic Sinhalese, who, if once the industry is started, will find a good market for the cocoons? At Beyrout, in the heart of the Lebanon territory, where the silk culture is carried on more systematically than elsewhere, a poundweight of cocoons will always fetch about 5 piastres (about tenpence English). Now, when one considers that there is 1s cost for upkeep, and how the men who bring the cocoons (muleteers) are generally imposed upon, one can imagine that the margin of profits must be considerable.

Apologizing for the length of my letter, which, if you think will be likely to make those "doubtful ones" take the matter up, you are welcome to publish it, yours faithfully, C. RALSTON WHITE.

REPORT ON CEYLON TEAS BY MESSRS. W. J. & H. THOMPSON.

Kandal Oya, 21st November 1883.

DEAR SIR,—In addition to Messrs. Thompson's remarks on plucking, they have been kind enough to report on samples of tea sent them to determine whether a *light* or a *full* fermentation makes the best tea: you will observe the question is still left rather unsettled:—

"We report on your samples in detail as follows:—

"*Broken Pekoe*" Full Ferment. Superfine wiry leaf, full of yellow tip, even bright infused leaf, rich full flavor, value 3s 3d to 3s 6d nominal.

"Do. Light Ferment. Similar style of leaf but tip less showy, infused leaf rather duller or greenish in color, more flavor with less richness in cup, value 3s 2d to 3s 4d.

"Pekoe Souchong. Full Ferment. Bold handsome leaf with tip, good infused leaf, good full flavor. 1s 6d.

"Do. Light Ferment. Very similar character but slightly inferior in leaf and liquor.

"From the foregoing you will see that we give the preference to the full fermented tea, but there is really very little choice: some might even like the others better for their extra flavor.

"The Broken Pekoes are teas of fancy character, and taking leaf and liquor together are choicer than any tea which we have seen imported *in bulk* from Ceylon although special samples up to the standard have been made from time to time. We assume that you cannot ship any quantity of the tea, but even if not it is most satisfactory to find that you have been successful in manufacturing tea as near perfection as possible."

I may mention that the samples were from leaf plucked of medium fineness, off the same field, treated with no especial care but in the ordinary way. The full fermented tea was fermented 3½ hours, and the lighter fermented only 1 hour and 20 minutes. It is rather startling that their values should approximate so nearly and that there should be still a doubt which is the best tea, the fact is, I suppose, that there is a demand for both qualities but that the demand for the lighter fermented tea is fluctuating and uncertain.—Yours faithfully, JAMES WIGHT.

KHAKI DYE.

Colombo, 23rd November 1883.

SIR,—Could you kindly inform me through the medium of your paper where I can get drill dyed brown or kharkee color for shooting purposes, in Colombo.—Yours obediently, SHIKARI.

[With the abundance of raw material for dyes in Ceylon, there ought to be no difficulty. Where are the Colombo dyers? Failing them the cloth can be obtained from India.—ED.]

LEAF FUNGUS DOES NOT PREVENT FRUCTIFICATION IN COFFEE?

Dimbula, 1883.

DEAR SIR,—The latest conclusions of astronomers and entomologists leave no doubt that all vegetable and animal life exists through the sun and its atmosphere, but they do not say that all decay is to be attributed to the same causes.

In your editorial note you tell me that the black spots on the coffee leaf have their origin in the atmosphere. It may be so, but it certainly requires some explanation of how it is the cause of life and also the cause of decay.

You also tell me that *H. V.* is a distinct external fungus, and in consequence does not grow on decaying matter.

The general term of fungi represents the varied members of this extensive class of plants, but very inadequately, since the class comprehends, besides the true mushroom or fungus, moulds, smuts, mildews, blights and puffballs. Then *H. V.* must belong to one of those and be governed by the same laws, one of which is they grow for the most part upon decaying matter.

You tell me that all the evidence is against me. If you would put down on paper a few items I should have the chance of refuting them. *

During the past three months my time has been occupied in finding out at what time of the life of the leaf the *H. V.* begins to appear, and I may safely say that it seldom if ever makes its appearance before they have attained the age of two months; from this and other undeniable facts, I am convinced that *H. V.* cannot be the cause of the unproductiveness of our coffee for the bean is only a transformation of the leaves, combined with albumen; it is therefore easy to see that fungi has nothing to do with fructification. [Q. E. D.—ED. C. O.]

In a manual of structural botany by Cooke (page 104) is the following:—"A great many fungi are true parasites producing diseased states of corn and dry rot in wood, and are found growing upon but without any great injury to other plants."—Yours truly, J. HAWKE.

P. S.—I am sending you some fibre, and would thank you for your opinion of it.

SULPHURIC ACID FOR GERMINATING SEEDS.

Central Province, 25th November 1883.

DEAR SIR,—The use of sulphuric acid in germinating seeds is alluded to in several places in your valuable publication, the *Tropical Agriculturist*, but the *modus operandi* is in no instance described. I shall, therefore, be much obliged if you or any of your correspondents can kindly furnish me with information on the following points:—

(1) How many parts of water should be mixed with one part of pure sulphuric acid?

(2) Should the seed be soaked in the solution, and, if so, for how long?—Yours truly, R. R.

CURING SKINS OF CHEETAHS, ETC.

Beruwala, Kalutara, 26th Nov. 1883.

DEAR SIR,—After skinning your animal, place the skin in a large cauldron in a mixture of alum and water and boil slowly until water begins to bubble, then remove it and scrape the inner-side well until all grease, &c. is removed, then boil again to a lesser heat and remove and scrape again, after which wash the skin in tepid water and dry in the sun—a little powdered chalk may be applied to the inner side after it is dry. This will soften the skin like kid or chamois leather. C. A. R.

PREPARATION OF TEA BY HAND AND MACHINE.

27th November 1883.

DEAR SIR,—In response to Mr. Owen's challenge, I have now to point out that the figures given in Mr. Armstrong's paper for manufacture, which Mr. Owen quotes and endorses, are *incorrect*.

The paragraph in question runs as follows:—

"By hand withering 1,600 lb. leaf		2 coolies
rolling	..	40
firing and charcoal..		16
Total for 400 lb. tea	...	58
By machine withering	...	2 coolies
rolling		3
firing	...	3
	...	8

saving in labor on 400 lb. tea 50 coolies. This really represents a saving of 7½ cents per lb."

Taking Mr. Armstrong's rate, which I find to be

* It is surely for Mr. Hawke to prove his position that *H. V.* is the result of vitiated juice.—ED.

33 cents per cooly, and working this out, I find it comes to the following:—

58 coolies at 33 cents	=	R19·14
Less 8 coolies ,,	=	2·64
		R16·50

or per lb. on 400 lb. a saving of 4·125c *not* 7½c as stated.

The same mistake appears in the former part of Mr. Armstrong's paper, under the heading cost of plucking, manufacture, packing, &c. The 6·300 cents for withering, rolling and firing, becomes, as shown above, R19·14 ÷ 400 = 4·785c, the total 15·785c instead of 17·500c, and the total cost of tea hand-made 37·285c not 39 cents.

Deducting from this the total cost of cultivation and manufacture by machinery, viz:—

Cultivation	21·500c.
Manufacture	11·160
	32 660 not 31·660 as

"misquoted" by Mr. Owen, we have 37·285c.
less 32·660

a saving of 4·625

instead of 6·340c, or a difference of 1·715c, due apparently to a clerical error, which has run through all the calculations.

As the cost of the operations in which machinery is used (and including withering) is seldom at 0 41c.

	0·25
and say at the outside, for re-firing	0·12
	0·78, it fol-

lows that the error now pointed out is equal to more than the total cost of manufacture by machinery; or in other words, as was said to you by the "gentleman of authority," to whom the starting of the discussion is due (and who was very undeservedly sneered at by your correspondents), the saving represented by Messrs. Armstrong and Owen is greater than the whole cost of the operations in which machinery is used, as shown in these calculations!

I am accused of misquoting Mr. Owen, and even you are down upon me. Now, in the abovementioned paragraph the saving by machinery is set down as 7½ cents for withering, rolling and firing, and half-a-cent is allowed as the saving on sorting—or together 7 ⅘c.! I only said 7⅘ cents.

These figures remained in my mind, and I quoted them as part of the original figures under discussion, although the estimated saving had been modified to 7 cents (Mr. Owen's Essay) or 6½ cents roughly and must now be again modified to 4·62 cents, or at 36 cents per cooly, 5 cents per lb.

ADAM'S PEAK.

[We insert the present letter only because the writer is specially anxious to set himself right. As regards saving by machinery, we are satisfied that it amounts to 5 cents per lb., while the saving in labour is still more important, in view of the fact that by the time Ceylon grows tea in tens of millions of pounds, coolies to hand-roll the quantity would not be forthcoming.—ED.]

REPORT ON CEYLON CEARÁ RUBBER.

New Peradeniya, 29th Nov. 1883.

DEAR SIR,—The following report on a sample of Ceara rubber I sent home is from Messrs. Lewis & Peat.—Yours faithfully, H. A. GILLIAT.

Copy.

In reply to your favour of the 29th. the samples of Ceylon Ceará rubber which you hand us seem of good quality, and we estimate the value at 2s 9d to 2s 10d per lb. in quantity and of easy sale. This is based on the present high price of Para, viz., 4s per lb. for fine. Like cinchona, rubber in small odd lots does not meet fair attention and frequently has to be sold under the value of quantities. Consumption is enormous—15,000 tons a year—and no lots of less than a ton or two ought usually to be imported. But as a specimen and for a trial a few cwts. might do at first. Value is still very high.—Dear sirs, yours faithfully. LEWIS & PEAT.

A PROBLEM FOR SOLUTION IN VEGETABLE PHYSIOLOGY.

Dimbula, 1883.

DEAR SIR,—The fall of leaves results from the choking up of their tissues by continued deposits during evaporation. Being unable to perform their functions they dry up, and die, and weakened at their point of attachment, or articulation, fall off by their own weight or contracting by loss of moisture disconnect themselves and *fall*.

Here is analysis of the foregoing:—

Their full development	60	days
Their choking up by deposits	120	do
Their decay	160	do

Advent of H. V. 60 days after their full development.

Acceleration of decay by H.V. unknown.—Yours truly, J. HAWKE.

BLACKSTONE TEA.

DEAR SIR,—In the tea memo. of Messrs. Thompson brokers, published in your issue of the 24th instant, there is a manifest error as regards the prices obtained for our August crop sold on 3rd October which affects the credit of our tea.

I send you copy of account sales furnished by Messrs. Wm. Law & Co. for your own satisfaction, which please return after perusal. The tea sold as follows:—

3 chests	Bro. Pekoe	275 lb	@ 2 4½	£35 0 7
6 ,,	Pekoe	471	1 6½	36 6 1
9 ,,	Souchong	715	1 2	41 14 2
1 ,,	Dust	102	1 1	5 10 6
19		1,583		£118 11 4

The receipt by us of a cheque at the above rates affords a more tangible proof of the correctness of the above than even the copy account sales. There is no mistake about the shipment, as our September shipment did not leave the estate till the latter end of the month, and could not have been sold on 3rd October, besides the number of chests do not correspond.—Yours faithfully, FRED. BARBER, Superintendent.

COFFEE AND THE LEAF FUNGUS.

DEAR SIR,—I had hoped "An Old Coffee Stump" would have said something either for or against the possibility of the advent of leaf-disease being due to insufficiency or absence of crossing during fertilization, but regret that he has done neither, as he has disposed of the subject without even having touched on the point in question. Before it can be disposed of, facts must be elucidated concerning the following:—From whence was the seed obtained that served to plant that estate (where leaf-disease was first reported)? Did the estate or estates in which the parent trees were located give an average or lower than the average crop in the season that that seed was saved? Were the parent trees in estates surrounded by jungle or in the midst of a group of opened properties. These points would require to be decided conclusively, in a manner which could admit of no possibility of error. Further, the same questions should be applied to a generation or two back, while there are other questions that suggest themselves but are not of such importance as these.

