The possibility of selecting a group of Eucalypts capable of furnishing bloom for bees to work on the year round is suggested and a list is given showing the blooming periods of the species growing on the station grounds. Data are also given on some strength tests of Eucalypts conducted by the Forest Service of this Department in cooperation with the State of California.

Basket willow culture, C. D. Mell (*Lebanon, Penn., 1908, pp. 10*).—This pamphlet contains practical instructions for planting, cultivating, harvesting, and marketing basket willows, together with notes on varieties, insect enemies, cost and profit of a basket willow holt, and utilizing willow bark.

The drifting-sand problem, W. Gill (*Jour. Dept. Agr. So. Aust., 11 (1908), No. 11, pp. 1028–1031*).—In addition to a brief discussion relative to the causes of drifting-sand areas and their treatment, a list is given of 28 shrubs and trees which the author considers best for sand-binding purposes in South Australia.

Silvical leaflets (*U. S. Dept. Agr., Forest Serv. Silv. Leaflets, 15, pp. 4; 16, pp. 2; 17, pp. 2; 18, pp. 5; 19, pp. 5; 20, pp. 2; 21, pp. 3; 22, pp. 3; 23, pp. 2; 24, pp. 2; 25, pp. 3; 26, pp. 2; 27, pp. 2; 28, pp. 3; 29, pp. 2; 30, pp. 2; 31, pp. 4; 32, pp. 3; 33, pp. 2; 34, pp. 2; 35, pp. 2; 36, pp. 2; 37, pp. 3; 38, pp. 7; 39, pp. 2; 40, pp. 2; 41, pp. 3; 42, pp. 4*).—A series of leaflets, each one dealing with the range and occurrence, climatic adaptability, habit, associated species, soil and moisture, tolerance, and reproduction of one of the following species of trees, the order given corresponding to the leaflet numbers above: White spruce (*Picea canadensis*), single-leaf piñon (*Pinus monophylla*), four-leaf piñon (*P. quadrifolia*), redwood (*Sequoia sempervirens*), bigtree (*S. washingtoni-*

ana), weeping spruce (*Picea breweriana*), Jeffrey pine (*Pinus jeffreyi*), amabilis fir (*Abies amabilis*), bristle-cone pine (*P. aristata*), bristle-cone fir (*A. venusta*), cottonwood (*Populus deltoides*), foxtail pine (*Pinus balfouriana*), Torrey pine (*P. torreyana*), black spruce (*Picea mariana*), blue spruce (*P. parryana*), California swamp pine (*Pinus muricata*), black hemlock (*Tsuga mertensiana*), tamarack (*Larix laricina*), digger pine (*P. sabiniana*), Coulter pine (*P. coulteri*), alpine larch (*L. lyalli*), knobcone pine (*P. attenuata*), white-bark pine (*P. albicaulis*), paper birch (*Betula papyrifera*), Monterey pine (*P. radiata*), swamp cottonwood (*Populus heterophylla*), chestnut oak (*Quercus prinus*), and sugar maple (*Acer saccharum*).

Exploitation of forests (*Le Brésil: Ses Richesses Naturelles; ses Industries. Rio de Janeiro: Centro Indus. Brasil, 1908, French ed., vol. 1, pp. 214–227*).—Notes on forest trees growing in northern, central, and southern parts of Brazil, including the local and botanical names, physical properties, and economic uses.

First report on a study of forest conditions of Kentucky, J. S. Holmes and W. Bradfield (*Bien. Rpt. Bur. Agr., Labor, and Statis. [Ky.], 17 (1906–7), pp. 37–120, map 1*).—The Forest Service of this Department, in cooperation with the Kentucky State Board of Agriculture, Forestry, and Immigration, is making a study relative to the present forest conditions in Kentucky and means for their improvement. Thus far, the study has been completed on 2 watersheds, the Big Sandy and Little Sandy rivers, including 11 counties in the eastern and northern sections of the mountain region.

The results of the investigation to date are embraced in the present report. Brief consideration is given to the physiographic features, classification, ownership, and valuation of land, and to transportation, and considerable tabular data is presented and discussed showing the annual output of forest products, together with the estimated present stands in this region. The forests are discussed both by type and species, and a local description is given of the forest conditions in each of the 11 counties to show the immediate need for the adoption of some definite method of caring for the forest land. An account is given of the timber and other forest industries relative to methods of exploitation and suggestions for their improvement. Other features discussed are agriculture and mining in their relation to forestry, protection from fire and stock, planting, and taxation. An appendix contains a list of trees and shrubs noted in the region, and a map showing forest conditions in eastern Kentucky is also given.

It is recommended that a technically trained and experienced forester be appointed to take charge of all State work, and that lands more valuable for forest purposes than other purposes should be held and administered by the State as State forests. The establishment of experimental planting stations and a fire warden system is also advised.

The management of the provincial forests of d'Amance, E. Cuif (*Rev. Eaux et Forêts, 47 (1908), Nos. 11, pp. 326–339; 12, pp. 353–362; 13, pp. 387–404; 14, pp. 421–428*).—A résumé of a recent report on this subject in which the various systems of management which have been in force in the d'Amance forest since 1826 are considered relative to the conditions under which they were exercised and the results produced from their execution together with recommendations for the future exploitation of this forest. Considerable tabular data relative to growth tables, etc., are given as well as tables outlining methods of exploitation for a period of 15 years from 1907 to 1921.

Report on the forest administration of the Central Provinces for the year 1906–7, A. F. Gradon, G. S. Hart, and C. G. Rogers (*Rpt. Forest Admin. Cent. Prov. [India], 1906–7, pp. 7+16+20+16+XCIX*).—This is the annual report of the forest conservators of the Northern, Southern, and Berar circles on the forest administration in the Central Provinces for the year 1906–7. The impor-

tant data relative to alterations in forest areas, progress on working plans, forest surveys, forest settlements, forest protection and exploitation, revenues, expenditures, yields, etc., together with a financial statement, are presented in tabular form.

Progress report on forest administration in the Province of Eastern Bengal and Assam for the year 1906–7, W. F. L. Tottenham (*Rpt. Forest Admin. East. Bengal and Assam, 1906–7, pp. 64+3, map 1*).—Data similar to the above are presented relative to the constitution and management of State forests in the Province of Eastern Bengal and Assam.

Annual progress report on forest administration of the lower provinces of Bengal for the year 1906–7, A. L. McIntire (*Rpt. Forest Admin. Bengal, 1906–7, pp. II+51+5*).—Data similar to the above are presented relative to the administration of the State forests of the lower provinces of Bengal.

Report on the forest administration of Southern Nigeria for 1906, H. N. Thompson (*Colon. Rpts., Misc. [Gt. Brit.], No. 51, pp. 4–90*).—A report on operations in the forest reserves of the Western, Central, and Eastern provinces of Southern Nigeria including an examination of the forest areas, alterations in area, forest protection, silvicultural operations and the exploitation of timber, rubber, gums, fibers, oil beans and seeds, with a financial statement for the year. Notes are also given on the work of the botanical stations and cultural experiments with various agricultural crops. In the appendices are descriptive notes on the forests of Southern Nigeria as well as notes on the climate of that country, and miscellaneous tabular data connected with the report.

The use of fluorid as a preserving material for wooden poles, R. Nowotny (*Österr. Chem. Ztg., 11 (1908), No. 12, pp. 164–166*).—A description is given of experiments under way in Austria in which zinc fluorid is being tested as a preserving fluid for telegraph poles, including data relative to the methods of impregnation, and penetration.

With poles treated with zinc fluorid in 1905 and 1906 and examined in 1907, from 88 to 100 per cent were found to be free from fungus attacks, whereas 50 per cent of the poles treated with copper sulphate were found to be more or less seriously attacked. With creosoted poles treated at the same time 93 to 100 per cent were found to be completely free from attack.

The chemical industries utilizing wood—its products and industrial extracts, P. Dumesny and J. Noyer (*L'Industrie Chimique des Bois—leurs Dérivés et Extraits Industriels. Paris [1908], pp. III+402, figs. 107*).—This is a scientific and technical treatise on the utilization of wood in the production of chemicals and extracts. The work is designed to meet the needs of both the manufacturer and the student.

Part 1 treats of the distillation of wood. General consideration is given to the development and extent of the industry and the physical and chemical properties of the principal products of distillation—charcoal, methyl alcohol, creosote, acetic acid, and acetone. An account follows of the important analytical methods and processes, including equipment employed in producing these and derived products.

Part 2 of this work deals with the analytical methods, processes, and apparatus employed in the manufacture of various tanning extracts, including extracts of chestnut, oak, quebracho, sumac, and various other tanning materials. Data are also given relative to capital employed, estimated cost of operations, importance and extent of the extract business in France, Corsica, and Italy, and imports and exports of extracts in France since 1900, as well as an account of the utilization of tanning extracts in the tannery.

Italian camphor, I. Giglioli (*La Canfora Italiana. Rome: Min. Agr., Indus., e Com., 1908, pp. 292, pl. 1, fig. 1; Atti 6. Cong. Internaz. Chim. Appl., 4*

(1906), pp. 200–342, fig. 1).—A monograph on the camphor tree (*Cinnamomum camphora*) and its products, from a historical, industrial, commercial, and cultural standpoint, with special reference to the introduction of camphor culture into Italy, together with tabulated data relative to analytical studies of camphor extracted from the leaves of trees growing in different parts of Italy.

The work concludes with an extensive classified bibliography of the camphor tree and its products.

Rubber extraction (*Le Brésil: Ses Richesses Naturelles; ses Industries. Rio de Janeiro: Centro Indus. Brasil, 1908, French ed., vol. 1, pp. 169–187*).—A general account of the rubber industry in Brazil, including the prevailing methods of exploitation, varieties, and the important rubber-producing regions, together with considerable statistical data relative to production, valuation, and exports of rubber.

Ecanda rubber (Raphionacme utilis), O. Stapf (*Roy. Bot. Gard. Kew, Bul. Misc. Inform., 1908, No. 5, pp. 209–215, pl. 1*).—The author is of the opinion that the tuberous rubber plant found in Portuguese West Africa and reported by C. E. de Mello Geraldes (E. S. R., 19, p. 345) is identical with specimens later received at Kew both from West Africa and from Mozambique. The important features of Professor Geraldes's account of this plant, including extraction tests, are given, together with a preliminary botanical description and a plate showing the specimens grown at Kew.

The plant, which belongs to the genus Raphionacme, of which about 20 species are known, nearly all of them natives of tropical Africa south of the equator, has been named *R. utilis* by Brown and Stapf.

DISEASES OF PLANTS.

Plant diseases in 1907, M. L. Mortensen, S. Rostrup, and F. K. Ravn (*Tidsskr. Landbr. Planteavl, 15 (1908), No. 1, pp. 145–158*).—A general survey of diseases of agricultural crops in Denmark during the year.

Trials with the hot-water treatment for six-rowed barley, F. K. Ravn (*Tidsskr. Landbr. Planteavl, 15 (1908), No. 1, pp. 159–176*).—Either of the following methods is recommended on the basis of the trials reported: Dipping the grain 20 times during 5 minutes in water at 56 to 57° C., and immediately cooling it in the air; or soaking the grain in cold water for 3 hours, subsequently allowing the wet grain to stand for 10 hours, then dipping it 20 times during 5 minutes in water at 50 to 52° C., and immediately cooling it in the air. The former method is to be preferred, as it gives the best germination of the barley. It is important in these treatments that the temperature be kept constant during the dipping, and that the cooling be done at once; the latter process is preferably done in the air, rather than by dipping in water.

Wart disease, or black scab, of potatoes (*Jour. Hort., 60 (1908), No. 3136, pp. 457, 458*).—A full description is given of the wart or black-scab disease of potatoes, a previous account of which has been noted (E. S. R., 16, p. 169). The disease, which is due to the fungus *Chrysophlyctis endobiotica*, appears to be spreading in parts of Europe.

For its control, the author recommends the treatment of potatoes immediately after harvest with sulphur, and, as the fungus is propagated in the soil, where a diseased crop has been grown rotation should be adopted. In the case of the 4-course rotation, it should be so arranged as to allow 8 years to intervene before the next planting of potatoes. Treatment of the ground with gas lime early in the spring, after which it is top-worked, has proved efficient in holding the disease in check. When potatoes are to be planted, it is recommended that the cuttings be dusted with sulphur and sulphur spread on the soil during

the progress of planting. Some varieties seem to be less subject to the wart disease than others, and, so far as possible, these should be employed.

The root rots of beets. W. Busse (*Bl. Zuckerrübenbau, 15 (1908), No. 19, pp. 297–300, pl. 1*).—Under the title of root rots are described the root rots of young garden and sugar beets caused by *Pythium debaryanum*, *Phoma betæ*, and *Aphanomyces lævis*. The methods of attack, peculiarities and differences of the diseases, and means of control are discussed.

The heart rot of sugar beets. A. Genty (*Sucr. Indig. et Colon., 71 (1908), No. 25, pp. 685–689*).—A description is given of the heart rot of sugar beets due to *Phoma tabifica* and of the conditions under which the disease is spread. Attention is called to the fact that certain races of beets seem more subject to the disease than others. The distance in planting was also found to exert an important bearing.

As general precautions to be taken for the control of this disease, the author recommends deep plowing early in the winter, at which time stable manure may be plowed in, and the use of large quantities of wood ashes at the rate of 2 to 2½ cubic meters per hectare (about 23 to 29 bu. per acre).

A mold of latouag wheat. L. Mangin and N. Patouillard (*Bul. Trimest. Soc. Mycol. France, 24 (1908), No. 3, pp. 156–164, figs. 4*).—According to the authors, the natives of Algeria preserve their wheat in silos, cavities in the earth, and similar places, in which, on account of the heat and humidity, the grain undergoes a series of fermentations which give special properties to it that are highly relished by the natives. Among the fermented wheats, a number of which are described, is one called latouag. In this case the wheat undergoes special changes by the action of molds, which give to it a decreased nutritive value and communicate to it certain toxic properties.

A study was made of this preparation, and the changed condition was found to be largely due to a fungus, which appears to be thus far undescribed. The authors give a technical description of it under the name *Monilia arnoldi* n. sp.

Bean anthracnose. H. H. Whetzel (*New York Cornell Sta. Bul. 255, pp. 431–447, figs. 6*).—As a result of 3 years' observations and experiments, the author has found it necessary to modify the generally accepted conclusions regarding the control of this disease, as given in Bulletin 239 of the station (E. S. R., 18, p. 51). The present bulletin is largely a criticism of the methods of treatment suggested in the previous publication.

It is claimed that experiments have shown that the benefits to be derived from seed treatment are very insignificant. The selection of clean seed by hand picking, while in some instances resulting in a diminished amount of disease, in general has proved of no value in eradicating or even partially controlling the spot. The removal of diseased seedlings, which is impracticable except in short garden rows, it is believed may be disregarded as a factor in controlling the disease. Spraying with Bordeaux mixture, if exceedingly thoroughly done, is effective in controlling the disease, but under field conditions with the present machinery it is not believed sufficiently advantageous to warrant the expense and trouble. The cultivation or working of beans when the plants are wet should be avoided as much as possible. On this point the author says there can be no dispute. The spores are held together in mass by a sort of mucilage which is dissolved during the time the plants are wet, and at this time any disturbance of the plants scatters the spores to other plants that may not be affected.

In considering methods of control of the disease, the author places most reliance on clean seed. This can be obtained by securing seed from noninfested regions or it may be by the careful selection of the beans in the field, seeing that no spots are to be found on any of the pods. If on careful inspection the pods appear sound, the seed within will not be diseased.

Further investigations are to be carried on on a number of lines with this disease.

Some apple leaf-spot fungi, C. P. HARTLEY (*Science, n. ser., 28 (1908), No. 709, pp. 157–159*).—The author reports studies of leaf spot of apples, in which 15 species of fungi were found present, only 4 being common enough to indicate any economic importance. These were *Coryneum foliicolum*, *Coniothyrium pirina*, an undescribed species of Tuberculariæ, and *Sphæropsis malorum*.

Studies were made with pure cultures of *C. pirina*, and the results of inoculations indicate that it is a facultative or wound parasite only able to produce spots on apple leaves provided it has killed or injured tissues in which to get a start. It probably causes a considerable amount of leaf spot, but this has not yet been demonstrated. The fungus was found to grow readily on dead twigs, and this led to its further study. A morphologically identical species was found on dead twigs of a quince bush, and pure cultures were successfully inoculated on apple leaves, producing the characteristic appearance. Later the fungus was found on dead apple twigs, and it is possible that it winters in this way. The author was unable to find fruits of the fungus on any fallen leaves during the winter or spring.

Inoculation experiments were also made with *C. foliicolum* with similar results, the Coryneum appearing even less actively parasitic than the Coniothyrium.

A leaf-spot fungus of the apple, J. L. SHELDON (*Torreya, 8 (1908), No. 6, pp. 139–141*).—During the past 5 years the author has been making a study of the causes of defoliation in the apple orchards of West Virginia, and during this time has examined hundreds of leaves. As a result he has found that the worst defoliated orchards showed that the fungi hitherto associated with defoliation were either not present or when present did not bring about defoliation. There was, however, a fungus belonging to the family Tuberculariæ universally present in the orchards and so plentiful that the lower branches of some of the trees were nearly defoliated, the remaining leaves being brown and crumpled.

A study of the fungus showed that it was an undescribed species, and the author gives a technical description of it under the name *Illosporium malifoliorum* n. sp. The spots caused by this fungus are said to be different from those caused by any other leaf spot of the apple and can be readily recognized even when the fungus is not in fruiting condition. In general, the spots are nearly circular, from 5 to 15 mm. in diameter, often coalescent. The spots are brown or mottled gray in color, the colors being more or less concentrically arranged. In the center of some of the spots is to be found a small gray or whitish spot, caused usually by the infection of the leaf by some other fungus. The larger and encircling spots are due to a secondary infection by the fungus under consideration.

Apple leaf spot, F. J. CHITTENDEN (*Jour. Roy. Hort. Soc. [London], 33 (1908), No. 2, pp. 500–511, figs. 3*).—A description is given of the blotching and scorching of apple leaves, due to the fungus *Cladosporium herbarum*. This disease is said to have been extremely prevalent during the season of 1907, the weather conditions being such as to cause a somewhat abnormal growth, which rendered the foliage subject to the attack of fungi.

From an investigation of a large number of varieties, the author finds that some varieties are apparently more liable to the attack of this fungus than others. The best method of prevention, so far as known, lies in the checking of the germination of the fungus by means of applications of dilute Bordeaux mixture.

Exoascus deformans, G. Zauli (*Bul. R. Soc. Toscana Ort., 3. scr., 12 (1907), No. 11, pp. 325–327; abs. in Jour. Roy. Hort. Soc. [London], 33 (1908), No. 2, p. 597*).—An account is given of experiments by V. Peglion for the control of *E. deformans* on the peach tree. It is said that this fungus can be successfully controlled by the use of a wash consisting of copper sulphate 2 kg., lime 1 kg., ammonium chlorid 0.2 kg., and water 100 liters. This should be applied before the opening of the buds, and if the season is favorable, a single washing of the trees is sufficient. If, however, the weather should prove rainy, a second application should be made while the trees are still in a dormant condition.

According to the account, a tree treated with this fungicide retained its leaves, whereas others not treated lost all theirs through attacks of the fungus. The treated tree fruited prolifically and the accustomed falling of the fruit did not occur.

American gooseberry mildew (*Dept. Agr. and Tech. Instr. Ireland Jour., 8 (1908), No. 3, pp. 479–484, pl. 1, figs. 3*).—A description is presented of the gooseberry mildew due to *Sphærotheca mors-uvæ*, attention is called to its destructive nature, and a warning given against the importing of plants from regions that are known to be infested by the fungus. Where the disease is present, spraying with Bordeaux mixture or some other fungicide and the burning of diseased plants, etc., are recommended.

A brief note is given of the European gooseberry mildew (*Microsphæra grossulariæ*), which is seldom found on the berries, confining its attacks chiefly to the leaves. This mildew, it is said, can be held in check by spraying with a solution of potassium sulphid.

[Some vine diseases], F. T. Bioletti (*California Sta. Bul. 197, pp. 147–158, figs. 12*).—A description is given of the powdery mildew of grapes due to *Oïdium* sp., the Anaheim or California vine disease, brunissure, black knot, and coulure. So far as known, the causes of these diseases are described and methods suggested for the prevention of injury by them.

Notes on grape downy mildew in 1907, H. Faes (*Chron. Agr. Vaud, 21 (1908), Nos. 8, pp. 189–193; 9, pp. 207–212*).—While the mildew was late in appearing during the summer of 1907, the conditions for its development were such that it spread rapidly and proved very destructive. Under the author's directions, experiments were carried on at the viticultural station in combating the disease, and an account is given of the results of the different treatments.

A 2 per cent Bordeaux mixture when applied in sufficient quantity proved efficient in controlling the disease. It was found that it should be applied at the rate of from 40 to 50 gal. per acre at the first spraying and from 75 to 100 gal. per acre for each subsequent application. The sprayings should be made at intervals of 15 days, and for the prevention of the powdery mildew sulphur should be applied at like intervals after the second or third spraying.

During the same summer the author tested the efficiency of combined fungicides when applied in liquid form. Plats of equal extent were sprayed with 1 and 2 per cent Bordeaux mixture, a 1 per cent solution of copper acetate, formalin, Bordeaux mixture neutralized with alkaline polysulphids, and formidol, which is said to be a combination of formic acid and copper. The resulting crops on the different plats were collected, and the yields were decidedly in favor of the Bordeaux mixture and the copper acetate solutions. Bordeaux mixture neutralized with alkaline polysulphids gave a much diminished yield of grapes, and formalin still less, the crop where this fungicide was used being almost an entire failure.

The use of proprietary mixtures for the control of downy and powdery mildew, J. Fischer (*Mitt. Weinbau u. Kellerw., 20 (1908), No. 7, pp. 104–109*).—A series of experiments was conducted to test the value of neutral

copper acetate, azurin, Antiperonosporina, Antiperonospora, Schloesing's Bordeaux mixture, Carat, and Reflorit as compared with Bordeaux mixture for the control of the downy and powdery mildew of the grape.

The author sprayed an equal number of vines with each of the mixtures and later carefully examined each of the stocks and determined the number of infected leaves on the treated plants. One hundred and fifty stocks which had been sprayed with Bordeaux mixture showed only 39 leaves containing downy mildew. None of the other preparations showed as favorable results, and the author concludes that when the cost of the material is considered as well as its efficiency, none of them are in any way to be considered superior to Bordeaux mixture as usually recommended.

Effect of some fungicides on the control of downy mildew, R. Meissner (*Weinbau u. Weinhandel, 26 (1908), No. 43, pp. 387, 388*).—In 1907 experiments were carried on with a number of proprietary fungicides for the control of the downy and powdery mildew of grapes, comparisons being made with Bordeaux mixture and soda Bordeaux. The results obtained showed that for practical purposes 1 to 2 per cent of Bordeaux mixture is the most efficient means for controlling downy mildew and sulphur for combating powdery mildew of the grape.

Two diseases of prickly pears, H. Tryon (*Queensland Agr. Jour., 21 (1908), No. 3, pp. 143–147*).—Descriptions are given of 2 diseases to which the prickly pear is said to be subject in Australia. The first is apparently due to some physiological disturbance, and while it appears at times to destroy parts of the plant and hold its spread in check, it does not seem to be of any great economic importance.

The second of these diseases, to which the name sleeping sickness has been given, is apparently due to a fungus attacking the roots of the plant, but the fungus has not as yet been fully identified. As far as observed, the disease spreads very slowly, and as it is a root disease there is apparently not much prospect of artificially communicating it.

The fir disease in Jura, E. Henry (*Bul. Soc. Sci. Nancy, 3. ser., 8 (1907), No. 3, pp. 361–378, fig. 1*).—Attention is called to the disease of firs attributed to the fungus *Phoma abietina* or *Fusicoccum abietinum*, which has been previously reported by the author (E. S. R., 19, p. 657). In that publication the author expressed doubt as to the fungus proving a serious menace to the forests, but other investigators having claimed that it would prove very destructive, he has investigated the subject anew, and from his personal investigations and testimony received from different regions he concludes that while the fungus is the cause of a disease resulting in the reddening of the foliage of the fir trees, the disease is of relatively little importance and apparently never causes the death of the tree.

A note on Micropera abietis, G. Fron (*Bul. Trimest. Soc. Mycol. France, 24 (1908), No. 3, pp. 169–171, fig. 1*).—A description is given of *M. abietis*, a fungus occurring on fir trees that has not hitherto been reported from France. The author points out some departures from the typical form characterized by Rostrup.

Extent and importance of the white pine blight, S. T. Dana (*U. S. Dept. Agr., Forest Serv. [Pamphlet], 1908, May 26, pp. 4, map 1*).—In the early summer of 1907 inquiries were received from various parts of New England regarding a peculiar blight of the white pine in that section.

Trees affected by the blight are readily recognized from the characteristic reddish-brown color assumed by the newest needles. The tip of the needle is always affected first, and the extent of the discoloration varies greatly in different needles and in different trees. Attacked trees look as though they had

been scorched by fire. As the needles of the white pine fall after 2 years, in case the newer ones are affected the trees become more or less defoliated.

This disease is now widely distributed throughout the central and southern parts of New England and occurs also in New York, New Jersey, and Pennsylvania. It has thus far caused but little damage, but if it proves to be infectious it may produce serious results. The cause of the trouble is unknown.

The blight on chestnut trees, J. MICKLEBOROUGH (*Conservation, 14 (1908), No. 11, pp. 585–588, figs. 2*).—An account of the occurrence and distribution of the blight of chestnut trees due to the fungus *Diaporthe parasitica*. The fungus has already caused the destruction of nearly all the chestnut trees in Prospect Park, Brooklyn, and is spreading rapidly in a number of other localities.

Extent and importance of the chestnut bark disease, E. R. HODSON (*U. S. Dept. Agr., Forest Serv. [Pamphlet], 1908, Oct. 21, pp. 8*).—A description is given of the chestnut bark disease due to *Diaporthe parasitica*, or *Valsonectria parasitica*, as it is sometimes called, previous accounts of which have been given (E. S. R., 19, pp. 250, 1051, 1154).

A disease of the Cineraria, F. J. CHITTENDEN (*Jour. Roy. Hort. Soc. [London], 33 (1908), No. 2, pp. 511–513, figs. 2*).—A report is given of a disease of Cineraria leaves, due to the fungus *Colcosporium senecionis*, which, in view of the fact that the fungus occurs on a large number of weeds, may prove quite troublesome.

Upon the Cineraria the attack is characterized by the appearance on the under surface of the leaves of orange-yellow, waxy-looking patches, covering areas varying from 0.25 in. in diameter to almost the whole surface of the leaf. As the disease spreads, the upper surface of the leaves becomes blackish in color. The yellow patches appear in September, and the yellow color is due to uredospores. Later these patches become red and bear the winter spores.

The injury to the plant arises from the fact that considerable nourishment is withdrawn by the fungus, and the plant also suffers by the disfiguring of the leaves.

The attacks of the fungus may be prevented by spraying with a solution of permanganate of potash.

The occurrence of Rhodochytrium spilanthidis in North America, G. F. ATKINSON (*Bot. Gaz., 46 (1908), No. 4, pp. 299–301; Science, n. ser., 28 (1908), No. 724, pp. 691, 692*).—The occurrence of the parasitic alga *R. spilanthidis* on the leaves of the ragweed (*Ambrosia artemisiæfolia*) in North Carolina is reported.

The parasite is an alga devoid of chlorophyll, and attacks the leaves, stems, pedicels, flower bracts, and other parts of the host plant. It begins its development in early summer on the small seedlings and by succeeding crops of zoospores continues the infection of these plants throughout the season, until finally the flower racemes are affected. The parasite has a reddish yellow oil deposited in the protoplasm, and this is so massed in the larger sporangia that it causes a bright red color visible through the thin layer of the cortical tissue. The plant is always located in or adjacent to the vascular bundles, and there is an extensive system of mycelial rhizoids which are profusely branched.

This parasite was first discovered in North Carolina by Dr. F. L. Stevens, who referred material to the author. Since the first collection was made in August, 1903, it has occurred in abundance every year, and 14 additional stations were reported in 1908. In many cases the ragweed is so affected that the destruction can be recognized from car windows.

Bordeaux mixture and other fungicides, G. QUINN (*Jour. Dept. Agr. So. Aust., 12 (1908), No. 2, pp. 146–149*).—Formulas are given for the preparation

of Bordeaux mixture, a new Bordeaux mixture made according to a formula in use at the Woburn Experimental Fruit Farm, and Burgundy mixture.

The new Bordeaux mixture is made by slaking 3 lbs. of quicklime in about 100 gal. of water and then adding 86 gal. of this clear solution to 14 gal. of water in which 6 lbs. 6½ oz. of copper sulphate has been dissolved. This will yield 100 gal. of a clear Bordeaux mixture that is said to be superior to and cheaper than that made according to the commonly accepted formulas.

Fungicides, H. H. Whetzel (*New York Cornell Sta. Circ. 2, pp. 9–16*).—Directions are given for the preparation of most of the common fungicides now in use, together with lists of the more common diseases which careful experiments have shown to be effectively controlled by the use of the fungicides.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Harmful and beneficial mammals of the arid interior, with special reference to the Carson and Humboldt valleys, Nevada, V. Bailey (*U. S. Dept. Agr., Farmers' Bul. 335, pp. 31, figs. 9*).—Among the problems to be solved by the settlers of the areas of western Nevada now being reclaimed and brought under cultivation are those connected with the present and prospective relation of the native mammals to agriculture. Farm crops, trees, live stock, poultry, and ditch banks suffer from the depredations of certain species. In indiscriminate retaliation on the part of the settler many beneficial animals are unwittingly destroyed.

In this bulletin is found an account of the animals of this region of economic importance accompanied by directions for their destruction or protection as the case may be. The following species are described as more or less injurious: Piute ground squirrel (*Citellus mollis*), antelope squirrel (*Ammospermophilus leucurus*), sagebrush chipmunk (*Eutamias pictus*), Carson meadow mouse (*Microtus montanus*), muskrat (*Fiber zibethicus*), Sonoran white-footed mouse (*Peromyscus sonoriensis*), cliff mouse (*P. crinitus*), large-eared mouse (*P. truei*), desert harvest mouse (*Reithrodontomys megalotis deserti*), house mouse (*Mus musculus*), common or brown rat (*M. norvegicus*), desert wood rat (*Neotoma desertorum*), Nevada pocket gopher (*Thomomys nevadensis*), sagebrush pocket gopher (*T. fisheri*), kangaroo mouse (*Microdipodops pallidus*), desert kangaroo rat (*Dipodomys deserti*), black-tailed jack rabbit (*Lepus desertícola*), cottontail (*L. nuttalli*), bobcat (*Lynx baileyi*), and coyote (*Canis lestes*). The short-tailed grasshopper mouse (*Onychomys brevicaudus*), desert fox (*Vulpes macrotis*), large skunk (*Mephitis major*), little spotted skunk (*Spilogale saxatilis*), badger (*Taxidea americana*), Arizona weasel (*Putorius arizonensis*), mink, otter, and bats are considered as mainly beneficial.

Game laws for 1908, T. S. Palmer and H. Oldys (*U. S. Dept. Agr., Farmers' Bul. 336, pp. 55, maps 4*).—This includes the essential features of changes in the game laws made during 1908. Data concerning the closed seasons for game in the United States and Canada, and laws relative to the export and sale of game, and the limits fixed for its capture have been brought together under State, Territory, and province headings. Details concerning hunting licenses and export regulations are shown in tabular form.

Distribution and control of wild rabbits in Mecklenburg, K. Friedericus (*Naturw. Ztschr. Forst u. Landw., 6 (1908), No. 3, pp. 161–196, pls. 2, figs. 2*).—During recent years wild rabbits have greatly multiplied in Mecklenburg and have caused a large amount of damage to vegetation of all sorts, particularly young shrubbery. In the year 1906–7, nearly 7,000 rabbits were killed by forest inspectors. Other means of control suggested by the author include the use of repellant substances on trees likely to be attacked or rabbit-proof wire fencing.

The author gives an account of the natural enemies of rabbits, including foxes, wild cats, weasels, and parasitic insects and worms. The most important means of controlling rabbits are to be found in the extensive use of traps, fumigation, and distributing poison.

The destruction of rats. B. GALLI-VALERIO (*Chron. Agr. Vaud, 21 (1908), No. 6, pp. 142–147*).—The damages caused by *Mus rattus* and *M. decumanus* are briefly described. These rats must also be considered as likely to carry various pathogenic bacteria and parasites from place to place. A rat virus was used but later was abandoned as being less effecitve than traps and other means of destruction.

The use of fluid cultures of mouse typhoid (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 6 (1908), No. 3, pp. 33–35*).—The effect of cultures of mouse typhoid bacilli is not to be observed until after 8 to 14 days. As a rule, the mice dead from this cause are not to be found on the surface of the ground, since they hide in their burrows before dying.

The ecological succession of birds, C. C. ADAMS (*Auk, 25 (1908), No. 2, pp. 109–153*).—A review is given of the more important literature on habitats and the succession of birds observed in various localities. Particular attention is given to the various associations or communities of birds which may be observed in one and the same localities at different seasons of the year. It is believed that a more complete knowledge of these matters will be of importance in gaining definite information as to the economic relations of birds.

The significance of insectivorous birds in agriculture, J. R. BOS (*Tijdschr. Plantenziekten, 12 (1906), No. 4–6, pp. 105–142*).—A general discussion is presented of the relationship of insectivorous birds to agriculture. Attention is given to the problems of determining the economic relations of various species of insects and of estimating the value or injurious character of birds which feed indiscriminately upon harmful and beneficial insects.

Proceedings of the twentieth annual meeting of the Association of Economic Entomologists (*Jour. Econ. Ent., 1 (1908), No. 2, pp. 81–159, figs. 4*).—A continuation of the proceedings of the association at the 1907 meeting (E. S. R., 20, p. 252). Brief notes are given on the various papers in the following paragraphs.

S. A. Forbes presented the results of Experiments with Repellents Against the Corn Root-Aphis. Seed corn was soaked in kerosene at the rate of a teaspoonful to 4 qts. of corn, in a 10 per cent alcoholic solution of oil of lemon, and in a 3 per cent solution of carbolic acid or formalin. As a result of these treatments the reduction in the number of aphids was 14 per cent after carbolic acid, 60 per cent after formalin, 84 per cent after kerosene, and 89 per cent after oil of lemon. The gain in the number of ears was about 20 per cent where the oil of lemon was used.

E. P. Taylor discussed the Life History and Control of the Green-Peach Aphis. In the author's opinion, *Myzus persicæ* has been confused with other species. The life history of this insect is presented in considerable detail. The insect may be controlled by the use of 5 per cent emulsion of kerosene in the spring.

W. E. Hinds and F. C. Bishopp presented A Key for the Classification of Entomological Records. This key contains a detailed outline of subject headings under which the records of entomological work and study and projects to be investigated may be suitably classified.

E. F. Phillips called attention to the desirability of a more thorough study of bee diseases. The men who have been selected as inspectors of apiaries have not always succeeded in controlling the spread of foul brood and other bee diseases. T. B. Symons reported a test of carrying on public spraying with charges merely covering the cost and general expenses. The results were quite

satisfactory. W. E. Britton gave an account of experiments with gases for fumigating nursery trees, already noted from another source (E. S. R., 19, p. 1053).

W. Newell and T. C. Paulsen outlined some results obtained in spraying experiments to destroy the foliage of cotton in the fall. In these experiments common salt, bicarbonate of soda, lye, hydrochloric acid, white arsenic, iron sulphate, and other materials were used. The iron sulphate gave quite satisfactory results. Some growth takes place after defoliation, but this is not regarded as a serious matter.

W. D. Pierce discussed The Economic Bearing of the Study of Parasites of the Cotton-Boll Weevil. It is suggested that cultural operations can be so organized as not to interfere with the hibernation or multiplication of the parasites of the weevil. C. T. Brues called attention to The Correlation Between Habits and Structural Characters Among Parasitic Hymenoptera. Some species of hymenopterous parasites show a very limited range of hosts, while others adapt themselves to a greater number of hosts. The latter are on the whole more decidedly dominant species.

E. D. Sanderson gave some of the results of a study of the codling moth in New Hampshire. It is estimated that 88 per cent or more of the total benefit of spraying was due to the effect on the first brood and through it on the second brood. It is believed that in New England the first brood may be controlled by spraying when the petals drop. F. L. Washburn described the process of Egg Laying of *Empoasca mali*. Notes on Some Insects of the Season were given by H. Osborn for Ohio, G. P. Welden for Maryland, E. P. Felt for New York, and W. Newell and A. H. Rosenfeld for Louisiana.

Proceedings of the Entomological Society of Washington (*Proc. Ent. Soc. Wash., 9 (1907), No. 1–4, pp. 164, pls. 7, figs. 9*).—At the meetings of the society, reports of which are included in this number of the proceedings, papers were read on various entomological subjects, some of which are of considerable economic importance. Among these papers mention may be made of the following:

Notes on Insect Enemies of Wood-boring Coleoptera, by W. F. Fiske; A Gallmaker of the Family Agromyzidæ, by F. D. Couden; A Preliminary Review of the Classification of the Order Strepsiptera, by W. D. Pierce; The Fashioning of the Pupal Envelope in *Lysiphlebus tritici*, by F. M. Webster; and A New Buprestid Enemy of *Pinus edulis*, by H. E. Burke.

Some features of the work of the State board of entomology. R. I. Smith (*Ga. Bd. Ent. Bul. 25, pp. 144–153*).—A historical statement is presented of the origin and work of the Georgia State Board of Entomology, particular attention being given to experiments on woolly aphis, green aphis of the apple, San José scale, fungus disease of the San José scale, and spraying for peach curculio.

Twenty enemies of agriculture. E. Hnos (*Estac. Agr. Expl, Ciudad Juárez, Chihuahua, Bol. 11, pp. 47*).—Economic and biological notes are presented on sheep bot flies, horse bot flies, cattle ticks, sheep ticks, grasshoppers, codling moth, fall webworm, cabbage aphis, tomato worms, bean ladybird, fleas, squash bugs, boll weevil, and other pests.

Injurious insects and their destruction. L. de Malafosse (*Jour. Agr. Prat. Vit. et Econ. Rurale Midi France, 103 (1907), No. 16, pp. 429–444*).—A popular account is presented of the extent of destruction caused by injurious insects and on practical means of combating them. Attention is particularly called to grain weevils, elm-leaf beetle, various other shade-tree insects, locusts, and flies and other insects that are concerned in the transmission of infectious diseases.

Entomological notes, C. Fuller (*Natal Agr. Jour., 11 (1908), No. 2, pp. 191–196*).—Brief notes are given on army worms, fruit-fly parasites, and San José scale.

Description of insects and their work. Insecticides, H. A. Surface (*Zool. Bul. Penn. Dept. Agr., 5 (1908), No. 12, pp. 361–424*).—Descriptive notes are given together with remedies for the common insect pests of fruits, garden crops, live stock, and household articles.

Notes on insect pests (*Jour. Bd. Agr. [London], 15 (1908), No. 1, pp. 45–47*).—In combating cockroaches good results should be expected from the use of pyrethrum, poisoned baits, and traps. Brief statements are made regarding the habits and means of combating celworms, springtails, mites on gooseberries, and Otiorhynchus.

Life histories and larval habits of the tiger beetles, V. E. Shelford (*Jour. Linn. Soc. [London], Zool., 30 (1908), No. 197, pp. 157–184, pls. 4*).—The author discusses suitable methods for rearing and studying larvæ of tiger beetles. Detailed notes are given on the life history of *Cicindela purpurea*, *C. formosa*, *C. hirticollis*, and other species. The eggs are laid in the spring or midsummer according to the species. The larvæ hibernate in the second or third stage of development and pupate the following June or during the second summer. The interval between generations in most species is two years. Observations were made on the influence of varying conditions of temperature, moisture, and food upon the development of tiger beetles.

The gum-lac insect of Madagascar, and other coccids affecting the citrus and tobacco in that island, R. Newstead (*Liverpool Univ., Inst. Com. Research Trop. Quart. Jour., 3 (1908), No. 6, pp. 3–14, figs. 22*).—A detailed description is given of *Gascardia madagascariensis*, *Lecanium nicotianæ*, and *Aleurodes voeltzkowi*, the latter two being described as new species, and also of a number of other scale insects observed in Egypt.

On a new genus of Ixodoidea together with a description of eleven new species of ticks, G. H. F. Nuttall and C. Warburton (*Proc. Cambridge Phil. Soc., 14 (1907), No. 4, pp. 392–416, figs. 45*).—Definitions are given of the anatomical terms used in the descriptions of ticks. The new species described by the author belonged to the genera Ixodes, Hæmaphysalis, Rhipicephalus, Amblyomma, Hyalomma, and Rhipicentor, the last genus being described as new.

An agricultural pest in Porto Rico, Bouvier (*Bul. Soc. Nat. Agr. France, 67 (1907), No. 9, pp. 820–825*).—An account is given of the habits and life history of *Scapteriscus didactylus*, known in Porto Rico as changa, with instances of the injury caused by this insect to various crops.

Phalacrus corruscus as an enemy of cereal smuts, K. Friederichs (*Arb. K. Biol. Anst. Land u. Forstw., 6 (1908), No. 1, pp. 38–52, pl. 1*).—*Phalacrus corruscus* has been found to exert an important influence in destroying the smuts of cereals. The larvæ of this insect have been found generally distributed in infected ears of grain in cases of wheat smut, loose smut of oats, and barley smut. A single infected kernel of grain may contain from 1 to 3 larvæ. The eggs are laid on the stem near the head of the grain or in the head near infested kernels. The larvæ feed upon the smut spores during their whole development and as soon as the mature size is reached they leave the plants and bury in the ground. An examination of fields infected with smut showed that nearly every infected head of grain contained several larvæ, sometimes more than a dozen. The insect in question is, therefore, considered as being of great importance in the control of smuts. The author found that the spores are all rendered incapable of germination by passing through the body of the larvæ,

Erroneous reports of cotton-boll weevil—its present status, F. SHERMAN, Jr. (*N. C. Dept. Agr. Ent. Circ. 21, pp. 4*).—Reports to the effect that the cotton-boll weevil has been found in North Carolina are declared to be without foundation. At present this insect occurs in eastern Texas, Oklahoma, Arkansas, Louisiana, and Mississippi.

Insect pests and diseases of sugar beets in 1907, O. FALLADA (*Mitt. Chem. Tech. Vers. Stat. Cent. Ver. Rübenz. Österr.-Ungar., No. 197, pp. 28–37*).—Brief accounts are given on the injuries caused to sugar beets by mole crickets, wireworms, snout beetles, flea beetles, red spiders, cutworms, plant lice, root worms, nematodes, and other insect pests. Mention is also made of losses caused by the occurrence of dry rot, scab, bacteriosis, and other fungus diseases.

Fumigation for the citrus white fly, as adapted to Florida conditions, A. W. MORRILL (*U. S. Dept. Agr., Bur. Ent. Bul. 76, pp. 73, pls. 7, figs. 11*).—Fumigation experiments with hydrocyanic-acid gas carried on in Florida for two winters, during the short dormant period (December, January, and February), when there were no winged insects, have demonstrated the practicability of this method for the control of the white fly. In an extended discussion of the conditions favoring or necessary to good results, the author considers the isolation of the grove, the importance of concerted action, the absence or elimination of food plants other than citrus, the season of the year, meteorological conditions, and the size of trees and their regularity of setting. It was found that fumigation could safely begin at sundown and that on cloudy days it was safe to fumigate at any time with untreated tents. The effect of wind was found to be so great that fumigation is not recommended when more than a slight breeze prevails. It is concluded that moisture on the leaves in the form of dew does not reduce the efficacy of the gas in destroying the insects but possibly increases it.

The many details relating to the equipment and methods of operation including quality and amount of the chemicals, tents and methods of handling, measuring trees, methods of generating the gas, estimation of time required for fumigation of the grove, and methods of computing approximate dimensions and cubic contents are discussed. The bell or hoop tent and the sheet tent are the two styles now in use.

A formula of 1 part potassium cyanid, 1 part sulphuric acid, and 3 parts water and an exposure of 40 or 45 minutes is recommended. Elaborate tables are given which show the results obtained from various sized trees at various strengths of gas. When the recommendations here made are followed, appreciable injury to orange trees will rarely occur and apparently never to tangerine and grapefruit trees. As occasional injury to the fruit may occur, it is thought best to pick the crop before starting to fumigate. The author recommends particularly the taking up of fumigation by the various counties under the direction of their horticultural commissioners. The Florida red scale (*Chrysomphalus ficus*) and the purple scale (*Lepidosaphes beckii*), two pests of citrus fruit are controlled by the fumigation for the white fly.

The entire cost of fumigating a tree measuring 42 ft. over the top from ground to ground and 59 ft. in circumference is estimated at 50 cents. It is further estimated that in 2 years the cost of spraying a tree of this size would double the cost of one fumigation. "In a series of 5 or more years spraying would doubtless cost fully 3 times as much as would control by fumigation, the labor involved would be far greater, and the results far less satisfactory. . . . Manatee County is the only large orange-growing district where the fungus diseases have proved of much assistance. . . . One year in three, it is the

experience of the growers in this county, the fungi have so thoroughly cleaned up the pest that the fruit is clean and requires no washing. . . . The writer's observations lead to the conclusion that in 90 per cent of the groves in those localities where the fungus diseases are most effective, for every dollar expended for well-conducted fumigation the profits from the groves will be increased not less than $4, or at the rate of 250 per cent on the investment. . . . The spores and mycelium of the fungi are not affected by fumigation, as far as has been determined thus far." A dosage table is appended.

Fungus diseases of scale insects and white fly, P. H. Rolfs and H. S. Fawcett (*Florida Sta. Bul. 94, pp. 5–17, figs. 20*).—Descriptions are given of species of fungi that have been found of economic importance in combating various scale insects and the white fly, which are troublesome in Florida on citrus trees. The fungi described are *Sphærostilbe coccophila*, *Ophionectria coccicola*, and *Myriangium duriæi*, which attack various species of scale insects, and *Aschersonia flavo-citrina*, *A. aleyrodis*, and an undetermined species of fungus, the spore-bearing stage of which is not known, which attack the white fly.

Methods for applying the fungi to infested trees are described, these consisting for the most part in fastening twigs or leaves carrying the fungus to infested trees. In the case of the red fungus of the white fly (*A. aleyrodis*), it has been found that this can be readily disseminated by spraying the spores directly on trees. Where this method is employed, a dozen or more leaves bearing abundant pustules of the fungus should be placed in a pail of water, stirred, and allowed to stand for 15 to 30 minutes. The mixture thoroughly stirred is then sprayed over the tree, care being taken not to use machinery that has been employed in the application of fungicides or insecticides.

In order that the introduction of these fungi should be effective, it is suggested that close observation be made of the entire orchard and that wherever the greatest amount of the scales or white flies are located the fungi be introduced in such position as to give the best opportunity for the spores to spread from one limb to another and from tree to tree.

The San José scale, E. D. Sanderson (*New Hampshire Sta. Circ. 5, pp. 12, pl. 1, figs. 5*).—A general account of this pest, including its life history, spread and means of spreading, food plants and remedies. It is stated that during the past 2 years a number of bad infestations covering several neighboring orchards have been reported.

The oyster-shell scale (*New Hampshire Sta. Circ. 4, pp. 4, figs. 3*).—Young apple and poplar trees are reported to have been killed by this insect, which has been found exceedingly abundant in young orchards of southern New Hampshire. Spraying as the young are crawling about in late May and early June with a 15 per cent kerosene emulsion or whale-oil soap at the rate of 1 lb. to 4 or 5 gal. of water is recommended. The whale-oil soap may be added to Bordeaux mixture if the latter is being used early in June.

Caterpillars injuring apple foliage in late summer, E. D. Sanderson (*New Hampshire Sta. Bul. 139, pp. 207–228, figs. 13*).—An account of the life histories and habits of the fall webworm, yellow-necked apple caterpillar (*Datana ministra*), red-humped apple caterpillar (*Schizura concinna*), hickory tiger moth (*Halisidota caryæ*), rusty tussock moth (*Notolophus antiqua*), and the white marked tussock moth (*Hemerocampa leucostigma*). As most of these caterpillars are injurious late in the summer, spraying about August 1 with Paris green or arsenate of lead is advised, the Paris green to be used 1 lb. to 100 gal. of water to which 1 or 2 lbs. of freshly slaked stone lime should be added, and the arsenate of lead to be used at the rate of 3 to 5 lbs. to 50 gal. of water. Spraying apparatus is also briefly discussed.

The apple leaf-aphis, E. D. SANDERSON (*New Hampshire Sta. Circ. 3, pp. 6, figs. 4*).—This pest is reported to have been quite abundant throughout the State during the season of 1908 and in some instances quite seriously injurious to young orchards. A brief account of its life cycle is given. The application of contact sprays in the spring before the aphids have become numerous enough to curl the foliage and thus be protected is recommended.

"A spray of 10 or 15 per cent kerosene emulsion; whale oil or fish oil soap, 1 lb. to 5 gal. of water; tobacco water, or any of the prepared tobacco extracts will kill the aphids if applied so as to hit them. . . . Winter spraying with lime-sulphur mixture as used for the San José scale will kill many of the eggs, but it is doubtful if it will entirely destroy them."

The gall and root forms of phylloxera, ANNA FOA and R. GRANDORI (*Atti R. Accad. Lincei Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 17 (1908), 1, No. 5, pp. 276–281*).—Detailed anatomical notes are given on the differences observed in various structures of these two forms of phylloxera.

Grape culture in California: Its difficulties; phylloxera and resistant vines, F. T. BIOLETTI (*California Sta. Bul. 197, pp. 115–147, figs. 12*).—"California produces, approximately, all the raisins, three-quarters of the wine, and a large share of the shipping grapes of the United States. . . . At present there are over 200,000 acres of vineyard in the State, and the prospects of continued expansion are favorable. . . . The phylloxera is well established now in nearly every large grape-growing section except those of southern California. There are still large areas of vineyard, however, in the San Joaquin and Sacramento valleys which have thus far escaped the pest."

The most plausible theory advanced to account for the slow extension of phylloxera is said to be that the winged form is absent or extremely rare in the interior of the State, no record existing of winged individuals having been found except in the coast valleys.

For the disinfection of cuttings the use of carbon bisulphid is advised. "For the disinfection of rooted vines dipping in hot water is recommended by the best European authorities. The roots should remain in water at 125 to 130° F. for 10 minutes. . . . It is probable that disinfection by means of hydrocyanic gas as practiced for nursery stock would be effective, but data is lacking on this point. . . . Cultivation is one of the most effective means of carrying the root insects from one part of the vineyard to another. Every effort should be made to discourage the introduction of cuttings, and especially of roots, from infested to uninfested districts."

It is estimated that nine-tenths of the resistant vines being planted in California at the present time are Rupestris St. George. While a most excellent stock for a large portion of the country, numerous cases of partial failure have been noted. Experiments made with various stocks and the experience of growers in relation to resistance are reported.

"For a great majority of our soils and varieties the two Riparia × Rupestris hybrids 3306 and 3309 promise to be superior in every way to the St. George. The former for the moister soils and the latter for the drier. . . . In places where the water stands for many weeks during the winter, or where the bottom water rises too near the surface during the summer, the most promising stock is Solonis × Riparia 1616."

A brief description of resistant stocks adapted largely from Les Vignes Américaines, by P. Viala and L. Ravaz (E. S. R., 15, p. 585), is given, accompanied by reproductions of original photographs.

The grape leaf-hopper, H. J. QUAYLE (*California Sta. Bul. 198, pp. 177–219, figs. 23*).—With the exception of the phylloxera, *Typhlocyba comes* is considered the most destructive insect pest of the vine in California. It is found

in practically all of the vine-growing sections, but is most injurious in the Sacramento and San Joaquin valleys. Another species (*Tettegonia atropunctata*) is frequently injurious in the coast valleys.

"The hoppers pass the winter as adult insects on a wide range of food plants that may be growing in the vineyard or vicinity.

"They attack the vine as soon as the foliage appears, and here they remain until the leaves fall in the autumn.

"One month after they begin feeding on the vine, the overwintering hoppers begin egg laying, which is continued over a period of a month or two, after which they die. The hoppers of the spring brood arising from eggs laid in May, become full grown in 3 weeks, begin egg laying 2 or 3 weeks later, and die off in August or September, making the life of this spring brood approximately 3 or 4 months. Hoppers arising from eggs laid by the spring brood in June and later, remain on the vine until the leaves fall in autumn. They then take to whatever succulent vegetation may be present in the neighborhood, where they live over winter and attack the vines again in the following spring. These begin depositing eggs a month after the leaves appear on the vine, and die off in midsummer, making the length of this life cycle approximately 1 year in the central valleys of California.

"The most satisfactory control method tried during the past 2 years was the use of the screen cage. This was found to capture about 85 to 95 per cent of the adult hoppers at a time in the spring before any eggs are deposited.

"Spraying for the nymphs about June 1, or just before the spring brood becomes mature, will kill a satisfactory percentage of the nymphs or young, but will not kill many adults, or prevent eggs, which are present at this time, from hatching later. . . .

"Plowing or other farm practices can not be relied upon, but when such measures are generally practiced throughout a neighborhood, they may aid in reducing the numbers somewhat."

A bibliographical list is appended.

The California grape root-worm, H. J. QUAYLE (*California Sta. Bul. 195, pp. 26, figs. 18*).—*Adoxus obscurus* has been a destructive enemy of the vine in Europe for many years, but while known to attack the leaves of the grape in California for a number of years only with the past year or two has it been known as a root feeder. As the life history and habits of this species are almost identical with the grape root-worm (*Fidia viticida*) of the Eastern States and since it is a great pest only in California, the common name "California grape root-worm" has been applied.

From June to May the insect is in its larval and pupal stages under ground, while during May and June it works on the parts of the vine above ground as a beetle. The eggs are laid in clusters of from 4 to 30 usually in crevices between the inner layers of the bark on old wood, as many as 79 eggs having been obtained from a single female. In breeding experiments eggs hatched in from 8 to 12 days. Upon emerging the larvæ make their way into the ground almost immediately, where they commence feeding, usually upon smaller rootlets at first which may be eaten entirely off. The larger roots are injured by their gouging out long strips of bark, and in cases of severe injury all the bark may be eaten away. Feeding is continued from the time they hatch in the spring until the vine becomes dormant in the fall. Some of the larvæ were found nearly full grown by September 1, while others were only half grown, the latter completing their growth in the spring. The larvæ were found as far down as 2½ ft. The full-grown larvæ which winter over in the ground change to pupæ in the early spring, ascending to within 4 to 8 in. of the surface before pupating. Two weeks are required for development in the pupal stage.

Upon emerging the adult beetles begin to attack growing parts of the vine above the ground, sometimes the framework of the leaf tissues being left, making a skeletonized effect, though often the entire substance is eaten away. The beetle also gouges out strips of bark of the tender shoots in the same manner that it works on the leaves. The berry itself does not escape attacks, as in July berries may be seen that are quite open or gouged out on one side and the growth interfered with as a result of attacks of these beetles in May or June. The beetles may continue to feed for a month or more. After feeding a couple of weeks egg laying commences.

As the pupæ are found at a depth of 4 to 8 in. below the surface and as any disturbance of the cell in which they are resting will generally prove fatal, many may be destroyed by deep cultivation for a radius of 2 to 3 ft. about the base of the vine. In experiments beetles were killed in from 2 to 3 days on leaves sprayed with lead arsenate in the strength of 5 lbs. to 50 gal. of water. One lb. of Paris green to 75 gal. of water also gave good results. The spraying should be done during the last of April or the first of May and applied mostly from above, as it is on the upper surface of the leaves and the shoots that most of the feeding is done. As the beetles are very readily jarred from the vine into crude petroleum or otherwise captured, this offers one of the most satisfactory means of control. A vine-hopper cage that has been used successfully in one locality is described. A bibliography is appended.

The effect of sulphur in vineyards upon earwigs and spiders, E. Molz (*Mitt. Weinbau u. Kellerw., 20 (1908), Nos. 1, pp. 4–9; 2, pp. 24–29*).—The repeated use of sulphur in vineyards destroys a considerable percentage of the earwigs. The sulphur is not poisonous to these insects but causes death by stopping up the tracheal system. Moreover the oxidation products of sulphur act as strong repellants in driving away earwigs. Sulphur appears to have no effect upon spiders.

Biological studies on bark beetles, C. Hennings (*Naturw. Ztschr. Forst u. Landw., 6 (1908), No. 4, pp. 209–229*).—The author presents biological and economic notes on a number of important beetles including *Hylesinus crenatus*, *H. fraxini*, *Ips typographus*, *I. acuminatus*, and *I. curvidens*.

On some Assam Sal (Shorea robusta) insect pests, E. P. Stebbing ([*Indian*], *Forest Bul. 11, pp. III+66, pls. 8*).—The insect pests of *Shorea robusta* are discussed in detail, the pests being classified according to the part of the tree to which they do damage. In the case of each forest pest, notes are also given on their predaceous and parasitic enemies. The more important species considered in the bulletin are *Hoplocrambyx spinicornis*, *Dialages pauper*, *Phlæosinus major*, and species of Xyleborus, Tomicus, Gryllus, and Lymantria.

The development of diptera in the brood chambers of Myelophilus piniperda, R. Kleine (*Berlin. Ent. Ztschr., 52 (1907), No. 2, pp. 109–113*).—*Myelophilus piniperda* is a beetle which makes its burrows between the bark and the cambium of weakened specimens of *Pinus sylvestris*. In studying the injuries caused by this insect the author found that at least 3 species of flies quite commonly breed in these galleries. These species are *Medeterus obscurus*, *Sciara analis*, and *Lonchæa vaginalis*. It is not determined whether these flies live in a parasitic or some other relation to the beetle.

Chionaspis euonymi, L. Faucheron (*Bul. Mens. Soc. Cent. Agr. Hort. et Acclim. Nice, 48 (1908), No. 3, pp. 75–78*).—The Japanese euonymus is badly infested with *Chionaspis euonymi*. A brief account is given of the life history of this insect and suitable insecticide treatment is recommended.

Injury to Ampelopsis quinquefolia by Spilosoma lupricipeda, E. Molz (*Ztschr. Pflanzenkrank., 18 (1908), No. 2, pp. 92–94, figs. 2*).—The author observed that the Virginia creeper is frequently injured to a serious extent by the

attacks of the caterpillars of *Spilosoma lupricipeda*. This insect feeds upon the smaller stems causing the parts above the injury to turn brown and wilt.

Nurseries and nursery inspection, T. B. Symons, J. B. S. Norton, and C. P. Close (*Maryland Sta. Bul. 130, pp. 79–128*).—A general account in which the authors consider selection and care of the nursery, soil and cultural methods, isolation from scale and yellows, importance of selecting buds and scions, growing low-headed trees, control of injurious insect and plant diseases with formulas for insecticides and fungicides, marketing of nursery stock, and the various State laws regarding inspection. Among the insects briefly discussed are the San José scale, woolly aphis, black peach aphis, green aphis of the apple, oyster-shell scale, scurfy scale, and caterpillars. Plant diseases are considered under the headings of leaf diseases, diseases of the wood, root troubles, and nursery sanitation.

The insect pest law, G. W. Herrick (*Mississippi Sta. Circ., June, 1908, pp. 7, fig. 1*).—The inspection law enacted by the legislature in 1908 is here given and explained. This law empowers the entomologist of the experiment station to promulgate such rules and regulations in regard to the inspection, transportation, and sale of nursery stock as he may deem necessary and also to make and enforce rules and regulations regarding the boll weevil. The rules and regulations governing the transportation of cotton seed in the State are given.

Comparative study of the value of various insecticides for the destruction of caterpillars, A. Truelle (*Jour. Agr. Prat., n. ser., 15 (1908), No. 18, pp. 565, 566*).—With regard to the effectiveness and intensity of action of various insecticides used without emulsion, tobacco powder was found to stand at the head of the list, followed by pyrethrum, Paris green, and various other insecticides, while hellebore was least effective. In emulsion, kerosene proved to be most effective and hellebore least so.

An apparatus for the preparation of kerosene emulsion, L. P. de Bussy (*Meded. Deli-Proefstat. Medan, 2 (1908), No. 3, pp. 237–240*).—Kerosene emulsion has recently been quite widely used in Deli as a contact insecticide for the control of thrips, plant lice, Capsidæ, and other pests. For use on sugar cane the author recommends an emulsion containing 1 part hard soap, 10 parts water, and 20 parts kerosene, the stock mixture to be diluted with 15 parts of water before using.

The etiology of so-called foul brood of bees, A. Maassen (*Arb. K. Biol. Anst. Land u. Forstw., 6 (1908), No. 1, pp. 53–79, pls. 2*).—In the opinion of the author foul brood is not a simple disease but should be considered as an affection of the alimentary tract of bee larvæ due to 3 micro-organisms (*Bacillus alvei, B. brandenburgiensis*, and *Streptococcus apis*). *B. alvei* and *S. apis* occur in both forms of foul brood, while *B. brandenburgiensis* is found only in the malignant form of foul brood in which the cells remain covered. Detailed notes are given on the growth and behavior of these organisms on various nutrient media. The author studied *B. larvæ* obtained from America and came to the conclusion that it is identical with *B. brandenburgiensis*.

FOODS—HUMAN NUTRITION.

A preliminary study of the effects of cold storage on eggs, quail, and chickens, H. W. Wiley et al. (*U. S. Dept. Agr., Bur. Chem. Bul. 115, pp. 117, pls. 13*).—In this extended study of cold storage and its effects information gathered from cold storage warehousemen is summarized, the results of investigations on the effects of cold storage on eggs, quail, and chickens are reported, and data regarding legislative enactments on the subject are given.

The investigations include chemical, bacteriological, histological, and macroscopical examinations with respect to eggs and chickens, and organoleptic tests and a bacteriological examination of quail.

The authors conclude from their investigations that "eggs in storage for one year show a loss of weight equivalent to 10 per cent of the total weight, which loss is largely water from the whites. Eggs after storage for 16.5 months lose their power of cohesion and emit a characteristic musty odor a few hours after opening. A lowering of the amount of coagulable proteid of the boiled sample is indicated, as well as a change in reaction and a lower percentage of lecithin phosphorus in the storage eggs. An increase in the lower nitrogen bodies, proteoses and peptones, accompanies the decrease of coagulable nitrogen in the boiled samples of storage eggs, while there is apparently a tendency for the amido bodies to decrease."

An examination of stored eggs showed that some of the egg constituents have a tendency to become crystalline on storage, small rosette crystals being found in the yolk of eggs thus kept for a few months. The attempts which were made to isolate and prepare these crystals for identification have not as yet given definite results. "It is perhaps possible that they belong to the class of substituted fatty bodies, but no definite statement can be made except that it seems that they are not tyrosin. The observations of these bodies seems to be entirely new, as no account has been found of them in other publications. It is probable, therefore, that their existence may be regarded as one of the means of distinguishing eggs which have been a considerable time in cold storage from fresh eggs."

As regards the general effects of cold storage on poultry, "summing up the organoleptic properties, it may be said that for a short time, possibly 6 weeks or even longer, there is no perceptible change produced in a chicken by having it frozen. There certainly does not seem to be any evidence that it is better, and there is no convincing evidence that it is any worse. After 3 months, however, the fresh chicken is easily distinguished by its properties, as a rule, from the cold storage chicken, even after cooking, and to an absolute certainty before cooking. This distinction between the fresh and stored bird becomes more and more marked as the time of storage is increased. In so far as the drawn and undrawn chickens are concerned there is much less certainty of being able to distinguish between them. However, 70 per cent of the jurors were able to pick out the undrawn bird by its stronger odor and taste after a storage period of from 6 to 15 months, but at the test representing 18.5 months' storage the two birds were about equally dry and tasteless.

"The general conclusion is, therefore, that in the case of frozen birds there is no indication of any improvement in quality, that is, in taste, odor, or flavor, during cold storage. There is a deterioration which is noticeable, even at the end of 3 months, and becomes more marked as the time of storage grows longer. Hence, without any reference whatever to the question of wholesomeness, cold storage prolonged for 6 months or more appears to be distinctly detrimental as far as taste, flavor, and palatability are concerned. . . .

"The findings of the macroscopic investigations emphasize and confirm the organoleptic tests previously discussed in that there was observed a decided fecal and irritating odor, suggesting rancid fat, in the case of the undrawn fowls long in storage, existing coincident with the taste which enabled the jury to distinguish between the two methods of dressing. On the other hand, in the drawn fowls there was a tendency to a rancidity of the fatty portions of the abdominal region and a development of an odor somewhat similar to that produced by a butyric fermentation. In general, however, in so far as the bacterial investigations have proceeded, there is little choice between the drawn

and the undrawn fowl. It is possible that on longer keeping there will be developed, in from one to three years, important differences between the drawn and undrawn fowls which will enable them to be distinguished, both by their bacterial flora and by their organoleptic and chemical properties."

The studies reported show that histological changes take place which are proportional to the length of time poultry is held in storage. "The sinuous outline of the fresh fibers soon disappears in cold storage, and the fibers are not by any means so flexible as they were in the fresh state." Some of the poultry examined had been kept in storage as long as four years. "The most obvious change, however, which takes place during this interval [up to 4 years] is manifested as a structureless, granular substance which lies between the individual fibers and between their aggregations which are known as bundles. The origin of the substance is in the fiber itself, and in the earlier periods of storage its composition, according to reactions obtained with various selective dyestuffs which afford excellent microchemical reagents, is not very different from that of the normal fiber. As the storage period is lengthened, however, most marked differences between the normal and cold stored tissues, as exhibited in the staining reactions, make their appearance, and such changes, whether referable directly to bacterial or enzymic action, are essentially chemical, and deal with the fundamental principles composing flesh foods. . . .

"The intestines, which are left in situ in storage birds, show a very marked degeneration. Their muscular walls grow thinner in cold storage until they are the merest remnants, which threaten to disappear altogether and which even very careful handling may easily rupture. This degeneration is noticeably active in the muscular rather than in the cellular tissues of the intestines. This is important when it is considered that the bacterial flora of the intestinal contents will, of course, contain any pathogenic germs which usually accompany the colon bacillus. Hence the perforation of the walls of the intestines, which apparently takes place by continued digestive processes even in cold storage, would open the way for a rapid migration of such bacteria on thawing and previous to cooking. Thus it is quite possible that dangerous bacterial organisms might be translated to the edible portions of the fowl through the perforations of the intestines in the period between thawing and cooking. This degeneration of the walls of the intestines must, therefore, be regarded as highly significant."

Canned salmon, A. McGill (*Lab. Inland Rev. Dept. [Canada] Bul. 150, pp. 10*).—Of the 90 samples of canned salmon collected in the different Canadian inspectoral districts all were found to be in good condition and true to name.

Poisonous fish, V. G. Heiser (*Ann. Rpt. Bur. Health Philippine Islands, 1907, pp. 70, 71*).—A brief account is given of several sorts of fish found in the Philippine Islands, which are actively poisonous when eaten. A. Seale cooperated in the investigation.

On the occurrence of copper in oysters, J. T. Willard (*Jour. Amer. Chem. Soc., 30 (1908), No. 5, pp. 902–904*).—The uniformity with which copper was found in the oysters examined, according to the author, warrants the conclusion that it is a normal constituent. The methods followed in the analytical work are briefly described.

Young bees as a delicacy, M. Takaishi (*Bul. Col. Agr., Tokyo Imp. Univ., 7 (1908), No. 5, pp. 641, 642*).—The use of young bees and bee larvæ as a food in Japan is discussed and an analysis of such canned bees reported.

Report on dehydrated vegetables, milk, egg, etc., H. A. Dent (*Navy Dept., Bur. Supplies and Accts., Mem. Inform. Off. Pay Corps, [etc.], No. 85, pp. 626, 627*).—Dehydrated eggs and a majority of the dehydrated fruits and vegetables tested on vessels of the U. S. Navy gave satisfactory results. The results ob-

tained with milk powder "would indicate that it is not as good a substitute for fresh milk as the tinned article." In making up rations the author suggests that 1½ lbs. of the evaporated vegetable should be considered a substitute for the ordinary allowance of similar fresh vegetables.

Concerning preserved egg yolk, A. SCHOONJANS (*Bul. Soc. Chim. Belg., 22 (1908), pp. 119–122; abs. in Chem. Zentbl., 1908, I, No. 18, p. 1733*).—Boric acid was identified in preserved egg yolk.

Flour bleaching, H. SNYDER (*Minnesota Sta. Bul. 111, pp. 101–143, figs. 3*).—The results of investigations of various questions related to the bleaching of flour by oxids of nitrogen are reported, including among others experiments on the digestibility by healthy men of bread made from bleached and unbleached flour, the character of the fat and gluten of bleached and unbleached flour, and the distribution and occurrence of nitrites in food products.

Quotations from the author's summary follow:

"The bleaching of flour is a natural process and takes place when flour manufactured from well cleaned wheat is stored in thoroughly ventilated warehouses. With natural aging and bleaching there is a slight improvement in bread-making value.

"The coloring matter of flour is an unstable organic compound readily acted upon by heat, light, air, and a number of chemical reagents. It is mechanically associated with the fat and gluten as an impurity.

"None of the methods proposed for flour bleaching except the use of minute amounts of nitrogen peroxid as that generated by the discharge of electricity in the air, have survived the experimental stage. . . .

"The fat from bleached and unbleached flour milled from the same wheat is identical as far as iodin absorption number, nitrogen content, and heat of combustion are concerned, no greater differences being observed between the fat from the two flours than in the case of duplicate determinations on the same sample.

"The glutens from the bleached and unbleached flours are identical in physical properties and show the same index of refraction.

"The nitrogen peroxid used in small amounts in the electrical bleaching of flour exerts no chemical action upon the flour other than upon the coloring matter. The nitrogen peroxid appears to act in its well known capacity of carrier of atmospheric oxygen, taking up oxygen from the air, oxidizing the coloring matter, and again taking up oxygen from the air without itself entering into the chemical composition of the flour.

"The nitrite reacting material in flour appears to be in physical rather than chemical combination. When the flour is heated, the nitrite reacting material imparted by bleaching is expelled. All of the nitrite reacting material in the gas employed for bleaching can be accounted for as soluble and volatile nitrites in the flour and in the air surrounding the flour, leaving no nitrite reacting material to chemically combine with the fat or gluten. When the bleaching gas was brought in contact with pure sand, with which it can not unite chemically, the same amounts of nitrites were absorbed as in the case of flour.

"In tests where different quantities of gas were used it was found that the amount of nitrite reacting material left in the flour increased with the amount of gas used up to a certain point, and that when a large excess of the gas was employed there was permanently retained in the flour no more than when less of the gas was used.

"It was found that no relationship whatever existed between the nitrite reacting material in the flour and in the bread. Breads from both bleached and unbleached flours when baked in a gas oven where there was poor ventilation contained the same amount of nitrites. When the breads were properly made

and baked out of contact with the combustion gases no reaction was secured for nitrites. Bread can not contain any appreciable amount of nitrite reacting material, as the carbon dioxid and organic acids produced during bread-making liberate nitrites.

"In 15 digestion experiments with men no difference whatever was observed in the digestibility of breads from bleached and unbleached flour. The bleaching of the flour exerted no influence whatever upon the amount of nutrients absorbed and digested. Artificial digestion experiments with pepsin solution gave similar results.

"A kerosene lamp will produce in 1 hour 0.00027 gm. of nitrite nitrogen. This is over five times more than is present in a pound of an average sample of commercially bleached flour. Nitrites are produced as a result of combustion of all fuels and organic substances containing nitrogen. Flour exposed to wood smoke for a few minutes will contain more nitrites than when electrically bleached. Foods prepared by recognized and approved methods, as smoking of meats, contain nitrites. Salted, smoked and cured bacon, hams and similar meats, contain much larger amounts of nitrites than bleached flour. . . .

"In bread-making tests of commercially bleached flours no difference whatever was observed between the breads produced from the bleached and the unbleached flours milled from the same wheats, except that the bleached flours produced a whiter bread and also showed a tendency to produce larger sized loaves. Bleaching of the flour did not impart any odor or taste to the bread or leave in it any residue. . . .

"The bleaching of flour has a slight drying effect resulting in the consumer receiving a proportionally larger amount of dry matter in the flour."

Causes of the quality strength in wheaten flour, A. E. Humphries (*Rpt. Brit. Assoc. Adv. Sci., 1907, pp. 487, 488*).—The author states that although climate and soil influence quality they are not the determining factors in producing strength in flour. Manuring or early cutting at harvest time has no beneficial effect on quality, nor does the percentage of natural moisture in well-harvested wheat indicate it. "Quick growth or rapid maturation of wheats grown in England is not correlated with strength."

According to the home-grown wheat committee of the National Association of British and Irish Millers strength should not be measured by the quantity of water required to make doughs of standard consistency, or the quantity of bread per sack, or the way flour behaves in the dough, "but by its capacity for making big, shapely, and therefore well-aerated loaves. This definition covers two characteristics; one, a flour's capacity for making gas in yeast fermentation, more particularly its capacity for making gas at the latest stages of fermentation; the other, its capacity when made into dough for retaining the gas so generated."

Some considerations determining the strength of flours, J. L. Baker and H. F. S. Hulton (*Rpt. Brit. Assoc. Adv. Sci., 1907, pp. 488, 489*).—From their studies of the subject the authors do not believe that the diastatic activity of flour is likely to afford evidence as to baking quality, but in their opinion a study of enzyms other than diastase which may be present, seems a hopeful line for investigation.

New process of bread making [using cotton-seed meal] (*Oper. Miller, 13 (1908), No. 6, p. 280*).—A brief account of the use of cotton-seed meal with wheat flour for making bread and similar foods, according to a process devised by C. E. Wait.

Do macaroons contain hydrocyanic acid (prussic acid)? W. T. Koch (*Pure Products, 4 (1908), No. 5, pp. 205–207*).—According to the author's observations, macaroons containing some bitter almonds or other fruit kernels which generate

hydrocyanic acid when well baked are not dangerous from the standpoint of hydrocyanic poisoning unless fresh sweet almonds, which contain active emulsin, are eaten at the same time. If, however, the sweet almonds are eaten before the macaroons "it may be assumed that the splitting off of hydrocyanic acid in the stomach is very slight, as the pepsin of the stomach considerably weakens the effectiveness of the emulsin."

Tarragon essence and some of the derivatives of tarragon, M. Daufresne (*Bul. Soc. Chim. France, 4. ser., 3 (1908), No. 5, pp. 330–335; Ann. Chim. et Phys., 8. ser., 13 (1908), Mar., pp. 395–432*).—An extended study of tarragon essence and its constituents.

Fecal contamination of fruit and vegetables, A. Ressel (*Über fäkale Verunreinigungen auf Obst und Gemüse. Inaug. Diss., Univ. Berlin, 1907, pp. 27; abs. in Hyg. Zentbl., 4 (1908), No. 1, p. 16*).—Investigations showed that Coli bacilli are very generally found on fruit and vegetables, which the author believes points to wide distribution in the atmosphere, etc., of fecal contamination.

Meat and food inspection, W. Robertson (*Chicago, 1908, pp. X+388, figs. 40*).—In this handbook for students and others the author has dealt with such questions as housing of dairy stock, control of milk traffic, distribution of milk, slaughterhouses, and meat inspection, and with local enactments bearing upon the feeding and housing of animals and related questions with special reference to conditions in Great Britain. The book also contains a supplement, Regulations governing Meat Inspection in the United States, by M. Herzog.

Notices of judgment (*U. S. Dept. Agr., Notices of Judgment 5–11, pp. 10; 12–17, pp. 13; 18–21, pp. 7; 22–24, pp. 7; 25, pp. 11; 26–27, pp. 4*).—These Notices of Judgment have to do with the misbranding of vanilla extract, cider, eggs, cocain hydrochlorid, flour, a drug and a drug product, canned blackberries, the adulteration of milk, and the adulteration and misbranding of whisky, honey, vinegar, and molasses.