It is to be deplored that so little is known of the actual predisposing causes which combine to induce attacks of parasitic fungi (especially on trees and shrubs). Dr. Carpenter, who was President of the Royal Microscopical Society of London, says :—"The prevalence of these blights to any considerable extent seems generally traceable to some seasonal influences unfavourable to the healthy developement of the wheat plant; but they often make their appearance in particular localities through careless cultivation, or *want of due precaution in the selection of seed.*" The converse of what I am trying to establish has been noted on several occasions, but one instance is as good as several. Mr. Knight crossed several varieties of wheat, and, in the Philosophical Transactions for 1799, page 201, he says "that in the years 1795 and 1796, when almost the whole crop of corn in the island was blighted, the varieties thus obtained, and these only, escaped in this neighbourhood though sown in several different soils and situations." This one fact in itself speaks volumes. Similarly with the potato disease, those varieties obtained through judicious crossing were generally found to escape its ravages.

My motive for publishing these ideas in your columns is not so much for the purpose of re-opening the well-worn question of "what ails our coffee trees?" as to lead to the prevention by adopting proper precautions, of a similar affection laying its powerful grasp on what will be soon our flourishing tea industry. Because the cultivation of a plant in large areas exposes it more particularly to the attacks of some disease, it is no reason why we should sit idly by, and bewail our fate when the epidemic occurs: it is our duty to endeavour to prevent by every means in our power the advent of such disease. There is nothing easier than the complete and instant destruction of laboratory specimens of a parasitic fungus by the aid of many simple chemicals, but the difficulty lies in the application and contact with success over large areas, as we have now on several occasions witnessed, and so our only course is prevention. The subject is worthy of consideration, and its thorough investigation would lead to the knowledge of much valuable information, and also to many side issues of interest and importance.

And now if you will permit me, I will answer some of the points you adduce in your editorial on this subject. The polymorphism of parasitic fungi has long been known, and displays several series of phenomena; and my remark that *Hemileia vastatrix* may have been always present must not be read as having been always an enemy to coffee, but that it possessed a host of some kind, and possibly was identical with its present form, but more probably presented a different appearance.

Next, as to grub: personally I believe that grub will devour any roots whether sound or diseased as their voracity precludes partiality; and it was acting on this belief that I used the words "let us take grub, adopting the decayed root theory." That they will eat roots that are sound and healthy, I am positive of; but that semi-decayed roots are just as alluring, I am equally positive of: indeed, where they exist in large quantities, they have little or no option in the matter.

I had considered the fact of the felling of forest having no influence to speak of with the increase or decrease of the average of rainfall so well established, that there was no need for me to dwell on the possibility of the present abnormal seasons being inferred therefrom.

Thanking you for so kindly giving me space for the publication of my ideas—but, unfortunately, justice to the subject cannot be done in a few letters to a newspaper without the risk of becoming at the same time wearisome to its readers, yours faithfully,

SWADDY.

[We quite appreciate the ability which this correspondent brings to the discussion of a very difficult subject. Granted the polymorphism of fungi in general, and of wheat rust in particular, all the naturalists agreed that *Hemileia vastatrix* was new to science and peculiar to coffee. Marshall Ward, in his elaborate reports, never once broached the idea that *Hemileia vastatrix* passed from one host to another, changing its form in the process?—ED.]

THE ALLEGED NEW FIBRE PLANT.

R. B. Garden, Peradeniya, 10th Dec. 1883.

SIR,—It may save inquiries to state for the information of your readers that the *Conocephalus niveus* mentioned in the letter from Mr. T. Christy printed in your last issue is the common little tree known to the Sinhalese as "gas-dûl," the tough fibre of which is used by them for fishing lines and similar purposes. It cannot be properly called "a variety of the China grass" to which it has very little resemblance, though both belong to the great family of nettles, figs and mulberries. The plant is more generally known as *Morocarpus* or *Debregeasia longifolia*.—Yours faithfully,

HENRY TRIMEN.

EUCALYPTUS IN SPAIN.—In a recent report from Malaga it is stated that the cultivation of the Eucalyptus has of late attracted considerable attention in the province of Malaga, which has been deprived of all but fruit trees, in order to supply the constant demand for charcoal caused by the extensive use of the fuel for cooking purposes. Large numbers of Eucalyptus in a healthy and flourishing state may now be seen along the line of railway from Malaga to Bobadilla, and in other places, and they are reported to have been effective, to some extent, in destroying fevers in the low districts, which were formerly uninhabitable. The Eucalyptus trees are also successfully used for avenues, and afford shelter from the sun on the roads near the city.—*Gardeners' Chronicle.*

NAMES OF OUR STAPLE PRODUCTS: OLD AND NEW.—Some time ago, Dr. Trimen was good enough to express himself as follows on a subject which puzzles a good many :—"*Cacao and Cocoa.*—In my use of these words, I think I have been generally guided by an impression that they refer respectively to the tree and to its commercial product. The aboriginal name of the plant in Guiana is 'cacao' (but how this may be pronounced I do not know). This native name was adopted (as in so many other cases) as the botanical one, and the spelling retained, and this must always remain, for no one is at liberty to alter what has once been duly published as a scientific name. The failure of the attempt to change the name *cinchona* into 'chinchona' shows how by common consent botanists resist such action; it is done in self-defence and to prevent botanical nomenclature becoming a chaos. It is to be regretted that the tree has not been generally called *chocolate-tree.* But the *product* is another thing. It is always and by everybody called 'cocoa,' and it would be fruitless to attempt to alter this. Therefore, it is, perhaps, a little pedantic to spell it 'cacao.' As for the coconut-palm, I think your printing rule of so spelling it practically useful. You will scarcely feel free to adopt the still more phonetic orthography employed on the wrappers of the 'sweet-stuff' sold in London shops as 'Coker-nut Rock.'" We fear it is too late now to settle the difficulty about 'cacao' and 'cocoa' by the adoption of the name 'chocolate-tree,' although in talking to strangers we find this term the readiest means of making them understand the nature of the plant; and among Ceylon planters, we fear, not one in twenty *writes* 'cacao,' while not one in a hundred *speaks* of the cultivation otherwise than 'cocoa.' Time, however, may correct this.

CEYLON PLANTERS IN FLORIDA:

ORANGE-GROWING IN THE SOUTHERN STATES.

From the letter of an ex Ceylon planter now settled on an orange-grove in Florida, we are permitted to make the following extracts of interest to our readers. We hope to learn more about the orange industry in Florida ere long.

———, Florida, 15th Oct, 1883.

Any news of the "old district" will be jolly to me. I can tell you, I think more of Ceylon than of Florida. I would give something to see it again.

You must bear in mind that the "United States" is a big place. I don't think one really realizes that until one begins to go about over here. Another thing is, it's a new country. As such, there is plenty of room for progress in every way. Also that a dollar is worth about 4s 2d. Now for what we are doing. We bought a small orange-grove about 1½ mile from the town of Ocala. Some of the trees are between 3 and 4 years old, some younger: a few are bearing oranges now, and they are almost ripe. Our grove is planted 20 ft. × by 20 ft. Some plant the trees 20 ft. × 30 ft. or 40 ft. apart as the fit seizes them. Orange cultivation is a recent thing here, and in this immediate neighbourhood most of the groves are young. As a rule, too, they mostly belong to people who follow other callings. For instance, a man is a lawyer; he has a share in a store (or shop), has an orange-grove and speculates in land. It's not a planting community I'm amongst, although there are a few who do simply go in for growing oranges; a great many men go in for growing early vegetables, too, on their groves, such as strawberries, Irish potatoes, tomatoes, cucumbers, melons, etc. The winter here is so mild that vegetables are grown here in the early part of the year, and these are shipped north. A very great deal of money is made in the south in this way. It's called truck farming. We had too much to do in getting our place into decent order to go in for anything of that sort. We may try next year. You know we only bought this place in February, and, as it had been rather neglected, there was plenty to do. We have had a house built and live on the grove. Our trees have put on a splendid growth. Trees are very scarce and dear. A bearing tree is worth $5. Then there is the cost of transplanting and keeping it watered for some time. The tree has to be cut back tremendously in moving, and of course it takes, I should think, at least two years then before it bears fruit. A sour tree has to be budded, that's to say you place a bud from a sweet tree into the stem of the sour tree—when the bud has taken properly, you cut off all above the sweet bud and only cultivate the sweet growth. This kind of tree bears fruit in about three years. Another kind of tree is the sweet seedling. That is grown from a pip of the sweet orange. This takes about eight years to come into bearing, but, when it does bear, it bears an awful lot: a tree bears up to some thousands of oranges. They seem hardy as far as I can make out. I don't mean to say that every tree will bear thousands, but they do seem to bear awfully. I know a fellow about 18 miles from here. He has under 100 acres. Last year he netted at least forty thousand dollars. Fancy that. Men who have groves in good districts in bearing are just coining money now. The American does n't mind paying if the article is good. The Florida orange is the best I've ever tasted. I don't think you could buy a good grove in bearing, for I really don't know what to say. A fellow asked me 75 thousand dollars for a grove of 20 acres with 1,200 trees on it in bearing. There is an immense speculation just now in groves. We did n't plunge, we thought it was best to go slowly. As to your question about making money, I hardly know what to say. A young fellow I knew at home came out here and lived with us, and eventually bought a quarter-share in our place. We made a little profit on that. Mind, he knew exactly what the place had cost us up to date and also what profit we made. I think undoubtedly we should be able to sell at a much greater price than we paid. We have had one or two offers, but they were not good enough. Labor is dear, a dollar a day for unskilled nigger labor. In the summer, the thermometer gets pretty high, 98 and even 100 at twelve; at two o'clock it's even hotter. We do what work we can ourselves and hire the rest. A dollar a day is rather high you know, it makes you think that the more you do yourself the better. We have been away for 7 weeks this summer. It was so hot and we had n't a cook. Fancy doing your own cooking with the thermometer at 98 in the shade. We do anything we can do on the grove. Still, labor forms a pretty good item in expences. Living is n't very dear. Eatables and whiskey. No beer! As to health, Pongo has had a little fever and chills. I have been well, although more in the sun than he of course. I've lost flesh. Our supplies we get in Ocala. We have a *mule* and cart. The mule ploughs, etc. It's not a bad life in a way. One ought to have money to start a place and then something to keep you going until you get returns either in the way of vegetables or oranges. No society, and *very few* nice neighbours. In time it may alter: Florida is getting such a great winter resort. We lived for the first nearly 5 months in a hotel in Ocala—that was before we built. Living, as I say, is cheap on the grove, but directly you go away it's dear. We are something over 1,200 miles from New York. Ten hours from here to Jacksonville and 48 hours from Jacksonville to New York: of course this is all by train. It does n't matter travelling much here, you can generally get a Pullman sleeping car. I have been about a little to different places, as, for instance, Boston, Niagara Falls, Philadelphia, Baltimore, St. Louis, Washington, New Orleans, Galveston and Austin in Texas, Norfolk, Charleston, Port Royal, Savannah, Fernandina, St. Augustine, and other places. Look those places up on the map and that will give you some idea. Just lately we have been to the White Mountains in New Hampshire. A charming spot, scenery something like the hills in Ceylon. We had a jolly time there, free from household and grove cares. A fair journey from here to there too. Travelling has cost a lot this year. However, one learns and sees. In carriage-hire (or what answers to the English cab) a dollar does not go quite as far as a shilling. The actual carriage is better, but the driver is an ass. The Irish element up North is pretty rough. The Irishman is the carriage driver, porter, etc., and a nuisance he is. The Americans are getting a little sick of the Irish. Down South, it's before the war or after the war. Apparently all the men in the South were officers. That's rather a bull: what I mean is, I have n't come across a private yet, but I have any amount of Captains, Colonels and Generals. One day in the train a passenger wanted to ask the colored porter a question. He commenced calling the nigger Captain. No response, so he worked up the grades until he got to General, then the nigger condescended to answer. These niggers earn enough in one day to loaf for the rest of the week. If you hear a colored man talking about a lady and gentleman, you know at once they were black. In speaking of white people they would say a white lady, etc. In working these niggers you have to stand over them—it's not like giving a coolie a task and giving him a name or not as the case may be. You cannot trust these fellows a bit. For a great many things I would much prefer living in Ceylon: for instance, the Ceylon planter is incomparably better than the Floridan. Living is much more comfortable there than here. Your labor is better. Of course, this is a much longer country to knock about in, but then one wants the coin to do that. I need hardly tell you its not all honey here any more than it is in Ceylon. One can hardly expect to make money when one has n't been in the country a year. Of course it would be much cheaper to get some one to look after one's grove until it come into bearing, but candidly I should n't like to trust anyone down here to do that. In this country, if you want anything done, do it yourself. We are the only Englishmen just here. I ought to tell you we have a nursery of young trees, about 800, which some day when they are a little larger we shall sell or perhaps buy some land and open another grove. Next year we shall get a little crop I hope. The trees blossom about February. About the price the fruit fetches From 100 to 130 oranges go to a box. Prices according to quality, say roughly on an average about $ 3-50-100ths a box. Transport from here to New York about 80 cents a box. Then the box itself costs about 15 cents. Mind I'm only speaking roughly from memory. Picking of course is not expensive. The older and larger your trees grow the more they shade the ground, therefore there is less weeding to do. I think 20 × 20 is close for trees, but you see it does n't cost any more to cultivate them close than it does far apart. Then you have the option later on of selling half your trees if you find they really are too close together, or making another grove with them. The soil is sandy, and it 's a marvel to me how things grow here. They do, and most luxuriantly. The timber is splendid. There is a magnolia tree just in front of our house, full 80 feet high. There is a risk to be run here, and that is frost. A severe frost would play the mischief. Well I remember ——— had a touch on ———. There is risk more or less in everything. A grove of 20 acres three years old about one mile from us was sold for 21,000 dollars. I really cannot tell you the price of groves, I can only tell you what they ask and what they sell for. You know as a planter so much depends on situation, soil, and size of trees, also uniformity of size, etc Will you send me a few cinchona seeds? I have a couple of coffee trees growing. Do you want to go in for the orange spec? I think there is money to be made in it. The Florida orange is preferred to the Mediterranean. An enormous lot of Mediterranean oranges are imported every year simply because Florida does n't grow enough. Much more fruit, I should think, is consumed here than in England. An American will have fruit before taking breakfast. Whenever they can get fruit they do.

A FEW MORE WORDS ABOUT CEARÁ.

We planters cannot afford in these dreadful times to lose any of our remaining resources. I recur to this subject of Ceará, because I am convinced that we are simply losing time by deferring to an indefinite period the tapping of our rubber trees. Recent remarks of a Haputale planter, who has tapped some of his trees for a short time, seem to confirm a very general idea, that the Cearás are not fit to be tapped until they have attained an advanced age; but, as this is not in accordance with my observations, and is, I believe, an erroneous view, I have referred to collectors of longer experience and more perseverance. Their evidence goes to show that young trees, say of 4 inches in diameter, yield, *on the whole*, a freer flow than older trees of 9 and 10, and that the quality of the milk is very nearly the same from both. My own observation indicates so much irregularity both in the flow and the quality of the milk, and the evidences fluctuate so much, that the principal lesson to be learnt therefrom is to avoid jumping to conclusions. It may, however, now be safely said that whatever our Cearás may be able to do for us they may do as effectually at 4 inches diameter as at any more advanced stage of growth. The difference, so far as is yet ascertained, is that more surface may be tapped at a time in the larger than in the small trees, and, consequently, more milk may be taken from the former than for the latter. It may possibly be that the wounds of the older tree bleed for a longer time than those of the younger, but the evidence on this point is very conflicting.

I do not profess to unfold all the secret of the art of extracting rubber from the Ceara, nor do I hope to obtain a revelation thereof by waiting with my hands in my pockets. What we want to know can only be learnt by persevering experiment: casual results are simply mis-leading.

As to curing, we have made some advance. If the milk be poured at once, as drawn into water, and if the day's mixture be allowed to stand for the night, the rubber will be found in the morning to have partially coagulated into a spongy mass of remarkable whiteness; and if this be washed, it will dry without forming the blow-holes which give such trouble in the drying of rubber that has been allowed to coagulate into a cake direct from the tree. The water in fact, removes some of the feculent matter, and is, in so far, useful, but the rubber so washed appears less strong and hard than that dried by minute division into strings. It remains to be proved whether washing, or drying in strings, will yield the best result. Both yield good rubber, if we can get enough of it.

As to collecting, the fitting of a leather lip to the collecting tin materially facilitates the collection of the milk, and is an important improvement on previous appliances made since the date of my last. Of still greater moment is the evidence, recently afforded, of the efficacy of mere pin-pricks as compared with the larger wounds made even by any improved pricker. This evidence so far as it goes seems to show that the milk may be drawn as effectually by pin-pricks as by an equal number of larger punctures! Should longer experience confirm this inference, we may extract the milk with a minimum injury to the bark, which appears to be the only injury inflicted by the operation. The rubber seems to be a mere secretion, and to take no important part in nourishing the tree.

An interesting experiment made by subjecting Ceara to great pressure, immediately after its removal from the tree, showed that the lacteals had been completely emptied in the act of removal. The only result of pressure was to extract a watery fluid without a particle of rubber in it. The lacteals appear to discharge their contents, almost instantly, on their having a vent, for a considerable distance round each puncture.

Hitherto the tapping practised under my direction, though persevering and sufficient for experimental purposes, has not been on a scale to produce the article in quantity sufficient for export, but now that minute punctures are found to be effectual and the method of collecting has been simplified, operations will be attempted on a larger scale. W.

TEA CULTIVATION AND PREPARATION IN CEYLON.

Paper on Tea by Mr. D. Mullens.

(*Read at a Meeting of the Maskeliya Planters' Association.*)

Maskeliya, 20th Dec. 1883.

Gentlemen,—I have been honored by you, through your Chairman and others, with a request that I should give you some of my experiences in tea manufacture and cultivation with special reference to Maskeliya. In response to so flattering an invitation, it behoves me to do my best, though I have but little confidence in my ability to do justice to a subject on which others more competent have spoken, and I have to ask your forbearance for the many shortcomings of which I shall doubtless be found guilty.

I shall not detain you with remarks on soil and climate, as I see but few here who are not practical planters, whom it would be presumptuous on my part to address on such points. Suffice it to say that Maskeliya appears to be specially favored in these important points. If anything is left to be desired it would, perhaps, be a trifle less rainfall. This drawback, however, (if indeed I am right in considering it such,) is one which we share with other successful tea districts. Nothing in point of soil, that I know of, can surpass the river-flats so common in this district, and on the uplands, I have seen tea growing with a vigour which must be most grateful to its proprietors. The yield of leaf, too, would appear to be satisfactory. In the case of the estate of which I have charge, the tea being planted up somewhat irregularly over a large expanse of coffee land, it is difficult to arrive at a certain estimate of the acreage, but so far as we can judge, the yield was between 200 and 250 lb. per acre on three years' old tea, which is highly satisfactory and promises very good results in the future.

My remarks will come under the following headings Planting, topping, pruning, plucking and the usual tea-house works. Most of these operations have been so fully and ably gone into by Mr. Armstrong, that I shall have but little to say about them, merely pausing when I think I can add something, or where my experience has been different from his.

Planting.—I prefer to plant up of amongst coffee without holing. And this not only for economy's sake, though in these days, that alone would be almost a sufficient reason, but because I believe it to be better in everyway. I have, I think, tried at various times, every way of planting, holing, planting with forks, and planting with alavangus, and I prefer the latter. Mr. Armstrong says of sowing at stake in coffee "loosen the soil with the ordinary fork, this is better than holing. As we are all aware, the coffee roots soon find their way into, and fill a hole in which the good surface soil has been scraped in this case to the detriment of the seed." Now this is excellent, but why not go further? What is bad for the seedling is surely bad for the young plant! I must confess to holding opinions with regard to holing which may be considered somewhat revolutionary, but which I venture to think, are not unsupported by reason. I find that when I suggest that holing may be unnecessary, and under certain conditions, even harmful, I am generally met by the answer that it may be all very well to dispense with holing in free rich soil, but what would I do in heavy soil? To which I reply that if ever holing be open to objection, it will be so in retentive soil, where water, unable to escape freely, remains in the hole, souring the good soil with which it has been filled, and causing root-rot. Those who, like me, have had to supply over and over again holed clearings in a wet district will know what I mean. As to the removal of stones, said to be one of the advantages of holing, are there no stones below the nine or twelve or more, inches to which you cut your hole? A young taproot will, I think manage to creep round a small stone, and a large one which it cannot get round, cannot be taken out of a nine or twelve inch hole. A field of coffee which was one of the last to succumb to the effects of leaf disease and bad seasons on a fine old Dolosbage estate, was a dibbled one and I know of an estate in Dimbula which is one of the most productive in the islnnd, which was dibbled also.

I now plant with allavangus. The coolydrives his allavangu well down, thoroughly breaking up the earth, and plauts as usual. Those who doubt the success of this plan, I would invite to inspect the four-year old trees on Adam's Peak and Peria Maskeliya, planted in this way.

Topping.—When young plants attain a height of five or six feet it is time to top them. I take them down at ouce to 18 inches. In this operation as in pruning, we should always have in view the object we wish to attain, *i. e.* the shape we wish the tree to take. My idea of a perfect tree is that it should have as much width as may be necessary with as little height as possible, I do not top lower than 18 inches, because by so doing, we should as a rule, take off too many laterals. I do not top higher, because I wish the plant to save its energy for extending its laterals, rather than expend it upon upward growth which will have to be cut away. The plant should not, however, be plucked regularly, as it will probably be too young to bear the removal of much leaf (the lungs of the plant,) without loss of vitality. But when it again reaches about three feet in height, further *upward* growth may be checked by the pluckers. The coolies should each have a stick cut to the height at which you wish to pluck, and they should not be allowed to touch anything below that height. At this stage plucking the side is most pernicious. The tree should be trained in this way, keeping it down and encouraging it to grow outwards and spread from the bottom, until it is three years old when it is ready for pruning and serious plucking.

Pruning.—On this important subject, there would seem to be many opinions, and somewhat of a lack of experience. Even the oldest tea in Ceylon which has been regularly worked, is still almost too young to have afforded quite sufficient opportunity for observation and experiment. But it is not with the tea as with the coffee planter, the youngest coffee planter having the accumulated experience of 40 years to refer to. And the experience of our elder brethren in India would appear to be not always to the point. The conditions of climate and soil are very different, and several imported styles of pruning have, to my knowledge, been tried and found wanting. For my own part, though I have now been some six years tea planting. I don't consider (since one only prunes once a year,) that I have yet had sufficient experience to pronounce *ex cathedra* opinions on pruning I think it best, therefore, as I am addressing practical planters, merely to offer suggestions and to point out, as well as I can, what appear to me to be the objects to be attained, leaving it to your practical experience to decide upon the best means to adopt.

It has lately been said that trees should be allowed to grow to 3 feet 6 and 4 feet, (with a minimum of 2 feet 6), the object of allowing them to grow to this excessive height, being I understand, to secure a large and flat picking surface, on the necessity of which much stress is laid. But it seems, I think, to be forgotten that the picking surface of each tree is necessarily limited by the distance from each other at which the bushes have been planted. Taking 4 feet by 4 feet as the usual planting distance, it follows that 2 feet from the centre of the bush is all that is required, since you can but cover the ground. And I think you will find no difficulty in Maskeliya *at least*, in doing this at a much lower height than 3 feet 9 or 4 feet. I can speak from experience of the bad effects of too high pruning—this being an error into which in former days I have myself fallen. The result of it is, that nearly all the young brown wood from which flushes are obtained, appears on the upper part of the bush the wood on the lower part having hardened as the tree grew upwards. There is thus a comparatively bare space from the point at what the branches diverge from the stem, to the foliage on the upper part of the tree. When you have attained (in 5 years from the first pruning or 8 years of age, which is Mr. Armstrong's limit, if I understand him aright) the extreme height to which you can allow your bush to grow and cut down to 2 feet 6 again, I fear you will find no brown wood *below* the knife, and the next year will have to be devoted to its formation, to the great detriment of the yield for that season. It seems to me that our effort should be directed to form a system, by which so much old white wood should be each year removed, (keeping the tree if possible, to a maximum height of say 2 feet 6 or so) as would allow of the growth of sufficient red wood in its place to carry on the flushes, without subjecting the tree to the severe shock entailed by cutting down from 4 feet to 2 feet six. This is the problem I submit to you for solution. It would have been solved for us had the late Mr. Cameron lived longer, I believe—I did not know Mr. Cameron personally but he told a friend of mine upon whose correctness I can confidently rely, and whom he was advising to cut down to 20 inches some trees which I had allowed in former days to grow too high, "that this measure was necessary to again get the trees into proper "form—this once done, so severe a pruning should never "again be necessary." I have spoken to many of Mr. Cameron's pupils and believe that such was generally tho tenor of his remarks upon this subject. "The system" which has been criticised with such severity and even violence, was never more than commenced, and to censure it as one of "severe cutting down," "hacking" &c., has been rashly done, appears to me to be something like condemning the music of an opera on hearing the tuning of the violins!