Pure food legislation, V. G. Heiser (*Ann. Rpt. Bur. Health Philippine Islands, 1907, pp. 26–41*).—The text is given of the Pure Food and Drugs Act of the Philippine Islands, which became effective in May, 1907. This law is practically identical with the United States Food and Drugs Act except for some modifications necessitated by local conditions.

Federal food laws. II, Meat and meat products, cider, fruit, vegetables, and eggs (*Pubs. Soc. Suisse Paysans, No. 27, pp. 148*).—A collection of Swiss pure food laws and enactments.

Food chemistry in the years 1906 and 1907, G. Fendler (*Ztschr. Angew. Chem., 21 (1908), Nos. 16, pp. 721–732; 17, pp. 769–777*).—A digest and discussion of work which has been published on methods of analysis, preservatives, meat and meat products, eggs, milk, and other foods and food groups, and related topics.

The household baker, J. J. Doherty (*Los Angeles, 1908, pp. 190, pl. 1*).—Recipes are given for the preparation of breads, pastries, desserts, candies, etc. Many of the dishes are those which are usually served in hotels and restaurants, but it has been the author's intention to give quantities suitable to household use. The volume is compiled on the basis of personal experience.

Cost of living in New Jersey (*Ann. Rpt. Bur. Statis. Labor and Indus. N. J., 30 (1907), pp. 141–157*).—The data summarized have to do with retail prices of foodstuffs for different New Jersey cities and towns for the month of June, 1907.

Report to the International Congress of Alimentary Hygiene on questions submitted, N. Zuntz (*Rev. Soc. Sci. Hyg. Aliment., 3 (1906), No. 5, pp. 749–762*).—The value of the respiratory quotient as a means of judging of the

function of a foodstuff, the definition of the term "foodstuff," the isodynamic replacement of nutrients in connection with the protein minimum and other questions are discussed.

Maintenance ration at different ages, E. Maurel (*Rev. Soc. Sci. Hyg. Aliment., 3 (1906), No. 5, pp. 763–854*).—A summary of available data and of the author's experiments, from which dietary standards are deduced for varying conditions of age, sex, body weight, activity, and surrounding temperature. For normal maintenance the author believes that the protein consumption need only slightly exceed 1 gm. per day per kilogram body weight during the first months after birth, and 1.75 gm. during infancy, gradually diminishing to 1.5 gm. during middle age and to less than 1 gm. during old age. He does not believe that smaller amounts than these are safe. On the same basis, the suggested energy requirement is 65 to 70 calories per day per kilogram of body weight at birth, 35 to 38 calories in middle life, 30 to 35 calories in the first period of old age, and 25 calories, or perhaps lower, in extreme old age.

School diet, P. Legendre (*Abs. in Rev. Sci. [Paris], 5. ser., 9 (1908), No. 23, p. 723*).—A discussion of the character and effects of the diet in French schools with reference to adequacy and hygienic requirements.

The author believes that children should not have meat until 7 years old and that the normal meat ration from 7 to 11 years is 100 to 120 gm., from 11 to 16 years 120 to 160 gm., and thereafter 200 gm. or more per day.

The régime and diet of a man engaged in intellectual work, M. de Fleury (*Rev. Soc. Sci. Hyg. Aliment., 3 (1906), No. 5, pp. 855–878*).—Chiefly a discussion of data relative to mental work and its relation to dietary requirements. Of 166 cases of sickness among brain workers of a sedentary life in which the symptoms were primarily those of nervous exhaustion, the author states that his diagnosis developed the fact that the great majority were due to errors in diet, as through overeating, abuse of meats, fatty foods, alcohol, coffee, tea, tobacco, and other stimulants. In his opinion the majority of brain workers over 40 years of age exercise too little and eat too much, and he proposes menus supplying about 82 gm. protein and 2,200 calories of energy per man per day, which he deems suitable for the average mental worker.

Chemical problems in hospital practice, O. Folin (*Jour. Amer. Med. Assoc., 50 (1908), No. 18, pp. 1391–1394*).—A summary and discussion of problems relating to nutrition, particularly phases of the creatin and creatinin question and other questions concerning metabolism.

The excretion of sulphurous acid by man in experiments with sodium sulphite, F. Franz and G. Sonntag (*Arb. K. Gsndhtsamt., 28 (1908), pp. 225–260; abs. in Chem. Zentbl., 1908, I, No. 15, pp. 1177, 1178*).—In a study of sulphurous acid, its sodium salts and their effects, it was found that the acid is very largely excreted in the urine as sulphate. However, with special precautions and within 10 minutes to a quarter of an hour after it was taken it was possible to detect SO_2 in the urine though the amount recovered was never greater than 1 per cent.

A respiration calorimeter, M. Letulle and Mlle. M. Pompilian (*Rev. Soc. Sci. Hyg. Aliment., 3 (1906), No. 4, pp. 645–665, figs. 14*).—The respiration calorimeter referred to in a previous note (E. S. R., 18, p. 962) is described in detail.

ANIMAL PRODUCTION.

Analyses of commercial feeding stuffs, B. L. Hartwell, J. F. Morgan, and L. F. Whipple (*Rhode Island Sta. Bul. 127, pp. 162–179*).—Analyses are reported of animal meal and bone, cotton-seed meal, linseed meal, gluten feed, brewer's grains, malt sprouts, wheat middlings, wheat bran, mixed feeds, prov-

ender, hominy meal, horse feeds, dairy and stock feeds, poultry feeds, dried beet pulp, and miscellaneous commercial feeds. Notes are given concerning the value of some of the samples analyzed.

Mealie meal. J. McCRAE (*Transvaal Govt. Labs. Ann. Rpt. 1906–7, p. 14*).—The average composition of a large number of samples of husked mealie meal analyzed is as follows: Moisture 11.94, protein 9.08, ether extract 3.49, nitrogen-free extract 73.86, crude fiber 0.67, ash 0.96 per cent, and of ground mealie meal, water 14.24, protein 8.74, ether extract 4.12, nitrogen-free extract 70.09, crude fiber 1.75, ash 1.06 per cent.

[Analysis of] rust affected straw. E. F. LADD (*North Dakota Sta. Rpt. 1907, pt. I, p. 42*).—In 6 samples of oat and wheat straw that had been affected by rust and analyzed to ascertain whether such straw retains its feeding value to a larger extent than straw not affected, the nutritive value was found to be not greater than that of the average straw which has not been affected seriously by rust. This would seem to indicate that not only is there less nutritive value contained in the kernel but there is also a deficiency of food material in the straw itself.

The adulteration of feeding stuffs. LEMMERMANN (*Illus. Landw. Ztg., 28 (1908), No. 85, pp. 733, 734*).—The author calls attention to the extent to which feeds now on the German market are adulterated, and advocates the passage of laws to prevent it. It was found that 80 per cent of all brands were adulterated. A sample of wheat bran contained 26 per cent of sand and a sample of barley bran 35 per cent of sand. A list of adulterated feeds is given.

Some recent feeding experiments. B. L. HARTWELL (*Rhode Island Sta. Bul. 127, pp. 143–161*).—This is a popular summary of recent feeding experiments at 18 experiment stations, prepared for the use of Rhode Island farmers.

Dried beet pulp as a feed for animals. L. MALPEAUX (*Sucr. Indig. et Colon., 72 (1908), No. 13, pp. 383–391*).—Four million tons of pulp are produced annually at the beet sugar factories of France. This must be removed in a very short time or it will decompose. Some is put into silos where it ferments with a loss of nutrients, although the digestion coefficient of the pulp is greater than that of beet roots, and the process renders the cellulose more digestible.

Analyses of pulp silage at different ages are given. At 8 months the total dry matter fell from 8.6 per cent to 5.92 per cent, the digestible protein from 0.135 to 0.082, and the carbohydrates from 2.76 to 1 per cent. Fermented pulp silage is thought to give a peculiar flavor to milk and to cause gastro-enteritis in children fed with such milk. Drying the pulp avoids this trouble, saves the loss by fermentation, and renders the material transportable. Drying the pulp by placing it in contact with sheet iron heated by steam is too expensive. In drying by hot air 60 to 70 carloads of coal are required to produce 100 carloads of dried pulp from 1,800 carloads of roots. The dried pulp should be soaked in water before it is fed to stock.

Tests with dairy cattle showed no appreciable difference in the flow of milk when fresh pulp and dried pulp were compared. Tests with sheep showed a greater gain in live weight with dried pulp, and this also appeared to be more palatable. Analyses of rations compounded with fresh and dried pulp are given.

Dried pulp as a food for cattle. P. DE GROULART (*Sucr. Indig. et Colon., 72 (1908), No. 14, pp. 418–420*).—Further notes as to the apparatus used for drying beet pulp noted above.

Beef production on high-priced land. H. J. WATERS (*Missouri Sta. Circ. Inform. 24, pp. 45, figs. 12; Ann. Rpt. Mo. Bd. Agr., 40 (1907), pp. 133–176*).—A summary of information, based largely on the station work, to show that by selecting good animals, providing suitable pasture in summer, and proper food

and care in winter baby beef can be produced at a profit on high-priced land. The silo is deemed as important on a beef as on a dairy farm. The summer season is the best time for the fattening period. "Obviously the man who raises cattle on high-priced land should feed them out as baby beef, and would have occasion to raise and feed in the same connection a large number of hogs, the legume area being especially adapted to the growing and finishing of hogs with a minimum loss from disease and with a maximum profit."

Experiments with diastasolin in the feeding of calves, E. HASELHOFF (*Fühling's Landw. Ztg., 57 (1908), No. 19, pp. 647–665*).—A ration of skim milk and diastasolin was much cheaper than whole milk, although at the commencement of the feeding period faster gains were made with the whole milk.

Mendelian characters among Shorthorn cattle, J. WILSON (*Sci. Proc. Roy. Dublin Soc., n. ser., 11 (1908), No. 28, pp. 317–324*).—The author has studied the data in volume 52 of the Shorthorn Herd Book to see if the Mendelian inheritance of coat color would throw any light on the origin of Shorthorn cattle. The results as expressed in Mendelian form are as follows: 95 reds crossed by reds produced 90 reds and 5 roans, 1 white crossed by white produced 1 white, 78 reds crossed by whites produced 78 roans, 370 roans crossed by roans produced 90 reds, 178 roans, and 102 whites, 426 roans crossed by reds produced 214 reds, 209 roans, and 3 whites, 53 roans crossed by whites produced 34 roans and 19 whites. These ratios show that the roan Shorthorn is a hybrid between two races, one white, the other red.

"It may be of some interest to show the colors of the calves when reds are crossed by roans—first, when the bull is red, and secondly, when the bull is roan. They are as follows: 150 red bulls produced from 150 roan cows, 86 reds, 63 roans, 1 white; 276 roan bulls produced from 276 red cows, 128 reds, 146 roans, and 2 whites."

Inheritance of coat color in the cattle of East Flanders, C. VAN DAMME (*Rev. Gen. Agron., n. ser., 3 (1908), No. 9, pp. 363–365*).—From a study of the herd book of the federation of breeders' associations of East Flanders for the years 1905–1907, the author finds that the red and white piebald is a very predominant color. When both parents were red and white the offspring were 96 per cent red and white, 2 per cent blue-gray, and 2 per cent black piebald. Blue-gray males crossed with blue-gray females gave 50 per cent blue-gray, 20 per cent black or black piebald, 20 per cent red piebald, and 10 per cent white. Blue-gray males crossed with black piebald females gave 40 per cent black or black piebald, 32 per cent blue-gray, 22 per cent red piebald, and 6 per cent white. Blue-gray males crossed with red piebald females gave 44 per cent red piebald, 20 per cent black or black piebald, 26 per cent blue, and 10 per cent white.

Cattle breeding in Zambi (*Bul. Off. État Indépend. Congo, 24 (1908), No. 6–9, Sup., pp. 195–200, pl. 1*).—The region about Zambi had 653 head of cattle January 1, 1908, a gain of 444 in the last 3 years. There are three types of cattle. The polled cattle are good grazers. Those with large well-formed horns are well adapted for dairying. The natural pastures are of good quality. On the bottom lands is a native grass, *Imperata cylindrica*, which is palatable when young and tender, but the best pastures are on the hillsides and high lands.

Ration experiments with lambs, 1906–7, G. E. MORTON (*Wyoming Sta. Bul. 79, pp. 3–14, figs. 3*).—Feeding tests since 1905–6 (E. S. R., 19, p. 266) are reported, each test lasting 14 weeks. When Shropshire-Merino lambs were divided into 2 lots of 40 each, the one receiving a ration of native hay, oats, and oil meal made an average gain per head of 20.3 lbs. at a cost of 6.63 cts. per pound, and the lot fed alfalfa hay and corn gained 34.3 lbs. per head at a cost of 4.26 cts. per pound. Of 2 lots of grade Cotswold lambs of 40 each, the

lot fed on peas in the field made an average gain per head of 18.3 lbs. at a cost of 7.6 cts. per pound, and the lot fed pea hay gained 5.8 lbs. at a cost of 8.67 cts. Shropshire-Merinos were also divided into 6 lots of 10 each, with the following results: The lot fed alfalfa hay and corn made a gain per head of 34.4 lbs. at a cost of 4.01 cts. per pound; the lot fed sweet clover hay, corn, and oil meal made a gain of 30.7 lbs. at a cost of 4.93 cts. per pound; the lot fed pea hay gained 16.9 lbs. at a cost of 3.68 cts. per pound; the lot fed native hay, Scotch barley, and oil meal gained 22.8 lbs. at a cost of 5.83 cts. per pound; the lot fed native hay, bald barley, and oil meal made a gain of 22.5 lbs. at a cost per pound of 5.83 cts.; and the lot fed native hay, spelt, and oil meal gained 13.8 lbs. at a cost of 9.07 cts. per pound.

"Scotch barley equals corn when fed with alfalfa hay. Alfalfa and ground flaxseed make a very satisfactory ration." Analyses of the feeds are given.

Rational sheep feeding, F. B. Mumford (*Missouri Sta. Circ. Inform. 25, pp. 15, figs. 3*).—A résumé of experiments at the station and elsewhere in feeding young lambs and in fattening growing lambs, together with a discussion of the feeding of breeding ewes.

"Lots receiving corn in the fattening ration, either in whole or in part, produced the best gains, were apparently in better finish, and in general were fed at a greater profit than the lots fed any other ration.

"A grain ration made up exclusively of wheat bran proved to be inferior for fattening lambs.

"The animals fattened on rape during the fall and in good condition at the beginning of the experiment were essentially as successful feeders as those in poorer condition that were pastured on grass during the same fall period."

Roots were a valuable addition to the grain ration. The use of a self-feeder was regarded as expensive. In the tests reported warm barns for fattening lambs were not found desirable. Shearing lambs in March produced an increased rate of gain, while shearing late in the fall is not deemed advisable.

The general management of sheep, A. Mansell (*Natal Agr. Jour., 11 (1908), No. 8, pp. 951–965*).—A popular article on sheep breeding and management.

Goat raising, with a description of German and Swiss breeds, G. Wilsdorf (*Die Ziegenzucht mit Ausführlicher Beschreibung der Deutschen und Schweizer Ziegenrassen und Schläge. Berlin, 1908, pp. VIII+228, figs. 52*).—A general treatise on goat breeding in Germany. A short historical sketch is followed by full descriptions of the principal breeds and their care and management in health and disease.

Feeds supplementary to corn for southern pork production, D. T. Gray, J. F. Duggar, and J. W. Ridgeway (*Alabama Col. Sta. Bul. 143, pp. 27–77*).—A summary of 3 years' work in feeding corn supplements to 90 hogs of somewhat better quality than the average hogs of the State. At the beginning of the test they averaged about 5 months of age and weighed about 70 lbs. each.

Money was always lost when corn was fed alone, as when so fed it realized on an average only 48 cts. per bushel. "When corn was supplemented with a partial ration of cotton-seed meal the daily gains and the financial outcome were satisfactory. Four deaths occurred as a result of the use of cotton-seed meal, but these deaths did not occur while the animals were eating the meal. All of the deaths have occurred soon after the animals were taken off of cotton-seed meal and placed upon a ration which contained no cotton-seed meal. This suggests the idea that cotton-seed meal may be stimulating in its effects—similar to the action of certain drugs—and when it is removed suddenly from the animals that death may occur through depression."

Peanuts made the most satisfactory pasture, soy beans ranking second. Tankage proved exceedingly satisfactory.

"Mature sorghum pasture has very little to recommend it as a feed for fattening swine. Both the gains and the financial outcome were unsatisfactory.

"When the sorghum was cut and carried to the hogs the results were better than when the hogs were made to graze the crop.

"The expense of extracting the juice from the sorghum and feeding the juice only prohibits its use in this way, although excellent daily gains were made. In no case was the juice found to be worth more than 1.8 cts. a gallon as a feed for hogs."

The results with various corn supplements for the past 3 years were as follows: When corn was fed alone the average daily gain was 0.69 lb. at a cost of 7.63 cts. per pound; with corn and cotton-seed meal 2:1 the daily gains averaged 1.04 lbs. at a cost of 5.75 cts.; with corn and tankage 9:1, 1.04 lbs. at a cost of 5.18 cts.; with corn and cowpeas 1:1, 0.94 lb. at a cost of 5.11 cts.; with corn and peanut pasture 1.01 lbs. at a cost of 3.2 cts. and with corn and sorghum pasture 0.37 lb. at a cost of 11.9 cts. With corn and cotton-seed meal 2:1 and peanut pasture the daily gains averaged 1 lb. at a cost of 2.14 cts.; with corn and cotton-seed meal 2:1 and sorghum pasture 0.46 lb. at a cost of 7.79 cts.; with corn and chufa pasture 0.72 lb. at a cost of 8.89 cts.; with corn and soy bean pasture 1.02 lbs. at a cost of 2.74 cts.; and with corn and cotton-seed meal 2:1 plus cut sorghum 0.75 lb. at a cost of 4.86 cts.

The cost of planting and cultivating the pasture is included in these figures. Corn was valued at 70 cts. and cowpeas at 80 cts. per bushel, and cotton-seed meal at $20 and tankage $40 per ton. "When hogs sell from 5 to 7 cts. a pound live weight the farmer can not afford to sell his corn for 70 cts. per bushel." Tables show the prices realized on each bushel of corn when hogs sold at various prices.

"While the results are not all in agreement, yet they seem to indicate that it is more often profitable to finish hogs upon dry feeds rather than to sell directly from pastures."

Slaughter tests were made, from which it is concluded that when hogs dress 72 per cent of the live weight it makes little difference whether they are sold at 5 cts. per pound live weight or 7 cts. per pound dressed weight if the expense of killing is not considered. At these prices, however, a hog that will dress 80 per cent is more profitably sold when dressed.

Swine feeding, C. A. Willson (*Missouri Sta. Circ. Inform. 28, pp. 16, figs. 3; Ann. Rpt. Mo. Bd. Agr., 40 (1907), pp. 216–231*).—A popular discussion of the care and management of swine, and of the investigations at several experiment stations on the subject.

The first farmers' bacon factory in the United Kingdom, L. M. Douglas (*Natal Agr. Jour., 11 (1908), No. 8, pp. 966–972, pl. 1*).—A study of the farmers' cooperative bacon factories which have stimulated the curing of bacon in Denmark, led to the formation of a cooperative factory at Roscrea, Tipperary County, Ireland, long noted as a pig-raising district. The factory has been in operation since January 2, 1908. There are about 28,000 shareholders. Two hundred pigs per week are handled, but the Wiltshire sides, sausages, and black puddings produced are not sufficient to supply the home demand.

Feeding and care of horses, E. A. Trowbridge (*Missouri Sta. Circ. Inform. 27, pp. 10, figs. 3; Ann. Rpt. Mo. Bd. Agr., 40 (1907), pp. 206–231*).—Contains general information regarding the feeding and care of stallions, breeding mares and foals, growing horses and work horses.

Dried potatoes as a food for horses, E. Parow (*Ztschr. Spiritusindus., 31 (1908), No. 42, pp. 462, 463*).—Additional notes (E. S. R., 19, p. 570), wherein

the author states that dried potatoes are much cheaper than oats and pound for pound are as valuable as a feed for horses.

The relation between form and function, with special reference to the horse, S. von Nathusius (*Fühling's Landw. Ztg., 57 (1908), No. 12, pp. 417–429, figs. 4*).—The author believes that a correlation exists between form and function, pointing out that a comparison of the forms of the greyhound and the thoroughbred horse, both of which have been bred to run at a high rate of speed for short distances only, shows a close resemblance, whereas the foxhound and the hunter, which must maintain a good speed for long distances have a form quite different. A large number of measurements on horses of different breeds are presented in support of the views of the author, who maintains that animals must be bred for a single purpose and that to obtain a certain function the breeder must consider the form in choosing the breeding stock.

The influence of eggshell on metabolism during incubation, F. Tangl and G. Hammerschlag (*Arch. Physiol. [Pflüger], 121 (1908), No. 8–10, pp. 423–436*).—Experiments with hens' eggs showed that both the shell and membrane lining it play a part in the development of the chick. During incubation organic and inorganic material disappear from the shell, the former in larger proportion. Of the total material thus removed more than half is organic material when expressed on a water-free basis. The greater part of the inorganic material thus removed consists of calcium.

According to the authors' figures, the shell of an egg weighing 60 gm. loses during incubation 0.4 gm. dry matter, of which 0.15 gm. is calcium and 0.2 gm. organic material.

The experimental data furnish an explanation of the well-known fact that eggshells become more fragile during incubation.

Breeds of poultry described and illustrated, O. Trieloff (*Das Grossgeflügel in Wort und Bild. Magdeburg, [1908], pp. 80, figs. 37*).—This work treats of the peacock, turkey, pheasant, goose, duck, bantam, guinea, and common fowl. Many and little known breeds are included.

Preservation of eggs, F. Prall (*Ztschr. Untersuch. Nahr. u. Genussmtl., 14 (1907), No. 7, pp. 445–481; abs. in Zentbl. Agr. Chem., 37 (1908), No. 7, pp. 486–489; Hyg. Viande et Lait, 2 (1908), No. 8, pp. 362–367.*)—Eggs kept in closed glass vessels embedded in sand spoiled in 6 weeks, thereby indicating the necessity of ventilation. Kept in cool cellars with good ventilation they remained fresh as long as when packed in sand, straw, or other material. Eggs coated with paraffin or with hydrofluosilicic acid soon spoiled. Better results were obtained by coating with shellac. Preservation by coating with permanganate of potash or a solution of water glass or Hanika's method of dipping in hot water and alcohol gave good results. A 10 per cent solution of water glass is considered the best liquid preservative, although glycerin, limewater, and a 3 per cent solution of water glass are good. In practice, dry preservation in cold storage near the freezing point with an atmosphere of 80 per cent humidity is especially recommended.

DAIRY FARMING—DAIRYING—AGROTECHNY.

Cropping systems for New England dairy farms, L. G. Dodge (*U. S. Dept. Agr., Farmers' Bul. 337, pp. 24, figs. 2*).—Typical farms, representing the best methods in the different sections of New England, are described to show what may be accomplished to increase the amount of milk and butter that can be produced per acre. A short rotation, which will include clover and corn silage, is recommended.

"In the most northern sections such as northern Maine, where corn is out of the question and potatoes fill the place of corn in a rotation, silage can still be made from Japanese millet or other crops and succulent winter feed thus provided. Clover and Italian rye grass are successfully used for silage in the State of Washington. This combination is worthy of trial in northern Maine."

On the feeding value of alfalfa, J. J. HANSEN (*Landmandsblade, 41 (1908), No. 21, pp. 275–278*).—A feeding trial with 40 cows lasting 140 days is reported, in which the comparative feeding value of sunflower-seed cake and green alfalfa was studied. The results suggest that 6 to 7 lbs. of green alfalfa have a nutritive value similar to that of ¾ lb. of sunflower-seed cake when fed to cows, whether these are pastured a portion of the day or fed wholly in the stable.

Comparison of cotton-seed meal and hulls with cold pressed cake as a dairy feed, J. G. LEE, Jr., and T. E. WOODWARD (*Louisiana Stas. Bul. 110, pp. 3–22*).—Experiments were undertaken in cooperation with the Bureau of Animal Industry of this Department to determine the true value of cold pressed cotton-seed cake, a comparison being made with a mixture of cotton-seed meal and hulls 2:1. Twelve cows were divided into 2 lots and fed for 2 periods of 28 days each. In the first period lot 1 received a maintenance ration of alfalfa hay and hulls 2:1 at the rate of 2 lbs. of the mixture for each 100 lbs. live weight, and in addition, a ration for milk production consisting of cotton-seed meal, cotton-seed hulls and corn meal 2:1:3 at the rate of 1 lb. of the mixture for every pound of milk produced. The 6 cows produced 3,535 lbs. of milk, at an average cost of 1.048 cts. per pound. Lot 2 received the same ration as lot 1, except that cold pressed cake was substituted pound for pound for the cotton-seed meal and hulls of the milk ration. The 6 cows in this lot gave 3,774.8 lbs. milk at a cost of 1.033 cts. per pound. During the second period the rations of the 2 lots were reversed, when lot 1, receiving the cold pressed cake, made 3,358.5 lbs. at a cost of 1.77 cts. per pound, and lot 2, on the hulls and cotton-seed meal, produced 4,043.3 lbs. of milk at a cost of 1.892 cts. per pound.

"Cold pressed cotton-seed cake is not as valuable for milk and butter production as an equal weight of choice cotton-seed meal and hulls mixed in the proportion of 2 parts of meal to 1 part of hulls. The analysis of cold pressed cake is a reliable indication of its feeding value." A table shows the estimated value of cold pressed cake as compared with cotton-seed meal and hulls at different prices. Analyses are reported of the feeds used in the tests.

Silos and silage in Maryland, H. L. CRISP and H. J. PATTERSON (*Maryland Sta. Bul. 129, pp. 78, figs. 74*).—This bulletin treats of the construction of wood and concrete silos, with illustrations and descriptions of about 70 silos now in use in Maryland. The various silage crops and their uses for different animals are discussed. A table showing the chemical composition of various silage crops is given, this including analyses made at the station of refuse from corn and pea canneries.

Feeding the dairy cow, C. H. ECKLES (*Missouri Sta. Circ. Inform. 26, pp. 17, figs. 5; Ann. Rpt. Mo. Bd. Agr., 40 (1907), pp. 190–206*).—Popular suggestions for the use of dairy farmers, with special reference to Missouri conditions.

Investigations on the effect of food fat upon the milk production of cows (*Bericht des Deutschen Landwirtschaftsrats an das Reichsamt des Innern betreffend Untersuchungen über die Wirkung des Nahrungsfettes auf die Milchproduktion der Kühe. B. Spezialberichte der Versuchsansteller. Berlin, 1907, pp. 411*).—A summary of this work has been previously noted (E. S. R., 19, p. 75).

The existence of a lactase in cow's milk, A. J. J. VANDEVELDE (*Acad. Roy. Belg., Bul. Cl. Sci., 1908, No. 5, pp. 563–577; Biochem. Ztschr., 11 (1908), No.*

1–3, pp. 61–66; abs. in Chem. Centbl., 1908, II, No. 9, pp. 815, 816).—The author continued the researches previously noted (E. S. R., 19, p. 777), with special reference to the question "Does cow's milk contain enzyms that are able to break down lactose in the absence of a lactic-acid bacteria?" Samples of milk were treated with iodoform, formaldehyde, and heat to render them germ free and kept at a temperature of 37.5° C. From a study of the chemical changes that took place the author concludes that lactase must be present in milk.

On the presence of hemolytic factors in milk, JANET E. LANE-CLAYPON (*Jour. Path. and Bact., 13 (1908), No. 1, pp. 34–37*).—"Milk when fresh contains both complement and amboceptor in about one-tenth strength that of serum.

"In order to obtain hemolysis, 'ox colloid' must be added, thus confirming Bordet's observations.

"On adding blood cells, which are capable of being hemolyzed by fresh ox serum to milk, the cream picks up the corpuscles and carries them to the top, forming a bright red plug. This plug is absent with milk heated for a few minutes to 70° C., and may be used as a test for heated or pasteurized milk."

A review of the literature on the transmission of immunity by milk is included.

Effect of heating upon the determination of leucocytes in milk, H. L. RUSSELL and C. HOFFMANN (*Amer. Jour. Pub. Hyg., 18 (1908), No. 3, pp. 285–291*).—The authors made a series of studies to compare the leucocyte content in raw and in heated milks.

Out of 60 examinations 50 showed an increased number of cellular elements in the sample heated to 70° over the unheated. When 31 samples were heated at different temperatures between 50 and 80° C., the most marked variation in cell content occurred between the temperatures of 60 and 70°.

Tests were made to ascertain if leucocytes were enmeshed by fat globules as they rise to the surface. As heating diminishes the creaming power of milk, a comparison was made of the supernatant liquid of unheated milk and that of heated milk after each had stood for 24, 48, and 72 hours. The average percentage of the original number found in the supernatant liquid of unheated milk was 74.5, and in milk heated to 70°, 3.54, which "leaves no doubt but that many of the cell elements in milk are not recovered in the sediment produced by centrifugalization under customary conditions. . . . A momentary exposure at 70° or above, or a more prolonged heating for a few minutes at 60° will so alter the physical arrangement of the fat globules in milk that practically all of the cellular elements may be recovered."

A preliminary note on a group of lactic-acid bacteria not previously described in America, E. G. HASTINGS (*Science, n. ser., 28 (1908), No. 723, p. 656*).—The author has found a lactic-acid bacterium which apparently belongs to the same class as those found in yoghourt and in Swiss cheese.

Bacteria in yoghourt, M. KLOTZ (*Centbl. Bakt. [etc.], 2. Abt., 21 (1908), No. 13–14, pp. 392–398, figs. 3*).—A review of the literature on yoghourt. See also a previous note (E. S. R., 19, p. 1076).

Yoghourt, W. HENNEBERG (*Milch. Ztg., 37 (1908), No. 43, pp. 506–508; Ztschr. Spiritusindus., 31 (1908), No. 39, pp. 425, 426*).—A popular article on the nature and the methods of preparing yoghourt.

The improvement of the milk supply, I. C. WELD (*Mo. Bul. Ind. Bd. Health, 10 (1908), No. 9, pp. 100–102*).—A lecture before a conference of the State board of health with dairymen, giving results of an examination of dairy conditions in the State. "Out of the 91 places inspected, the highest scoring dairy was entitled to 84.4 points out of a possible 100. The lowest scoring dairy was

entitled to only 12.8 points. The average score of the entire 91 places inspected was 36.25 points."

Necessity for a standard of cleanliness in all milking competitions at agricultural shows, J. Howard-Jones (*Jour. Roy. Sanit. Inst., 29 (1908), No. 10, pp. 576–580*).—The observations of the author, who attended a milking competition at a leading agricultural show, would seem to indicate a general lack of cleanliness among the milkers. The cows were not groomed and but one milker rejected the first flow of milk. The author suggests that more attention should be paid to the hygiene of the milker.

The history of milk hygiene to the middle of the nineteenth century, W. Hanauer (*Hyg. Rundschau, 18 (1908), No. 20, pp. 1201–1214*).—A brief review of German work on this subject.

Dairy products in Switzerland in 1907, Leopold (*Mitt. Fach Ber. Erstat. K. K. Ackerb. Min. [Vienna], 1908, No. 9, pp. 6, 7*).—Contains statistics of the amount and value of exports and imports of dairy products in 1906 and 1907.

Report of the Bernese dairy school, A. Peter (*Jahresber. Molk. Schule Rütti-Zollikofen, 21 (1907–8), pp. 56, figs. 3*).—This report includes analyses of milk, cream, and butter, and a summary of the work done at this institution.

[Analyses of milk, condensed milk, and butter], J. McCrae (*Transvaal Govt. Labs. Ann. Rpt. 1906–7, pp. 9–13*).—The proportion of adulterated samples of all milk examined was 15.87 per cent. Added preservatives were found in 6 cases. The proportion of fat in full cream condensed milk increased the past year.

Contributions from the dairy institute of Greifswald. I, The advantages of formalin as a preservative in the manufacture of butter and cheese, R. Eichloff (*Milchw. Zentbl., 4 (1908), No. 3, pp. 115–119; abs. in Centbl. Bakt. [etc.], 2. Abt., 21 (1908), No. 17–19, pp. 584, 585*).—The addition of 1 part of formalin to 10,000 parts of milk slightly hinders the separation of cream. Formalin doubled the length of time required for souring when added to raw or pasteurized cream or to cream inoculated with a pure culture of lactic-acid bacteria. It is suggested that in practical butter and cheese making it may be an advantage to add formalin when slow ripening of cream or curd is desired.

Studies on the rational manufacture of Grana cheese, C. Gorini (*Centbl. Bakt. [etc.], 2. Abt., 21 (1908), No. 10–12, pp. 309–317; Milchw. Zentbl., 4 (1908), No. 6, pp. 241–250*).—A second report (E. S. R., 19, p. 574) on the causes of the defects in Grana cheese. It is considered that the cheese would be of better quality and of a more uniform character if more attention was given to the hygiene of the milk from which it is made and if pure cultures were used. As now manufactured the variety of organisms present tend to make the cheese variable in texture, color, and flavor.

Some essentials in cheese making, C. A. Publow (*New York Cornell Sta. Circ. 3, pp. 17–24, fig. 1*).—An outline of the best method of Cheddar cheese making is presented with a discussion of important factors. "The most important step in cheese making is to have the curd firm in the whey before the required amount of acid has developed." Directions for using the acidimeter are given in detail.

Defects in American Cheddar cheese, C. A. Publow (*New York Cornell Sta. Bul. 257, pp. 3–16*).—A ready reference list of the causes of defects in flavor, texture, color, and finish of American Cheddar cheeses and their remedies.

Investigations of a severe disease of Gorgonzola cheese, C. Gorini (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 17 (1908), 1, No. 8, pp. 568, 569; abs. in Chem. Zentbl., 1908, II, No. 1, p. 89*).—Preliminary notes of a disease that yellows and softens the texture and produces an abnormal odor in

Gorgonzola cheese. The author thinks it appears simultaneously with *Oïdium lactis*, and allied species of bacteria.

Trials of new dairy appliances, B. MARTINY (*Arb. Deut. Landw. Gesell., 1908, No. 144, pp. 68, pl. 1, figs. 30*).—Results of a trial of new kinds of separators recently placed on the market are given, and a contrivance for disinfecting a cow's udder is figured and described. This consists of a waterproof canvas which can be strapped to the animal so that the disinfecting liquid will come in contact with the udder for several minutes.

The Dalén and Celsing milking machine (*Nord. Mejeri Tidn., 23 (1908), No. 21, pp. 246, 247*).—A brief description of a new Swedish milking machine.

A practical milk cooler, H. J. GERSTENBERGER (*Jour. Amer. Med. Assoc., 51 (1908), No. 16, pp. 1328, 1329, fig. 1*).—A description of a galvanized cooling can made to accomodate a 5 gal. milk can.

Unfermented apple juice, H. C. GORE (*U. S. Dept. Agr., Bur. Chem. Bul. 118, pp. 23, figs. 4*).—This bulletin gives results of experiments since 1906 (E. S. R., 19, p. 276), on the preservation of unfermented apple juice. The usual objections to sterilizing, that a cooked taste is added to the juice and that it remains sterile for a limited period only, have been met. By using a pasteurizer costing $12 apple juice was heated from 65 to 70° C. and kept in paraffined kegs for 6 months without loss from fermentation. It can also be successfully sterilized in tin containers, but heating to a temperature of 65° C. for a half hour was not quite sufficient to sterilize all the varieties tested. The best treatment for sterilizing in glass was found to consist in heating for 1 hour at 65° or one-half hour at 70° C. The latter temperature did not produce a marked loss in flavor.

In clarification tests, large quantities of sediment were removed by passing juice from apples ground the previous evening through a cream separator, but clarification was not so complete as with perfectly fresh juice the previous year. Before canning or bottling apple juice it may be carbonated, although a foreign flavor is added. When benzoate of soda was added to unfermented apple juice in quantities varying from 0.03 to 0.15 per cent alcoholic fermentation was checked, but acetic acid and other fermentations developed with a consequent depreciation in flavor.

Improved methods of wine making, F. T. BIOLETTI (*California Sta. Bul. 197, pp. 159–168, fig. 1*).—The main work in enology has been to demonstrate and popularize certain principles and methods of wine making which have been shown to be useful by the experiments at this station. The new method of wine making (E. S. R., 17, p. 1187) has given good results, but improved varieties of grapes must be grown for the best results in the interior valleys.

The best yeast tested at the station was one originating in Champagne and is strong enough to ferment wines perfectly dry with over 15 per cent of alcohol. "It can withstand as high temperatures and as large an amount of sulphurous acid as any of our native yeasts which have been tested. One of its principal advantages is its tendency to form a concrete sediment, which remains at the bottom of the fermenting must or wine, and very much facilitates the racking and clearing. It has also been found equally suitable for champagne and cider-making. . . . The utility of pure yeast in our California wineries may be considered as demonstrated, but too much must not be expected of it. It will not prevent the ill effects of careless or ignorant practice, and no wine maker who can not make good wine without pure yeast will succeed with it."

Considerable attention has been given to the testing of the color capabilities of various varieties in different sections and to the devising of methods of utilizing economically the color which exists in the grapes now grown. The color of

all varieties is less in quantity and less stable in character in the warmer climates and richer soils. "For the San Joaquin Valley the best grapes for color, of those commonly grown in the State, are St. Macaire, Gros Mansenc, and Barbera, in the order named. Wines made from these varieties at Tulare and Fresno have from half again as much to three times as much color as the Bouschets, and the tint is better and more stable."

Experiments showed that at the end of 10 months wines made by heat extraction had lost 48 per cent of their color and those by the ordinary method 55 per cent. The color remaining in the pressed pomace can be extracted and utilized by refermenting with white or lightly colored grapes.

The varieties of grapes which have given good results in the coast region failed to produce good dry wines in the hot interior, though many of these varieties could be used successfully if they could be blended in the fermenting vat, or soon after, with 25 to 50 per cent of other varieties. Valdepeñas has proved the most satisfactory variety as a dry wine grape for the interior valleys, though unsatisfactory in cool regions. Dry white wines of fair quality can be made in the hot interior districts more easily than red, but have some of the same defects, namely, lack of acidity, flavor and freshness. Burger has been found to be a variety peculiarly suited to these regions, yielding a neutral, clean tasting wine, which only requires blending with a full flavored wine from the coast regions to be worthy of aging and bottling. The white varieties which have developed the highest acidity have been West White Prolific and Vernaccia Sarda. Johannisberger and Franken Riesling have given unexpectedly good results in the San Joaquin Valley.

The rôle of malic-acid fermentation in the manufacture of wine, A. Rosenstiehl (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 2, pp. 150–153; abs. in Jour. Soc. Chem. Indus., 27 (1908), No. 16, pp. 870, 871*).—The proportion of malic acid is important, as carbonic acid is necessary to protect the wine from premature decay and is produced from malic acid by the action of *Micrococci malolacticus*.

Artificial refrigeration in enology, R. Pini (*Rev. Vit., 30 (1908), No. 775, pp. 449–456; Bul. Assoc. Chim. Sucr. et Distill., 26 (1908), No. 4, pp. 256–266*).—This is a paper read before the First International Congress on Refrigeration, held at Paris, 1908, in which the author relates the advantages of artificial refrigeration, and the various processes of making and storing wines.

VETERINARY MEDICINE.

Animal industry and animal diseases in German Southwest Africa, W. Rickmann (*Tierzucht und Tierkrankheiten in Deutch-Südwestafrika. Berlin, 1908, pp. XII+364*).—The natural conditions in German Southwest Africa are favorable for grazing on a large scale in some localities and for raising fine stock on a small scale in other localities. The author suggests means for the improvement of horses, cattle, sheep, goats, hogs, and poultry and for the more economic management of animal industry.

The larger part of the volume is occupied with a detailed discussion of the diseases which affect animals in German Southwest Africa. Particular attention is given to malaria of horses, glanders, strangles, tetanus, rinderpest, Texas fever, pleuro-pneumonia, anthrax, blackleg, mange, fowl cholera, East coast fever, tuberculosis, rabies, swine plague, and a large number of accidental and organic diseases. Directions are given for carrying out simple and complex surgical operations and for the care of instruments and the administration of remedies.

Meat inspection and diseases of animals, J. B. Cleland (*Jour. Dept. Agr. West. Aust., 16 (1908), No. 2, pp. 119–126, pl. 1*).—Detailed statistical notes are

given on the number of cattle, sheep, calves, pigs, and goats slaughtered for food during the year 1906–7, together with a statement of the number of animals and parts condemned and the causes of condemnation.

Public abattoirs a necessity to eradicate consumption, etc., W. Holder (*Jour. Roy. Inst. Pub. Health, 16 (1908), No. 3, pp. 166–171*).—Attention is called to the frequency with which meat inspectors detect cases of anthrax, cysticerci, trichina, tuberculosis, and other diseases of animal parasites which may be transmitted to man. Meat inspectors are, therefore, considered as performing an important function in the protection of human health. It is recommended that laws should be passed requiring the erection and use of public abattoirs in every town and village.

The cat: A neglected factor in sanitary science, Caroline A. Osborne (*Pedag. Seminary, 14 (1907), No. 4, pp. 439–459*).—On account of the intimate association of the cat with other species of domestic animals and with man, and particularly children, it has seemed advisable to study the possibly important agency of the cat in the intertransmission of infectious diseases.

According to the results obtained by various investigators cats are susceptible to the majority of infectious diseases which attack man and animals. Even if the cat does not become infected with the disease it is still possible for this animal to transmit the disease upon its fur. Notes are given on the evidence thus far obtained connecting cats with the transmission of mange, diphtheria, scarlet fever, tuberculosis, smallpox, anthrax, malignant edema, ringworm, and a great variety of external and internal animal parasites. The author concludes that cats should be kept away from all sources of infection in order to prevent the unnecessary spread of infectious diseases.

The relation of the soil to certain diseases, Ludewig (*Ztschr. Veterinärk., 20 (1908), No. 3, pp. 108–112*).—According to the universal experience of veterinarians the soil is concerned in the transmission of such diseases as anthrax, blackleg, hemorrhagic septicemia, and swine erysipelas. Attention is called to the importance of preventing the excessive contamination of soil with the virus of these diseases, for after the soil has once become contaminated it is a difficult matter to disinfect it.

A theory of natural immunity of living tissue, F. Holzinger (*München. Med. Wchnschr., 55 (1908), No. 12, pp. 691, 692*).—In the opinion of the author living tissue at times is immune for the reason that the osmotic process in it hinders the development of micro-organisms. A considerable diminution in this activity is necessary before the micro-organisms can develop and produce a general infection.

Hemolysis and antihemoglobin, O. Demees (*Cellule, 24 (1907), No. 2, pp. 421–456*).—The experiments reported by the author were carried out on rabbits. It appears possible to obtain sera which contain antihemoglobin but are not hemolytic. Antihemoglobin and hemolysin are therefore distinct. Uninjured red blood corpuscles do not fix antihemoglobin and this substance has no effect upon the hemoglobin contained in the intact corpuscle.

Experiments with Bacterium anthracis, anthrax vaccines, and hyperimmunization, H. J. Milks (*Louisiana Stas. Bul. 109, pp. 3–21*).—As the result of experiments made in growing the anthrax bacillus upon different media liable to be found in pastures it is concluded that the organism will grow in low swampy places and even in any place where sufficient moisture is present. It is thought this may possibly explain its prevalence in certain years. Several experiments with guinea pigs, mice, rabbits, and sheep, made to determine the virulence of different commercial anthrax vaccines, resulted in the finding of a large variation.

In the immunity experiments 2 sheep that had survived the infection of one-half loop of agar culture were inoculated repeatedly at intervals of about 2 weeks with increased doses. "The inoculated material was from 24-hour agar cultures washed off and suspended in sterile water. The inoculations were made on the inside of the thigh in each case. No more serious symptoms developed than a slight swelling at the point of inoculation and a slight elevation of temperature."

An appended summary of data regarding the disease has been previously noted (E. S. R., 12, p. 787).

The application of atoxyl in veterinary medicine, Walther (*Berlin. Tierärztl. Wchnschr., 1908, No. 15, pp. 265, 266*).—Clinical notes, together with a statement of the results obtained, are given for a number of cases in which atoxyl was used in the treatment of hemoglobinuria and pneumonia in horses. Atoxyl appeared to have very little beneficial effect in the control of hemoglobinuria but a considerable percentage of cases of pneumonia were beneficially affected. In 2 cases, however, no effect of the atoxyl was to be observed.

Treating rabies with atoxyl, B. Heymann (*Ztschr. Hyg. u. Infektionskrank., 59 (1908), pp. 362–366*).—On account of the favorable results reported by a number of investigators from the use of atoxyl and other arsenical compounds in treating diseases caused by trypanosomes the author tested atoxyl in the treatment of rabies. The experimental animals were rabbits which received intramuscular inoculations of fixed virus. The animals were then treated subcutaneously or intravenously with daily doses of atoxyl ranging from 0.01 to 0.1 gm. No beneficial results were observed. In fact some of the animals succumbed sooner than would have been the case without the use of atoxyl. In view of the results obtained the author believes that neither trypanosomes nor spirilla can be considered as playing an etiological rôle in rabies.

Infection and immunization of mice against rabies through the alimentary tract, R. Repetto (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 15, pp. 716–718*).—Previous investigators have indicated the possibility of infecting and immunizing mice through the ingestion of rabies virus. The author soon found in his investigations that the ingestion of rabies virus exercised a more or less pronounced effect in immunizing mice against a subcutaneous inoculation with street virus. All the rats with which the author experimented died of rabies as result of feeding on rabies virus and 75 per cent of the mice were also fatally infected by feeding upon virus for 1 month. After mice and rats had been immunized by ingestion of an attenuated virus they proved to be resistant to subcutaneous inoculation. In further experiments with 10 mice it was found that feeding for some time upon normal nerve substance brought about a quite pronounced degree of immunity to rabies.

The hereditary transmission of immunity to rabies, P. Remlinger (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 7, pp. 321–323*).—In order to gain fresh evidence on the possibility of the transmission of immunity to rabies in animals the author experimented with rabbits. Experimental female rabbits were immunized shortly before the period of gestation and in some cases naturally immune males were used in breeding experiments. Results obtained by the author indicate that immunity is never transmitted by the male, while the female may transmit immunity in a considerable percentage of cases. Nevertheless under identical conditions such transmitted immunity may be fleeting and of low power. The blood of young animals which have acquired immunity by hereditary process appears not to have any immunizing value.

Biological and pathogenic properties of Sterigmatocystis lutea, Sartory and Jourde (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 10, pp. 548, 549*).—When rabbits are inoculated in the peripheral vein of the ear with

Sterigmatocystis lutea, serious lesions are produced in various parts of the body. This species of fungus appears to possess a very marked pathogenic power even higher than that of *Aspergillus fumigatus*.

The treatment of trypanosomiases, A. Laveran and A. Thiroux (*Ann. Inst. Pasteur, 22 (1908), No. 2, pp. 97–131*).—A number of arsenical preparations were used in the treatment of guinea pigs artificially inoculated with trypanosomes, chiefly *Trypanosoma gambiense*. A mixture of atoxyl and biniodid or bichlorid of mercury produced a cure in 3 out of 12 cases. Atoxyl alone appeared to be without any pronounced effect. Arsenious acid used alone gave variable results. The effect was more pronounced when the intervals between the doses were short. It appears to be best to administer arsenious acid by way of the mouth. Trisulphid of arsenic produced a cure in 6 out of 13 cases when used in a colloidal solution either as a hypodermic injection or administered by way of the mouth.

Experimental studies on tuberculosis, E. Levy, F. Blumenthal, and A. Marxer (*Centbl. Bakt. [etc.], I. Abt., Orig., 46 (1908), No. 3, pp. 278–285*).—The attempt has previously been made to find more or less indifferent substances in which tubercle bacilli could be gradually attenuated. The authors experimented with galactose, glycerin, and urea, tubercle bacilli subjected to the influence of these substances being tested for virulence by inoculation into guinea pigs.

It was found that tubercle bacilli are killed by maintaining them for 4 to 5 days in a 25 per cent solution of galactose when added at the rate of 5 mg. of bacteria per 4 cc. of the medium. After remaining 1 day in a concentration of 5 mg. bacteria per 4 cc. of an 80 per cent solution of glycerin, tubercle bacilli were so attenuated as not to be pathogenic for guinea pigs except in large doses. In a 25 per cent solution of urea the tubercle bacilli, when added at the rate of 5 mg. per 4 cc. of the solution, lost their virulence completely after 2 days.

Tuberculous infection through the alimentary canal, M. P. Ravenel and J. Reichel (*Jour. Med. Research, 18 (1908), No. 1, pp. 1–18*).—In order to test the power of tubercle bacilli to penetrate through the walls of the alimentary tract, guinea pigs were inoculated with an emulsion of tubercle bacilli in doses of 2 cc. directly into the stomach. This method of procedure was adopted in order to avoid infection of the cervical lymph glands.

Tuberculous lesions were found generally distributed in various organs, and in about 56 per cent of cases the tubercle bacilli reached the lungs within 24 hours after introduction into the stomach. While the results obtained from these experiments are not considered sufficiently positive to exclude the possibility that infection may have taken place through the blood to some extent, yet the distribution of the lesions convinced the authors that the bacilli passed through the alimentary tract.

Tuberculous infection and the diagnosis of this disease, S. Arloing and L. Thévenot (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 11, pp. 561–563*).—An invasion of tubercle bacilli may produce a latent infection which disappears without producing any lesions at the point of infection. The greater or less limitation of the anatomical signs of infection depends upon the virulence of the bacilli and the relative immunity of the animal. Since the primary lesions of tuberculosis may be very slight, it is easy to understand that an experimental diagnosis by means of tuberculin may be depended upon as reliable even in the absence of readily detected post-mortem lesions.

The susceptibility of mammals to tuberculin, A. Marie and M. Tiffeneau (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 11, pp. 501, 502*).—New-born animals endure an extremely large dose of tuberculin administered hypodermic-

ally. If healthy rabbits are injected with tuberculin and receive a second dose within 17 hours the second dose like the first is without any injurious effects.

The simultaneous application of tuberculin by the hypodermic, ophthalmic, and cutaneous methods, U. Selan (*Clin. Vet. [Milan], Sez. Prat., 31 (1908), No. 12, pp. 195–198*).—A tuberculin test was made on 22 cattle, to which the three methods of using tuberculin were applied simultaneously. The hypodermic method gave reliable negative or positive results according as the animal was free from or affected with tuberculosis, the cutaneous and ophthalmic methods, on the other hand, being negative in all cases.

Ophthalmo and cuti-reaction in bovine tuberculosis, Garth, Kranich, and Grünert (*Deut. Tierärztl. Wchnschr., 16 (1908), No. 14, pp. 197–202*).—In testing the ophthalmo-reaction and cuti-reaction to tuberculin the authors found that no reaction could be obtained unless a strong tuberculin was used. It also appeared to be necessary to proceed with unusual caution, otherwise the experiment was in all cases doomed to failure.

The cutaneous and conjunctival reaction to tuberculin, H. Wildbolz (*Berlin. Klin. Wchnschr., 45 (1908), No. 11, pp. 545, 546*).—The experiments reported in this paper were made on rabbits, which the author believes to be better adapted for experimental tests with tuberculosis than are guinea pigs. The conjunctival reaction was in all cases of shorter duration than the cutaneous reaction. The former reached its maximum after about 8 to 10 hours and disappeared after 48 hours. The cutaneous reaction reached its highest point on the second or third day and persisted for 4 or 5 days.

The specific value of conjunctival reaction to tuberculin, F. Arloing (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 15, pp. 722–724*).—In the experiments carried on by the author it appeared that the conjunctival reaction to tuberculin is not specific. When tuberculin was instilled into the eye 6 hours after an injection of diphtheria toxin a pronounced general reaction took place with all of the usual symptoms observed in a positive tuberculin test.

The increased susceptibility to tuberculosis as a result of tuberculin injection, A. Slatineano and D. Danielopol (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 9, pp. 418, 419*).—In experiments with guinea pigs it was found that no increased susceptibility to tuberculosis was apparent after the injection of tuberculin until 4 days had elapsed. On the fifth day a considerably increased susceptibility was apparent, the guinea pigs developing very acute and generalized cases of tuberculosis when inoculated with virulent tubercle bacilli 5 days after the tuberculin injection.

The passage of tubercle bacilli into the milk, A. Coquot (*Bul. Soc. Cent. Méd. Vét., 85 (1908), No. 6, pp. 146–152, fig. 1*).—Tubercle bacilli were introduced directly into the mammary artery of a cow and this cow was later slaughtered and examined with reference to the possible location of the tubercle bacilli. Soon after inoculation the milk was examined at frequent intervals to determine whether tubercle bacilli had passed into it. The temperature of the animal was somewhat elevated by the inoculation but no inflammation occurred in the udder. Milk drawn from the udder under careful aseptic precautions was used in inoculating guinea pigs but proved in every instance not to be tuberculous.

The milk of reacting but not clinical cases of tuberculosis in cows, R. Ostertag (*Ztschr. Fleisch u. Milchhyg., 18 (1908), No. 7, pp. 205–211*).—The results obtained by various investigators in studying the milk of cows which react to tuberculin but do not show clinical signs of tuberculosis are critically reviewed by the author and a brief account is given of experiments recently undertaken by him along this line. The milk of 18 reacting cows was inoculated into guinea pigs without producing any result and similar negative results

were obtained from inoculating pigs and feeding calves. These experiments were continued for 2 to 5 months.

Similar negative results were obtained by Müller with the milk of 9 cows, Ascher with the milk of 7 cows, and Stenström from 50 cases. The author concludes that the milk of cows that merely react to tuberculin but do not show clinical symptoms of the disease does not contain tubercle bacilli. The proper means of preventing the infection of milk with tubercle bacilli is to eliminate all cases of mammary tuberculosis and other clinical cases.

Tubercle bacilli in the milk of tuberculous cows, D. A. de Jong (*Centbl. Bakt. [etc.], 1. Abt., Orig., 46 (1908), No. 3, pp. 213–217*).—Many investigators have worked on the problem of determining whether it is possible to fix a limit in the progress of tuberculosis beyond which the milk becomes dangerous. The author considers it desirable to secure fresh evidence on this point. Of the 11 cows upon which he made experiments, 1 showed clinical symptoms of tuberculosis, while in the other 10 the disease could not be diagnosed except by the use of tuberculin, yet in 3 of the 10 reacting cows the milk contained virulent tubercle bacilli. The conclusion is therefore drawn that in order to be on the safe side it is necessary to exclude the milk of all tuberculous cattle.

The frequency of tubercle bacilli in the market milk of the city of Washington, D. C., J. F. Anderson (*Jour. Infect. Diseases, 5 (1908), No. 2, pp. 107–115*).—Noted from another source (E. S. R., 19, p. 1175).

Combating tuberculosis by control of dairy by-products, H. Martel (*Indus. Lait. [Paris], 33 (1908), No. 9, pp. 135–145*).—Statistics are presented showing the percentage of tuberculosis among hogs and other animals which are fed on dairy by-products with or without previous sterilization. The importance of sterilizing such by-products is clearly indicated by these statistics. It is recommended that all dairy by-products be sterilized before being used.

Chronic pseudotuberculous enteritis in cattle, Bugge and W. Albien (*Berlin. Tierärztl. Wchnschr., 1908, No. 10, p. 175*).—The author's report that in a study of chronic enteritis of cattle they have at last isolated pseudotubercle bacilli and have shown that the disease is not a form of tuberculosis. A further study will be made of the subject as a basis for a more complete report.

Chronic bronchitis and broncho-pneumonia in cattle, L. Reisinger (*Monatsh. Prakt. Tierheilk., 19 (1908), No. 5–6, pp. 193–225, figs. 3*).—*Bacillus pyogenes* appears to become associated secondarily with this disease or becomes more virulent when the mucous membrane of the bronchi is affected injuriously by irritants of various sorts. While *B. pyogenes* is to be considered as a secondary rather than a primary cause of the disease it nevertheless produces during its development specific tissue changes by which the disease is characterized.

The Koopmansfontein lamziekte experiment, J. Spreull (*Agr. Jour. Cape Good Hope, 32 (1908), No. 3, pp. 289–300, figs. 6*).—Cattle selected for experimental purposes were divided into a number of different lots which received different treatment for the purpose of determining the effects of such treatments upon the development of lamziekte. Some of the cattle were given access to a salt lick, others received bone meal, and still others tar or ashes. The disease is believed by the author to be of a bacterial nature, but the use of bone meal is of great benefit in preventing its development.

A practical method of determining the dose of serum required to protect contact animals in outbreaks of rinderpest, G. K. Walker (*Jour. Trop. Vet. Sci., 3 (1908), No. 1, pp. 28–32*).—It usually requires much tact on the part of veterinary officers to put in operation any system of vaccination against rinderpest among cattle belonging to ignorant natives. Some experiments have

been carried on to determine roughly the size of the dose of serum to be used in the field in preventing the development of rinderpest in cattle which have been exposed to the disease. It is estimated that in outbreaks where the mortality is less than 50 per cent before inoculation, hills animals be given the standard dose for plains animals. If the mortality is between 50 and 75 per cent the dose for plains animals is to be doubled and if the mortality exceeds 85 per cent the dose should be 18 times that recommended for plains animals. During the past 5 years the number of animals inoculated has ranged from 17,000 to 84,000, while the number of animals which have died after inoculation has ranged only from 2 to 35.

Enzootic enteritis of calves and serum therapy, I. Sacchini (*Clin. Vet. [Milan], Sez. Prat., 31 (1908), No. 10, pp. 165–169*).—In certain localities enteritis of calves appears in enzootic form and causes serious losses. The extent of the injury from this disease depends somewhat upon the time of year and considerable difference is also observed in the susceptibility of individual calves. A serum treatment has been devised by the author which gives fairly satisfactory results.

Septic pneumonia of calves, Schreiber (*Tierärztl. Zentbl., 31 (1908), No. 8, pp. 116–118*).—Septic pneumonia is due to a micro-organism which so very closely resembles that of swine plague that when inoculated into swine it produces an infection scarcely to be distinguished from it. The use of a curative serum within 8 to 14 days after the appearance of the disease has given satisfactory results.

Stomach worms in calves, J. M. Moras (*An. Soc. Rural Argentina, 41 (1907), No. 53–54, pp. 181–187*).—Brief notes are given on the distribution of stomach worms, particularly *Strongylus ostertagi* in Argentina, and on the injurious effects which they produce in young calves. The symptoms and means of diagnosis are briefly described. As a means of combating the disease the author recommends the use of a vermifuge containing 5 gm. male fern, 1.5 gm. creosote, 3 gm. thymol, and enough alcohol and gum arabic to dissolve and emulsify the thymol. This mixture is then diluted in 200 gm. of water.

The warble fly. Experiments on cattle as to its treatment and life history, G. H. Carpenter and J. W. Steen (*Dept. Agr. and Tech. Instr. Ireland Jour., 8 (1908), No. 2, pp. 227–246, pls. 2*).—The life history of the warble fly was carefully followed through by the authors and a series of experiments was carried on with the carbolic dip, train oil and tar, kerosene emulsion, and other similar mixtures to determine the possibility of controlling this pest by spraying the cattle. It was found that the various insecticides which have been recommended for preventing egg laying by the warble flies are practically valueless. Some of them, such as train oil, spirits of tar, and sulphur, are not only useless but harmful to the skin. In Ireland *Hypoderma bovis* is the common species, *H. lineata* being very rare. The eggs are laid mostly on the legs and may be licked off by the cattle, after which they hatch and the young larvæ penetrate through various organs reaching their final location under the skin. Careful experiments in muzzling calves, however, showed that the larvæ may bore directly through the skin.

Since all of the insecticides proved useless the authors recommend that the maggots in the skin of infested animals be destroyed in the winter and spring. It is believed that a united effort along this line would exterminate the warble fly within a period of 3 years.

Report upon the eradication of the cattle tick in Lincoln and Claiborne parishes, W. Newell and C. E. Mauldin (*Crop Pest Com. La. Circ. 21, pp. 4*).—Attention is called to the benefits which will accrue to the cattle raisers of Louisiana from the eradication of cattle ticks. The work which has already

been done through the cooperation of the Bureau of Animal Industry of this Department with State authorities is regarded as very encouraging.

Studies on Malta fever among Algerian goats in 1907, E. Sergent, V. Gillot, and G. Lemaire (*Ann. Inst. Pasteur, 22 (1908), No. 3, pp. 209–216, figs. 2*).—During the season of 1907 the milk of 609 Algerian goats was carefully examined. In 26 of these animals the milk agglutinated *Micrococcus melitensis*, although the micro-organism was not found in the milk except in 2 of the 26 cases. Malta fever, therefore, appears to prevail among Algerian goats to the extent of 4.2 per cent as compared with 30 to 50 per cent among the goats of Malta.

Immunization of swine against hog cholera, J. W. Connaway (*Missouri Sta. Circ. Inform. 29, pp. 22, figs. 8; Ann. Rpt. Mo. Bd. Agr., 40 (1907), pp. 97–119, figs. 8*).—This is an address delivered at the first annual meeting of the Missouri Swine Growers' and Breeders' Association. A general account of the disease is followed by a report of experiments on methods of immunizing swine, that have been conducted in cooperation with the Bureau of Animal Industry of this Department.

Pigs injected simultaneously with 20 to 30 cc. of serum and 1 to 2 cc. of virulent hog-cholera blood were found to be largely immune when exposed to the natural disease or fed upon viscera obtained from hogs that had died from a natural infection of cholera. Serum obtained from animals that following recovery from the disease had been fed upon infected viscera was found to have some power to protect against the disease, but its potency was not as great as the serum obtained from animals hyperimmunized by the injection of a large amount of infectious blood. "Our observations show that the serum is not effective when inoculated into an animal which is showing symptoms of the disease, but it shows a very high protective value in preventing the development of the disease. . . . In practical work in the field we hardly think that it is necessary, where animals are already exposed to the disease, to resort to the inoculation of the virulent blood."

Hogs that have been shown at State fairs should be placed in temporary quarantine for several weeks before returning them to the general herd. The liberal use of quicklime for disinfecting the grounds and the dipping of the hogs that have been exposed in any of the carbolic dips in general use are recommended as means for preventing the spread of the disease.

Borna horse disease, Liebener (*Berlin. Tierärztl. Wchnschr., 1908, No. 11, pp. 197–202*).—The literature relating to this disease is briefly reviewed and notes are given on the prevalence of the disease in various localities. As a rule treatment is without any avail. Slightly beneficial results have been obtained by the author from the administration of calomel and the application of ice packs to the neck. No benefit is derived from blood letting. The disease may be best controlled by careful destruction of carcasses and disinfection of stalls and all infected material.

The introduction of glanders with English horses, B. Bang (*Maanedskr. Dyrlæger. 19 (1908), No. 11, pp. 430–437*).—Among 29 English horses of good form and apparently in normal health the author found upon their arrival in Denmark that 7 were affected with glanders and 4 of them soon showed clinical symptoms. The animals had already been passed as healthy by an inspector. Attention is called to the necessity of exercising more care in the inspection of horses imported from other countries.

A preliminary report on some diseases of chickens, H. J. Milks (*Louisiana Stas. Bul. 108, pp. 3–11, pls. 4*).—Enterohepatitis of chickens previously reported from the New England, Middle, and Western States has been found by the author in several widely separated localities in Louisiana. Although thus far

found only in chicks under 6 weeks of age it is evidently quite common in the State. The course of the disease is quite rapid with a mortality of from 30 to 50 per cent of the chicks hatched. The report given is based upon an examination of 17 chicks. The author describes the symptoms and post-mortem appearances, and gives a complete account of a typical case. The causative organism is thought to be closely related to if not identical with the organism described by Smith (E. S. R., 7, p. 524), as *Amœba meleagridis*. Remedies previously suggested by the Bureau of Animal Industry of this Department (E. S. R., 19, p. 988) are discussed.

A bacterial disease was discovered in a flock where it was very fatal to chicks under 5 or 6 weeks of age. The course of the disease is said to have been very rapid, chicks dying during the night without previously having shown signs of illness. The symptoms and results of post-mortem and microscopic examinations are reported accompanied by a description of the organism. Two chicks and one of three mice died when inoculated with cultures of the organism.

The action of the aggressin of fowl cholera, E. Weil (*Arch. Hyg., 65 (1908), No. 2, pp. 81–106*).—The aggressin isolated by the author from cases of fowl cholera produces a striking susceptibility when inoculated into fowls. Control birds resisted a dose of virus ten times as great as was required to kill fowls previously treated with the aggressin. The aggressin, however, seems not to possess any toxic properties, since no injurious effects were produced in the experimental animals by increasing the dose eight times. A brief bibliography relating to this subject is appended to the article.

Fowl plague with special reference to its pathological anatomy, Freese (*Deut. Tierärztl. Wchnschr., 16 (1908), No. 12, pp. 173–177*).—Fowl plague is known to affect chickens, turkeys, guinea fowl, pheasants, geese, and sparrows. The lesions of the disease resemble those produced by poisoning with phosphorus. It is to be distinguished from fowl cholera by the presence of hemorrhages under the epicardium, an exudate in the pericardium, and intense enteritis in the case of the latter disease. Until recently no good evidence has been obtained in Germany that this disease affects geese. A number of cases of spontaneous infection were noted.

Studies and micro-photographs of the pathogenic protozoa, T. von Wasielewski (*Studien und Mikrophotogramme zur Kenntnis der Pathogenen Protozoen. Leipsic, 1908, pt. 2, pp. 175, pls. 8, figs. 26*).—A detailed account is given of the distribution of animal parasites in the blood in Germany. The author had occasion to study these parasites in material obtained from birds and mammals. Particular attention is given to Filaria, trypanosomes, hemagregarines, Plasmodium, especially the species found in birds, Hemoproteus, and Leucocytozoon. The blood parasites which cause plasmodiosis of birds were followed through 45 generations.

Animal parasites, E. Perroncito (*Ann. R. Accad. Agr. Torino, 49 (1906), pp. 3–17*).—Parasitism of young pigs with *Rhabdonema strongyloides* is sometimes so excessive as to cause death. Notes are given on fatal infestation with these parasites. The lungs, heart, pleura, and peritoneum showed no lesions. Brief notes are given on sanitary methods of preventing reinfestation with these parasites.

A study was made of multilocular echinococci in sheep. These parasites appear to be very common in sheep according to the author's experience. A form of cachexia is described caused by fluke worms and accompanied with jaundice. In cases of excessive infestation it is held that anemic and cachectic conditions often develop.

RURAL ENGINEERING.

Road materials of southern and eastern Maine, H. Leighton and E. S. Bastin (*U. S. Dept. Agr., Office Pub. Roads Bul. 33, pp. 56, pls. 3, map 1*).—This bulletin, prepared in cooperation between the U. S. Geological Survey, the State Survey Commission of Maine, and the Office of Public Roads, is the first of a series having in view the description, location, and testing of available road materials in the different States.

In Maine the area reported upon did not include the northern part because of its sparse population and the relative unimportance of the road problem. The principal source of road material in the area reported upon is stated to be the gravels, but owing to their great abundance and irregular distribution an extensive study of these could not be included except in those cases where detailed studies have already been made. The bulletin is especially devoted to road materials located near the large cities and to deposits favorably situated as regards shipment.

After a brief discussion of the general geology of the section and an outline of the methods used in testing the various specimens of rocks, the materials are described and discussed, grouped (1) according to variety and (2) according to localities with the varieties common to each.

Specifications and notes on macadam road construction, A. N. Johnson (*Engin. News, 60 (1908), No. 19, pp. 489–492*).—This is a paper read before the Western Society of Engineers, October 21, 1908.

The author, who is Illinois State highway engineer, expresses radical views on the construction of macadam roads, chief among which is that of using the large-sized stone for a wearing surface. He recommends that the first course of macadam should consist of broken stone from ¾ to 1½ in. in size, thoroughly raked and harrowed so that all the small particles will reach the bottom, because, since this is the state of stable equilibrium, the roller will compact it more readily. Also, in badly drained roads, if the smallest pieces are at the bottom the ground surface is less likely to be disturbed when the frost comes out of the ground. He believes there is no valid reason for bonding the lower course, but it should be thoroughly and slowly rolled to lock the pieces together. If the voids are filled with fine material this locking can not be obtained.

The second course should consist of a layer of 1½ to 3-in. stone having a Duval coefficient of wear of not less than 15, because this size will lock more firmly than a 1-in. and make the surface more resistant. The layer when consolidated should be 2 in. for a 6-in. road, or 4 in. for a 10-in. road. The larger the exposed pieces the greater will be the resistance to wear. Although the bottom layer may be of any kind of nonabsorbent, enduring material, the second layer should be more carefully selected.

The third course should consist of rock screenings containing all the dust, the sizes of these being from ¼ to 1 in., governed by the softness of the material. The screenings should be wet and rolled, and the second course so thoroughly rolled before screenings are placed on it that travel will not displace the pieces enough to allow the latter to pass through. In this paper the author observes that "the first place to give has been where there evidently has been a cluster of fine particles."

Macadam roads, A. B. Fletcher (*U. S. Dept. Agr., Farmers' Bul. 338, pp. 39, figs. 10*).—This is a condensed and revised edition of Bulletin 29, Office of Public Roads (E. S. R., 19, p. 386). It describes in some detail the essential features of the best practice of macadam road construction in rural sections with data as to costs. Standard details of construction used by the Massachusetts

highway commission and excerpts from the specifications for State-aid roads in that State are also included.

Highway improvement in Vermont, C. W. GATES (*Ann. Rpt. [Bd. Agr. Vt.], 28 (1908), pp. 67–72, figs. 8*).—In this report of the State highway commissioner there is an outline of Vermont's State-aid policies and notes on the improvements accomplished in the past year under them. The greatest mileage in the State-aided roads now consists of improved gravel roads with Telford foundation, and several of this type are illustrated.

Dust preventives, P. HUBBARD (*U. S. Dept. Agr., Office Pub. Roads Bul. 34, pp. 64, pls. 3, figs. 6*).—This bulletin is intended to furnish specific information concerning the materials and methods employed in dust prevention on all classes of roads. It is based on a review of all available literature supplemented by results secured from actual experiments conducted by the Office of Public Roads. Two general methods of attacking the dust problem are, (1) to apply material to hold down the dust, (2) to employ methods of construction designed to reduce its formation. This bulletin deals with the first method and the materials used are discussed in two classes: water, salt solutions and the lighter oils being considered temporary binders, and the tars, solid and semisolid materials, permanent binders. The bulletin concludes with a chapter on methods of examination and tentative specifications for the various preventives.

Irrigation in Mexico (*Bol. Soc. Agr. Mexicana, 32 (1908), No. 42, pp. 821–825*).—This article contains the terms of a contract recently let by the Mexican Government for the enlargement and construction of irrigation works including dams, canals, and reservoirs.

Yuma irrigation dam, D. A. WILLEY (*Sci. Amer., 99 (1908), No. 18, pp. 302–303, figs. 3*).—This describes some of the difficulties which presented themselves in this project and the way they were overcome, resulting in the successful control of a river which is liable to fluctuations of as much as 30 ft. in a week, and which flows through a channel of soft silt which has been accumulating for centuries.

A drainage system was considered necessary in conjunction with the irrigation works because of the flatness of the land and the high ground-water level, and consists of a main canal through the center of the irrigated areas, utilizing the natural drainage channels when possible.

A new scraper excavator (*Engin. News, 60 (1908), No. 18, p. 483, figs. 2*).—There is described a drag scoop bucket so designed that it will not "ride over" hard material. A heavy bail is rigidly attached to the side, which can, however, be set at various angles to the mouthpiece, thereby allowing the depth of cut to be gauged.

The applications of the motor in agriculture (*Auto. Agr. [Paris], 1908, No. 13, pp. 5–7, figs. 5*).—In this article the author briefly discusses the requirements of practical motor traction engines, with an analysis of the forces involved. It is stated that special attention should be given to securing the best point of application of the power, as in most engines the greater part is required to transport the motor itself. In this respect machines fitted with drums have an advantage over those in which the plows are connected directly.

Traction motors (*Agr. Prat. Pays Chauds, 8 (1908), No. 67, pp. 288–297, figs. 4*).—Two types of gasoline engines, fitted with hoisting drums for hauling plows, etc., and two types of gasoline traction engines and their various applications are described, with tables showing the results of efficiency tests.

Traction culture machines, V. FRÉMIER (*Auto. Agr. [Paris], 1908, Nos. 11, pp. 5–9, figs. 10; 12, pp. 6–11, figs. 16*).—This is a series of articles describing the different types of engines which have been invented for machine cultivating,

with a view to illustrating the problems of their economical operation and the various methods which have been devised to solve them. The account includes machines operated by electric motors and by explosive engines, and those with fixed plows and with rotating plows geared to the motors.

Statistics of agricultural implements (*Bur. of the Census [U. S.], Manfrs. 1905, pt. 4, pp. 129–153*).—Noted from another source (E. S. R., 19, p. 488).

Hydro-electric plants, M. RINGELMANN (*Jour. Agr. Prat., n. scr., 16 (1908), No. 40, pp. 433–440, figs. 5*).—This article describes several hydro-electric power plants in which the flow of small streams or brooks is used to generate light and power for rural homes. It contains data on the cost of installing and operating the equipment.

RURAL ECONOMICS.

The results of investigations on the returns in agriculture (*Ann. Agr. Suisse, 9 (1908), No. 2, pp. 33–72*).—This is a detailed report of investigations carried on cooperatively between the department of agriculture and farmers in Switzerland as to the gross and net returns derived from farms operated under different systems of management in 1906, the returns being compared with those secured during the preceding 5 years.

The average profits as ascertained from 230 holdings were: On farms up to 12½ acres in size, $21 per acre; from 12½ to 25 acres, $21.50; from 25 to 37½ acres, $17; from 37½ to 75 acres, $18; and from farms of more than 75 acres, $10.25 per acre. Nearly 80 per cent of the products raised on Swiss farms consisted of animal, dairy, and poultry products, an enormous quantity of such products being annually exported.

Six years of investigations concerning agricultural profits in Switzerland (1901–1906), J. R. BONHOMME (*Jour. Agr. Prat., n. scr., 16 (1908), No. 43, pp. 533–537*).—This is a review of the investigations noted above, with particular emphasis on the returns secured in 1906. See also a previous note (E. S. R., 20, p. 291).

Finnish agriculture, A. BORCHARDT (*Ber. Land u. Forstw. Ausland, 1908, No. 17, pp. 113, figs. 6, maps 2*).—This publication discusses the climate, population, production, consumption, and trade of Finland, and describes at some length the agricultural administration of the country, including cooperation, agricultural societies, agricultural laws, credit systems, systems of farm management, and the commerce in the different farm products.

Agriculture in Portugal, C. DE MELLO (*Rev. Gén. Agron., n. scr., 3 (1908), No. 6–7, pp. 261–264*).—A description of the extent, geography, population, and agricultural production of Portugal is given in this article. Portugal is the most agricultural country in Europe. Of a population of 5,428,800 in 1900, 3,092,730 derived their living from agriculture, a ratio of 56.64 per cent, as compared with 55 per cent in Austria, 47 in France, and 34 in Belgium. The average size of holdings is 1.55 hectares (about 3.81 acres).

Agricultural Hungary (*Budapest: Gort., 1908, pp. VII+136, figs. 66*).—This publication by the Hungarian minister of agriculture, in addition to general data on the extent of land, number and size of agricultural holdings, the ratio of the people engaged in agriculture, the division of the land according to classes of cultivation, and the kind and quantity of products raised, presents a detailed account of the agricultural industry in Hungary. Data are also included as to the government encouragement of agriculture by means of educational institutions, the establishment of scientific and experimental stations, legislation in behalf of agricultural laborers, water regulation, soil improvement, and agricultural administration.

The population of Hungary at the close of 1905 numbered 20,548,472, of whom 68.4 per cent were engaged in agriculture. The division of the land into the various forms of productive agriculture gives a total of 32,500,000 hectares, of which only 1,700,000 hectares, or 5.23 per cent, are unproductive.