And it appears to me a debateable question which is the "*severe*" system! I am inclined to think it too high pruning system may be entitled to the designation for the cutting of a foot to 18 inches off a large bush entails the removal of a great quantity of heavy wood. This is waste, for it cost the tree and the soil much to produce this wood. The aim of a system perfected on the lines I have endeavoured to indicate, would be avoid this waste as much as possible.

Plucking.—With regard to plucking, there are various systems. I will call the bud or tip No. 1, and the rest in succession, 2, 3 and 4. I pluck with one motion of the fingers 1, 2 and three-quarters of No. 3, leaving the leafbud at the base of the latter, and with another motion of the hand I take ¾ of No. 4, providing it be in a suitable condition (*i.e.* not "bangy" or hard) and leaving its leaf-bud also. This leaves two leaf-buds to carry on the flushes. Plucking in this manner I am well content if I can average 15 lb. leaf per cooly. By taking more stalk and coarser leaf you can get more per cooly. You will also probably get a lower price for your tea. It must be borne in mind that save the cost of plucking, every expense is the same on a pound of sixpenny, as on a pound of two and sixpenny tea. In this district, as in Ambagamuwa, I find the pickings come on in average weather, in a period varying from 10 to 14 days, say 12 on the average. I have had here a heavy plucking in 8 days, but that was an exceptional flush, which is a different thing from an ordinary picking and does not, in my experience, occur more than twice or so, in a season. The sides of the bushes should not be touched until, at all events, the shoots are well above the height at which you mean to prune. Young trees should never have their sides plucked at all. Every shoot may be plucked that is large enough to deal with as described above. Picking thus, with two leaf buds left on the shoot, I do n't see how there can be any *over-plucking.* My standing orders are to pluck round in ten days, but the rounds are lengthened or shortened according to circumstances. About 2½ rounds in the month is perhaps the usual thing. I cannot recommend cooty-sacks for picking leaf. Every picker should have two baskets, a large and a small one, and the contents of the latter should be frequently emptied into the former, the leaf being well stirred up with the hand, to prevent adhesion and heating. Heated green leaf gives red leaf in the tea.

Withering.—Wither leaf well, underwithered leaf makes the worst possible tea. It is well to arrange the tea house in such a manner, as to have withering space in various temperatures, so that in wet weather the withering may be hastened and in very hot weather retarded. It is useless to endeavour to describe well-withered leaf. It must be seen.

Rolling.—Roll hard. You can't hurt well-withered leaf by hard rolling, and the strength of the liquor and twist of the leaf are, I believe, improved by it. I have noticed several rolling tables in this district which are too high. The height most suitable to ordinary sized coolies is 2 feet 6 inches from the ground to the top of the table. A cooly cannot exert his strength to break the leaf cells and force the juice out of the leaf, if the table is too high. The coolies should be very careful to pick out all hard leaf which will not take twist. If this is neglected there will be much open and red leaf in the made tea. I always ball the roll, as I think there is little doubt the leaf keeps twist better. Very many good tea makers do not however think it necessary. A cooly rolls 40lb. leaf, which he should finish in a good withering day by 2 o'clock. A man can, therefore, roll more, but to give him a longer task would probably necessitate night work, which is to be avoided as much as possible.

Fermenting.—Maskeliya tea has a very pleasant sweet flavor with moderate strength, and a bright outturn. I find that these characteristics are best preserved by fermenting rather lightly than otherwise. The first shipment I sent from here, did not fetch such good prices as the succeeding breaks, and I attribute this in a great measure to my having been too anxious to secure a full coloured outturn, and having consequently fermented a little more than was suitable to the tea. Fermentation here with the tea-house temperature at from 80° to 90° takes generally from 1½ to 3 hours, though I have known it come on in half-an-hour. I seldom allow over 3½ hours, but would rather fire it somewhat green than wait longer. Like withering, it is not easy to describe what constitutes good fermentation. Books are very misleading on this point, it being so difficult to give in words a proper idea of a shade of colour.

Sorting.—I never pick out red leaf except in very bad weather. If the pluckers and rollers have done their duty properly, there should be no more red leaf in the tea than the sorters can pick out. Small pieces of red leaf go out with the fannings. For this, as for all tea-house works except perhaps fanning, I prefer men to women. There is no rule for the employment of any particular sieves, the class and make of the tea must determine this. For fine teas, some planters use 14, 10 and 8 or 7; some use 12, 10 and 7; and some 12, 8 and 6, &c. Mr. Armstrong has gone into this matter so fully that I need not detain you. The main points are:—

1. Not to make too many qualities.
2. Not to let the fine qualities broken pekoe and pekoe slip into the lower grades.
3. Not to pass the tea too often through the sieves and thus destroy the bloom.
4. Not to make much dust.

Sorting should be done as soon after making the tea as possible. If the tea has been kept some time, that which has to be broken through a sieve, should be gently warmed to make it brittle and thus avoid much rubbing on the sieve. The percentage of each grade should be carefully watched. Something is going wrong when the tea ceases to turn out its usual percentage of each grade. My outturn last season was as follows:—Broken pekoe 25 per cent; pekoe 40 per cent; pekoe souchong 19; fannings and dust 14; broken mixed 2

Firing.—I do not use gratings in my chulas. I think they make the draught uneven, and consequently one side of the fire burns much quicker than the other, and burning of the tea is apt to ensue. I allow firing coolies 40 minutes to each tray, they often do it in less time, but seldom take longer. The quicker tea is fired the better, therefore the trays should not be covered more than ½ inch deep with roll.

Packing.—I recommend packing, like sorting, to be done as soon as possible: in fact, pack everyday if possible. This of course precludes bulking, but bulking is not advisable unless tea is made in very large quantities, for this reason, that to make up a sufficiently large break, you would have to keep the tea open longer than is at all good for it. I do not think tea should be strongly fired before packing. It only requires to be thoroughly warmed so that there may be no moisture remaining.

The cost of all works connected with tea cultivation and manufacture has been so fully and repeatedly gone into, in essays, and in articles and correspondence in the public papers, that I can find nothing to say which has not been said. Mr. Armstrong gives four estimates for tea, f. o. b. I shall recommend the Maskeliya planter to accept that which gives 400 lb. per acre at 40 cents as the safest. Account sale charges, including freight, should not exceed 10 °/₀ on the gross return, and an average gross price of 1s 3d per lb. is at present a more than safe estimate. My average for last year was 1s 5d, and I learn from Mincing Lane correspondents that Ceylon tea is in "growing favor." I am sure you will agree with me that these figures show a very reasonable margin of profit; and I think we may look for improvement in the future, unless the price of tea falls very materially. For it seems to all that tea in Ceylon improves with age, both in quantity and quality, at all events up to a certain point. Mr. Armstrong's account of Rockwood yield shows a steady increase, and as to quality I feel sure I may venture to assert that our two oldest estates, Rockwood and Loolcondera, are now turning out finer teas than at any previous time.

I also hold a theory, that in some places, if not everywhere, the soil and climate of Ceylon are so favourable to the growth of tea, that the hard leaf of comparatively low class hybrids becomes softer and resembles that of high class bushes. The following instance is to the point. Some months ago, I was walking past some tea bushes which had been allowed to grow up for seedbearing. My attention was drawn to a tree which appeared to have so small a leaf that I wondered how it came to escape being cut down as not good enough for seed. To my surprize, however, I discovered that on a sucker, it displayed leaves almost large enough for an indigenous plant. I plucked a sample of each class of leaf and took them home. That morning a Visiting Agent and a tea planter came to my bungalow. The one gentleman said the smaller leaf was not tea at all (so poor looking it was) and the other admitted it was tea, but said he would buy no seed off such a plant, but would willingly purchase seed off the other variety! Yet both leaves were from the same tree, which I believed was developing a larger leaf under the influence of rich soil and suitable climate. I have some plants from an estate which is not remarkable for the high class jat of its bushes, which plants are certainly better than their parents. So that "taking one consideration with another," I cannot say I think much importance need be attached to the outcry lately raised against planting from good Ceylon seed.

Before finally quitting the subject of tea manufacture, I would point out the fallacy of an apparently very common opinion that there are many secrets in the art. Some practical experience is necessary in this as in almost everything, and the advice of an experienced man is at first advisable in order that the tyro may learn when such operation is properly completed lest his leaf should be under or over withered, under or over fermented, &c., &c. These necessary matters being learnt, there remains only one great secret, and that is *care*. Each of the several operations must be perfect or the best tea will not be made. Thus, though the leaf were carefully plucked, and well withered and rolled, all might be spoilt if the fermentation were bad. The art of making good tea may be compared to a chain—the value of which depends upon the perfection of each separate link. And now, gentlemen, while offering you my best wishes for the approaching new year, let me add my congratulations on the improved prospects which apparently lie before you. We cannot perhaps expect that the profits of tea cultivation, will equal those of the best days of coffee, for I believe there are but few agricultural products so remunerative as that was, and in some instances still is. But the R100 or R120 per acre of profit which tea offers is surely not to be despised, and the probability of permanency appears to be all in favor of tea, for it must surely be less exhausting to tree and soil to produce a leaf crop than a seed crop, especially in a climate so well supplied with moisture. And though it is not within the prescribed limits of this paper to discuss coffee, yet as an old coffee planter, I trust I may be pardoned for remarking on the improved appearance of good coffee in Maskeliya this year. So that with the good coffee that yet remains to you, perhaps coming to the front again, and that which is gone planted up with vigorous tea fetching high prices, I think we may not be accused of being over-sanguine if we venture to hope that the dark cloud which has so long hung over as, if not yet dispelled, is slowly but not less surely lifting, and giving glimpses of its silver lining, ere it passes away to return no more.

It only remains for me now, gentlemen, to thank you for the compliment you have paid me in asking me to address you—and for the patient courtesy with which you have listened to my humble efforts.

"HAND GUIDE TO THE ROYAL BOTANIC GARDENS, PERADENIYA, CEYLON."

To Dr. Trimen we are indepted for a copy of the neat and useful Guide which he has been prepared for visitors to the beautiful Gardens over which he presides: it is illustrated by a lithographed plan, reference to which shows how almost surrounded by the folds of the python-like Mahaweliganga the gardens are. Deferring a more extended notice, we make a couple of extracts to show the calibre of the Guide :—

A Botanic Garden in the tropics is somewhat bewildering to those accustomed to the neatness, order, and regularity of such establishments in temperate countries. The plants to be grown are mainly trees and shrubs suitable to the climate, and planted in the open ; we cannot, as at home, produce artificially the conditions necessary for species of other climes by specially-regulated houses where the different sorts can be classified, neatly ticketed and arranged for easy examination. Here nature asserts herself, almost uncontrolled ; she gives us grandeur of form, wealth of foliage, exuberance of growth, and splendour of colour—unfading beauties, but of a quite different end from those of the sweet summer flower gardenkir the well-kept stoves and greenhouses of England.

The route given can be followed almost throughout by carriages. It is of course not intended that it, or any other particular course should be necessarily taken ; but in a single visit of limited duration it is the best that can be followed But to really see the Garden, enjoy its beauty and variety, and investigate its treasures, the visitor should leave his carriage and explore the narrower roads and paths on foot.

The Gardens contain considerably over 2,000 species, mainly trees and shrubs. A few only are noted in this hand-guide, being such as are especially remarkable for utility, beauty, rarity, singularity, or associations, and are in accessible situations. A provisional Catalogue can be obtained in the Gardens, and a complete one is in preparation.

The Royal Botanic Gardens at Peradeniya were established in 1821, six years after the final occupation of the Kandyan Kingdom by the English. The site is less than four miles from Kandy on the Colombo road, and occupies a loop of the river Mahaweli, which surrounds it on all sides except the south, where it is bounded by the high road. The area, nearly 150 acres in extent, is beautifully undulated, its average elevation above sea-level being about 1,540 feet. The climate is hot, moist, and very equable; the mean annual temperature is about 77° F., April and May being the hottest and December the coldest months. Rain falls on about 200 days in the year, the annual rainfall being about 85 inches ; it is pretty evenly spread though the year, but is heaviest in October and November and in June, at the full establishment of the N. E. and S. W. monsoon, respectively. February and March are the dryest months, but even then there are showers at no distant intervals.

Before its occupation as a Botanic Garden the greater part of the land had been a royal demesne occasionally occupied as a residence by the Kings of Kandy. The earth-mound and ditch along the south boundary are still evident, and remains of stone buildings have been found. The name *Péra*=guava, and *deniya*=an enclosed place—indicates its use as a fruit garden of which the existence of some very old mango trees is further evidence. On another part of the site stood a small temple or flower shrine and priest's house abandoned, however, before the formation of the Garden. * * * *

The Director has also under his charge, as adjuncts to the Peradeniya Gardens, smaller branch establishments in different climatic districts of Ceylon.

Hakgala Gardens are situated at an elevation of 5,500, feet about six miles to the East of Nuwara Eliya on the road to Badulla. They were opened in 1860 as a Cinchona nursery. The climate admits of the cultivation there of numerous European and Australian plants, and those of the tropical mountain regions

Henaratgoda Garden is a completely tropical one, scarcely above sea level, and in a wet steaming climate which varies little. It is about three-quarters of a mile from the Railway Station of the same name on the Colombo-Kandy Railway. Many of the plants grown at Peradeniya flourish there with far greater luxuriance, and others can be cultivated there only. It was opened in 1876.

Anuradhapura Garden.—This is in process of formation at the ancient capital of Ceylon, 90 miles north of Kandy (74 from Matale), in a district which possesses a hot dry climate with a short rainy season, like the Carnatic or Coromandel Coast. Here such plants and crops as are intolerant of continuous and excessive moisture can be cultivated.

VALUE OF CACAO PROPERTY.—One of our merchants, Mr. George Fitt (already a successful cacao planter, owning an old cacao property in Chaguanc, purchased by him some years ago of the Colonial Company for $12,000, for which today he would not take $100,000), has just become the owner, by purchase, of a couple of adjoining cacao estates in Montserrat, one Tutelar and Esperanza, at present yielding about 150, and the other El Salvador about 300 bags per annum. Being young estates, and situate in a growing quarter, they only want ordinary care with barracks for more labourers and some loose capital, to develop into a more valuable property. For the former Mr. Fitt has paid $20,000 and for the latter $43,200 (£9,000). On the former we understand there are about 18 to 19,000 trees (young, and in bearing) and on the latter about 55,000. The first measures 91 acres, of which about 70 are in cultivation, and some acres under contract to plant cocoa, and the second 195a., of which 180a. are cultivated. When the trees are all bearing, they will give 600 bags a year. The trees are usually 12 feet apart. We are informed that the cacao trees on the *Maracas Bay* estate average 3 lb. a tree, about double the mean of other estates taken together. The soil is a rich black humus. Upwards of 200 large pods were lately counted on one tree, but some of these may drop or wither before maturity. They seemed to be more than the tree could have the force to mature. It is reported of a fortunate cacao planter of one of the northern districts, who had the luck not many years ago, to invest in a large, old and backward property abounding in rich black soil, that after deducting the losses caused by the hurricane of September 1st 1878, he cleared the sum of two thousand pounds sterling from the operations of last crop.—*Trinidad Chronicle.*

Correspondence.

To the Editor of the Ceylon Observer.

RHEA FIBRE: M. FAVIER'S PROCESS.

Ragalla, Udapussellawa, 9th Dec. 1883.

Sir,—In your articles on Fibres (page 456), it is said that M. Favier's process is applied to green rhea, and that a boiling process which involves the use of much fuel is carried out.

In December last M. Favier showed me his machine at Avignon, most carefully encased in deal boards to conceal its working; but he showed to me the dry chips which fall from the machine, and told me that the sticks had to be thoroughly dry. With these chips and refuse the small one-horse or half-horse-power engine is fed, and they are more than sufficient to feed it, the sticks containing about 20 °/ₒ fibre and 80 °/ₒ refuse: so that I fancy the process quoted as M. Favier's is some former one, not that now in use under a patent.

M. Favier, in reply to some questions, stated that he would not sell any machine, but that he would sell the use of it or the use of the patent in any country, and would, if a Ceylon company or syndicate came to him, be open to terms and would state so many shares to represent the value of the patented machine—but he refused to go into any particulars off-hand. In fact, M Favier would wish to have shares in every case in which his invention may be used, which at least shows strong confidence in its value.

M. d' Hunières, who was Managing Director of the San Remo Luano Co. which bought the use of the machine in Italy, was found to be using the money of the Company for his own affairs, and has been put in prison. He had been "wanted" by the French police for some time. So that I fear that the story of plantations in Java was false, but I believe the Company is not much affected by his misdeeds.

The samples now at your office are from samples worked up from M. Favier's dry process.

The Sinhalese name for *Urtica verrugosa* (Trimen) is *Gambatu*, not "Gambake," according to a Kalutara man.—Yours faithfully,

COST OF TEA: HAND-MADE AND BY MACHINE.

Oonoonagalla, Madulkele, 12th Dec. 1883.

Dear Sir,—Your correspondent "Adam's Peak" having at last given his reasons for calling in question the accuracy of my statements, I trust you will allow me the right of final reply.

In page 18 of Mr. Armstrong's paper is a calculation, *now* quoted by your correspondent, in which is a palpable clerical error. This calculation was never referred to nor quoted by me, the correct figures being those on page 15, for the quotation of which alone I accept the responsibility. These figures give "withering, rolling, and firing," at 6½ cents, and the attempt in the part of your corrrespondent to prove them wrong by assuming the correctness of the other figures, where the error really lies, does justice to his ingenuity, but, surely, assumes a great lack of commonsense on the part of your readers.

In support of my statement that Mr. Armstrong's figures, as *quoted by me*, are correct, I would refer you to Mr. Hay's statement (*T. A.* page 385) where he endorses them, and even raises the amount in question to 7 cents on the authority of Mr. Hughes of Gallebodde. The point, therefore, is, do you and your readers place greater faith in the published results of Messrs. Armstrong, Hay and Hughes, all of which agree closely, or in those of your anonymous correspondent, whose only claim to authority (while he preserves his anonymity) is his *ipse dixit* in the second paragraph of his last letter: "I did so [accused Mr. Owen of ludicrous inaccuracy] because *I knew* the cost of various operations referred to" (the italics are mine)?

Apart from the clerical error in page 18 of Mr. Armstrong's paper, which, as I have shown, is entirely beside the question as far as I am concerned, and which I have no doubt that gentleman will correct, "Adam's Peak" 's whole arugment falls to the ground, and his charge of "ridiculous inaccuracy" as applied to me recoils on himself unless he still maintains the somewhat untenable position that every writer on the subject but himself is in error.

Apart from this unfortunate subject, I hardly think sufficient stress is laid on the many other ways in which machinery will, in the future, effect a saving over hand-work. A factory fitted with all appliances is of much smaller size than one for hand-work, and, hence, some portion of the outlay in machinery is recouped at the outset. Then it must be remembered that almost double the labour force would be required on a garden not fitted with machinery; and this would mean extra line room, with numerous other petty expenses and a largely increased item for supervision; the providing of work for a double labour force in slack seasons, and the annoying consciousness that the heavier the plucking, the smaller the proportion of hands that can be spared to bring the leaf in; extra kangani's pay in consequence of the necessity for a large labour force with proportionately small weeding contracts, and various other similar items which will occur to one. I think the question is more accurately stated in this way:—"What extra amount will hand-manufacture cost?" That it would be adequately represented by less than 7 cents (with water-power and every appliance in saving labour, where all the various considerations are taken into question,) I do not believe, but to tabulate correctly the numerous *indirect* savings would be impracticable. These remarks do not of course apply to the lowcountry, where labour is cheaper, and water-power the exception.—Yours faithfully, T. C. OWEN.

[Of course, cost of machinery, interest, and tear and wear must be taken into account, but we do not suppose any human being doubts the vast advantages of good machinery.—Ed.]

DR. TRIMEN ON *C. LEDGERIANA*.

R. B. Garden, Peradeniya, 22nd Dec. 1883.

Sir,—One has often cause, here in Ceylon, to regret the distance in space and time which separate us from home, but never more so than when it leaves us so long in ignorance of the death of our friends. When you did me the favour of publishing in your columns of 26th November my reply to Mr. Howard's papers on *Cinchona Ledgeriana*, the veteran quinologist had already passed away. Death closes all controversies, and my remarks must remain unanswered. Most men however have done their work at the age to which Mr. Howard had attained, and in his case there can be no doubt as to the permanent value of his long-continued and persevering labours. I also wish to record my sense of the ready promptitude with which he was always ready to make his great knowledge and experience of use to both individuals, and the public. This aid in this way, will indeed be much missed in the east.

I write now, however, to set right a little irregularity incident to this sad event. I timed sending my paper to you so that it might appear simultaneously in the *Ceylon Observer* here, and the *Pharmaceutical Journal* at home—as was explained in the prefatory letter printed with it—and but for the sad occurrence we deplore this would have been the case. My MS.

reached the Editor of the *Pharmaceutical Journal* on the 21st November, the very next day Mr. Howard's death occurred, and Dr. Paul, thinking that under the circumstances I might perhaps wish to revise the paper, has now kindly given me the opportunity of doing so.

I have, however, no desire to make any alteration. Even if there be anything which might be now preferably rewritten, the fact of the paper being already published in your columns, as communicated to the *Pharmaceutical Journal*, would be a literary objection of an insuperable kind. As it is however not likely that my article can appear in the periodical to which it was first addressed in less than a month's time, I have thought it desirable to give this explanation.—I am, sir, yours faithfully, HENRY TRIMEN.

KERR'S PATENT TEA-ROLLER.

DEAR SIR,—I have much pleasure in confirming what you say about Mr. Kerr's tea-roller, having seen it work, with the result it gives. It is just the thing for small tea estates, doing its rolling well and requiring very little power, while its cost will, I believe, be very reasonable. You do not say what is the amount of leaf it will roll per hour, but I believe a moderate-sized machine worked by two coolies can work off over a hundred pounds weight of green leaf per hour. The double machine, involving only a proportionately small extra cost and driving power, will probably become the favourite. As deeds are better than words, I may add I have ordered two machines. TEA PROPRIETOR.

NEW PRODUCTS, FIBRES, &c.

DEAR SIR,—When the successful cultivation of such staple products as coffee is becoming doubtful, owing to the ravages of leaf-disease from some kind of grub infesting them, which will eventually alike infest cinchona, tea, and other products, unless the cause which produces them is removed, which cause must be found from circumstances far remote from those that are supposed, to attempt to cure leaf-disease without removing the cause is like attempting to cure a patient with a bad stomach with a rotten carcase by his side; the remedy is extremely simple and feasible, scarcely involving even increased expenditure. It would be interesting to know whether the disease affects native plantations also, such plantations, I mean, as are found about the dwelling premises of the Kandyan villages: I cannot remember of any complaint being made of their trees being affected, and I have never observed, during my visits to the villages, of the existence of sickly trees, which, on the contrary, appear to be richly nourished, only by the soil afforded by the decayed vegetables round the trees, in some places heaped up to a foot or so in height. For the present the remedy must remain a secret.