Agricultural labor in Hungary. M. J. BERNARD (*Bul. Soc. Nat. Agr. France, 68 (1908), No. 8, pp. 603–606*).—Notes on an article appearing in the *Revue de Hongrie* by Daranyi, minister of agriculture, which gives a brief history and discusses the present status of the agricultural labor problem in Hungary.

Among the more recent reforms mentioned are the sanitary construction of about 8,000 houses for farm laborers which the occupiers can purchase if so desired; the establishment of a government fund of a million crowns (about $242,500) to aid laborers in case of sickness, accident, incapacity for work, etc.; free service in finding places for farm laborers out of employment; and the awarding of a decoration of honor to the laborers who have been 40 years on the same farm. The tendency of these reforms has been to check rural depopulation in Hungary.

The agricultural labor problem. E. VON KAHLDEN (*Der Boden die Landwirtschaftlichen Verhältnisse des Prussischen Staates. Berlin, 1908, vol. 8, pp. 383–436*).—This is a general historical review of the development of farm labor conditions in Prussia presented in the expectation that a survey of past history would offer some solution of the present-day agrarian problem. The scarcity of farm labor is regarded as of first importance and in the solution of the problem both the farmer and the government are urged to cooperate.

The wages of agricultural laborers in Bohemia. K. M. HERGEL (*Wiener Landw. Ztg., 58 (1908), No. 81, pp. 799, 800*).—This article gives the daily, monthly, and yearly wages in money of male and female agricultural laborers in different districts of Bohemia, together with such other privileges as meals, clothing, lodgings, and social favors which increase to a considerable extent the economic value of the laborer's income. In some districts where the money wage is high and other privileges numerous the income of the farm laborer is equal or even superior to the income of factory and industrial workers.

Agricultural holdings bill, 1908 (*London: Govt., 1908, pp. III+28*).—The text of the law to take effect January 1, 1909, regulating the relations between landlord and tenant regarding compensation for improvements, damage by game, disturbance, and similar matters, is reported.

The legal status of agricultural cooperative societies. R. WORMS (*Bul. Soc. Nat. Agr. France, 68 (1908), No. 7, pp. 494–502*).—The author shows by court decisions and other means what constitutes an "agricultural cooperative society" and what are the limitations of its functions to enable such an organization to reap the benefits of the laws enacted in France for the encouragement of agricultural credit and the exemption of small farmers from certain forms of taxation.

The purpose of the law relating to the organization and operation of agricultural cooperative societies. E. NAQUET (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 29 (1908), No. 40, pp. 406–414*).—The text of the law of June 15, 1908, is given and discussed with regard to its probable effects on the future successful operation of such organizations in France.

First fruits of cooperation in India. H. W. WOLFF (*Econ. Rev., 18 (1908), No. 2, pp. 154–157*).—The author points out the beneficial results accruing to the peasant class in India through the introduction and development of mutual agricultural credit banks during the past few years. The Raiffeisen system is believed to be best adapted to India. Among the results mentioned the following are most significant: Farmers have received higher prices for their products, the number of live stock has increased, wells have been dug, hus-

handry has been improved, discharged native soldiers have been assisted in the purchase of land, and the perennial burden of debt has been lightened and shifted from the extortionate money lender, whose charges range from 25 to 100 per cent, to the mutual credit village bank at rates of interest ranging from 5 to 6¼ per cent.

Cooperative credit in Bengal (*Indian Agr., 33 (1908), No. 11, pp. 326, 327*).—On June 30, 1908, the societies numbered 326 and the membership 11,076, the corresponding figures for June 30, 1907, being 165 and 6,903, respectively. The common objects of borrowing by the ryots are to pay off old debts and to purchase cattle. "The rate of interest offered by some of the societies is only 6 per cent, whereas the lowest rate charged by money lenders is 18.75 per cent and the most common rate is 31.25." The greatest need at the present time is said to be competent honorary organizers to assist the government in organizing and instructing the peasant class.

Agricultural credit. E. Carnaroli (*Riv. Internaz. Sci. Soc., 45 (1907), Nos. 179, pp. 373–401; 180, pp. 509–525*).—This article discusses the essential characteristics of agricultural credit and gives the status of the movement in Italy and foreign countries. An extensive bibliography is included.

Immigrants of the agricultural class in the Northwest Provinces. A. Blue (*Census and Statis. [Canada] Bul. 6, pp. XI+58*).—Statistics of agricultural immigration into Manitoba, Saskatchewan, and Alberta from January 1, 1891, to June 24, 1906, are reported and discussed, including data relating to the countries from which the emigrants came, the number of families and persons per family, the live stock per farm, and the extent of farm lands occupied and in crops per family in 1906. The immigrant families numbered 50,321, embracing 205,774 persons, and occupied 11,678,357 acres of land, of which 2,307,979 acres were in crops.

Government crop reports: Their value, scope, and preparation. C. C. Clark (*U. S. Dept. Agr., Bur. Statis. Circ. 17, pp. 7–16*).—This is an account of the origin and development of the system of collecting and issuing Government crop reports, the methods employed to secure accurate data, and the value of crop statistics not only to farmers but to commercial interests of every kind and class.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 10 (1908), No. 12, pp. 89–96; Sup., pp. 97–104*).—These numbers give the crop conditions in the United States and foreign countries, with statistics on the exports of durum wheat, range of prices of agricultural products, the acreage, production, and value of the principal farm crops of the United States in 1908, and the annual report of the Bureau of Statistics for the fiscal year 1907–8.

Farm bookkeeping. H. G. Lamb (*New York, 1908, pp. VIII+69*).—This is a book of instruction in double-entry bookkeeping intended particularly for practical use on the farm.

AGRICULTURAL EDUCATION.

Agriculture in the rural schools. Nellie B. Chisholm (*Mich. Farmers' Insts., Inst. Bul. 14, pp. 283–286*).—In this address before a Michigan county farmers' institute the author emphasized the demands of the new education as a preparation for life and pointed out ways in which the teaching of agriculture helps to meet these demands. Her point of view is epitomized in the statement that "what American agriculture needs more than anything else is that it become intellectualized, that it be made the purpose and object of mental as well as physical effort."

What can the public schools do to improve industrial conditions? J. E. WARREN (*Ann. Rpt. Bd. Ed. [Mass.], 71 (1906–7), pp. 243–252*).—The writer describes features of instruction in agriculture and domestic science in some schools of Massachusetts, and urges the extension of work of this kind among public schools.

The future of agricultural education in Michigan, F. W. HOWE (*Schoolmaster, 2 (1908), Nos. 6, pp. 307–312; 7, pp. 368–372*).—The writer describes the present facilities for teaching agriculture of different grades in Michigan and outlines plans for the further development of instruction in agriculture in the public schools of the State.

Form of organization for movable schools of agriculture, J. HAMILTON (*U. S. Dept. Agr., Office Expt. Stas. Circ. 79, pp. 3–8*).—Suggestions are given for the organization, equipment, and conducting of movable schools of agriculture as one of the means of disseminating agricultural information.

Report on the organization of forestry instruction in Sweden, U. WALLMO ET AL. (*Stockholm, 1908, pp. XI–429*).—A report of a committee of experts appointed by the Swedish Department of Agriculture in 1906. Brief statements are given of the organization of instruction in forestry in Denmark, Finland, Prussia, Saxony, Wurttemberg, Bavaria, Austria, Hungary, Switzerland, and this country, together with the sources of information.

Royal Horticultural School, Dahlem, J. KOCHS (*Ber. Deut. Pharm. Gesell., 18 (1908), No. 6, pp. 325–342, figs. 13*).—An illustrated description of the equipment and work of the school as embodied in the report of an inspection by the German Pharmaceutical Society.

Missouri Housekeepers' Conference Association (*Missouri Sta. Circ. Inform. 30, pp. 42, dgm. 1; Ann. Rpt. Mo. Bd. Agr., 40 (1907), pp. 428–469, dgm. 1*).—This contains the constitution and proceedings of the first meeting of the Missouri Household Conference Association on January 7–10, 1908, including the following papers: Household Adjustment to Technical Development, by Miss Caroline L. Hunt; The Pure Milk Problem, by Mrs. Walter McNab Miller; The Revival of Missouri Handicrafts, by Mrs. F. H. Seares; The Present Crisis of the American Home, by Charles A. Ellwood; The Home—A Business Proposition, by Mrs. Emma Page Tracy; The Home Economics Movement, by H. J. Waters; The Inductive or Scientific Method of Teaching Cooking, by Miss Louise Stanley; and Home Economics, Why it Should be Taught in the Schools, and What it Includes in the University of Missouri, by Miss Edna D. Day.

Report of the committee on children's gardens for the year 1907, H. S. ADAMS (*Trans. Mass. Hort. Soc., 1907, II, pp. 227–251, pls. 2*).—There were 49 entries in 1907 for children's garden prizes offered by the Massachusetts Horticultural Society. Of these 28 were school gardens, 7 school grounds, and 14 children's home gardens. The report states that Smith, Mount Holyoke, and Wellesley Colleges now have courses in gardening which provide the proper foundation for school garden work. It also contains abstracts of addresses made at the Children's Garden Conference in Boston, December 14, 1907, school garden reports from Springfield and Roxbury, Mass., and home garden reports from the Marlborough School and Home Industrial Association, the Waltham Home Garden Association, the Reading Home Gardens, and the Fairhaven Home Gardens. The abstract of an address by A. C. Boyden, principal of the State Normal School at Bridgewater, contains suggestions for natural science gardens and their functions in school work.

Importance of school gardens and methods of proper management, P. EMERSON (*Ann. Rpt. N. H. Hort. Soc., 1 (1907), pp. 114–121*).—This is a discussion of the importance and value of school gardens as a factor in education.

School gardens, L. C. Corbett (*Florists' Ex., 26 (1908), No. 8, pp. 254, 255*).—A paper read before the convention of the Society of American Florists, at Niagara Falls, N. Y., August 21, 1908.

School gardens, W. T. Carter, Jr. (*Farm and Ranch, 27 (1908), No. 38, p. 3*).—Suggestions for school garden work in the country schools.

Possibilities for the teaching of household arts in the rural schools, Helena Pincomb (*School News and Pract. Ed., 22 (1908), No. 1, pp. 20–22, figs. 5*).—Suggestions for conducting household arts instruction in rural schools, and a list of desirable articles for equipment and their cost are given.

Teaching soils in the public schools, W. T. Carter, Jr. (*Farm and Ranch, 27 (1908), No. 37, pp. 3–5*).—The importance of teaching agriculture is urged, references to suitable literature and suggestions for securing equipment are given, and suggestive lessons concerning soils in relation to moisture and air, temperature, and fertility are outlined.

Agriculture in public schools, A. D. De Witt (*Schoolmaster, 2 (1908), No. 6, pp. 313–316*).—An outline is given of the course of study at the St. Louis (Mich.) High School, which includes instruction in agriculture during the second and third years.

One hundred experiments in elementary agriculture for California schools, R. O. Johnson (*San Francisco, 1908, pp. 42*).—The experiments given in this pamphlet are grouped under 2 headings, (1) the needs of the plants, and (2) supplying the needs of the plants. There are experiments to show the need of plants for water, air, warmth, light, carbon, nitrogen, sulphur, and oxygen, with supplementary exercises to illustrate the preparation of oxygen, hydrogen, nitrogen, limewater, and carbon dioxid. The experiments showing how to supply the needs of the plant illustrate osmosis, preparation of crude phosphoric acid, potash, and saltpeter, tests for acids, alkalis, and salts, percolation, capillarity, evaporation, transpiration in plants, the circulation of water in plants, and other physiological phenomena of plant growth.

Experimental studies of plant growth, B. M. Davis (*Miami Bul., 7. ser., 1908, No. 1, pp. 32, figs. 17*).—The writer has outlined suggestions to teachers and 42 experimental studies of plant growth to follow his exercises on The Soil and Its Relation to Plants (E. S. R., 19, p. 390). In this later series he takes up the germination of seeds and simple physiological experiments in the development of the seed grain, including such matters as the development of starch and sugar and tests for these substances, the absorption of carbon dioxid by the leaf, the giving off of oxygen, transpiration, and regions of growth in different parts of the plant. A list of materials and their cost is given.

Sheep, R. J. Kinzer (*Industrialist, Farmers' Inst. Ser., 1 (1908), No. 4, pp. 155–193, figs. 7*).—This article considers the breeds, feeding, care, and management of sheep under the following topics: Selecting a breed, including brief descriptions of the more common breeds in America, how to judge a sheep, general care and management, selection of quarters, breeding season, shearing, and care of the flock. There are also 2 contributed articles, viz, Sheep on the Farm, by John D. Marshall, of Walton, Kans., and Problems of the Sheep Industry in Kansas, by E. D. King, of Burlington, Kans., as well as score cards for sheep.

Study of birds and their economic value, W. L. Finley (*Leaflets Listing and Describing Birds of Oregon, No. 1, pp. 7, fig. 1*).—This is the first of a series of leaflets to be issued by the Oregon State biologist for the use of pupils in the public schools and others interested in nature study. It considers the following subjects: How to interest children, discrimination between useful and harmful birds, changes that affect bird life, how birds regulate outbreaks of

insect life, studying the food of birds, value of birds to agriculturist and horticulturist, and birds as natural resources.

The preparation of the seed bed, V. M. SHOESMITH (*Agr. Col. Ext. Bul. [Ohio State Univ.], 4 (1908), No. 1, pp. 4–12, figs. 12*).—Reasons for plowing and harrowing the land are given, and also some suggestions concerning methods.

Some nature biographies, J. J. WARD (*London and New York, 1908, pp. 307, pls. 13, figs. 195*).—Life histories of moths, butterflies, plants, and jellyfish portrayed largely by means of illustrations from photographs.

The garden book for young people, ALICE LOUNSBERRY (*New York, 1908, pp. 290, pls. 49*).—A popular account of the garden work of a boy and girl during one season.

Making hay, A. M. TEN EYCK (*Industrialist, Farmers' Inst. Ser., 1 (1908), No. B, pp. 43, figs. 4*).—Contains suggestions on cutting, curing, storing, baling, and marketing the hay crop, and plans for construction of hay sheds.

Weeds, V. H. DAVIS (*Agr. Col. Ext. Bul. [Ohio State Univ.], 3 (1908), No. 9, pp. 15, figs. 14*).—This elementary study indicates how weeds injure the farmer and how they spread by natural and artificial methods, and suggests methods of combating them.

MISCELLANEOUS.

Eighteenth Annual Report of North Dakota Station, 1907 (*North Dakota Sta. Rpt. 1907, pt. 1, pp. 86*).—This contains the organization list, titles of station bulletins and press bulletins issued during the year, a brief report of the director, departmental reports containing articles abstracted elsewhere in this issue, and a financial statement for the fiscal year ended June 30, 1907.

A circular of information concerning the New Hampshire Agricultural Experiment Station (*New Hampshire Sta. Circ. 6, pp. 15, figs. 10*).—This is a brief account of the organization, equipment, and lines of work of the station with a list of the publications available for distribution.

List of publications of the Rhode Island Agricultural Experiment Station, Kingston, R. I., available for distribution May 1, 1908 (*Rhode Island Sta. Bul. 128 App., pp. VII*).

Experiment Station Work, XLVIII (*U. S. Dept. Agr., Farmers' Bul. 334, pp. 32, figs. 2*).—This number contains articles on the following subjects: Plant breeding on the farm, sorghum for silage, dry rot of corn, starch from sweet potatoes, profits from tomato growing, the keeping of apples, weed seeds in manure, weed seeds in feeding stuffs, forage crops for pigs, market classes and grades of horses and mules, profitable and unprofitable cows, blackhead in turkeys, extraction of beeswax, and an improved hog cot.

NOTES.

Arizona Station.—The El Paso and Southwestern Railway Company has made an initial contribution to the station of $2,000 for dry farming investigations. A location has been selected in the Sulphur Spring Valley 18 miles north of Douglas on a tract representative of a large section which it is thought may be utilized for dry farming. The agriculturist is to have charge of the work.

F. C. Kelton has been appointed assistant engineer and entered upon his duties January 15.

California University and Station.—An agricultural and horticultural demonstration train was sent out through the Sacramento Valley, November 9–17, 1908, manned by a corps of about twenty lecturers and demonstrators from the university and station staff. The train received an enthusiastic reception, the lecture car frequently proving inadequate to accommodate those in attendance.

Connecticut College.—Howard D. Newton, assistant in chemistry at Yale University, has been appointed instructor in chemistry.

Illinois University.—The State Corn Growers' and Stockmen's Convention was held at the college of agriculture January 18–30, with a registration of 660, of whom 372 were young men under 26 years. In addition 95 women took the corresponding course for housekeepers.

S. A. Forbes, professor of zoology since 1884, has resigned the position, to take effect September 1, but will remain director of the State Laboratory of Natural History and State entomologist.

Purdue University and Station.—More than 800 farmers and about 100 farm boys attended the one-week course in agriculture at the university, beginning January 11, and there were over 100 farmers' wives and daughters in attendance at the corresponding course in domestic science. The State Corn Show was a special feature, with entries representing over 5,000 farmers and farmers' boys, many of whom were formally organized into corn clubs.

On January 14 occurred the dedication of the new station building recently completed at a cost of about $100,000. This is a two-story and basement structure of vitrified brick with Bedford stone trimmings and tile roofing and fireproof throughout. Its dimensions are 200 by 56 ft., with two wings with a width respectively of 100 and 80 ft., making it the largest and most complete building in America devoted exclusively to station work.

The dedicatory exercises were opened by President Stone of the university with a brief review of the legislative and executive history of the station. Director Goss followed with a paper discussing its past achievements and present needs.

The dedicatory address was given by Director W. H. Jordan, of the New York State Station, who took for his subject The Value and Function of an Agricultural Experiment Station. In this very suggestive address were discussed the function of the experiment station, the point of view which should dominate its organization, and the attitude which should be assumed toward it

by the farmers of its State in their demands upon it. Dr. Jordan stated that the primary and the chief product of an experiment station should be scientific truths that are a real addition to agricultural knowledge, resting on sound and adequate investigations and capable of application to the varying farm conditions in the State which it serves. The station worker should be, he believed, first of all a man of high scientific attainments. It was not regarded as essential that he be experienced in the art of agriculture, although "he should be familiar with the agricultural conditions and practices that relate to his particular field of investigation." He should be fundamentally a seeker after truth for truth's sake, keenly alive to his responsibility as a leader, and with a strong sympathy with the problems of the farm. The farmers of a State, he declared, are entitled to the utmost results possible, but there can not safely be coercion by insistence upon a time limit. Nor should the station be hampered by requests for popular instruction nor for formulating rules of farm practice for individual needs, although "the obligation of an experiment station to point the way to the application of knowledge to farm practice should be fully recognized and fully met." He believed that there existed in indiscriminate extension of public assistance in agriculture a possible danger of impairing individual or community initiative and responsibility. In his opinion most careful differentiation was necessary between the things which should be done for the farmer and those which he should do for himself.

Iowa College.—At the two-weeks' short course held at the college, beginning January 4, the total enrollment reached nearly 800, chiefly in live stock and grain judging. It had been expected that the holding of local short courses at twenty points in the State would lead to a diminution in the attendance, but the effect seemed rather to stimulate additional interest, all previous records being broken. Meetings were held during the course by several State agricultural organizations, and there were also a large number of demonstrations, lectures by well-known speakers, an exhibition of automobiles adapted to farm conditions, and a competitive judging contest.

W. H. Peters, assistant professor of animal husbandry, and F. G. Churchill, assistant in chemistry, have accepted appointments at the Manitoba College of Agriculture, the former as professor of animal husbandry and the latter as lecturer in soil physics.

Kansas College.—C. G. Elling, assistant animal husbandman, has resigned to accept a commercial position in Cuba.

Maine University.—The dedication of the new agricultural building took place January 20. The speakers included Hon. E. B. Winslow, of the board of trustees, Governor B. M. Fernald, State commissioner of Agriculture A. W. Gilman, State Superintendent of Schools Payson Smith, and Dean Hurd. The dedicatory address was by Dean Davenport of the Illinois University and Station, his subject being The Development of our American Agriculture, What It Is, and What It Means. In this address the vital public interest in a successful agriculture was pointed out, and the fundamental purpose of agricultural education and research was defined as the development of agriculture as a productive occupation and of the agricultural people as a numerous and important part of the social and political fabric. The details of this development were considered to consist in making agriculture profitable, productive, and permanent, the country both comfortable and beautiful, and its people broadly educated.

The new hall of agriculture is a three-story and basement brick structure of Tudor style, 100 by 63 ft., and costing about $50,000. In the basement are located an animal operating room, laboratories for veterinary science, forestry, soil chemistry, and soil physics, a photography room and rooms for the storage

of tools, apparatus, etc. The dean's offices are on the first floor, together with offices of the departments of animal industry and agricultural chemistry, the extension department and the library. On the second floor are located the departments of agriculture and forestry, the bacteriological laboratory, and the museum; and on the third floor are the offices and class rooms of the horticultural department, drafting rooms, and a large lecture hall. The various laboratories are fully equipped with water, gas, and steam, and the interior and the furnishings are in dark mission oak.

About 50 ft. to the rear of the agricultural building is the new stock-judging pavilion, octagonal in shape, and 50 ft. in diameter. This is also of brick and is of the same general style as the main building. The judging ring is 25 ft. in diameter, and is surrounded by seats in amphitheater style, with a seating capacity of about 350 people.

In connection with the dedicatory exercises a meeting was held of the New England Federation of Agricultural Students.

Massachusetts Station.—C. S. Pomeroy has resigned as assistant horticulturist to accept a position in connection with the field investigations in pomology of this Department.

Minnesota University and Station.—L. D. Niles has been appointed assistant in animal husbandry.

Missouri University and Station.—The Farmers' Week, held at Columbia under the auspices of the State Board of Agriculture during the week of January 4 was extremely successful, attracting an attendance of over 1,000. A large number of organizations participated in the meetings, including in addition to the College of Agriculture and the State Board of Agriculture, the State Board of Horticulture, Improved Live Stock Breeders' Association, Dairy Association, Butter Makers' Association, Corn Growers' Association, Sheep Breeders' Association, Swine Growers and Breeders' Association, Highway Engineers' Association, Jersey Cattle Breeders' Association, Bee Keepers' Association, Home Makers' Conference, and the American Breeders' Association.

The general exercises were opened by President A. Ross Hill of the university, former Secretary of Agriculture Norman J. Colman, and Dean Waters. Illustrated lectures were given by H. W. Mumford on Live Stock and Agricultural Conditions in Argentina and How They Affect the American Live Stock Industry, and by W. J. Spillman on Mendel's Law. C. A. Zavitz discussed the work of the Ontario Agricultural and Experimental Union, and Assistant Secretary of Agriculture W. M. Hays gave an address urging the betterment of general farm conditions and especially of rural schools. During the week practical demonstrations were given in soil, seed, and dairy work, stock and grain judging, and there were corn, fruit, and dairy products shows. In the Home Makers' Conference a Model Kitchen was on exhibition and an address was given by Miss Martha Van Rensselaer, of Cornell University, on What the State May Do for Farmers' Wives. An account of the meeting of the American Breeders' Association is given elsewhere in this issue.

R. J. Carr has been appointed assistant in animal husbandry, vice C. W. Rine, whose resignation has been previously noted.

Nebraska University.—The eighth annual joint meeting of the various State agricultural associations was held at the university farm January 18–22, the various organizations holding meetings including the Board of Agriculture, the Horticultural Society, the Veterinary Medical Association, the Dairymen's Association, Poultry Association, the Improved Live Stock Association, the Swine Breeders' Association, the associations of breeders of Poland China and Duroc Jersey swine and Red Polled, Aberdeen-Angus, and Shorthorn cattle, the Bee Keepers' Association, the Corn Improvers' Association, the Farmers' Institute

Conference, and the Home Economics Association. A large number of experts from several agricultural colleges and experiment stations and from this Department participated in the various programmes.

A special feature of the meetings was the dedication on January 19 of Home Economics Hall—a three-story structure of gray pressed brick, costing about $70,000. The dedicatory address was delivered by Mrs. Ellen H. Richards, of the Massachusetts Institute of Technology.

The short winter courses at the school of agriculture opened with an enrollment of about 250, making the total number of agricultural students in the university about 850, of whom 110 are in university courses in agriculture, forestry, and home economics, and the remainder in the school of agriculture.

North Carolina State Station.—Tait Butler, veterinarian and animal husbandman, resigned January 1 to become editor of *Southern Farm Gazette*, published at Starkville, Miss. C. D. Harris, assistant chemist and microscopist, has resigned to engage in commercial work. J. L. Burgess, formerly of the Bureau of Soils of this Department, has been appointed to conduct work in the study of leading southern crops, their improvement by selection and breeding and the adaptation of crops to type soils.

Ohio University.—A four-year course in forestry has been added to the curriculum and will be offered beginning with the next academic year.

The first annual State corn show was held at the university, November 23–25, under the auspices of the State Corn Improvement Association. In a corn-judging contest a number of trophy cups were offered by agricultural newspapers, the station director of cooperative experiments, a member of the station staff for the best record of management in raising field corn, and by the faculty of the college of agriculture for the best exhibit from high schools. At an evening session addresses were given by C. P. Hartley, W. J. Spillman, and A. D. Shamel of the Bureau of Plant Industry, and H. H. Johnson of the Bureau of Statistics of this Department, Governor A. L. Harris, J. E. Wing, C. W. Burkett, and others.

The first movable school of agriculture to be undertaken in the State was held at Paulding during the week of October 28, under the supervision of the extension department. The school was arranged for by the president of the local national bank and was very successful. A small fee was charged to defray expenses. There was an enrollment of 85 farmers.

Oklahoma College and Station.—The death is reported of F. C. Burtis, agriculturist and horticulturist in the college and station from 1900–1902, and agriculturist until 1906. Professor Burtis was graduated from the Kansas College in 1891, and served as assistant agriculturist in the Kansas Station prior to his Oklahoma appointment. In the course of his work in Oklahoma he outlined and developed the course in agriculture, assisted in establishing the short courses, and organized the college creamery.

Pennsylvania College and Station.—A better-farming train, manned by a corps of lecturers from the college and station staff, has been sent out over the Pennsylvania Railroad, traversing the southeastern part of the State. The train was a new feature in that section and attracted much attention both from farmers and the general public.

Rhode Island College.—In the announcement of the extension department of this college for 1909 the list of technical and popular lectures by members of the faculty has been increased to seventy-four, and covers nearly every phase of the college work. These lectures are available to associations of engineers and mechanics, granges, and other farmers' organizations and meetings of educational associations. The extension department also offers to conduct

correspondence courses on general fruit culture and gardening, and to advise with individuals concerning reading courses.

South Carolina College and Station.—The agricultural faculty and station staff have formed the Clemson Biological Club for which weekly meetings are contemplated. George G. Ainsley, of the Bureau of Entomology of this Department, has accepted the position of assistant professor of entomology in the college.

South Dakota College and Station.—The new school of agriculture is proving very popular, 107 students being enrolled for the first year's work.

The station has undertaken experiments with horses to determine the digestion coefficients of several of the new grains grown in the Northwest.

Utah College and Station.—Instead of the usual short winter courses for practical farmers, the college this year has held a two-weeks' round-up farmers' institute at the college, with W. L. Carlyle as a special lecturer on live stock. About 75 farmers attended this course and nearly all of the 250 regular students in agriculture availed themselves of its privileges. A farmers' institute train consisting of lecture and exhibition coaches has made a tour of the State, stopping at every town reached by the railroad. Domestic science and dairy work were made special features. The train was enthusiastically received, and in many places overflow meetings in halls and meeting houses were necessary.

E. H. Favor, assistant horticulturist, has resigned to engage in commercial work.

Vermont Station.—R. E. Vaughan, assistant horticulturist, has resigned to become instructor in agronomy and kindred subjects in the secondary school at Mount Hermon, Mass.

Virginia College and Station.—The better-farming special train sent out over the Norfolk and Western Railway by the college and station in cooperation with the State truck station, the tobacco substations, and the State department of agriculture, November 4–13, 1908, met with good success, about 5,000 people visiting the train. The initial enrollment in the farmers' short course is nearly 50, a large increase over the preceding year.

Washington College and Station.—A. G. Craig has resigned as instructor in horticulture in the college and assistant horticulturist in the station to engage in commercial work.

West Virginia University.—A six-day tour of the State by a better-farming special train aroused much interest. Fully 14,000 people visited the train, and in one small town 350 farmers were on hand in a pouring rain at 8:30 in the morning. In some towns the stores were closed and special meetings were held by the board of trade and other organizations in connection with the trip.

American Breeders' Association.—The fifth annual meeting of this association was held at Columbia, Mo., January 6–8, in conjunction with a large number of State organizations participating in the exercises of Farmers' Week. Addresses were delivered at the general sessions by Assistant Secretary of Agriculture W. M. Hays, on Plant and Animal Breeding and on Country Life Education, and by H. J. Webber on Simple Methods of Breeding.

The programme consisted largely of reports and papers submitted from the various standing committees. Its scope may be indicated by the following partial list of papers: The Elimination of Undesirable Vegetable Varieties, by L. H. Vaughan; Permanent Collection of Plants and Animals for Breeding Purposes, by David G. Fairchild; The Problem of Fixation in Cotton Hybrids, by R. J. H. De Loach; Some Cytological Aspects of Cotton Breeding, by W. Lawrence Balls; Methods of Breeding Alfalfa, by G. F. Freeman; Methods of Improving Alfalfa by Selection, by J. M. Westgate; A Pure-line Method in Corn Breeding, by G. H. Shull; Spontaneous Hybrids of Native Californian Trees, by W. L. Jepson; Practical Possibilities of Grafting and Budding Forest

and Nut Trees, by G. L. Clothier; The Elimination of the Gullied Hillside Through Tree Breeding, by J. R. Smith; Breeding Sorghum, by C. O. Townsend; Work Conducted by the United States Department of Agriculture in Breeding High Grade Strains of Sugar Beet Seeds and Testing Imported Varieties, by J. E. W. Tracy; Some Principles of Poultry Breeding, by C. B. Davenport; Natural *v.* Artificial Incubation in Poultry Breeding, by James Dryden; The Factor Hypothesis in Relation to Plumage Color, by C. B. Davenport; A Few Preliminary Experiments on the Effect of the Age of the Parents Upon the Vigor of Chickens, by Horace Atwood; Some Observations in Telegony, by E. H. Riley; Breeding Tobacco for High and Low Nicotine Content, The Relation of Nicotine to the Quality of Tobacco, by W. W. Garner; History of Zimmer Spanish Tobacco, by A. D. Selby; Tobacco Seed Separation, Selection, and Propagation, by D. P. Cooley; The Production of a New Strain of Tobacco and its Development, by J. B. Stewart; Maryland Tobacco Breeding Work, by D. E. Brown; Work on Tobacco Breeding in Kentucky and Tennessee for 1908, by W. H. Scherffius; Report on the Improvement of Filler and Wrapper Tobacco in Eastern Texas by Seed Selection, by W. M. Hinson; The Present Status of Apple Breeding in America, by S. A. Beach; Characteristic of Wealthy Apple Seedlings, by W. T. Macoun; Effect of Different Methods of Selection on the Fixation of Hybrids, by W. J. Spillman; What are Factors in Mendelian Explanation? by T. H. Morgan; Inbreeding and Degeneration, by C. B. Davenport; Influence of Food Supply on Variation, by H. H. Love; Bud Variations and Their Meaning, by H. J. Webber; A Plan for Breeding Swine, by D. A. Gaumnitz; Fundamental Principles of Successful Swine Breeding, by William Dietrich; Experiments on Living Birds to Determine Effect of Humidity on Coloration of Plumage, by C. W. Beebe; Propagation of Game Birds in Captivity, by Wallace Evans; A Statement of Necessary Changes in Game Laws in the Interest of Breeders, by D. W. Huntington; Genetic Laws Applied; Results with Hybridized Swine, by Q. I. and J. P. Simpson; Hybridizing the Virginia Deer, by J. W. Griggs; General Report on the Raising of Deer, by D. E. Lantz; and Another Mode of Species Forming, by Luther Burbank.

Among the committees submitting formal reports were the following: On Pedagogics of Breeding, E. Davenport; On Pure Bred Seed and Plant Business, by C. A. Shamel; On Breeding Roses, by W. Van Fleet; On Breeding Forage Crops, by C. V. Piper; On Breeding Nut and Forest Trees, by G. B. Sudworth; On Breeding Poultry, by C. B. Davenport; On Breeding Sheep and Goats, by W. C. Coffey; and On Eugenics, by David Starr Jordan. Many other reports and papers were also submitted and will be incorporated in the annual report of the proceedings, which it is hoped to issue at an early date.

The association adopted a resolution favoring the amendment of State game laws to permit the sale at all times of live game for propagation and the sale, except during the breeding season, of game reared in a wild state by breeders and farmers. Federal legislation was advocated in connection with the taking of the Thirteenth Census whereby in certain parts of the country data may be collected relative to heredity in man, and the committee on eugenics was authorized to prepare schedules for the purpose.

Officers were elected for the ensuing year as follows: Hon. James Wilson, Washington, D. C., president; William George, Aurora, Ill., vice-president; W. M. Hays, Washington, D. C., secretary; N. H. Gentry, Sedalia, Mo., treasurer; O. E. Bradfute, Cedarville, Ohio, chairman, and C. B. Davenport, Cold Spring Harbor, N. Y., secretary of the animal section; and H. J. Webber, Ithaca, N. Y., chairman, and N. E. Hansen, Brookings, S. Dak., secretary of the plant section.

American Society of Agricultural Engineers.—The second annual meeting of this society was held at the University of Illinois December 29 and 30, 1908.

Following an address of welcome by Dean Davenport, J. B. Davidson, of the Iowa College, gave the presidential address. In this he called attention to the remarkable extension of engineering features into agricultural work during the past decade through improved farm implements, farm buildings, field and sanitary drainage, and water supply, the securing and applying of irrigation water, and good roads, and emphasized the consequent need of instruction in agricultural engineering at the agricultural colleges. He also discussed the purpose and scope of the society, pointing out that all those engaged in farm-implement design and manufacture, architects of farm buildings, drainage, irrigation, and highway engineers, and related lines of work are eligible to membership.

E. W. Hamilton gave an account of the farm motor contest recently held at the Winnipeg Industrial Exhibition, and discussed the benefits of such competitions. E. A. White presented a paper on The Plow Contest. Pumping Machinery for Irrigation Purposes was discussed in a paper by H. M. Bainer, Ditch Excavating by Machinery by A. E. Miller, and the Economical Location and Arrangement of Farm Buildings by E. W. Hamilton. Some Pressing Agricultural Problems were discussed by M. L. King, who called attention to the need of special agricultural knowledge in the solution of many engineering problems.

As at the previous meeting, considerable attention was given to educational phases. W. M. Nye presented a paper entitled Should a Course in Farm Mechanics be Offered in Agricultural High Schools? J. F. Steward discussed Methods of Instruction in Farm Machinery as seen from the Manufacturer's Standpoint, and I. H. Bartholomew gave an address on The Relation of the Implement Manufacturer to the College Department of Agricultural Engineering.

An outline of a college course of study in rural engineering, as prepared by the committee on instruction in agriculture of the Association of American Agricultural Colleges and Experiment Stations, was submitted to the society and after discussion referred to a committee to confer with the committee of the association.

In an address on The Need for Work in Agricultural Engineering by the National Government, R. P. Teele, of this Office, outlined the methods and policies of this Department. It was pointed out that although buildings, implements, and machinery together represented over 25 per cent of the fixed capital of the farmer little was being done in this field. The plan of organization most desirable for carrying on such investigations was discussed, and a committee appointed to study the question and confer with the Association of American Agricultural Colleges and Experiment Stations.

Officers were elected as follows: President, J. G. Wynne, Madison, Wis.; vice-presidents, C. A. Ocock, of the Wisconsin University, and R. P. Teele, of this Office; secretary, L. W. Chase, of the Nebraska University; and treasurer, E. A. White, of the Illinois University. The third meeting of the society will be held at the Iowa College in December, 1909.

Proposed Association of Plant Pathologists.—At a meeting of plant pathologists held at Baltimore, December 30, 1908, in connection with the meetings of the American Association for the Advancement of Science, a temporary organization was effected by the election of the following officers: President, L. R. Jones, of the Vermont University and Station; vice-president, A. D. Selby, of the Ohio Station; and secretary and treasurer, C. L. Shear, of this Department; with J. B. S. Norton, of the Maryland College and Station, and B. M. Duggar, of the Cornell University and Station, as additional members of the council. The council is to consider matters relating to permanent organization and policy, and arrange for the next meeting.

American Forestry Association.—This association held its twenty-eighth annual meeting at Washington, D. C., January 13 and 14. Governor Curtis Guild, of Massachusetts, was elected president to succeed Secretary Wilson, of this department, who declined reelection. Among the resolutions adopted was one in advocacy of national legislation providing for instruction in forestry in agricultural colleges.

Necrology.—Dr. J. W. Fletcher, botanist and entomologist of the Central Experiment Station farm, Ontario, since 1887, died November 8, aged 56 years. Doctor Fletcher took a prominent part in securing the establishment of the Dominion experimental farms, and was also entomologist of the Canada geological survey. He was the author of numerous bulletins and other articles dealing with Canadian insect life and other scientific subjects. The January number of *The Ottawa Naturalist* contains a list of his extensive writings and many tributes to his life and work.

Charles Baltet, one of the foremost practical horticulturists and horticultural writers of France, died at his home at Troyes, November 24, at the advanced age of 78. For more than fifty years M. Baltet was intimately connected with the development and progress of French horticulture. He was the leading spirit in the founding of the National Horticultural School at Versailles, and always remained a friend to that institution. He was also well known in many countries through his numerous papers and treatises on various phases of practical horticulture, among which may be mentioned L'art de greffer, Traité de la culture fruitière commerciale et bourgeoise, and L'horticulture dans les cinq parties du monde. For the last-named work he received a prize of 10,000 francs from the National Society of Horticulture of France.

The death of the distinguished meteorologist, J. M. Pernter, at the age of 60 years, at Vienna, December 20, 1908, is announced. Doctor Pernter held the chair of meteorology and geo-dynamics in the University of Vienna and became director of the Austrian Central Meteorological Institute when J. Hann retired from this position to devote himself to special research. Doctor Pernter was well known for his work on meteorological optics and other phases of meteorological science, as well as for his work in developing the weather service of Austria. He also contributed to the discussion of the question of cannonading against hail. He organized and for several years presided over the International Meteorological Commission and was among the first to secure the establishment of a chair of meteorology in one of the higher institutions of learning.

George Nicholson, curator of the Royal Gardens at Kew from 1886–1901 and a prolific contributor to the English horticultural press, died September 20, aged 61 years.

The death is noted of Alexander Craw, since 1904 superintendent of entomology for the Hawaiian Board of Commissioners of Agriculture and Forestry, aged 58 years.

LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS REVIEWED.

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau requests and remittances should be directed to the Chief of the Bureau. The price of *Experiment Station Record* is $1.50 per volume, or 15 cents per number. The prices of other technical publications are given above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XX. MARCH, 1909. No. 7.

At the semicentennial of the Michigan Agricultural College, President Roosevelt indicated a keen interest in the welfare of the people living on farms, especially as to their home surroundings and their social relations. In his address on that occasion he declared that "no farmer's life should lie merely within the boundary of his farm," and that under present conditions the problem of the farm is much more than the growing of wheat and corn and cattle. "The problem of production has not ceased to be fundamental but it is no longer final; just as learning to read and write and cipher are fundamental but are no longer the final ends of education. We hope ultimately to double the average yield of wheat and corn per acre; it will be a great achievement; but it is even more important to double the desirability, comfort, and standing of the farmer's life. . . . We must try to raise the average farm life, and we must also try to develop it so that it shall offer exceptional chances for exceptional men."

Concerning the relating of education to the people of the country, he declared that we should "seek to provide for the people on the farms an equipment so broad and thorough as to fit them for the highest requirements of our citizenship, so that they can establish and maintain country homes of the best type, and create and sustain a country civilization more than equal to that of the city."

That this thought was not a passing fancy was made evident by frequent reference to these matters by the President since his address. His interest in this subject found expression in his appointment last August of a special commission, known as the Commission on Country Life, to gather information and advice as a basis for recommendations to Congress. In making this appointment he said: "The farmers have hitherto had less than their full share of public attention along the lines of business and social life. There is too much belief among all our people that the prizes of life lie away from the farm. I am therefore anxious to bring before the people of the United States the question of securing better business and better living on the farm, whether by cooperation between farmers for buying, selling, and borrowing, by promoting social advantages and opportunities in the country, or by any other legitimate means that will help to make

the country life more gainful, more attractive, and fuller of opportunities, pleasures, and rewards for men, women, and children of the farms."

The President defined the field of the commission and his expectations in regard to it in the following terms: "I shall be glad if the commission will report to me upon the present condition of country life, upon what means are now available for supplying the deficiencies which exist, and upon the best methods of organizing permanent effort in investigation and actual work along the lines I have indicated. You will doubtless also find it necessary to suggest means for bringing about the redirection or better adaptation of rural schools to the training of children for life on the farm. The National and State agricultural departments must ultimately join with the various farmers' and agricultural organizations in the effort to secure greater efficiency and attractiveness in country life."

The commission consisted of Dean L. H. Bailey, of the New York State College of Agriculture, chairman; Mr. Henry Wallace, editor; President Kenyon L. Butterfield, of the Massachusetts Agricultural College; Mr. Gifford Pinchot, of the U. S. Forest Service; and Mr. Walter H. Page, editor. The commission met and adopted plans for its work the latter part of September. It appointed Dr. E. W. Allen, assistant director of this Office, to act as its executive secretary. Subsequently William A. Beard, of California, and Charles S. Barrett, of Georgia, were added to the commission.

The commission devoted itself principally to securing a consensus of opinion as to the actual conditions prevailing over the country with reference to the social and sanitary conditions surrounding life in the country, educational facilities, facilities for communication and for the conduct of business, farm labor and tenancy, cooperation in buying and selling, and similar matters; and to becoming familiar with the various agencies in a position to assist in promoting rural welfare. Its work was divided among the members, such subjects as the social and sanitary conditions of the farm home, problems of education, farm labor and tenancy, sociological problems, etc., being assigned to different members.

The purpose of the commission, as stated in the President's message to Congress transmitting the report of the commission, was "not to help the farmer to raise better crops, but to call his attention to opportunities for better business and better living on the farm." Agricultural production is, in the judgment of the President, being adequately provided for by other organizations, for, as he says, "the National Department of Agriculture, which has rendered services equaled by no other similar department in any other time or place;

the State departments of agriculture; the State colleges of agriculture and the mechanic arts, especially through their extension work; the State agricultural experiment stations; the Farmer's Union; the Grange; the agricultural press; and other similar agencies, have all combined to place within the reach of the American farmer an amount and quality of agricultural information which, if applied, would enable him, over large areas, to double the production of the farm."

A circular containing questions under twelve general heads was distributed widely over the country. About 550,000 copies of this circular were mailed, not only to the farmers themselves, but to men in contact with country life, members of agricultural organizations, business and professional men, and others. Copies were sent to the newspapers of the country, to railroad officials, a large number of bankers and business men, country ministers and physicians, women's clubs, village improvement societies, and rural delivery carriers. The questions contained in the circular were also extensively printed by agricultural and other papers, with invitation to write to the commission along the lines of the questions. About 116,000 replies to this circular were received, as well as a large number of independent communications.

The commission held public hearings of from one to three days' duration at thirty different places in the United States, which were attended by representatives from forty States and Territories. At the President's suggestion meetings to discuss country life questions were held in district schoolhouses in almost every State, and reports of the meetings were sent to the commission.

The commission finds that while in a general way the American farmer was never more prosperous or better off than he is to-day, "agriculture is not commercially as profitable as it is entitled to be for the labor and energy that the farmer expends and the risks he assumes," and "the social conditions in the open country are far short of their possibilities." The leading specific reasons for this condition are stated to be—

"A lack of knowledge on the part of farmers of the exact agricultural conditions and possibilities of their regions;

"Lack of good training for country life in the schools;

"The disadvantage or handicap of the farmer as against the established business systems and interests, preventing him from securing adequate returns for his products, depriving him of the benefits that would result from unmonopolized rivers and the conservation of forests, and depriving the community, in many cases, of the good that would come from the use of great tracts of agricultural land that are now held for speculative purposes;

"Lack of good highway facilities;

"The widespread continuing depletion of soils, with the injurious effect on rural life:

"A general need of new and active leadership.

"Other causes contributing to the general result are: Lack of any adequate system of agricultural credit, whereby the farmer may readily secure loans on fair terms; the shortage of labor, a condition that is often complicated by intemperance among workmen; lack of institutions and incentives that tie the laboring man to the soil; the burdens and the narrow life of farm women; lack of adequate supervision of public health."

The three great general and immediate needs of country life as summarized by the President from the findings of the commission are: "First, effective cooperation among farmers, to put them on a level with the organized interests with which they do business.

"Second, a new kind of schools in the country, which shall teach the children as much outdoors as indoors and perhaps more, so that they will prepare for country life, and not as at present, mainly for life in town.

"Third, better means of communication, including good roads and a parcels post, which the country people are everywhere, and rightly, unanimous in demanding.

"To these may well be added better sanitation; for easily preventable diseases hold several million country people in the slavery of continuous ill health."

The report of the commission states that the subject of paramount importance as developed by the inquiries of the commission is education. "In every part of the United States there seems to be one mind, on the part of those capable of judging, on the necessity of redirecting the rural schools. There is no such unanimity on any other subject. It is remarkable with what similarity of phrase the subject has been discussed in all parts of the country before the commission. Everywhere there is a demand that education have relation to living, that the schools should express the daily life, and that in the rural districts they should educate by means of agriculture and country life subjects. It is recognized that all difficulties resolve themselves in the end into a question of education." The commission is of the opinion that "the most necessary thing now to be done for public-school education in terms of country life is to arouse all the people to the necessity of such education, to coordinate the forces that are beginning to operate, and to project the work beyond the schools for youth into continuation schools for adults." The commission therefore suggests the establishment of nation-wide extension work. "The first, or original, work of the agricultural branches of the land-grant colleges was academic in the old sense; later there was added the great field of experiment and research; there now should be added the third coordinate branch, comprising extension work, without

which no college of agriculture can adequately serve its State. It is to the extension department of these colleges, if properly conducted, that we must now look for the most effective rousing of the people on the land."

The commission believes that the development of the best in country life is largely a question of guidance. "The exercise of a wise advice, stimulus, and direction from some central national agency, extending over a series of years, could accomplish untold good, not only for the open country, but for all the people and for our institutions.

"In the communities themselves the same kind of guidance is needed, operating in good farming, in schools, churches, societies, and all useful public work. The great need everywhere is new and young leadership, and the commission desires to make an appeal to all young men and women who love the open country to consider this field when determining their careers. We need young people of quality, energy, capacity, aspiration, and conviction, who will live in the open country as permanent residents on farms, or as teachers, or in other useful fields, and who, while developing their own business or affairs to the greatest perfection, will still have unselfish interest in the welfare of their communities."

The commission points out, and the President concurs in the conclusion, "that the most important help that the Government, whether National or State, can give is to show the people how to go about these tasks of organization, education, and communication with the best and quickest results. This can be done by the collection and spread of information." The President urges that "it is of the first importance that the United States Department of Agriculture, through which as prime agent the ideas the commission stands for must reach the people, should become without delay in fact a Department of Country Life, fitted to deal not only with crops, but also with all the larger aspects of life in the open country."

The work of this commission broadly emphasizes the need, hitherto chiefly felt within a comparatively narrow circle, of broadening the scope of our agricultural colleges and the State and National departments of agriculture. So far these institutions have directed their energies mainly toward stimulating agricultural production. The agricultural experiment stations are organized under Federal and State legislation which practically limits their work to the problems of production.

It is well that this is so. When the stations were established the time was not ripe for economic and sociological studies among rural people in the United States. If the stations had been permitted to engage in statistical or other general inquiries regarding agricultural conditions, it seems probable that their energies would have been

largely dissipated in ill-considered general studies. The prime necessity was to establish agricultural production on a rational and scientific basis. This great task was laid upon the stations and the National Department of Agriculture. The concentration of effort in this direction was most fortunate and has led to results of permanent and incalculable value. This work is yet far from completion, but the institutions for research relating to agricultural production are now firmly established, have won the confidence and support of the agricultural community, and so demonstrated their usefulness that public funds are liberally bestowed on their maintenance.

It is highly important that the stations and other agencies for such research should continue to be held strictly to this business. Accurate knowledge of the natural conditions governing agricultural production is the only sure basis for the permanent prosperity of agricultural communities. It would be most unfortunate if any movement should arise which would divert these research agencies from strict adherence to the program of close and accurate studies relating directly to agricultural production.

But it is equally clear that the time has now come for exact and comprehensive studies of the economic and social conditions of agricultural communities. The wisdom of agricultural production in any particular line is determined not only by the familiarity which producers may have with the requirements of the product as related to the natural conditions in their region but also by the economic conditions prevailing in or affecting this region. Whether New England or Oregon farmers would better engage in wheat growing or dairy husbandry will depend not only on their knowledge of soils, methods of culture, and varieties of wheat, but also on the cost and value of the crop, the state of the wheat market in this and other countries, and other economic conditions. This is obvious when we state it, but oftentimes in our zeal to promote agricultural research relating to production we have laid so much stress on the necessity for an accurate knowledge of the factors of production that we have produced the impression among agricultural people that if they only knew enough about the laws governing production they could successfully engage in any kind of agricultural pursuit despite the most unfavorable economic conditions. Such wrong conceptions have, for example, led many to imagine and deplore a decadence of agriculture in regions where changes in economic conditions were destroying certain agricultural industries and bringing in others which eventually at least will prove more satisfactory and remunerative. It was inevitable that grain growing should cease to be the predominant factor in eastern agriculture, but more prosperous agricultural communities will result when dairy husbandry and horticulture are more firmly established and wisely conducted. Grazing may be for a time

the most prosperous agriculture on our western plains, but why regret if the herdsman is supplanted by the irrigator?

And even when the importance of economic factors as related to agricultural production has been acknowledged it has too often been forgotten that agriculture is not likely to prove a satisfactory and attractive pursuit in any community, however favored as regards skill in production and success in buying and selling unless the social conditions are also favorable to country life.

The awakening of interest in the economic and social problems of agricultural communities which is bound to follow the inquiries of the Commission on Country Life will have only a transient effect unless it is succeeded by the establishment of permanent institutions for the study of such problems and the preparation of experts in these lines. When we consider the vast extent of our country and the varied character and environment of our agricultural people it can hardly be expected that any satisfactory solution of the complex economic and social problems of different regions can be reached until after many years spent in the most careful study of local conditions by thoroughly trained experts. At present we have neither the facts nor the experts.

To secure the experts it will be necessary to broaden the work of our agricultural colleges and build up in them strong departments of agricultural economics and sociology. A beginning has been made in this direction, but present provision for such studies is wholly inadequate. It seems likely that the same process of evolution must go on in these departments as has occurred in the departments for agricultural production. First, a few men will roughly block out the problems and attempt instruction on them. Then the need of research will be apparent, and fragmentary efforts will be made in this line. But the departments of instruction in agricultural economics and sociology will never be in satisfactory condition until agencies for systematic research in these lines are established and have done considerable work.

Herein lies a great opportunity for the National and State departments of agriculture and the agricultural colleges. It is the joint work of all these agencies which alone will secure the best results. The report of the Commission on County Life points out the path along which progress should be made in the immediate future. Our chief purpose here is to emphasize the importance of the work of this commission as related to our agricultural colleges. It will be well if these institutions follow closely the work of the commission and get ready to take up the work when the commission leaves it.

One factor in the present development of our agricultural colleges is of great importance in this connection. As is well known, these

colleges are now proceeding rapidly with the formation of departments for extension work. In this way they are being brought into much closer personal touch with the agricultural people. This is already giving the colleges a new and broader view of the problems of rural life. The varied human needs of agricultural communities and the dignity and worth of agricultural people are being borne in upon the colleges as never before. The movement for agricultural education is no longer a narrow and intellectual paternalism in which the few are condescending to advise the many. It is being more and more permeated with the spirit of comradeship and good fellowship in which all are uniting to advance a common cause. This drawing together of the institutions for agricultural education and the people should make it much easier to get at the real heart of rural economic and social questions and in the end exercise a profound influence toward their satisfactory solution.

That the great impetus which science has in recent years given to agriculture in the United States has also been felt in other American republics is shown by the activity which has been displayed in many of these countries in reorganizing old and establishing new agricultural institutions, by increased demand upon this country for men to take charge of these institutions, and by the large number of young men of these countries seeking advanced training in agriculture in the United States.

Evidence of the importance which science applied to agriculture is assuming in other American republics was furnished by the First Pan-American Scientific Congress recently held at Santiago, Chile, which was attended by representatives from all of the American republics except Haiti, and at which discussion of subjects related to agricultural education and research formed a prominent feature of the proceedings. A section of the congress was devoted exclusively to the consideration of such subjects, and steps were taken to make this feature even more prominent at the next congress, which is to be held at Washington in 1912.

It is believed that those in this country interested in the broad development of agricultural education and research and in extending and strengthening our scientific relations with other countries, particularly those of continental America, will find in this congress a valuable means to this end. Attention is therefore particularly called to the account of the Santiago congress which is given on page 695 of this number of the Record, and occasion is here taken to emphasize the importance of making the agricultural education and research features of the Washington congress worthily representative of the progress in these subjects in America and an incentive and aid to future development.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

Annual reports on the progress of chemistry for 1907 (*Ann. Rpts. Prog. Chem. [London]*, *4* (*1907*), *pp. X+362, fig. 1*).—This is the fourth volume of this series of reviews of progress in chemistry issued by the London Chemical Society. As heretofore, it includes reports on general and physical chemistry by A. Findlay, inorganic chemistry by H. Marshall, organic chemistry by H. J. H. Fenton, C. H. Desch, and J. T. Hewitt, stereochemistry by H. O. Jones, analytical chemistry by A. C. Chapman, physiological chemistry by W. D. Halliburton, agricultural chemistry and vegetable physiology by A. D. Hall, mineralogical chemistry by A. Hutchinson, and radioactivity by F. Soddy.

The section on agricultural chemistry and vegetable physiology reviews investigations in soil bacteriology, chemistry, and physics; chemistry of the growing plant; manures and manuring; chemistry of animal nutrition; and chemical analysis. "The record of the year includes no notable discovery nor any paper that is likely to be reckoned in the future as of fundamental importance; in several directions, however, good progress has been made, although, as the subject opens up, it is only to disclose its increasing complexity."

General chemistry of enzyms, H. Euler (*Ergeb. Physiol., 6* (*1907*), *187–243*).—An important summary of data regarding enzyms. Such questions are taken up as classification, preparation, the influence of temperature on enzym activity, and the question of kinasins, ko-enzyms, or activators.

The data of geochemistry, F. W. Clarke (*U. S. Geol. Survey Bul. 330, pp. 716*).—"To bring some of the data together, to formulate a few of the problems, and to present certain general conclusions in their modern form are the purposes of this memoir. It is not an exhaustive monograph upon geochemistry, but rather a critical summary of what is now known and a guide to the more important literature of the subject." The different chapters treat of the chemical elements, the atmosphere, lakes and rivers, the ocean, the waters of closed basins, mineral wells and springs, saline residues, volcanic gases and sublimates, the molten magma, rock-forming minerals, igneous rocks, the decomposition of rocks, sedimentary and detrital rocks, metamorphic rocks, metallic ores, the natural hydrocarbons, and coal.

The determination of the equilibrium of ammonia under pressure, F. Haber and R. Le Rossignol (*Ztschr. Elektrochem., 14* (*1908*), *Nos. 45, pp. 181–196, pl. 1; 34, pp. 513, 514; abs. in Sci. Abs., Sect. A—Phys., 11* (*1908*), *No. 129, p. 538*).—This is a further contribution to the discussion of this subject which has been going on for some time between the authors (E. S. R., 19, p. 910) and Nernst and Jost. Further determinations are reported which confirm the author's previous results but do not agree with Nernst's theoretical calculations or the results obtained by Nernst and Jost at temperatures between 685° and 1040° F.

On the equilibrium weights of ammonia, F. Jost (*Ztschr. Anorgan. Chem., 57 (1908), No. 4, pp. 414–430, fig. 1; Ztschr. Elektrochem., 14 (1908), No. 28, pp. 373–375; abs. in Sci. Abs., Sect. A—Phys., 11 (1908), No. 129, pp. 537, 538*).—New measurements with the Nernst electric pressure furnace of the partial pressure of ammonia formed from nitrogen and hydrogen are reported. The conclusions of Haber and Le Rossignol are criticised.

On the constitution of phosphoric acid, F. C. Palazzo and F. Maggiacomo (*Gaz. Chim. Ital., 38 (1908), II, No. 2, pp. 115–123*).—A theoretical discussion.

The determination of phosphoric acid, N. von Lorenz (*Chem. Ztg., 32 (1908), No. 60, pp. 707–709; abs. in Chem. Abs., 2 (1908), No. 20, p. 2767*).—From a comparison of his method with the citrate method the author concludes that while the accuracy of the latter depends upon a compensation of errors the former gives directly accurate results. The author's method, moreover, is quicker, more convenient, more generally applicable, and does not require the previous removal of silica.

The determination of phosphoric acid by the von Lorenz method, O. Fallada (*Mitt. Chem. Tech. Vers. Stat. Cent. Ver. Rübenz. Indus. Österr. Ungar., No. 202, pp. 7–10; abs. in Chem. Zentbl., 1908, II, No. 9, pp. 827, 828*).—Comparative tests of this method and of the Wagner molybdic and citrate methods on Thomas slag, spodium, and superphosphate are reported. The results indicate a high degree of reliability for the method.

Action of ammonium citrate on calcium phosphate, A. Barillé (*Jour. Pharm. et Chim., 6. ser., 27 (1908), No. 9, pp. 437–441; Ann. Chim. Analyt., 13 (1908), No. 7, pp. 264–266; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 548, II, p. 496; Chem. Zentbl., 1908, I, No. 26, p. 2130; Chem. Abs., 2 (1908), No. 17, p. 2354*).—Experiments with dicalcium and tricalcium phosphates show that both salts are soluble and that the solubility varies with their physicial condition. The author concludes that the ammonium citrate solution not merely dissolves the phosphates, but forms true double salts with them.

A simple method for the determination of potash in silicates. W. Autenrieth (*Zentbl. Min. u. Geol., 1908, pp. 513–517; abs. in Chem. Zentbl., 1908, II, No. 13, pp. 1125, 1126; Chem. Abs., 2 (1908), No. 22, p. 3038; Jour. Chem. Soc. [London], 94 (1908), No. 552, II, p. 897*).—The silicate is reduced with hydrofluoric acid and sulphuric acid. The potash is precipitated with Koninck's sodium cobalti-nitrite reagent, but finally converted into either chloroplatinate or perchlorate and so weighed.

A short volumetric method for the estimation of sulphuric acid. T. Cooksey (*Jour. and Proc. Roy. Soc. N. S. Wales, 41 (1907), pp. 216–218*).—A method based upon "the volumetric estimation of the excess of barium chlorid left in solution after precipitation of the sulphuric acid as sulphate of baryta" is described.

Mechanical and physico-chemical analysis of soil, F. Hiti (*Estac. Agr. Cent. [Mexico] Bol. 4, pp. 10*).—The methods proposed by Grandeau for this purpose are described.

The estimation of phosphoric acid in foods, E. Wörner (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 12, pp. 732–734*).—In the method described by the author the food material is oxidized with nitric and sulphuric acids, the phosphoric acid precipitated with molybdate solution, and the precipitate heated with excess of standardized sodium hydroxid solution. Ammonia is thus expelled and its quantity as determined by titration is a measure of the phosphoric acid present.

The detection of pentoses by means of orcin hydrochlorate. J. Pieraerts (*Bul. Assoc. Chim. Sucr. et Distill., 26 (1908), No. 1–2, pp. 46–62*).—The results

of the author's extended study of methods were favorable to the use of orcin hydrochlorate.

Detection and estimation of rice husk in feeding stuffs, F. SCHRÖDER (*Arb. K. Gesundhtsamt., 28 (1908), No. 1, pp. 213–224; abs. in Analyst, 33 (1908), No. 388, p. 280*).—Rice husks may be detected by the microscope, but the quantity present must be determined before the feeding stuff can be said to be adulterated. This can be done by determining the ash and silica content. The author reports the percentages found in different brans.

The proteins of egg yolk, R. H. A. PLIMMER (*Jour. Chem. Soc. [London], 93 (1908), No. 550, I, pp. 1500–1506*).—A new proteid was identified in egg yolk for which the name livetin is provisionally suggested. "Vitellin and this new protein showed a very close similarity to one another, but they differ considerably from ovalbumin, and it may be concluded that this protein is another constituent of egg yolk. It is suggested that the protein may be vitellin without the phosphorous-containing portion."

Experimental and analytical data are reported.

The albumen of turkey egg white, W. WORMS (*Zhur. Russ. Fiz. Khim. Obshch., 38 (1906), pp. 597–607; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 6, pp. 363, 364*).—The author isolated and studied a crystalline albumen which is regarded as an isomer of the albumen in the white of hens' eggs.

The detection of protein by means of formaldehyde, L. VON LIEBERMANN (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 4, p. 231*).—A note on the detection of protein by means of formaldehyde and concentrated sulphuric acid containing a little iron oxid.

Identification of different plant proteids by means of specific sera, D. GASIS (*Berlin. Klin. Wchnschr., 45 (1908), No. 7, pp. 358–360*).—Proteids from beans, lentils, peas, wheat, rye, barley, maize, beet seed, and rice were studied with bean, rye, rice, and beef antisera. The results, according to the author, show that plant proteids may be differentiated by the biological method when the proper quantitative relations are observed. The reaction is weaker or more pronounced according to the remote or near relationship of the different plant proteids used. In general, plant proteids are more readily differentiated by means of the precipitin reaction than are animal proteids. A bibliography is appended to the report.

The estimation of dry matter in gluten, M. P. NEUMANN and P. SALECKER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 12, pp. 735–738*).—Moist gluten is pressed to the bottom of a flat nickel dish and dried in an air oven at 120° C. Constant weight is obtained in 3 hours.

Saccharid substances, E. SILZ (*Bul. Assoc. Chim. Sucr. et Distill., 26 (1908), No. 1–2, 40–45*).—In a report presented at the First International Congress for the Repression of Adulteration of Foods and Drugs the author defines sugar and similar goods and outlines commercial procedures regarded as legitimate.

The inversion of cane sugar by invertase, C. S. HUDSON (*Jour. Amer. Chem. Soc., 30 (1908), No. 7, pp. 1160–1166*).—According to the author's conclusions which are based on experimental data "the inversion of cane sugar by acids follows, even in its first stages, the unimolecular order, and second. . . . the polarimetric measurement of the inversion of cane sugar by invertase involves a large source of error which can be avoided by adding alkali to the inverting solution before each reading of the polariscope.

Detection of δ-fructose in the presence of other natural sugars, M. J. PIERAERTS (*Rec. Cén. Agron., n. ser., 3 (1908), Nos. 5, pp. 218–227; 6–7, pp. 266–272*).—A critical study of methods.

The estimation of sugar in beet stalks and dried pulp, J. Robart (*Bul. Assoc. Chim. Sucr. et Distill., 26 (1908), No. 1–2, p. 65*).—A discussion of the methods advocated by Zlobinsky (E. S. R., 19, p. 810).

A reaction for the detection of natural and artificial honey, J. Fiehe (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 1–2, pp. 75–77*).—The test described is based on the detection by means of resorcinol and hydrochloric acid of the decomposition products formed during the manufacture of invert sugar from which artificial honey is prepared. With invert sugar an orange red color is obtained, changing to cherry red and then to brown red. Pure natural honeys do not give such a reaction though a transient pink coloration may sometimes be noted.

The rapid estimation of starch in sausage and other meat products, Telle (*Ann. Chim. Analyt., 13 (1908), No. 4, pp. 144–146*).—A modification of Baudry's method of estimating starch is described, which the author considers satisfactory.

Detection of horse meat in sausage, etc., Telle (*Ann. Chim. Analyt., 13 (1908), No. 4, pp. 143, 144*).—A note on methods of detecting horse meat.

Methods employed for the analyses of wines, alcohols, brandy, and liqueurs (*Bul. Mens. Off. Renseig. Agr. [Paris], 7 (1908), No. 5, pp. 522, 523*).—The French official methods in accord with the law of August 1, 1905, are briefly outlined.

A new method for the determination of fixed and volatile acids in wine and other fermented beverages, M. E. Pozzi-Escot (*Bul. Assoc. Chim. Sucr. et Distill., 26 (1908), No. 1–2, pp. 68, 69; abs. in Chem. News, 98 (1908), No. 2548*).—The fixed acids are precipitated as salts of barium. The volatile acids are determined by subtracting the fixed acids from the total acidity.

Citric acid in wine, M. A. Hubert (*Ann. Chim. Analyt., 13 (1908), No. 4, pp. 139–141*).—A discussion of the occurrence of citric acid in wine and its detection.

Note on the formation of formaldehyde in solutions of cane sugar and its bearing on Hehner's test for formaldehyde in saccharin mixtures, A. A. Ramsay (*Jour. and Proc. Roy. Soc. N. S. Wales, 41 (1907), pp. 172–175*).—The author identified formaldehyde in aqueous solutions of cane sugar, boiled and distilled, and discusses the bearing of such results on the identification of added formaldehyde in food products.

Titration of formaldehyde in colored solutions, S. P. L. Sörensen and H. Jessenhansen (*Compt. Rend. Lab. Carlsberg, 7 (1908), No. 2, pp. 58–71*).—From the results of experimental studies on the determination of formaldehyde in gelatin, casein, egg albumen, and serum albumen, the authors conclude that solutions may be decolorized with nitrate of silver in a slightly acid solution without causing any considerable loss of nitrogen.

The detection of formaldehyde, F. von Fillinger (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 4, pp. 226–231*).—A study of methods.

The identification and estimation of boric, salicylic, and benzoic acid in foods and condiments, W. von Genersich (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 4, pp. 209–225*).—A critical study of methods.

The detection of saponin, J. Rühle (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 3, pp. 165–171*).—A critical study of Brunner's method which the author considers satisfactory.

The valuation of saffron for dairy purposes, K. Teichert (*Milchw. Zentbl., 3 (1907), No. 8, pp. 369–374; 4 (1908), No. 3, pp. 108–111*).—The author outlines what he considers a more reliable method for the determination of the amount of coloring matter than is now in use. The methods for obtaining the percentage of moisture and ash are also given.

The preservation of milk samples for analytical purposes, K. Windisch (*Milchw. Zentbl., 4 (1908), No. 3, pp. 97–108; abs. in Centbl. Bakt. [etc.], 2. Abt., 21 (1908), No. 17–19, pp. 577, 578*).—A list of reagents that have been used as preservatives is discussed and the literature cited. The author made a series of tests with potassium bichromate and copper ammonium sulphate, and presents tables showing the results obtained with varying amounts of these substances. Milk retained normal characteristics for 4 weeks with 0.15 to 0.25 per cent solution of potassium bichromate and 1.0 to 1.5 per cent copper ammonium sulphate. A 2 per cent solution of the latter preserved the milk a week longer. In summer months a stronger solution is needed than in the winter.

Rapid estimation of potassium bichromate in milk, Goutère (*Ann. Chim. Analyt., 13 (1908), No. 7, pp. 262, 263*).—This is accomplished by adding potassium iodid and hydrochloric acid to the ash, and determining the iodin set free by titration with sodium hyposulphite.

Contributions from the dairy institute of Greifswald. II, Studies on the Adams method of estimating fat, R. Eichloff (*Milchw. Zentbl., 4 (1908), No. 3, pp. 120–124*).—With sour milk exact results were obtained only by the use of fat-free paper.

An automatic device for measuring reagents used in determining milk fat by the Gerber method (*Apoth. Ztg., 23 (1908), No. 68, p. 607; Schweiz. Wchnschr. Chem. u. Pharm., 46 (1908), No. 40, pp. 638, 639, figs. 6*).—It is claimed that by two movements of the hand the amount of milk or of the reagents used in the Gerber method can be quickly and accurately measured.

A new automatic milk-measuring device, O. Wendler (*Milch Ztg., 37 (1908), No. 42, pp. 494, 495, figs. 3*).—Notes on the device noted above.

New apparatus for estimating the moisture content of butter (*Milch Ztg., 37 (1908), No. 41, pp. 485, 486, figs. 5*).—This is a special form of balance with a graduated arm. The sample of butter is weighed before and after heating to expel moisture. The percentage of moisture lost is easily computed from the scale.

Total solids in mill products by the refractometer, S. S. Peck (*Hawaiian Sugar Planters' Sta., Div. Agr. and Chem. Bul. 27, pp. 5–25*).—At this station 25 samples of waste or final molasses were examined for the purpose of comparing results obtained by desiccation and by the refractometer. Thirteen samples showed a larger amount of solids with the refractometer. The determination of total solids in 18 samples of various juices by the refractometer usually gave lower results than the Brix spindle. With 2 samples of massecuite the refractometer gave satisfactory results. "Under the present method of determining solids in the residual juice in the bagasse the refractometer finds no place. . . Boiling to a definite percentage of solids in the massecuite is possible by the use of the brasmoscope. . . The refractometer is an effectual substitute when boiling to string-proof and not as difficult of application. . . The refractometer offers a rapid and convenient method for checking the correctness of the graduations on Brix spindles." A table of dry substance from refractive index at 28° C., by H. C. Prinsen-Geerligs, is appended.

Refractometer in the control of sugar manufacturing processes, F. Strohmer (*Mitt. Chem. Tech. Vers. Stat. Cent. Ver. Rübenz. Indus. Osterr.-Ungar., No. 206, pp. 13, figs. 5*).—From the experimental data reported the author concludes that the refractometer may be made of great importance in controlling sugar house processes.

A new soil sampler, W. H. Stevenson (*Science, n. ser., 28 (1908), No. 722, pp. 614–616*).—This is a brief description of a soil sampler fully described in a bulletin of the Iowa Station (E. S. R., 19, p. 709).

METEOROLOGY—WATER.

The weather service and meteorology in the United States and Canada. P. Polis (*Ber. Landw. Reichsamte Innern [Germany], No. 7, pp. 43, figs. 12, maps 2.*—This is an account of observations made during a trip to the United States and Canada during the summer and fall of 1907. The object of this trip was to study the organization of the meteorological service, especially the weather service, and the telegraphic and other methods of distributing information about the weather in the United States, with a view to improving the German weather service. The author states in conclusion that the organization of the weather service in the United States may be taken as a model and that its methods of distributing meteorological information, weather maps, and forecasts are the best in the world. He was particularly impressed with the rapidity with which the daily weather maps were prepared, printed, and distributed, and with the dissemination of the weather forecasts by means of telegraph, telephone, and weather signals.

Third annual report of the meteorological committee (*Ann. Rpt. Met. Com. [Gt. Brit.], 3 (1908), pp. 164, pls. 5, figs. 3*).—This consists as usual of administrative reports regarding organization and operations (during the year ended March 31, 1908) in marine meteorology, forecasts and storm warnings, climatology, publication, investigation of the upper air (by W. H. Dines), and miscellaneous subjects, with appendixes as follows: Report by the liquidator of the meteorological council, supply of information to the public, lists of observers who sent in "excellent" meteorological logs during the year and of logs and documents received from ships, distribution of instruments, report on inspection of meteorological stations, list of persons and institutions from whom publications and meteorological data have been received and to whom publications are sent, and financial statement.

The report calls attention particularly to progress made in the organization of international cooperation during the year.

During the year 1907 the percentage of complete success in the forecasts for the whole of the British Isles was 54, of the sum of complete and partial successes 91, the average for 10 years 86.5.

The daily normal temperature and the daily normal precipitation of the United States. F. H. Bigelow (*U. S. Dept. Agr., Weather Bur. Bul. R, pp. 186*).—The results of the calculation to a uniform basis of the reliable available data on temperature and precipitation in the United States are given in tabular form in this bulletin. It is stated that "these tables of daily normal temperature and precipitation are now in use in the climatological work of the Bureau throughout the United States, and they have superseded all the daily normals which were prepared several years ago from much less extensive data than were available in the formation of these tables."

Monthly Weather Review (*Mo. Weather Rev., 35 (1907), No. 13, pp. XIX+607–616+19, pls. 31, charts 6*).—The report contains the usual summaries of general climatic conditions with regard to pressure, temperature, precipitation, relative humidity, climatological tables, table of contents, index, etc., of the Monthly Weather Review for 1907, and an appendix containing the annual report of the Chief of the Weather Bureau for the year ended June 30, 1907.

The most notable abnormal meteorological features of the year were the wide fluctuations in the seasonal temperature, resulting in "the extreme warmth of the latter part of March over the districts east of the Rocky Mountains, and the continued cold attending the progress of the later spring and early summer months over the greater part of the same districts. . . .

"Temperature was below the normal during the greater part of the year over all northern districts of the United States and also over the whole of Canada, except portions of British Columbia. The total deficiency, however, was generally less than 2°. Over the southern portions of the United States there was a corresponding excess, which prevailed by small amounts during most of the months of the year. . . .

"In general the precipitation for the year was above the normal in the central portions of the Middle Atlantic States, portions of the Lake region, the Ohio and middle Mississippi valleys, the central Gulf States, and in the Rocky Mountain and Plateau districts, and portions of western Oregon and northern California.

"Over the South Atlantic coast, the southern Appalachian region, Florida Peninsula, the west Gulf States, the Great Plains from Texas to the northern boundary, portions of the Lake region, and along the north Pacific coast there was a general and well-marked deficiency in the annual precipitation.

"Along the immediate Atlantic coast from Chesapeake Bay to Florida, and over eastern Texas and the western portions of Louisiana and Arkansas, the deficiency ranged from about 5 to more than 20 in.

"The general distribution of precipitation during the various seasons of the year was such that except over small areas there was no important interest that suffered materially from either excess or deficiency of moisture."

Meteorological statistics for 1907. F. H. Loud (*Colo. Col. Pub., 12 (1908), Sci. Ser., No. 5, pp. 101–136*).—The equipment and methods of observation at the observatory of Colorado College are described and a record is given of observations on temperature, pressure, humidity, rainfall, etc., during the year.

Climate [of Maryland]. W. B. Clark and E. B. Mathews (*Md. Geol. Survey [Rpt.], 6 (1906), pp. 22½–237, figs. 7*).—This is a general description of the more important climatic factors of the State.

The meteorological service and the climate of São Paulo. J. N. Belfort Mattos (*Sec. Agr. Com. e Obras Pub. Estado São Paulo, Secc. Met. [Pub.], Ser. 2, No. 3, pp. 17, maps 3*).—A brief historical note regarding the meteorological service is given and the general climatic features of the State of São Paulo are described, with tables showing averages of results of observations on temperature, pressure, humidity, rainfall, cloudiness, and direction of wind for the warmest month (January), coolest month (July), for the different seasons, and for the year as a whole.

The weather of 1907 at the Midland Agricultural and Dairy College, Kingston-on-Soar, Notts (*Midland Agr. and Dairy Col. Bul. 10, 1907–8, pp. 111–114, dgm. 1*).—The results of the usual meteorological observations are summarized in notes and a table and diagram.

Dew measurements during 1904 to 1907. N. Passerini (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 5 (1908), No. 3, pp. 37½–387*).—Determinations of the amount of water collected on a surface 1 decimeter square, the velocity of the wind, and the state of the sky during the period named are reported. The total amounts of water so collected were as follows: 1904, 81.7 gm.; 1905, 88.6 gm.; 1906, 76.1 gm.; and 1907, 72 gm. The annual periods of maximum and minimum deposition varied widely during the different years.

Report on the work of the station of agricultural climatology of Juvisy during 1907. C. Flammarion (*Bul. Mens. Off. Renseig. Agr. [Paris], 7 (1908), Nos. 8, pp. 966–979, figs. 6; 9, pp. 1101–1113, figs. 3*).—As usual, this report contains records of observations on atmospheric pressure, the temperature of the air, soil, and underground water, and the relative humidity, rainfall, sunshine, cloudiness, radiation, wind, influence of different colored lights and of the moon

on growth of plants, and the falling and renewing of leaves. The data are recorded in tables and diagrams.