With regard to new products and industries, I believe fibres appear to be pre-eminent. The natives obtain some very fine bark from trees in the jungles with which they tie their fences: the fibres of these trees must be very strong. I am sorry I did not try to find out what fibre or bark it is. In the exhaustive report about fibres in the supplement of the *Observer* of 5th inst., which I got by chance, nothing is mentioned about the fibres obtainable from the suriya tree (*Thespasia populnea*) and from the allied species *Althæa malvaceæ*, marshmallow, *Hibiscus esculenta*, the common bandakai. The fibres of the American aloes, pine, and varieties of the *Bombax* or *Gossypium*, also allied to the *Hibiscus* family, appear to be the most favoured; yet those of the *Hibiscus* species are deserving of trial. In the Lunatic Asylum at Colombo sometime ago, Dr. Wambeek used to get fibres made, as a healthy occupation to the insane, from aloe and pineapple leaves. These were steeped in water, beaten with a mallet, then washed and beaten again; when the pulpy part was removed, the fibres were removed by fingers, used as the teeth of a comb: indeed the wooden combs that are sold in the markets for the use of the poorer classes of people may be well used, being less liable to break or to bend; perhaps metal ones also can be used. A report of the industrial operations, including arrowroot making, appeared as a leader in the "Examiner" about the middle of 1860, which is worth perusal. The fibres of the mudar, *Calotropis gigantea*, are largely used by the fishers, for making twine for their nets. The trees and plants are cut and dried in the sun, then the fibres are peeled off and twisted into twine. All the plants that I have mentioned above seem to thrive in any locality regardless of climate and soil; require no effort in cultivating, but a saline atmosphere and saline soil are preferable to the varieties of the aloes, whilst the pineapple, I believe, grows on rocky soil. The bandakai (*Hibiscus esculenta*) is generally cultivated; but a wild specimen of this as well as the roseola (*Hibiscus acidulata*) commonly called the. Footprint, with fleshy red or pink calyx are found wild and in a creeping state in the jungles on the Badulla road from Batticaloa. The mudar plant, again thrives well on sea-and, and the advance of seas, and which form into hills in Hambantota is to a great extent arrested by the growth of these plants; the flowers are eaten by goats there.—I am, yours truly. SILEX.

THE LEAF-FUNGUS.

DEAR SIR,—I have just read "Swaddy"'s last letter, and will endeavour to answer his several questions, so far as they are capable of being answered. But before doing so, I should like to say that, neither at the time of the appearance of the leaf-fungus, nor since, have I been able even to suspect the source whence it originated. From time to time I have combatted the many ramdom guesses that have been hazarded as to its origin, nearly everyone of which I knew, from the real circumstances of the case, to be untenable. It appeared suddenly and mysteriously on the Madulsima range, which was, then, the outermost eastern zone of the coffee region, all beyond being undulating lowcountry to the sea. That it had already an existence on some other plant flourishing only in that district, I did, indeed, suggest some years ago; but I did not suspect that it was Buddhistical in its nature, having afflicted the vegetable kingdom since creation, under endless forms. Doubtless, in common with every other vital organism, it has been evolved from some simpler primordial element; but "polymorphism" somewhat disturbs this theory, and is like a great "fault" in the vein of that science. Polymorphism, once established as a fact, would, indeed, offer a possible solution of the mystery; but to establish that hypothesis, it would be necessary to discover one or more of its co-existing forms, and be able to transfer it, experimentally, from its shape on, or in, the one host—be that vegetable or animal—to its fungoid condition on the coffee leaf. The tapeworm has a polymorphous existence, so has the butterfly and a hundred other insects; but as I understand "Swaddy," the polymorphism of the leaf-fungus is something quite distinct from the familiar and necessary metamorphic stages in the life-history of these beings, that, in fact, it may and does change its being, and with each new host becomes a new creation able to propogate itself without returning to its original form. This is interesting and worthy of some further examination. In the meantime, I express no opinion upon it. I will now answer "Swaddy"'s questions.

1. I was silent on the subject of *insufficiency or absence of crossing during fertilization*, because, as I

believe all the coffee in Ceylon comes from one stock. I do not know with what other stock it could be crossed. In this respect, its fertilization, or source, was the same as all the young coffee plants or seeds which were being planted, *the same year*, on the many clearings all over the country. Unless, indeed, in a few exceptional cases (so late as that year) seed from very old coffee might be said to be only two degrees removed from the first importation, instead of as was generally the case everywhere many generations removed!

2. Question 1st.—*From whence was the seed obtained that served to plant that estate (where leaf-disease has first reported)?* First, as to my qualification to answer these questions: I opened and planted these estates myself. I procured stumps (and stumps only with one exception to be presently noticed) from every possible quarter. No nurseries existed that first year, and no seed was used at all. Previous to that year, extension round about Badulla was limited and slow, jungle plants plentiful and nurseries almost unknown. The land was felled at once after it was bought, and there was a scramble for plants. I, as well as my few neighbours, scoured the villages all round for miles; and, so far as I can remember, these plants *only* were used, except a few I collected from the Spring Valley forest, and some others above referred to. The Sinhalese brought them up in bundles already stumped (so that their leaves were not observed) and were paid cash on delivery. Notwithstanding this, the coffee on "Doomoo" and "Galloola," apart from leaf-disease, and in spite of leaf-disease, turned out equal to any in the country. Whence the coffee trees in these many villages came and what was *their* condition *when* the seed dropped from them which produced these stumps, this deponent knoweth not—nor does any other man.

But it so happens that one circumstance, pertinent to this enquiry, I do know and remember. So greatly was I driven for plants, that I fell back upon quite young seedlings from under the trees on a small estate of my own, in the Laggaloya valley, at the foot of the Madulsima range, which estate, *that year*, bore considerably over 10 cwt. per acre! And finer or healthier young coffee never was seen. These small seedlings I planted on Galloola between the river and O'Brien's gap, the very part upon which Mr. Donald Reid first discovered the fungus, and where very soon after (for I was at home at that time) I saw boys and girls trying to check its spread by picking them off to be burnt. At that time the parent trees had no disease upon them. Now, whencesoever the plants were obtained, the leaf-disease did not appear upon them until the third year of their age, when they were large trees: they were planted in virgin forest soil; had never been manured *at all*; had been always kept quite free from weeds; were (as I have said before, but repeat here to make this account an exhaustive one) in detached clearings with forest, in a detached district, full of bees *at the time* and for some years after. And here, perhaps, the editor will permit me to digress, just to say that I noticed his exclamation of surprise on my making this assertion on a previous occasion and to explain that on and off I resided on Doomoo from 1869 (the year of its discovery) till 1873 when I left for good.

I have little more to add. "Swaddy" will find his other questions included in the above answer. The subject is important as affecting the possible appearance of some such fungoid growth on our tea trees, but I do not think we are any nearer to a solution of the mystery. The selection of seed for annuals (such as wheat) *must* be of high importance, as any imperfection in it is shown at once in the germ and plant it produces; and for perennials it should not be neglected. But, surely, if a seed produces a healthy tree, vigorous and prolific for years, not much fault can be found with it.

Every effect has a cause, but the origin of leaf-disease has yet to be discovered: so has its remedy and cure. But looking round me now, after ten years absence from the country, knowing what the leaf-disease was in its earliest years and seeing what it is now in its dotage, I cannot help coming to the conclusion that weakly old coffee in old districts owes its present condition far more to cinchona and *grub* than to leaf-desease, *unless* its present rootless condition is also a consequence of the fungus, in which case Mr. Grub is a very much abused gentleman. Insufficiency of roots and not of foliage (otherwise than as an effect) is what ails our coffee trees at present.—Yours truly,

A O. C. S.

RHEA FIBRE: M. FAVIER'S PROCESS.—We call attention to the interesting letter from Mr. Kay-Shuttleworth on this subject, which will be found on page 486. Our correspondent will be interested to learn that Dr. Forbes Watson and Mr. R. Collyer—than whom not two men living have given greater attention for a very long period to the question of utilizing rhea fibre—after being present in Paris at a series of demonstrations of the value of the Favier as well as the Frémy process, returned to England highly satisfied with the result. But they were then induced to attend trials of the Death & Elwood's machine with rhea, and the result according to Mr. Thomas Christy and the *Planters' Gazette* is that both these authorities agree that from the English machine we have as good results as from the Favier process, if not the Favier Frémy process combined. We await the confirmation of this report from Messrs. Watson and Collyer, for, if the £5,000 offered by the Indian Government is to be claimed, their report must soon appear. Meantime, nothing can be more satisfactory than the samples left at our office of M. Favier's work, referred to by Mr. Kay-Shuttleworth. The manager of a large planting company in Southern India writes to enquire if we can supply Dr. Forbes Watson's report on the cultivation of rhea. This was published at Allahabad many years ago, but we have come across a copy from which we are taking all that is of practical value for republication in the *Tropical Agriculturist*. In a previous letter lying by us since November 19th, Mr. Kay Shuttleworth wrote:—"But since I last wrote to you about the *local kind*, I have seen it growing in every part of the hill-country that I have visited, from above 6,000 down to Polgahawella. Enclosed is a rough specimen of the local fibre which you will find very similar to the sample given me by M. Favier. The names of the local kind are *Urtica verrucosa* and *Morocarpus* (*Debregeasia*) *longifolia*. The Sinhalese call it 'gam batu,' and the Tamils use it for fishing in Tanjore, &c., but I forget what they call it. That it grows throughout the hill-country here, and in the plains of India, and that other varieties grow in the Dehra Doon in India, and that the French and Italians are cultivating it in their warmer valleys is certain, but how will it pay us commercially, or as a planter's crop? If it pays in Italy and France, as M. Favier thinks it does, for he has shares in such plantations, surely it may be expected to pay in a country where it is indigenous, if we have the proper appliances, &c. But where in these days is the money, or the faith in Ceylon that would bring money for even a certainty? For such tried things as tea and cocoa and Uva coffee and cinchona it is hardly to be got, so I fear that any one of the hundred and one other tropical things must wait a bit."

GUM FROM THE GRASS TREE.

TO THE EDITOR OF THE "AUSTRALASIAN."

SIR,—You will oblige your readers in this district if you could give any information as to the gathering the gum from the grass tree, the time for gathering, the process of separating it from the roots, &c.—it seems to be found about the roots and fibrous matter, and difficult to separate—and any other information that would be useful. Enclosed is a paragraph which has incited us to ask for information.—DROMANA.

[The material portion of the clipping is as follows:—"The *Braidwood Despatch* hears that between Milton and Moruya there are no less than 200 men now employed gathering grass-tree gum, which is in great demand in the English market, where it is at present fetching £80 per ton. The men thus employed are reported to be earning as much as £1 per day. They take out a timber licence, and can go anywhere on Crown land. The pursuit is so profitable that the free selectors have great trouble in keeping off trespassers from their lands."]

WOOD AND TREES.

SIR,—I address with all deference such a well-known authority on trees in Assam as Mr. Sam Peal, but what he says in your issue of 22nd May anent Gowry and Pan Sopa trees having no heart, is contrary to what I believe, for, as far as I have seen, if these trees be exposed to the weather, the *pallak* or sap-wood soon goes and leaves a heart, or what I take to be such. Gowry is of no use for posts, while Pan is. Korika is of little use in the ground, but fine for upper work. There is also another Sopa called Kotal Pattia Sopa, somewhat like Tita Sopa, but the bark and also leaves are like a kotal (Jack), only larger. There are very few of this jât. I have great faith in the Sopas, and I know of a bungalow whose posts are only some 15 years old, and almost all the Nahors are eaten or rotted through and through at ground level, while the Tita Sopas are as sound as the day they were put in. I know of a Tita Sopa post which has been in a "Nangohr" for over 20 years, and is quite sound. It is extraordinary how little planters know about the different trees by which they are surrounded, bar the very commonest; and we ought to feel much obliged to Mr. Peal for his kindness in allowing us to benefit by his experiences, which extend over so many years.—Yours, &c., BLACKWATER.

THE PHILIPPINE ISLANDS.

Our Consul at Manilla (Mr. Richard Wilkinson), reports that in consequence of the abolition of the tobacco monopoly in the Philippine Islands, and the development which the cultivation of the plant is expected to acquire, the Spanish Government has resolved to dispose of the waste crown lands in the tobacco districts, and certain prescriptions regulating their sale have been published, by virtue of which foreigners are allowed to become purchasers on the following conditions, namely:—1. That they reside in the Philippine Islands, and are duly registered in the books of their respective Consulates; 2. That their lands to be sold should they leave these islands, and establish their domicile elsewhere; and 3. That in the event of the death of a landed proprietor, his heirs be compelled to reside within the territory of the Philippine Islands, or sell the property. The acquisition of land by foreign Companies or associations is absolutely prohibited. The waste crown lands are very extensive, and the Government would be greatly benefited by the sale of the same if only purchasers could be found; unfortunately, excepting a few districts where the extraordinary fertility of the soil and the facilities for irrigation have attracted a large population, these islands, as a whole, are but thinly populated, and consequently the scarcity of labour deters would-be purchasers from investing their money in land speculations, which promise no immediate returns. The Chinese, who might have supplied necessary labour, are not partial to agricultural pursuits, and notwithstanding the treaty stipulations, which only permits their residing in the Philippine Islands on condition of their dedicating themselves to agriculture, scarcely 100 individuals, out of a resident Chinese population of upward of 40,000 souls, devote themselves to that industry.—*Chamber of Commerce Journal.*

TEA INDIGENOUS (?) TO CEYLON.

(*From Bennett's "Ceylon and its Capabilities."*)

The jungles adjoining this place, and throughout the Mahagampattoo district, abound with the "wild tea tree," as it is called, but which, I am informed, is a species of *orchis*. It bears yellow flowers; and the poorest people are accustomed to use the leaf both for food and drink; for the former, boiled and mixed with *Tyre*, and for the latter, an infusion of the green leaf. It is called *Gal-Kuroo* by the Singhalese; who also employ the leaf of another plant, which greatly resembles that of the *Thea Bohea*, L., and is called by them *Rata-Thé-Kola*, (or Red-Tea leaf,) in a similar manner.

Although the infusion of the green leaf is a very bitter drink, it is an excellent tonic, and its taste may be greatly improved by the addition of the indigenous lemon grass (*Andropogon Schœnanthus*, L.) and sugar; but that made with the dried leaf, is a tolerable substitute for Bohea tea.

The late Assistant Staff Surgeon Crawford, at the time he superintended the hospital duties at Batticaloa, in 1826, sent me, by a native *Dhoney* bound to Hambantotte, a collection of insects and plants; and, among, the latter, a very fine specimen of what he considered the real tea, in flower. It fully answered the generic description of the *Thea Bohea* of Linnæus; and, as it both flowered and seeded freely, I made a sketch of it, of which an engraving is annexed, but I was altogether unsuccessful in my own researches for the plant in the jungles of the Mahagampattoo.

Mr. Crawford did not assume any merit to himself as having made a new discovery, and it is very clear that the Dutch were well aware of the tea plant being indigenous in the eastern province; but it is to be wondered at, that the government has not, long ere this, directed its attention to so important an object of commerce; for if it be worth while to cultivate tea in so distant a country as Assam, with all its inconveniencies and dangers, surely it would be a more lucrative speculation, in a colony so much nearer home, and with increased facilities of export. But this, like the bread fruit tree, is another *chance* discovery; and a better acquaintance with Ceylon in 1787—1789, would have rendered the two expensive trips to Otaheite, for supplying the West Indies with bread fruit plants, inexpedient; for they could have been obtained in any quantity from this island, and have obviated all the disastrous consequences of the mutiny on board His Majesty's ship "Bounty."

Captain Percival, in his "Account of Ceylon," published in 1805, informs us, "that the tea plant has also been discovered native in the forests of the island. It grows spontaneously in the neighbourhood of Trincomalee, and other northern parts of Ceylon. General Champagné informed me that the soldiers of the garrison frequently use it. They cut the branches and twigs, and hang them in the sun to dry; they then take off the leaves, and boil them to extract the juice, which has all the properties of that of the China leaf. I have in my pocket a letter from an officer in the 80th regiment, in which he states that he had found the real tea plant, in the woods of Ceylon, of a quality equal to any that ever grew in China, and that it was in his power to point out to government the means of cultivating it in a proper manner."

MANUFACTURE OF CAMPHOR IN JAPAN.*

The manufacture of camphor is an important industry on the island of Kiu Shiu (Kew Shew).

From the port of Nagasaki there were exported in the year 1882, 15,186·18 piculs, valued at 227,792 dollars. A picul is 133⅓ pounds. From other ports of the island not yet open to foreign trade, a large quantity was shipped by native merchants in native vessels to Shanghai in China, and Hong Kong, whence it finds its way to India and England; little or none of it is exported to the United States. The camphor tree grows abundantly all over this portion of Japan. It is found alike on high elevations and in the valleys and lowlands. It is a hardy, vigorous long-lived tree, and flourishes in all situations.

Many of these trees attain an enormous size. There are a number in the vicinity of Nagasaki which measure

* Report by Consul Jones, of Nagasaki. Reprinted from the *St. Louis Druggist*, August 18, 1883.

ten and twelve feet in diameter. The ancient temple of Osuwa at Nagasaki is situated in a magnificent grove of many hundred grand old camphor trees, which are of great age and size, and are still beautiful and vigorous. I am told that there are trees in other places in Kiu Shiu measuring as much as twenty feet in diameter. The body or trunk of the tree usually runs up twenty and thirty feet without limbs, then branching out in all directions, forming a well proportioned, beautiful tree, evergreen and very ornamental.

The leaf is small, elliptical in shape, slightly serrated, and of a vivid dark-green colour all the year round, except for a week or two in the early spring, when the young leaves are of a delicate tender green. The seed or berry grows in clusters and resembles black currants in size and appearance. The wood is used for many purposes, its fine grain rendering it especially valuable for cabinet work, while it is used also for ship-building. The roots make excellent knees for ships.

I have sent many seeds of the camphor tree to the United States, in the hope of adding to our own arboriculture.

In the manufacture of camphor the tree is necessarily destroyed, but, by a stringent law of the land, another is planted in its stead. The simple method of manufacture employed by the natives is as follows:—

The tree is felled to the earth and cut into small pieces, or more properly speaking, into chips.

A large metal pot is partially filled with water and placed over a slow fire. A wooden tub is fitted to the top of the pot and the chips of camphor wood are placed in this. The bottom of the tub is perforated, so as to permit the steam to pass up among the chips.

A steam-tight cover is fitted on the tub. From this tub a bamboo pipe leads to another tub, through which the inclosed steam, the generated camphor, and oil flow. This second tub is connected in like manner with a third.

The third tub is divided into two compartments, one above the other, the dividing floor being perforated with small holes, to allow the water and oil to pass to the lower compartment. The upper compartment is supplied with a layer of straw, which catches and holds the camphor in crystal in deposit as it passes to the cooling process. The camphor is then separated from the straw, packed in wooden tubs of 133½ pounds each, and is ready for market.

After each boiling the water runs off through a faucet, leaving the oil, which is used by the natives for illuminating and other purposes.—*Pharmaceutical Journal.*

TASMANIAN NOTES.

There are few more pleasant places for spending a holiday in than Tasmania, which affords the two great requisites for exciting interest, viz., the most charming scenery and novelty. It may appear far afield, but all places near home are comparatively devoid of novelty, and such thorough and comfortable communication is now established with the Australian colonies that getting there is merely a pleasant episode of travel. Less than six weeks suffices to make the voyage of 12,000 miles—a voyage full of interest in itself, the only part likely to prove at all tedious being the sixteen or seventeen days from the Red Sea to the Australian coast. But it is not so much the voyage as what may be seen at the end of it which concerns us now. Riding along these roads, which often pass through lovely valleys inclosed by slopes covered with beautiful ferns and immense trees, having an undergrowth almost tropical in its luxuriance one comes suddenly on some fine house standing back in its own park, so thoroughly English, that imagination immediately rushes to some well-remembered home spot. Familiar English trees planted around, and English grasses growing luxuriantly, tempt one to an entrance, and, entrance once made, the most unbounded hospitality and a thoroughly cordial welcome is pressed on the visitor. From some of these houses in the interior, where I have been so cordially welcomed, lovely views extend. The island is particularly mountainous, having very few level tracts of country, so that its scenery is most picturesque. There is abundance of timber on all the mountains, principally Eucalyptus; all the trees are evergreen, and afford a dark background to the beautiful undergrowth and ferns.

As regards life in the country stations, much of course depends on the season of the year, but there is always something entertaining going on. Life is generally of the simplest and most healthy description, to bed early and up with the sun being the great rule, as there is no daylight to waste, especially busy attimes. On most stations the management of sheep is the principal business, but others are devoted to cattle, and some to horses. Branding cattle, and driving large mobs, is most difficult, but, to most Englishmen who are sufficiently skilful, it is a novel and entertaining work. No little skill is required in managing the stockwhip—generall, a lash some 20ft. long on a handle of 2ft., heavily weighted at the butt for balance—or in avoiding the rush of some infuriated animal. Sometimes gentle management induces the animals to go quietly, but no reliance is to be placed on this. Suddenly some fierce old bull rushes out from the herd, and, though the rest may be kept together, and so managed, he must be fetched back alone. Away go the stockmen, galloping across the rough country, and if the trees have not been cleared, a good stock-horse (any other horse is useless for this work) will wind in and out between them till the animal is headed, and compelled to go back; his furious rushes are then avoided by the cunning horse, until at last, thoroughly subdued, the animal is driven in. Many are the narrow escapes which these stockmen go through; it is, of course, impossible to gallop over this rough ground with impunity; but accidents are comparatively few. I have seen some very exciting scenes in the branding of cattle, which are driven into the large and very strongly built stockyard surrounded by an open fence of stout timber some 7ft high. Around the top of this a plank runs, on which those engaged with the cattle walk round, and select the animals which are to be dealt with. The beasts sometimes make the most frantic endeavours to reach those dealing with them, and care must be taken lest some long-horned brute touch the legs, as a fall into the yard would be almost surely fatal. From the yards the animals are driven for actual branding into a narrow race, and there fastened, with ropes round the body, to the side, while the branding iron is applied.

Exciting sport may, of course, always be found in riding. There is sure to be a horse which takes some riding, and one may try one's hand. An attempt of this kind should, however, be very carefully considered before being made. Suppose the horse is a real Australian buck-jumper, as I have found to my cost, it is no pleasant thing to find oneself hoisted violently in the air, and the horse's head and neck—in fact, his whole fore-quarters—vanish suddenly from sight.

There is plenty of what may be considered more legitimate sport in the way of shooting to be had, and in some parts of the island it is excellent. Several very good days may be had after kangaroo and wallaby. Unfortunately, the former were destroyed in such wholesale fashion that they have been driven far back from the haunts of men, and laws have been passed for their preservation. The kangaroo is excellent eating, only the hind-quarters being used; the flesh tastes something between venison and mutton, and soup made from the tail is very good. The tanned skin makes a very valuable leather, not quite so strong as pig and not quite so soft as kid.

A most amusing and strange shooting experience is opossum shooting. This is in the winter, because then alone the furs are valuable, and at night, because then alone is the opossum on the move; by day he lies *perdu* in some hollow of a tree. The opossum, though marsupial, seems to show an affinity to the cat tribe—at least as regards tenacity of life—for I never found anything yet so hard to kill. I have seen one hit hard, and knocked off a branch of a tree some 50ft. from the ground, fall to the ground in the shape of a ball, jump at once and scuttle off, till brought down by another shot.

Some of the bird shooting is splendid sport, wattlebirds, as they are called, being very good. There is on the rivers some very good wild duck shooting, especially on the Jordan, a small tributary of the Derwent, and not far from Hobart.—V. D. —*Field.*

SUGAR-CANE CULTIVATION IN BRITISH BURMAH.