Study of the climate of Rennes, C. Cloarec (*Trav. Sci. Univ. Rennes, 5 (1906), pp. 103–112; 6 (1907), pp. 17–31, fig. 1*).—This is more particularly a study of daily variations of temperature based upon observations during 25 years, 1879–1903. These studies indicate a certain periodicity in the variation of temperature throughout the month, namely, an elevation from the second to the ninth, a fall from the ninth to the twenty-first, an elevation from the twenty-first to the twenty-eighth, and a fall from the twenty-eighth to the second of the month following.

Meteorological observations at the Ploti Experiment Station, 1907, M. Boulatovitch and A. Winkler (*Ghodichnuĭ Otchet Ploty. Selsk. Khoz. Opuitn. Stantziĭ, 13 (1907), pp. 1–53, 161–167*).—The total rainfall in 1907 was 11.37 in., the mean for 13 years being 16.26 in. This low rainfall is exceptional, but one other year, 1904, approaching it with a total rainfall of 11.6 in. Precipitations so small as to be of little value were very numerous during the year, there being 116 rainy days. The deficiency of rainfall was especially noticeable in May and October, as these are usually the months of greatest precipitation.

The total evaporation for the year was 28.3 in., the mean for 13 years being 32.5. The mean relative humidity was 70 per cent, being 3 per cent below the 13 year average.

The average temperature for the year was 7.8° C., or 1.1° lower than the 13 year average; the maximum, 34.7°, was on August 21, and the minimum, —24°, January 21 and 24. The maximum temperature of the surface soil was 59.6° C., the minimum —26.7°.

The average atmospheric pressure was 29.54 in., or 0.02 in. above the normal. The number of hours of sunshine was 1,971.2, or 79.5 hours below the normal.

Report of the meteorological commission [Cape of Good Hope], 1907, C. A. Smith et al. (*Rpt. Met. Com. [Cape Good Hope], 1907, pp. XIV+73*).—This report contains a brief account of the general work of the commission during 1907, a table showing distribution of instruments during 1907, a financial statement, and results of observations during the year on evaporation, temperature, pressure, sunshine, radiation, and rainfall at various stations throughout Cape of Good Hope, as well as observations on surface temperature of the sea.

A comparison of the rainfall of Sydney and Melbourne, 1876–1905, A. Duckworth (*Jour. and Proc. Roy. Soc. N. S. Wales, 41 (1907), pp. 190–195, pls. 2*).—Comparisons of total rainfall, variation, and distribution are made in notes, tables, and diagrams.

Problems of the artesian water supply of Australia, with special reference to Professor Gregory's theory, E. F. Pittman (*Jour. and Proc. Roy. Soc. N. S. Wales, 41 (1907), pp. 100–139, pls. 2*).—This article deals at some length with the objections urged by Gregory against the hydrostatic pressure theory, and then considers the theory which he propounds in lieu of it, viz, that the artesian water supply of the Australian basin "has been evolved from underground masses of igneous rocks, and is forced above the surface in bores by the influence of temperature and rock pressure." The author does not accept this theory as compatible with the actual conditions prevailing.

Chlorin and solid matter in river water, J. Sack (*Inspectie Landb. West-Indië Bul. 13, pp. 24–29*).—Determinations of chlorin and solid matter in samples of water of a number of Javan streams at different seasons of the year are reported.

The decomposition and nitrification of sewage (1) in alkaline solutions, (2) in distilled water, J. E. Purvis and R. M. Courtauld (*Proc. Cambridge Phil. Soc., 14 (1907), No. 4, pp. 354–360*).—Studies of the decomposition and

transformation of nitrogen compounds in solutions of sodium chlorid, magnesium sulphate, and magnesium chlorid, of strengths equivalent to that of the corresponding salts found in the water of the British Channel, when 1 per cent sewage was added to them, either singly or combined, show that the salts seriously interfere with the decomposition of the sewage. "There was only a slow production of the two ammonias, although there was a progressive decline in the amount; and the nitrates were so small in amount that they must have been less than 0.005 part per 100,000. And the present experiments prove that when sewage was incubated in slightly alkaline solutions there were definite amounts of nitrates produced, whilst there was a greater production when the incubations were in distilled water alone. . . . There can be little doubt, therefore, that the salts in sea water do interfere with the development of useful nitrifying organisms whose normal action under proper conditions is to convert sewage into substances like nitrates."

Royal Commission on Sewage Disposal, H. C. H. Shenton (*Surveyor, 34 (1908), Nos. 871, p. 342; 872, pp. 352–354; 873, pp. 376–378; 874, pp. 401–404; 875, pp. 430–432; abs. in Science, n. ser., 28 (1908), No. 717, pp. 405, 406; Chem. Abs., 2 (1908), No. 23, pp. 3251–3253*).—This report contains the results of a large number of hearings by the commission as to the relative merits of various methods in use in England for purifying town sewage. Among the general conclusions reached by the commission are the following:

"We are satisfied that it is practicable to purify the sewage of towns to any degree required, either by land treatment or by artificial filters, and that there is no essential difference between the two processes, for in each case the purification, so far as it is not mechanical, is chiefly effected by means of microorganisms. The two main questions, therefore, to be considered in the case of a town proposing to adopt a system of sewage purifications are: First, what degree of purification is required in the circumstances of that town and of the river or stream into which its liquid refuse is to be discharged? Second, how the degree of purification required can, in the particular case, be most economically obtained. . . . We may state that we know of no case where the admixture of trade refuse with the sewage makes it impracticable to purify the sewage either upon land or by means of artificial processes, although in certain extreme cases special processes of preliminary treatment may be necessary."

The commission is also of the opinion that while "no land is entirely useless . . . peat and stiff clay lands are generally unsuitable for the purification of sewage."

Royal Commission on Sewage Disposal (*Surveyor, 34 (1908), No. 869, pp. 284–286; Brit. Med. Jour., 1908, No. 2497, p. 1447*).—The summary of conclusions and recommendations of the report of the commission referred to above is quoted and commented upon.

SOILS—FERTILIZERS.

Bibliography of the geology of Connecticut, H. E. Gregory (*Conn. State Geol. and Nat. Hist. Survey Bul. 8, pp. 123*).—This bibliography contains a number of references to articles relating to the soils of the State.

The distribution and location of moors in Germany, P. Krische (*Illus. Landw. Ztg., 28 (1908), No. 48, pp. 419–421*).—Data on this subject are summarized and briefly discussed. See also a previous note (E. S. R., 20, p. 16).

Agrologic study of an estate by the synthetic method of J. Hazard, A. Grégoire and F. Halet (*Bul. Inst. Chim. et Bact. Gembloux, (1908), No. 75, pp. 1–43, pls. 2, figs. 2, charts 4*).—This article reviews briefly the history of the

development of agronomic charts and discusses their practical value, and reports detailed studies of the topography, geology, hydrology, and composition and structure of soils of a large Belgian estate. The practical application of the results of this study in the culture and management of the estate are also discussed. A strong plea is made for the more extended preparation and use of such surveys.

Agronomic charts, E. Leplae (*Rev. Gén. Agron., n. ser., 3 (1908), No. 6–7, pp. 252–261*).—This is a discussion of the agricultural value of such charts in reply to the article by Grégoire and Halet noted above.

The agronomic chart of Belgium and analyses of soils, E. Leplae (*Rev. Gén. Agron., n. ser., 3 (1908), No. 5, pp. 193–217*).—The author calls attention particularly to the great diversity of methods which have been proposed and are used for the charting of soils and for their physical and chemical examination, and urges the importance of systematic inquiry with reference to the adoption of uniform methods.

Agronomic charts, A. Grégoire and F. Halet (*Ann. Gembloux, 18 (1908), No. 7, pp. 395–402*).—The authors take exception to the conclusion of Leplae that it is not feasible to prepare agricultural charts of Belgium which are of special practical value.

Agronomic charts, A. Proost (*Rev. Gén. Agron., n. ser., 3 (1908), No. 9, pp. 346–349*).—This is a reply to Leplae's criticisms noted above.

The study of soils (*Rev. Gén. Agron., n. ser., 3 (1908), No. 9, pp. 349–351*).—A further discussion of the utility of agronomic charts or soil maps.

Agrological studies, L. A. Rebello da Silva (*Rev. Agron. [Portugal], 5 (1907), Nos. 11, pp. 333–337; 12, pp. 365–371; 6 (1908), No. 1, pp. 5–9*).—A classification including 5 groups is described, with mechanical analyses by Schöne's method of 13 samples of Portuguese soils.

The use of geo-agrological maps in the assessment of taxes in the valleys and plains of the Province of Verona, E. Nicolis (*Atti. e Mem. Accad. Agr. [etc.] Verona, 4. ser., 7 (1907), pp. 123–213, map. 1*).—Such a map is given and its preparation and use explained.

Analyses of soils from Papua, F. B. Guthrie and R. S. Symmonds (*Agr. Gaz. N. S. Wales, 19 (1908), No. 4, pp. 326, 327*).—Physical and chemical analyses of 12 samples of soils from this region are reported. These show that the soils are as a rule very fertile loam. Only one sample was found to be acid. In all other cases the soils were abundantly supplied with lime. The soils were as a rule well supplied with nitrogen and phosphates, but were invariably low in potash.

Soil analysis as applied to forestry, Vater (*Tharand. Forstl. Jahrb., 58 (1908), No. 1, pp. 1–20*).—This is a general discussion of the importance of soil analysis as applied to forestry.

A study relative to the causes of the dying out of artificial forest plantings in the steppes, S. Kravkov (*Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 9 (1908), No. 1, pp. 96–118*).—As a result of a preliminary investigation made in 1906 and 1907 in the experimental forest of Veliko-Anadol, the author concludes that the generally accepted hypothesis that the high salt content of the steppe soil is the chief cause of the failure of artificial forest plantings is not confirmed. He is led to believe that the trees may die at a certain age through lack of sufficient assimilable phosphoric acid and nitrogen, and in some cases of potash. These constituents are sometimes completely absent in assimilable form in the deep soil layers as the result of depletion by forests already established.

This dying out is observed only in those places in the steppe forest region where, owing to the peculiar surface formation, definite physical properties of

the soil and subsoil, or peculiar meteorological conditions, the subsoil does not become moistened down to the water level. A part of the plant food taken up by the trees is returned to the surface of the soil by the decayed leaves. In the absence of sufficient moisture to thoroughly wet the subsoil, however, the leaf ash constituents are not washed very deep; hence an annually increasing exhaustion of certain soil layers leading to the death of new forest plantings when the roots reach these layers.

Theoretical considerations regarding factors influencing certain of the so-called physical properties of soil, P. Ehrenberg (*Mitt. Landw. Inst. Breslau, 4 (1908), No. 3, pp. 445–493; abs. in Chem. Zentbl., 1908, I, No. 26, p. 2197; Chem. Ztg., 32 (1908), No. 73, Repert., p. 463*).—This article discusses at considerable length the theory of colloids, nature of colloids in cultivated soils, and importance of colloids in relation to the physical, chemical, and biological properties and processes of soils.

On physical properties of soils, H. Rodewald (*Fühling's Landw. Ztg., 57 (1908), No. 13, pp. 455–458*).—A review of the above article.

Note on a flowing (melting) soil, A. Grégoire (*Bul. Inst. Chim. et Bact. Gembloux, 1908, No. 75, pp. 86–98*).—A study of the structure and physical properties of a fine-grained soil which easily breaks down and forms a liquid mass when wet is reported.

The lines of flow of water in saturated soils, L. F. Richardson (*Sci. Proc. Roy. Dublin Soc., n. ser., 11 (1908), No. 27, pp. 295–316, figs. 7*).—This article explains "a simple method for determining the relation between the distance apart of ditches and the height to which the saturating water will rise with a given rainfall, special reference being made to the draining of peat-mosses." The formulas and diagrams deduced for the purpose are based upon Boussinesq's differential equations for the percolation of water in a nonexpanding, porous soil, which in turn are founded on the supposition that the general velocity of the water is proportional to the pressure gradient.

The relation of soils to water with special reference to the formation of ground water, C. Mezger (*Gesndtsing., 31 (1908), No. 16, pp. 241–251, figs. 4*).—This is a discussion of the balance of evaporation, precipitation, and drainage, and the relation of soils to hygroscopic moisture, as brought out by the work of various investigators.

Soil wastage, T. C. Chamberlin (*Pop. Sci. Mo., 73 (1908), No. 1, pp. 5–12*).—The causes, extent, and practical means of prevention of soil exhaustion by erosion and leaching are discussed in this article, and it is shown that the solution of the problem lies in due control of the water which falls on the surface and that "all the rainfall during the growing season, and much or all of that which can be carried over from the nongrowing seasons" can be used with profit by the adoption of suitable methods of tillage and cropping.

Soil temperature investigations, A. Hecker (*Fühling's Landw. Ztg., 57 (1908), No. 13, pp. 458–471*).—Extensive series of observations are reported which lead to the conclusion that certain fertilizers, particularly well-rotted manure, lime, kainit, etc., exert a marked influence on the temperature conditions of the surface soil. This action is considered to be indirect and due to the influence of these substances on the physical properties and processes of the soil.

Manure, lime, and magnesia make the soil porous and thus reduce conductive power for heat. Kainit and nitrate of soda in large amounts make the soil more compact and thus increase conductive power. Under the first condition variations in temperature are greater than under the second, i. e., there are higher temperatures during the day and lower during the night.

Observations and researches in soil temperature, S. de Grazia (*Staz. Sper. Agr. Ital., 41 (1908), No. 2–4, pp. 97–114; abs. in Chem. Zentbl., 1908, I, No. 26, p. 2197*).—This is a study of the effect of stable and green manures on soil temperature.

The experiment was made in pots kept under shade to avoid solar radiation and care was taken to prevent the earth in the pots from being wet by rains. In one pot the earth was compressed so as to resemble sod; in the others the earth was left loose as in well worked soil. With one of these well pulverized cow manure was incorporated and into the others green manures as follows: Beans, vetch, lupines, rye, and barley. The manure was used at the rate of about 22 tons per acre, and was so compressed as to fill the space from 10 to 25 cm. below the top of each pot. A thermometer was placed at each of these depths.

In the loose soil the temperature was slightly higher than in sod at both depths. The stable manure caused an increase of temperature at both depths, but the green manure was always more effective. Of the green manures, the legumes gave better results than the grasses, and of the legumes vetch was most effective and beans least so.

Fixation of atmospheric nitrogen by leguminous plants, M. Passon (*Bol. Inst. Agron. [São Paulo], 1 (1908), No. 2, pp. 56–63*).—The yield of dry matter and nitrogen content of fertilized (with potash and phosphoric acid) and unfertilized velvet beans, cowpeas, and *Arachis prostrata* are reported. The use of the mineral fertilizers increased both yield and nitrogen content and is considered a profitable practice in the growing of leguminous plants for green manuring.

Experiments on cross-inoculation of different genera of leguminous plants with pure cultures of tubercle bacteria, F. Nobbe, L. Richter, and J. Simon (*Landw. Vers. Stat., 68 (1908), No. 3–4, pp. 229–252; abs. in Deut. Landw. Presse, 35 (1908), No. 52, pp. 556, 557*).—The results of cross-inoculation with *Pisum sativum, P. arvense, Vicia sativa, V. villosa, Medicago lupulina, M. sativa, Trifolium pratense, T. repens, T. incarnatum, Laburnum vulgare, Lotus corniculatus, Robinia pseudacacia, Ornithopus sativus, Onobrychis sativa,* and *Lupinus luteus* are reported, showing that pure cultures from tubercles of one member of a genus are effective on other members of the same, and, as a rule, only of the same, genus. There was, however, in these experiments complete interchangeability in case of peas and vetches and partial in case of lupines and serradella.

Nitrogen in dead forest cover, E. Henry (*Rev. Eaux et Forêts, 47 (1908), No. 9, pp. 274–278; Bul. Soc. Sci. Nancy, 3. ser., 9 (1908), No. 4, pp. 353–357*).—This is a review of investigations relating to this subject which confirm the author's conclusion that under favorable conditions there is always a decided increase of nitrogen by the fixation of the free nitrogen of the air in dead forest cover.

The influence of bacteria on evaporation from soils, R. Stigell (*Centbl. Bakt. [etc.], 2. Abt., 21 (1908), No. 1–3, pp. 60, 61*).—Observations on the rate of evaporation of water from Petri dish cultures of *Bacillus subtilis, B. coli communis, B. mesentericus fuscus,* and *Proteus vulgaris* in quartz sand, water, and bouillon show that evaporation was in all cases greater and more rapid in sterile cultures than in those inoculated with the organisms. This is attributed to utilization of moisture by the organisms, absorption in their metabolic products, and reduction of the porosity of the medium by the metabolic products of the organisms.

Concerning the difference of behavior of soil organisms when in solution and when in soils, F. L. Stevens, W. A. Withers, et al. (*Abs. in Jour. Elisha Mitchell Sci. Soc., 24 (1908), No. 2, p. 51; Science, n. ser., 27 (1908), No. 704,*

p. 994).—This is a summary of a preliminary report giving the results of numerous experiments which show "that the activities of ammonifying, nitrifying, denitrifying, and nitrogen-gathering bacteria are different in soils from what they are in solutions and that no adequate knowledge of the efficiency of these various soil organisms in effecting chemical change can be attained by tests conducted in solutions. Even the relative powers of different organisms or of different soils is largely affected by the conditions of the test. It seems therefore that in the study of soil bacteria the work must be done with soils, rather than with solutions, or at least that frequent controls or checks in soil must be made."

Nitrification in acid soils. A. D. Hall, N. H. J. Miller, and C. T. Gimingham (*Proc. Roy. Soc. [London], Ser. B, 80 (1908), No. B 539, pp. 196–212; abs. in Jour. Soc. Chem. Indus., 27 (1908), No. 11, p. 581; Jour. Chem. Soc. [London], 94 (1908), No. 548, II, p. 524*).—The more important features of this article are summarized as follows: "In the soil of certain of the permanent grass plats at Rothamsted, which is distinctly acid in consequence of the long-continued use of ammonium chlorid and sulphate as manure, nitrification is greatly reduced, and the nitrifying bacteria are only found sparingly. In bulk, nitrification still goes on slowly, despite the acidity of the soil. Water extracts of the soil will not permit of nitrification unless they are previously neutralized. The amount of nitrate produced would not be sufficient for the nitrogen taken up by the crop, which must, in the main, utilize the ammonium salts without previous change. The acidity is chiefly due to sparingly soluble 'humic' acids; free hydrochloric and sulphuric acids are also present, because the soil extract contains soluble acid in quantities comparable to the amount of chlorids and sulphates also present, and to the ammonium sulphate and chlorid annually supplied as manure.

"The acidity is not brought about by purely chemical or physical actions of the soil upon the ammonium salts, but by various microfungi which are able to remove ammonia from a solution of its salts and set free the acids with which it was combined, the acidity attained in this way being equivalent to that of the soil water on the acid plats.

"The authors attribute the continuance of the nitrification in these soils to the irregular distribution of the materials composing them; though acid as a whole, they still contain some calcium carbonate, each of the particles of which forms a center for the nitrification process. The decline in fertility of the acid plats may be attributed to the repression of the normal bacterial activities of the soil and the encouragement of the growth of molds."

Nitrogen-fixing bacteria. III. F. Löhnis and N. K. Pillai (*Centbl. Bakt. [etc.], 2. Abt., 20 (1908), No. 24–25, pp. 781–799; abs. in Chem. Ztg., 32 (1908), No. 50, Repert., p. 323; Jour. Chem. Soc. [London], 94 (1908), No. 548, II, pp. 522, 523*).—Repeating and verifying work of other investigators, the authors studied (1) the most suitable culture solutions for nitrogen-fixing organisms, (2) the effect of manuring on fixation, and (3) variations in fixing power from month to month throughout the year.

The experiments were as a rule made by inoculating 100 cc. of the culture solution with 10 gm. of soil.

Mannite and xylose were found to be the most efficient sources of carbohydrates in nutrient solutions, humus the least efficient. Manuring did not greatly increase the rate of fixation, but superphosphate was very effective in this respect. The crop yields varied quite uniformly with the rate of fixation. The fixing power of soils from plats varied from month to month during the year, there being 2 maxima, one in the spring and another in the autumn. See also previous work (E. S. R., 19, p. 624).

On dicyandiamid bacteria, R. Perotti (*Centbl. Bakt. [etc.], 2. Abt., 21 (1908), No. 7–8, pp. 200–231*).—The literature of investigations on this subject is reviewed, and an account is given of the author's investigations on the activity of bacteria in culture media containing dicyandiamid, isolation and determination of species growing in such media, the changes which the species bring about in the media, comparison of dicyandiamid with other sources of nitrogen food for the organisms, and growth of field crops on media containing dicyandiamid.

In media containing grape sugar and dicyandiamid (not exceeding 1 to 2 parts per 1,000) as the only source of nitrogen, there was a vigorous and characteristic growth of micro-organisms, including various bacteria and fungi, some new, others common forms. Certain of the forms apparently found the conditions in dicyandiamid media more favorable than others, but there was great variation in the morphology and cultural relations of the organisms which utilized dicyandiamid as a source of nitrogen to best advantage. Some of these organisms utilized other sources of nitrogen, particularly amids, as well as dicyandiamid. The activity of the organisms resulted in a slight decrease in the percentage of dicyandiamid without a corresponding increase of ammonia. Contrary to the statement of Ulpiani, the dicyandiamid did not undergo fermentative action.

The general conclusion drawn from this work is that dicyandiamid is a very good nitrogen food for many micro-organisms. Higher plants grow about as well in sterile media containing dicyandiamid as in those inoculated with dicyandiamid bacteria.

The article concludes with a bibliography of 35 references to the literature of the subject.

A review of the bacteriology of ammonium compounds, P. Ehrenberg (*Fühling's Landw. Ztg., 57 (1908), No. 13, pp. 449–455*).—The relation of micro-organisms to the transformation and fixation of ammonia in soils is briefly discussed. It is stated that experiments made by the author suggest that the greater effectiveness of ammonium salts in experiments in zinc pots than in experiments in the field may be due to the action of the zinc in interfering with the activity of organisms which fix ammonia in the soil and thus decrease its efficiency, the beneficial action of the zinc in this respect overbalancing its direct injurious effect on the growth of the crop.

The fixation of ammoniacal nitrogen by zeolites in soils, T. Pfeiffer, A. Hepner, and L. Frank (*Mitt. Landw. Inst. Breslau, 4 (1908), No. 3, pp. 321–330; abs. in Chem. Ztg., 32 (1908), No. 54, Repert., p. 353; Centbl. Agr. Chem., 37 (1908), No. 11, pp. 722–724; Ztschr. Angew. Chem., 22 (1909), No. 5, p. 207*).—This is a second report on this subject (E. S. R., 17, p. 536). A study of the loss of nitrogen from soils fertilized with blood meal and ammonium sulphate, with the addition in one series of pots of calcium carbonate and in another of calcium zeolite, showed that where the zeolite was used there was a considerable reduction in the loss of nitrogen from the soil, but that in the case of oats the nitrogen so fixed was not utilized until the second crop, indicating that the ammonia was too firmly fixed by the zeolite to be available in the course of the first season.

The action of ammoniacal nitrogen under the influence of applications of lime, T. Pfeiffer, A. Hepner, and L. Frank (*Mitt. Landw. Inst. Breslau, 4 (1908), No. 3, pp. 331–339; abs. in Chem. Ztg., 32 (1908), No. 54, Repert., p. 353*).—In pot experiments it was found that on peat soils an application of lime promoted the action of ammonium sulphate. On pure sandy soils the application of very large amounts of lime exerted an injurious effect upon

the action of the ammonium salt. On loam soils the use of as much as 1 per cent of lime in the form of carbonate showed no injurious effect, but was beneficial, especially for the second crop.

The causes of the difference in effect of ammonium sulphate and nitrate of soda. F. Löhnis and E. Blobel (*Fühling's Landw. Ztg., 57 (1908), No. 11, pp. 385–402*).—The conclusion reached by the authors from experiments on different kinds of soil is that contrary to Wagner's view there is practically no loss of nitrogen in the process of nitrification in the soil. Evaporation of ammonia assumes importance only in certain cases, and as a rule furnishes no explanation for the lower efficiency of sulphate of ammonia. Interference with the progress of nitrification frequently exerts an injurious influence on the fertilizing value of ammonium salts. The absorption and fixation of ammonia, as well as the activity of ammonia-assimilating organisms, must be taken into account. Sometimes these exert a favorable influence but are often injurious. The associated constituents are in part beneficial and in part injurious to the growth of the crop.

The causes of the difference in effect of ammonium sulphate and nitrate of soda. F. Löhnis and E. Blobel, trans. by A. Koning (*Ann. Gembloux, 18 (1908), No. 12, pp. 672–699*).—A French translation of the article noted above.

The utilization of nitrogen in the form of ammonium nitrate. T. Pfeiffer, A. Hepner, and L. Frank (*Mitt. Landw. Inst. Breslau, 4 (1908), No. 3, pp. 341–349; abs. in Chem. Ztg., 32 (1908), No. 54, Repert., p. 353; Zentbl. Agr. Chem., 37 (1908), No. 10, pp. 663, 664; Jour. Chem. Soc. [London], 94 (1908), No. 553, II, p. 980*).—A series of pot experiments with ammonium nitrate is reported, the results of which indicate that this material stands as a fertilizer between nitrate of soda and sulphate of ammonia. It exhibts to a certain extent the undesirable properties of ammonium compounds, but under certain conditions it may be as effective as nitrate of soda. In combination with insoluble phosphates its action exhibits both the physiologically acid and the physiologically alkaline properties described by Prianishnikov.

The addition of phosphates increased both the yield of crop and the amount of nitrogen assimilated. Contrary to Wagner's observation, the authors found that the addition of sodium chlorid produced no effect upon the action of the ammonium nitrate.

Tests of the new fertilizing materials lime nitrogen, nitrogen lime, and lime niter. B. Sjollema and J. C. de Ruijter de Wildt (*Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], 1907, No. 2 pp. 5–50, pl. 1; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 549, II, pp. 623, 624; Zentbl. Agr. Chem., 38 (1909), No. 1, pp. 6–8*).—Studies of the effect on germination of calcium cyanamid and of the various products resulting from its decomposition in water are reported, as well as pot experiments to test the relative value of lime nitrogen and basic lime nitrate as compared with nitrate of soda.

In the germination experiments with mustard grown in sand it was found that the free lime and gases evolved by the action of water on calcium cyanamid had no injurious effect. The injury observed was attributable to the cyanamid and basic cyanamid formed. No injurious effect resulted from the presence of dicyandiamid. The injurious effects were most marked in sterile sandy soil, less marked in case of heavy moor soils and humus sand, and not observable in case of sandy moor soils.

The experiments show that lime nitrogen may exert an injurious effect in two ways: (1) By interfering with germination, as explained above, and (2) by inducing unhealthy conditions and finally death at a later period in the growth of the plants. As explained, the first of these injurious effects is at-

tributable to cyanamid, the second to dicyandiamid, as shown by pot experiments with mustard and buckwheat.

The high fertilizing effect obtained with lime nitrogen with rye and oats indicate, however, that as a rule the injurious effects of the cyanamid are not marked in practice.

Taking the effectiveness of nitrate of soda in these experiments as 100, that of sulphate of ammonia was 90 and of lime nitrogen 120. No injurious effect was observed in case of oats when the lime nitrogen was applied only one day before seeding.

Fertilizer experiments with nitrogen lime for potatoes, A. STUTZER (*Jour. Landw., 56 (1908), No. 2, pp. 141–144; Deut. Landw. Presse, 35 (1908), No. 58, p. 620; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 550, II, p. 726*).—Comparative tests of nitrogen lime, nitrate of soda, and sulphate of ammonia in field experiments during 1907 are reported. The best results were obtained with the nitrogen lime, the poorest with ammonium sulphate. This is attributed to the fact that the season of 1907 was very wet.

Fertilizer experiments with lime niter on tobacco and tomatoes in 1907, A. STUTZER (*Ztschr. Landw. Versuchsw. Österr., 11 (1908), No. 5, pp. 531–538*).—Pot experiments with varying amounts of lime niter in comparison with nitrate of soda are reported. While the results obtained were not entirely conclusive they indicated that the lime niter, especially when applied in the larger amounts, was as effective as the nitrate of soda. The burning quality of the tobacco was not injuriously affected by the use of the lime niter.

Experiments in manuring wheat with calcium nitrate, G. PARIS (*Staz. Sper. Agr. Ital., 41 (1908), No. 2–4, pp. 171–191; abs. in Chem. Zentbl., 1908, I, No. 26, p. 2200*).—The author gives the results of experiments as reported by numerous Norwegian, Swedish, Danish, and German investigators, and from them concludes that calcium nitrate and nitrate of soda are equivalent in fertilizing action and that calcium nitrate, on account of its lime content, is to be preferred to nitrate of soda, especially in soils deficient in lime.

The author's experiment was made on volcanic soil deficient in lime and magnesia and was a comparison of calcium nitrate, nitrate of soda, and nitrate of soda and slaked lime. The results confirm those of the investigators mentioned above. The author further concludes that calcium nitrate as compared with nitrate of soda has a much greater resistance to denitrifying microorganisms. This conclusion has also been reached by other investigators.

On the utilization of the atmospheric nitrogen in the production of calcium cyanamid, and its use in agriculture and chemistry, A. FRANK (*Chem. News, 97 (1908), Nos. 2534, pp. 289–292, fig. 1; 2535, pp. 303–306, figs. 2; abs. in Amer. Jour. Sci., 4. ser., 26 (1908), No. 155, p. 509*).—This paper explains the need of finding new means of utilizing atmospheric nitrogen, describes the development of the Frank-Caro process of preparing calcium cyanamid, names the industrial plants applying the process, and discusses the use of the product.

It is asserted "what makes cyanamid especially valuable as a manure is its after effects. It is generally decomposed by the chemical and bacteriological constituents of the soil into ammonia, which becomes fixed by the vegetable mold, and is not, as with Chili saltpeter, liable to be washed into the drains and so practically lost. For this reason cyanamid which has not been used during the first harvest is always available for the second."

Phosphate deposits of Algeria and Tunis (*Bul. Imp. Inst., 6 (1908), No. 1, pp. 81–83*).—This is a brief account of these deposits prepared in view of "the rapidly increasing production of rock phosphates in Algeria and Tunis, and the apparently inexhaustible nature of the deposits in these countries."

Phosphate production in Algeria and Tunis, 1907 (*Chem. Indus. [Berlin], 31 (1908), No. 10, pp. 276, 277*).—Statistics of production and export are given for 1906 and 1907. The total exports in 1907 amounted to 1,300,000 tons. It is estimated that the exports for 1908 will amount to 1,720,000 tons.

The composition and value of sugar beet vinasse, F. Verbièse and E. Darras-Verbièse (*Betterave, 18 (1908), Nos. 450, pp. 144–146; 451, pp. 163, 164*).—Analyses of a number of samples of this material are given. The data relating to the fertilizing value of the substance show that nitrogen varies from 0.591 to 1.243 kg. per cubic meter of material, phosphoric acid from 0.211 to 0.525 kg., and potash from 0.905 to 1.724 kg. These figures indicate that the material has considerable value as a fertilizer.

Commercial fertilizers, J. S. Burd (*California Sta. Bul. 201, pp. 273–293*).—This bulletin contains tabulated analyses and valuations of 230 samples of fertilizers and fertilizing materials collected and examined during the half year ended June 30, 1908. The California fertilizer law allows a deficiency of 0.25 per cent in nitrogen, 0.5 per cent in potash, and 1 per cent in available phosphoric acid. Fifty-four of the samples reported in this bulletin showed greater deficiencies than these in one or more constituents.

Analyses of commercial fertilizers and Paris green, J. E. Halligan et al. (*Louisiana Stas. Bul. 113, p. 3–154*).—This bulletin summarizes the results of analyses of 5,267 samples of fertilizers and 40 samples of Paris green inspected under the State laws during the season of 1907–8, and discusses briefly the quality and valuation of the various materials examined. It is stated that on the whole the fertilizers were up to the manufacturers' claims and of good quality. The comparatively few failures to comply with the guaranty are attributed to poor mechanical mixture. All of the samples of Paris green examined showed more than the 50 per cent of arsenious oxid required by law, the average percentage found by analysis being 55.85 per cent.

Analyses and valuations of commercial fertilizers, C. S. Cathcart et al. (*New Jersey Stas. Bul. 215, pp. 3–39*).—This bulletin reports the results of analyses and valuations of 464 samples of fertilizing materials collected during the season of 1907–8.

Report of analyses of samples of fertilizers collected by the commissioner of agriculture during 1908 (*New York State Sta. Bul. 304, pp. 255–331*).—This bulletin gives the results of analyses by the station of samples of fertilizers collected by the State commissioner of agriculture during 1908.

AGRICULTURAL BOTANY.

Experiments in the nutrition of plants, A. Petit (*Bul. Mens. Off. Renseig. Agr. [Paris], 7 (1908), No. 7, pp. 820–833*).—On account of the claims that green plants are able to utilize glucose in solution through their roots, the author investigated the subject from the standpoint of the horticulturist, hoping to counteract the effect of cloudy days and long winter nights in the forcing of vegetables, flowers, etc.

In the preliminary experiments, which were carried on in November and December, coleuses, calceolarias, and abutilons were grown in pots 15 cm. in diameter filled with earth. To one lot 4 gm. of glucose and to another lot 8 gm. of glucose were given in 2 doses at 15-day intervals. Each pot was fertilized with 0.5 gm. sulphate of ammonia and 0.2 gm. phosphate of potash. The weight of the plants was determined at the end of December, when those receiving the greater quantity of glucose were so manifestly inferior to those not receiving the glucose that the experiment was repeated with a still greater

reduction in the amount of glucose and an increase in the amount of other fertilizers. In this experiment the presence of the glucose was not only unfavorable, but in some instances was positively detrimental to the growth of the plants.

A third experiment was carried on in February and March in a similar way, in which 0.5 gm. of glucose was added to each pot at 8-day intervals, comparisons being drawn between the growth of plants in pots deprived of nitrogen and others receiving sulphate of ammonia. In this case it was thought possible to test the effect of glucose in favoring the fixation of nitrogen by the micro-organisms in the soil. The weight of the plants, determined as before, plainly indicated a reduction of growth in every case where the glucose had been added.

A final experiment was conducted in forcing strawberries, and while the author proposes to continue his experiments next winter, he does not think that there is anything to warrant the hope that any notable improvement can be secured by the use of glucose for the early forcing of plants.

In connection with the growth of beans, the author tested the value of the application of nitrate of soda to the pots, contrasting the total weight of the plants and the yield of the green pods where nitrate of soda was added with the same grown in pots containing no nitrogen. The application of the nitrate notably increased the development of the plants and pods and also the earliness of their yield. The best results were obtained where the nitrate of soda was applied a few days after the beans had germinated and begun growth.

Investigations on the localization of saccharose in sugar beets. J. Peklo (*Sitzber. K. Böhm. Gesell. Wiss. Math. Naturw. Cl., 22 (1907), pp. 1–28, pl. 1; abs. in Bot. Centbl., 108 (1908) No. 9, pp. 239, 240*).—By means of Senft's method, which consists of the use of phenylhydrazin, sodium acetate, and glycerin, the author made some micro-chemical investigations to determine the localization of saccharose in sugar beets, and found that for the most part it is localized in the neighborhood of the sieve tissues.

Observations on the osmotic properties of the root hairs of certain salt-marsh plants. T. G. Hill (*New Phytol., 7 (1908), No. 6–7, pp. 133–142, figs. 5*).—A study was made of various salt-marsh plants to determine the effect of differences in the salinity of the soil upon the plants and how the plant accommodates itself to the fluctuating concentration of the soil water.

The results of the investigations clearly showed that the root hairs of Salicornia, growing in places where the soil water is strongly saline, can adapt their internal osmotic pressure to the osmotic strength of the soil water. It was found that the osmotic pressure in different root hairs of the same individual plant varies, as a rule the younger hairs having a higher equivalent. The cells of the root cap have a very low coefficient. The osmotic pressure of root hairs of different individuals of the same species may also vary.

On transferring isolated seedlings from relatively strong saline solutions to fresh water, the tips of the root hairs were found to swell and assume abnormal shapes. Branching was also occasionally seen. The cellulose wall of the tip of the root hair under some conditions may become thickened, and this is believed to be possibly of value in giving the end a greater strength in order to protect against a sudden increase in the internal pressure.

The amount of sodium chlorid in seedlings seems to increase from the root upward, the salt being most abundant in the higher region of the hypocotyl and in the fleshy cotyledons.

The action of compressed gas on the activity of micro-organisms and ferments. C. Foa (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5 ser., 15 (1906), II, pp. 53–58, fig. 1; abs. in Bot. Centbl., 107 (1908), No. 24, pp.*

622, 623).—Experiments showed that a pressure of 4 atmospheres of hydrogen in the presence of normal amounts of oxygen had no injurious effect on the life of micro-organisms or on the activity of enzyms and toxins. A pressure of 4 atmospheres of oxygen or of carbon dioxid checked the development of micro-organisms. Their activity was checked in proportion to the superficial area of the colonies. Compressed oxygen checked the activity of yeasts, but not their cell-free alcoholic fermentation. Carbon dioxid under pressure checked both.

The addition of reducing substances, such as glucose and soda, increased the development of anaerobic organisms under pressures of 4 to 5 atmospheres of oxygen. *Sarcina aurantiaca* was rendered colorless by this combination of conditions. The addition of such materials to compress carbon dioxid was without effect.

The effect of dialysis on vegetable rennets, C. Gerber (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 14, pp. 601–603*).—In a previous paper (E. S. R., 20, p. 26), the author called attention to the fact that in the juices of a number of plants rennets were obtained which had the power of coagulating milk. In the present paper he gives an account of investigations on the dialysis of the juices of some plants containing rennet, in which he found that when dialyzed the juice obtained from a species of fig was 4 times less active and that from a paper mulberry 8 times less active than the original sap. It was also found that on precipitating the sap obtained from the osage orange and dissolving the precipitate in a salt solution, the dialyzed liquid was 9 times as active as the filtrate. The addition of a large amount of water to the plant juices had the same effect as dialysis.

Arsenic in vegetation exposed to smelter smoke, R. E. Swain and W. D. Harkins (*Jour. Amer. Chem. Soc., 30 (1908), No. 6, pp. 915–928*).—The basis of the work described has been the vegetation of Deer Lodge Valley and adjacent territory in Montana, particular attention being paid to hay and wild grasses, as it was claimed that live stock were suffering from poisoning due to eating grasses and hay that had grown in regions subject to smelter fumes.

Both arsenic trioxid and copper were determined, and in some samples of grass were obtained as high as 1,550 parts per million of arsenic trioxid and 1,800 parts of copper. In comparison the authors grew cereals in soil samples that were taken outside of the range of smelter smoke. In no case did they find more than 0.0002 per cent of arsenic trioxid in the mature plants, while as high as 0.0263 per cent was obtained from grass grown on the same soil 5 miles from the smelter but in the direction of the prevailing winds. Analyses were made of a number of other plants which showed that the large amounts of arsenic trioxid were deposited upon the plants and could not have been absorbed from the soil.

The results of the investigations showed very plainly that the greatest accumulation of arsenic occurred after the period of growth was ended and the plant was dead. There was little doubt that the rains during the summer washed much of the arsenic from the vegetation, while in the winter the grass was protected by snow. That the arsenic is deposited rather than absorbed is shown by the fact that by shaking dry hay or grass grown in the vicinity of the smelter, a finely divided powder was obtained that was much higher in arsenic than the grass from which it came.

Comparisons are given of analyses of grasses and other plants taken from the vicinity of smelters in other parts of the country.

Effect of illuminating gas and ethylene upon flowering carnations, W. Crocker and L. I. Knight (*Bot. Gaz., 46 (1908), No. 4, pp. 259–276, figs. 4*).—On account of the common belief that plants do poorly in houses lighted with gas and because of various inquiries from carnation growers as to the effect of illu-

minating gas upon the flowering carnation, the authors have carried on some experiments, which are described in detail, to determine the effects and toxic limits of illuminating gas and ethylene on the buds and flowers of the carnation. In a later paper they expect to describe in detail the effects of illuminating gas and its main constituents upon the vegetation of the carnation.

The authors found the flowers of the carnation to be extremely sensitive to traces of illuminating gas in the air. With the varieties Boston Market and pink Lawson, 3 days' exposure to 1 part in 40,000 kills the young buds and prevents the opening of those already showing petals. In the same varieties 1 part gas in 80,000 causes the closing of the open flowers after 12 hours' exposure. This injury takes place directly on the bud or flower exposed and not indirectly through absorption by the roots. The so-called "sleep" of the carnation is probably often caused by traces of illuminating gas in the air.

Ethylene is even more fatal to the flowers of the carnation. Three days of exposure to 1 part in 1,000,000 prevents the opening of buds just showing the petals, and 12 hours' exposure to 1 part in 2,000,000 causes the closing of flowers already open. There is apparently evidence to indicate that the toxic limit of illuminating gas upon these flowers is determined by the ethylene it contains.

As yet no chemical test has been found that is delicate enough to detect the least trace of illuminating gas that will cause injury to carnations.

The viability of seeds, J. J. Thornber (*Plant World, 11 (1908), No. 7, pp. 158, 159*).—Observations are reported on the viability of seeds after continuous prolonged submergence. The experiments were conducted at the Arizona Experiment Station and were suggested by the conditions which obtain in the valley of the Colorado River in southwestern Arizona, which is subject to an annual rise in May and June following the melting of the snows in the mountains near its source. There is practically no rainfall in this section, and annual crops are grown by sowing seed on the flood plains before the season of high water begins.

In the experiments noted, the seeds were sown in soil in the usual manner and flooded to a depth of 12 in. for a period of 38 days, which is about the period of average submergence over the lower flood plain of the Colorado River. With this treatment the percentages of germination of normal seeds were as follows: Bermuda grass 42, Johnson grass 45, amber cane 45, wild hemp (*Sesbania macrocarpa*) 75, Japanese rice 36, Honduras rice 23, and sugar beets 16. No germination resulted with oats, rye, corn, millet, or Jerusalem corn after more than a few days' submergence. Where the period of submergence was extended to 50 days, the percentages of germination were: Bermuda grass 14, Johnson grass 23, amber cane 45, Honduras rice 23, and wild hemp 13. Of radish, rutabaga, sugar beet, and tomato seed, 100 per cent germinated after being under water for 21 days, cabbage and celery seed 75 per cent, and watermelon seed 33 per cent. In the latter instance the seed was not placed in the soil.

On the longevity of seeds, A. J. Ewart (*Proc. Roy. Soc. Victoria, n. ser., 21 (1908), No. 1, pp. 1–210, pls. 2*).—A study has been made of a large number of seeds, ranging from fresh seeds to those known to be 60 or more years old, to determine their germination. In all, more than 3,000 tests were made, embracing many species and genera. The results of the tests are given in alphabetical lists, and with these are incorporated all the previous records that the author was able to verify or correct.

In summarizing the tabulated results, the author divides seeds into 3 biological classes, according to their duration of life under optimal conditions. These are short-lived or microbiotic seeds whose duration does not exceed 3 years, mesobiotic seeds which may last 3 to 15 years, and macrobiotic seeds which may last from 15 to over 100 years.

In an appendix, Miss Jean White gives an account of experiments in which she found that hard seeds which are incapable of imbibing water owe their failure to take up water to the presence of a cuticular layer, and that when this is removed or penetrated either by mechanical means or the action of acids, the seeds swell rapidly and, if their vitality is sufficient, germinate quickly.

It is claimed that Becquerel's conclusions that the impermeability of the coats of macrobiotic seeds is a gradual result of their aging are incorrect. The impermeability is due to the presence of a cuticle developed during ripening, and its presence or absence determines whether a seed will or will not have a long life in the soil, but not whether it will have a long life when preserved in dry air. Macrobiosis is the result of a biological adaptation of the protoplasm, in which an impermeable cuticle plays a merely accessory or aiding part.

Methods and causes of evolution, O. F. Cook (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 136, pp. 35*).—A discussion is given of the methods and causes of evolution, with special reference to the application of the ascertained facts to breeding, acclimatization, etc.

The present state of knowledge of heredity in Pisum, R. H. Lock (*Ann. Roy. Bot. Gard. Peradeniya, 4 (1908), No. 3, pp. 93–111*).—A summary is given of the most important facts so far recorded with regard to heredity in Pisum, and attention is called to some of the gaps which still remain in our knowledge of the subject.

The author states that the behavior of the color characters of the testa and corolla has been worked out completely and described in terms of Mendelian segregation with the help of the idea of the masking of several characters when certain other characters are absent. The principal gaps remaining in our knowledge relate to the heredity of the purple pod and of the allelomorphs concerned in determining the number and length of internodes.

FIELD CROPS.

The revegetation of overgrazed range areas, A. W. Sampson and F. V. Coville (*U. S. Dept. Agr., Forest Serv. Circ. 158, pp. 21*).—The work here reported was conducted for the purpose of determining the relative importance of the native grasses and forage plants on the Wallowa National Forest in eastern Oregon, and to ascertain the rapidity and extent to which the important forest plants are regenerating upon overgrazed areas, what plants under the present grazing system are succeeding upon depleted range areas, and by what system of grazing the former productiveness of the range may be restored through natural reseeding.

Four zones of vegetation are recognized and described. The lower, or yellow pine zone, ranges in altitude from 3,000 to 4,500 ft. and its vegetation is made up largely of bunch grass, those occurring in the greatest abundance being blue bunch grass (*Festuca arizonica*), big bunch grass (*Agropyron spicatum*), little blue grass (*Poa sandbergii*), and mountain June grass (*Koeleria cristata*). The lodgepole pine zone occupies the altitudes ranging from 4,500 to 6,800 ft. The most characteristic tree of this region is the lodgepole pine. The open grass land areas in the zone are comparatively small. While no particular grasses are especially characteristic of this zone, smooth wild rye grass (*Elymus glaucus*), short awned brome grass (*Bromus marginatus*), western needle grass (*Stipa occidentalis*), and pine grass (*Calamagrostis suksdorfii*) are among the more common species. The third, or whitebark pine zone, is from 6,500 to 8,500 ft. above sea level and is named after its most typical tree. The most striking features of this area are the great preponderance of open grass lands and the

general broken character of the forests. Mountain bunch grass (*Festuca viridula*) is preeminent in importance among the forage plants of the entire range, and associated with it are the mountain blue grasses (*Melica spectabilis* and *M. bella*). In a variety of situations, particularly in the moist habitats, mountain timothy (*Phleum alpinum*), Alpine redtop (*Agrostis rossæ*), hair grass (*Deschampsia cæspitosa* and *D. elongata*), several species of rushes and showy flowering plants eaten by stock are found. Sickle sedge (*Carex deflexa*) is important in this zone because of its rapid succession on denuded bunch grass areas. The fourth, or timberless zone, ranges in altitude from 8,000 to 9,500 ft. Herbaceous vegetation is sparse and dwarfed. A rather striking example of this feature is the stunted condition of *Trisetum spicatum* in this region. Alpine bunch grass (*Festuca brachyphylla*), *T. spicatum*, and *C. preslii*, which furnish some forage in the zone below, occur in considerable abundance. The records show an average annual precipitation of 18.95 in. in the valley surrounding the mountains, and the average annual temperature from observations made at four stations was 45.2° F. At one of the stations the temperature extremes were 110° in summer and —17° in winter.

Observations on the mountain bunch grass area reported include notes on the production of flower stalks, maturity and germination of seeds, and the destruction of seedlings by trampling. It was found that on the areas examined the plants of highest forage value, including mountain bunch grass, are not reproducing by seeds, and that most of the seedlings were sedges and particularly sickle sedge, which composed at least nine-tenths of all the seedlings. It was determined that 32.7 per cent of the seedlings found on the areas under observation were destroyed by trampling.

The results of this work show clearly that the present regulations are ineffective in bringing about the natural regeneration of the valuable grazing plants. It is believed that a system of range control, whereby the overgrazed areas may be protected from grazing animals during the period required for the maturing and dissemination of the seeds, will be as effective in the restoration of the range as a complete rest for a period of years. Moderate fall grazing, after the forage plants have performed their full functions, is considered as in no way interfering with their regeneration but rather as proving beneficial and insuring a higher percentage of germination. If such system were undertaken at the start only the more severely overgrazed areas would be closed to stock during the period required for the grazing plats to mature seed. In 1907 the seeds of the leading forage plants were matured and dispersed by September 5, and as the regular grazing on this range continues from September 20 to 30 the utilization of the forage crop under this system would be assured.

Deep fall plowing and the seed bed, S. A. Knapp (*U. S. Dept. Agr., Bur. Plant Indus. Doc. 403, pp. 7, fig. 1*).—This publication discusses the preparation of the seed bed, the root system of corn, deep plowing and the deepening of the soil by this means, points out the advantages resulting from a deep and thoroughly pulverized seed bed filled with humus, and enumerates the conditions of soil and subsoil unfavorable to deep plowing. The discussions have reference mainly to southern agricultural practice.

Electricity and agriculture, O. Lodge (*Mark Lane Express, 99 (1908), No. 4008, pp. 91–93, figs. 3; Nature [London], 78 (1908), No. 2023, pp. 331, 332, figs. 2; Elect. Engin., 4 (1908), pp. 113–114; abs. in Agr. Gaz. [London], 68 (1908), No. 1803, p. 40, figs. 3; Sci. Abs., Sect. B—Elect. Engin., 11 (1908), No. 129, p. 405*).—Tests on a large scale at Bitton, England, of Lemström's method of electrification of soils are reported. The installation on the 10 to 11 acres subjected to the treatment is described.

"The method is to stretch over the field to be treated a number of wires on poles, sometimes like low telegraph wires, but high enough for loaded wagons and all the usual farming operations to go on underneath the wires without let or hindrance. The wires are quite thin, and are supported by a few posts in long parallel spans, about 30 ft. apart. They are supported on the posts by elaborate high-tension insulators, and they extend over all the acreage under experiment, a control plat of similar lands under similar conditions being, of course, left without any wires.

"The system of conductors is then connected at one post with a generator supplying positive electricity at a potential of something like a hundred thousand volts, and with sufficient power to maintain a constant supply of electricity at this kind of potential.

"Leakage immediately begins, and the charge fizzes off from the wires with a sound which is sometimes audible, and with a glow which is visible in the dark. . . .

"The electrification is maintained for some hours each day, but is shut off at night; it is probably only necessary to supply it during the early morning hours in summer time, and in springtime or in cold cloudy weather for the whole day, or during the time of the plant's greatest activity. But at what stages of the growth of a plant the stimulus is most effective has still to be made out. . . .

"The power required to generate the electricity is very small, for although the potential is high the quantity is insignificant, and the energy is accordingly comparatively trivial. . . .

"The electricity can . . . be generated by the revolving glass plates of a static influence machine, usually known . . . as a Wimshurst machine; or it can be generated by transforming up to high tension, and rectifying to one direction, the current of . . . a dynamo. The first is in many respects the simplest."

Increases of 30 to 40 per cent in yield and improvement in quality of wheat due to electrification are reported. A 35 per cent increase in yield and earlier ripening were observed in case of strawberries, and a 25 per cent increase in yield and larger sugar content in case of mangolds. Improvement in growth was observed in case of raspberries and tomatoes. Electrification was applied for from 600 to 1,000 hours in case of the crops experimented with.

Duty of water, G. H. True (*Nevada Sta. Bul. 63, pp. 24, 25*).—The results of a study on the amount of water necessary to produce farm crops are given in the following table:

Results of applying various amounts of water to cereal crops.

Crops.	Number of irrigations.	Depth of water.	Yield.	
			Per acre.	Per acre-foot of water.
		Ft.	*Bu.*	*Bu.*
Wheat	10	2.14	45.5	21.2
Do	7	1.97	48.0	24.4
Do	4	1.49	55.8	37.4
Do	4	1.59	46.0	28.9
Do	0	.....	13.4	.....
Barley	8	1.34	33.8	22.4
Do	5	1.28	53.5	41.8
Do	3	.93	52.0	56.0
Do	2	.99	58.5	59.1
Do	0	.....	34.0	.....
Oats	10	2.15	68.0	31.6
Do	7	2.13	121.5	57.0
Do	4	1.32	123.5	93.5
Do	4	1.43	99.4	62.5
Do	0	.....	33.8	.....

Alfalfa cut for the first time last season and grown on land not requiring an excessive amount of water yielded 7.36 tons per acre in three cuttings, with a depth of 3 ft. of water for irrigation. An old alfalfa field on gravelly land yielded but 2 tons of hay per acre, with a depth of 8.5 ft. of water applied in irrigation.

American dry farming, W. STRAWBRIDGE (*Agr. Jour. Cape Good Hope, 32 (1908), No. 6, pp. 737–740*).—The American system of dry farming is briefly summarized as follows: "(1) Fine deep sandy loam is best for dry farming. (2) Disk or lightly plow directly the crop is off. (3) Plow deep, 7 to 9 in., during the summer or autumn. (4) Harrow same day, immediately after plowing or disking, after each fall of rain, and as late in the season as possible after the crop is up several inches. (5) Pack the soil, if loose, to make it firm and retentive. (6) Do not allow any weeds to grow. (7) Keep the top 3 in. of soil loose and dry, but not too fine, so as to be dust. (8) If soil is likely to drift, harrow when damp; should that not be successful, do not fallow. (9) Only sow the best dry-grown seed. (10) Sow thinly to get good results; thick sowing in dry country has proved unsuccessful. (11) Sow the seed of wheat 2 to 3 in. deep on top of damp, moist subsoil. (12) Do not attempt dry farming with a gravel or rubble below a shallow soil. (13) Practice rotation of crops to maintain the fertility of the soil, and in cases where land can not be fallowed."

[Agriculture in the Congo Free State], PYNAERT (*Bul. Off. État Indépend. Congo, 24 (1908), No. 1–2, Sup., pp. 1–49, pl. 1*).—This is a report covering the third quarter of 1907 on the work conducted at the agricultural experiment station of Eala. Notes are given on a botanical garden, an experimental garden, and a model farm. The different species and varieties of plants added to the botanical garden are listed and the yields from rubber, spice, perfume, dye, drug, textile, oil, forage, and fruit crops are noted.

[Experiments with field crops], B. W. KILGORE ET AL. (*Bul. N. C. Dept. Agr., 29 (1908), No. 2, pp. 75*).—Variety, distance, fertilizer, and cultivation experiments are reported with cotton and corn, and directions are given for the preparation of composts and the use of fertilizers for tobacco. The experiments with cotton and corn were carried on at the Edgecombe, Red Springs, Iredell, and Transylvania test farms.

The varieties of corn averaging highest yields of shelled corn at Edgecombe during 8 years were Cocke Prolific, Weekley Improved, Sanders Improved, and Holt Strawberry; at Red Springs during 2 years Native, Cocke Prolific, Holt Strawberry, and Weekley Improved; and at Iredell, Weekley Improved, Sanders Improved, Cocke Prolific, and Boone County White. The earliest varieties tested on these farms are Iowa Silver Mine, Riley Favorite, Leaming Yellow, Reid Yellow Dent, Boone County Special, and Boone County White; the medium-maturing varieties, Biggs Prolific, Craig Prolific White, Cocke Prolific, and Craig Prolific Strawberry; and the late-maturing varieties, Holt Strawberry, Marlboro Prolific, Sanders Improved, Weekley Improved, and Mosby Prolific. Notes on the varieties tested in 1907 are given, and the sorts adapted to the eastern, Piedmont, and mountain sections are enumerated. The average of 6 years' results on the Edgecombe farm indicate that planting 4 by 3 ft. is best suited to the soil, and at Iredell and Red Springs, as an average of 3 and 5 years' results, respectively, 5 by 2 ft.

As an average of 8 years' tests with cotton, Russell Big Boll and Culpepper Improved ranked as the best varieties on the Edgecombe farm; as an average of 5 years' tests, Culpepper Improved, Excelsior Prolific, King Improved, and Russell Big Boll were ranked on the Red Springs farm; and as the result of 5 years' work, King Improved, King Improved Native, and Edgeworth on the

Iredell farm. The individual tests ranged from 530 to 915 lbs. of seed cotton at Edgecombe, 204 to 533 lbs. at Red Springs, and 455 to 565 lbs. at Iredell. The earliest varieties were Dozier Improved, King Improved, Hodge, Shine Extra Early Prolific, and Webb; the medium-maturing varieties, Culpepper Improved, Cook Improved, Excelsior Prolific, Peterkin Improved, and Edgeworth; and the later-maturing varieties, Russell Big Boll, Black Texas Wood, and Moss Improved. The highest percentage of lint was secured in Moss Improved, King Improved, Brown Texas Wood, Peterkin Improved, Cook Improved, Tool Early Prolific, Excelsior Prolific, Brown No. 1, Edgeworth, and Mortgage Lifter. With these varieties in 1904, the percentage of lint to seed varied from 35.42 in Excelsior Prolific at Edgecombe to 43.03 per cent in Moss Improved at Iredell. Russell Big Boll, Culpepper Improved, Edgeworth, Doubleheader, and Brown No. 1 of the varieties tested possess the largest sized bolls and the largest seed. The average results of distance tests at Edgecombe and Red Springs during 4 years favor about 3½ ft. by 16 in. at Edgecombe and about 4 ft. by 16 in. at Red Springs, and the average results of 5 years at Iredell favor planting 3⅓ ft. by 16 in.

Notes on varieties of cotton tested in 1907 are given, varieties adapted to different sections of the State are enumerated, and cultural and improvement methods are suggested.

Rotation experiments with cotton, corn, cowpeas, and oats, W. R. Dodson (*Louisiana Stas. Bul. 111, pp. 3–15*).—These experiments were conducted at Baton Rouge and Calhoun. The fields were approximately 6 acres in size, and one-third of the area was planted each year to cotton, one-third to corn with cowpeas, and one-third to rust-proof oats followed by cowpeas the same season. In this rotation each plat of land produced in 3 years one crop of cotton, one of corn, one of oats, and two of cowpeas. One-half of each plat was fertilized and the other half was made dependent upon the rotation and the cowpeas for the maintenance of fertility up to 1907, when 150 lbs. of acid phosphate per acre was added to the cowpea crops. The cotton received 30 bu. per acre of compost made up of 2 tons of acid phosphate, 100 bu. of stable manure, and 100 bu. of green cotton seed, the corn received 30 bu. per acre of compost made up of 1 ton of acid phosphate, and the same quantities of stable manure and green cotton seed used for corn, the oats were fertilized with 200 lbs. of cotton-seed meal and 100 lbs. of acid phosphate per acre, and the cowpeas with 50 lbs. of acid phosphate and 50 lbs. of kainit.

At Calhoun the cotton yielded the largest money returns on both fertilized and unfertilized land. Oats and cowpeas closely approximated the value of the cotton crop on the unfertilized land. The average of 15 crops of fertilized cotton was 1,513 lbs. of seed cotton, as compared with 466 lbs. of seed cotton on the unfertilized part of the plat. The estimated cost of the fertilizer for cotton was $5.50, for corn $6, and for oats $2.95 per acre. The fertilizer applied gave an average gain of 1,047.8 lbs. of seed cotton, 21.99 bu. of corn, and 25.4 bu. of oats. The average yield of corn and oats amounted to 31.4 bu. and 41.8 bu., respectively, on the fertilized land, and 9.41 bu. and 16.4 bu., respectively, on the unfertilized soil. In the beginning of these tests the fertilizers used were applied without profit and even at a loss, but later when the soil had again been brought up to a certain degree of fertility good profits were secured.

The results of 10 years' work at Baton Rouge resulted in an average yield of 1,242.6 lbs. of seed cotton, 45.1 bu. of corn, and 46.5 bu. of oats on the fertilized parts of the plat, as compared with 1,034.3 lbs. of cotton, 35.8 bu. of corn, and 35.2 bu. of oats on the unfertilized portion of the plat. The largest money value, $47.42 per acre, was secured from cotton, as against $43.92 from oats and

peas, and $41 from corn and peas, counting cotton at 10 cts., oats at 45 cts., corn at 60 cents., hay at $14, and cotton seed at $14.

Several plans for rotations are outlined and notes are given on the culture of oats in Louisiana.

Grain without irrigation, G. H. True (*Nevada Sta. Bul. 63, p. 25*).—Winter barley grown without irrigation gave a yield of 23 bu. of grain per acre. Spring-seeded White Australian wheat without irrigation yielded 9.4 bu., Velvet Don 12 bu., Beardless barley 16 bu., and rye 14 bu. per acre. The author believes that by properly handling the land in certain localities of the State fair crops of grain may be grown without irrigation.

The systematic classification and naming of grain varieties for practical purposes, von Rümker (*Jahrb. Deut. Landw. Gesell., 23 (1908), No. 1, pp. 137–160*).—This article proposes and discusses schemes for the classification and naming of varieties and strains of rye, wheat, barley, and oats. The terms "Landsorte," "Veredelte Sorte," "Hochzucht," "Neuzüchtung," "Originalsaatgut," and "Nachbau" used by German seed breeders and seed dealers are defined.

Alfalfa, J. M. Westgate (*U. S. Dept. Agr., Farmers' Bul. 339, pp. 48, figs. 14*).—This publication, which is to supersede Farmers' Bulletin 215 (E. S. R., 16, p. 965) discusses the history and present condition of alfalfa in the United States, describes the plant and the conditions to which it is adapted, enumerates the requirements for securing and maintaining a stand including general cultural directions, and discusses the utilization of the crop for various purposes. Notes are also given on growing winter grain in alfalfa fields, the effect of alfalfa culture on the land, the adaptability of the crop to rotations, methods of breaking up alfalfa sod, and alfalfa seed production. Descriptions of the different types of alfalfa now grown in the United States are presented, methods of combating the enemies of the plant are outlined, and special instructions for growing alfalfa in different sections of the United States are given.

Alfalfa investigations, S. C. Dinsmore (*Nevada Sta. Bul. 63, pp. 37–39*).—In 1906 a study of alfalfa was begun to determine the variations in chemical composition at different stages of growth. Samples were taken at intervals of a week from April 16, when the plant was 3 in. high, until September 1, just after the flowering stage. Analyses of samples collected to July 30 are reported.

Data for the international commission for the improvement of barley (*Wchnschr. Brau., 24 (1907), Nos. 40, pp. 534–542; 41, pp. 569–574*).—Studies on the distribution and grouping of the chemical constituents in the barley plant are reported in detail, with a summary of the results.

It is shown that the proportion of hull and the structure of the hulls apparently bear no relation to the protein content of the grain. The structure of the hulls is considered a constant variety characteristic. A high proportion of hull is regarded as typical of all barleys with a 1,000-grain weight as dry matter of less than 36 gm. In spring varieties having a 1,000-grain weight above 36 gm. the proportion of hull was not found to vary widely. Early varieties are said to contain 8 per cent of hull and late varieties about 9 per cent. The highest proportion is found in the winter varieties. Early or late seeding and a short or long growing period influenced this factor. Thin hulls, which are most common in seasons of normally early maturity, increase the possibility of injury to the grain in threshing. Fertilization, cultivation, and the distance between drills have no influence on the development of the hulls.

A protein content of 8 per cent is regarded as typical for a normally nourished crop, and deviations from this percentage are considered as abnormal and as due to irregularities in the metabolism of the plant. The fat content in pure varieties under normal conditions constitutes about 2 per cent of the dry matter.

Variations from this figure result from physiological causes, being associated with a high content of carbohydrates or of ash. Salts retard fat formation, while the lack of salts, and especially of alkalis and lime, promote it.

The normal ash content is about 3 per cent of the dry matter. The ash is reduced when the plant is insufficiently nourished, and an abnormally high ash content is attributed to overfeeding with salts or to too early ripening.

A new basis for barley valuation and improvement, A. MANN (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 16, pp. 8, figs. 3*).—From the investigations described the author concludes that the diastatic and cytatic starch ferments in barley are wholly a product of the scutellum and are secreted by its epithelial layer. While a minute trace of these ferments is found in the starch cells, this is practically negligible because it plays so slight a part in the normal starch conversion. It is stated that the aleurone layer has nothing whatever to do with this process.

The results of these investigations further led to the conclusion that a broad, circular, slightly convex type of scutellum, having long, narrow epithelial cells, is a characteristic of the best grades of malting barley, while a narrow, deep sunken type, with short and broad epithelial cells is indicative of barley inferior for malting purposes. This correlation is considered of value as furnishing a means of recognizing the grade of any variety of barley, and also as pointing out that any improvement in malting barley must include an improvement of the scutellum.

The Mendelian and DeVriesian laws applied to cotton breeding, R. J. H. DELOACH (*Georgia Sta. Bul. 83, pp. 43–63, figs. 7, dgms. 2*).—Cook and Kilgore cottons were selected for breeding purposes, with the view of combining the good qualities of both varieties and to making an application of Mendel's law. Hybridization was begun in August, 1906, with the result that 9 capsules were secured with Cook as the mother variety and 3 capsules with Kilgore as the female parent. In 1907 the 9 capsules produced 140 plants, of which 115 were of the Cook type, 14 of the Kilgore type, and 11 of the hybrid type, while the 3 capsules produced 26 plants, of which 7 were of the Cook type, 18 of the Kilgore type, and 1 of hybrid character. The results of each series showed the dominance of characters of the female parent and, with some exceptions, very little breaking up of characters. The capsule coming nearest reaching Mendelian proportions produced 21 plants, of which 11 were of the Cook type, 5 of the Kilgore type, and 5 of hybrid type, and these plants were selected for further work.

Tests were made of single capsule, single plant, and progeny. Nine capsules were fertilized on one plant and three each on the other plants entering into the experiment. In the single capsule test 1,282 plants were produced, including of the Cook, Kilgore, and hybrid type 583, 334, and 365 plants, respectively. In the individual plant test 1,167 plants were secured, and of these 485 were of the Cook type, 411 of the Kilgore type, and 279 were hybrids. The results of the progeny test with 570 plants were 260 of the Cook type, 100 of the Kilgore type, and 210 were hybrids. It was found that variation in types occurred almost as often in the single capsule test as in the other two experiments.

In the case of plant 3 in the first experiment, all plants from the first capsule reverted to the male parent type, while all from the second capsule reverted to the female type and those from capsule 3 were ideal hybrids. The author states that should these experiments be continued all three experiments would be dropped except the hybrid types of capsule 3 in the first experiment. The results have shown that there is a great variation in the activity of different individual capsules, and that certain of these seem to approach fixation, and that every capsule on a hybrid plant will not always contain exact Mendelian

proportions. The author also concludes that these results were not due to mutation and that their occurrence can be explained through Mendel's law. A bibliography covering the period from 1859 to the present day, representing the books and pamphlets consulted for the work in hand, is appended.

Reappearance of a primitive character in cotton hybrids, O. F. Cook (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 18, pp. 11*).—In a discussion of this subject the author points out that hybrids between the Kekchi cottons of Guatemala and varieties of the Sea Island and Egyptian series commonly show seeds with green fuzz in the first generation. As this character does not normally appear in either of the parental varieties, it is considered as probably an ancestral character of both of them. The fact that the green fuzz largely disappears in the second generation of the hybrid is taken as indicating that the recall of this character to expression in the first generation marks a preliminary stage in the process of conjugation. "The complete results of conjugation first become visible in the second generation, when the parental characters reappear in many combinations and gradations. . . . The practical point is that such departures from the parental characters in the first generation of a hybrid may not remain to detract from the value of later generations. Hybrids in which these undesirable primitive characters come into expression must be grown for at least two generations before selection can be effectively applied. The characters shown by the first generation do not afford any practical indication regarding the characters of the later generations."

British cotton cultivation, W. Dunstan (*Colon. Rpts., Misc.* [*Gt. Brit.*], *No. 50, pp. 46*).—Reports on the quality of cotton grown in the British possessions are presented. The regions considered are Cyprus in Europe, the Sudan, East Africa Protectorate, Uganda, Nyasaland Protectorate in East Africa, Rhodesia, Transvaal, Orange River Colony, Natal, and Cape Colony in South Africa, Gambia, Sierra Leone, Gold Coast, Lagos, Southern Nigeria, and Northern Nigeria in West Africa, the Seychelles, the Straits Settlements, the Federated Malay States, and British North Borneo in Asia, Australia, British New Guinea, the West Indies, British Guiana, Honduras, and Bermuda. These reports form an account of progress in native cultivation and experimental trials fostered and inaugurated largely by the British Cotton Growing Association.

An excellent quality of American cotton is reported as growing in the Zoutpansberg district of the Transvaal, and it is believed that American cotton has apparently proved successful in Nyasaland and Uganda.

Cotton production, 1907, W. M. Steuart and D. C. Roper (*Bur. of the Census* [*U. S.*] *Bul. 95, pp. 58, figs. 7, dgms. 4, map 1*).—This bulletin presents data with reference to the annual cotton production in the United States as returned by ginners and delinters, distributed by States from 1899 to 1907 and by counties from 1903 to 1907; statistics as to annual production compiled from trustworthy sources of previous years beginning in 1790; figures on the world's cotton production in 1907 by countries; illustrated discussions on the growing, harvesting, and handling of cotton; and data regarding the production of cotton seed and the manufacture of and trade in cotton-seed products.

The total crop of 1907, including linters, is given as 11,425,156 running bales or bales as pressed at ginneries. The distribution of the crop was as follows: Upland cotton, square bales, 10,871,652; upland cotton, round bales, 198,549; Sea Island cotton, 86,895 bales, and linters, 268,060 bales. The average production of cotton in the United States for the last 6 years is 345,914 bales in excess of the crop of 1907.

Flax experiments, 1906 (*Dept. Agr. and Tech. Instr. Ireland Jour., 8 (1908), No. 3, pp. 423–440*).—The largest average yield of retted straw, 3,127 lbs. per

acre, was secured where 3 cwt. of kainit and 2½ cwt. of rape meal was applied during the winter. The average yield of scutched flax was also largest in this test, and the average returns from the scutched flax ranked first with £13 9s. 3d. The average returns from flax and tow per acre amounted to £13 16s. 1d. The cost of the manure in this experiment amounted to £1 and the profit per acre from the use of the manure to £3 6s. 1d., being a greater return than that secured from any other application in the test. On the manured plats receiving potash in some form no yellowing took place.

Experiments with Dutch and Riga seed were conducted at 8 centers. The Dutch seed consisted of Riga Child imported from Holland and a Belfast brand of Dutch seed, and the Riga seed consisted of Pernau Crown imported from Russia and a Belfast brand of Riga seed. The Dutch seed gave better returns than the Riga seed. The Riga Child seed imported from Holland produced the higher yield of straw and fiber at 5 centers of the 8, but the average returns were in favor of the Belfast brand of Dutch seed. At 6 centers Pernau Crown seed proved more profitable than the Belfast brand of Riga seed.

A test on the rippling of green straw resulted in a balance against rippling of 2s. 5d. in net returns per ton of green straw. When the straw is rippled the seeds suitable for feeding purposes are saved from the green bolls. The profitableness of rippling is dependent almost entirely on the amount of seed carried by the crop.

Jute and jute substitutes from West Africa (*Bul. Imp. Inst., 6 (1908), No. 2, pp. 126–135*).—Samples of jute and jute substitutes, including *Hibiscus esculentus*, *H. quinquelobus*, *H. lunariifolius* (?), *Honckenya ficifolia*, and *Urena lobata* were examined and their chemical composition is reported. The samples were secured from Sierra Leone, Northern and Southern Nigeria, and Gambia.

Report on field trials on varieties of mangel (*Midland Agr. and Dairy Col. Bul. 6, 1907–8, pp. 53–63*).—Prizewinner and Red Intermediate produced the largest yield but with a low percentage of dry matter, while Sugar Mangel and New Golden King gave the smallest yield but with the highest percentage of dry matter of any in the test. Golden King had the lowest percentage of roots gone to seed and Sugar Mangel the highest. The varieties recommended for the Midlands are Prizewinner, Red Intermediate, and Normanton Globe, the yields for these varieties in these experiments being 30 tons 2 cwt., 30 tons 1¼ cwt., and 25 tons 15¼ cwt., respectively.

The origin of the cultivated potato and the bud variations of wild tuber-bearing solanums under cultivation, E. Heckel (*Sur les Origines de la Pomme de Terre Cultivée et sur les Mutations Gemmaires Culturales des Solanum Tubérifères Sauvages. Marseilles, 1907, pp. 82, pls. 8, figs. 17*).—The history of the potato is given and the author's observations on different wild solanums under cultivation are presented. *Solanum commersonii* and its wild varieties did not undergo any variation at Marseilles. It is stated that bud variation gives to the species much greater vigor so that all parts increase in size, that the flowers as well as the tubers enlarge and change in color, and that even the form of the fruits which sometimes appear on the mutations while the type species remain sterile may be modified. The products of these mutations, although from very different types, resemble each other morphologically much more than those from the original types.

The dry matter and starch content of potatoes, S. Hals (*Tidsskr. Norske Landbr., 14 (1907), No. 11, pp. 464–469*).—Analyses of 66 samples of Norwegian potatoes show that the starch content increases with the dry matter content. Potatoes containing from 16 to 17 per cent of dry matter contained 67.4 per cent of starch in the dry matter, and potatoes containing over 23 per cent of dry matter contained 73.9 per cent of starch in the dry matter. Nonstarchy

solids ranged from 5.39 per cent in the potatoes with low dry matter content to 6.49 per cent in the potatoes with high dry matter content. The percentage of ash and fiber did not vary much, but the content of other nonnitrogenous substances increased with the dry matter.

Experiments with barnyard manure and commercial fertilizers for potatoes, 1904–1907, W. Christie (*Ber. Hedemarkens Amts Forsögsstat. Virks., 3 (1907), pp. 5–51*).—The data secured in 28 different series of fertilizer experiments with potatoes showed that the best general results were obtained from 200 kg. of 20 per cent superphosphate and 100 kg. of 37 per cent potash salt applied with 70,000 kg. of barnyard manure per hectare. The same application with the potash omitted apparently increased the starch content to some extent. An application of 350 kg. of 20 per cent superphosphate, 200 kg. of 37 per cent potash salt, and 160 kg. of sodium nitrate per hectare produced as heavy yields as the use of 70,000 kg. of barnyard manure, but gave a somewhat higher starch content than the use of the manure alone.

[Trials with sugar beets and potatoes] (*Univ. Col. Reading, Agr. Dept. Bul. 2, pp. 12*).—Cooperative sugar beet experiments were made with the Kleinwanzleben and Improved White varieties. The yield of roots ranged from 12½ to 24½ tons per acre, Improved White being the better yielder. The sugar content of the roots varied from about 16 to 18 per cent, Kleinwanzleben being generally the better of the two varieties.

The varieties of potatoes compared belonged to the Up-to-Date, Maincrop, Imperator, and Abundance groups. In the Up-to-Date group 1 oz. of seed potatoes produced on an average 1 lb. of crop in the first year, and 0.77 lb. in the following season. The next best yield was obtained in the Imperator group, being 0.87 lb. per ounce of seed potatoes the first year and 0.51 lb. the second. Results with Irish, Scotch, and English seed potatoes in all trials showed that the best and largest crops were obtained from the Irish and the second best from the Scotch strain.

Experiments on the defoliation of sugar beets, F. Strohmer, H. Briem, and O. Fallada (*Mitt. Chem. Tech. Vers. Stat. Cent. Ver. Rübenz. Indus. Osterr.-Ungar., No. 198, pp. 1–12*).—After briefly reviewing the results obtained by different investigators along this same line, the authors present and discuss the data secured in their own work. Beets were grown on 5 plats, the seed being planted April 6, and the crop being hoed on April 17, May 6 and 20, and June 6. On the last-mentioned date the beets were thinned and a top-dressing of nitrate of soda was given.

The comparable results on the different plats were as follows: Plat 1, defoliated July 12, produced 40.25 kg. of leaves and 110.2 kg. of roots; plat 2, defoliated July 30, 41.50 kg. of leaves and 104.3 kg. of roots; plat 3, defoliated August 24, 37.50 kg. of leaves and 132.5 kg. of roots; plat 4, only partially defoliated on August 24, 38 kg. of leaves and 126.5 kg. of roots; and plat 5, on which the plants were allowed to retain their leaves, 50.60 kg. of leaves and 174 kg. of roots. The conclusion is drawn that complete, as well as partial, defoliation of the sugar beet reduces total yield as well as sugar production, and that this reduction is greatest when the leaves are removed immediately preceding that period of growth in which the greatest sugar formation in the leaves takes place, which is about the end of July and the beginning of August. It was further found that early and complete defoliation increased the ash content and the crude fiber of the roots and in general reduced their quality. Defoliated beets showed about the same changes that are shown in beets grown with insufficient light. The data also indicate that the oxalic acid content of the dry matter of the leaves is considerably higher during all phases of the

development of such sugar beets than in the dry matter of the leaves of normally developed mature sugar beets.

Beet sugar, Z. C. ELKIN (*Bur. of the Census [U. S.], Manfrs. 1905, pt. 3, pp. 445–455*).—Statistics for the manufacture of beet sugar as reported in the censuses of 1880, 1900, and 1905, with the percentages of increase from 1900 to 1905, are reported and historical notes on the industry are given. According to a summary presented in tabular form the number of establishments in 1905 was 51, the capital invested $55,923,459, and the value of products $24,393,794. Data on the industry in the different States are given in tables.

Experiments with seedling and other canes in the Leeward Islands in 1906–7, F. WATTS ET AL. (*Imp. Dept. Agr. West Indies Pamphlet 50, 1907, pp. 53*).—A summary is here given of the results of experiments with varieties of sugar cane carried on in Antigua and St. Kitts during 1906–7. The work was conducted on 8 estates in each island for the purpose of finding varieties likely to increase the output of sugar and showing greater resistance to insect pests and plant diseases.

In Antigua good results as plant canes were obtained with Sealy Seedling, D 109, D 625, B 208, and B 156. As rattoons, Sealy Seedling, B 156, B 376, and D 109 gave the best results in the order named. B 208 did not seem to commend itself as a rattoon cane on much of the sugar land.

In St. Kitts, B 208, D 116, and Sealy Seedling gave the best results as plant canes. B 208 and D 116 also stood first and second, respectively, in average yield for the past 7 years. As rattoons these same two canes ranked first the past season, being followed by Mont Blanc and D 74. Sealy Seedling occupied twelfth place in average results among the rattoons in 1906–7.

In Antigua 26.2 per cent of the total sugar acreage of the island is now devoted to the newer varieties, while in St. Kitts the newer canes already occupy 71 per cent of a total of 7,516 acres.

Manurial experiments with sugar cane in the Leeward Islands in 1906–7, F. WATTS ET AL. (*Imp. Dept. Agr. West Indies Pamphlet 51, 1908, pp. 43*).—Experiments have been started on rattoon canes following plant canes which have received no commercial fertilizers. These tests are known as the new series, while the old series consists of experiments in progress on rattoon canes following plant canes which have received commercial fertilizers.

In the nitrogen series of tests the most remunerative returns were secured where 40 lbs. of nitrogen per acre was given in the form of nitrate of soda and used in conjunction with potash and phosphate. Without the use of potash and phosphate the nitrogenous fertilizers also proved profitable. The use of dried blood was unsatisfactory. This season superphosphate afforded better results than basic phosphate, but even in this form it did not appear remunerative. The use of moderate quantities of potash proved beneficial, and small dressings of 20 lbs. of potash per acre were as satisfactory as larger doses. The use of guano gave an insufficient increase in the crop to cover the expense of its application.

The average results in the old series of experiments during 7 years are regarded as showing fairly conclusively that in Antigua and St. Kitts nitrogen is of the greatest value to the rattoon crop and that the requirements are met by the use of from 2 to 2¾ cwt. of sulphate of ammonia per acre or from 2½ to 3½ cwt. of nitrate of soda given in one application; that potash is doubtfully remunerative and if used should not exceed in quantity 20 lbs. per acre, and that phosphates are not profitable. These statements presuppose that when the land was prepared for plant canes it was manured with about 20 tons per acre of good barnyard manure or its equivalent.

Report on field trials on varieties of swedes (*Midland Agr. and Dairy Col. Bul. 7, 1907–8, pp. 67–78*).—In general the bronze-top varieties outyielded the purple-top sorts. Ne Plus Utra, which ranked first in yield and dry matter, produced 19 tons 17 cwt. of roots and 3,633 lbs. of dry matter per acre. It is regarded as the best swede for the Midlands.

Report on field trials on manuring of swedes (*Midland Agr. and Dairy Col. Bul. 4, 1907–8, pp. 27–40*).—The results here reported show that a dressing of 191 lbs. of nitrate of soda, 520 lbs. of superphosphate, and 60 lbs. of sulphate of potash per acre was the most profitable application. A small dressing of barnyard manure and commercial fertilizers gave a larger crop than the use of manure alone either in small or in large dressings. Basic slag and superphosphate proved to be the best sources of phosphate for swedes, and dissolved bone and bone meal the least satisfactory. It was found that if part of the nitrogen is applied after thinning it is best to supply that given at seeding in the form of sulphate of ammonia, and that if all the nitrogen is given as nitrate of soda it is advisable to apply it all at the time of sowing.

Propagation of tobacco in Cuba, C. F. Baker (*Estac. Cent. Agron. Cuba Bul. 10, English ed., pp. 22, figs. 8*).—This bulletin is a popular treatise on tobacco culture under Cuban conditions. The subjects discussed are seed selection, varieties, seed beds and their preparation, planting, and transplanting.

Tobacco (*Bur. of the Census [U. S.], Manfrs. 1905, pt. 3, pp. 553–579*).—In this report the manufacture of tobacco is divided into two principal groups, cigars and cigarettes, and chewing and smoking tobacco and snuff. A summary of the statistics of the combined industry from 1860 to 1905, with percentages of increase, shows that in 1905 the number of establishments was 16,828, the capital invested $323,983,501, the cost of materials used $126,088,608, and the value of products $331,117,681. Tabulated statistics are given by States, Territories, and geographic divisions.

The perennial sow thistle and some other weed pests of 1908, J. E. Howitt (*Ontario Dept. Agr. Bul. 168, pp. 24, figs. 26*).—This bulletin presents information regarding the perennial sow thistle (*Sonchus arvensis*), bladder campion (*Silene inflata*), stinkweed (*Thlaspi arvense*), Russian thistle (*Salsola kali tragus*), field pepper grass (*Lepidium campestre*), dodder (*Cuscuta epithymum*), and the orange hawkweed (*Hieracium aurantiacum*), with a view to aiding in checking or exterminating these various weeds which are spreading rapidly over Ontario. Special attention is given to the perennial sow thistle and five different methods for combating it are outlined.

HORTICULTURE.

Forcing plants by warm baths, H. Molisch (*Umschau, 12 (1908), No. 39, pp. 771–773, figs. 4; abs. in Sci. Amer. Sup., 66 (1908), No. 1714, p. 298*).—The author investigated a method used by certain practical gardeners in forcing plants by means of warm water. The method consists in soaking cut branches or rooted plants of various trees and shrubs in warm water for from 9 to 12 hours, and then growing them in the usual manner.

In November, 1907, 3 freshly cut branches of Forsythia were immersed for 12 hours in water, the temperature of which varied between 77 and 90° F. These were then placed in a hothouse with their cut ends in water, together with 3 branches which had not been immersed. In 12 days' time the bathed branches were in full bloom while all the buds on the other branches still remained closed. A rooted lilac bush immersed for 12 hours in hot water at a temperature of 88 to 98° F. was afterwards placed in a moderately warm forcing house with a temperature of 59 to 64° F. Forty days after the bushes were

in full leaf and flower, whereas the buds on an untreated bush were just beginning to open. A portion of the young catkins on a hazel stem with many branches was immersed in hot water for a period of 12 hours while the remaining catkins remained dry. Six days later the bathed catkins attained their full development while the unbathed catkins showed no perceptible change. A similar experiment with Forsythia emphasized the local character of the influence of the warm bath.

It was also found that if the bathed branches or plants are not placed at once in the forcing house, but are first exposed to the open air for 2, 3 or 4 weeks, under ordinary autumn or winter conditions, and are then cultivated in the hothouse, the bathed portions show the same advance over the unbathed portions as though they were placed in the hothouse immediately after the bath. This process is applicable to the hazel, lilac, dogwood, gooseberry, larch, black alder, horse chestnut, willow and other plants and immersion from 6 to 12 hours is generally sufficient. Plants bathed beyond 12 hours are likely to suffer from lack of oxygen.

The temperature of the bath varies with different plants. Hazel, Forsythia, gooseberry, and lilac are sufficiently stimulated by a bath at 86° F., whereas a temperature of 95 to 104° F. is better for the horse chestnut and appears to be necessary for the black alder and birch. Some plants appear to be influenced by the warm bath immediately after the leaves fall; other plants must first go through a period of rest. On the other hand, the effect of the bath gradually diminishes toward the end of the winter rest period. A warm bath in autumn was found to produce immediate effect on the male catkins of the hazel, whereas the leaf buds could not be stimulated by a warm bath until January. It is believed that this method will prove of practical value to florists in forcing shrubs.

Distribution of seeds and plants, E. J. Wickson and R. E. Mansell (*California Sta. Seed Bul. 1908–9, pp. 6*).—A tabulated statement on the distribution of seed made by the station from 1902 to 1908 is given, the aims and methods of the work are pointed out, and a number of garden vegetables and fruits are described.

Ginseng and other medicinal plants, A. R. Harding (*Columbus, O., 1908, pp. 317, pls. 2, figs. 87, dym. 1*).—This popular work contains a considerable amount of information compiled from various sources relative to the technical and common names, habitat, range, botanical characteristics, collection, prices, and uses of a large number of medicinal roots, barks, and leaves. Particular attention is paid to the culture of ginseng and Golden Seal. Illustrations are given of the plants under discussion.

Orchard fruits in the Piedmont and Blue Ridge regions of Virginia and the South Atlantic States, H. P. Gould (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 135, pp. 102, pls. 4*).—This is the first report on a series of fruit district investigations which the Bureau of Plant Industry is conducting. It discusses the physical and climatic conditions of the Piedmont and Blue Ridge regions and contains notes on the range and behavior of a large number of varieties of apples, pears, peaches and plums grown therein. The varieties of apples and peaches are also grouped according to their behavior at different altitudes in different latitudes, and phenological records compiled from the observations made of some of the more important varieties of fruits by a large number of fruit growers are given. The text is accompanied with a map showing the pomological regions of the South Atlantic States.

Although the study has not been continued sufficiently long to warrant many definite deductions, it is believed that the information presented will prove of value to prospective orchard planters.

Orchard report of Baton Rouge Station (*Louisiana Stas. Bul. 112, pp. 3–49, figs. 14*).—This report summarizes the observations made on the varieties of orchard and small fruits tested in the station orchard at Baton Rouge since its establishment in 1889–90. The report concludes with a discussion of orchard pests and diseases and their control, and orchard fertilizers. It is believed that the observations are sufficiently complete to prove of value to those interested in fruit culture upon the bluff soils of the State.

[Reports of the fruit experiment stations], H. L. Hutt et al. (*Ann. Rpt. Fruit Expt. Stas. Ontario, 14 (1907), pp. 19–94, figs. 9, map 1*).—A progress report on the work of variety testing at the various fruit experiment stations throughout Ontario, including separate reports by the experimenters in charge of each station. In the appendix are given lists of the varieties of fruits recommended to be grown for market in the province, including lists of varieties especially adapted to the sections represented by each station.

Fruit culture, A. Gomes do Carmo (*O Brasil: Suas riquezas naturaes; suas industrias. Rio de Janerio: Centro Indus. Brasil, 1908, Portugese ed., vol. 2, pp. 335–378*).—An account is given of the present status of fruit culture and wine making in Brazil including descriptive lists of tropical and acclimatized fruits adapted to that country.

The influence of peat mull on the root development of young fruit trees, Yunge (*Ber. K. Lehranst. Wein, Obst u. Gartenbau Geisenheim, 1907, pp. 78, 79, fig. 1*).—Finely divided peat dust saturated with liquid manure and worked into the soil in a similar manner to that used with stable manure was found to produce a strong fibrous root growth with young fruit trees. As a result of this trial the station recommends the use of peat mull to nurserymen.

May weather and fruit harvests, F. H. Hall (*New York State Sta. Bul. 299, popular ed., pp. 2–8*).—A popular edition of Bulletin 299 of the station previously noted (E. S. R. 20, p. 41).

Investigations on the life activities of stored fruits, O. Schneider-Orelli (*Landw. Jahrb. Schweiz, 22 (1908), No. 10, pp. 545–563*).—The author briefly reviews the literature on this subject and reports on several respiration and transpiration experiments conducted with fruit stored in bright and dark locations, together with experiments on the respiration of injured stored fruits.

Sunlight, through its warming effect, was found to increase both the respiration and transpiration of stored fruit and should not be allowed to enter the storage place. Diffused daylight on the other hand did not appear to materially influence the life activities of stored fruit. Where there was injury to the fruit, however, a respiration acceleration was evident for several days.

Seedless grapes and orchard fruit, H. Müller-Thurgau (*Landw. Jahrb. Schweiz, 22 (1908), No. 10, pp. 564–597, figs. 7*).—A study of the recent literature on this subject with an account of recent observations made by the author. The subject is discussed under the following general headings: The occurrence of parthenocarpie with pip fruits, the importance of parthenocarpie for the orchard, parthenocarpie with grapes, conditions favorable to the development of seedless fruits, and the influence of the seed upon the size, shape and inner structure of the fruit. A bibliography is appended.

Fertilizer experiments with grapes, E. Zacharewicz (*Rev. Vit., 30 (1908), No. 770, pp. 313–318*).—A further report on fertilizer experiments being conducted with grapevines on different soils in the department of Vaucluse. Practically the same conclusions are reached as in the work previously noted (E. S. R., 19, p. 946).

Viticulture in the department of Constantine, H. Perruchot (*Bul. Off. Gourt. Gén. Algérie, 1908, No. 20, Sup., pp. 239–275*).—A report on viticultural conditions in Constantine, Algeria, relative to the methods of combating the

phylloxera and the reconstitution of the vineyards with American stocks. Notes are given on those stocks which have shown the best results together with varieties of French grapes adapted for grafting on these stocks, data on the cost of replanting vineyards, and the production and commerce of wine.

Coffee, S. F. RANGEL (*O Brasil: Suas riquezas naturaes; suas industrias. Rio de Janeiro: Centro Indus. Brasil, 1908, Portuguese ed., vol. 2, pp. 1–103*).—An account of the coffee industry with special reference to coffee culture in Brazil including data relative to the history, botany, chemical composition, physiological properties and distribution of coffee, the climate and soil requirements, cultural operations, insect pests, harvesting, drying, preparation for export, consumption, substitutes, and the cost of production, together with statistics on production, imports and exports for a large number of years.

Cacao, J. R. MONTEIRO (*O Brasil: Suas riquezas naturaes; suas industrias. Rio de Janeiro: Centro Indus. Brasil, 1908, Portuguese ed., vol. 2, pp. 217–229*).—An account of cacao culture in Brazil including statistics on production and exports of cacao.

In defense of chestnut groves, I. GIGLIOLI (*A Difesa dei Castagneti. Rome, 1908, pp. 3–163*).—A report of an investigation relative to the present condition of the chestnut groves in Italy, the extent to which they have been damaged by the manufacture of tannic acid from chestnut wood, and suggestions for the extension of chestnut culture and protective measures for the future.

Pecans and other nuts in Texas, R. T. MILNER (*Texas Dept. Agr. Bul. 2, pp. 5–48*).—This is a compilation of papers on various phases of pecan culture and nut culture in general, presented with a view of stimulating nut culture in Texas. The papers were selected chiefly from the papers and addresses of the Texas Nut Growers' Association and have been classed under the following general headings: General directions for pecan culture; the best pecan; transplanting, budding, and grafting; top-working; walnuts; and marketing pecans.

Budding new tops on pecan trees, H. H. HUME (*Amer. Fruit and Nut Jour., 5 (1908), No. 90, pp. 8–11, figs. 7*).—An illustrated discussion of the method of top-working pecan trees by the use of annular buds, including data on the cost of the operation and a discussion of the advantages of top-working by cutting back and budding.

Shade trees, E. A. START, G. E. STONE, and H. T. FERNALD (*Massachusetts Sta. Bul. 125, pp. 3–64, figs. 34*).—This bulletin, which was prepared and published jointly by the Massachusetts Agricultural Experiment Station and the Massachusetts Forestry Association, discusses various questions relative to shade trees and their management, including the law of shade trees in the highway and street and on private property, the tree warden's outfit and duties, the characteristics and value of the more important species of shade trees and their adaptability for different environments, transplanting and pruning, tree surgery and tree guards, the injurious effects of gas and electricity and methods of prevention. In conclusion the more important insect enemies are figured and described and the best-known methods of treatment are given.

Shade trees for North Carolina, W. W. ASHE (*N. C. Geol. and Econ. Survey Bul. 16, pp. 72, pls. 10, figs. 18*).—This bulletin is published with the view of stimulating and encouraging judicious planting of shade trees in North Carolina and contains suggestions relative to the time and method of planting, pruning, care of newly planted trees, general suggestions for street planting, and the arrangement and combination of trees for various purposes. Descriptions are given of the majority of shade trees suitable for street and park planting in different sections of the State. The advantages to be derived by judicious street tree planting are further emphasized by means of illustrations.

Gardens old and new, edited by H. A. TIPPING (*New York and London, [1908], pp. XI+346, pl. 1, figs. 397*).—This is the third of a series of volumes, all of which portray English country homes and their garden environments. The present volume contains about 400 photographic illustrations with descriptive text.

Gardening for women, FRANCES G. WOLSELEY (*New York and London, 1908, pp. XV+289, pls. 32, figs. 13*).—A popular work in which the author draws attention to the qualifications of women for taking up various phases of gardening, points out the advantages to be derived by employing them, and outlines their position in supplementing and increasing the work done by male gardeners. Several chapters of the book are devoted to syllabuses of colleges and schools in Great Britain and elsewhere, which are deemed of value in training women for gardening pursuits.

Window gardening, H. B. DORNER (*Indianapolis, 1908, pp. 153, pl. 1, figs. 43*).—A practical work on window gardening in which the author discusses various forms of containers, potting methods, soils, watering, fertilizers, light, heat and ventilation, insect enemies, propagation by seed and by cuttings, and gives detailed directions for the culture of a large number of bulbs, foliage plants and flowering plants suitable for window culture.

Water lilies and how to grow them, H. S. CONARD and H. HUS (*New York, 1907, pp. V+228, pls. 31*).—A popular work containing directions for the culture of various kinds of water lilies, together with chapters on the making of ponds and the use of accessory plants. The relative values of the different varieties in the various groups are pointed out and lists are given of water lilies for special purposes.

FORESTRY.

Douglas fir: A study of the Pacific Coast and Rocky Mountain forms, E. H. FROTHINGHAM (*U. S. Dept. Agr., Forest Serv. Circ. 150, pp. 38, figs. 3*).—This circular discusses the history, distinguishing characteristics, silvical forms, geographical distribution, and silvical regions within the range of Douglas fir, together with the silvical characteristics and requirements of the two forms, and systems of management in the different silvical regions.

The author concludes that of the two forms of Douglas fir, one of which inhabits the region between the Cascades and Sierra Nevada and the coast, and the other the Rocky Mountain region, the coast form is superior for forest planting in almost every respect. The mountain form is better adapted for ornamental purposes or for regions where the climate is unfavorable to the growth of the coast form. Attention is called to the great desirability of selecting seed for future plantings from rapid-growing, straight, symmetrical trees.

The pine: Economic and statical investigations of the forest division, Eberswalde Forest Research Station, A. SCHWAPPACH (*Die Kiefer: Wirtschaftliche und Statische Untersuchungen der Forstlichen Abteilung der Hauptstation des Forstlichen Versuchswesens in Eberswalde. Neudamm, 1908, pp. IV+180*).—In addition to normal yield tables for the pine based upon studies of Prussian pine stands for the past 30 years, considerable tabular data are given and discussed relative to studies of the effect of various methods of culture and of different degrees of density upon the development of pine forests, assortment yield tables, and investigations on the productiveness of pine forestry under different systems of treatment.

In the appendix tables are given for different experimental areas in which the trees are classed according to their diameter at 1.3 meters (about 5 ft.) from the ground.

Production and consumption of basket willows in the United States for 1906 and 1907, C. D. MELL (*U. S. Dept. Agr., Forest Serv. Circ. 155, pp. 14*).—This is a statistical review of the basket-willow industry in this country based largely on brief reports from 161 domestic manufacturers of willow ware.

It is estimated that 2,282,000 lbs. of willow rods were consumed in this country in 1907 as compared with 1,798,000 lbs. in 1906. There was a slight advance in price for home-grown rods, particularly for the higher grades, in 1907, as well as a marked tendency on the part of manufacturers to either grow their own stock or to use domestic willows of high grade.

Forest economics—silviculture, L. GRANDEAU (*Ann. Sci. Agron., 3. ser., 3 (1908), I, pp. 372–438; II, No. 1, pp. 1–156*).—Résumés and in some cases full reports are given of a large number of papers presented before the section of forest economics and silviculture of the Eighth International Congress of Agriculture at Vienna in 1907. In Volume I are considered creation and treatment of forests from the standpoint of production and quality, the cultural importance of acclimatized varieties of our forest species, and the utility of and favorable methods of afforesting pine lands. The reports in Volume II deal with studies by research stations on wood transportation and the utilization of wood for construction purposes, remedial measures against injuries to forests from industrial fumes and insects, new tendencies and methods in forest management, the basis of an equal tax on wood properties, legislative measures for the protection of landscapes and natural areas, wood commerce in Europe and the influence of good roads on this commerce, international unification of units of measure and standards of sorting for building timber, and the use of beech wood in the chemical industries.

On the preservation of seeds of deciduous trees, C. VANDERBISSE (*Ann. Gembloux, 18 (1908), No. 10, pp. 559–585*).—A thesis in which the author discusses the factors influencing seed germination, reviews the various processes employed for saving the seed of the principal hardwood species, and presents data on the preservation of acorns by several different methods. A brief bibliography is appended.

On the combating of hardpan by cultural methods, N. VON LORENZ (*Zur Bekämpfung des Ortsteines durch Kulturelle Makregeln. Vienna, 1908, pp. 3–23, figs. 5*).—The forestry experiment station at Mariabrunn is conducting experiments with a view of rendering hardpan soils suitable for forestry. A detailed account is given of the results secured to date with plantations of oak, beech, white pine, fir, and locust set out in 1904. Chemical fertilizers and green manures have been used with the plats. The results thus far indicate that with the methods used hardpans not much more than 20 cm. (about 8 in.) thick can be improved sufficiently to grow profitable stands of spruce, white pine, oaks and eventually locust, and possibly beech.

The principles of spacial arrangement in forests, C. WAGNER (*Die Grundlagen der Räumlichen Ordnung im Walde. Tübingen, 1907, pp. V+320, pl. 1, figs. 43*).—In this work the author examines in detail the various phases of forestry, including silviculture, forest protection, utilization, and management, relative to their requirements with respect to space arrangement, with a view of formulating principles for the development of a system of forest management which shall provide for a separate and independent consideration of space and time. This the author believes can be best accomplished by natural regeneration over very restricted areas, and he advocates the selection strip method of felling, "Blendersaumschlag," which provides for cutting the mature wood in progressive narrow strips on the side of the forest which presents the most favorable conditions for the natural regeneration of the trees.

Annual report of the director of forestry of the Philippine Islands for the period July 1, 1906, to June 30, 1907, G. P. AHERN ET AL. (*Philippine Bur. Forestry Rpt. 1907, pp. 5–37, maps 2*).—This report includes a report of the second annual conference of the foresters of the Philippine Bureau of Forestry with a list of recommendations adopted at the conference relative to various phases of the work; a report of the committee on free use privileges with a proposed amendment to the Free-Use Act designed to regulate the abuse of privileges granted under the act; considerations relative to the present status and possible development of lumbering operations; and an outline of the work of the bureau in investigating the amount, character, value, and uses of the Philippine forest products. Tabular statements are given of the licenses and applications granted for lumbering, clearings, and homesteads, utilization of forest products, amount of timber taken by leading licensees, import and export of lumber, revenues, and expenditures.

Desirable tracts of public forests are said to be available and unoccupied in several of the provinces. Maps of these districts have been made and estimates prepared showing the stand, varieties of merchantable timber, possibilities of logging, etc. Available forest tracts in Negros Occidental, and northeastern Mindoro, together with a report of an examination of pine lands tributary to Baguio, Province of Benguet, are considered in the present report.

Report of the conservator of forests, C. E. LEGAT (*Transvaal Dept. Agr. Ann. Rpt. 1907, pp. 178–192*).—An account of nursery and planting operations conducted at the various forest centers including a financial statement for the year.

The royal Bavarian forestry administration and its historical development in the nineteenth century, J. KEIPER (*Forstw. Centbl., n. ser., 29 (1907), No. 9–10, pp. 499–531, pl. 1; 30 (1908), Nos. 2, pp. 61–76, pl. 1; 3, pp. 121–141; 4, pp. 181–199, pl. 1*).—From the standpoint of management the author divides the Bavarian forest administration into four well-defined periods of development which are discussed in their order as follows: From 1803 to 1821; 1822 to 1853; 1853 to 1855; and 1855 to the present time.

Report on the history of the woodlands of the town of Ettlingen, M. SEEGER (*Karlsruhe, 1908, pp. 90, map 1*).—A thesis on this subject accepted by the Grand-ducal Technical High School at Karlsruhe for the degree of doctor of engineers. The work includes a historical account of the Ettlingen forests relative to their management, forest policy, protection, exploitation, etc. A brief bibliography is appended.

Annual report on the literature and important happenings in the realm of scientific forestry, forest zoology, agricultural chemistry, meteorology and forest botany for the year 1907, H. WEBER (*Allg. Forst u. Jagd Ztg., 1908, Sup., pp. 89*).—This report contains abstracts of the important literature on the various phases of forestry together with notes on important occurrences in the forest world for the year 1907. The topics included are silviculture, utilization, management, valuation and statics, the theory of forest mensuration and yields, administration, history, policy, statistics, news of forest unions and hunting clubs, zoology, botany, and soil physics.

DISEASES OF PLANTS.

Observations on the biology of Botrytis cinerea, F. T. BROOKS (*Ann. Bot. [London], 22 (1908), No. 87, pp. 479–487, figs. 4*).—A study was made of *B. cinerea* to determine if possible the conditions under which it is able to infest its host plants. The conidia were found to develop and grow luxuriantly in gelatinized grape extract, and infection experiments were carried on with pure

cultures of the fungus applied to lettuce plants. Where the spores were placed directly upon uninjured leaves no infection took place, but wherever the leaves were wounded, either by tearing or burning with a hot platinum needle, infection ensued.

While carrying on these experiments, the author noted that the plants on which the leaves had begun to turn yellow were readily infected. Subsequent investigations, in which plants were kept for 5 days in the dark and spores placed upon them when the leaves were beginning to show signs of yellowing, showed that the fungus was readily introduced into otherwise sound tissues.

Another experiment was carried on in which lettuce was grown in cultures from which some of the supposedly essential organic constituents were omitted. After 6 weeks' growth in such cultures, the plants were inoculated by placing Botrytis spores upon the leaves, but without any infections.

In conclusion the author states that "whatever may be the causes at work in the living cell which confer immunity or predisposition on the species of host plant, or which confer virulence or impotence on the spore, they lie deeper than nutrition."

The physiology and development of some anthracnoses, C. W. EDGERTON (*Bot. Gaz., 45 (1908), No. 6, pp. 367–408, pl. 1, figs. 17*).—A study of some anthracnoses has been carried on to determine the perfect stage of as many forms as possible, to ascertain whether the forms of Gloeosporium found on the apple represent a single species or more than one, and to learn whether species of Gloeosporium may be distinguished by cultural methods. In the study the author investigated the anthracnoses of about 30 different host plants from 50 or more sources. The genera that are known to be connected with anthracnoses are Gnomonia, Glomerella, and Pseudopeziza.

From an economic standpoint, the most important species belong to the Glomerella type, which is distinctly separated from the other types of anthracnoses both by its perfect and imperfect stages. There seem to be a large number of closely related forms that are extremely variable. Furthermore, many forms vary under artificial cultivation and doubtless also under natural conditions. Some of these forms seem to be similar enough to be considered the same, while others are dissimilar enough to be classed as distinct species.

In relation to the forms occurring on the apple, there seem to be two distinct forms of anthracnose separated by thermal lines. That occurring in the southern part of the country differs in the presence of perithecia, a slightly different acervulus, and entirely different cultural characters. From his investigations the author is led to believe that too much dependence should not be placed on cultural characters for the determination of the species.

On the specialization of a form of Sphærotheca humuli, J. A. STEINER (*Centbl. Bakt. [etc.], 2. Abt., 21 (1908), No. 22–23, pp. 677–736, pl. 1, figs. 3*).—Experiments by the author showed that there is a biological form of *S. humuli* occurring on various species of Alchemilla, and he describes it under the name of *S. humuli alchemillæ*. His experiments showed that there is little difference between infection by ascospores and by conidia of the fungus, and that of the form described several races exist capable of infecting some species of Alchemilla and not others.

The Sporotrichum bud rot of carnations and the silver top of June grass, F. C. STEWART and H. E. HODGKISS (*New York State Sta. Tech. Bul. 7, pp. 83–119, pls. 6*).—The carnation bud rot described by the authors is said to be identical with that discussed in Bulletin 103 of the Nebraska Station (E. S. R., 19, p. 855). It is known to occur in several greenhouses in New York, Illinois, and Nebraska, but it is not believed to be of great economic importance.

Carnations affected with bud rot are invariably infested with a fungus associated with a particular species of mite. The same fungus and mite are frequently found similarly associated on June grass (*Poa pratensis*). The relation of the mite to the carnation disease is not entirely clear, but it probably acts as a carrier of the fungus. The relation of the mite to the silver top of grass has not been investigated.

The fungus on the carnation has hitherto been given a different name from that on the grass, but as it was first described from the grass, the name should be *S. poæ* The mite, previously described as *Pediculoides dianthophilus* (E. S. R., 19, p. 860), has been positively identified as *Pediculopsis graminum.*

The authors of the present bulletin do not agree with Heald that the bud rot is necessarily a disease of neglected houses, as it has proved troublesome in a number of greenhouses on Long Island that are exceptionally well managed.

The smuts of cereals, their distribution and control, R. Falck (*Jour. Landw., 56 (1908), No. 2, pp. 173–182, pl. 1*).—This is a lecture presented before the Agricultural Society of Breslau, giving a summary of information regarding cereal smuts, their distribution, and means for control.

Rust in wheat, R. H. Biffen (*Jour. Bd. Agr. [London], 15 (1908), No. 4, pp. 241–253*).—After a general account of the life histories, destructiveness, and other characteristics of rusts, the author describes his breeding experiments with various wheats in seeking forms immune to rust, particularly to the yellow rust (*Puccinia glumarum*), a preliminary account of which has already been noted (E. S. R., 19, p. 44).

After finding a number of varieties of wheat that were practically immune to the yellow rust, hybridizing experiments were carried on between a variety of Club, an immune variety, and Michigan Bronze, a very susceptible variety. The cross-bred plants proved very susceptible to the disease, but a fair crop of grain was produced. A study of the material in subsequent generations showed that the head characters and immunity or susceptibility are unit characters that seem to be transmitted, and four fixed types have been secured, namely, immune Club, susceptible Club, an immune loose-headed variety similar to Michigan Bronze, and a susceptible variety of the same. Two of these varieties closely resemble the parents and two show fresh combinations of the characters present in the two parent plants. Further trials are being conducted with these varieties in order to demonstrate that the new character combinations are perfectly fixed. The immune varieties of wheat which have been raised in the course of these preliminary experiments have no particular value beyond their immunity.

During the process of the investigation an opportunity was offered to estimate the extent of damage caused by rust. Numbers of each type were harvested separately, and the yield of grain of the diseased plants compared with those in a healthy condition was in the ratio of 0.2 to 1.

Bean diseases in 1908, H. Querner (*Ztschr. Landw. Kammer Braunschweig, 77 (1908), No. 31, pp. 367, 368*).—During 1908 serious losses were occasioned by the occurrence of bean anthracnose (*Glæosporium lindemuthianum*) and red spiders (*Tetranychus telarius*). For the prevention of the first, the author recommends better drainage of the soil, with care in the selection of seed, and where seed is suspected of being diseased, treating it with a solution of ammoniacal copper carbonate. For the control of the red spider no definite means are described.

The more important diseases of cabbage in Holland, H. M. Quanjer (*Natuurk. Verhandel. Holland. Maatsch. Wetensch. Haarlem, 3. ser., 6 (1906), No. 2, pp. 1–84, pls. 8*).—After describing cabbage culture in the north of Holland, an account is given of some of the more important insect and fungus pests

to which the crop is subject. Among those mentioned are *Contarinia torquens*, *Anthonomyia* sp., *Baris* sp., *Phoma oleracea*, etc. In addition to these, descriptions are given of some troubles due to faulty cultivation.

Corky scab of potatoes (*Jour. Bd. Agr. [London]*, *15 (1908)*, *No. 8, pp. 592–599, pl. 1*).—A description is given of corky scab of potatoes caused by the fungus *Spongospora scabies*. This fungus is said to be abundant in Great Britain, Ireland, and Norway, and found to some extent in Germany.

Soaking diseased potatoes for 2 hours before planting in a solution consisting of ½ pt. of formalin in 15 gal. of water is recommended. The application of lime to the soil would probably aid in checking the disease.

Black scab in potatoes (*Dept. Agr. and Tech. Instr. Ireland Jour., 8 (1908)*, *No. 3, pp. 441–443, pl. 1*).—A description is given of the black scab, or wart disease, of potatoes, due to the fungus *Chrysophlyctis endobiotica*, which is apparently becoming very serious in parts of Great Britain. Preventive measures which include rotations in which potatoes do not occupy the soil for a considerable number of years are recommended.

An important new potato disease in Germany, G. Schneider (*Deut. Landw. Presse*, *35 (1908)*, *No. 79, p. 832, figs. 2*).—An illustrated account is given of the wart, or black scab, of potatoes due to *Chrysophlyctis endobiotica*, which has lately appeared in parts of Germany.

The occurrence of Chrysophlyctis endobiotica in Westphalia, A. Spieckermann (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 6 (1908)*, *No. 10, pp. 113–116, figs. 2*).—A description is given of the wart disease of potatoes due to *C. endobiotica*, together with suggestions for the prevention of the spread of that pest.

Recent investigations of potato diseases, and of diseases of potatoes and root crops during storage, F. K. Ravn (*Tidsskr. Landbr. Plantcarl*, *15 (1908)*, *No. 2, pp. 344–354*).

Fire blight in fruit trees, W. B. Mack (*Nevada Sta. Bul. 63, pp. 52, 53*).—Attention has been directed to a disease of apple trees. An examination showed that the trouble was of bacterial origin and that undoubtedly the organism is *Bacillus amylovorus*, the species which causes the bacterial blight of pears, apples, and quinces. The disease is said to be of common occurrence in the vicinity of the station and is causing material damage to the orchards. It is to be the subject of further investigation.

The leaf browning of sweet cherries in Germany, K. von Tubeuf (*Naturw. Ztschr. Forst u. Landw., 6 (1908)*, *No. 6, pp. 330–332, figs. 3; abs. in Bot. Centbl., 108 (1908)*, *No. 14, p. 365*).—An account is given of a disease of sweet cherries, due to *Gnomonia erythrostoma*, which has recently made its appearance in the Bavarian Palatinate. The fungus has appeared in great abundance, causing a browning of the leaves, and is characterized by the leaves remaining attached to the trees during the winter. The spores are said to be 2-celled instead of 1-celled, as previously reported by Frank.

The effect of various copper preparations and other fungicides on the flowers of the grape, E. Molz (*Mitt. Weinbau u. Kellerw., 20 (1908)*, *No. 6, pp. 87–91, fig. 1*).—The effect of 2 applications of several fungicides and insecticides on the flowers of the grape was investigated. The treatments were made in June and July, intervals of about 10 days occurring between the applications. Among the substances employed were soda Bordeaux mixture, neutral copper acetate, azurin, a fungicide the formula of which is recommended by Vermorel, several dust preparations of Nordlinger, Nonnit, and sulphur, comparisons being made with Bordeaux mixture, a 1 per cent solution of which was used in the first spraying and a 2 per cent solution in the second.

The Bordeaux mixture did not injure either the leaves or the flowers, while the other liquid sprays were all more or less destructive of the flowers, and some injured the foliage as well. Nonnit destroyed a portion of the flowers and burned the leaves to a considerable extent. None of the fungicides used in a dry form proved injurious.

Gum disease of citrus trees in California, R. E. Smith and O. Butler (*California Sta. Bul. 200, pp. 235–272, figs. 14*).—According to the authors, the most common and characteristic citrus tree diseases in California are included under the general term gum disease, and the present bulletin considers various citrus troubles, showing the features which they have in common and discussing their nature, together with means of prevention and cure.

Gum disease, or gummosis, is a term applied to a condition in which an exudation of a gummy sap takes place through the bark. The disease is attributed to various causes, but so far as known it is not infectious. A common form in California to which the term gummosis is applied occurs on the lemon, although the characteristic trouble is not confined to these trees. An examination of diseased trees showed that the gum does not originate in the bark, but breaks out through the latter by mechanical pressure from within. The affected area may be large or small and may spread until the trunk is completely girdled. In severe cases the bark of the affected portions dies and the tree may do likewise. The relation of soil and location of orchards to this disease is discussed, and it is shown that almost invariably gummosis is found in trees growing in poorly drained situations, such as the lower slopes of orchards, or where the orchard is on heavy soil or poorly drained due to hardpan or other causes. The effect of the disease upon the tissues is described and methods of control are suggested, among them the avoidance of unfavorable conditions in planting, the use of sour-orange roots as stock, high budding, cultural prevention, improvement of soil conditions, slitting and stripping the bark on diseased areas, etc. Where the bark is cut it has been found advantageous to cover the wounds with a form of grafting wax to prevent the entrance of fungi. Attention should be paid to soil improvement and pruning, and it has been found that good drainage and the proper aeration of the roots by boxing or digging away about the trees and placing sand about the trunks are on the whole practical means for the prevention of gummosis.

Another citrus tree disease described is that known as scaly bark, or psorosis, which is primarily a disease of the orange and which apparently rarely occurs on other citrus trees. This disease is distinguished from gummosis by its occurrence at any point on the trunk or branches of a tree, and there is apparently no direct connection between the soil and the location of the affected area. The appearance of the disease is well described by the name scaly bark. The authors say that there seems to be a connection between the irregular water supply and the occurrence of scaly bark, and an extreme case is cited which seems to prove their claim. The relation of scaly bark to gummosis is discussed, and for the control of the former the authors say that treatment does not promise very satisfactory results and that precautions for the prevention of the disease are more to be sought than methods for its treatment. The methods of treatment are essentially the same as those described for gummosis.

Brief notes are also given on the gumming of nursery trees, foot rot, Florida die back or exanthema, and twig blight.

Phoma abietina, a parasitic disease of the fir, E. Mer (*Rev. Eaux et Forêts, 47 (1908), No. 20, pp. 609–621*).—In 1890 the author published an account of a disease of fir trees in which a kind of canker was formed by *P. abietina*. During a recent outbreak of a disease of firs in the Jura Mountains, he was led to

investigate its cause. At first there appeared to be no relation between the 2 diseases, as no Phoma was found in dead material. In a subsequent and more careful study, however, the presence of a fungus was indicated, although in the last instance the disease differed quite markedly from the previous attack.

In the present outbreak the fungus seems to attack the young twigs, causing their destruction within a relatively short time, and the injury to the tree is much more serious than that formerly observed. A number of causes are mentioned as probably contributing to the unusual severity of the fungus attack, among them the prevailing high winds, the severe winter of 1906–7 followed by a prolonged drought in the summer, rocky soil, etc., all of which weakened the trees and made them more liable to attack.

The leaf cast of white pine, K. von Tubeuf (*Naturw. Ztschr. Forst u. Landw., 6 (1908), No. 6, pp. 327–330, figs. 3; abs. in Bot. Centbl., 108 (1908), No. 14, p. 365*).—A description is given of a disease of white pine, due to the fungus *Hypoderma brachysporum*, which causes a falling of the leaves. In addition to white pine, it also occurs on *Pinus excelsa*.

A note on the mildew of oaks, Griffon and Maublanc (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 8, pp. 437–439*).—During the summer of 1908 the oaks in many parts of France are said to have been severely attacked by a white mold of which only the Oïdium phase is known. All the species of deciduous oaks seemed to be subject to this fungus, a few being particularly injured. It has been impossible to definitely determine the species, but a species (*Microsphæra alni*) occurring on the alder has been considered as possibly attacking the oak. Observations, however, showed that while beech trees seem to be subject to the same mildew as the oaks, the alders have escaped even when growing in close proximity to diseased oak trees. It is thought that if the species is the same as that occurring on the alder, possibly it is a specialized form which now occurs only upon the oak.

On account of the difficulty of treating oak trees, no practical means are known for combating the fungus.

Mildew of oaks, Boudier (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 9, pp. 461, 462*).—Attention is called to the abundant occurrence during the past season of a mildew of oaks in many localities of France. While the fruiting form of the mature fungus has not yet been found, attention is called to the fact that a mildew (*Erysiphe quercus*) was found on leaves in the vicinity of Paris and described some 60 years ago. The author thinks that perhaps this species may be the one under consideration.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Report on economic zoology for the year ending April 1, 1907, F. V. Theobald (*Jour. Southeast. Agr. Col. Wye, 1907, No. 16, pp. 29–180, pls. 29, figs. 20*).—An extensive report with biological and economic notes is given of the principal animal pests of the year. These are arranged under the following headings: Animals injurious to man's domesticated animals, fruit trees and bushes, vines, fruit, corn crops, root crops, pulse, hops, vegetables, flowers, forest trees, man's stores; those causing annoyance to man; and general notes. Among the principal attacks were those of a new gooseberry cecidomyia, leaf hoppers, a black currant mite, eelworms, pigmy mangold beetle, and the turnip gall weevil.

The faunal affinities of the prairie region of Central North America, A. G. Ruthven (*Amer. Nat., 42 (1908), No. 498, pp. 388–393, map 1*).—This subject is briefly considered, references to the literature being given.

The commoner birds of our gardens; their habits and foods, C. H. HOOPER (*Jour. Roy. Hort. Soc. [London], 33 (1908), No. 2, pp. 427–450, fig. 1*).—Following an account of their habits and food, the author gives a classification of birds as to food, and discusses their influence upon insects injurious to fruit, their injury to fruit, and methods for modifying the harm done.

The birds of Maine, O. W. KNIGHT (*Bangor, Me., 1908, pp. XVIII+19–693, pls. 26, map 1*).—This work includes "a key to the description of the various species known to have occurred in the State, an account of their distribution and migration, showing their relative abundance in the various counties of the State as well as other regions, and contributions to their life histories." The faunal areas of the State are considered and a bibliographical list, arranged in chronological order, is appended.

Bibliography of Canadian zoology for 1906, J. F. WHITEAVES (*Proc. and Trans. Roy. Soc. Canada, 3. ser., 1 (1907), Sec. IV, pp. 209–218*).—In this list, which does not include entomology, are given the publications of 56 authors.

Bibliography of Canadian entomology for the year 1906, C. J. S. BETHUNE (*Proc. and Trans. Roy. Soc. Canada, 3. ser., 1 (1907), Sec. IV, pp. 131–141*).—This includes 109 titles ascribed to 56 authors.

Uniform common names for insects, A. F. BURGESS (*Jour. Econ. Ent., 1 (1908), No. 3, pp. 209–213*).—A list of the common names of 142 insects which have been accepted by the American Association of Economic Entomologists.

American insects, V. L. KELLOGG (*New York, 1908, pp. XIV+694, pls. 13, figs. 812*).—In this second and revised edition are included 19 chapters and an appendix. The first 3 chapters consider the structure and special physiology, development and metamorphosis, and the classification of insects. Chapters 4–15 are devoted to a description of the insects composing the various orders. Chapters 16–18 take up insects and their relation to flowers, color and pattern and their uses, and insects and disease, and chapter 20 the collecting and rearing of insects. Chapter 19, on reflexes, instincts, and intelligence, is added in this edition. It is stated that the book is written with the endeavor to foster an interest in insect biology on the part of students in natural history, nature observers, and general readers.

Forest entomology, A. T. GILLANDERS (*Edinburgh and London, 1908, pp. XXII+422, figs. 351*).—In the first 10 chapters of this volume on forest insects the nature of their injury, prevention, and remedial measures, with references to the literature consulted, are discussed under the various orders of insects.

In chapter 11 are given hints on collecting, preparing, and mounting, and in chapter 12, insecticides and general remedies. In chapter 13, beneficial insects are discussed. Chapter 14 is devoted to a tabular list of trees injured, with the nature of the injury, and scientific names of the insects causing it.

Proceedings of the twentieth annual meeting of the Association of Economic Entomologists (*Jour. Econ. Ent., 1 (1908), No. 3, pp. 169–209, pls. 2*).—A continuation of the report of the proceedings of this meeting previously noted (E. S. R., 20, pp. 252, 552).

A paper upon The Orange Worm (*Trypeta ludens*), by A. L. Herrera (pp. 169–174), discusses the occurrence of the pest in Mexico, the natural enemies, and artificial means of control. A bibliographical list is also given. H. J. Quayle, in a paper on A New Root Pest of the Vine in California (pp. 175, 176), gave a brief account of *Adoxus obscurus* and *A. vitis* and the injury caused by them, and also discussed The California Life History of the Grape Leaf-hopper (*Typhlocyba comes*) (pp. 182, 183). C. P. Gillette, in a paper entitled *Aphis gossypii* and Its Allies (pp. 176–181), considered the identification of the several species, the influence of the host plant upon aphid characteristics, the possibility of *A. gossypii* and *medicaginis* laying eggs, and food plants. The Life

History of the Striped Cucumber Beetle, with a Brief Account of Some Experiments for its Control, is the title of a paper presented by T. J. Headlee (pp. 203–209), in which an account is given of life history, injury to plants, natural enemies, and methods of combating *Diabrotica vittata*.

Papers are also included by H. A. Gossard on The Catalpa Bud Maggot (*Cecidomyia catalpæ*) (pp. 181, 182), on Notes of the Season (pp. 183–191), and on The Honey and Pollen-yielding Plants of Texas, by A. F. Conradi (pp. 191–203).

Report of the sixth annual meeting of the American Association of Horticultural Inspectors (*Jour. Econ. Ent., 1 (1908), No. 3, pp. 220–224*).—A brief report is given of the meeting held at Chicago, Illinois, December 27, 1907.

Twenty-third report of the State entomologist on injurious and other insects of the State of New York, 1907, E. P. Felt (*N. Y. State Mus. Bul. 124, pp. 541, pls. 44, figs. 49*).—During the year under report a wide departure of the climatic conditions from that of normal years apparently accounted for a remarkable dearth of injurious insect outbreaks. The spread of the San José scale continued and in some instances, where little effort was made to check its ravages, practically the entire fruit crop was ruined. Several shade-tree pests caused considerable devastation.

The green-striped maple worm (*Anisota rubicunda*) was abundant in one county where it stripped the leaves from large blocks of forests. The snow-white linden moth (*Ennomos subsignarius*) was very abundant on beech trees in the Catskills and defoliated these trees over large areas in one locality.

Notes for the year include data on the red-humped apple-tree caterpillar, lesser peach borer, lesser apple worm, apple maggot or railroad worm, San José scale, grape-root worm, white-marked tussock moth, elm-leaf beetle, sugar-maple borer, white grubs, *Epizeuxis denticulalis*, *Archips sorbiana*, birch-leaf bucculatrix, *Leucobrephos brephoides*, and the periodical cicada. *A. sorbiana* was brought into the State in April, 1906, on Japanese maple imported direct from Japan, but these were destroyed and none are supposed to have escaped. Biological and economic notes and bibliographical references are given on *Anisota rubicunda*, *Heterocampa guttiritta*, *Ennomos subsignarius*, and *Ancylus nubeculana*. Lists are given of the publications of the entomologists during the year 1907 and of contributions to the State collection.

Appendix A consists of a list of the William W. Hill collection of lepidoptera embodying 10,000 species which has been added to the State collection. In Appendix B is given a catalogue of the Phytoptid galls of North America by George H. Chadwick. In this list a total of 170 forms are recorded and references to the literature are given. In Appendix C appears a report of the entomological field station conducted at Old Forge, New York, in the summer of 1905, by James G. Needham. This contains information on new methods employed in ecological work, data on the food of fishes, and biological notes on a number of aquatic forms, particularly May flies, dragon flies, and crane flies. A new genus and two new species are described, and a table of classification, the larval habits, and a key to the genera of North American crane flies are included, together with an account of the appendages of the second abdominal segment of male dragon flies by Oliver S. Thompson, and descriptions of new North American Chironomidæ by Oscar A. Johannsen, with bibliographical references by each. In Appendix D are given descriptions of new species of Cecidomyiidæ, a discussion of the Circumfili of the Cecidomyiidæ, and studies with preliminary keys for the recognition of certain Cecidomyiidæ.

Injurious insects, F. García (*New Mexico Sta. Bul. 68, pp. 5–63, figs. 35*).—A general account is given of the more important injurious insects occurring in the State, these being considered under the headings garden insects, insects

injurious to staple crops, and fruit insects. Directions are given for the preparation and application of insecticides with estimates of the probable costs of the materials. A brief account of the spring grain aphis or green bug, by F. M. Webster, and the New Mexico law on orchard inspection are appended.

Entomological notes, W. B. Gurney (*Agr. Gaz. N. S. Wales, 19 (1908), No. 6, pp. 503–507, figs. 3*).—These notes include an account of beetles attacking furniture and woodwork, of pea and bean weevils, and of an aphis causing scab on white-skinned sheep, cattle, and horses. The clover aphis appears to be the cause of the affection here reported. An account is also included of beetles of the species *Xylotrupes gideon* attacking cocoanut palm in the Solomon Islands.

Imported insect pests, H. M. Lefroy (*Agr. Jour. India, 3 (1908), No. 3, pp. 237–244*).—With a view to the adoption of measures for preventing the introduction of insect pests into India, the author here considers the probable origin of those common to that country. He concludes that the evidence derived from this examination is reassuring, that with the few prominent exceptions it points to a natural immunity from undesirable introductions, partly because of the natural isolation of India, but largely on account of its climate. It is stated that the only measures at present taken against such introduction is the fumigation of all American cotton-seed at ports of entry to insure the destruction of the boll weevil.

Report of the entomologist, C. B. Simpson (*Transvaal Dept. Agr. Ann. Rpt. 1904–5, pp. 332–354*).—An account is given of the extensive work carried on against the brown locust (*Pachytylus sulcicollis*), and the purple locust (*Acridium purpuriferum*). Other work is reported under the headings of bee keeping, insects injurious to man, insects injurious to domesticated animals, insects poisonous to animals, forest insects, insects injurious to orchards, insects injurious to field crops, and insects affecting garden crops.

Effects of spraying with arsenical solutions for locust destruction, H. Ingle (*Transvaal Dept. Agr. Ann. Rpt. 1905–6, pp. 190–192*).—In order to determine the danger to cattle, birds, and poultry from eating the grass or locusts poisoned with arsenate of soda and sugar solution as used by the division of entomology, analyses were made. The results show that it is necessary to prevent stock from entering the fields of grass recently sprayed, although the danger of poisoning stock diminishes rapidly after rain has fallen. In regard to the danger to poultry from eating the locusts the author states, "it is evident from the determinations that the amount of arsenic in locusts which have died from arsenical poisoning is not very great, and that unless fowls eat an inordinate number of the insects, the danger of poisoning the poultry is not excessive. At the same time, since fowls are very greedy for locusts, care should be taken to prevent them from gorging themselves with the poisoned insects, or harmful effects may follow."

The codling moth, C. W. Howard (*Transvaal Agr. Jour., 6 (1908), No. 24, pp. 523–526, pl. 1*).—A brief description is given of the pest and its introduction from Cape Colony, which is now overrun. At present, with the exception of one locality in which extermination is being attempted, there is practically no codling moth in the Transvaal. Imported apples and pears which bear evidence of its presence to the extent of 1 per cent are destroyed.

Woolly aphis and tobacco extract, C. P. Lounsbury (*Agr. Jour. Cape Good Hope, 33 (1908), No. 2, pp. 188–193, fig. 1*).—This aphis is stated to be the most troublesome apple-tree pest in Cape Colony. The value of tobacco extract is discussed, and notes are given on other remedies and on the life cycle of the insect.

The apple sawfly (Hoplocampa (Tenthredo) testudinea) (*Bd. Agr. and Fisheries [London], Leaflet 205, pp. 2, fig. 1*).—This leaflet gives a description of the pest, the nature of its injury, its life history, and methods of treatment.

The fruit fly parasite, L. J. Newman (*Jour. Dept. Agr. West. Aust., 17 (1908), No. 1, pp. 561–563, pls. 2*).—An undetermined chalcid parasitic upon *Ceratitis capitata* was introduced from India by Compere in December, 1907. During transportation pupæ containing the hibernating parasites were kept on ice for 60 days. The chalcid, which is about $\frac{1}{16}$ in. in length, attacks the maggots from any quarter, depositing eggs in the body of the host. The average number of parasites per fly larva is 15, though as many as 30 have been found. A succession of parasites has been kept going, and 150 colonies of not less than 500 parasites have been liberated, but the results can not be determined until another summer. Life history notes and methods of breeding the parasites are given.

The San José scale in Arkansas, C. F. Adams (*Arkansas Sta. Bul. 102, pp. 221–236, figs. 12*).—This insect is said to be rapidly becoming the most injurious insect of the orchard in Arkansas. The author here considers the life history of the pest, the nature of its injury, and remedies.

Report of the viticultural station and phylloxera service on the work during 1907 (*Phylloxéra. Rap. Stat. Vit. et Serv. Phyllox. [Canton de Vaud], 1907, pp. 60*).—A detailed account is given of experiments made with insecticides in freeing the vines from phylloxera, of the laws and regulations concerning the pest, and of newly discovered infestations.

The European elm scale (Gossyparia spuria), S. B. Doten (*Nevada Sta. Bul. 65, pp. 5–34, pls. 14*).—This pest which has been injuriously abundant in Carson City for some years has more recently appeared in Reno, where many of the residence streets are lined with young elms, killing a large number and greatly injuring hundreds of others. Numerous photographic illustrations and drawings accompany the account of its life history and habits.

Experiments were conducted in which lime-sulphur wash, kerosene emulsion, and scalecide were used. In every instance where lime sulphur was used the author infers that many hibernating larvæ escaped. He considers it best to wash away all visible clusters of dead females from the bark before spraying with this insecticide, in order to destroy the concealed winter larvæ, and suggests that after spraying, in order to destroy the living female scales which escape the action of the insecticide, the trees be washed late in May or early in June with a stream of water under high pressure. Kerosene emulsion containing at least one-sixth kerosene, which is considered as too strong to use even on dormant elms, was required in order to kill the hibernating larvæ. It is inferred that scalecide can be used at a strength as low as 1 : 15 if the application wets the hibernating larvæ completely.

The author states that he has washed the winter larvæ out of cracks and crevices with a strong stream from a garden hose at a distance of 10 ft. from the nozzle. He further states that where such a stream is thoroughly applied, once in April just before the leaves begin to show and once in June before the young scale insects appear, that the trees will be comparatively clean the following winter. As too close growing and poorly pruned trees furnish favorable conditions for the development of this scale, the axe, grubbing hoe, and pruning saw should first be used, followed by the garden hose and, where necessary, the spray pump as a last resort.

Observations on the genus Contarinia, E. P. Felt (*Jour. Econ. Ent., 1 (1908), No. 3, pp. 225–227*).—The author considers briefly the species belonging to the cecidomyid genus Contarinia and the nature of their injury.

Notes on the preparatory stages of some species of Canadian lepidoptera, J. Fletcher and A. Gibson (*Proc. and Trans. Roy. Soc. Canada, 3. ser., 1 (1907), Sec. IV, pp. 57–70*).—Descriptions and biological notes are given on the

immature stages of the species *Mamestra grandis*, *M. adjuncta*, *Xylina disposita*, *Gluphisia severa*, *Petrophora ferrugata*, and *Gonodontis duaria*.

Upon the life cycle of Phylloxera quercus, B. Bonfigli (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 17 (1908), II, No. 5, pp. 248–253*).—In connection with this account the author gives three schemes which graphically illustrate the life cycle.

Notes on Trogoderma tarsale, C. O. Houghton (*Jour. Econ. Ent., 1 (1908), No. 3, pp. 216, 217*).—The author records this species as developing to maturity by subsisting upon dry hickory-nut shells.

Saxon forest pest, C. B. Hurst (*Daily Consular and Trade Rpts. [U. S.], 1908, No. 3302, p. 11*).—Caterpillars of the species *Ocneria monacha* are reported as very destructive to forests, particularly conifers, in one district of Saxony. Distribution by railroad trains and destruction by attraction to light and by hand picking of the moths by children are mentioned.

Is it wise to dip nursery stock? F. H. Hall (*New York State Sta. Bul. 302, popular ed., pp. 2–4*).—A popular edition of Bulletin 302 of the station previously noted (E. S. R., 20, p. 256).

Insecticide materials and their application, with suggestions for practice, J. B. Smith (*New Jersey Stas. Bul. 213, pp. 3–46*).—In this account the author discusses spraying machinery, insecticides and their application in orchard practice, particularly as relating to the San José scale, codling moth, and plum curculio.

Analyses of Paris green and lead arsenate, C. S. Cathcart (*New Jersey Stas. Bul. 214, pp. 3–14*).—Analyses are reported of 19 samples representing 17 brands of Paris green bought in the original packages and of 7 samples representing 6 brands bought in bulk. While the weights of the samples, as received in their original packages, with one exception, equaled or exceeded the weights claimed, there was a shortage in the actual weight of Paris green in 9 of the 19 samples ranging from 2.50 to 25 per cent with an average of 9.28 per cent. All of these samples contained not less than 50 per cent of arsenious oxid combined with copper as required by the New Jersey law, except one sample which contained a large proportion of white arsenic. The average composition of the samples analyzed was as follows: Total arsenious oxid, 57.14 per cent; water-soluble arsenic compounds, 1.41 per cent; copper oxid, 29.38 per cent; and arsenious oxid combined with copper, 54.94 per cent.

Analyses of 15 samples of 9 brands of lead arsenate are reported and show the following variation: Moisture, from 25.35 to 56.66 per cent; arsenic oxid, from 4.21 to 20.48 per cent; lead oxid, from 16.07 to 44.32 per cent; water-soluble arsenic, from 0.20 to 0.79 per cent. This large variation is considered as due to some extent to the evaporation of water after leaving the factory.

On six new species of Ixodidæ, including a second species of the new genus Rhipicentor, W. F. Cooper, B. A. Cantab, and L. E. Robinson (*Proc. Cambridge Phil. Soc., 14 (1908), No. 5, pp. 457–470, figs. 24*).—Descriptions and illustrations are given of the six new species *Amblyomma longirostrum*, *A. cœlaturum*, *Rhipicentor nuttalli*, *Aponomma javanense*, *A. simplex*, and *A. quadratum*.

On the habits, life cycle, and breeding places of the common house fly, R. Newstead (*Ann. Trop. Med. and Par., 1 (1908), No. 4, pp. 507–520, pls. 6*).—A report is given of investigations carried on in the city of Liverpool to ascertain the nature and extent of the breeding places of *Musca domestica*, which appears to comprise 90 per cent of the flies there met with in the houses. Examinations were made of various breeding places, an account of which is given. Under the most favorable conditions, the flies develop in from 10 to 14 days. Suggestions as to remedies include the removal in summer

of all refuse litter and excreta at intervals not greater than 7 days, and the application of Paris green (2 oz. to 1 gal. of water) to refuse, excreta, and screenings of stables. Brief notes on 8 other species of flies and 2 species of beetles met with during the investigation accompany the report.

Flies as carriers of contagion in yaws. A. Robertson (*Jour. Trop. Med. and Hyg. [London], 11 (1908), No. 14, p. 213*).—As a result of examinations the author concludes that the house fly is capable of carrying the virus of yaws.

Bee pirates. C. W. Mally (*Agr. Jour. Cape Good Hope, 33 (1908), No. 2, pp. 206–213, figs. 4*).—The terms "bee pirate" and "bee tiger" are used in connection with certain "digger wasps" particularly *Philanthus diadema* and *Palarus latifrons*, which prey upon hive bees. The bees are caught by these pirates and stored in cells in the ground to serve as food for the larvæ when they hatch.

Notes are given on the life history, habits, and natural enemies of the former species, for which no satisfactory remedy has yet been found. Brief notes are given on the latter species, as well as several methods for fighting it.

Some information on silkworm culture in the Philippine Islands. W. Schultze (*Philippine Agr. Rev. [English ed.], 1 (1908), No. 6, pp. 250–253, pl. 1*).—Experiments have been carried on and are still under way with a view to determining the possibility of introducing the industry into the islands. The species *Attacus atlas*, *A. ricini*, and *Antheræa semperi* are found in the islands but, so far as known, there are no cultivated species. Experiments made with *Bombyx mori* and directions for raising silkworms are given. A law prohibiting the importation by private concerns of live silkworms or eggs gives protection against the introduction of diseases, which at present do not exist in the islands.

FOODS—HUMAN NUTRITION.

Report of the State food commissioner of Illinois, 1907. A. H. Jones (*Ann. Rpt. State Food Comr. Ill., 8 (1908), pp. 252, pl. 1*).—This volume contains reports of the various pure food officials and the State food and feeding stuffs laws, tentative food standards, court decisions, and similar data.

Report of State analyst. T. J. Bryan (pp. 33–124).—Details are given of the examination under the State pure food law of a large number of samples of butter and butter substitutes, milk and cream, flavoring extracts, jellies, jams, and preserves, spices, vinegar, maple sugar, and sirup, confectionery, etc., and also of 108 samples of feeding stuffs of which only 8 were legal. "Practically all of the 100 were illegal, through lack of guaranty or because the license fee had not been paid."

Milk and milk products, water, foods, and condiments. C. Aumann (*Ber. Landw. Vers. Stat. Hildesheim, 1907, pp. 14, 15*).—A brief account of the examination at the station of a number of samples of dairy products, water, foods, and condiments.

Food laws in the United States. C. A. Neufeld (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 1–2, pp. 111–128*).—A discussion of American pure food laws.

Ohio general food and drug law. R. W. Dunlap (*Columbus, O., 1908, pp. 4*).—The text of the Ohio general food and drug law as amended May 1, 1908, is given.

Labels and rulings. E. F. Ladd (*North Dakota Sta. Spec. Bul. 7, pp. 8*).—The author quotes resolutions adopted September 17, 1907, at a convention of pure food officials of the middle Western States which were designed to facilitate and secure uniform enforcement of the various State pure food laws. The resolutions are discussed and explained.

Progress in the chemistry of food and condiments in the year 1907, H. Kuttenkeuler (*Chem. Ztg., 32 (1908), No. 59, pp. 693–695; 60, pp. 709–711; 61, pp. 720, 721*).—A digest of investigations which have been reported during the year.

The effect of certain preservatives on chopped meat, O. Mezger and K. Fuchs (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 12, pp. 715–728*).—Chopped meat to which benzoic acid was added showed a pale color on the surface although the red color of the interior was little changed. Sodium benzoate increased the color of such meat. Alkaline sodium phosphate strengthened the color at first. Commercial preservative salts were also tested.

Lard from oily hogs, W. D. Richardson and F. O. Farey (*Jour. Amer. Chem. Soc., 30 (1908), No. 7, pp. 1191, 1192*).—The authors report determinations of the melting point and other constants of back fat, leaf lard, and ham fat from so-called oily hogs.

Examination of sausages and their hygienic preparation, W. G. Savage (*Jour. Roy. Sanit. Inst., 29 (1908), No. 8, pp. 366–373; Vet. Rec., 21 (1908), No. 1053, pp. 160–162*).—The author investigated the kind and number of bacteria present in sausages with reference to their age and the method of preparing the sausage casings. It is a common practice to pickle sausage casings in salt, the method employed varying under different circumstances. According to the author "the action of sodium chlorid upon bacteria is a very weak one, and brine solutions have to be both fairly concentrated and prolonged in their action to effect the death of pathogenic bacteria."

The occurrence of monaminic acids in meat extract, K. Micko (*Ztschr. Physiol. Chem., 56 (1908), No. 2, pp. 180–211*).—Alanin, glutaminic acid, and taurin were identified in meat extract, the total quantity amounting to 0.51 per cent of the extract or 85 per cent of its ash free dry matter.

A study of the extractive material of fish flesh, A. Suwa (*Zentbl. Physiol., 22 (1908), No. 10, pp. 307–310*).—Creatin was found in quantity in extract prepared from fish flesh but ignotin and histidin in minute quantities only. Methyl guanidin and neurin were also found. The author states that other bases are present and that the work is being continued.

Preparing preserved crabs without boric acid, P. Buttenberg (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 1–2, pp. 92–109*).—The author regards rapid and cleanly work as absolutely essential to the preparation of these goods without preservatives. Fractional sterilization gave practically sterile goods.

Judging preserved egg yolk, A. Brüning (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 7, pp. 414, 415*).—From a bacteriological study the author concludes that heating to at least 120° C. is essential in the preparation of preserved egg yolk for food purposes.

Note on a sample of preserved egg yolk, A. Schoonjans (*Bul. Soc. Chim. Belg., 22 (1908), No. 3, pp. 119–122*).—Analytical data are reported. The material contained boric acid.

The influence of heat on the lecithin-phosphoric acid content of egg pastes, W. Ludwig (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 11, pp. 668–680*).—The analytical studies reported and discussed have to do with the question of the changes in egg pastes when stored.

Paste goods containing eggs, Witte (*Ztschr. Öffentl. Chem., 14 (1908), No. 17, pp. 326–331*).—Analytical data obtained with noodles, egg noodles and similar goods are reported and discussed with reference to judging this class of food products.

Determining the baking quality of flour, M. Renner (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 4, 234–238*).—In a study of Liebermann's

method it was noted that 3 white, finely ground flours yielded gluten with a lower expansion value than coarser flours. This value also diminishes the longer the flour is kept and if the flour becomes acid the decrease is very marked.

Determining the volume of bread, M. P. NEUMANN and P. SALECKER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 5, pp. 285–290, figs. 2*).—According to the authors' investigations better results are obtained with water than with fine seed in determining the volume of a loaf by displacement. When water is used the bread must be first coated with paraffin. The apparatus which they use is described.

Experiments with special bread made from the entire grain, H. STRUNK (*Veröffentl. Mil. Sanitätsw., 1908, No. 38, pp. 35–52; abs. in Chem. Zentbl., 1908, I, No. 20, p. 1848*).—Digestion experiments and other studies showed that the nitrogenous material in this bread was not more thoroughly assimilated than in ordinary army bread. On the other hand, the assimilation of mineral matter, especially phosphoric acid, was increased. The bread under consideration was made by a special process in which the bran is separated, treated in such a way as to soften it, and then mixed with the flour in bread making.

Concerning bread facilities, H. BISCHOFF (*Ztschr. Hyg. u. Infektionskrank., 59 (1908), pp. 154–160; abs. in Chem. Zentbl., 1908, I, No. 26, p. 2197*).—The author concludes that army bread should be made from flour with a low bran content.

Helianthus tubers, a new vegetable, L. KROEBER (*Apoth. Ztg., 23 (1908), No. 430; abs. in Chem. Ztg., 32 (1908), No. 54, Repert., p. 353*).—A brief note on the culture and use of helianthus tubers as a vegetable. They resemble potatoes in the method in which they are used and suggest artichokes in flavor.

A sample of Chinese soy, A. HERLANT (*Bul. Soc. Roy. Sci. Méd. et Nat. Bruxelles, 66 (1908), p. 35; abs. in Biochem. Zentbl., 7 (1908), No. 11–12, p. 481*).—Soy is described and an analysis of a Chinese sample is reported.

Chemical study of a sugar yielding grass, E. PERROT and E. TASSILLY (*Bul. Soc. Chim. France, 4. ser., 3 (1908), No. 12, pp. 740–742; abs. in Chem. Abs., 2 (1908), No. 22, pp. 3113, 3114*).—Analyses showed that *Panicum stagninum* contained 10 per cent cane sugar, 7 per cent dextrose, and emulsin. No glucosids or invertase were identified. This plant grows in the marshy regions about the Niger and is used in making a sort of sirup and other food products or drinks.

The endo- and ektoinvertase of the date, A. E. VINSON (*Jour. Amer. Chem. Soc., 30 (1908), No. 6, pp. 1005–1020*).—The following is quoted from the author's summary of his work and discussion of problems concerned with the ripening of dates:

"The invertase of the date remains insoluble in all ordinary solvents throughout its green stages, but becomes readily soluble on ripening. The change in the behavior of the invertase toward solvents coincides very closely in point of time with the passage of the tannin into the insoluble form. Tannin in relatively large amounts does not retard the action of date invertase either in the extract or in the pulp. Soluble tannin, however, hinders the solution of date invertase in water, but the invertase can be extracted by glycerol, provided the glycerol is added at the same time the tannin is added. Green date invertase can not be extracted by crushing and macerating the green fruit with glycerol, therefore the invertase is not rendered insoluble by the escape of soluble tannin on crushing the tannin cells. This conclusion is confirmed by the behavior of the invertase in the tannin-free portion of the date after the tannin-bearing tissues have been completely removed. There is no direct connection between the change in the state of the tannin and that of the invertase.

"The inversion of cane sugar by the green date pulp is not accomplished by the living protoplasm liberating a soluble ferment from a pre-existing insoluble zymogen or by rendering active a pro-ferment. The rate of inversion by equivalent amounts of green and ripe pulp of the same variety are practical identical. Protoplasmic poisons—picric acid, chromic acid, and formaldehyde—retard the action of green and ripe pulp but to approximately the same degree. If the living protoplasm were in any way connected with the inversion, the retardation would be greatly intensified in the case of green date. Green date tissue is not rendered inactive by soaking in ether, chloroform, acetone, etc."

Sulphurous acid content of California dried fruit, S. A. Prstibytek (*Chem. Ztg., 32 (1908), No. 61, Repert., p. 394*).—Of the 50 samples examined 40 contained on an average 75.4 mg. sulphurous acid per 100 gm. Plums, apricots, and dates were found to contain no sulphurous acid, and 1 sample of apples and 1 of raisins contained only very little.

Composition of some fruit juices and alcohol fruit extracts used for making bonbons, sirups, liqueurs, etc., Chauvin, Joulin, and Canu (*Monit. Sci., 4. scr., 22 (1908), II, p. 449; abs. in Chem. Ztg., 32 (1908), No. 67, Repert., pp. 426, 427*).—A number of analyses are reported and discussed.

J. Halmi's study of Hungarian fruit juices, W. Plahl (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 7, pp. 416, 417*).—A polemical discussion of work previously noted (E. S. R., 20, p. 263).

Examination of currant juice, Elisabeth Van West (*Chem. Weekbl., 5 (1908), No. 13, pp. 216–221, dgm. 1; Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 10, pp. 595–598, dgm. 1*).—The amount of dry matter in currant juice and its relation to specific gravity and other characteristics were studied with a view to judging quality. In the author's opinion, determining the specific gravity furnishes a fairly accurate means of judging quality for commercial purposes.

Examination of lemon juice, G. Devin (*Veröffentl. Mil. Sanitätsw., 1908, No. 38, pp. 1–7; abs. in Chem. Zentbl., 1908, I, No. 20, pp. 1848, 1849*).—The keeping quality of lemon juice was studied with commercial samples and material prepared by the author, his conclusion being that pasteurized lemon juice will keep well and that the addition of alcohol is not essential. Chemical preservatives should be excluded.

The declaration of marmalades, fruit juices, and other fruit products, A. Beythien (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 1–2, pp. 77–86*).—The author reports and discusses the recommendations of the Society of German Food Chemists.

Marmalades, F. Härtel (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 1–2, pp. 86–92*).—A discussion on the manufacture and declaration of marmalades.

The occurrence of arsenic in marmalades, G. Rupp (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 1–2, pp. 40–43*).—Minute suggestions of arsenic were found in a number of samples of marmalade. The arsenic was accidentally present and due to the use of sirup made by inverting starch.

The effect of color on the composition of cider during fermentation, A. Andouard (*Bul. Sta. Agron. Loire-Inf., 1906–7, pp. 62–64*).—The effect of colored light on cider fermentation was studied with reference to the question of colored glass containers for cider. Green, yellow, red, and violet light did not materially modify the composition of the cider. With blue glass the alcohol, peptin, sugar, tannin, and dry matter were notably diminished, while the volatile acid and total acid were in a measure correspondingly increased. Cider kept in uncolored glass was intermediate in composition.

Extract material of cider, A. Andouard (*Bul. Sta. Agron. Loire-Inf., 1906–7, pp. 32–37*).—The results of a number of analyses are reported.

Quality and composition of Charente wine, J. M. Guillon (*Rev. Vit., 29 (1908), Nos. 733, pp. 6–8; 734, pp. 37–41; 736, pp. 92–94; 737, pp. 129, 130*).—Analytical data are reported and discussed.

White wine which has been decolorized, R. Orlianges (*Rev. Vit., 29 (1908), Nos. 736, pp. 99–101; 737, pp. 124–129*).—Analyses of wine decolorized by different processes are reported in comparison with red wine and legal enactments regarding such wines discussed.

Citric acid and natural wines, H. Astruc (*Ann. Chim. Analyt., 13 (1908), pp. 224–226; abs. in Chem. Zentbl., 1908, II, No. 5, p. 432*).—Investigations led the author to conclude that citric acid, like tartaric acid, is to be regarded as a normal constituent of wine.

Caffein-free coffee, K. Scheringa (*Pharm. Weekbl., 45 (1908), pp. 773, 774; abs. in Chem. Zentbl., 1908, II, No. 4, p. 341*).—Analyses of commercial so-called caffein-free coffee prepared in Bremen showed that it was not caffein free though it contained only about one-twentieth as much as ordinary coffee. The fat content was, on the other hand, much higher than usual.

Caffein-free coffee, K. Lendrich and R. Murdfield (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 12, pp. 705–715*).—The so-called caffein-free coffee examined contained about one-sixth as much of this constituent as natural coffees and showed a lower amount of water soluble material.

Hibiscus seeds as coffee adulterant, A. R. Chiappella (*Bul. Soc. Bot. Ital., 1905, No. 9, pp. 264–276, figs. 2; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 7, p. 424*).—An illustrated description of these hibiscus seeds and their structure with a view to their detection by microscopical methods when used as an adulterant of coffee.

Examination of teas on sale in Turkestan, Karpow (*Ztschr. Angew. Chem., 21 (1908), pp. 1319–1321; abs. in Chem. Ztg., 32 (1908), No. 55, Repert., p. 359*).—Analyses are reported. The thein content was noticeably low.

The composition of Horlick's malted milk, G. F. Richmond and W. E. Musgrave (*Philippine Jour. Sci., 3 (1909), No. 2, pp. 87–90*).—A detailed analysis is reported. The work was undertaken especially to study fat content. Extraction with petroleum ether gave 8.18 per cent fat.

Medicinal foods (*Jour. Amer. Med. Assoc., 48 (1907), pp. 1612–1614, 1694; 49 (1908), pp. 1294, 1295; abs. in Chem. Abs., 2 (1908), No. 12, pp. 1740, 1741*).—Analyses of 18 samples of so-called predigested foods such as peptonoids, peptones, etc., and of a sample of cow's milk are reported. The average energy value of these goods, including the alcohol in them, was 802.4 calories per 500 gm. and their value is accordingly regarded as limited.

Book of recipes (the auto-cook) (*Grand Rapids, Mich., 1908, pp. 156, fig. 1*).—A collection of recipes for cooking meat, vegetables, puddings, etc., by means of a fireless cooker. In many cases the use of heated soapstone plates is recommended as a source of heat in the cooker, particularly as a means of baking.