The Indian Government is steadily pursuing its recent policy of endeavouring to develop the Sugar industry of the Empire—an important fact, considering that the production of India is estimated already to amount to something like 5,000,000 tons a year. If this vast weight were proper prepared the produce of India would be trebled, and she would supply the world with Sugar. Among other reports the Government have recently received one from Mr. SMEATON on Sugar in British Burmah. This is reprinted in a recent *Indian Agriculturist*, and the following are extracts from it. The lands visited all appear admirably suited for the growth, but the production is very small, and the means of cultivation are primitive. In the district of Thonegwa (the first visited) the Cane is cultivated in plots of about half an acre, and always in close proximity to the banks of the creek or its feeders, for the sake of irrigation at the spring tides. The Canes here on a clay soil average from ten to twelve feet in height, and from one to one and a half inches in thickness. They appeared hard and coarse, were white in colour, and contained more water than saccharine matter. The cultivators, chiefly Upper Burmans, show great care with their crops, which is evident from the bamboo supports, the pruning, and the trenches dug from the flow of fresh water at the rise and fall of the tide. The mode of cultivation is rude. In March the cultivator takes up his plot of grass and tree jungle, cuts down the trees and burns the grass, and leaves everything in a state of ashes. The land is then left during the remainder of the hot season, by which time, grass and weeds having sprung up, he proceeds to plant, no ploughing taking place, but the weeds are pulled up as he goes on. The planting is done in lines and the roots backed up, and when this process is completed the business of planting is at an end, with the exception of a weeding day once a month, the backing up of the stems with bamboo, and pruning the stems when three or four months old. No manure is given to the land, which is virgin soil, cultivators declaring they would not grow Cane on any but new land, which could have the fertilising ashes of burnt grass and tree roots. Two crops as a rule are taken from the same roots, but the second is quite inferior and the cultivator pays little attention to it. The average yield in this district is about 4,000 canes to two and a half acres, the gross value of which may be estimated at about R36, or say £3 12s. The canes grown are used as sweetmeats and are not pressed for Sugar; with such a rude method the labour involved is comparatively trifling, so that the cultivator really obtains the whole produce for himself.

In the Beelin district, however, everything was very different, for here the cultivation is paid considerable attention to. A good deal of money is yearly expanded on the manufacture of course Sugar, and large quantities are annually exported. Mr. Smeaton in his report says the soil is good, the land well watered and drained, and in every way suited to Cane cultivation. Though the industry is a new one, Cane-growing not being known twenty-five years ago, there are said to be about 800 cultivators at work; and the Madras (white) Cane is the only one known. The land is tilled, of which about 3,840 acres seem to be under Cane, in much the same way as at Thonegwa, for the jungle is cut, burnt, and cleared during the dry months, and allowed to lie till August; but the same land is used over again, for in the Beelin district they plough the land after the first crop. The soil does not appear to suffer, for year after year Cane is grown on the same fields, and even after the Cane harvest paddy is planted, because the Planters declare the rotation to be beneficial, both to the paddy and to the Cane. The Sugar pressing mills are near the fields, and the Cane is brought in and pressed as it is cut. As is to be supposed, their mills are rude and primitive, but are said to be thoroughly effective. The boiling process begins as soon as there is a supply of juice, so that all three processes—cutting, pressing, and boiling—go on simulataneously. The article turned out, called Kyantaga, or Jaggery, is said to be far superior to the Indian "Goor." The average yield on the Beelin tract is 3,500 lbs. per acre, which compares favourably with the other Sugar-growing countries. The cost of manufacture is said to be from 80 to 120 rupees per acre, averaging 100 rupees or £10. The value of the Sugar produced is 300 rupees, leaving a profit of 200 rupees of £20 per acre. The following are some further extracts from Mr. Smeaton's report:—"The produce per acre does not compare unfavourably with that of other Sugar-growing countries. The best estates in the West Indies rarely yield more than 5,000 lb. of Sugar to the acre. Trinidad yields on the average about 2,200 lb. of Sugar per acre. The best land in India only yields 1,500 lb. of Sugar to the acre Beelin yields 3,500 lb. of a light brown, coarse Sugar. It remains for experiment to determine what proportion of white crystallized Sugar can be obtained from the present product. Judging by appearance, colour, and taste, I should say it is likely to be considerable. The market value of Sugar land appears to be about R80 per acre. This is nearly quadruple of the average value of paddy land in the Pegu Division ascertained up to date. The initial expenses to a man without capital are heavy, because he has to go much into debt with the local money lender, the peasants themselves being poor. The gross produce of the Beelin tract must be something very considerable; I should say, at the lowest computation, 2,000,000 viss, or about 7,000,000 lb. of Sugar. A great deal is consumed locally. There is a large export to Rangoon, Moulmein, and the Shan states. The money value of this gross produce is six lakhs of rupees. The Government revenue from the entire tract is R2,400. There can be no doubt in my mind, after what I have seen, that the Beelin tract is in a remarkable degree suited to the cultivation of Sugar-Cane. The fact that the same land can go on from year to year producing Cane at a constant and high rate is very striking, not to speak of the further fact that the land can bear, and bear well, other crops in the event of a rotation being expedient. Cotton would, I am certain, thrive, and cotton-cane is a good rotation. Wheat would thrive too, and in the river-side belt so would tobacco. What I would propose, then, in this part of the country is, first, to have the whole adjacent tracts carefully examined to see if the same physical features are found in them. Towards north and south I think the same sort of country will be found. I would depute one of the settlement officers to make the examination, and I would supplement their inquiry by analysis of the soil in a number of different places. Then, should the sorrounding country be found homogeneous and likely to be as suitable for Cane as the present limited tract, I would reserve the entire available area as a Sugar-Cane tract to to be granted solely for Cane cultivation and nothing else; I would have a rough survey made of it; and I would invite cultivators to take up land within it, and offer a fixed advance to each per acre taken up, to defray the initial expenses and set the cultivator afloat, say from R30 to R50 per acre. The Sugar-cane tract which I have just examined in the Hanthawaddy district is in the Lawadee circle of Angyee sub-division on the banks of the Irrawaddy. The spring tides of March and April give all the irrgation. But the cultivators say that the plants would die if they were not thus irrigated. I noticed ono curious thing. The current is so strong at times, that when the river is in flood, anything lying loose on the ground is apt to be carried away. So the cultivators, who had just planted out some Cane, pegged in the tops, and secured them by a bamboo string, to prevent them being washed away. The cane which I saw standing was certainly most luxuriant. There were as many as six to eight Canes on each plant, and they were very tall and thick, quite like the large West India Cane, and very handsome, over an inch in diameter, and ten to twelve feet high. All the Canes are sold for sucking, none are pressed for Sugar. One cultivator declared he got 10,800 Canes on about two acres, which he sold at R2 R2-8, to R3 per 100. He paid rent to another cultivator for the land (which he also had partially to clear) at R1 per acre.—*Produce Markets' Review.*

THE COFFEE QUESTION.

THE BRAZIL-COFFEE AT THE EXHIBITION AND THE JAVA-COFFEE.

The "*Handelsbericht van Rotterdam*," No. 1743, of 24th July has done us the honour to take over and criticize our article on coffee in the "Algemeene Handelsblad" of 19th July last. This article was merely written to give some answer to the questions put by the Chamber of Commerce at Batavia, and this was, also in our eyes, rather too cursory for the importance of the subject. We wish now to fill up a few lacunæ we have observed in it, by pursuing our observations according to the views prevalent in Brazil, still in the character of representative of the Society "Centro da Lavoura e Commercio" at Rio de Janeiro.

We now follow the very pertinent arguments of the "Handelsbericht" of Rotterdam.

In Europe, the Brazilian coffees presented at the different markets, are really considered as of inferior quality. For this, there are two reasons: the first is that most of the Rio coffees of superior quality go to the United States of America; the second, that the greater part of the better qualities of the Rio and Santo coffees, is often sold in Europe under other appellations. Yet the total of the fine sorts of coffee in Brazil, exceeds that of the fine qualities of any other of the producing countries. Both for the exports and imports the cyphers of the Brazilian coffees in the seaports are no doubt correct; these cyphers undergo a good deal of modification on changing of hands for the first time; but directly the retail business commences, not a quarter of the original names of Brazilian coffee is found back that was exported from South America.

But quite lately I saw at Paris, in several shops, large samples of superior coffee, ticketed with the names of the most celebrated sorts of coffee; it was not difficult to point out the true source of those magnificent samples, and even to pitch upon the very Province of Brazil, whence this coffee derived. But not only in Europe do we see this phenomenon of competition by substitution. On occasion of the Continental Exhibition in Buenos Ayres, 1882, a great number of sorts of coffee could be seen announced in all the Chandlers' shops as Yungas, Bolivia and Mocha, as also Java and Ceylon, to the Haiti and Brazilian coffees. The prices ranged from 25 pesos downwards to 10 pesos per K. G. (= $2\frac{1}{2}$ to 1 guilder). We need not add that the Brazil coffees were at the lowest price (10 pesos), and yet it could easily be proved by the 70 samples which Brazil sent to that Exhibition, that almost all those coffees, from the Mocha to the Jacmel, were of Brazilian growth.

As to the coffees of Central America we may affirm, that though we will by no means deny the eminent qualities of these coffees, so well-known and so much liked on the world-markets, yet it is generally conceded that the preparing in those parts is not done with the same care as in Brazil, and that the costing prices cannot by far contend with the South-American. And as we are only concerned with the truth, we think we may declare that not a little Brazilian coffee is sold under the specious names of Laguara, Guatemala, Costa Rica, Martinique, etc.

With regard to the coffee of Java, it is indisputable that this is one of the best in quality, and appears on the prices-current as one of the most reputed sorts. Brazil acknowledges this superiority, feels not in the least mortified by it, she is rather pleased at it, since a good deal of Brazil coffee is sold for Java coffee, especially in North America; Brazil, instead of complaining of a fact, (which for the matter of that occurs so frequently in commerce), does her best to improve her product more and more, hoping that a time may come, if such is possible, when *good* Java will be sold under the Brazilian mark. And if we would only hold to the true qualities, as is after all the right way, and not to the outward appearance of the article, that is to say, if we would judge by the true standard of the beverage, then it must be acknowledged that infinitely nicer coffee is drunk in Brazil, than any where in Holland. The coffee they give you to drink in Amsterdam, Rotterdam and the Hague, cannot in any respect be compared with what is poured out to you at Rio Janeiro, Santon and San Paolo. On this subject the writer of the work: "*Le pays de Café*," Paris, 1882, says:—

"On our travels to Rio de Janeiro, last summer, we tasted in that town the most fragrant and tonic coffees that we ever tasted in our lives. The smallest *restaurants* in that capital of Brazil served us always to coffee of a better quality than you get in the greatest establishments in France. And as to the coffees, which we had the honour to be treated to by the great planters themselves, no coffee in the world is to be compared to them.

Lately during our two months' stay in Holland, we have gained the experience that the coffee drunken there is not much better than what is drunk in the great establishments in France. Thus while acknowledging the superior quality of the Java-coffees, we must yet maintain, that Brazil also exports splendid coffee in great quantities, though I concede that the majority of Brazilian coffees do not come up to the same standard.

Now what regards the earthy taste, or rather the smell generally found in the Brazilian coffee, this will disappear more and more, thanks to the adoption of drying trays of plaster, of cement, and stone or brick; these are so abundantly to be had in South America, that Brazil could now easily export sufficient coffee for the consumption of the world, entirely free from the objectionable smell or flavour. In a few years this extraneous flavour will disappear altogether, thanks to the almost general discarding of earthern drying-pans, and the drying-pans improvised on the plantations during the gathering of the crop. Then the Brazil-coffee will be entitled, besides its aromatic flavour and genuine qualities to boast of its strength and tonic virtues, such as no other coffee can present in the same degree, and which will stamp this coffee as the most proper to supercede alcoholic drinks; *i.e.* to fulfil the highest and most useful purpose that mankind can expect from this beverage.