Cheap food (*Brit. Med. Jour., 1908, No. 2463, pp. 639, 640*).—A discussion of municipal kitchens, workingmen's restaurants, and similar institutions in Europe, which are designed to supply food of good quality at low cost.

The relation of nutrition investigations to questions of home economics, C. F. Langworthy (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1907, pp. 355–368*).—The results of the nutrition investigations of this Office which bear particularly upon home management problems are discussed, especially with reference to variety in the diet and ways of obtaining it, the preparation of food in the home,

food and its preparation in relation to hygiene, home conveniences and related problems, educational work in connection with home economics, and similar questions. Attention is also directed to the fact that this Office has for a long time systematized the collection and dissemination of information regarding the general subject of nutrition.

The physiology of digestion and nutrition, O. COHNHEIM (*Die Physiologie der Verdauung und Ernährung. Berlin and Vienna; rev. in Brit. Med. Jour., 1908, No. 2489, pp. 746, 747.*—A text-book based on the author's lectures in which nutrition, digestion and related questions are discussed on the basis of the results of recent investigations.

Food problems, M. RUBNER (*Volksernährungsfragen. Leipsic, 1908, pp. 144; rev. in Zentbl. Physiol., 22 (1908), No. 11, pp. 349–351*).—The questions especially discussed are protein minimum and the economic effects of the diet of the poor. The author points out the distinction between the physiological and the practical protein minimum and gives reasons for his belief in the desirability of a reasonably generous protein standard.

Appetite from a theoretical and practical standpoint, W. STERNBERG (*Zentbl. Physiol., 22 (1908), No. 11, pp. 329–335*).—From a discussion of various questions concerned with taking food and fasting in man and animals the author concludes that appetite can not be explained simply on the basis of secretion of digestive juices nor can aversion to food be explained solely by the lack of such secretion. He believes that appetite is to be regarded as muscular motion or a manifestation of it.

Concerning work of digestion, E. HEILNER (*Ztschr. Biol., 50 (1908), No. 4, pp. 488–503*).—On the basis of experimental evidence, the author concludes that the term "work of digestion," which has been proposed, is not satisfactory and that "specific dynamic effect of nutrients" is preferable.

The rôle of digestive juices in metabolism as shown by data obtained by the polyfistula method, E. S. LONDON (*Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, n. ser., 3 (1908), No. 14, pp. 529–531*).—A discussion based on the author's experiments in which he points out that digestive juices are to a large extent resorbed and hence should be taken into consideration in discussions of metabolism.

Metabolism experiments on the protein requirement of the child, H. LUNGWITZ (*Stoffwechselversuche weber den Eiweissbedarf des Kindes. Berlin and Halle, 1908, pp. 82; rev. in Brit. Med. Jour., 1908, No. 2489, p. 747*).—In the experimental dietaries protein supplied about 17 per cent of the total energy and about one-half of the protein was of vegetable origin. With less protein the children lost weight while more was found to be wasteful and often harmful.

Diminished muscular activity and protein metabolism, P. A. SHAFFER (*Amer. Jour. Physiol., 22 (1908), No. 4, pp. 445–455*).—The experiments reported were made with healthy men and according to the author support the belief that "with sufficient food either an increase or a decrease of muscular activity within physiological limits has per se no effect upon the protein metabolism as indicated by the nitrogen and sulphur partitions in the urine. We can not, of course, believe that a long-continued diminished activity would not cause a change in the composition of the urine, because the intensity of metabolic processes in a muscle atrophied from disuse is certainly less than in a healthy muscle; but such a change in the composition of the urine should be considered not the direct result of decreased activity, but the result of a pathological condition, which, it may be, was brought about by a diminished activity. Exercise is necessary for health, but the amount of muscular energy expended in a given day (provided the amount is not excessive for the particu-

lar subject) does not appear to affect any of the nitrogenous substances of the urine excreted on that or following days."

Concerning the extractives of muscle. X, The identity of novains with carnitin. R. Krimberg (*Ztschr. Physiol. Chem., 55 (1908), No. 6, pp. 466–480*).—A continuation of the study of meat extractives (E. S. R., 20, p. 365).

Concerning the extractive material of muscle. The relation of oblitin to carnitin. R. Krimberg (*Ztschr. Physiol. Chem., 56 (1908), No. 4, pp. 417–424*).—According to the author's investigations oblitin is readily formed from carnitin. This is taken into account in a critical discussion of the chemistry of meat extract.

Experiments on the effect of a maize diet. Some properties of zein. S. Baglioni (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 17 (1908), I, No. 9, pp. 609–617*).—From experiments with small animals and laboratory data, the conclusion is reached that maize as the sole food for a long time is harmful, probably owing to some specific action of zein.

Concerning the digestion of fat in the animal body. S. Levites (*Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, u. ser., 3 (1908), No. 10, pp. 370–372*).—Using dogs with fistulæ the author studied the digestibility of fatty acids and their salts and found that the salts were better assimilated. In the case of palmitin and oleic acid, however, the differences were not very decided, but with stearic acid, which has a high melting point, the difference was so great as to indicate that this acid can only be assimilated in the intestine as a salt.

The action of gastric juice on starches. H. Roger and L. G. Simon (*Presse Méd. [Paris], 1907, No. 87, pp. 697, 698; abs. in Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, u. ser., 3 (1908), No. 9, pp. 353, 354*).—Gastric juice, the authors state, affects starch solutions in such a way that the action of pancreatin is intensified. This is due to the swelling of the starch grains and to chemical changes in which starch is converted into dextrin. When starch solution is treated with gastric juice and the starch precipitated with alcohol, the filtrate on the addition of iodin shows a red-violet color while a control sample under similar conditions remains colorless. Ptyalin also intensifies the action of pancreatin in the intestinal tract.

Experiments on carbohydrate metabolism. J. E. Johansson (*Skand. Arch. Physiol., 21 (1908), No. 1, pp. 1–34*).—As shown by the respiratory quotient experiments reported, sugar under ordinary dietary conditions causes a decided increase in the production of carbon dioxid which within limits is proportional to the amount of sugar taken. The maximum increase was noted with about 150 gm. of sugar. Levulose increased carbon dioxid production about twice as much as a like amount of dextrose. If the stored glycogen is low the increased carbon dioxid production is less than under normal conditions and sometimes is not evident. The increased carbon dioxid output is difficult to explain on the basis of increased labor of digestion.

With subjects in health neither dextrose or levulose were excreted in the urine except during the period of increased carbon dioxid output. On the other hand, cane sugar was excreted also after this increased output had subsided. The maximum absorption of sugar in the intestine, according to the author, is not over 80 gm. per hour. The maximum carbon dioxid output for cane sugar and levulose was about 35 gm. per hour with a lower value for dextrose and milk sugar.

With diabetic patients the normal increase in carbon dioxid output was noted in some cases while in other cases it was less than normal or absent.

The influence of mineral matter in the formation of the tissues. J. Gautier (*Rev. Soc. Sci. Hyg. Aliment., 3 (1906), No. 5, pp. 894–908*).—A discussion of the relations of mineral and organic matter, based on investigations of the

author and others, from which he concludes that mineral matter, in the form of calcium, magnesium, potassium, and sodium, is indispensable to the life of both the cell and the tissues, and that magnesium, by the reduction of CO_2 from the air is the means by which nutrients enter into both plant and animal life.

The action of chocolate and coffee on renal excretion, P. FAUVEL (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 17, pp. 854–856, dgm. 1*).—In the experiments reported it was found that both chocolate and coffee increased markedly the purins in the urine but notably diminished uric acid without at the same time causing a retention of this acid in the body.

On the duration of rest after eating, HALLOPEAU (*Rev. Soc. Sci. Hyg. Aliment., 3 (1906), No. 5, pp. 917–919*).—The author favors, for mental workers, a rest of short duration after the midday meal and an extended rest after the evening meal.

ANIMAL PRODUCTION.

Digestion experiments with the native hay of the Truckee meadows, S. C. DINSMORE and P. B. KENNEDY (*Nevada Sta. Bul. 64, pp. 5–23, pl. 1*).—Five feeding trials of hay from native grasses and sweet clovers of the Truckee meadows and lasting 14 days each were made with two 3-year old sheep. The second growth hay of the first experiment consisted principally of spike rush (*Elcocharis arenicola*), Nebraska sedge (*Carex nebraskensis*), brown-top sedge (*C. athrostachya*), and native clover (*Trifolium spinulosum*). About half of the clover sample in experiment 2 consisted of *T. hybridum* and *T. spinulosum*, the remainder being composed of several varieties of native grasses and sedges. The bulk of the hay in sample 3 consisted of Buckley blue grass (*Poa buckleyana*), alkali meadow grass (*Puccinellia airoides*), and spike rush. The hay of experiment 4 was largely timothy and tickle grass (*Hordeum jubatum*). Common wire grass (*Juncus balticus*) and brown-top sedge composed about one-half of sample 5, the other species present, but in small quantities, being common blue grass (*Poa pratensis*), white-top (*Agrostis exarata*), small-leafed red-top (*A. microphylla*), slough grass (*Beckmannia erucæformis*), and salt grass (*Distichlis spicata*).

The following table shows the average coefficients of digestibility of the different samples:

Average coefficients of digestibility of Nevada native grasses—Experiments with sheep.

Experiment No.—	Sample.	Dry matter.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.
		Per ct.	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*
1	Second growth hay	75.66	71.19	79.12	77.39	77.91	62.58
2	Clover	65.78	52.07	61.69	70.91	66.37	44.11
3	Native blue grass	64.41	46.79	69.27	68.35	65.86	44.52
4	Timothy	74.16	63.85	72.13	78.16	74.08	58.71
5	Wire grass	65.57	51.17	70.71	61.34	75.98	48.39
Average all experiments		69.11	57.01	70.58	71.22	72.04	51.72

"The native hay of the Truckee meadows has proved, so far as can be determined by digestion experiments, to be an excellent forage for fattening stock. It could perhaps be more economically fed if a fodder containing more protein (e. g., alfalfa) were fed along with it. . . .

"The second growth crop was superior to any of the samples, as it most nearly approximated a standard ration for fattening stock."

Feeding for meat production. H. P. ARMSBY (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 108, pp. 89, fig. 1*).—This is a general discussion of principles underlying feeding for meat production. Recent investigations on the laws of growth and the process of fattening are reviewed, with special reference to the choice of animals for meat production, feed requirements, and practical management.

Two physiological processes are involved in commercial meat production, namely, growth and fattening. Growth is largely synonymous with increase of protein tissue, and the rapidly growing cells demand a liberal supply of protein. The average rate of growth diminishes from birth onward. Fattening is the accumulation of adipose tissue with its prime object the improvement in the quality of the lean meat.

"The amount of protein gained is largely dependent upon the age and to a less degree upon the individuality of the animal, although probably affected to some extent by the supply of feed protein. The fat formation, on the other hand, is primarily dependent, in a broad way at least, upon the total feed supply. Accordingly, we should anticipate that the composition of the increase would vary with the age of the animal.

"A deficient protein supply may, of course, limit growth for lack of material, while the same appears to be true of the ash supply. On the other hand, while there are some indications that an abundant protein supply may stimulate slightly the process of growth and lead to its early completion, the effect seems to be at best slight, and it remains true that the production of protein tissue is substantially a function of the animal and not of the food, and that improvement in this respect is a problem for the breeder rather than for the feeder.

"Fattening, on the contrary, is a process which in a given animal at least is largely under the control of the feeder. . . . Fattening may take place at any age, although the greater demand for material for growth in the young animal tends to reduce the proportion of the food available for fattening."

It is believed that the minimum protein supply can not be formulated with exactness, yet "there must be a sufficiency to replace the amounts katabolized in the vital processes and to supply material for new growth. The animal must also receive an amount of potential energy in an available form sufficient to maintain the normal activities of the body and to leave a surplus for storage in the form of flesh and fat." It is pointed out that many animals have been fattened on Indian corn rations, with a ratio of 1 : 10, but that possibly cheaper meat might have been produced had more protein been supplied, although satisfactory results have been reached on rations containing scarcely half the protein called for by the Wolff standard. With any given type of animal the age at which it will reach marketable form and size is fixed by its individuality.

The author does not attempt to formulate numerically the total feed requirements of growing animals, but "is inclined to question whether such standards, however accurate they may be made and however great their statistical value, can ever play any large part in practical feeding operations." In growing animals an important element is considered to be the fact that moderate exercise tends to stimulate the growth of the muscular system.

The relation of steer feeding to farm economics. F. C. QUEREAU (*Tennessee Sta. Bul. 79, pp. 3–26, figs. 12, charts 3*).—This bulletin contains a report of steer-feeding experiments with corn, soy beans, and cowpeas. In 1906–7 an acre of corn lasted 4 steers for 54 days and produced a gain of 129 lbs. The soy-bean acre lasted a similar lot of steers 80 days and produced a gain of 406 lbs., and the cowpea acre lasted 54 days, producing a gain of 289 lbs. In 1907–8 the gains for corresponding lots of steers were for the corn lot 203 lbs., the soy bean lot 541 lbs., and the cowpea lot 327 lbs.

"The yields per acre for the 2 years were approximately the same, viz, 34 bu. of corn and 3,544 lbs. of stover, 20 bu. of soy beans and 2,905 lbs. of straw, 13 bu. of cowpeas and 1,365 lbs. of straw." The increased gains in weight in 1907–8 over those of the previous year is accounted for by the fact that the steers were of a little better quality than those of 1906–7. The cost of growing the corn was $14.86 per acre, the soy beans $13.09 per acre, and the cowpeas $14.51 per acre. Thus, though the three crops cost about the same per acre they gave widely different results when fed. The financial statement is given in full as illustrative of the advantage of growing and feeding legumes to steers from the standpoint of maintaining the fertility of the farm, which is further discussed.

Steer-feeding experiments, J. C. Burns (*Texas Sta. Bul. 110, pp. 3–23, figs. 5*).—A continuation of previous work (E. S. R., 19, p. 674), but with longer feeding periods.

There were two sets of feeding experiments. In the first, Kafir corn, milo maize, and molasses were compared with Indian corn for fattening cattle. In the second, cotton seed was compared with cotton-seed meal as a supplement to Kafir corn. Thirty 2-year-old Aberdeen-Angus steers were divided into 5 lots and fed for 120 days. The first 4 lots were fed an average daily ration per head of 3 lbs. cotton-seed meal and 12 lbs. hulls. In addition lot 1 received 17 lbs. Indian corn; lot 2, 17 lbs. Kafir corn; lot 3, 17 lbs. milo maize; and lot 4, 8 lbs. molasses and 9 lbs. Indian corn. The ration of lot 5 was 17 lbs. Kafir corn, 4 lbs. cotton seed, 1 lb. cotton-seed meal, and 12 lbs. hulls.

Lot 1 made an average daily gain per head of 2.1 lbs., at a cost of 13.7 cts. per pound. Lot 2 gained 2.47 lbs., at a cost of 10.5 cts. Lot 3 gained 2.12 lbs., at a cost of 12.3 cts. Lot 4 gained 2.26 lbs., at a cost of 11.1 cts. Lot 5 could be contrasted with lot 2 for only 90 days, for which lot 2 made an average daily gain per head of 2.51 lbs., at a cost of 10.7 cts. per pound, and lot 5 gained 2.04 lbs. at a cost of 13.7 cts. per pound. In the slaughter test the results were quite uniform for all the lots, varying only from 60.5 to 61.9 per cent dressed weight.

The following conclusions were drawn:

"Kafir corn was cheaper than Indian corn and yielded better gains.

"Milo maize was cheaper than Indian corn and yielded slightly better gains.

"Molasses very profitably replaced nearly half the Indian corn in a mixed ration of molasses, Indian corn, cotton-seed meal and hulls.

"Cotton-seed meal at $26 per ton was much more profitable than cotton seed at $12 per ton in supplementing a Kafir corn ration with cotton-seed hulls as roughage."

Preliminary report on grazing experiments in a coyote-proof pasture, J. T. Jardine and F. V. Coville (*U. S. Dept. Agr., Forest Serv. Circ. 156, pp. 32, figs. 2*).—This circular reports experiments of the Forest Service, in cooperation with the Bureau of Plant Industry, to devise methods of increasing the forage value of the grazing lands included in the National Forests. At present a large amount of forage is destroyed by herding and trampling.

To test the action of sheep when protected from marauding animals, a pasture of 2,560 acres in the Wallowa National Forest, Oregon, was surrounded with a coyote and wolf-proof fence at a cost of $6,764.31. The fence consisted of a closely barbed hog wire laid along the surface of the ground, a 36-inch strip of woven wire 3 in. above it, a light barbed wire 6 in. above the woven wire, and at the top, 8 in. above the last, a heavy twisted wire without barbs. Animals of prey in the pasture were either killed or driven out. So far the fence has proved to be coyote proof. Grizzly bears managed to get through the fence, though black and brown bears made unsuccessful attempts. Badgers

could dig under the fence and probably cats can climb over or through it. Changes are suggested for similar fences.

A study of the action of sheep is summarized as follows: "When entirely protected from destructive animals a band of dry sheep will separate into bunches, perhaps come together again, and again separate while grazing; they will graze much more openly and do much less trailing than when they are herded; they may travel as far or farther in one day than when herded, but the movement is much less injurious to the forage crop, because they pass over an area only once and are then scattered so that only one animal strikes a plant, whereas when herded they may pass backward and forward over an area many times, and perhaps as many as 50 sheep may strike one plant; their natural tendency is to bed at night in bands, but in smaller bands than when herded; and they much prefer a bed ground that has often been used to one that is entirely new."

[Experiments with lambs and swine], G. H. True (*Nevada Sta. Bul. 63, pp. 27–29*).—Crosses of the Dorset and Merino were made in order to furnish lambs for the Easter market at San Francisco. Lambs born in the winter of 1905–6 made a satisfactory gain of over 4 lbs. per week. The ewes were fed alfalfa hay, chopped roots, barley, and bran. The lambs also received some grain. The first shipment was sold for 20 cts. per pound dressed weight. The remainder brought 35 cts. per pound on board cars at Reno.

In 1905, 4 Tamworth sows and a boar were purchased to conduct an experiment in bacon production. Twenty pigs were born and were kept with the sows in an alfalfa pasture. There being no shade the pigs were seriously affected by sunburn and some of them died. The ears of the old sows were also affected. The author thinks that in a region of bright sunshine black pigment in the skin is necessary for protection.

Pig-feeding experiments, F. B. Linfield (*Montana Sta. Bul. 73, pp. 43–59*).—A study of supplementary feeds in economic fattening of hogs, which is a continuation of previous work (E. S. R., 18, p. 71).

The first experiment was undertaken with 16 grade Berkshires, 5 months old, divided into 4 lots and fed for 50 days, to compare the effect of adding skim milk, alfalfa, and sugar beets to a grain ration. The average daily gains per head were for the lot fed grain alone 1.1 lbs., at a cost of 4.50 cts. per pound; for the lot receiving the grain and skim milk ration 1:3, 1.9 lbs., at a cost of 3.76 cts. per pound; on the grain and alfalfa ration 1.26 lbs., at a cost of 4.15 cts. per pound; and on the grain and sugar-beet ration 1.63 lbs., at a cost of 3.61 cts. per pound.

To compare varying amounts of skim milk 3 lots, with 5 young hogs in each lot, were fed for 1 month rations of grain and skim milk 1:5, 1:3, and 1:1. The average daily gains per head were respectively 1.1 lbs, 1.2 lbs., and 1.4 lbs., at a cost respectively of 3.36 cts., 3.68 cts., and 3.4 cts. per pound. The same hogs, with one additional, were also divided into 4 lots and fed for 65 days to compare peas and barley, and to determine the value of roots and clover when fed with grain. The average daily gains per head were, on the ration of peas and oats 3:1, 1 lb., at a cost of 7.68 cts. per pound; on barley and oats 3:1, 1.03 lbs., at a cost of 5.74 cts.; on barley and oats 3:1, and sugar beets, 0.84 lb., at a cost of 5.71 cts.; and on barley and oats 3:1 and clover, 0.83 lb., at a cost of 6.19 cts. per pound. One lb. of sugar beets was fed to 3 lbs. of grain and 1 lb. of clover was fed to 5 lbs. of grain.

Experiment 4, which included 12 hogs divided into 4 lots and lasted 80 days, was made to compare supplementary foods with barley and oats fed in the ratio of 4:1 as a basal ration. On the barley and oats alone the daily gains per head averaged 1.3 lbs., at a cost of 3.65 cts. per pound; on the grain and skim

milk, 1:3, 1.7 lbs., at a cost of 3.64 cts.; on the grain and clover or grass ad libitum, 1.38 lbs., at a cost of 4.05 cts.; and on the grain and tankage 8:1, 1.55 lbs., at a cost of 4.51 cts. per pound.

In the fifth experiment 9 pigs were divided into 3 lots and fed for 72 days to compare a full grain ration of barley and oats 4:1 in pens and on pasture with a one-half grain ration and pasture. On the full ration and pasture the average daily gain per head was 1.37 lbs., at a cost of 4.24 cts. per pound; on the half ration and pasture, 1.03 lbs., at a cost of 2.82 cts.; and with the full ration in pens, 1.57 lbs., at a cost of 3.96 cts. per pound.

In experiment 6, 9 Poland-China pigs, 10 to 12 weeks old and averaging about 40 lbs. each, were fed for 28 days on a mixed grain ration consisting of 2 parts peas, 2 parts barley, 1 part oats, and 3 lbs. of skim milk to 1 lb. grain. The average daily gain was 0.92 lb. per day, at a cost of 3.62 cts. per pound. In the next experiment the same pigs were fed for 44 days a basal ration of barley and oats 4:1. Lot 1 received sugar beets in addition and made a daily average gain per head of 1.1 lbs., at a cost of 3.86 cts. per pound. Lot 2, fed the grain and skim milk 2:1, made corresponding gain of 1.69 lbs. at a cost of 4.2 cts. per pound. Lot 3, fed the grain and tankage 8:1, gained 1.3 lbs. at a cost of 4.65 cts. per pound.

In experiment 8 there were 4 lots of 3 pigs each and fed for 65 days. Lot 1, receiving equal parts of barley, wheat, and oats made a daily average gain per head of 1.3 lbs., at a cost of 5.02 cts. per pound. Lot 2, fed the grain and skim milk 1:3, gained 2.1 lbs., at a cost of 4.62 cts. per pound. Lot 3, fed the grain and sugar beets ab libitum, gained 1.83 lbs. at a cost of 4.45 cts. per pound. Lot 4, fed grain and clover hay ab libitum, gained 1.7 lbs. at a cost of 4.58 cts. per pound.

A summary of results of these and the previous experiments is given. "For conditions in Montana the value of the supplemental food is: First, skim milk; second, roots; third, tankage; fourth, pasture; fifth, clover and alfalfa. . . . Peas make a more efficient hog feed than does barley, but because of the greater cost of the peas the barley makes a more economical ration."

Some poultry experiments, T. I. MAIRS (*Pennsylvania Sta. Bul. 87, pp. 3–48, figs. 13*).—In the poultry experiments of 1906 the points under observation were rate of growth, food consumed, weight at different ages, relative weight of pullets and cockerels, and the loss in dressing and drawing. The chicks were fed corn and wheat in equal parts and a mash consisting of 50 lbs. corn meal, 25 lbs. wheat bran, 15 lbs. gluten feed, 5 lbs. oil meal, 7½ lbs. alfalfa meal, and 13 lbs. animal meal.

Feed required per pound of gain and average weight at different ages.

Lot.	Breed.	Time hatched.	Number of chicks.	Feed per pound gain 6-13 weeks of age.	Feed per pound gain 13-26 weeks of age.	Average weight.

6	White Wyandottes	May 13	37	.....	.....	[a].54	1.01	5.22

[a] 8 weeks old.

The Brahmas were not uniform in size, but the Wyandottes were. At 28 weeks of age the pullets in lot 1 averaged 5.04 lbs. in weight and the cockerels 6.24 lbs. At 26 weeks the pullets in lots 3 and 4 weighed 2.89 lbs. and the cockerels 3.64 lbs. At the same age the pullets and cockerels in lot 5 weighed 4.19 and 5.07 lbs., respectively. In a slaughter test the White Wyandottes dressed better than the other breeds, the pullets averaging 65.45 per cent of live weight and the cockerels 60.99 per cent.

The experiments in 1907 were made to determine the comparative growth of different breeds of chickens when given the same food, the comparative value of wet and dry mash, and the relative merits of the various breeds experimented with as to ease of fattening and fitting for market. The results are deemed indicative rather than conclusive, since they show tendencies rather than absolute characters.

Lots 2, 3, 4, and 5, consisting respectively of 56 White Leghorns, 12 White Brahmas and 14 Buff Cochins, 28 Barred Plymouth Rocks and 13 Rhode Island Reds, and 34 White Wyandottes, were fed a mash of ground wheat, corn meal, millet seed, oats, barley, buckwheat, and Kafir corn, and made an average gain of 2.42 lbs. in 14 weeks. Lot 1, consisting of 40 White Leghorns, and lot 6, consisting of 10 Rhode Island Reds and 36 Barred Plymouth Rocks, received the same feeds but in dry form and gained 1.52 lbs. per head in the same time.

"Ignoring chicks which died during the trial, the heaviest gains were made by White Wyandottes on wet mash and the lightest by White Leghorns on dry feed. Barred Rocks and White Leghorns on wet mash made practically the same gains and weighed practically the same to begin with. The mortality among the Barred Rocks, however, was much greater than among the Leghorns. The gains made by the Brahmas and Cochins were practically alike. The Rhode Island Reds made the poorest gains of any breed on wet mash and the best on dry mash. The Rhode Island Reds and Barred Rocks on dry mash, however, were not strictly comparable with the other lots, as they were much larger. The average mortality on wet mash was more than ten times as great as on dry. Only one chick out of 86 died on dry mash, while 19 out of 157 died on wet mash.

"Between the ages of 6 and 13 weeks it required from 4 to 4.75 lbs. of feed to produce a pound of gain. Between the ages of 13 and 26 weeks it required from 4.75 to 5.75 lbs. of feed to produce a pound of gain.

"Chicks forced when young do not make as rapid growth as they approach maturity as those fed a more moderate ration.

"Chicks weighing less than 1 lb. seem to grow faster on a wet mash; those weighing 1.5 lbs. or more do best on dry feed.

"The loss among chicks on wet mash was much greater than among those on dry feed, even when weighing less than 1 lb. each.

"The slaughter tests indicate that the American breeds dress out better than either the Mediterranean or Asiatic breeds, and that in general pullets dress out better than cockerels. When rather small, weighing less than 3.5 lbs., live weight, the cockerels of the Mediterranean and Asiatic breeds seem to dress out better than the pullets."

An experiment in forced molting by partial starving with 18 White Leghorns seemed at first to depress, then increase slightly the egg production, but the net results at the end of 3 months were unfavorable. From incubator tests of 1906 it would appear that eggs set about the middle of April produced the highest percentage of chicks and eggs set the last of May the lowest. "The eggs of the different breeds in order of their weight were as follows: Black Minorca, Light Brahma, Barred Rock, White Leghorn, White Wyandotte, Rhode Island Red,

White Crested Black Polish, Buff Cochin. A great deal may depend upon the strain, as it is known that some hens of any breed normally lay larger eggs than others of the same breeds.

"The weight of chicks when hatched does not seem to be in direct proportion to weight of eggs."

Temperatures of a Rhode Island hen taken during the incubation period are reported. The morning temperature varied from 103 to 105° F. and the evening temperature from 102 to 104.5°. Included in the bulletin are also tables which give full data on amount of grain eaten, the weekly gain in weight, and the percentage of blood, feathers, and other by-products of the slaughter test.

General information on the management of poultry is presented. Colony poultry houses and a trap nest are figured and described. Data are given on the selection of breeding stock, management of incubators, and the feeding and fattening of chickens, construction of fattening crates, killing and dressing poultry, treatment of roup and gapes, and preserving eggs.

The molting of fowls, J. E. Rice, Clara Nixon, and C. A. Rogers (*New York Cornell Sta. Bul. 258, pp. 19–68, figs. 22*).—This includes a study of sequence in plumage in the domestic fowl and experiments in trying to "force the molt" by partial starving.

It was found that a Leghorn chick has pinfeathers for flight when it comes from the shell. "In 2 or 3 days it develops pinfeathers that will become main tail feathers. The down grows longer and on certain areas of the body develops shafts. Within a few days the shafts burst open, allowing the web of the feather to spread out, but the down often clings to the tip of the opened feather. The ragged appearance to be noticed on 2 or 3 weeks' old chicks is due to this clinging of the down tips. The first body feathers to appear are those at the throat, just above the crop. From this point a line of feathers extends down each side of the crop and breast. When this line begins to show, a tuft appears on each thigh and a line down the spine. The feathered areas increase in size as the chick grows older, so that at the age of 4 or 5 weeks they have grown together and the healthy chick looks to be well feathered. . . . The first feathers were stained red and those that replaced them were stained black. At the age of 8 weeks all the red feathers in tail and wings had been molted, and at 13 weeks all the black feathers had been replaced by white ones."

Just before maturity another molt takes place. "The pullets appeared to undergo this molt whether they laid or not. After the pullets began to lay they seemed to shed no more feathers so long as they continued in production. When they ceased to lay many of them began to molt. In some cases the molt was complete, extending to the flights and the tail; in others it went no farther than the body feathers, while in still others it included only a few feathers on different parts of the body. . . . The first mature molt comes at the end of the first year of laying. . . . The rotation followed closely that of the prenuptial molt before egg production commenced—the oldest feathers being shed first."

To test forced molting 232 single comb White Leghorns were divided into 6 lots. "The attempt to force the molt was by means of restricting the amount of food rather than by changing the quality of the ration. The starvation period lasted for 4 weeks. In the first week the amount of food was gradually reduced to one-half the usual quantity. In the following 2 weeks about one-third rations were fed, which were gradually increased in the fourth week till, at its close, the flocks which had been starved were given all they would eat." To aid in observing the molt and to detect quickly fowls that had escaped from the pens the hens were dipped in proprietary aniline dyes, orange, violet, carmine, and green being found to be the most enduring colors.

The starved fowls lost an average of 0.42 lb. in weight during the process of molt, losing weight in every case but many regaining the lost flesh before the molt was completed. "About one-half of the fowls in all of the flocks were beginning to molt in the first period, beginning August 11, and on September 29, 1907, about 90 per cent of the starved hens and 78.8 per cent of the fed hens were molting. By October 27 the percentage of molting was about equal and continued on this equality to the end of the molt. In regard to new plumage, on October 27, only 6.3 per cent of the starved hens and 5.9 per cent of the fed hens were completely refeathered. November 25 only 34.4 per cent of the starved, and 62.2 per cent of the fed hens were completely renewed, while as late as December 30, there still remained 16.6 per cent of the starved and 15.5 per cent of the fed hens which were not in their new coats.

"On the whole it may be said that from August 25 to October 23 the starved flocks showed a larger percentage of individuals molting. After that time there was more molting among the fed hens, though both flocks completed the molt at about the same time. . . . The average time required to complete the molt of the 3-year-olds was nearly 104 days; of the 2-year-olds, about 101 days, and of the 1-year-olds, 82 days. The starved 1-year-olds averaged to molt more quickly by 33 days, than did the fed; the starved 2-year-olds were little affected; while the starved 3-year-olds averaged 20 days longer in molting than did the fed birds. The average time required to complete the molt of the three starved flocks were 93.8 days; of the three fed flocks 97.4 days.

"All this would indicate that the molting process continues much longer than is usually supposed, and that there is considerable variation in the time of beginning the molt between different individuals, and between flocks of different ages, also a wide variation in the length of time it requires individuals to complete the molt. One is further impressed with the fact, that, so far as this experiment is concerned, the method of feeding did not materially alter the normal conditions of molting, except with the 1-year-old fowls.

"It is apparent that, as molting increased, egg-production decreased. This was true almost without exception with both starved and fed flocks during each period. It was strikingly true during the starvation period. While some of the hens continued to lay after beginning to molt, and a few began to lay before completing their new coat, no hen continued to lay during the entire molting period.

"Persistent layers, unless broody, appeared to begin the molt within a week after the last egg, and were usually in heavy molt in less than 2 weeks. Those beginning to molt after October 1 shed more quickly and re-feathered more quickly than those molting earlier, especially to the stage of advanced molt, when their bodies were well protected.

"Broodiness influenced the time of molt to a great degree. . . . The mortality in all the pens was large. It averaged 18.8 per cent among the starved and 20 per cent among the fed flocks. The two flocks of 3-year-olds had a mortality of 21 per cent; the 2-year-olds 16 per cent, and the 1-year-olds 20 per cent. . . . In these observations it was found that the hens, from all pens, which began to molt before September 15, averaged 108 days molting, while those which began after that date molted in 81 days. . . .

"In the absence of reliable data as to the best method of feeding fowls during the critical period of the molt, it would seem desirable to follow the practice commonly believed to be correct; namely, to feed liberally on rations which are easy of digestion and rich in protein and oil. . . .

"The rotation of molting was practically the same with hens of all ages—the oldest feather being shed first. The chick and hen both feathered more

quickly in such areas as would protect the vital parts. From the incubator to the laying period the chicks experienced at least four molts, either partial or complete.

"Hens have individual traits as to season of molting, but seldom as to rotation of molt. Young hens molted more quicky than older ones. . . .

"The 'forced molt' in one year did not influence materially, as to time and completeness, the molt of the succeeding year. . . .

"The starvation process appeared to increase broodiness. . . . As compared to the fed flocks, the starved hens molted slightly earlier and more uniformly. They were in somewhat better condition at the end of the molt; molted (average) in slightly less time; gained less above first weight during molt; gained slightly more in weight during the year; resumed production somewhat more quickly after molt; laid a few more eggs during winter; were materially retarded in egg production; produced less eggs after the molt was completed; produced eggs at a greater cost per dozen; consumed slightly less food during the year; had slightly less mortality; showed slightly more broodiness; paid a much smaller profit.

"The fowls produced the largest profits in the order of their ages. The 1-year-old hens produced the greatest number of eggs and gave the largest net profits. The 2-year-olds were a close second with the 3-year-olds somewhat farther behind, having, however, a good balance profit to their credit.

"There was considerably less mortality in the 2-year-olds, which were hopper fed dry mash, than in either the 1-year-olds or 3-year-olds, which were fed a wet mash."

DAIRY FARMING—DAIRYING.

Home-grown rations in economical production of milk and butter. J. N. PRICE (*Tennessee Sta. Bul. 80, pp. 31–50*).—Experiments to demonstrate the value of feeding home-grown rations to dairy cows are reported. "The feeds used in this experiment were corn silage, corn stover, alfalfa hay, soy-bean straw, soy-bean meal, corn-and-cob meal, cotton-seed meal, and [a proprietary] dairy feed. Corn silage was the basis of all the rations, every cow getting corn silage throughout the entire experiment. The other feeds were so combined that soy-bean straw was fed against corn stover, soy-bean hay against alfalfa hay, and soy-bean meal against cotton-seed meal." Analyses of these feeds are given. Each experiment comprised three periods of 30 days each and included 2 lots of 4 cows each.

The average yield per lot per period on the corn stover ration was 1,757 lbs. milk, at a cost of 7.9 cts. per gallon, and on the soy-bean straw ration it was 1,978 lbs. milk at a cost of 6.66 cents per gallon. In the experiment in which alfalfa hay was compared with soy-bean hay, the average yield on the alfalfa hay ration was 1,822 lbs. milk, at a cost of 9.44 cts. per gallon, and on the soy-bean hay ration 2,067 lbs. milk, at a cost of 3.96 cts. per gallon. When soy-bean meal was compared with cotton-seed meal as a supplement to corn-and-cob meal, corn silage, and alfalfa, the average yield on the cotton-seed meal ration was 1,633 lbs. milk at a cost of 10.17 cts. per gallon, and on the soy-bean meal ration 1,723 lbs. milk at a cost of 9.47 cts. per gallon.

"A ton of soy-bean hay that will yield 560 lbs. of beans and 1,440 lbs. of straw, and can be produced for $7, has a higher feeding value than a ton of alfalfa hay, which at present prices will cost from $20 to $25 on the market. . . .

"Since the home-grown rations used in this experiment produced larger yields, kept the animals in better health, and greatly reduced the cost of pro-

duction, and since such feeds can be produced on any Tennessee farm, the dairymen of this State should resort to the growing of their own dairy feeds as a relief from present market conditions. . . .

"The following rotation is recommended for Tennessee:

"1st year: Red clover (two crops for hay, or one for hay and one for fall pasture) or alsike (one crop for hay and one for late pasture).

"2d year: Clover followed by soy beans. (Vetch may be sown in the beans in August and top-dressed with six loads of manure during the winter, and turned under in the spring for green manure).

"3d year: Corn for grain, stover, and silage.

"4th year: Oats and vetch, or rye and vetch, or barley and vetch, for green feed or hay; or barley, oats, or wheat for grain."

Two milking machines have been used at the station for a year and a half. The following conclusions were drawn:

"Under the conditions existing during the test at the station, machine milking has been at least equal, if not slightly superior, to hand milking.

"Under average conditions a cow is milked as clean with the machine as by hand. An expert operator can milk cleaner with the machine than the average man will by hand.

"If the teat-cups and mouthpieces are properly adjusted the machine is not injurious to the teats and udder or objectionable to the cows, some even preferring it. . . .

"Troubles that occur in operating are due more to misuse than to any fault of the machine."

Records from Indiana dairy herds, O. F. Hunziker, H. A. Hopper, and H. J. Fidler (*Indiana Sta. Bul. 127, pp. 163–216, figs. 26*).—This bulletin is the result of 2 years' work in collecting and arranging data concerning the annual production of milk and butter fat of Indiana cows, the cost of feed per cow, the relation between yield and profit, and the influence of pure-bred stock upon production and profit. Records of individual herds are given with numerous suggestions for increasing the profits of dairy herds.

"The average of 197 yearly records was: Milk, 5,901.5 lbs.; butter fat, 244.5 lbs.

"The best herd averaged 6,656.6 lbs. of milk and 301.1 lbs. of butter fat. The poorest herd averaged 3,347.5 lbs. of milk and 152.8 lbs. of butter fat. The best cow produced 10,426 lbs. of milk containing 448 lbs. of butter fat. The poorest cow produced 3,248 lbs. of milk containing 109 lbs. of butter fat. . . .

"With the prices used, the best herd returned $2.56 for $1.00 in food, while the poorest herd returned only $1.20. . . .

"The average profit in graded herds was $36.04; in nongraded herds $19.62. . . .

"Even though these herds are above the average, 6 cows were kept at a loss, 49 cows made less than $11 profit, and 21 per cent of the herds contained unprofitable cows. . . .

"On an average, 100 lbs. of milk cost four times as much as 1 lb. of butter fat.

"The average profit on the 197 cows was $26.80. This can easily be doubled.

"A pure-bred dairy sire is the milk producer's best investment; anything short of a pure-bred male is too expensive at any price.

"Since careful grading and good management have not only increased the production of butter fat 64 lbs. per cow, but also reduced its cost of production 3.5 cts. per pound, rapid improvement should be sought through the continuous use of high-class dairy sires of some recognized breed.

"The dairymen must keep yearly records of their individual cows, discard the poor ones and raise the heifer calves from the best cows by a pure-bred sire. Records for short periods are inconclusive."

The university dairy herd; management and records, 1907–8, G. C. Humphrey and F. W. Woll (*Wisconsin Sta. Bul. 167, pp. 3–27, pls. 2, figs. 5*).—Methods of feeding and management of the university herd are described and the herd records for the year ending May 13, 1908, are tabulated and discussed as in previous years (E. S. R., 20, p. 77).

The herd consists of 8 Jerseys, 8 Guernseys (2 grades), 8 Holsteins, 4 Ayrshires, and 2 Brown Swiss. The cow making the largest profit produced 13,186.2 lbs. milk, with an average fat content of 3.62 per cent, equivalent to 477.96 lbs. butter fat. The product is valued at $140.59, and the feed cost $45.28. For the past 5 years the herd averaged 7,246.1 lbs. milk per cow per year, containing 4.23 per cent of fat, equivalent to 306.16 lbs. butter fat. The average cost of feed was $37.03, and the average value of the product $81.69. The live weight of the cows, amounts of feed eaten, and analyses of the feeding stuffs are given.

Concerning the changes of the bacterial flora of fresh milk during the so-called incubation period, A. Wolff (*Centbl. Bakt. [etc.], 2. Abt. 20 (1908), Nos. 18–20, pp. 545–563; 21–23, pp. 651–675; 24–25, pp. 737–780; abs. in Milchw. Zentbl., 4 (1908), No. 7, pp. 314–320*).—A study was made of the bacterial content of milk from the time of milking until the coagulation period. The milk from one stable was run through a strainer and collected in a covered tin vessel, and that from another stable was run over a cooler into tin cans at a temperature of 15° to 16° C. Extended tables show the bacterial content of milk when kept at different temperatures.

The bacterial flora was divided into six groups, as follows: (1) Cocci; (2) lactic acid forms; (3) short-rod forms not belonging to the coli group, (a) the alkali-producing nonliquefying, (b) the other nonliquefying, (c) liquefying, (d) those unaffected by pasteurizing; (4) coli-aerogenes group; (5) spore-forming, (a) aerobic, (b) facultative anaerobic, (c) obligate anaerobic; (6) miscellaneous. The behavior of the different forms grown as pure cultures is described. Two new species of coccus were discovered, which the author calls *Sarcina mobilis* A. and *S. mobilis* B.

In milk kept at 5° to 7° C. all kinds of bacteria increased for 3 days, especially the cocci and the alkali-producing rods. At 20° all kinds increased faster than at the lower temperatures. The first 3 hours lactic-acid forms were not much in evidence, but after that they made a proportionally larger gain than the others and soon composed over 90 per cent of the flora. At 30° the lactic-acid forms gained still more rapidly and in a few hours were the only kinds present except a few alkali-producing forms. At 37° the lactic-acid forms also increased, likewise the gas-forming coli group. Lactic-acid forms were more numerous in the milk that was run over the cooler than that strained into the covered vessel. They do not grow rapidly at the low temperatures but at the higher temperatures develop so rapidly as to be harmful to many other kinds.

In milk passed over the cooler *Bacterium güntheri* was more abundant than streptococcus at first, but when kept at 5 to 7° the latter increased much the faster. At higher temperatures *B. güntheri* increased as a rule faster than streptococcus, and in raw milk in some temperatures it increases so fast that eventually it checks itself. Although it has generally been supposed that *B. güntheri* does not form spores and is killed by pasteurizing, the author found that acidity caused the germs to adhere in small clumps and that some of them do not succumb to pasteurizing.

Of the spore-building forms the aerobic and the facultative anaerobic were represented by the hay and potato bacillus group and were present in fresh milk only in small quantity and as a rule only in the spore form. In pasteurized milk they gradually increased in number. The obligate anaerobic and the gas-producing bacteria of the coli-aerogenes group were not abundant, but when present they increased at all temperatures between 5 and 37°. With an increase in temperature the same species of coccus forms continued to predominate. The alkali-producing nonliquefying forms appeared able to thrive unhindered by the lactic-acid forms. The liquefying short-rod forms were present in large numbers except at 5 to 7°. After the second day *B. fluorescens* multiplied so rapidly that on the fourteenth day it composed nearly half the bacterial flora.

A bibliography is appended to the article.

The effect of pasteurization upon the development of ammonia in milk. W. G. Whitman and H. C. Sherman (*Jour. Amer. Chem. Soc., 30 (1908), No. 8, pp. 1288–1295*).—The bacterial decomposition of proteins in milk was studied by measuring the amount of ammonia produced. The methods of determining the ammonia were those previously used (E. S. R., 16, p. 946; 18, p. 1077) for examining fresh samples of milk. Ten samples of milk were obtained from different dealers and each divided into three portions, of which the first was untreated, the second pasteurized at 65°, and the third pasteurized at 85°.

The average amount of ammonia found in the raw milk after 2 days was 0.0056, after 4 days 0.0081, after 7 days 0.0065 per cent. In the portion pasteurized at 65° the average per cent of ammonia after 2 days was 0.0011, after 4 days 0.0057, and after 7 days 0.0065 per cent. In the portion pasteurized at 85° the results were 0.001, 0.0047, and 0.0116, respectively. There was a steady increase in "cleavage ammonia" in all samples of raw milk during the first 10 days, but practically no gain after that. The pasteurized milk, on the contrary, showed little increase the first 10 days but after that the "cleavage ammonia" increased rapidly. From the second to the seventh day of standing the acidity and ammonia increased in about the same proportions. Pasteurization retarded souring but favored the development of an offensive putrid odor and a bitter taste.

"Ammonia as a measure of the decomposition of proteins in milk appears to be especially useful in samples which have been pasteurized at high temperatures and in which the development of ammonia is continuous; in samples which have been pasteurized at low temperatures or not at all, the sanitary significance of the ammonia determination is less certain, since the ammonia content at any given time can not be assumed to be proportional to the extent to which protein decomposition has taken place."

Chemical evidence of peptonization in raw and pasteurized milk. Rachel H. Colwell and H. C. Sherman (*Jour. Biol. Chem., 5 (1908), No. 2–3, pp. 247–251*).—This study was undertaken to supplement that of ammonia content noted above. Nine samples of milk were mixed and divided into four portions. One portion was untreated and the others pasteurized by heating for 20 minutes at 60, 70, and 90°, respectively. The samples were then cooled and allowed to stand at room temperature. After 2 and 4 days they were tested for odor, acidity, and peptone.

"The results of this investigation, together with that of the effect of pasteurization upon the development of ammonia in milk, tend to emphasize from the standpoint of the subsequent chemical changes the desirability of low temperatures as recommended by Rosenau and others, in pasteurizing milk when necessary as a safeguard against infectious diseases and the objectionableness of depending upon pasteurization as a preservative measure. The importance of keeping milk cold and consuming it quickly are apparently not diminished

by its pasteurization even under conditions so favorable as to preclude subsequent contamination."

A study of moisture in butter, G. L. McKay and J. Bower (*Iowa Sta. Bul. 101, pp. 156–177*).—This bulletin contains the results of a series of experiments conducted with butters obtained from different sources to ascertain the effect of different percentages of moisture on the keeping quality and flavor of butter, and a method of controlling the moisture content is presented.

Of 107 samples examined, 11 showed a moisture content of over 16 per cent and when scored for quality averaged 86.68. Eleven samples containing between 15 and 16 per cent scored 89.3. Eleven samples contained between 14 and 15 per cent moisture and scored 89.84. Thirty-two samples that contained between 13 and 14 per cent scored 90.3. Forty-two samples contained less than 13 per cent moisture and scored 89.02. "The lowest moisture content of any sample . . . is 8.6 per cent. The average score of this butter is 80. The highest is 23.01 per cent with an average score of 88.25. The highest average score is 95.25. This sample shows a moisture content of 15.29 per cent." These results are somewhat different from those noted in earlier work (E. S. R., 16, p. 916). "It is therefore impossible to state that high-water content, between 15 and 16 per cent, necessarily means a low score or that a low-water content, below 13 per cent, means a high score, or vice versa."

Data obtained in educational scoring contests in Minnesota and Wisconsin are summarized in conjunction with those of this station, and the conclusion is drawn that there is no definite relation between the score and the moisture content.

The bacteriological effect of various waters on milk, cream, and butter was studied by F. W. Bouska, with the following conclusions: "Most waters produce flavors in pasteurized milk and cream. In pasteurized cream with a starter added, and in raw cream, only some waters produce flavors. Flavors are usually produced in butter from unripened cream and in unsalted butter, but only by some waters in salted ripened cream butter. Waters containing bacteria will not necessarily produce bad flavors. To accomplish this the bacteria in question must be able to grow in competition with other bacteria in the presence of salt and lactic acid."

In continuation of earlier work (E. S. R., 15, p. 397) on the keeping quality of butter, 25 samples of butter were scored when fresh and after keeping in cold storage 6 months. "Taking the average results given, there was a slight gain in points given for flavor in favor of the butter containing the higher percentage of water. There is also shown a certain gain in points given for body. The butter containing the lower moisture content appears from the scores given to have lost slightly in flavor, two of the samples being scored off one point." Of the samples sent to English markets those having the lower amounts of water received the highest score, but this may be due to different methods of scoring. "Contrary to the opinion expressed by some writers, that only 14.5 per cent of moisture could be obtained by churning in the granular condition, as high as 15.8 per cent was obtained."

Three types of churn were used in studying methods of controlling the moisture content in order to obtain data upon which to base further experiments. "In no case was overchurning practiced. The aim was to get a complete gathering of fat, without precluding the possibility of removing the buttermilk. The granules, on completing the churning, might be described as having an irregular minute granular condition collected loosely into larger irregular forms. This allowed of thorough washing of butter to get rid of the buttermilk, and at the same time reduced the loss of fat in the buttermilk. Tests from time to time showed from 0.05 per cent to 0.12 per cent. The butter

was first sprayed. It was then washed thoroughly, using about as much water as buttermilk. The water was then removed and fresh water added. Then the rollers were put in motion and butter worked off in the water, using slow gear. . . . After the first few churnings all the cream was pasteurized at a temperature ranging from 165 to 185° F. From 5 to 15 per cent starter was added and in most cases immediately cooled to churning temperature. It was then held over night and churned the following morning. A record of the churning was kept and butter analyzed for moisture by the official method."

The moisture content ranged from 13.33 to 19.76 per cent, but after an effort was made to control it the percentage ranged from 13.73 to 16.3. "Where creameries are not supplied with the necessary machinery to control the temperature, where no attention is paid to the other factors and where unskilled men are employed, there can be no control of moisture. . . . Leaky or slushy butter does not mean butter of high moisture content. . . . Overrun is no indication of moisture content. . . . It is possible to control moisture so that a variation exceeding 1 per cent above or below a safe margin need not be exceeded. Under favorable conditions it need not be more than 1 per cent.

"In all cases extreme temperatures should be avoided, though no set temperature can be recommended because of the multiplicity of conditions. Large churnings, rich cream, cream which has been subjected to uniform conditions, such as cream of whole-milk creameries, are favorable factors in control."

Proteolytic changes in the ripening of Camembert cheese, A. W. Dox (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 109, pp. 24*).—The investigations reported were carried on in cooperation with the Connecticut Storrs Station.

The author finds that the most potent factor in ripening of Camembert cheese is the proteolytic enzym of *Penicillium camemberti*. This enzym is of the nature of erepsin although tryptophan is absent. Galactase, rennet, and lactic acid bacteria have little to do with ripening, which begins at the surface and works toward the center. When paracasein, the principal protein, is hydrolyzed, the resulting products are caseoglutin, peptones, caseoses, polypeptids, amino-acids, and ammonia. Paranuclein was not found, and hence the ripening of Camembert cheese can not be a peptic digestion.

An aqueous extract of cheese was acidified and the precipitate washed, dried, and the fat extracted with ether. A small part of the remaining precipitate was found to be soluble in a 5 per cent solution of sodium chlorid, while the greater part was soluble in 50 per cent alcohol. The smaller fraction was "dissolved in alkalis, reprecipitated by acids, excess of which dissolved the precipitate. The substance was readily attacked by trypsin, dissolving completely in 24 hours and giving a solution from which no precipitate was obtained by saturation with ammonium sulphate."

The analysis of a sample dried at 110° C. showed that it was paracasein. The alcohol soluble part was poured in water and the gummy precipitate was dried, extracted with ether, analyzed, and its analysis and properties were found to agree with those of caseoglutin, which has not been observed before in digestions with pure enzyms. No tyroalbumin was found.

The caseoses of the cheese were separated into the four fractions described by Pick (E. S. R., 9, p. 723), as follows:

"Protocaseose, by half saturation of the neutral solution with ammonium sulphate; deuterocaseose A, by two-thirds saturation; deuterocaseose B, by complete saturation; and deuterocaseose C, by acidifying the filtrate from B. In the early stages of ripening, the protocaseose predominates. In the ripened cheese, however, protocaseose and deutero B are present in about equal amounts, and together form about three-fourths of all the caseoses. A distinction will be noticed here from the albumose formation observed by Zunz in peptic diges-

tion. According to Zunz, after deutero B has reached its maximum, deutero A predominates, and finally deutero C."

Heteroalbumose could not be derived from the casein, although traces were found which probably came from albumin. The filtrate from the caseoses was treated with ammonia and ferric ammonium sulphate. The resulting brown precipitate corresponds to the α- and β-peptones of Siegfried. Further treatment by washing with iron alum, decomposing with barium hydroxid, expelling the ammonia, removing the barium with sulphuric acid, and concentrating in alcohol gave a substance analogous to Winterstein's α-peptone (E. S. R., 16, p. 196) in the precipitate, and β-peptone in the filtrate, present in equal amount and comprising about 1.6 per cent of the cheese. After the removal of caseoses and peptones, polypeptids were found.

Using Kossel's older method (E. S. R., 10, p. 313), diamino acids or hexone bases were found in a 3 kg. sample of cheese in the following amounts: Histidin 1.1 gm., arginin 0.6 gm., and lysin 1.9 gm. Other hexone bases were present in small amounts. Another 3 kg. lot of cheese, examined for monoamino acids, yielded about 5 gm. glutaminic acid, 8 gm. tyrosin, and 14 gm. leucin. Folin's method is recommended for the determination of ammonia. The author failed to find indol, skatol, mercaptan, hydrogen sulphid, phenols, and other putrefactive products except in cheese otherwise unfit for eating. The greater part of the phosphorus is liberated and appears as acid calcium phosphate.

Paraffining butter tubs, L. A. Rogers (*U. S. Dept. Agr., Bur. Anim. Industry Circ. 130, pp. 6, fig. 1*).—By applying paraffin to butter tubs there is less loss of weight in the butter, as is shown in the following experiment: Twelve paraffined tubs containing 766½ lbs. of butter lost 7¼ lbs. in shipment. A similar lot of 12 paraffined tubs containing 756 lbs. of butter lost only 1¼ lbs. "If properly applied 2 or 3 oz. of paraffin should be sufficient to coat a 60-pound tub. A good grade of paraffin can be bought for 8 or 9 cts. a pound.

"It is more difficult to prevent mold on prints wrapped in paper and packed in boxes, because the air can not be excluded as it can in tubs. The boxes may be protected from mold by paraffining. Liners should be stored and protected from dust, and cartons should be so paraffined that they will not absorb water." The proper temperature to apply the paraffin is about 240° F. The author has devised a machine for spraying the paraffin on the tub, which is described.

Officials, organizations, and educational institutions connected with the dairy interests, 1908 (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 135, pp. 31*).—This contains an address list of the principal officials in the Dairy Division of this Department, State dairy officials, National, International, Canadian, and State dairy associations, medical milk commissions and associations of breeders of pure-bred dairy animals, outlines of courses in dairying in agricultural colleges and other institutions, and an outline of the work carried on by the Dairy Division and also that in the interest of dairying conducted by the Farmers' Institute Specialist of this Office.

VETERINARY MEDICINE.

Report of the department of veterinary science and bacteriology, 1907, W. B. Mack (*Nevada Sta. Bul. 63, pp. 43–52, pls. 4*).—An account is given of a horse affected with chronic hydrocephalus, of pervious urachus in a foal, and of traumatic pericarditis in a heifer. A detailed report is also given of the symptoms found in sheep that had fed on poisonous plants and of the result of postmortem examinations. The condition found in a fowl affected with fibro-sar-

coma, the author summarizes as follows: "There was a generalized malignant tumor growth of fibro-sarcomatous character, apparently originating in the ovary or oviduct, spreading by metastasis throughout the generative system and the mesenteric circulation, causing a thickening and hardening of the tissues, marked venous stasis, extensive ascites, cachexia, and finally death."

Annual reports of proceedings under the diseases of animals acts, the markets and fairs (weighing of cattle) acts, etc., for the year 1907 (*Bd. Agr. and Fisheries [London], [Vet. Dept.], Ann. Rpts. Proc., 1907, pp. 97, maps 6*).—A general report is presented of the outbreak of infectious diseases of animals and the work of control in Great Britain. Maps showing the relative number of outbreaks of sheep scab and swine fever for the years 1905, 1906, and 1907 accompany the report and statistical data are appended. There were no confirmed outbreaks of rinderpest, rabies, sheep pox, foot-and-mouth disease nor pleuro-pneumonia during the year. There was a noticeable decrease in the outbreaks of glanders, while swine fever and sheep scab greatly, and anthrax slightly, increased in number of outbreaks.

Attempts were made to determine in what material anthrax spores might be introduced on the farm, as circumstantial evidence had particularly pointed to feeding cakes. In connection with experiments along this line the author states that "the number of samples of cake examined up to date is 58, and in addition 14 samples of other feeding stuffs, including barley meal, rice meal, Indian meal, compound meals, barley dust, and molassine meal, and in no case has a positive result been obtained with them."

A parasitic mange order which deals with horses, asses, and mules was in force, 228 outbreaks having been reported.

Report of the principal veterinary surgeon, C. E. Gray (*Transvaal Dept. Agr. Ann. Rpt. 1904–5, pp. 60–74, map 1*).—Rhodesian redwater returns show a decrease of about one-half in the number of outbreaks recorded and a corresponding decrease in the number of deaths. Success in dealing with East Coast fever has been due to the East Coast fever ordinance, which gives the department power to slaughter stock running on infected farms and to fence in infected or suspected areas on terms favorable to the owners. Glanders and lung sickness decreased in prevalence while ulcerative lymphangitis increased during the year. Rinderpest did not reappear. The author also reports on the occurrence of mange, swine fever, anthrax, scab, and tuberculosis.

Report of the principal veterinary surgeon, C. E. Gray (*Transvaal Dept. Agr. Ann. Rpt. 1905–6, pp. 61–80, map 1*).—Quarantine has been removed from numerous areas which were formerly infected with East Coast fever and many of these have been successfully restocked with cattle. Opposition to the compulsory fencing of infected and suspected farms and locations has died out to a great extent and applications for the enclosure of farms under the East Coast fever ordinance are said to be increasing. Under this ordinance Sekukuniland was enclosed as a whole and an infected section therein fenced off for the purpose of protecting native cattle to the number of 17,000 that are still healthy. There was a considerable decrease in the number of fresh outbreaks as compared with the previous year. An increase in the number of outbreaks of glanders and swine fever is reported. Lung sickness, epizootic lymphangitis, and mange are said to be on the decline. Only 10 outbreaks of anthrax were recorded during the year. Tuberculosis has not made much headway and rabies has not made its appearance in the Transvaal, though prevalent in Rhodesia.

Report of the government veterinary bacteriologist, A. Theiler (*Transvaal Dept. Agr. Ann. Rpt. 1904–5, pp. 75–187, pls. 2*).—In this report the author gives a detailed account of investigations conducted during the year 1904–5.

The main object is said to have been that of the study of horse sickness, especially the production of serum that would be free from hemolytic effect. This is considered as having been accomplished since the results of the last experiments resulted in a loss of but 3 per cent due to horse sickness. Biliary fever or piroplasmosis of the horse, mule, and donkey has been determined to be due to same species of Piroplasma. The native equines are said to be immune to the disease while imported animals are susceptible. The disease is inoculable with blood of an immune horse into a susceptible mule. The strongest immunity against this disease may break down under the influence of a virulent fever such as that of horse sickness.

It has been determined that immune cattle do not carry East Coast fever infection. Experiments indicate that it is possible to clean an infected area, even when there are susceptible cattle running on it, if the cattle as soon as their temperature rises are confined so that they are not allowed to drop ticks on the pasture.

From experiments conducted the author concludes that the natural transmission of spirillosis is due to the progeny of *Rhipicephalus decoloratus* that have developed on cattle suffering with or immune from spirillosis. It was found possible to inoculate spirillosis into susceptible cattle and sheep with the blood of sick and immune animals.

Results obtained from heartwater experiments are said to indicate that it is possible to produce a serum which may be applied against the disease. Experiments in immunizing sheep against blue tongue show that the serum of immune sheep hyperimmunized to the extent of 500 cc. of virulent blood injected at different intervals has highly developed protective qualities which it is thought will permit of its use for practicable injection. Swine plague was for the first time discovered in the colony. A swine fever or complication of swine fever and swine plague also occurred. Bursattee, a wound disease caused by a hyphomycete and known in India among horses was observed in one case. As a result of preliminary dipping experiments the author recommends dipping as a measure for cleaning a farm from ticks, but it should be carried out systematically and for a long period. Pleuro-pneumonia is considered to be on the decrease. A herd of camels imported from Somaliland was destroyed having been found infected with surra.

Report of the government veterinary bacteriologist, A. THEILER (*Transvaal Dept. Agr. Ann. Rpt. 1905–6, pp. 81–109*).—A piroplasmosis which has been determined as distinct from *Piroplasma bigeminum* is here described as *P. mutans*. It has been found that an animal can be infected with the former singly and later with the latter. *P. mutans* has all the characteristics of *P. bigeminum*, as it remains in the immune animal and can be transmitted with the blood.

The inoculation of mules against horse sickness for the public was started in November. During the year 2,325 mules were inoculated in the Transvaal with a loss of 3.8 per cent from inoculation, while in Rhodesia 388 mules were inoculated with a loss of 2.3 per cent. In connection with the injection of serum it was found that various kinds of virus from immune animals were more virulent than those in use. This is said to make it necessary to alter the method of inoculation. Experiments undertaken to determine the possible rôle of mosquitoes in the transmission of horse sickness failed, as it was not possible to keep the mosquitoes alive in the stable. This, however, is said to be in accordance with the theory that the disease is thus transmitted as stable horses do not as a rule contract the disease. Equine piroplasmosis has been

found to complicate horse-sickness inoculations in mules to the extent of 0.8 per cent and to be responsible for 14.3 per cent due to hyperimmunization. That the disease is inoculable with immune blood is said to have been demonstrated during the previous year. Inoculations of mules with immune blood is considered as having proved a complete success. As some of the donkeys inoculated suffered somewhat severely, it is recommended that inoculations of imported animals be made only under the most favorable conditions. While inoculations of susceptible horses with immune donkey blood proved a failure there is said to be better prospect of utilizing the blood of immune mules. The disease has been experimentally determined to be transmitted by *Rhipicephalus evertsi* and not by *R. decoloratus*. This tick takes the infection in the larval and nymphal stages and transmits it during the adult stage.

The author confirms the work of Dorset, Bolton, and McBryde of this Department in finding hog cholera to be caused by an ultravisible virus that can be inoculated with blood. The author's observations seem to support the view that hog cholera is the disease and swine plague the complication.

Details are given of the routine work, and a tabulated record of the results of examinations of pathological specimens and blood smears received is appended.

Additional investigations of bovine and human viruses, L. Cobbett and A. S. and F. Griffith (*Roy. Com. Tuberculosis, Second Interim Rpt., 3 (1907), pt. 2, App., pp. V+261, pls. 3, charts 16*).—This volume contains results of experiments conducted in addition to those previously noted (E. S. R., 20, pp. 184, 185), with the object of throwing light on collateral questions. Among those reported are the following: Cultural characters of the bovine tubercle bacillus; changes in reaction produced in broth by human and bovine tubercle bacilli; modification experiments with tubercle bacilli of bovine origin; minute nonprogressive tubercles found in calves injected with tubercle bacilli of human origin, which are unable to provoke a progressive infection in this species of animal; the distribution of nonvirulent tubercle bacilli of human origin in the body of the calf after subcutaneous injection; and dissemination of tubercle bacilli in different species of animals after subcutaneous inoculation.

The tuberculosis problem, A. R. Ward and C. M. Haring (*California Sta. Bul. 199, pp. 221–234, figs. 2*).—During the past 4 years the station has made tuberculin tests of dairy cows in the various counties of the San Francisco Bay region and in the Sacramento and San Joaquin valleys. "In all 1,976 tests have been made, of which 453 (22.9 per cent) showed reactions. Only 4 herds, the largest consisting of 39 cows, were free from tuberculosis. A much smaller proportion of isolated cows were affected than those in herds. Of 71 animals, isolated, or in groups of 5 or less, only 6 (8 per cent) reacted. A more accurate statement of the prevalence of tuberculosis, as shown by our experience, would be one compiled from results of the tests of whole herds the first time that they had been tested. In this case the figures show 1,022 animals tested, with 326 condemned (31.9 per cent). Tuberculosis was found in 82 per cent of the herds tested."

A general account is given of the disease and of the methods by which it may be controlled. The tuberculin testing outfit is described and directions given for making the test. It is stated that under conditions to be personally arranged between the inquiring dairymen and the veterinarians the station will undertake to supply free tuberculin and give direct assistance in interpreting the temperature records. The authors also consider the prevention of entrance of the disease and methods by which an infected herd can be changed to a healthy one.

Infection through resorption of tubercle bacilli in the gastrointestinal canal, E. Oberwarth and Lydia Rabinowitsch (*Berlin. Klin. Wchnschr., 45*

(*1908*), *No. 6, pp. 298–301; abs. in Bul. Inst. Pasteur, 6 (1908), No. 9, p. 407*).—Experiments were conducted in which tubercle bacilli of bovine origin were introduced directly into the stomachs of young pigs. Examination of one killed 22 hours later showed the presence of the bacilli in the blood, in the lungs, and in the mesenteric glands. In a second which died on the fourth day following the infection the bacilli were found in the liver, lungs, and kidneys. In a third which lived 3 weeks after the infection bacilli were found in the blood, lungs, and mesenteric glands. It appears that tubercle bacilli pass within a comparatively few hours into the blood and lungs and that they can remain for a considerable period in a latent state without the appearance of lesions.

The penetration of the intestinal wall by tubercle bacilli, M. Herman (*Bul. Acad. Roy. Med. Belg., 4. ser., 21 (1907), No. 8–9, pp. 545–556; abs. in Bul. Inst. Pasteur, 6 (1908), No. 9, p. 406*).—In experiments made, negative results were obtained from a monkey. Positive results were obtained in a goat of 4 years, in all of 4 adult guinea pigs used, in 3 of 4 young guinea pigs, and in one of 5 rabbits.

The simultaneous inoculation subcutaneously of a pathogenic bacillus (Sirault's bacillus of meat poisoning) appears to favor the passage of the bacilli through the mucous membrane by lowering the vitality. The irritation of the intestine through the ingestion of the same bacillus appears to have rather prevented the passage.

Split products of the tubercle bacillus and their effects upon animals. V. C. Vaughan and S. M. Wheeler (*Abs. in Med. Rec. [N. Y.], 71 (1907), No. 25, p. 1051*).—The tubercle cell was split up into two portions—cell poison and cell residue. The cultural medium was concentrated and precipitated with five times its volume of absolute alcohol and this precipitate then broken up into two portions, the precipitate poison and the precipitate residue. The portion of the cultural medium left after the removal of the alcoholic precipitate was designated as the final filtrate.

Single doses of the cellular substance were injected into the abdominal cavities of 24 guinea pigs in doses varying from 5 to 200 mg. In no case was death caused directly by the injection, and it gave no immunity to a subsequent inoculation with a virulent bacillus.

The toxic effect of the cell poison on animals was shown to be through the respiratory center. When given in sufficient quantities it killed within an hour both healthy and tubercular animals. There was no evidence that it elaborated any antitoxin, and it was harmful with nothing to recommend it. What was true of the cell poison was equally true of the precipitate poison and the final filtrate. The effects of the cell residue on animals were practically nil. The precipitate residue had no recognizable ill effects upon healthy animals but had some specific effect upon tuberculous animals.

Vaccination against tuberculosis in cattle with bovovaccine, H. L. Russell and C. Hoffmann (*Wisconsin Sta. Bul. 165, pp. 3–13*).—Experiments were made to determine the extent to which bovovaccine immunizes cattle. Thirty-four head of young stock all under 6 months of age that had passed the tuberculin test, though taken from an infected herd were injected May 9, 1906, with bovovaccine and isolated until after a second injection 3 months later. In order to test the infectiousness of the barn originally occupied, 10 nonreacting calves not vaccinated were placed with the vaccinated stock on July 6 to serve as a control. After the second vaccination all experimental animals were pastured with the infected stock and from the beginning of November all animals were housed in the infected barn. Tuberculin tests were made in 3, 5, 8, 14, and 17

months following the second vaccination with the results shown in the following table:

Results of tuberculin tests made upon vaccinated and control animals.

Date tested.	Number tuberculin tested.		Vaccinated.			Control.		
	Vaccinated.	Control.	Positive.	Negative.	Doubtful.	Positive.	Negative.	Doubtful.
May, 1906	34	10	34	.....	.....	.....	10	.....
November, 1906	10	10	1	8	1	0	10	0
January, 1907	24	5	4	18	2	5	0	0
April, 1907	13	10	4	9	0	8	2	0
October, 1907	29	2	8	19	2	.....	2	.....
January, 1908	28	2	6	22	0	.....	2	.....

At a post-mortem examination made in May, 1907, lesions were found in 3 different lymphatic glands and the pleura of 2 of 5 control animals examined. It appears probable that the immunization process sensitizes the animal for a time so that it is more susceptible to tuberculosis than at first. After a time this condition of sensitization disappears and the body acquires increased powers of resistance. Post-mortem examinations of 4 of the vaccinated animals that had given apparent reactions at least twice resulted in the finding of typical more or less extensive tubercular lesions. From the fact that but one reacted within a year after the completion of the vaccination it is concluded that the infection was acquired subsequent to the completion of the immunizing process.

The authors conclude that while vaccination materially increases the resistance of most animals it does not do so in all cases. Considering the expense of the process, the time required, the fact that only young stock can be treated and that they must be separated from all sources of infection during the immunizing process, and that a certain percentage of the vaccinated animals will acquire infection in spite of the treatment, the practicability of the method is considered doubtful. The experiments have not been continued a sufficient period of time to determine the permanence of the immunity produced, but European investigators are said to have found that the immunity induced disappeared within a year or two after the vaccination. The authors do not consider the system in its present stage of development as one to be recommended to the farmers of the State.

Persistence of tuberculin in the body of the goat. A. Slatineano and C. Jonesco-Mihaiesti (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 9, p. 420*).—Tuberculin was found in the blood of a goat 12 days and in the urine 18 days after the injection of 10 cc. into the veins.

Osteoporosis in animals. H. Ingle (*Transvaal Dept. Agr. Ann. Rpt. 1905–6, pp. 198–207*).—Bones from diseased and healthy mules, horses, and donkeys were analyzed, and the following conclusions drawn: "(1) That in animals free from disease, the bones contain larger proportions of total ash, lime, and phosphoric acid than are to be found in the bones of animals suffering from the disease; and (2) that the ratio of nitrogen to ash in the bones furnishes perhaps the easiest and most direct method of judging of the freedom or otherwise of the animal from osteoporosis." Bones of diseased animals also appeared to contain more silica than those of healthy animals.

As a result of his investigation the author believes that the abnormal condition of the bones is induced by the use of foods not necessarily deficient in lime and phosphates, but in which the ratio of lime (and perhaps magnesia)

to the phosphoric acid is too low. He considers the disease probably caused by some organism which finds such a condition of the animal favorable for its development.

A note on the occurrence in America of chronic bacterial dysentery of cattle, L. Pearson (*Amer. Vet. Rev., 32 (1908), No. 5, pp. 602–605*).—An account is given of the occurrence in Pennsylvania of this disease, which is said to have been reported from Europe by Bang under the name of chronic pseudotuberculous enteritis (E. S. R., 18, p. 777), and by M'Fadyean as Johne's disease (E. S. R., 19, p. 183).

Texas fever, M. Francis (*Texas Sta. Bul. 111, pp. 3–13, charts 3, map 1*).—Directions are given for the inoculation of animals and accompanied by charts that show the different types of inoculation fever. From some 5,000 animals inoculated at the Texas Station it is estimated that 3 per cent were lost from inoculation fever and 5 per cent more from fever and casualties during the following year.

In view of the fact that horses are not susceptible to the disease, experiments were made to determine if horse serum could not be used to control Texas fever. Following inoculations with 1 cc. of virulent blood, 5 susceptible yearling steers were daily injected subcutaneously with horse serum in doses varying from 100 cc. in steer No. 1 to 1,000 cc. in steers Nos. 4 and 5. Fever records show that no benefit resulted. To test the hemolytic effect that the serum might have, a Texas cow was injected with 1,000 cc. of horse serum on 3 consecutive days but without producing any apparent sickness. Experiments were also made to determine the possible curative effect that quinin might have. Doses of 2, 4, and 8 dr. were given animals daily during the fever periods but without apparent benefit. Two animals were injected subcutaneously each day for 11 days with bimuriate of quinin with urea, one receiving doses of 5 gm., the other of 10 gm. This was commenced on the third day following the inoculation of 1 cc. of virulent blood. No beneficial effects were obtained while in both animals symptoms resembling tetanus developed, the cramps and rigidity becoming so intense that both died. When quinin was injected intravenously it apparently paralyzed the cardiac muscles and the author considers the drug too dangerous to give in this way.

Swamp fever, G. A. Charlton (*Ann. Rpt. Dept. Agr. Prov. Saskatchewan, 1906, pp. 146–152*).—For many years a very fatal disease of horses has been observed at various points in the Canadian west. Though most commonly called swamp fever it has been known as pernicious anemia, typhoid fever, malaria, influenza, mud fever, etc. The term swamp fever owes its origin to a belief that the sickness is caused by the eating of hay cut from the sloughs or by the drinking of slough water. The evidence obtained fails to indicate that the use of such hay or water has any direct influence in causing the disease. From analogy with other diseases known to be transmissible by insects it seems very probable that this disease is carried by some bloodsucking insect. The localities in which the disease occurs are usually low lying districts in which sloughs are found and which are most favorable to the development of certain insects.

The season of the year during which the disease is most prevalent extends from July to December. Among the striking points that are observed in the study of cases is the advancement that the disease has made in many instances before objective symptoms are noted. The anemia, which is one of the most notable features of the disease, is frequently so marked and progressive as to justify the designation pernicious.

On two farms reported the mortality amounted to nearly 80 per cent of the horses affected. A proportion of the animals that apparently recover are

subsequently unfitted for work. Rabbits, young cats, and a dog were injected subcutaneously with blood and gland juice from typical cases. Two of the smaller cats thus treated died within a day or two of each other about 3 months after injection, but the symptoms shown were not sufficiently characteristic to permit one to say that they died of swamp fever. Two horses were injected subcutaneously with blood from cats that seemed to show positive symptoms and a third with blood from a horse suffering with the disease without evidence of infection. Although many examinations have been made the search for a specific organism in the blood has not so far been successful.

The artificial impregnation of mares. L. VAN MELDERT (*Ann. Gembloux, 18 (1908), No. 8, pp. 461–469, figs. 8*).—A description of the process and the implements used by veterinarians in France.

Pathological investigations of fowl cholera. W. JUNGKLAUS (*Pathologisch-anatomische Untersuchungen bei akuter und chronischer Geflügelcholera. Inaug. Thesis, Leipsic, 1908; abs. in Bul. Inst. Pasteur, 6 (1908), No. 10, p. 457*).—The author considers an examination of the blood in septicemic forms and inoculation in chronic forms always necessary to confirm the diagnosis.

Experiments in the transmission of spirillosis of fowls by Argas reflexus. C. SHELLACK (*Centbl. Bakt. [etc.], I. Abt., Orig., 46 (1908), No. 6, pp. 486–488; abs. in Bul. Inst. Pasteur, 6 (1908), No. 12, p. 554*).—In 2 of 4 cases in which *A. reflexus* was used the author succeeded in transmitting *Spirochæte gallinarum*. In one case infection was induced by the bite of 4 ticks that had become infected 7 days before. The second case followed the bites of 6 ticks of which the most recently infected had been fed 64 days before on a fowl affected with spirillosis.

On the penetration of eggs by bacteria. G. CAO (*Ann. Ist. Ig. Sper. Univ. Roma, 18 (1908), No. 1, pp. 39–63; abs. in Bul. Inst. Pasteur, 6 (1908), No. 10, p. 472*).—Fresh and unfertilized eggs were found nearly always free from bacteria while 50 per cent of the fertilized eggs were contaminated. It was experimentally determined that microbes quickly penetrate the shell. Fresh eggs delay pollution by micro-organisms when such are placed in contact with the shell and even attenuate their virulence. This, however, is not the case with old eggs. During the first few days the development of bacteria within the egg appears to be slow.

Index-catalogue of medical and veterinary zoology. C. W. STILES and A. HASSALL (*Pub. Health and Mar. Hosp. Serv. U. S., Hyg. Lab. Bul. 37, pp. 401*).—The author indexes of medical and veterinary zoology, upon which the present authors have been working for several years, are to be supplemented by subject and host indexes. The present bulletin, which is devoted to trematodes and the diseases caused by them, is the first volume of such indexes. An alphabetical list of specific and subspecific names, with type hosts, is given, but the greater part of the bulletin is occupied with a bibliography of diseases, genera, and specific names.

Friedberger and Fröhner's veterinary pathology, trans. by M. H. HAYES (*Chicago and London, 1908, vols. 1, pp. XX+731; 2, pp. 702*).—In this revised and enlarged edition, prepared by the wife of the late translator, the arrangement of the first English edition (E. S. R., 16, p. 1128) is discarded and the German text and the division of volumes and chapters adopted in the sixth German edition are strictly adhered to. It also contains notes on bacteriology by R. T. Hewlett.

Observations on the veterinary schools in Europe. P. A. FISH (*Amer. Vet. Rev., 32 (1908), No. 4, pp. 449–468, figs. 12*).—This is an account of the requirements for entrance, tuition, courses, equipment, methods, etc., at 12 veterinary colleges in 6 different countries visited by the author.

RURAL ENGINEERING.

Progress in drainage, C. G. Elliott (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1907, pp. 387–404, figs. 8*).—A brief review of the history of drainage is given, beginning with tile drains installed in France as early as 1620, followed by a discussion of the function of water in the soil and the regulation of its amount by drainage.

Outlets are stated to be a prime consideration for all drainage undertakings and must be provided if not available. Natural conditions, therefore, impose a community of interest requiring cooperation upon the landowners. Resulting from this are the State general drainage laws which though simple in principle have met with certain difficulties in operation. "The effectiveness of the law depends upon the attitude of the people who are directly concerned in the proposed drainage."

Unanimity of opinion where the question of sharing cost enters, is difficult to secure and often results in objections to assessments and plans, consequently impeding the progress of the work.

It is stated that results accomplish more in inducing farmers to drain than theorizing, and three examples of successful drainage operations are given. Contributing to the drainage progress which was necessary to meet the improved economic agricultural conditions are the experience of early drainage work and mechanical aids, especially the adaptation of the steam shovel to the excavation of large ditches. The cost has also increased with the price of labor. Mistakes resulting from lack of established precedents and disregard or ignorance of others' experiences have naturally been made, such as too small channels, sizes of drains not proportioned to meet requirements of various soil and climatic conditions, and weak levees, the failure of which retards progress by discouraging landowners.

The future field of drainage engineers is deemed to be not only swamp and uncultivated lands, but the improving of over 20,000,000 acres of land now farmed, the production of which it is believed may be increased 20 per cent. The article concludes with a discussion of the benefits of drainage and of localities which may be drained.

Practical farm drainage, C. G. Elliott (*New York, 1908, pp. XV+188, figs. 46*).—This is a revised edition of the author's book of the same title but has been entirely rewritten with an addition of considerable new material. It presents for the use of farmers the main established theories and methods of drainage applicable to their needs. Of the new chapters, that on cooperative work which is frequently necessary to secure a satisfactory outlet for drains contains some suggestions for sharing the cost when the work is done by mutual agreement. A chapter is devoted to special problems in drainage, which treats briefly of muck lands, erosion of hillsides, salt marshes, alkali lands in humid sections, and bottom lands. The concluding chapter discusses the drainage of irrigated lands, a branch which is stated to be attracting much attention in the older irrigated sections.

Losses of irrigation water and their prevention, R. P. Teele (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1907, pp. 369–386, figs. 4*).—A summary of available data in which are discussed losses from canals, prevention of seepage losses, losses in the application of water to land, and influence of laws, contracts, and regulations on waste of water.

Irrigation in southeastern Australia (*Engineer [London], 106 (1908), No. 2759, p. 504*).—This is a short account of what has been accomplished in reclaiming the arid lands of Australia and of the steps leading to the Murrumbridge project now under construction. This includes a curved dam 232 ft.

high and 910 ft. long at the crest, capable of holding back 766,324 acre-feet of water. Its object is not to raise the level of the water but to hold it back and regulate the flow, which, after passing down in its original bed for 220 miles, is diverted by a low weir into a distributing canal 132 miles long with a branch 34 miles long.

Irrigation and seepage experiment (*Rpt. Cawnpore [India] Agr. Sta., 1907, pp. 66–70, fig. 1*).—This is a brief account of experiments being made to ascertain the amount of water necessary for maize, wheat, and local crops. Two tables furnish the data collected to date.

Physical tests of Iowa limes, S. W. Beyer (*Iowa Geol. Survey Ann. Rpt., 17 (1906), pp. 91–150, pls. 20*).—This article explains the difference between white, brown, and argillaceous or siliceous limes; describes the processes of slaking, setting and hardening, and the preparation of lime mortar; and reports tests of mortars made with high-calcium white limes and magnesian and dolomitic limes.

The limes tested were high-grade products representative of pure white and of magnesian or dolomitic lime. With such limes it was found, as a rule, that the maximum strength is attained at the end of a setting period of 6 to 9 months. "This is most pronounced where the higher percentages of sand are employed. The notable exceptions to this rule are found with the lowest sand-lime ratios, the lower percentages of water used to slake, and are most conspicuous in the strongly dolomitic limes." Since carbonation occurs to only a limited extent during the first 6 or 9 months, the change which occurs during the setting of mortar is considered to be largely the crystallization of the lime hydrate.

"In general, the greatest strength comes with the lower percentages of water used in slaking. Equal amounts by weight of water and of dry quicklime give in the majority of cases the highest results. Higher proportions are detrimental to tensile strength. This is more especially noticeable in the white limes. . . . As a rule, the highest strength is given by the lowest proportions of sand, the curves being about equally divided between equal parts by weight of sand and dry quicklime and two of sand to one of lime." The highest strength was obtained with a 1 : 1 or 50 per cent mixture of lime and sand.

"The white limes require more water to slake properly, generate more heat in slaking, slake much more rapidly, and reduce to a more uniform paste than the magnesian limes. The dolomitic limes set and harden more slowly but in many cases attain strengths so much greater than do the white limes as to be almost out of comparison. They will, therefore, stand greater dilutions of sand and still be sufficiently strong to meet the requirements of practical use."

Modern silo construction, J. B. Davidson and M. L. King (*Iowa Sta. Bul. 100, pp. 94–150, figs. 45*).—This gives the results of investigations of existing silos, and discusses fully the relation of construction to their failure or success, as it was learned that many of the failures were due to improper construction. In answer to circular letters reports of 161 silos were received and 112 silos were examined by the junior author.

It is stated that the essentials of good construction require air-tight walls and doors, walls smooth inside and rigid enough to withstand the pressure of the silage, and an air space between the walls to prevent freezing. The proper location contributes to the success of the silo, and the reports indicate that this should be outside of all buildings. A discussion of the different types and their cost includes silos of wood, brick, concrete, steel, cement-block, and stone, as well as of common building tile, for which there is a design submitted in detail.

How to build a stave silo, B. H. Rawl and J. A. Conover (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 136, pp. 18, figs. 18*).—This gives complete directions for the construction of stave silos and their foundations and contains suggestions for determining the proper size.

[A new pea and bean thresher], F. C. Quereau (*Tennessee Sta. Bul. 79, pp. 26–28, fig. 1*).—A detailed description is given of an implement which this station has tested for 2 years with very satisfactory results. It resembles the ordinary grain separator in general make-up but the distinctive differences are large knife-edged cylinder teeth and notched sharp-edged concave teeth.

It is stated that in the tests, which included 200 bushels of cowpeas and soy beans, representing 8 varieties of the former and 2 of the latter, and with the vines in all degrees of toughness and stages of curing, a surprisingly high percentage of separation resulted.

Electricity and agriculture, W. H. P. Cherry (*Agr. Gaz. N. S. Wales, 19 (1908), No. 11, pp. 869–890, figs. 22*).—This is a popular account of the manufacture of atmospheric nitrates, calcium cyanamid, the Thwaite and other methods of electroculture, radioculture, experiments in electroculture by Lemström, Sir Oliver Lodge, by this Department, the Hawkesbury Agricultural College, and also in South Australia. The possibility of establishing nitrogen-fixing industries in Australia is discussed as well as the application of the electricity as power in household and farm work. A portable farm telephone is described.

RURAL ECONOMICS.

The agricultural and transportation industries, E. Lambert (*L'Industrie Agricole et l'Industrie des Transports. Paris, 1908, pp. 344*).—This book is divided into three parts dealing, respectively, with (1) the plant and the soil, (2) fertilizers, and (3) the relation between agriculture and transportation. It is pointed out in a prefatory chapter that agriculture has developed more slowly than other industries, but that it has greater future possibilities and will undoubtedly outstrip them. A special plea is made for the more complete industrialization of agriculture, and to this end the general adoption of more scientific methods and improved transportation facilities to promptly deliver supplies and move crops are considered essential. The great advantage to agriculture of increased and improved water transportation is particularly emphasized.

The book therefore deals with scientific methods of increasing and maintaining the fertility of soils and with improved methods and means of transportation.

The position of agriculture from the economic point of view, Vibrans (*Ztschr. Landw. Kammer Braunschweig, 77 (1908), No. 31, pp. 364–367*).—The author discusses the food values of agricultural products with a view of inducing interest by the government in a more rational system of taxation. It is believed that the government should encourage the branches of agriculture producing the necessaries rather than the luxuries of life. The author favors the higher taxation of beer and tobacco, the prohibition of or increased duty on the transportation of potash, the reduction of taxation on sugar, and the encouragement of the production of staple crops, the ultimate aim being to make Germany a self-supporting nation.

Note on agriculture in Japan, F. A. Nicholson (*Madras: Govt., 1907, pp. VI+122, pls. 2, fig. 1*).—The area of Japan is given as about 94,000,000 acres, of which only 12,778,124 acres, or 13.53 per cent, was under cultivation in 1905. The population was 47,812,702, and as Japan is practically a self-sustaining people, the whole nation secures its subsistence and other necessaries on an

area of 0.267 acre per head. Japan is a country of small holdings. Farms below 2 acres formed 55 per cent, those between 2 and 3¾ acres 30 per cent, and those above 3¾ acres 15 per cent, the average for the country at large being 2.55 acres.

Information is also given regarding Japanese manurial practices, the preparation of composts, the governmental organization of agricultural education and research, experiment station work, and agricultural associations. Probably in no other country in the world are the latter so general and so well organized as in Japan. Recently there were in existence 58,547 associations in 47 prefectures, 638 counties, and 13,509 towns and villages. The extensive work undertaken by the village associations is also described.

Agriculture in Japan, F. A. Nicholson (*Jour. Jamaica Agr. Soc., 12 (1908), No. 10, pp. 329–333*).—A summary of the above.

Cooperative farming, W. Bulstrode (*London, 1908, pp. 23*).—This pamphlet outlines a plan of cooperative farming on a large scale which if put into practice it is believed would offer a solution of the problem of rural depopulation in England and be of far-reaching and lasting benefit to national prosperity.

The economic and social significance of agricultural cooperative associations in Germany, M. Grabein (*Wirtschaftliche und soziale Bedeutung der ländlichen Genossenschaften in Deutschland. Tübingen, 1908, pp. VIII+196*).—This is a history of the different kinds of agricultural cooperative associations in Germany from their origin to the year 1907.

Land and agricultural banks in European countries, A. K. Eckerbom (*K. Landtbr. Akad. Handl. och Tidskr., 47 (1908), No. 3, pp. 113–145*).

The farm help problem, B. W. Potter (*Agr. of Mass., 1907, pp. 139–163*).—This is a paper read at the public winter meeting of the Massachusetts State Board of Agriculture held at Boston, December 3–5, 1907.

The speaker discusses the causes of the scarcity of farm help in Massachusetts, chief of which he believes is found in the unprosperous condition of agriculture in the State. Among the remedies suggested are making life more attractive for the laborer on the farm, such as providing plenty of good food, comfortable sleeping rooms or separate homes, not more than ten hours of labor, treating him well socially, and giving him employment the year around; the use of more and better agricultural machinery and the undertaking of those branches of agriculture such as meat production which require the employment of less labor; the proper education of farmers' children to keep them on the farms; the payment of wages commensurate with or superior to those paid in factories and other town occupations; and the selling of products by farmers directly to consumers, either individually or through cooperative associations.

The paper is followed by a discussion.

[Agricultural labor conditions in Germany] (*Ztschr. Agrarpolitik, 6 (1908), No. 10, pp. 528–545*).—Summaries of official reports relating to agricultural labor conditions in the different provinces in 1907 and 1908 are presented in this article.

How can the ever-increasing scarcity of German agricultural laborers be prevented? Kayser (*Deut. Landw. Presse, 35 (1908), No. 84, pp. 882, 883*).—The author shows how the number of rural families have decreased in Germany since 1871 by emigration to America and other countries, removal to the cities, employment on railroads and in the industries, and similar ways, and enumerates the reasons for rural depopulation. The only remedy in the author's opinion is the payment of higher wages to farm hands and giving them better home surroundings. To this end the author proposes to tax every farmer who employs a foreign farm laborer 50 marks a year. This tax it is estimated would yield an income of about 30,000,000 marks (about $7,000,000) which should be de-

voted to the building of better houses for farm laborers. It is believed that this proposal, in connection with the payment of higher wages, would ultimately result again in the increasing settlement of German agricultural families on the land and be a practical solution of the rural labor problem.

Is the agricultural laborer in East Prussia a proletarian? A. HOFFMEISTER (*Ztschr. Agrarpolitik, 6 (1908), No. 10, pp. 516–522*).—The author criticises the conclusions of Weber that the position of the farm laborer in East Prussia is constantly tending to a lower standard of living. On the contrary, from investigations made by the author and others on a large number of farms, the conclusion is reached that industrious families are able to save from 58 to 300 marks and even as high as 500 marks (about $119) annually from their earnings, and that "the economic and social condition of the farm laborer in East Prussia is constantly improving and is not forcing him into the ranks of the proletariat."

The article contains a bibliography relating to the agricultural labor problem in Germany, with particular reference to East Prussia.

Report of the international jury. Agriculture, horticulture, feeding stuffs, L. GRANDEAU (*Rapports du Jury International. Agriculture, Horticulture, Aliments. Paris, Govt., 1905–6, vols. 3, pt. 5, pp. III + 754, figs. 193; 4, pt. 5, sect. 1, pp. 751, figs. 125; sect. 2, pp. 752, figs. 129; sect. 3, pp. 663, figs. 106*).—This is a general treatise on the agriculture, horticulture, and foods and feeding stuffs of the 100 countries in the world, based on the exhibits at the Paris Exposition in 1900. These phases of agricultural economic life are separately discussed, and the data having been compiled from official sources serve as useful comparisons of the population, agricultural production, and rural economy of the nations of the world at the opening of the twentieth century.

Imports of farm and forest products, 1905–1907 (*U. S. Dept. Agr., Bur. Statis. Bul. 70, pp. 62*).—Detailed statements of imports of farm and forest products, including the countries from which consigned, are reported. The value of farm products imported in 1907 was $626,836,808, the value of forest products $122,420,776, both being increases over 1906 (E. S. R., 19, p. 589).

Exports of farm and forest products, 1905–1907 (*U. S. Dept. Agr., Bur. Statis. Bul. 71, pp. 78*).—Detailed statistics of exports of farm and forest products, including the countries to which consigned, are reported. The values of farm and forest products exported in 1907 were $1,054,405,416 and $92,948,705, respectively, as compared with the values of $976,047,104 and $76,975,431 in 1906 (E. S. R., 19, p. 589).

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 11 (1909), No. 1, pp. 1–8*).—The condition of crops in the United States and foreign countries, data on the farm values of principal crops and range of prices of agricultural products in the United States, and special articles on the monthly marketings by farmers of important crops during the year ended June 30, 1908, and the monthly movement of wheat in international trade during 1908 in comparison with similar data for the two preceding years, are reported.

Agricultural statistics of Ireland, with detailed report for the year 1907, W. G. S. ADAMS (*Dept. Agr. and Tech. Instr. Ireland, Agr. Statis. 1907, pp. XXXVII + 149*).—Statistical data of crop areas and production, number and classes of live stock, number and size of holdings, bee keeping, and forestry in Ireland during 1907 are reported. The holdings numbered 599,872, of which 516,298 exceeded 1 acre in extent, 153,728 contained between 5 and 15 acres, 135,233 between 15 and 30 acres, 74,799 between 30 and 50 acres, and 58,029 between 50 and 100 acres.

AGRICULTURAL EDUCATION.

Progress in agricultural education, 1907. D. J. Crosby (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1907, pp. 237–306, figs. 18*).—A review is given of the work of the different educational agencies for the promotion of agriculture in this country and abroad, with special attention to the fiftieth anniversary of the establishment of the first agricultural college in this country, the training of teachers in agricultural colleges and normal schools, and descriptions of the agricultural features of instruction in a number of high schools.

Statistics of land-grant colleges and agricultural experiment stations, 1907. Marie T. Spethmann (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1907, pp. 199–236*).—A compilation from official sources of general statistics, courses of study, attendance, value of funds and equipment, revenues, and additions to equipment of the land-grant colleges, and of the lines of work, revenues, and additions to equipment of the agricultural experiment stations in the United States.

Statistics of educational institutions, 1904–5 (*Österr. Statis., 79 (1908), No. 3, pp. LXIII+348*).—Statistics for 1904–5 similar to those for 1903–4 previously noted (E. S. R., 18, p. 995).

A successful agricultural high school (*Pacific Rural Press, 76 (1908), No. 13, pp. 193, 204, 205, figs. 6*).—A description of the organization, equipment, and courses of study of the California Polytechnic School at San Luis Obispo.

Crookston School of Agriculture. W. Robertson (*Minn. Farm Rev., 1½ (1908), No. 9, pp. 164, 165, fig. 1*).—A description of the buildings and work of this institution.

For the promotion of the culture and uses of fruit (*Ber. Landw. Reichsamte Innern [Germany], No. 6, pp. VI+177*).—This is a report of the German Pomological Society on courses of instruction for fruit experts, one of which was held in Dresden on September 10 and 11, 1906, and the other in Lübeck, July 29–31, 1907, and on courses for fruit packing.

School gardening in the province of La Union. N. H. Foreman (*Philippine Agr. Rev. [English ed.], 1 (1908), No. 2, pp. 95–99, pl. 1*).—This extract from the report of the author, who is supervising teacher at Lubao-Aringay, gives a brief account of the school garden work in the province of La Union. Every school has a garden in which instruction is given in the use of fertilizers, cultivation of plants, use of products, and the saving of seeds. The success of the work is attributed largely to the fact that each pupil was given his own individual plat, thus giving him definite ownership and a right to use or sell the products of his garden.

Boys' corn growing contest. S. M. Jordan (*Mo. Bd. Agr. Mo. Bul., 6 (1908), No. 4, pp. 9, figs. 6*).—Announcement of prizes offered, rules governing the contest, and of boys' and young men's short courses, and directions for planting, cultivation, etc.

With a prosperity train in Georgia. S. M. Ball (*World's Work, 16 (1908), No. 3, pp. 10445–10453, figs. 8*).—This is an account of the six-weeks run in the winter of 1908, of a special train manned by the Georgia College of Agriculture.

The farmers' institutes in the United States, 1907. J. Hamilton (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1907, pp. 307–354*).—This is the annual report of the Farmers' Institute Specialist of this Office for 1907. It includes a discussion of the progress and problems of the institute movement, an account of the annual meeting of the American Association of Farmers' Institute Workers, a discussion of the agricultural education extension movement, and detailed reports and statistics on farmers' institutes in the different States and Territories.

Agricultural education through rural schools, E. D. Sanderson (*N. H. Col. School Bul. 1, pp. 20, figs. 7*).—A discussion of the purposes and possibilities of instruction in agriculture in high schools and in rural elementary schools, with special application to the schools of New Hampshire.

The need of technical education in our public schools, W. D. Gibbs (*Ann. Rpt. N. H. Hort. Soc., 1 (1907), pp. 104–108*).—This subject is discussed from the New Hampshire point of view with reference to the teaching of agriculture, manual arts, and home economics in the public schools, and the organization of special secondary schools to give instruction primarily in these subjects.

Agricultural education in the schools, K. L. Butterfield (*Trans. Mass. Hort. Soc., 1908, 1, pp. 111–121*).—Vocational training is discussed, likewise the question whether agriculture shall be introduced into existing schools or await the establishment of special agricultural schools. The author believes that agriculture should be put into the regular work of existing schools and that separate schools should be established wherever they can be maintained.

The rural school and its relation to the community and agriculture, K. L. Butterfield (*New England Farmer, 87 (1908), No. 40, p. 8*).—An abstract of a lecture dealing with ways in which the rural school may more completely serve the community interests. Some of the ways suggested are to enlist the support of the community, relate the school system to the industry of the community, develop the spirit of social service within the schools, relate the school more completely to the intellectual life of the community, and let the teacher become a community leader.

Elementary principles of agriculture, A. M. Ferguson and L. L. Lewis (*Sherman, Tex., 1908, pp. XV+304, figs. 179*).—This text-book is intended by the authors for use in the common schools. The authors deal with agriculture as a three-phase subject—a business, a science, and an art or craft. They approach it from the botanical side, dealing first with the morphology and physiology of plants in an elementary way, then with plants in relation to soils and moisture, and following with such matters as rotation of crops, propagation of plants, pruning and training of plants, and fungus diseases, insects, and birds in their relations to plants.

Several chapters of the text-book are devoted to animal husbandry—types and breeds of cattle, horses, hogs, sheep, goats, and poultry, the nutrition of the animal body, and farm dairying—and several chapters to special topics, such as home grounds, school gardens, forestry, and farm machinery. There is, however, no discussion of the leading farm crops of the Southwest. An appendix contains lists of books on agriculture, formulas for insecticides and fungicides, tables relating to the composition of American feeding stuffs, the digestible nutrients and fertilizing constituents in stock feeds, feeding rations, and a glossary and index.

Plowing and harrowing, C. L. Goodrich (*Hampton Leaflets, n. ser., 4 (1908), No. 10, pp. 17, figs. 12*).—An elementary study of plows followed by information concerning the reasons for plowing, when and how to plow, and similar matter concerning harrows and harrowing.

Soil studies, F. W. Taylor (*N. H. Col. School Bul. 2, pp. 22–44, figs. 14*).—An outline suitable for the guidance of teachers of rural schools is followed by simple and easily performed exercises and experiments with soils for use in the grammar grades. A list of reference books and pamphlets is appended.

Seeds and seedlings, C. Brooks (*N. H. Col. School Bul. 3, pp. 47–59, figs. 9*).—Suggestions are given for studies of seeds, germination, and the early development of the seedling.

What trees do, W. R. Lazenby (*Agr. Col. Ext. Bul. [Ohio State Univ.], 4 (1908), No. 2, pp. 12, figs. 12*).—This bulletin explains the various functions performed by trees.

MISCELLANEOUS.

Annual Report of the Office of Experiment Stations, 1907 (*U. S. Dept. Agr., Office Expt. Stas. Rpt. 1907, pp. 414, figs. 40*).—This includes the usual report on the work and expenditures of this Office for the fiscal year ended June 30, 1907, and the agricultural experiment stations in the United States, including Alaska, Hawaii, and Porto Rico; statistics of the land-grant colleges and experiment stations for 1907; a brief account of the twenty-first annual convention of the Association of American Agricultural Colleges and Experiment Stations; a report of the superintendent of the agricultural experiment station in Guam; and several articles and reviews abstracted elsewhere in this issue.

Annual Report of Nevada Station, 1907 (*Nevada Sta. Bul. 63, pp. 57*).—This contains the organization list, and reports of the board of control, the director, and heads of departments. The report of the director includes a financial statement for the fiscal year ended June 30, 1907. The experimental work reported in the departmental reports is abstracted elsewhere in this issue.

Bulletins of Alabama College Station (*Alabama College Sta. Indexes to Vol. XIV, Buls. 135–138, and Ann. Rpt. 1906, pp. 109–112; Vol. XV, Buls. 139–141, and Ann. Rpt. 1907, pp. 189–192*).—Indexes are given to the publications issued from January to December, 1906, and from January to December, 1907, together with a list of bulletins available June, 1908.

Index to papers relating to plant-industry subjects in the Yearbooks of the United States Department of Agriculture, J. E. Rockwell (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 17, pp. 55*).

Classified list of available publications of the Bureau of Animal Industry (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 134, pp. 8*).—A classified list of the publications of the Bureau available for distribution September 1, 1908.

A primer of conservation, T. Cleveland, Jr. (*U. S. Dept. Agr., Forest Serv. Circ. 157, pp. 24*).—This contains excerpts from addresses given at the White House Conference of Governors, May 13–15, 1908, a discussion of the significance of the conference, the declaration of principles adopted, brief statements by men prominent in national affairs upon the subject of conservation, and the letter of the President appointing the National Conservation Commission.

Declaration of Governors for conservation of natural resources (*U. S. Dept. Agr., Farmers' Bul. 340, pp. 7*).—This contains the declarations of principles adopted at the conference referred to above.

NOTES.

Delaware College and Station.—A science club with weekly meetings has been organized among the members of the agricultural department of the college and the station staff.

Georgia College.—A farmers' congress and a farmers' wives' congress were held at the college January 18–23. The dedication of the new agricultural building was a feature of the exercises of the week.

Guam Station.—The first two loads of improved agricultural tools and implements, most of which were entirely new to the agriculture of the island, have been received. It is planned to take up experiments with field and sweet corn, tobacco and coffee, and as to the use of leguminous trees and plants. A collection of the mealy bugs threatening the cocoanut industry is being made. To bring the station closely into contact with the farmers from the start a circular letter of inquiry has been distributed, in which suggestions are invited as to the lines along which improvement in agricultural conditions is most essential.

Iowa College.—James A. King, assistant in farm crops in the agricultural extension work, has resigned to engage in commercial work.

Kansas College.—P. J. Newman has been appointed assistant in chemistry.

Massachusetts Station.—James T. Howard has been appointed inspector in both the fertilizer and feed and dairy division of the chemical department, vice W. K. Hepburn, resigned.

Michigan College.—The enrollment of short-course students reached 204, making the total enrollment of the college 1,364, and taxing the present accommodations to the utmost.

Nebraska University and Station.—The short winter course in the school of agriculture closed with an excursion to the South Omaha Stock Yards. Special facilities were available for the inspection and judging of the different types of cattle, and this was followed by a demonstration in cutting beef, pork, and mutton.

T. A. Kiesselbach has been appointed adjunct professor of agronomy in the department of field crops, and Erwin Hopt has been appointed assistant in that department.

Cornell University and Station.—M. V. Slingerland, assistant professor of economic entomology in the college of agriculture, and entomologist in the station, died March 10 at the age of 44 years. Professor Slingerland was graduated from Cornell in 1892 and had been associated with the entomological work of the institution since 1890. He was the author of an unusually large number of bulletins and other articles on entomological subjects, and served as president of the Association of Economic Entomolgists in 1903.

Ohio Station.—Ralph E. Caldwell has been appointed assistant in animal husbandry.

Oklahoma College and Station.—John A. Craig, formerly director of the Texas Station, has been appointed director of the station and has entered upon his duties. According to *Breeders' Gazette*, H. P. Miller has accepted the principalship of the short courses in agriculture and domestic economy.

Oregon College and Station.—Alfred G. Lunn has been appointed assistant in the department of poultry husbandry.

Porto Rico Station.—William Hess, formerly gardener of the Florida Station, has been appointed expert gardener and has entered upon his duties.

Rhode Island Station.—Through the efforts of the station there has been organized in the State an agricultural experimental union. Each member agrees to conduct one simple experiment on his farm during the summer, and the results will be presented at an experience meeting to be held the following winter. Little interest was manifested when the subject was first broached, but the movement is now growing rapidly and is expected to result in a large and promising organization.

The vacancy caused by the resignation of J. S. Irish, assistant biologist, has been filled by the appointment of R. C. Waite, a graduate of the Michigan College.

Vermont Station.—Joseph W. Wellington has been appointed assistant horticulturist.

Washington College and Station.—Ira P. Whitney has resigned as instructor in dairying and dairy expert to assume charge of a large dairy farm in Montana. C. C. Thom, demonstrator in physics at the Ontario Agricultural College and Experimental Farm, has been elected soil physicist of the station, vice H. B. Berry, who has been appointed instructor in agronomy. Alex Carlyle has been appointed assistant cerealist of the station and entered upon his duties February 15.

Wisconsin University.—A tuberculosis exhibit consisting of the State exhibit at the International Congress on Tuberculosis, together with reproductions of the principal features of other exhibits at that congress, has been prepared by the department of bacteriology and the State antituberculosis association and is to be sent out to cities in the State by the university extension division.

The annual convention of the State board of agriculture was for the first time held at the college of agriculture, the meetings taking place February 3 and 4. A number of State live stock associations also met at the time. The speakers included several members of the staff of the college and station, as well as of other institutions.

The enrollment in the short courses reached 444, a gain of 51 over the previous year. Nearly every county of the State was represented, besides 8 other States, England, Japan, India, and Panama. At special exercises held February 13 in connection with the short courses, President Van Hise, on behalf of the university, presented to Charles P. Goodrich, a Jefferson County dairyman, Arthur L. Hatch, a Door County horticulturist, and Henry Wallace, of Iowa, editor of *Wallace's Farmer*, engrossed testimonials setting forth the appreciation by the university of their services to agriculture. This is believed to be the first formal recognition by educational institutions of the services to agriculture of private individuals.

First Pan-American Scientific Congress.—The following account of this congress is furnished by Mr. George M. Rommel, of the Bureau of Animal Industry of this Department, who was one of the delegates from the United States to the congress.

The first Pan-American Scientific Congress was held at Santiago, Chile, from December 25, 1908, to January 5, 1909. More than 200 delegates were present and every American republic except Haiti was represented. There had been held previously three scientific congresses at which the Latin-American republics were represented—at Buenos Ayres, Montevideo, and Rio de Janeiro. Shortly after the last of these congresses an invitation was extended to the United States to participate in the fourth congress, and the invitation was accepted, Congress appropriating $35,000 early in 1908 to be used by the Secretary of State in defraying the expenses of a delegation from this Government.

Ten delegates were appointed by Secretary Root, seven being university professors, and the remainder government officers. The delegation was composed as follows: Prof. L. S. Rowe, University of Pennsylvania, chairman; Prof. Paul S. Reinsch, University of Wisconsin, vice-chairman; Prof. Hiram Bingham, Yale University; Prof. A. C. Coolidge, Harvard University; Col. W. C. Gorgas, U. S. Army; Prof. W. H. Holmes, Smithsonian Institution; Prof. Bernard Moses, University of California; Mr. Geo. M. Rommel, U. S. Department of Agriculture; Prof. W. R. Shepherd, Columbia University; and Prof. W. B. Smith, Tulane University. The university men on the government delegation also represented their respective universities, and the following educational institutions sent delegates direct or were represented by alumni residents in South America: Chicago, Cornell, Harvard, Illinois, Michigan, Minnesota, and Northwestern universities. The National Education Association and the Association of American Universities were likewise represented.

The congress attracted a great deal of interest throughout South America, and wherever the delegates went they were received with marked attention. In Chile itself the government and the public vied with each other in providing entertainment, while the press paid an unusual amount of attention to the proceedings, publishing entire the official reports of each section.

The congress was divided into the following sections: I, Pure and applied mathematics; II, physics and chemistry; III, natural sciences, anthropology, and ethnology; IV, engineering; V, medicine and hygiene; VI, jurisprudence; VII, social science; VIII, pedagogy; and IX, agronomy and zootechnics. The attendance was largest in the sections on medicine and hygiene, social science, and pedagogy. In the section on agronomy and zootechnics, the attendance was small but representative. The greater part of the time of this section was taken up with discussions of agricultural education, and the fact is of the highest importance as showing the interest which our southern neighbors have in the training of young men to become expert farmers and stockmen or to engage in research work in agricultural science.

The trend of discussion in this section can be best shown by quoting verbatim the resolutions on agricultural education presented by the section to the congress. They were as follows:

Agricultural education for its development should be divided into three grades; superior, secondary, and practical-elementary.

A. Superior agricultural education.—The section of agronomy and zootechnics declares that it regards as indispensable that the American countries which have not already done so give to superior education in agriculture the character of university instruction.

To this end a faculty of agronomy should be established with due provision that the institutions which give this instruction are supplied with the necessary laboratories and are located on property of their own, in which said instruction can be amply applied and demonstrated.

B. Secondary education.—The instruction of a secondary character should be theoretical and practical, and should be distinguished by its local character, confining especially the work done to the branches of agriculture peculiar to the region in which they are situated, and developing the teaching of them under a local management. The institutions which give this instruction should be established on farm properties of sufficient extent, conveniently located, and adapted to an economical development so as to train agriculturists and specialists capable of directing work on a rural establishment.

C. Practical-elementary education.—The practical-elementary education should be local and made specific in certain branches of agronomic science best suited to local application, developing the work in detail and supplying the proper ex-

planation as each act is performed, in all the operations which deal with the planting, development, and management of a farm property of the kind and importance which the school should have in mind.

D. In order to complete agricultural education, the American countries should keep in view: (1) Supplementary establishments for agricultural and experimental development such as agricultural experiment stations, laboratories of vegetable pathology and vitology, special stations, agricultural statistics, etc.; (2) the development of extension teaching through the medium of demonstration farms, by the aid of local farmers, and, in general, by all the means of propaganda which enable agricultural instruction to reach the farmer himself so as to guide him in his work.

E. The secondary and practical-elementary agricultural instruction, as well as the different activities involved in official agricultural propaganda, should be organized systematically in accordance with the needs of the country, and should be placed in charge of the executive power, for the attainment of which purpose the government should possess a central administrative mechanism, capable of regulating the system and controlling its results; a ministry of agriculture, with its dependencies, being the most efficacious of all.

F. In order to awaken and stimulate a desire for agricultural study, the section of agronomy and zootechnics believes: (1) That the primary schools in the country, and even in cities in agricultural districts, should include compulsory agricultural education as an integral part of their course of study; (2) that in the courses of study in normal schools, instruction in theoretical and applied agriculture should be included, in order to render teachers capable of giving such instruction in the primary schools.

The thought of the South Americans on this matter is readily seen to be similar to that of North Americans, and while the importance of agricultural education is not yet so fully recognized as in the United States, nor the schools now established so well equipped, the foundations are being laid for excellent work.

In research work, comparatively few papers were presented, but some interesting ones were read on veterinary science and zootechnics, horticulture, soils, and plant pathology. Experiment stations are not numerous in South America, but those which are established, as for example, at São Paulo in Brazil, at Santa Catalina in Argentina, and at Santiago in Chile, appear to be doing good work, especially in agronomy.

The action of the congress in selecting Washington as the meeting place for the second Pan-American Scientific Congress is of great interest to North Americans, and our experiment station men will then have an unequaled opportunity to become acquainted with the agricultural leaders of South America. The congress will be held during the year 1912, the exact date being left to the organization committee, which as appointed by the Santiago congress is as follows: Prof. L. S. Rowe, University of Pennsylvania, chairman; Hon. John Barrett, Director Bureau of American Republics; Hon. E. E. Brown, U. S. Commissioner of Education; Prof. W. H. Holmes, Chief Bureau of Ethnology, Smithsonian Institution; and Mr. Geo. M. Rommel, Bureau of Animal Industry of this Department.

Seventh International Congress of Applied Chemistry.—This body is to meet in London May 27 to June 2. The congress will be organized into sections of analytical chemistry, inorganic chemistry, metallurgy and mining, explosives, organic chemistry and allied industries, industry and chemistry of sugar, starch industry, agricultural chemistry, hygiene, medical and pharmaceutical chemistry, bromatology, photographic chemistry, electrical and physical chemistry, and law, political economics and legislation with reference to chemical

industries. Dr. H. W. Wiley of this Department is chairman of the American committee, and its section on agricultural chemistry is composed of C. G. Hopkins, chairman, R. J. Davidson, J. G. Lipman, F. T. Shutt, and J. T. Willard. F. P. Veitch and P. H. Walker are among the members of the section on analytical chemistry, A. S. Cushman that of inorganic chemistry, A. H. Bryan that of the industry and chemistry of sugar, and M. E. Jaffa that of the subsection on hygiene and medical chemistry. The subsection on bromatology is made up of W. D. Bigelow, chairman, E. M. Chamot, C. F. Langworthy, Graham Lusk, and W. W. Skinner.

Fourth International Congress of Dairying.—The committee in charge of this body announces that it will meet at Budapest, June 6–10, 1909. The congress will be organized in sections of dairy industries, dairy machinery and apparatus, and scientific exhibits and methods of experimentation. Additional information may be obtained from the Deutschen Milchwirtschaftlichen Vereins, Friedenau, Friedrich-Wilhelm—Platz 2.

British Association for the Advancement of Science.—This organization is to meet at Winnipeg, Manitoba, August 25 to September 1. Maj. P. G. Craigie is to act as chairman of the subsection on agriculture.

Opening of Wisley Laboratories.—A laboratory and research station at the Wisley Gardens, Surrey, has recently been opened under the management of the Royal Horticultural Society. A one-story building, fitted up with a students' laboratory, a small research laboratory, a photographic room, and a small glass annex for experiments in plant physiology and pathology has been erected, together with a range of greenhouses, the total cost being about $8,000. F. J. Chittenden has been appointed director.

Agricultural Work in Portuguese East Africa.—E. C. Heron, formerly engaged in experimental work in Australia and the Transvaal, has been appointed bacteriologist in the department of agriculture of Portuguese East Africa, and T. R. Sim, ex-conservator of forests of Natal, has been temporarily engaged to study the forests of the Inhambane and Zambesi districts. Laws have recently been enacted regulating the importation of plants and animals, and measures are in operation in the southern half of the country for the eradication of the cattle diseases which have seriously restricted the agricultural development of the region.

Italian Colleges of Agriculture.—A recent number of *Cornell Countryman* contains an interesting interview with Professor John Craig, in which he describes the five colleges of agriculture in Italy, located respectively at Portici, near Naples, Perugia, Pisa, Bologna, and Milan. Two of these institutions are under the direction of the State Department of Public Instruction and three under the Department of Agriculture. The entrance requirements to the colleges of agriculture are the same as to the universities. The enrollment of students is relatively small, not more than 150 students being in attendance at any institution. These students belong to two classes, the sons of landholders who wish to prepare themselves to manage their estates and those who are preparing to teach agriculture.

New Agricultural School in Venezuela.—The President of the State of Zulia has authorized the establishment of the first school of agriculture in the State to be located at Maracaibo. It will receive an appropriation of about $78 a month and be under the supervision of the Association for the Improvement of Agriculture and Live Stock.

A Home and Colonial Training School for Women.—*Farm Life* for January 2, 1909, contains a description of the equipment and course of study of Arlesey College, Bedfordshire, England, which was opened at the beginning of 1908, with Miss Turner as principal. The full course of training extends over two

years, and includes housework in all its branches, the care of bees, pigs, and poultry, and simple gardening. During the first six months of the course students do the cooking the first week, the housework the second, and the third they go into the garden. Then they can go outside and specialize or work in the house entirely. Not more than 8 students, between the ages of 18 and 30, are received for training at one time.

Withdrawal of Phosphate Lands from Entry.—Following an estimate at a recent meeting of the National Conservation Commission by the Geological Survey that at the present rate of production the known available supply of high-grade phosphate rock will last only about 50 years longer, about 7,500 square miles of public lands in Wyoming, Idaho, and Utah believed to contain phosphate deposits were on December 10 withdrawn from entry by the Secretary of the Interior. It is expected that a further examination of these lands will be undertaken by the Geological Survey as soon as possible, looking toward their careful classification and the restoration to agricultural entry of such portions as are found to contain no phosphates.

New Journals.—*The Porto Rico Horticultural News* is being issued as the official organ of the Porto Rico Horticultural Society. Among the associate editors is D. W. May, Director of the Porto Rico Station, and a recent number includes articles by M. J. Iorns and H. C. Henricksen of the station staff.

Boletin de la Union Agricola de Chiapas has been established as the monthly official organ of the Agricultural Union of Chiapas, Mexico.

The initial number of *Mitteilungen des Kaiser Wilhelms Instituts für Landwirtschaft in Bromberg* has been issued and contains an extended report by the plant pathologist of the institute on plant diseases and insect pests in Posen and West Prussia during 1907, together with several shorter communications. It is expected to issue from 4 to 6 numbers of the publication annually.

The Journal of Industrial and Engineering Chemistry is being published as a monthly by the American Chemical Society, with W. D. Richardson as editor. The initial number contains editorials, original articles and brief notes on topics of interest to industrial chemistry, quotations, book reviews, notes of the meetings of scientific societies, trade and industrial notes, and official regulations and rulings.

The Journal of Home Economics has been established as the organ of the American Home Economics Association with its secretary as editor. For the present five numbers a year are to be issued. The initial number contains an account of the formation and purpose of the association; a report of the proceedings of the first convention and of the meeting of the teaching section of the Lake Placid Conference which preceded it; papers on Cost of Board on Minnesota Farms, by T. P. Cooper; Domestic Art Subject-Matter for Secondary Schools, by Anna M. Cooley; Training of Dietitians for Hospitals, by Florence R. Corbett; The Dietitian in Tubercular Sanitoria, by H. M. King; and The Visiting Dietitian, by W. S. Gibbs; notes on illustrative material for domestic science and on domestic-science teaching in New York City schools; brief reviews of books and other literature; miscellaneous notes; the constitution of the association; and a list of the original members.

The Pacific Rural Press of December 19, 1908, announces the opening early in December of the Imperial Valley Collegiate Institute at Heber, Cal. Agriculture is to be one of the prominent departments of the Institute and has been placed in charge of Charles J. Booth, a 1908 graduate of the California University.

Abstracts of English Experimental Work in Agriculture.—Beginning with the September number, the *Journal of the Board of Agriculture* is including each month brief summaries of experimental work recently reported by the agri-

cultural colleges, agricultural societies, and other agricultural research organizations of England, Scotland, and Wales. It is planned to group these abstracts so far as possible by subjects, the September number reporting experiments with cereals and the October number experiments conducted during the last 2 years with root crops.

Chemiker Zeitung.—Attention is called to the fact that beginning with the thirty-third year, this journal of scientific, industrial, and commercial chemistry will be issued three times a week instead of semiweekly as heretofore. This has been rendered necessary by the rapid accumulation of information bearing upon the relation of science to industry, no small feature of which, as shown by the pages of the *Chemiker Zeitung*, is due to the application of chemical science to agriculture.

Miscellaneous.—Dr. G. Karsten, custodian of the Botanic Garden at Bonn, has been chosen as successor to the late Dr. F. Noll, Director of the Botanic Garden and Institute of Halle.

About 1,200 persons attended the lectures and discussions offered during farmers' week, January 25–30, at the St. Lawrence School of Agriculture, Canton, N. Y.

The Tenth International Conference of Sheep Breeders will be held June 21 in Gloucester, England. The subject for discussion, How Can We Improve the Sheep Industry? will be opened by George McKerrow, of Wisconsin.

The New York Botanical Garden has begun the issuing of a mycological journal to which the name *Mycologia* is given, volume 1, No. 1 appearing in January, 1909. It is issued under the editorship of W. A. Murrill, with a staff of associate editors, and is in continuation of the *Journal of Mycology*, published by the late Dr. W. A. Kellerman. The first number contains papers on Illustrations of Fungi, The Boletaceæ of North America, Notes on North American Hypocreales, A Bacterial Disease of the Peach, and The Problems of North American Lichenology.

Sir Daniel Morris, who retired from the office of Commissioner of the Imperial Department of Agriculture for the West Indies on November 30, 1908, has been appointed to the newly created office of scientific adviser to the Secretary of State for the Colonies in matters pertaining to agriculture in the British tropical possessions. Sir Daniel Morris organized the Department of Agriculture of the West Indies in 1898, utilizing for this purpose the various educational agencies already in existence in the islands, but also introducing and training a number of young university science graduates in the work of the department. Among the most notable of the achievements of the department under his administration were the inauguration and holding of annual or biennial conferences and the reestablishment of the cotton industry, which had almost been extinct in the West Indies for about 100 years. The honor of knighthood was conferred upon him in 1903 in recognition of his valuable services as commissioner of agriculture.

EXPERIMENT STATION RECORD.

VOL. XX. MARCH, 1909. No. 8.

With the rapid extension and development of research agencies in agricultural experimentation there has come about a remarkable increase in both the number and the importance of the publications to be reviewed. Thus, during the last fiscal year the scientific publications of the State experiment stations and this Department alone increased 10 per cent in number. It is believed that there has been a corresponding increase in agricultural literature from other sources, and in addition the adoption by the Office of methods whereby there has been a more systematic examination of the foreign literature has tended to bring to light a number of articles of value from obscure sources not hitherto accessible. The abstracts of the literature have thus rapidly accumulated, while at the same time various circumstances have operated to delay their publication.

In order to provide for the publication of this accumulated material it is proposed to include in the current volume (XX) of the Record two numbers composed almost wholly of abstracts. The present number (No. 8) is the first of these abstract numbers. The second will probably be issued about the close of the present fiscal year and will constitute No. 12 of the current volume. This will terminate the volume, thereby securing conformity with the fiscal year instead of closing with the August number as heretofore.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

A short and accurate method for the estimation of iron, alumina, and phosphoric acid when occurring together, T. Cooksey (*Jour. and Proc. Roy. Soc. N. S. Wales, 41 (1907), pp. 163–171; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 533, II, pp. 987, 988*).—A combination of well-known volumetric methods is employed as follows:

"To the solution, which must be sufficiently acid to produce a yellow color and not a reddish one with the iron present, is added a definite quantity of a standard solution of sodic dihydric phosphate. In case the original solution is too strongly acid, this can be partially neutralized by caustic potash or by evaporation; and it is convenient to work with 20 or 30 cc. of solution containing not more than 0.1 gm. of the mixed oxids. With this amount of liquid, the precipitation can be conveniently carried out in a 100 cc. flask. Caustic potash of decinormal strength is gradually run in under constant shaking until the pink tint with methyl orange has just disappeared. The volume is made up to 80 or 90 cc. and warmed for a short time on the water bath. This heating causes the precipitate to coagulate and quickly settle. The precipitate is now filtered off and well washed with hot water until the filtrate gives no cloudiness with silver nitrate when tested for chlorids, assuming them to be present. A few more washings after this stage is arrived at, thoroughly stirring up the precipitate on the filter, are then sufficient. The filtrate and washings together will then make 200 or 250 cc. Calcium chlorid in excess is added, the whole made slightly acid to methyl orange by a few drops of decinormal hydrochloric or sulphuric acid, and boiled to get rid of any carbonic acid. The procedure is the same as that previously described. The precipitated phosphates are dried, and can be removed from filter paper, the latter burnt off in platinum crucible at low temperature and the remainder of precipitate added. The whole is then heated by Bunsen burner to constant weight. It is perhaps advisable not to raise to too high a temperature. The iron can be separately estimated either in the original solution or by dissolving up the phosphates with a few drops of strong hydrochloric acid and making use of the iodin and thiosulphate method.

"We have now the weight of the total iron and aluminum phosphates, the amount of iron, and the amount of phosphate left in solution. The amount of iron phosphate corresponding to the oxid of iron found, is subtracted from the total weight of phosphates, the difference gives the aluminum phosphate. By subtracting the known quantity of phosphoric acid added from the sum of the three amounts of phosphoric acid found, that is, that combined with the iron, that combined with the alumina, and the amount left in filtrate, we obtain the original phosphoric acid in solution."

Qualitative analysis of phosphates and other salts soluble in acid media, H. Caron and D. Raquet (*Ann. Chim. Analyt., 13 (1908), No. 10, pp. 373–378*).—A systematic plan of procedure is described.

The determination of phosphoric acid by the Pemberton method, G. H. G. LAGERS (*Ztschr. Analyt. Chem., 47 (1908), No. 9–10, pp. 561–571; abs. in Chem. Zentbl., 1908, II, No. 16, pp. 1379, 1380*).—Comparisons of the gravimetric method with the original Pemberton method and the Pemberton method modified by the addition of about 0.58 mg. of sulphuric acid are reported. The unmodified method gave uniformly high results. The modification gave results closely agreeing with those obtained by gravimetric analysis.

The direct determination of phosphoric acid as ammonium phosphomolybdate, E. RABEN (*Ztschr. Analyt. Chem., 47 (1908), No. 9–10, p. 546; abs. in Chem. Zentbl., 1908, II, No. 16, p. 1379; Jour. Chem. Soc. [London], 94 (1908), No. 552, II, p. 896; Chem. Ztg., 32 (1908), No. 97, Repert., p. 630*).—Results are reported which show that phosphoric acid may be quite accurately determined by precipitating with ammonium molybdate according to Woy's method, removing the ammonium nitrate by washing a few times with warm 70 per cent alcohol, once with strong alcohol, and finally with a few cubic centimeters of ether, and weighing the dried precipitate.

The quick colorimetric determination of small amounts of water-soluble phosphoric acid, I. POUGET and D. CHOUCHAK (*Bul. Soc. Chim. France, 4. ser., 5 (1909), No. 3, pp. 104–109; Chem. Ztg., 32 (1908), No. 70, p. 832; abs. in Analyst, 33 (1908), No. 392, p. 441*).—The method is based upon the intensity of cloudiness produced in nitric acid (7 to 8 per cent) solution of phosphates by the addition of strychnin of known strength.

Titration of phosphoric acid in the presence of chlorids, V. BOULEZ (*Chem. Ztg., 32 (1908), No. 67, p. 796; abs. in Chem. Abs., 2 (1908), No. 21, p. 2917*).—The author claims priority for discovery of a volumetric method for the determination of phosphoric acid in the presence of strong alcohol and chlorids.

A simple method of determining caustic lime, M. PÖPEL (*Ztschr. Angew. Chem., 21 (1908), No. 40, p. 2080; abs. in Chem. Ztg., 32 (1908), No. 89, Repert., p. 573*).—A method based on distillation with ammonium chlorid, collection in acid of the ammonia driven off, and titration is recommended. After the air is driven off carbon dioxid may be determined in the residue by adding hydrochloric acid.

On the determination of caustic lime, R. NOWICKI (*Ztschr. Angew. Chem., 21 (1908), No. 45, p. 2318*).—It is pointed out that the method proposed by Pöpel and noted above is inaccurate because it is based upon the assumption of the indifference of calcium carbonate to ammonium chlorid solution, whereas a very large proportion of the ammonia in ammonium chlorid is shown by the author's experiments to be driven off when the latter is boiled with calcium carbonate.

Methods of water analysis, J. H. BREWSTER (*Municipal Engin., 35 (1908), No. 3, pp. 162–167*).—This paper explains briefly the possibilities and limitations of analysis and sanitary survey in judging of the sanitary quality of waters, and indicates the most reliable methods which have been proposed for this purpose.

The determination of oxygen consumed in waters, E. M. CHAMOT (*Amer. Jour. Pub. Hyg., 18 (1903), No. 3, pp. 280–284*).—The procedure used in the laboratory of sanitary chemistry of Cornell University is described as follows:

"Two hundred cubic centimeters of the sample are placed in a 400 cc. Erlenmeyer flask; 10 cc. of dilute sulphuric acid (1:4) added and from a burette standard potassium permanganate (1 cc.=0.0001 gm. available oxygen) introduced very slowly, drop by drop. As soon as a permanent pink color results the burette reading is recorded, and the flask allowed to stand a few minutes so as to note whether decolorization will take place. The standard permanganate is again added until the total volume introduced is equal to 10 cc.; the

flask is then placed over a Bunsen or ring burner (best if heated over the free flame) and brought as rapidly as possible to a boil. The boiling is continued for exactly five minutes, the flask removed, allowed to stand for one minute, the excess of permanganate carefully destroyed by standard oxalic acid solution (1 cc.=1 cc. permanganate) and the permanganate again added until a trace of pink appears and persists for one minute. From the total volume of permanganate the volume of oxalic acid used is deducted.

"In order that the results obtained may always be comparable an excess of at least 2 cc. must at all times remain."

Examinations of a large number of samples of water by this method indicate that oxygen consumption is of little value in judging highly colored surface waters. With ground waters which are colorless or nearly so there appears to be a somewhat close relation between high oxygen consumed and high bacterial flora and vice versa. Five minutes' boiling is thought to be sufficient to decompose all easily oxidizable organic matter, and this is believed to be all that is necessary to determine in such analysis.

New methods of analysis (*Mem. Dir. Fomento [Peru], 1907–8, vol. 1, pp. 80–88*).—Methods used in the analysis of guanos and soils are briefly described.

Further notes on humus acids, A. J. Van Schermbeek (*Jour. Prakt. Chem., n. ser., 78 (1908), No. 17–18, pp. 285–288*).—The author reiterates his criticisms of the Tacke-Süchting method (E. S. R., 20, p. 308).

The isolation of dihydroxystearic acid from soils, O. Schreiner and E. C. Shorey (*Jour. Amer. Chem. Soc., 30 (1908), No. 10, pp. 1599–1607, pl. 1*).—The methods employed in isolating this body are described and tests of its toxicity in experiments with wheat seedlings are reported. It was found that the toxicity of the substance was "as great in a concentration of 100 parts per million as in a concentration of 200 parts per million, which is approximately a saturated solution, and the toxic effect is marked even when the concentration is as low as 20 parts per million."

Organic chemistry for advanced students, J. B. Cohen (*New York and London, 1907, pp. VIII+632*).—Chemical theories and other related topics are discussed in this volume. Special interest for students of nutrition attaches to the chapters on carbohydrates, fermentation and enzym action, the purin group, and the proteids, which summarize the more important work which has been done and the theories at present held.

Physiological chemistry, W. D. Halliburton (*Ann. Rpts. Prog. Chem. [London], 4 (1907), pp. 226–260*).—A critical summary and review of investigations reported on the chemistry of proteids and other questions of physiological chemistry.

Hydrolysis of vicilin from the pea, T. B. Osborne and F. W. Heyl (*Jour. Biol. Chem., 5 (1908), No. 2–3, pp. 187–195*).—The results of hydrolysis of vicilin are very similar to those obtained with legumin, the most marked difference being that vicilin yielded no glycocoll. Less alanin and arginin and more glutaminic acid were also found than in legumin. "It is probable that vicilin is a distinct protein or mixture of proteins and not an altered product of legumin, for the seeds of the vetch which contain legumin yield no vicilin."

Hydrolysis of legumelin from the pea, T. B. Osborne and F. W. Heyl (*Jour. Biol. Chem., 5 (1908), No. 2–3, pp. 197–205*).—The products obtained by the hydrolysis of legumelin from the pea (*Pisum sativum*) were studied in comparison with other pea proteids and leucosin of wheat.

"The results of this hydrolysis show legumelin to be distinctly different in constitution from the other proteins with which it is associated in the pea. The properties and ultimate composition of legumelin closely resemble those of leucosin from the wheat embryo, and this resemblance extends not only to the

general proportion of the several amino-acids, but also to the total quantity obtained from each of these albumins. . . .

"It is not improbable that legumelin is a constituent of the physiologically active tissues of the seed, rather than a reserve food substance for the developing seedling.

"This supposition in regard to leucosin is supported by the fact that this albumin is located almost entirely in the embryo of the seed and that it resembles more closely, both in properties and composition, the proteins of physiologically active tissues of animals, than those which unquestionably form the reserve food protein of the endosperm of other seeds.

"As the leguminous seeds do not contain a sharply differentiated embryo and endosperm, but are composed of tissues which combine the functions of both, it is not possible to locate any one of their proteins in any particular part of these seeds. The just-mentioned similarity, however, of legumelin to leucosin is suggestive of similarity also in their physiological functions."

On the influence of temperature upon the solubility of casein in alkaline solutions, T. B. Robertson (*Jour. Biol. Chem., 5 (1908), No. 2–3, pp. 147–154*).—The author has continued his researches on the chemical properties of casein (E. S. R., 18, p. 873).

"The solubility of the casein in alkaline solutions is considerably augmented by carrying out the process of solution at temperatures above 40° C.

"It is pointed out that this fact is not in harmony with the view that a rise in temperature increases the degree of hydrolytic dissociation of solutions of the caseinates.

"In explanation of this fact and of the increase in alkalinity and electrical conductivity of caseinate solutions upon heating, which were observed by Osborne, it is suggested that the influence of heat upon proteins consists, among other effects, in shifting equilibria of the type: $HXOH+HXOH \rightleftarrows HXXOH+H_2O$ in the direction of higher complexes, and that heat coagulation is a result of repeated condensations of this type.

"The solubility of casein in solutions of various concentrations of potassium hydroxid, lithium hydroxid, and calcium hydroxid at various temperatures has been determined."

The establishment of the equivalent weight of casein and a new method for its estimation, G. T. Matthaiopoulos (*Ztschr. Analyt. Chem., 47 (1908), No. 8, pp. 492–501; abs. in Analyst, 33 (1908), No. 390, pp. 365, 366*).—The author's method is based on the fact that casein behaves like an acid toward phenolphthalein. Dilute sulphuric acid is added to milk until the casein is coagulated. The filtrate is titrated with sodium hydroxid and its amount compared with the amount required when the casein is not removed. Using this method the author has determined the equivalent weight of casein to be 1,131.5.

Medico-legal studies of starch by means of polarized light, M. Herman (*Bul. Soc. Chim. Belg., 22 (1908), No. 8–9, pp. 340–342*).—The author discusses the importance of this method of analysis.

The determination of pepsin with the report of a new method, E. Fuld and L. A. Levison (*Amer. Med., n. ser., 3 (1908), No. 2, p. 57–63*).—The titration method for estimating pepsin, which the authors propose, involves the use of a 1 per cent solution of edestin in dilute hydrochloric acid. The application of the method to problems of theoretical and practical interest is discussed and from the data presented the authors conclude that the method gives more satisfactory results than the older methods and is to be recommended for exact work.

The estimation of fat in dry milks, B. G. McLellan (*Analyst, 33 (1908), No. 390, pp. 353–356; abs. in Jour. Soc. Chem. Indus., 27 (1908), No. 18, p. 954*).—"The fat may be completely extracted by means of ethylic ether of specific gravity 0.720 if 5 gm. of the sample be placed in a cartridge in a Soxhlet apparatus, allowed to soak over night in the solvent, extracted during the whole of the next day, again soaked in the solvent over the following night, and extracted an hour or two the next day."

The estimation of fat in dry milks, H. Droop-Richmond (*Analyst, 33 (1908), No. 391, pp. 389, 390*).—A discussion of the Werner-Schmid and the Röse-Gottlieb methods. The author modifies both methods "by extracting the whole of the fat by successive treatment with solvents rather than to take an aliquot part for evaporation and weighing, as this avoids one source of error." The method is given in detail.

A new method for milk testing, W. M. Doherty (*Analyst, 33 (1908), No. 388, pp. 273–275*).—To see if any relation existed between the ash and other milk solids, the author compared the amount of phosphoric acid with the other solids. The phosphoric acid is fairly constant and does not follow proportionally the amount of solids-not-fat. "Beginning from the milk ash properly incinerated the phosphoric acid may be estimated in 10 minutes or even less. . . . In no case, using the phosphoric acid method, did actual watering escape detection. . . . It would appear that the phosphoric acid method is capable of indicating results nearer the truth than those obtained by the determination of the solids-not-fat."

The detection of watered milk by means of the refractometer, C. Mai and S. Rothenfusser (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 1–2, pp. 7–19; abs. in Rev. Gén. Lait, 7 (1908), No. 6, p. 138*).—This is a review of previous investigations and an account of the results obtained by the authors' use of Ackermann's method (E. S. R., 18, p. 811). From the examination of 5,000 samples the authors believe that the refractometer is a reliable instrument for detecting the adulteration of milk, and they have prepared a table by which the percentage of watering may be estimated from the amount of refraction. Normal milk has a refraction number of 39. If a sample is 36.5 or less it is proof of adulteration. Milk containing 50 per cent of water had a refraction number of 30.9. The percentage of fat does not affect the refractive power, neither does the addition of formaldehyde.

A simple colorimetric method for the determination of formalin in milk, E. W. T. Jones (*Chem. News, 98 (1908), No. 2556, p. 247; abs. in Analyst, 34 (1909), No. 394, pp. 22, 23*).—The author describes a method by which he has obtained satisfactory results. The operation can be performed in an hour or less, and requires only 10 cc. of milk. The reagent used is prepared from iron wire dissolved in hydrochloric acid, oxidized with nitric acid, and precipitated with ammonia.

The limits of experimental error in estimating the amount of moisture in butter, A. Schoonjans (*Bul. Soc. Chim. Belg., 22 (1908), No. 8–9, pp. 342–360*).—Since the maximum moisture content of butter is fixed by law in some countries a rapid and accurate method is an important consideration. The methods of Wauters (E. S. R., 18, p. 873) and other investigators, and also the official methods of European countries, are reviewed.

The author evaporated butter under different conditions. In a sample of butter placed in a paper-covered beaker and heated in an oven in boiling water, the moisture content was estimated at 16.81 per cent. In another sample of the same butter 18.15 per cent of moisture was obtained in an uncovered beaker heated in an oven in air at 115° C. This indicated that exact values were not attained.

The detection of benzoic acid in butter, G. Halphen (*Ann. Chim. Analyt., 13 (1908), No. 10, pp. 382–384; abs. in Analyst, 33 (1908), No. 392, p. 420*).—The author gives the details of a method for detecting benzoic acid in butter even when present in small quantities. It is based on the formation of ammonium diaminobenzoate, which gives a brownish red coloration in an alkaline solution.

The unsaponifiable constituents of cocoanut fat and its detection in admixture with butter, H. Matthes and E. Ackerman (*Ber. Deut. Chem. Gesell., 41 (1908), No. 10, pp. 2000, 2001; abs. in Analyst, 33 (1908), No. 390, p. 357*).—The authors have found that cocoanut fat contains in addition to ordinary phytosterol a second phytosterol. This gives similar color reactions but yields an acetate which combines with 2 molecules of bromin, forming a sparingly soluble tetrabromid which is characteristic. Cholesterol in butter does not form an acetate tetrabromid, hence this reaction is suggested as a direct method for detecting the presence of vegetable fat as an adulterant.

Microscopic examination of powdered cocoa and chocolate, E. Collin (*Jour. Pharm. et. Chim., 6. ser., 28 (1908), No. 7, pp. 295–303, fig. 1*).—The microscopic structure of the anatomical elements of cocoa and chocolate is discussed and illustrated with a view to facilitating the judging of the character of such goods by microscopic methods.

Detection of vegetable albumin in sausage, A. Beihe (*Ber. Chem. Untersuch. Amt. Chemnitz, 1907, p. 14; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 6, p. 360*).—According to the analytical data reported vegetable proteid materials have characteristic forms and the presence of such material may be detected with the microscope.

The detection of plant protein in sausage, A. Schmid (*Jahresber. Thurgauischen Kanton. Lab., 1907, p. 7; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 6, p. 360*).—The examination of a number of sorts of sausage did not indicate the presence of vegetable albumin.

The estimation of saltpeter in sausage meat and ham, H. Kreis (*Ber. Chem. Lab. Basel, 1907, pp. 20, 21; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 6, p. 360*).—Analytical data are reported.

Normal occurrence of citric acid in wines, E. Dupont (*Ann. Chim. Analyt., 13 (1908), No. 9, pp. 338–343*).—A summary and discussion of the author's investigations on the occurrence of citric acid in wines.

The natural citric acid content of wines, E. Dupont (*Rev. Vit., 30 (1908), Nos. 765, pp. 173–177; 766, pp. 203–207*).—A report of the examination of a number of wines which showed the presence of citric acid in certain samples.

Citric acid in natural wines, M. H. Astruc (*Ann. Chim. Analyt., 13 (1908), No. 6, pp. 224–226*).—A contribution to the question of the natural occurrence of citric acid in wine.

Citric acid in natural wines, M. G. Deniges (*Ann. Chim. Analyt., 13 (1908), No. 6, pp. 226, 227*).—The author claims priority in the identification of citric acid as a constituent of certain wines.

New method for determining fixed and volatile acid in wine, M. E. Pozzi-Escot (*Bul. Soc. Chim. Belg., 22 (1908), Nos. 8–9, pp. 338–340*).—Noted from another source (E. S. R., 20, p. 612).

The indirect determination of the acidity of wine, G. Favrel (*Ann. Chim. Analyt., 13 (1908), No. 9, pp. 343–346*).—A study of methods.

The determination of succinic acid in wine and fermented liquors in the presence of fixed acids, M. E. Pozzi-Escot (*Bul. Assoc. Chim. Sucr. et Distill., 26 (1908), No. 3, pp. 185, 186; Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 14, pp. 600, 601; Ann. Chim. Analyt., 13 (1908), No. 11, pp. 439, 440; abs. in Chem. Zentbl., 1908, II, Nos. 10, p. 912; 18, p. 1541; Jour. Soc. Chem. Indus.,*

27 (1908), No. 21, p. 1078).—The author proposes a rapid method of estimating succinic acid by precipitation with bromid of barium after the other substances have been removed by various reagents.

Physicochemical analysis of wine, P. Dutoit and M. Duboux (*Ann. Chim. Analyt., 13 (1908), Nos. 11, pp. 417–427, figs. 5; 12, pp. 461–468, figs. 4; Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 2, pp. 134–137; abs. in Jour. Soc. Chem. Indus., 27 (1908), No. 16, p. 871*).—By adding a solution of barium hydroxid in small portions to wine, and determining the electrical conductivity after each addition, it is possible to estimate consecutively the sulphates, total acidity, and tannin substances.

The estimation of volatile bases in wine, P. Dutoit and M. Duboux (*Schweiz. Wchnschr. Chem. u. Pharm., 46 (1908), No. 44, pp. 703–706, fig. 1*).—The results of gravimetric and volumetric estimation of ammonia in wine do not agree, the discrepancies being ascribed to the presence of organic bases. The authors have continued the physicochemical methods noted above for the estimation of ammonia and organic volatile bases.

Notes on essential oils, F. Watts and H. A. Tempany (*West Indian Bul., 9 (1908), No. 3, pp. 265–277, dyms. 2*).—In this article are described the characteristics of oils obtained from lemon grass, bay leaves, and camphor, with remarks on their distillation. A simple form of still is described and illustrated. Chemical analyses are given.

Oil of orange, E. Dowzard (*Amer. Jour. Pharm., 80 (1908), No. 10, pp. 474–476*).—The specific gravity and other constants were determined in 17 samples of normal and adulterated sweet orange oil.

"It is customary to report the rotation of orange oil at 20° C. It is not, however, necessary to determine the rotation at this temperature, as by using the above corrections the constant may be determined at any temperature between 10° and 30° C.

"Owing to the high rotatory power of orange oil, sophistications such as turpentine and lemon oil are easily detected. In doubtful cases the oil should be distilled and the rotation of the first 10 per cent of the distillate determined. The rotation should be not at all or only slightly lower than that of the original oil. . . .

"The common adulterants of orange oil are turpentine, lemon oil, terpenes of lemon and orange oils, and alcohol. All lower the rotation except orange oil terpenes. Alcohol may be detected by shaking a known volume of the sample with water. The alcohol is removed by the water, which of course is increased in volume. Resin has been used as an adulterant and may be detected by a residue determination. The residue on evaporation of pure oil is from 2 to 4 per cent."

Per cent tables for oil in cotton-seed products, C. H. Herty (*Chapel Hill, N. C., 1908, pp. 50*).—A rapid and simple method for obtaining the oil content is described. It is stated that by its use and that of the tables prepared the oil content of cotton seed can be estimated in 30 minutes.

Carrotene from carrots and the substances which accompany it, H. Euler and E. Nordenson (*Ztschr. Physiol. Chem., 56 (1908), pp. 223–235; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 550, II, p. 724*).—From 23 kg. carrots 0.7 gm. carrotene and xanthophyll were separated, as well as 13 gm. phosphatids, lecithin, etc., and 3.5 gm. of an unknown oil, 0.5 gm. daucosterol, and 1.3 gm. phylosterol.

A note on the analysis of cutch and the preparation of pure catechin, P. Singh (*Indian Forest Mem., 1 (1908), No. 1, Chem. Ser., pp. 20, pls. 6*).—Consideration is given to the chemistry of cutch and catechin with special reference to the methods of extracting catechin from cutch. The methods of analysis are

discussed and attention drawn to the importance of entirely freeing cutch from catechin and removing all traces of tannin from the latter. A method devised by the author for the entire isolation of pure tannin-free catechin is described and discussed.

The technique of the chemical examination of human feces, F. Oefele (*Technik der Chemischen Untersuchung des Menschlichen Kotes. Leipsic, 1908, pp. 103*).—The systematic examination of the feces by physical, microscopic, and chemical methods is described in this volume, which is designed as a handbook and laboratory guide.

The precipitation and the quantitative determination of creatin in urine by means of picric acid, M. Barberio (*Rend. Soc. Chim. Roma, 6 (1908), No. 10, pp. 158–160*).—A study of methods.

Analyses of wines (*Ann. R. Staz. Agr. Forlì, 1907, No. 36, pp. 13, 14.*)—Analyses of a number of samples of wine are reported and data summarized regarding a number of wines, feeding stuffs, and other materials analyzed.

Report of the analyst [for the year ending November 30, 1907], H. C. Lythgoe (*Ann. Rpt. Bd. Health Mass., 39 (1907), pp. 359–386*).—This report contains analyses and other data relative to milk and milk products, cider, maple products, meats, pickles, and various other substances.

Report on the work of the agricultural chemical control station of Saxony, 1907, H. C. Müller (*Ber. Agr. Chem. Kontrollstat. Halle, 1907, pp. 56*).—During the year 38,821 samples were examined, including 23,031 samples of milk and milk products, 7,932 samples of fertilizer, 4,808 samples of seeds, and 2,036 samples of feeding stuffs, besides many other substances.

Miscellaneous analyses, J. C. Brunnich (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1907–8, pp. 68–71, 78–83*).—Analyses are reported of butter, milk, whey, cheese, parchment papers, waters, dipping fluids, grasses, and forage plants.

[Miscellaneous analyses], 1907, K. Rördam (*Tidsskr. Landökonom., 1908, No. 3, pp. 145–162*).—A report of the chemist of the Royal Danish Agricultural Society, which contains analyses of butter and oleomargarine, feeding stuffs, artificial fertilizers, and soils, as made for members of the society.

[Miscellaneous analyses], C. F. Juritz (*Rpt. Senior Anal. Cape Good Hope, 1907, pp. 88–104*).—Analyses of "vacca melk," "lacvitum" (a dried milk), wines, water, and sheep and cattle dips.

METEOROLOGY—WATER.

Meteorological observations by farmers, Grohmann (*Illus. Landw. Ztg., 28 (1908), No. 82, pp. 709, 710, fig. 1*).—Brief directions for the simpler observations are given.

Sunspots and weather predictions (*Rev. Gén. Agron., n. scr., 3 (1908), No. 9, pp. 343–346*).—The results of observations bearing on this subject are briefly summarized in this article. These indicate in general that while there is apparently a relation between sunspots and weather conditions on the earth, this fact has not yet been made of much importance in weather forecasting.

On the accumulation and consumption of soil moisture in river plains, E. Oppokov (*Sur l'Accumulation et la Consommation de l'Humidité dans le Sol des Bassins des Fleuves de Plaines. St. Petersburg, 1908, pp. 24*).—This study is based on figures showing the amount of precipitation and run-off of the Dnieper at Kiev during 29 years, 1876 to 1905.

The low run-off of wet years following dry years observed in these studies is ascribed to the fact that in dry years the subterranean waters are lowered and in the wet years raised again to the normal level. This restoring of the equilibrium between the subterranean waters and the moisture of the soil is

called "accumulation," and the following equation is given to represent the circulation of water in wet years following dry years: Rainfall—run-off=loss of water by evaporation+accumulation.

Years of drought are usually years of increased temperature and therefore of increased evaporation, and the conclusion is drawn that the difference between rainfall and run-off does not represent the real amount of evaporation, but that some of the water evaporated is drawn from the subterranean waters. Therefore for dry years the equation for circulation of water would be: Rainfall—run-off+consumption=loss of water by evaporation, "consumption" being the term used to denote the amount of water taken from the subterranean supply during years of drought. This consumption of subterranean waters in years of drought is proved by lowering of wells and drying up of marshes during such years. This is due largerly to transpiration by forest growth and other forms of vegetation.

This is confirmed by study of conditions in the upper basin of the Dnieper in the wooded belt of Russia.

The hydrologic influence of forests under such conditions in years of drought is sometimes entirely injurious, for they become the chief agents of evaporation, although in cold and rainy years they may be useful, since they accumulate more water than they expend. On the other hand, the peaty soils of the marshes absorb moisture drained from higher ground and instead of giving it off to the rivers evaporate it into the atmosphere. Then they gradually encroach on the bed of streams and in the end turn them into marshes.

Summarizing his studies, the author therefore concludes that during dry years, often two in succession, there is apparent a considerable consumption of the reserve moisture held in the soil of the basin and expended by evaporation. This expenditure is replaced by the rains of the following year. This consumption and accumulation is often as much as the run-off. The real amount of evaporation is more than the difference between rainfall and run-off in years of drought, but evaporation is not as much as the difference between rainfall and run-off in wet years. The run-off is relatively large in dry years and relatively small in wet years, because of the slowness of the movement of subterranean moisture.

Forests and marshes of the basin may be considered the most serious agents of evaporation in dry years and their influence extends into the years following dry years. It appears that one should estimate the influence of the forests upon the river flow in the zone given, and generally in central Russia, as almost nil under normal meteorological conditions. This influence is almost negative in dry years in the south and central zones, but it may be that it becomes positive in the north and central zones in wet years if the forests are really capable of accumulating more moisture in times of slight evaporation than they expend in their periods of active growth.

The part played by marshes in feeding rivers is negative in dry years, insignificant in normal years, and not as useful in wet years as one might expect. The draining of marshes lessens useless evaporation and helps to increase flow of rivers in summer.

It must be admitted that marshes are not the most serious factors in the feeding of rivers by subterranean waters, but rather the sandy soils, which are perfect carriers of subterranean water, not alone to the rivers but also to the marshes, which have great need of them in dry years.

The rôle of forests, marshes, and other sorts of vegetable coverings consists chiefly in evaporating the water of the basin and acts indirectly on the formation of atmospheric precipitation.

Climatic and soil moisture conditions in the Great Plains area, L. J. Briggs (*Proc. Trans-Missouri Dry Farming Cong., 1908, pp. 194–205, dgm. 1, map 1*).—This paper contains a brief statement of the character of the investigations on the physical conditions of soil and climate in connection with crop production, and gives some of the results which have been recently obtained on experimental farms conducted by this Department in cooperation with State experiment stations in the Great Plains area.

Climate of the city of Buenos Aires (*Yearbook City Buenos Aires, 17 (1907), pp. 3–50, dgms. 13*).—This report contains a brief historical review of observations in Buenos Aires, with compilations of the results of these observations, some of which date back as far as 1805. The data for 1907 include results of observations on pressure, temperature, rainfall, humidity, velocity of the wind, sunshine, and ozone, carbon dioxid, ammonia, and organic nitrogen in the air, as well as bacteriological analyses of the air and determinations of free ammonia, organic nitrogen, and nitrous and nitric acids in the rain water.

The climate of Abbassia near Cairo, B. F. E. Keeling (*Survey Dept., Egypt, Paper No. 3, pp. 61, pls. 8*).—This report summarizes observations made during the 35 years ending in 1903, giving also the mean values for this period. "As far as possible the results have been summarized in the form of tables, the descriptive part being confined within the limits necessary for explaining them. At the end of the report are given summarized climatological tables, on the plan of the model tables given by Hann in his Climatology. . . . For each of the principal meteorological elements are given the necessary corrections to reduce the means deduced from the present readings made three times a day, to the true daily means published before the closing of the observatory as a first-order station.

"Two series of charts are given at the end. The first series shows the annual curves obtained from the monthly means of each of the principal elements, the second shows the mean daily curves."

The weather of Saxony during 1907 (*Jahresber. Landw. Königr. Sachs., 1907, pp. 2–23*).—The weather conditions for the year at a number of places in Saxony are summarized in notes and tables. The mean temperature of the year was about normal, the highest temperature recorded being 31.9° C., August 6, the lowest, —27.3°, January 23. The rainfall was 819 mm. as compared with a normal of 682 mm. The evaporation was 513 mm. The cloudiness (66 per cent) was about normal.

Damage caused by hail in Servia (*Matér. Statis. Roy. Serbie, 1907, No. 7, pp. XXI+98, map 1*).—Detailed data (in Servian and French) regarding damage caused by hail in Servia from 1896 to 1905 are recorded.

Amount and composition of drainage waters collected from drain gages during 1906–7, J. M. Hayman (*Rpt. Cawnpore [India] Agr. Sta., 1907, pp. 57–62, pls. 2; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 552, II, pp. 890, 891*).—Data from June 1 to October 31 are given for rainfall, percolation, and nitrates in drainage water in case of 2 three-foot and 2 six-foot uncropped drain gages built in 1903. Of the 34.38 in. of rainfall 19.2 and 16.7 in., respectively, percolated through the 2 six-foot gages and 18.2 and 19.9 in. through the 2 three-foot gages. Nitrates were removed in the drainage in case of the six-foot gages at the rate of 180.3 and 200.5 lbs. per acre; in case of the three-foot gages at the rate of 66.7 and 85.6 lbs. per acre. For previous work see an earlier note (E. S. R., 18, p. 815).

Variations in the substances contained in natural waters, C. Weigelt and H. Meihring (*Chem. Indus. [Berlin], 31 (1908), No. 15–16, pp. 472–486*).—Numerous analyses of river waters are reported, showing the variation at different periods in mineral matter and oxygen.

Some features of Iowa ground waters, W. S. HENDRIXSON (*Proc. Iowa Acad. Sci., 14 (1907), pp. 187–199*).—The character of these waters is briefly discussed on the basis of chemical analyses of a number of samples from deep and shallow wells. The investigations were made in cooperation with the U. S. Geological Survey.

Methods of sterilizing water by means of permanganate of potash, FERRAUD and G. LAMBERT (*Rev. Hyg. et Pol. Sanit., 30 (1908), No. 7, pp. 553–563*).—The methods of Hy and Lambert are described, and tests of their efficiency are reported. The general conclusions reached are that all reactions which involve the precipitation of manganese oxid in a solution of permanganate may be used as bases for processes for the sterilization of water. The bactericidal action is due solely to the formation of this precipitate. The authors are of the opinion as the result of these and previous experiments that the bactericidal action is a phenomenon of radio-activity.

The Merthyr sewage farms, T. F. HARVEY (*Jour. Roy. Sanit. Inst., 29 (1908), No. 10, pp. 648–655; Surveyor, 34 (1908), No. 862, Sup., pp. 14–16*).—The methods of sewage disposal which have been in use at Merthyr since 1858 are briefly described, but particular attention is given to the present methods of disposal on two sewage farms. The sewage from a city of about 100,000 population is satisfactorily disposed of on these farms by surface irrigation.

"It may be fairly claimed that the working of the Merthyr sewage farm . . . . has been successful, and while the stipulation that 'profit is to be subservient to the proper disposal of sewage' has been strictly adhered to, the pecuniary result has been satisfactory. Taking an average over the last ten years, the yearly general expenditure on all the farms has been £1,914 4s. 9d. [about $9,417] and the yearly revenue £2,744 17s. 4d. [about $13,312.56] showing a profit over and above the working expenses of £802 12s. 7d. [about $3,892.72] per annum."

SOILS—FERTILIZERS.

Studies on soils, A. ATTERBERG (*Landw. Vers. Stat., 69 (1908), No. 1–2, pp. 93–143, figs. 2; abs. in Chem. Ztg., 32 (1908), No. 87, Repert., p. 554; Chem. Abs., 3 (1909), No. 2, pp. 220, 221*).—In continuation of previous investigations (E. S. R., 15, p. 549) the author studied the properties and arrangement of the physical constituents of soils of different types. Among the topics reported upon are the size and methods of separation of different soil constituents; the hygroscopicity of fine sand; the volume, air space, and capillarity of sandy soils; evaporation from sands; the relation of sand to precipitation; percolation in sand; relation of sand to root hairs of plants; the flocculation of fine sand; Brownian motion; the rational classification of sand; and analyses of glacial and alluvial sandy soils.

A modified classification of the sandy particles in soils is proposed. The word sand is confined to the coarse sand of dry sandy soils. The fine sand of better soils is termed "mo." Sand finer than 0.02 mm. in diameter is considered to be clay-like in properties. The word "ler" is used to designate the finest sand and amorphous clayey particles. The more important capillary properties of the sand particles are discussed.

The annual fluctuations of soil temperature in different climates, W. KÜHL (*Der jährliche Gang der Bodentemperatur in verschiedenen Klimaten. Inaug. Diss., Univ. Berlin, 1907, pp. 68, dgms. 4*).—Data from a number of places in Europe, Asia, Australia, and Central America are compiled and analyzed, the yearly fluctuations of soil temperature with reference to air temperature being illustrated in a series of diagrams. A bibliography of 47 references is given.

The temperature of soils and water near Breslau in comparison with the temperature of the air, B. Schulze and H. Mehring (*Fühling's Landw. Ztg., 57 (1908). No. 20, p. 673–678, dgms. 3*).—The results of observations during a series of years (1901–1906) on the temperature of the soil at depths of from 20 to 130 cm., of the water of the Oder River, and of the air are summarized and compared.

The extremes of temperature at each depth were very nearly the same for the 6 years, but decreased in different cases with the depth in the soil. The greater the depth the greater the lag of the soil temperatures behind the air temperatures.

The average annual temperature of the soil at a depth of 20 cm. was 8.7° C., corresponding very closely with that of the air (8.6°) and being about 1° lower than that of the river water. The mean temperature at depths of 40, 70, 100, and 130 cm. was almost the same, 9.2 to 9.4°.

The behavior of the organic matter of soils and the osmotic pressure of the same, J. König, J. Hasenbäumer, and H. Grossmann (*Landw. Vers. Stat., 69 (1908), No. 1–2, pp. 1–91, figs. 5; abs. in Chem. Zentbl., 1908, II, No. 14, pp. 1198, 1199; Chem. Ztg., 32 (1908), No. 86, Repert., p. 548; Jour. Chem. Soc. [London], 94 (1908), No. 552, II, p. 888; Jour. Soc. Chem. Indus., 27 (1908), No. 23, pp. 1166, 1167; Chem. Abs., 3 (1909), No. 2, p. 221*).—In continuation of previous investigations, the authors studied 9 typical soils with reference to their chemical and physical properties and the behavior of the organic matter of the soils under treatment with steam under pressure and when subjected to oxidation by means of hydrogen peroxid.

The methods and apparatus used in these treatments are described and data are given for soil constituents dissolved by treatment with steam and with hydrogen peroxid and for the carbon dioxid evolved in the treatment with the latter substance. The laboratory experiments were supplemented by a series of pot experiments in which treated and untreated soils were used for the growth of barley and oats with and without the addition of fertilizer mixtures of different kinds. The methods used and the results obtained in a series of studies of the osmotic pressure of the soil and of various salts, carbohydrates, etc., are given in detail. The results of the investigations were in brief as follows:

(1) By treatment of soil with steam under pressure the plant food present in the form of complex salts or inorganic matter is brought into solution. While the pressure to be used will depend upon the kind of soil, 5 hours' treatment with steam under a pressure of 5 atmospheres (5 liters of water to 500 gm. of soil) was usually found to be the most effective treatment.

(2) This treatment is capable of showing the larger differences in a content of more easily soluble nutrients, but is not capable of showing the small differences due to the use of fertilizers.

(3) Treatment with hydrogen peroxid renders soluble like but somewhat higher quantities of these plant food constituents, but this method is not capable of indicating slight differences in soluble constituents, as for example, those due to application of fertilizers.

(4) A small proportion of the soil constituents not dissolved out of soils by pure water or by water containing carbon dioxid becomes soluble in water under treatment with steam under pressure in the presence of humus acids or by oxidation. This is thought to indicate that part of the constituents are present in complex or organic combination, as has been found to be the case in moor soils. These constituents, which perhaps are in combination with humus acids, are doubtless important sources of mineral nutrients of plants.

(5) The humus was found to occur in soils in forms which varied in ease of oxidation.

(6) The quantities of plant food constituents dissolved by treatment with steam or by oxidation calculated to a soil depth of 20 cm. and the amounts taken up by plants show a definite relation only in the case of potash, but is so consistent in case of this constituent that treatment with steam seems to be well adapted for the determination of available potash in soils. Apparently potash is also set free during the growth of plants either as a result of decay or of root activity.

(7) The pot experiments showed that the percentage of mineral matter in fertilized plants was usually much smaller than in unmanured plants, probably due to the more rapid growth of the plants. The absorbent power of the soil for water, as well as the use of fertilizers, reduces evaporation, and thus aids the growth of plants by furnishing a more uniform supply of water.

(8) It was found that soils possess a small but decided osmotic pressure, and this furnishes a means of securing valuable information as to the solubility of the soil constituents. Suggestions are made as to the application of measurement of osmotic pressure in the study of soils.

(9) According to the authors' observations very small amounts of soluble salts (a few milligrams in 100 gm. of soil) may be observed by means of osmotic pressure. The osmotic pressure was also found to stand in direct relation to the amount of dry matter in plants grown on the soil.

(10) The amount of water entering the osmometer, which in these experiments consisted of clay tubes and also filter cylinders, depended upon the thickness of the tube and the kind of semipermeable membrane used. Clay filter cylinders which under a pressure of 1½ atmospheres allowed 900 cc. of water to pass through in 10 minutes were found to be most suitable. Such cylinders, provided with a double semipermeable membrane consisting of one side of glue solution and formaldehyde and on the other of potassium ferrocyanid and copper sulphate, furnish a very durable osmometer, which can be used six times if after each test it is washed out and treated (hardened) with formaldehyde.

(11) With filter cylinders of lower permeablity (700 cc. of water in 10 minutes) a slower exchange of solution occurs, but the relationship remains the same between the various salts and the soil if tubes of the same permeability are employed. For comparative purposes it is recommended that substances of known osmotic pressure, as for example, one hundredth-normal ammonium sulphate or one hundredth-normal saccharose, be used.

(12) The method may also be used for the determination of the molecular weights of certain substances since the amount of water entering the osmometer stands in inverse relation to the molecular weight.

The water problem in agriculture, E. J. Russell (*Nature [London]*, *78 (1908)*, *No. 2023, pp. 322, 323*).—Recent reports on soil moisture and its conservation, more particularly that of J. W. Leather on the loss of water from soil during dry weather (E. S. R., 20, p. 214), are briefly reviewed in this article.

The loss of water from soil, C. von Seelhorst (*Jour. Landw., 56 (1908)*, *No. 2, pp. 208, 209; abs. in Chem. Zentbl., 1908, II, No. 7, p. 632*).—It was found that in cylinders recently filled with soil the percolation was greater and evaporation less than in case of cylinders which had been filled for some time.

Studies of soil moisture in the Great Plains region, F. J. Alway (*Jour. Agr. Sci., 2 (1908)*, *No. 4, pp. 333–342*).—These studies were made in connection with a series of investigations which have been noted from time to time (E. S. R., 19, p. 516). The observations reported were made during July, 1904,

and September, 1905, on the Canada Experimental Farm at Indian Head, and at Moose Jaw, Saskatchewan. The samples were taken from foot sections down to a depth of 6 ft. on uniform and mixed soils.

Data are given for total percentage of water, hygroscopic coefficient, and percentage of free water. The conditions on cropped and fallow soils were compared. The results are summarized as follows:

"(1) All determinations of soil moisture should be made to a depth of from 4 to 5 ft. for wheat and oats, and to a depth of 6 or 7 ft. for grasses.

"(2) Unless all the soil under consideration is very uniform, determinations of the hygroscopic coefficient are indispensable. The determination of this value is extremely important even where the soil is uniform.

"(3) The storage capacity for available water of the two soil types studied may be placed at from 5 to 7 in. of rainfall for wheat and oat crops.

"(4) A better idea of the moisture conditions of the soil at Indian Head may be obtained from a casual examination in the field than from the drying and weighing of the samples, unless the hygroscopic coefficient is considered.

"(5) The moisture stored in the subsoil during the previous summer, and not the frost of the preceding winter, is the cause of the high yields of wheat and oats obtained in southern Saskatchewan.

"(6) The soil of southern Saskatchewan does not remain permanently frozen at any depth.

"(7) Investigations of the moisture conditions to a depth of only 12 to 16 in. are of no value and may often be entirely misleading."

Studies on the soils of the northwestern portion of the Great Plains region: Nitrogen and humus, F. J. Alway and R. S. Trumbull (*Amer. Chem. Jour., 40 (1908), No. 2, pp. 147–149*).—In connection with studies of these soils previously reported (E. S. R., 19, p. 516), the authors determined the nitrogen and humus content of 20 samples of soils at different depths from this region. The results in general show "that the surface soil of the semiarid portions of western Canada possesses the characteristics of humid regions, while the subsoil shows the marked peculiarities of the subsoils of other arid regions."

The humus content varied from 0.8 to 2.45 per cent, the total nitrogen from 0.1 to 0.3 per cent. The total nitrogen in form of humus nitrogen varied from 27.3 to 60 per cent, the percentage of nitrogen in humus from 4.08 to 7.14.

A soil survey of seventeen counties of southern Indiana, C. W. Shannon et al. (*Ind. Dept. Geol. and Nat. Resources Ann. Rpt., 32 (1907), pp. 17–298, figs. 30, maps 17*).—This report includes a brief account of the Indiana soil survey as organized under the State department of geology, by C. W. Shannon; a discussion of the chemical composition of Indiana soils, with descriptions of methods of soil analysis used, by R. E. Lyons; descriptions of Indiana soil types, by C. W. Shannon; and accounts of soil surveys of Monroe, Brown, Lawrence, Martin, Orange, Washington, and Jackson counties, by C. W. Shannon and L. C. Snider; of Decatur, Jennings, Jefferson, Ripley, Dearborn, Ohio, and Switzerland counties, by L. C. Ward; and of Clark, Floyd, and Harrison counties by R. W. Ellis.

The survey is conducted on a plan similar to that of the Bureau of Soils of this Department, which has covered 19 counties of the State.

Agricultural soils [of Maryland], W. B. Clark and E. B. Mathews (*Md. Geol. Survey [Rpt.], 6 (1906), pp. 209–223*).—A general description is given of the typical soils of different sections of the State, attention being called particularly to their great diversity.

Canada's fertile northland, edited by E. J. Chambers (*Ottawa: Govt., 1908, pp. 139, pls. 16, maps 5*).—Maps and descriptions are given of "the northern portions of the provinces of Quebec, Ontario, Saskatchewan, Alberta, and

British Columbia, the Yukon Territory, and those vast regions known as the Northwest Territories." The agricultural possibilities of the region are discussed.

On the occurrence of phosphoric acid in buntersandstein and soils of the eastern Black Forest, M. Bräuhäuser (*Mitt. Geol. Abt. K. Württemb. Statis. Landesamts, 1907, No. 4, pp. 22*).—Determinations of phosphoric acid in a large number of samples of sandstone are reported and the bearing of the phosphoric-acid content of the rocks upon the soils derived from them is discussed. While the percentage of phosphoric acid found is quite variable, it is in many cases sufficiently large to account for the large supply of phosphoric acid in soils derived from them.

Soils, H. Ingle (*Transvaal Dept. Agr. Ann. Rpt. 1907, pp. 240–247*).—Analyses of a number of samples of Transvaal soils are reported, the results confirming previous conclusions that as a rule these soils are poor in organic nitrogenous matter, lime, and phosphoric acid, but rich in potash compounds. The presence of ferrous compounds was detected in newly broken soil, especially in case of the black soils, but it is thought that these compounds do not occur in sufficient amounts to be a serious evil. The soils were found to vary considerably in suitability for irrigation, the black soils rich in organic matter and in lime being particularly difficult to handle when first brought under irrigation. The soils rich in lime are also rich in organic matter, while most of the red porous soils examined are remarkably poor in humus.

Analyses of soils, C. F. Juritz (*Rpt. Senior Anal. Cape Good Hope, 1907, pp. 97–102, map 1*).—The more important results obtained from an examination of 69 samples of soils from different parts of Cape of Good Hope are summarized and a detailed study of the soils of the government experiment station at Robertson is reported, with a map showing surface distribution and soil profiles.

On eruptive soils, E. C. J. Mohr (*Bul. Dept. Agr. Indes Néerland., 1908, No. 17, III, pp. 12*).—Under this name are included various kinds of volcanic soils which prevail in Java. Brief descriptions of the formation and character of these soils are given.

Soils of nonsugar districts (*Ann. Rpt. Bur. Sugar Expt. Stas. [Queensland], 1907, pp. 1–3*).—Analyses of samples of typical soils from a number of districts are reported.

The nitrogen compounds of the fundamental rocks, A. D. Hall and N. H. J. Miller (*Jour. Agr. Sci., 2 (1908), No. 4, pp. 343–345*).—The results of determination of carbon and nitrogen in unweathered samples of a number of deep-seated rocks and of nitrates produced by the weathering of the ground rocks are briefly reported and discussed in this article.

The authors conclude "that the nitrogen compounds of the soil are not wholly of recent origin, but have in part been derived from the rock out of which the soil has been formed by weathering. In some of the clay soils the proportion of nitrogen due to the original rock is likely to be considerable, which may account for the comparative infertility of many clay soils which by analysis appear to be rich in nitrogen. Such nitrogen compounds are, however, to some slight extent slowly attacked by bacteria and yield nitrates available to the plant."

On the question of nitrification in the sea, B. L. Issatschenko (*Abs. in Centbl. Bakt. [etc.], 2. Abt., 21 (1908), No. 13–14, p. 430*).—A report is given of the discovery of a nitrifying bacterium from the depths of the Arctic Ocean.

Quantity of nitric nitrogen in soils variously cultivated, C. Montanari (*Staz. Sper. Agr. Ital., 41 (1908), No. 5–6, pp. 209–222*).—The experiments here reported were to determine the amount of nitric nitrogen in the soil during

the growing period of various crops. The crops were wheat, medic, and fall-sown rape followed by corn. Samples of soil were taken from 0 to 10 in. and from 10 to 20 in.

It was observed that the average amount of nitrates found in the case of wheat and of rape and corn was greater in the lower stratum, but with medic, especially in summer and autumn, the average amount was greater in the upper stratum. For all crops named the smallest quantity was found in February, March, and June, and the largest quantity from July to December. The author thinks the greater amount in the upper stratum in the case of medic is due to the fact that the roots of this plant have tubercles which absorb less nitrates in the upper stratum of the soil, while wheat, rape, and corn have abundant absorbing roots near the surface.

Determinations were also made of the nitric nitrogen in the soil moisture with the result that the least was found in March and June and the most in August, that is, at the time when the soil has least moisture.

These experiments were terminated at the end of the third year, so that sufficient data were not obtained to warrant definite conclusions.

White mustard in its relation to nitrogen assimilation. O. Lemmermann and E. Blanck (*Landw. Vers. Stat., 69 (1908), No. 1–2, pp. 145–160*).—The experiments reported were conducted for the purpose of determining more definitely the influence of white mustard on the nitrogen content of the soil. The results and views of different investigators are briefly noted and the authors' own work is described.

The results of soil analyses made showed that during the period of vegetation a soil growing peas had a higher nitrogen content than the same kind of soil growing barley and mustard. It was further found that if during the period of growth any nitrogen assimilation in the soil took place the quantity assimilated in the soil growing mustard was not greater than that in the soil producing barley.

To samples of soil from these different plats weighing 1,000 gm. was added 20 gm. of sugar as a source of energy to the soil bacteria. Analyses of these samples were made 46 and 92 days after this treatment. Analyses of the soils from the different plats without the sugar treatment showed that under the influence of mustard roots no nitrogen increase in the soil had taken place. On the other hand, the samples treated with sugar showed marked differences in the nitrogen assimilated, from which the authors conclude that in all these soils nitrogen-assimilating organisms were present. After 46 days the barley soil showed 1.458 mg. of nitrogen per 100 gm. of soil, the mustard soil 3.232 mg., and the pea soil 16.402 mg. For the 92-day period the figures were 6.886, 9.132, and 14.926 mg., respectively.

Work of the chemical laboratory of the Ploti Experiment Station, 1907. B. Welbel and A. Winkler (*Ghodichnuiĭ Otchet Ploty. Selsk. Khoz. Opuitn. Stantsiĭ, 13 (1907), pp. 105–160, 175–191*).—The work here reported followed in the main the same lines and confirmed in large measure the results of previous investigations (E. S. R., 19, p. 923), but in view of the fact that conditions are more or less abnormal in lysimeters the field studies on nitrification were extended during the year and were supplemented by pot and box experiments on the same soils. This report deals more particularly with the results of studies of nitrification in plats occupied by spring and winter wheat and by fallow. On the spring wheat plats the influence of previous crops of leguminous plants, cereals, or three years' bare fallow was studied, and on the winter wheat plats the influence of different kinds of fallow (black and green) and of farm manure.

The results show in general that the cultural methods commonly found to increase the yield of wheat have in every case increased the activity of nitrification in soils, the different methods of experimenting giving like results in this respect. It was shown in pot experiments that not only the assimilable nitrogen but also the available phosphoric acid was increased by fallow and by the application of manure.

The action of carbon bisulphid and other substances on soils, K. Störmer et al. (*Jahresber. Ver. Angew. Bot., 5 (1907), pp. 113–131+XXXIII–XXXIX*).—In continuation of previous experiments the authors tested the effect on the yield of crops grown in pots of treating the soil with carbon bisulphid, carbon tetrachlorid, chloroform, benzol, toluol, xylol, phenol, o-cresol, m-cresol, p-cresol, alcohol, and ether.

All of these, except p-cresol, alcohol, and ether, decidedly increased the yield of crops following fall application of the substances. Previous experiments had shown that all of the substances increased the yield. An increase of yield apparently occurs whether the substance used is a source of carbonaceous food for soil organisms or not, or whether the soil is "sick" or not. The authors attribute the effect of the substances to their action on the nitrogen and the flora and fauna of the soil. This phase of the subject was studied by the authors in water cultures and pot experiments. In the latter carbon bisulphid was used at the rate of 1.6 gm. per kilogram of soil, carbon tetrachlorid 2.4 gm., benzol 1.6 gm., xylol 1.6 gm., phenol 1.25 gm., and p-cresol 1.25 gm.

The authors' results agree with those of Wagner and Pfeiffer in showing that carbon bisulphid and like substances reduce denitrification and fixation of nitrogen. Nitrification was also retarded at first, but ammonification was not retarded to a like extent and later the ammonia was rapidly nitrified.

On the influence of oxygen on the decomposition of vegetable matter, D. Carbone and R. Marincola-Cattaneo (*Arch. Farmacol. Spr. e Sci. Aff., 7 (1908), Nos. 6, pp. 265–276; 7, pp. 289–301*).—From a detailed technical study of the behavior of different organisms under varying culture conditions with reference to the oxidation of organic matter, the authors confirm the conclusion of Rossi that the Schizomycetes are not as a rule very active agents of decomposition of organic matter. Many active agents of decomposition, however, are found among the Eumycetes. Oxygen seems as a rule essential to the most efficient action of the organisms decomposing organic matter, although the authors' results indicate that it is not possible to divide the agents of decomposition strictly into aerobes and anaerobes. The authors attribute to the higher fungi the more important rôle in the decomposition of organic matter in general, and particularly cellulose, either in the absence, but especially, in the presence of oxygen. They are thus important agents in the formation of humus in the soil.

Notes on the rôle of micro-organisms in modern agriculture, especially in cultivated soils, B. Heinze (*Abs. in Centbl. Bakt. [etc.], 2. Abt., 21 (1908), No. 17–19, p. 543*).—This is a review of present knowledge on various phases of the subject.

Nutrition of nitrogenous bacteria, Helene Krzemieniewska (*Bul. Acad. Sci. Cracovie, 1908, pp. 445–448; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 550, II, p. 722*).—The author's investigations point to the conclusion that potassium salts are essential for the nutrition of nitrogenous bacteria notwithstanding the statement of Gerlach and Vogel to the contrary.

Inoculation experiments with Azotobacter; bacteriological studies in Madison soil; ammonification in culture solutions as affected by soil treatment, J. G. Lipman (*Abs. in Centbl. Bakt. [etc.], 2. Abt., 21 (1908), No. 17–19, pp.

541, 542).—This is the author's abstract of an article in the report of the New Jersey Stations for 1907 (E. S. R., 19, p. 1017).

Legume bacteria. S. F. Edwards and B. Barlow (*Abs. in Centbl. Bakt. [etc.], 2. Abt., 21 (1908), No. 17–19, p. 541*).—This is the authors' abstract of Bulletin 164 of the Ontario Department of Agriculture (E. S. R., 19, p. 1121).

Beneficial bacteria for leguminous crops, G. H. Earp-Thomas (*Proc. N. Y. Farmers, 1907–8, pp. 23–41*).—This article describes various methods which have been employed for the preparation of cultures of the organisms of the root tubercles of leguminous plants, and reports particularly the successful use of cultures prepared by the author's method, in which the attenuated tubercle organism is restored to full vigor by inoculation through a series of young plants in succession. This is substantially a process of selection and results in securing organisms of high virility.

The resistant power of root bacteria of leguminous plants and its importance in soil inoculation, J. Simon (*Jahresber. Ver. Angew. Bot., 5 (1907), pp. 132–160, fig. 1*).—A study of the culture conditions most favorable to the production of active inoculation and nitrogen assimilation is reported. Among the conclusions reached is that for isolation of the organisms gelatin can not be dispensed with, but that for the further growth of the organisms soil and soil extract (with the addition of mannite and grape sugar) is preferable. Carbon bisulphid is a valuable means of restoring the biological equilibrium in soils and of promoting the growth of leguminous plants, but its use on a large scale is impracticable.

Increasing the yield of crops, especially serradella, by inoculation with Nitragin, Westmann and Hiltner (*Jahrb. Deut. Landw. Gesell., 23 (1908), No. 2, pp. 281–308*).—Very beneficial effects from the use of Nitragin, especially on serradella, are reported. Hiltner reports that his experiments show that the addition of nutrient materials at the time of inoculation is not necessary on moor and other humus soils and frequently of no effect on other soils. Of the nutrient substances calcium carbonate is especially effective. Tricalcium phosphate, humus, and milk powder are also effective, while superphosphate and lime nitrogen are decidedly injurious. Mixtures of peptone and grape sugar have often shown their effectiveness, but peptone and cane sugar has frequently proved decidedly more effective.

The new agriculture, W. B. Bottomley (*London, 1908, pp. 15, pl. 1, figs. 6*).—In this article a brief account is given of the results obtained from the use in different parts of the British Isles of the inoculating material distributed by the author, and reference is made to the possibility of using inoculation as a means of increasing the growth of nonleguminous plants. It is stated that a special culture suited to the Tropics has been extensively distributed for test in the West Indies and other tropical possessions of the British Empire, especially with a view to increasing the growth of sugar cane.

The productiveness of the soil, A. Grégoire (*Ann. Gembloux, 18 (1908), No. 8, pp. 455–460*).—In this, the concluding paper of a series of articles on this subject (E. S. R., 19, p. 1015; 20, pp. 16, 217, 314, 521), the author considers briefly three classes of factors which determine the productiveness of soils, namely, (1) factors over which man can exercise no control, (2) factors which are partly under his control, and (3) factors which are entirely under his control.

The author is inclined to Kellner's view that each plant has special needs which are the outcome of its evolution under the conditions of the environment in which it has developed, and therefore soils may be classified according to the plants which they are capable of bringing to normal development. This furnishes a safe basis for the preparation of useful agronomic charts.

On the planting and reclamation of moors and bogs in Belgium, with special reference to the use of artificial manures, A. P. GRENFELL (*Quart. Jour. Forestry, 2 (1908), No. 4, pp. 267–282, fig. 1*).—This article gives an account of drainage and reforestation experiments in the royal forests of Hertogenwald, of eastern Belgium, and of drainage, irrigation, trenching, fertilizing, and fixation of moving sands on the dry sandy heaths and marshes of the Campine. Systems of drainage employed are described with specifications of cost.

In the improvement of the soils of the Campine "recourse is had to artificial manures, sometimes to road scrapings and town refuse, or both together; or better still to artificial combined with green manures, especially lupines. In the last case catch crops, especially barley, can be reaped, which will materially diminish the cost.

"The use of basic slag and kainit, also of lupines, has become part of modern practice for the planting and reafforestation of the Campine, and has already given satisfactory results."

Analyses of typical soils of the Campine at different depths are reported.

Progress in moor culture during the last 25 years, M. FLEISCHER ET AL. (*Die Entwickelung der Moorkultur in den letzten 25 Jahren. Berlin, 1908, pp. XXVIII+233, pls. 6, figs. 107*).—This volume was prepared in celebration of the first 25 years' existence of the Association for the Advancement of Moor Culture in the German Empire.

It contains a brief review of the work of the association by M. Fleischer, and papers on state work on moor culture in Prussia by H. Thiel; the moor culture station of Bremen by B. Tacke et al; state work in moor culture in Bavaria by A. Baumann; the scope and results of the German-Austrian Moor Culture Association by H. Schreiber; progress in moor culture in Denmark by T. C. Westh, in Sweden by H. von Feilitzen, in Norway by J. G. Thaulow, and in Finland by A. Rindell; the most important forms of humus and peat in the North German moors by C. A. Weber; colonization of the upland moors by Quaet-Faslem; the use of convicts in moor culture and colonization by Krohne; the formation and care of meadows and pastures on upland moors by B. Tacke, and on lowland moors by Krahmer; moor drainage by Sarauw; moor structures by Krüger; and the present status of the industrial use of peat as fuel by L. C. Wolff.

New methods in the field of moor culture, B. TACKE (*Ann. Sci. Agron., 3. ser., 3 (1908), I, pp. 68–72; Zentbl. Agr. Chem., 37 (1908), No. 5, pp. 291–295*).—This is a report submitted to the Eighth International Congress of Agriculture at Vienna, which deals briefly with kinds and character of moors, and their preparation for cultivation, drainage, cultivation and utilization, fertilizing, suitable systems of farming, and colonization.

Modern and early work upon the question of root excretions, H. S. REED (*Pop. Sci. Mo., 73 (1908), No. 3, pp. 257–266*).—This article reviews the work on root excretions by different investigators and reports some of the results secured by the Bureau of Soils of this Department. Soil upon which wheat failed to grow after continuous wheat culture yielded a small quantity of a crystalline organic compound which, when dissolved in pure water, showed a toxic action upon wheat plants while relatively harmless to cowpeas. In a similar way cowpea-sick soil furnished crystals found to be harmful to cowpeas but relatively harmless to wheat plants. The same soil in which neither plant was grown yielded none of these substances, and hence it is concluded that these substances were formed as a result of the plant growth in that soil.

Crop rotation and soil exhaustion, F. FLETCHER (*Separate from Cairo Sci. Jour., 2 (1908), No. 19, pp. 8*).—Noted from another source (E. S. R., 20, p. 521).

Annual review of agronomy. D. Zolla (*Rev. Gén. Sci., 19 (1908), No. 14, pp. 577–585*).—This article reviews new theories of soil fertility, particularly those advanced by the Bureau of Soils of this Department, and experiments on the use of manganese as a fertilizer, on the permeability of soils as related to irrigation, and on the utilization of alkali soils for the culture of rice in La Camargue.

Experiments on the decomposition and fertilizing value of manure. B. Sjollema and J. C. de Ruijter de Wildt (*Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], 1907, No. 1, pp. 21–68, figs. 2; abs. in Zentbl. Agr. Chem., 37 (1908), No. 10, pp. 652–654*).—A series of studies of the fermentation and tests of the fertilizing value of manure, in comparison with other nitrogenous fertilizers, in continuation of previous investigations (E. S. R., 18, p. 325), are reported.

The experiments on decomposition were made with 2 kg. lots of fresh cattle manure treated in different ways for 2 months. The manure from these experiments as well as fresh manure was used in comparison with nitrate of soda and sulphate of ammonia on oats followed by rape grown in cylinders. The results show that an important loss of free nitrogen may take place in manure, the loss depending, in addition to length of fermentation and temperature, largely upon the amount of exposure to the air. At room temperature the loss is much smaller than at a temperature of 35 to 37° C., and ceases at about 50°. The exact cause of the loss was not determined in the experiments, but appeared to be due to oxidation of ammonia by micro-organisms. With protection from the air no loss of nitrogen occurred either in the form of free nitrogen or of ammonia, not even with a very vigorous gas formation (methane and carbon dioxid) lasting several months. With fermentation under aerobic conditions combustion of organic material apparently occurred whereby oxygen was partly taken up by other compounds of the manure, or decomposition took place whereby carbon dioxid was formed without absorption of oxygen. Both with protection from and exposure to the air the furfurol-producing substances in manure were attacked, and more violently than the other constituents of the manure.

The cylinder experiments showed that the ammonia content of the manure is not always a correct measure of the fertilizer effect. The composition of the nitrogen compounds can not be taken exclusively, since the more or less fermented state of the nitrogen-free constituents must also play a large part. The nitrogen in those kinds of manure in which the furfurol-producing constituents were most fermented had the best effect. This is attributed to destruction of the food for denitrifying organisms. Anaerobic fermentation at higher temperature increased decidedly the direct fertilizing value of stable manure, since with a violent fermentation of the organic material and decomposition of furfurol-producing constituents, vigorous formation of ammonia takes place, and no loss of nitrogen either as ammonia or in a free state need be feared. Of manure in which favorable decomposition has taken place about one-third of the nitrogen can be taken up by the plant roots within a single month, so that the ratio of availability of this nitrogen to that of nitrate of soda is about 50:100. Fresh manure shows in the same year a greater after-effect than one subjected to fermentation, but this is not enough to compensate for the smaller increase of the first crop. The after-effect of stable manure which has fermented at various temperatures under aerobic and anaerobic conditions is slight in the same year, and the experiments reported show no noteworthy difference in the amount of this after-effect.

Note on the absorption of atmospheric moisture by certain nitrogenous manures, G. BROWNLEE (*Jour. Agr. Sci., 2 (1908), No. 4, pp. 380, 381, chart 1; abs. in Chem. Abs., 3 (1009), No. 1, p. 93*).—"Ten gm. each of the manures sulphate of ammonia, nitrate of soda, calcium cyanamid, and nitrate of lime (Notodden, 1906) were exposed to air in a room the windows of which were kept open during the experiment, and the changes in weight noted for a period of 29 days. At the same time barometric and temperature (wet and dry bulb) readings were taken daily.

"The percentages of moisture in the manures at the commencement were as follows: Sulphate of ammonia 4.52, nitrate of soda 2.85, calcium cyanamid 0.50, nitrate of lime 2.02. . . .

"The sulphate of ammonia became rather drier during the experiment and was quite powdery at the finish.

"The nitrate of soda was found at the end to be wettish underneath. Apparently its condition varies with the state of the atmosphere. In another experiment on a different sample of the ordinary commercial salt, when the air was very moist for many days in succession, nitrate of soda became quite wet. Evidently this manure can not always be conveniently kept under ordinary conditions.

"The calcium cyanamid remained unchanged in appearance throughout the experiment. It was, however, partly caked, though quite dry and powdery to the touch. (H. von Feilitzen states [E. S. R., 19, p. 221] that calcium cyanamid prepared by the Polzenius process contains a slight excess of calcium chlorid, which renders the product very hygroscopic, causing it to cake together in hard lumps and to burst the containing sacks.) On opening a bottle containing calcium cyanamid there is always a smell of ammonia, showing that this substance would deteriorate if left exposed.

"The nitrate of lime showed signs of becoming wet after a few hours' exposure and by the third day was quite liquid. It is, therefore, obvious that the Notodden product as made in 1906 must be deemed unsatisfactory from a farmer's point of view."

The changes in weight and in atmospheric conditions are illustrated in a chart.

Impurity of nitrate of soda and the use of crude nitrate, S. DE GRAZIA (*Staz. Sper. Agr. Ital., 41 (1908), No. 5–6, pp. 258–269*).—The author has already reported on this subject with reference to rye.[a] In that report it was established that the impurities in nitrate of soda were beneficial, but the nature of the impurities was not determined.

The experiments here reported were with wheat and barley in pots and included comparisons of various salts found in commercial nitrate of soda—sodium chlorid, potassium iodid, and magnesium sulphate.

The conclusion reached is that the salts constituting the impurities of commercial nitrate of soda, except perchlorate of potash, are of value to plants, and that within certain limits a less refined nitrate is more profitable as a fertilizer than a purer salt.

Comparative tests of sulphate of ammonia and nitrate of soda, BACHMANN (*Landw. Wchnbl. Schles. Holst., 58 (1908), No. 42, pp. 708–712*).—The results of 4 years' tests with rye, oats, barley, kohl-rabi, sugar beets, and potatoes on different kinds of soil are summarized. The results varied widely, particularly with the ammonium sulphate, showing that the fertilizing value of this material is particularly dependent upon the character of the season, moisture, temperature, etc.

---

[a] Staz. Sper. Agr. Ital., 39 (1906), No. 6–7, p. 529.

Comparison of organic nitrogenous fertilizers with nitrate of soda, M. Popp (*Landw. Vers. Stat., 68 (1908), No. 3–4, pp. 253–300; abs. in Chem. Ztg., 32 (1908), No. 48, Repert., p. 311; Chem. Zentbl., 1908, I, No. 26, pp. 2199, 2200; Jour. Chem. Soc. [London], 94 (1908), No. 550, II, pp. 727, 728; Chem. Abs., 3 (1909), No. 2, pp. 221, 222; Zentbl. Agr. Chem., 37 (1908), No. 12, pp. 796–805; Ztschr. Angew. Chem., 22 (1909), No. 5, p. 207*).—Blood meal and horn meal were mixed in amounts furnishing 0.2 and 0.4 gm. of nitrogen with 250 gm. of soil and ammonia and nitrates determined in the water extract at the beginning and after 2, 6, and 12 weeks. Experiments in large cylinders to study the rate of nitrification and effect on growth of rye, wheat, oats, and carrots in rotation were also made with these materials and with castor-bean meal, raw bone meal, dry ground fish, meat meal, molasses manure, poudrette, wool dust, leather meal, etc.

There was very slight increase of ammonia until after 2 weeks' time, and under the most favorable conditions not more than 14 per cent was found. The addition of calcium carbonate but slightly increased the rate of formation of ammonia.

It was observed that by distillation of the soil extract the total amount of ammonia present was not found, a certain amount, especially in the case of loam soils, being held so firmly that it was not washed out by the water. The dried blood uniformly yielded more ammonia than the horn meal. In no case was there a complete transformation of the organic nitrogen into nitric nitrogen. Under the most favorable conditions 72 per cent of the nitrogen was thus transformed in the case of dried blood and in case of horn meal about 57 per cent.

The relative efficiency of the different materials in the cylinder experiments was on the basis of nitrate of soda as 100: Blood and horn meal 70; fish meal, castor-bean meal, and meat meal 60; poudrette and bone meal 55; molasses manure 40; wool dust 25; and leather meal 10.

The use of nitrogenous fertilizers and of nitrate of lime, L. Malpeaux (*Jour. Agr. Prat., n. scr., 16 (1908), No. 35, pp. 265–267*).—Comparative field tests of nitrate of soda, sulphate of ammonia, nitrate of lime, and cyanamid on wheat, barley, sugar beets, potatoes, onions, and poppies during 1907 are reported.

Tests of the fertilizing value of synthetic calcium nitrate, N. Passerini (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. scr., 5 (1908), No. 3, pp. 388–392*).—In case of potatoes calcium nitrate and sodium nitrate were about equally effective in increasing the total yield and size of tubers. The two nitrates were about equally effective in increasing the yield of wheat.

New sources of nitrogen, D. A. Gilchrist (*County Northumb. Ed. Com., Bul. 11, pp. 62, 63*).—In comparative tests of calcium cyanamid, sulphate of ammonia, and nitrate of soda on mangel-wurzels it was found that the lime nitrogen gave poorer results in the dry season of 1905 and better results in the wet season of 1907 than the other nitrogenous fertilizers. In the case of oats in 1907 the lime nitrogen compared favorably with sulphate of ammonia. The fertilizers were used at rates furnishing 50 lbs. each of nitrogen per acre.

Results of fertilizer experiments with nitrogen lime, Bachmann (*Landw. Wchnbl. Schles. Holst., 58 (1908), No. 31, pp. 553–555*).—Comparative tests of nitrogen lime and sulphate of ammonia applied in the fall and in the spring on rye, oats, potatoes, and grass are reported.

The nitrogen lime gave the best results with winter grain when applied full ration in the fall about 8 days before seeding and harrowed in. The nitrogen lime was completely absorbed by the soil and was not washed out of sandy soils during the winter. A top-dressing with nitrogen lime on winter grain

gave good results when applied early in the spring. Fall application, however, is preferable. For summer crops the nitrogen lime should, if possible, be applied 8 days before planting and harrowed in. Its use as a top-dressing in this case is not to be recommended.

Experiments with lime nitrogen as a fertilizer, C. DUSSERRE (*Chron. Agr. Vaud, 21 (1908), No. 19, pp. 415–421*).—A number of cooperative experiments with farmers on cereals, grass lands, and potatoes are reported, the results in general showing that the lime nitrogen is a very efficient fertilizer on cereals and hoed crops, but is not well suited for top-dressing of grass lands.

Prize contest in trials of calcium cyanamid in comparison with other nitrogen fertilizers (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 5 (1908), No. 2, pp. 65–171*).—In order to obtain extensive data on the comparative value of various nitrogenous fertilizers this contest was established upon the following conditions: Diplomas of honor and cash prizes to the amount of $320 were offered. The cash prizes were 6 in number; one of $80 for comparative trials on a total area of not less than 2½ acres; 2 of $60 each for total areas of not less than 1¼ acres; and 3 of $40 each for total areas of not less than ¾ acre. The area of each plat on which calcium cyanamid was used was required to be not less than ⅛ acre. The nitrogen fertilizers to be compared with calcium cyanamid were to be the ones in use in the locality, and complementary fertilizers were to be used according to the needs of the crops or soils.

There were 16 entries, but reports were received from only 13. There are 9 reports each on wheat and corn, 5 on beets, 3 on potatoes, 2 on oats, and 1 each on flax, hemp, olives, and tobacco.

The results are varied and a detailed study of the reports is necessary to arrive at any definite conclusions.

Influence of soil humidity on the fertilizing action of calcium cyanamid, S. DE GRAZIA (*Staz. Sper. Agr. Ital., 41 (1908), No. 2–4, pp. 115–126; abs. in Chem. Zentbl., 1908, I, No. 26, p. 2198*).—A study of the effect of different degrees of moisture on the action of various chemical fertilizers is reported. The experiment was carried on in pots, each containing 2 kg. of air-dried earth. Three types of soil were used, namely, clayey, calcareous, and sandy.

The fertilizers used were calcium cyanamid, nitrogen lime, dicyandiamid, and sulphate of ammonia, and the different degrees of moisture used were certain percentages of the maximum quantity that each type of soil will retain by imbibition, as follows: 0, 10, 30, 60, and 90 per cent. The fertilizers were well mixed with the soil on April 25 except the sulphate of ammonia, which was applied in solution on May 19 and on May 21. Eleven selected seeds of rye were sowed in each pot. The degrees of moisture mentioned above were maintained from the time the fertilizers were applied until about 2 days before the sowing; then the pots were exposed to the air for nearly 2 days in order to have the earth in all the pots contain a like amount of moisture. Then such an amount of water was added as would give each type of soil 40 per cent of the quantity of moisture it would retain. This degree of moisture was maintained throughout the remainder of the experiment.

In the pots without fertilizer the effect of the higher degrees of moisture before sowing was shown especially with clayey soil. The calcium cyanamid gave better results with larger amounts of moisture, the largest being on clayey soil. The nitrogen lime showed a similar effect of moisture, but gave a smaller product. The different degrees of moisture had no effect on the dicyandiamid in any type of soil. The same is true of sulphate of ammonia.

In conclusion the author recommends that calcium cyanamid should be applied when the soil is wet or when there is good prospect of rain, and that in

any case it should be well worked into the soil, that it may have as much moisture as possible.

On the nitrification of calcium cyanamid in various types of soil, S. DE GRAZIA (*Staz. Sper. Agr. Ital., 41 (1908), No. 5–6, pp. 241–257; abs. in Chem. Zentbl., 1908, II, No. 12, p. 1060*).—This is a report of pot experiments on the nitrification of calcium cyanamid compared with sulphate of ammonia in sandy, clayey, humus, and calcareous soils. The results obtained are summarized as follows:

The nitrification of calcium cyanamid differs from that of sulphate of ammonia chiefly in the fact that until decomposition begins the cyanamid has a harmful effect on the micro-organisms of the soil. This is shown less in slowness of the action than in delay of its beginning.

This specific behavior of calcium cyanamid can not be considered as making it inferior to sulphate of ammonia, since no harm can result when the fertilizer is applied before the sowing.

The nitrification of calcium cyanamid begins and is completed much more rapidly in soils rich in organic material (nonacid) and in clayey soils than in sandy and limy soils.

Such marked influence of the nature of the soil probably depends on the degree of fermentation and especially on the absorptive capacity of each type of soil.

Absorption of calcium cyanamid in soil, H. KAPPEN (*Landw. Vers. Stat., 68 (1908), No. 5–6, pp. 301–331; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 556, II, p. 728; Chem. Zentbl., 1908, II, No. 9, pp. 818, 819; Chem. Abs., 3 (1909), No. 3, p. 351*).—From experiments with different kinds of soil the author concludes that the absorptive power of soils causes a decomposition of calcium cyanamid into lime, which is readily absorbed, and cyanamid, which is less readily absorbed. Cyanamid is also produced by carbon dioxid, and when these two agencies operate at the same time the production of free cyanamid is very rapid. This production of cyanamid produces a favorable effect on the growth of plants because the free cyanamid is more easily attacked by bacteria than the alkaline calcium cyanamid. In soils of low absorptive power the transformation of calcium cyanamid is slower and under these conditions germination and growth of plants may be injuriously affected by the undecomposed cyanamid compounds. The influence of absorption on the poisonous action of calcium cyanamid is therefore indirect and due to the fact that conditions favorable to the rapid conversion of poisonous compounds into harmless substances are thereby produced.

Experiments with calcium cyanamid and leucite as fertilizers for wheat and beans, I. BANDINI (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 5 (1908), No. 3, pp. 267–275*).—The results of the plat experiments reported show that the cyanamid was inferior to nitrate of soda as a fertilizer for wheat. In experiments with beans, leucite combined with mineral phosphate gave a larger crop and greater net return than potassium chlorid so combined.

On the causes that determine the liberation of potash in leucite in cultivated soil, L. BERNARDINI (*Staz. Sper. Agr. Ital., 41 (1908), No. 5–6, pp. 304–320*).—In central and southern Italy leucite occurs frequently and quite abundantly in soils of volcanic origin, and this study was undertaken to determine the possibility of utilizing leucite as a source of potash.

The author found that leucite yields its potash when shaken with solutions of sodium and ammonium salts. This action is a chemical phenomenon due to a reaction between the insoluble mineral and the salt in solution resulting in a double exchange of bases. This reaction in the case of ammonium salts is of importance in relation to the process of ammonification of the organic sub-

stance and the mineral parts of the soil. The organic substance of cultivated soil by a series of fermentative processes becomes mineralized and in this fermentative process the organic nitrogen is changed to carbonate of ammonia. The carbonate of ammonia, like other ammonium salts, reacts with the minerals of the soil, making insoluble its ammonia and thus protects it from the washing effect of rain.

The author has been able to demonstrate to his own satisfaction that by the action of the dilute solution of carbonate of ammonia upon leucite a compound is formed—ammonio-leucite—that contains ammonia in place of potash, ammonia that does not yield to water, but that can be easily set free by an alkali or by heat.

What are the laws controlling the assimilation of potash from the soil by plants? G. WIMMER ET AL. (*Arb. Deut. Landw. Gesell., 1908, No. 143, pp. 169; abs. in Mitt. Deut. Landw. Gesell., 23 (1908), No. 30, pp. 254, 255; Chem. Ztg., 33 (1909), No. 8, Repert., p. 32*).—This subject is discussed on the basis of long series of experiments with special reference to the utilization of the potash of the soil and of that applied in fertilizer, and with a view to determining the conditions under which potash manuring is likely to be profitable. The function of potash in plant life is explained, the method of the experiments is described, and the results are discussed in detail.

It is shown that the assimilation of potash from the soil by the plant depends in the first place upon chemical process, upon absorption of potash by the soil, upon soil moisture conditions, upon the season, and finally upon the fertilizing; in the second place upon the return of potash from the plant to the soil, the action of lower organisms, and absorption of potash by nematodes. The absorptive power of soils for potash increases the longer potash manuring is delayed. Fixation is more rapid in moist soils than in dry. Potash is therefore better utilized in a dry season than in a wet season, and assimilation is more evenly distributed throughout the growth of the plant. In absorptive soil, therefore, benefit is to be expected from potash manuring only when potash enough is supplied to more than satisfy the absorptive capacity of the soil.

The assimilation of potash is increased by liberal applications of nitrogen and phosphoric acid. The fact that many plants contain less potash when ripe than at the time of greatest growth is thought to indicate that some of the potash finds its way back to the soil. A considerable amount of potash is rendered available by lower organisms in the soil. On the other hand, it has been shown that nematodes take up a considerable amount of potash, which is thus rendered unavailable for the rest of the season. Treatment of the soil with carbon bisulphid by killing the nematodes releases this potash and thus benefits the crop.

While present knowledge does not furnish a basis for positive judgment in advance as to whether a given soil will benefit by potash manuring, chemical analysis, especially determination of potash-absorbing constituents, will aid field experiments to this end.

Comparative tests of the agricultural value of phosphoric acid of ordinary superphosphate, of dried and calcined phosphate and of metaphosphate of lime. M. DE MOLINARI and O. LIGOT (*Ann. Gembloux, 18 (1908), No. 9, pp. 499–503, pl. 1*).—This investigation was undertaken because it had been observed that many commercial superphosphates contained considerable amounts of calcium metaphosphate resulting from the heating of the monocalcium phosphate in the process of drying.

The experiments, which were made with oats grown in pots, show that in sandy clay soil under the experimental conditions superphosphate dried at 160° and superphosphate dried and calcined gave results similar to those obtained

with ordinary superphosphate. The action of phosphoric acid of metaphosphate, however, is decidedly inferior to that of the superphosphates. On sandy soil the effect of the dried and calcined superphosphates was less than that of superphosphate dried at 160°. It appears, therefore, that the character of the soil exerts an influence upon the assimilation of these forms of phosphoric acid.

The value of phosphoric acid in superphosphates and in Thomas slag, P. de Caluwe (*Engrais, 23 (1908), No. 45, p. 1075*).—A review of the investigations of de Molinari and Ligot referred to above.

The factors which influence the fertilizing effect of difficultly soluble phosphates, H. G. Söderbaum (*Landw. Vers. Stat., 68 (1908), No. 5–6, pp. 433–450; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 550, II, p. 728; Chem. Zentbl., 1908, II, No. 9, p. 819*).—Tricalcium phosphate and bone meal combined with nitrogen in different forms (sodium and ammonium nitrate, ammonium sulphate, and urea), and also with potassium chlorid and sulphate and sodium carbonate, were compared with superphosphate on oats and barley grown in cylinders containing 25 kg. each of sandy soil. See also a previous note (E. S. R., 17, p. 1053.)

On oats tricalcium phosphate gave slightly lower results with ammonium nitrate and slightly higher results with ammonium sulphate than with sodium nitrate. On barley receiving bone meal, ammonium nitrate gave lower results than sodium nitrate, ammonium sulphate reduced the yield 46.6 per cent, and a mixture of sodium nitrate and ammonium sulphate increased the yield (4.1 per cent) as compared with sodium nitrate alone. The addition of potassium sulphate to the tricalcium phosphate and ammonium sulphate gave somewhat higher results (with oats) than when potassium chlorid was used, but with bone meal and ammonium sulphate, potassium chlorid gave distinctly better results (with barley) than potassium sulphate.

In another series of experiments, ammonium salts (both nitrate and sulphate) were more effective than sodium nitrate in increasing the yield of oats when used with tricalcium phosphate and bone meal, respectively. Bone meal and ammonium nitrate gave higher results with barley than sodium nitrate and bone meal, while tricalcium phosphate and ammonium nitrate gave lower results. Both phosphates, but especially the tricalcium phosphate, gave much lower results with ammonium sulphate than with sodium nitrate. The addition of sodium carbonate (furnishing sodium equivalent to that of the nitrate of soda) to ammonium sulphate with bone meal gave a slightly (1.1 per cent) higher yield of barley than sodium nitrate and bone meal. With tricalcium phosphate, the addition of sodium carbonate with ammonium sulphate nearly doubled the yield obtained with ammonium sulphate and tricalcium phosphate, although the yield was still more than 50 per cent below that obtained with sodium nitrate and tricalcium phosphate.

With ammonium sulphate and phosphates, sodium carbonate very slightly reduced the yield of oats as compared with ammonium sulphate and phosphates alone.

While the author believes that the physiological reaction of the accompanying nitrogenous fertilizer plays an important part in determining the fertilizing effect of fertilizers, as stated by Prianishnikov (E. S. R., 18, p. 539) and others, many other factors, such as kind of plant, soil, and other fertilizing materials used, may mask or even reverse the influence of this factor.

Increase or decrease of nitrogen in the soil by manuring, D. A. Gilchrist (*County Northumb. Ed. Com., Bul. 11, pp. 26–29*).—It is shown that in experiments on grass land during 11 years the use of phosphatic fertilizers increased the soil nitrogen about 851 lbs. per acre over that of soil receiving no fertilizer. The plats receiving sulphate of ammonia and nitrate of soda in addition to the

phosphatic fertilizers contained less nitrogen than those receiving phosphate alone.

Note on the effect of lime upon the availability of the soil constituents, F. B. GUTHRIE and L. COHEN (*Jour. and Proc. Roy. Soc. N. S. Wales, 41 (1907), pp. 61–66; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 552, II, p. 889*).—For an abstract of other reports of this work see a previous note (E. S. R., 20, p. 125).

Concerning the influence of various relations between lime and magnesia on the development of plants, L. BERNARDINI and G. CORSO (*Staz. Sper. Agr. Ital., 41 (1908), No. 2–4, pp. 191–208*).—Culture experiments with rye, corn, and kidney beans are here reported. Rye and corn were cultivated in a nutritive solution containing per 1,000 cc. of distilled water: Nitrate of soda 1 gm., mono-potassium phosphate 0.5 gm., potassium chlorid 0.25 gm., calcium sulphate 0.5 gm., and iron chlorid trace. To this sulphate of magnesia was added in varying amounts to give the following proportions of lime to magnesia: 3, 2, 1, ½, ⅓.

Rye gave the best result in the solution in which the relation of lime to magnesia equaled 1, and better results with the higher proportions than the lower; corn gave the best result with the proportion of lime to magnesia equal to 2, and better with the higher than the lower, showing that an excess of lime does less harm than an excess of magnesia.

In the pot experiments soil of known composition was used and the proportions between lime and magnesia were made the same as in the nutritive solution experiments and the same results were obtained with rye and corn; with kidney beans the proportion of lime to magnesia equal to 3 gave the best result.

In field experiments with corn 6 plats were manured as follows: I, 535 lbs. of gypsum per acre; II, 356 lbs. of air-slaked lime per acre; III, 1,070 lbs. of sulphate of magnesia per acre; IV, 1,780 lbs. of sulphate of magnesia per acre; V, 178 lbs. of oxid of magnesia per acre; and VI, none. Plat V gave the best return, but the differences were not so marked as in the solution and pot experiments.

Cooperative fertilizer trials in Malmöhus County, Sweden, 1907, L. FORSBERG and M. WEIBULL (*Malmö. Läns K. Hushåll. Sällsk. Kvrtlsskr., 1908, No. 1, pp. 123–140, dgms. 2*).—Trials with different fertilizers for root crops, potatoes, small grains, etc., were conducted on 45 farms in southern Sweden on a plan similar to that followed in earlier years. The amounts of calcium carbonate and assimilable lime in the soils on which the fertilizer trials were conducted are reported.

Chemical manures in Italy, TOWSEY (*Dipl. and Cons. Rpts. [London], Ann. Ser., 1908, No. 4145, pp. 30–32*).—From statistics given in a bulletin of the Italian ministry of agriculture it is shown that the chemical fertilizers prepared in Italy are principally superphosphates and sulphate of ammonia. Of the former, about 800,000 metric tons of mineral superphosphate and 50,000 metric tons of bone superphosphate were produced in 1907. Of sulphate of ammonia about 10,000 metric tons was produced as a by-product of the gas industry and 100 metric tons from other sources. Of organic nitrogenous manures there was probably produced about 40,000 metric tons. There were in 1907 82 factories in Italy for the preparation of superphosphates, supplying practically all of this material consumed in Italy and a certain amount for exportation to neighboring countries. The sulphate of ammonia produced is about half of that required. In addition 41,900 metric tons of nitrate of soda, 7,000 metric tons of potash salts, and 100,000 metric tons of Thomas slag were imported in 1907.

The nitrogen question in Germany, N. Caro (*Die Stickstofffrage in Deutschland. Berlin, 1908, pp. 63, figs. 62; rev. in Bl. Zuckerrübenbau, 15 (1908), No. 15, p. 244*).—This is a second unrevised edition of this paper, which was presented before the Polytechnic Society of Munich in April, 1907. It discusses the need of nitrogen and the supply from various sources, particularly from the air; refers briefly to the Birkeland and Eyde process for making basic lime nitrate; and more fully describes the progress made in the manufacture of calcium cyanamid by the Frank and Caro process.

Valuation and extent of the nitrate of soda deposits of Chile, A. Bertrand (*Engrais, 23 (1908), No. 28, pp. 661, 662; Rev. Gén. Agron., n. ser., 3 (1908), No. 6–7, pp. 248–252*).—This is a summary of a report of the inspector appointed by the Chilean Government to investigate this matter. This report combats the idea that these deposits are rapidly approaching exhaustion.

The great nitrate fields of Chile (*Bul. Internat. Bur. Amer. Repub. (English Sect.), 27 (1908), No. 1, pp. 26–45, figs. 21*).—This article discusses briefly the extent, character, present output, and future possibilities of these fields.

Composition of some Chilean caliches, F. W. Dafert (*Monatsh. Chem., 29 (1908), pp. 235–244; abs. in Jour. Soc. Chem. Indus., 27 (1908), No. 13, p. 684*).—Analyses of 8 samples of caliche from widely different sources are reported and show that in all cases the water-soluble portion contained calcium, magnesium, potassium, sodium, nitrates, chlorids, sulphates, and iodates. "In most cases, perchlorates also were present; and in the 2 specimens richest in nitrates, small quantities of chromate were found. In no case did the soluble portion contain bromid, borate, nitrate, ammonia, carbonate, phosphate, or iodid. The specimens richest in sodium nitrate contained also much potassium nitrate."

Nitrate facts and figures, 1908, A. F. B. James (*London, 1908; rev. in Chem. News, 98 (1908), No. 2536, p. 11*).—The book gives statistical data regarding the mining and railway companies engaged in the nitrate industry.

Production of ammonium sulphate and gas from peat, A. Frank (*Ztschr. Angew. Chem., 21 (1908), No. 30, pp. 1597–1600; Österr. Chem. Ztg., 11 (1908), No. 16, p. 220*).—Reference is briefly made to a process by which moist peat may be economically converted into sulphate of ammonia and gas for power purposes. It is claimed that by this process 2,000 kg. of peat containing 50 per cent of water can be made to yield 2,800 cubic meters of gas of 1,000 horsepower hours and 40 kg. of sulphate of ammonia. The great economic importance of such a process is pointed out.

The nitrification of peat, J. P. Wagner (*Deut. Landw. Presse, 35 (1908), Nos. 55, p. 587; 72, p. 762*).—The utilization of peat for the preparation of niter beds according to the Bazin process (E. S. R., 20, p. 23) and in compost with sewage is discussed.

The nitrification of peat (*Deut. Landw. Presse, 35 (1908), No. 70, pp. 739, 740*).—The processes proposed by Wagner (above) are considered too expensive to be profitable under present conditions.

The nitrification of peat, G. Neuhauss (*Deut. Landw. Presse, 35 (1908), No. 57, p. 609*).—Earlier uses of peat in the preparation of niter beds than that of the process proposed by Bazin are noted, but such processes are considered impractical on account of their expensiveness.

On the utilization of the nitrogen of distillation residues, J. Effront (*Monit. Sci., 4. ser., 22 (1908), II, pp. 429–434; Österr. Chem. Ztg., 11 (1908), No. 21, pp. 285–288; abs. in Chem. Zentbl., 1908, II, No. 6, p. 548; Chem. Abs., 2 (1908), No. 18, p. 2597; Sucr. Indig. et Colon., 72 (1908), No. 11, pp. 328–331*).—Attention is called to the need of practical means of preventing the large losses of nitrogen which occur in distillery wastes, and the author describes a method of fermentation with yeasts in alkaline solution by which

it is claimed that almost the whole of the nitrogen is converted into ammonia and at the same time acetic and other acids are formed. Similar results were obtained by using pure or mixed cultures of soil organisms. The active agent in this transformation is thought by the author to be an enzym "amidase." One thousand kg. of molasses treated with cultures of garden soil which had been heated 1 hour at 70 to 80° yielded 75 kg. of ammonium sulphate and 95 to 120 kg. of acetic, propionic, and butyric acids.

The preparation and utilization of atmospheric nitrogen compounds, EYDE, WAGNER, and DUBISLAV (*Arch. Deut. Landw. Rats, 32 (1908), pp. 55–89*).—This includes discussions of the preparation of Norwegian niter by the Birkeland and Eyde process, the importance of the nitrogen of the air for practical agriculture, and the utilization of German water powers for the preparation of nitrogen compounds from the air.

The fixation of atmospheric nitrogen as cyanamid (*Nature [London], 78 (1908), No. 2021, pp. 273–275, figs. 6*).—The Frank and Caro process is described and reference is made to a number of new works which are being established to employ the process. It is stated that works are being constructed on the Canadian side of Niagara Falls "with a capacity of from 5,000 to 6,000 tons per annum, which it is hoped to enlarge later on so as to produce 40,000 tons."

On the formation of nitrogen oxid in high tension arcs, F. HABER and A. KOENIG (*Ztschr. Elektrochem., 14 (1908), No. 41, pp. 689–695; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 553, II, pp. 940, 941*).—This is a second paper on this subject (E. S. R., 19, p. 1023). Unusually high oxidation, 10 per cent in case of air and 14.5 per cent in case of mixtures of equal parts of oxygen and nitrogen, was obtained at temperatures above the melting point of platinum.

On the oxidation of nitrogen in cooled high tension arcs under reduced pressure, A. KOENIG (*Uber die Oxydation des Stickstoffes im gekühlten Hochspannungsbogen bei Minderdruck. Diss. Tech. Hochschule Karlsruhe, 1907, pp. 76, figs. 8*).—The introductory portion of this thesis discusses briefly the nitrogen cycle and the nitrate question; the theoretical part discusses the question as to whether nitrogen oxidation in the electric arc is of thermal origin. The same question is taken up in detail from an experimental standpoint in the fourth part. The general conclusion is reached that in cooled arcs there occurs purely electrical oxidation of nitrogen.

The manufacture of cyanamid in France, C. PLUVINAGE (*Jour. Agr. Prat., n. ser., 16 (1908), No. 36, pp. 298–303, figs. 4*).—This is a description of the factory which has been established at Notre-Dame-de-Briançon, Savoy.

On the formation of lime nitrogen, M. JACOBY (*Über die Bildung von Kalkstickstoff. Diss. Dresden, 1908, pp. 86; rev. in Chem. Ztg., 32 (1908), No. 64, Repert., p. 412*).—This records a study of the nature of the process of combination of nitrogen with calcium carbid both with and without the addition of other substances, and of the changes the product undergoes on standing.

On the fixation of nitrogen by calcium carbid, G. POLLACCI (*Ztschr. Elektrochem., 14 (1908), No. 36, pp. 565, 566; abs. in Chem. Ztg., 32 (1908), No. 84, Repert., p. 532; Jour. Chem. Soc. [London], 94 (1908), No. 552, II, p. 836; Sci. Abs., Sect. A—Phys., 11 (1908), No. 131, p. 648*).—Tests of the effect of potassium carbonate and of varying pressure of the nitrogen on the process of its fixation with carbid are reported. The addition of the carbonate reduced the temperature necessary to fixation and yielded a product of greater fertilizing value (containing potash) than is obtained with the ordinary process.

Lime nitrogen and its manufacture, E. KEMPSKI (*Illus. Landw. Ztg., 28 (1908), No. 78, pp. 677–679, figs. 9*).—This is a brief general account of the manufacture of this product and of factories which have been established for its preparation in different parts of Europe.

Present status and tendencies of the electro-chemical manufacture of nitrate of lime (*Bul. Mens. Off. Renseig. Agr. [Paris], 7 (1908), No. 7, pp. 816–820*).—Processes of manufacture are described, possible improvements indicated, and the cost of production with present methods discussed.

The origin of potash deposits. E. ERDMANN (*Ztschr. Angew. Chem., 21 (1908), No. 32, pp. 1685–1702*).—The literature of this subject is reviewed.

The utilization of potash in industry and agriculture. P. KRISCHE (*Die Verwertung des Kalis in Industrie und Landwirtschaft. Halle, 1908, pp. 181, pl. 1, figs. 16*).—This is a compilation of information regarding the principal sources of potash, the development of the potash industry, the industrial and agricultural utilization of potash, and the outlook of the potash industry.

The use of crude potash salts in German agriculture in the years 1906 and 1902. SIEMSSEN (*Arb. Deut. Landw. Gesell., 1908, No. 147, p. XVI+24, map 1; abs. in Mitt. Deut. Landw. Gesell., 23 (1908), No. 36, p. 299*).—Statistics of the use of potash salts in agriculture in Germany are given in some detail, especially with reference to showing the extension of such use from 1902 to 1906. The total consumption of potash salts in the German Empire in 1902 was about 1,186,743.75 tons, in 1906 2,028,072.97 tons, or at the rate of about 140 tons per 10,000 acres of arable area in 1902 and 234.18 tons in 1906.

The phosphate of Thomas slag. V. A. KROLL, Jr. (*Stahl u. Eisen, 28 (1908), p. 675; abs. in Chem. Ztg., 32 (1908), No. 54, Repert., p. 354*).—It is reported that one of the principal constituents of Thomas slag is a hitherto unknown silico-phosphate, a double salt of lime and ferrous oxid with 5-basic phosphoric acid which crystallizes in hexagonal pyramids.

The phosphates of Florida (*Amer. Fert., 29 (1908), No. 4, pp. 5–9*).—An account is given of the history and present condition of the Florida phosphate deposits, with data as to the extent to which the different classes of phosphate have been exploited.

Phosphate in South seas. J. D. DREHER (*Daily Consular and Trade Rpts. [U. S.], 1908, No. 3274, p. 12*).—It is stated that deposits estimated at 50,000,000 tons occur in Ocean and Pleasant islands in the Gilbert group. Smaller deposits are reported from a number of other islands. A London company controls and is beginning to exploit the larger deposits.

The composition of the products of the eruption of Vesuvius in April, 1906. G. PARIS (*Staz. Sper. Agr. Ital., 41 (1908), No. 5–6, pp. 321–328*).—As a result of his own analyses and those of a number of other investigators, the author concludes that in the products of the eruption nitrogen compounds are found that form ammonia under the influence of a high degree of heat in the presence of soda or of lime, and he concludes further that these compounds are not stable, but undergo a slow decomposition, probably by bacterial action, as a result of which they yield ammonia.

The fall of volcanic material was injurious to crops then in the soil on account of its high degree of acidity (0.417 per cent calculated as hydrochloric acid), the large percentage of soluble salts (0.9 to 1.64 per cent of substance), and its weight. The material has, however, notably increased the fertility of the soil, since it has increased the proportion of potash, of phosphoric acid, and of nitrogen, and in some cases has also modified the physical properties of the soil.

Australian fish fertilizer. H. D. BAKER (*Daily Consular and Trade Rpts. [U. S.], 1908, No. 3310, p. 15*).—A brief account is given of the use of dead sharks and barracouta in apple orchards near Hobart, Tasmania. As the untreated fish is very offensive, a factory has been established for extracting the oil and preparing a dried fish fertilizer. This factory, which has been built on North West Bay near Hobart, has a capacity of 40 tons of raw fish per day. There is said to be an inexhaustible supply of fish in the vicinity.

In experiments made by a representative of the Tasmanian government in the preparation of the dried fish fertilizer a product was obtained containing 9 per cent of nitrogen and 5.77 per cent of phosphoric acid.

On the composition of the ash of a New South Wales seaweed, Ecklonia exasperata, and the percentage of iodin present, C. J. White (*Jour. and Proc. Roy. Soc. N. S. Wales, 41 (1907), pp. 95–99*).—The ash of *Ecklonia exasperata* was found to contain potash 24.59, soda 18.15, lime 5.5, magnesia 5.19, phosphoric acid 0.75, sulphuric acid 14.98, chlorin 15.62, and iodin 0.89 per cent.

Analyses of soils, guanos, and other fertilizing materials (*Mem. Dir. Fomento [Peru], 1907–8, vol. 1, pp. 62–69*).—Mechanical and chemical analyses of a number of samples of soil from different parts of Peru, and chemical analyses of guanos and other fertilizing materials are given in tables.

Commercial fertilizers and chemicals, T. G. Hudson, R. E. Stallings, et al. (*Bul. Ga. Dept. Agr., 1908, No. 46, pp. 207*).—This report gives the text of the State fertilizer laws and rulings of the commissioner of agriculture under the law, general information relating to the culture and fertilizing of various crops, to methods of feeding stock and amount, and to character of feeding stuffs sold in Georgia, and analyses and valuations of 1,822 brands of fertilizers inspected up to August 1, 1907, representing estimated sales of about 840,000 tons.

The new Ohio [fertilizer] law (*Amer. Fert., 29 (1908), No. 2, pp. 10, 11*).—This law took effect November 1, 1908. Its enforcement is placed in the hands of the secretary of the State board of agriculture.

AGRICULTURAL BOTANY.

Botanical features of North American deserts, D. T. MacDougal (*Carnegie Inst. Washington Pub. 99, pp. 111, pls. 62, figs. 6*).—A description is given of the desert regions of North America, particular attention being paid to those between Texas and California and extending into Mexico. The geology of the region in the vicinity of Tucson, Ariz., is described, after which an account is given of the vegetation in that region. The temperature, water, and soil relations of desert plants are discussed at considerable length, after which the conditions contributory to the formation of deserts are described and their extent throughout the world traced.

Distribution of the roots of some annual cultivated plants, V. Rotmistrov (*Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 8 (1907), No. 6, pp. 667–705; 9 (1908), No. 1, pp. 1–24*).—The author has made a study of the vertical and lateral distribution of roots of a considerable number of plants of economic importance. The season's average growth of roots is shown in the following table:

Vertical and lateral distribution of roots in the soil.

Kind of plant.	Length of roots.		Kind of plant.	Length of roots.	
	Vertical.	Lateral.		Vertical.	Lateral.
	Cm.	*Cm.*		*Cm.*	*Cm.*
Barley, 2-rowed	120	90	Beans (Prineess of Orleans)	85	60
Barley, 6-rowed	111	86	Broad beans	110	84
Wheat	103	92	Do	110	90
Oats (Continental sort)	110	94	Poppy	102	80
Oats (Canary)	107	54	Flax	105	64
Rye	118	60	Camelina	104	96
Millet	105	110	Sunflower	144	120
German millet	106	92	Castor bean	120	100
Sorghum (black)	110	80	Cotton	95	104
Sorghum (yellow)	106	110	Potato	60	100
Maize	113	134	Beet	146	110
Peas	92	104	Cucumber	105	84
Beans (Glory of Lyon)	96	104			

Specialization and the origin of alternation of host plants in the Uredineæ. W. KRIEG (*Naturw. Wchnschr., 23 (1908), No. 36, pp. 561–573, figs. 5*).—A review is given of recent publications relating to specialization among certain species of rusts.

The present status of agricultural plant breeding. C. FRUWIRTH (*Med. Klinik, 4 (1908), Nos. 14, pp. 501–503; 15, pp. 541–543; 16, pp. 589–591*).—The history of plant breeding is briefly reviewed and the different methods of plant improvement by means of selection and hybridization are described. Mendel's law is considered in this connection and the use made of grafting is also noted.

Notes on bud mutations of Solanum maglia. E. HECKEL (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 15, pp. 615–617*).—For several years the author has been carrying on experiments with a number of species of Solanum to determine if possible the origin of the cultivated potato, and in the present paper he gives an account of the third generation of a bud sport of *S. maglia* that appears to have become fairly constant.

The author found that by growing this species in soils that were highly fertilized with chemical fertilizers and hen manure the plant was caused to mutate, producing tubers of various forms and colors. Where grown under other conditions, the plant showed no variation from the wild type. The third generation mutants grown alongside of ordinary potatoes showed very marked resistance to the Phytophthora disease, and the author believes that he has secured material not only of biological interest but also of practical value, since the new form appears to be adapted to wide variation in cultural conditions and is resistant to disease.

On the influence of wound stimuli on the formation of adventitious buds in the leaves of Gnetum gnemon. J. VAN BEUSEKOM (*K. Akad. Wetensch. Amsterdam, Proc. Sect. Sci., 10 (1907), pt. 1, pp. 168–181*).—The occurrence of adventitious buds on the leaves of a specimen of Gnetum has been under observation for some time at Utrecht, and the author has undertaken to ascertain the cause of their abnormal development.

The formation of these buds was traced to punctures of a species of Aspidiotus. In their early aspect the abnormal tissues are yellowish, resembling in some degree the stigmonose of carnations, which has been shown by Woods to be due to aphid punctures (E. S. R., 12, p. 460). Unlike the carnation disease, there does not appear to be any irritating excretion on the part of the insect, and it is concluded that the leaf of *G. gnemon* may be stimulated to the formation of intumescences and hence adventitious buds by wounding, providing this is very slight, and that consequently the process is to be regarded as a reaction on the wound stimulus.

Some notes on grafting varieties of beans. L. DANIEL (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 2, pp. 142–144*).—The author found in experiments with 2 races of beans grown in Knop's solution that one was very subject to chlorosis, the leaves fell early, and flowering was retarded, while the other developed normally. He then made reciprocal grafts and found that the characteristics of the stock were transmitted in considerable degree to the graft. The chlorotic form when grafted upon the other developed normally and flowered early and abundantly. The form that was green and in every way normal when grown upon its own roots when grafted upon the chlorotic stock was affected with chlorosis, the leaves were poorly developed, and flowering was retarded. In addition to these gross differences, microscopic transformations were also noted.

A method for the quantitative determination of transpiration in plants. G. F. FREEMAN (*Bot. Gaz., 46 (1908), No. 2, pp. 118–129, fig. 1*).—A form of transpiration apparatus is described which is a modification and adaptation of

that used by Lamarlière and Verschaffelt. By its use, the transpiration of a plant under known and constant conditions can be accurately measured, and it is possible to demonstrate individual differences in the transpiration rates in different plants of the same species. This apparatus is designed for securing data as a basis for plant selection and breeding.

A new respiration calorimeter, G. J. Pierce (*Bot. Gaz., 46 (1908), No. 3, pp. 193–202*).—The author describes experiments with Dewar flasks, both silvered and unsilvered, in which the temperature of germinating peas, growing yeasts, etc., was determined. These flasks come in several shapes and appear well adapted for use as respiration calorimeters where the heat and energy of respiration are to be determined. For class use they are said to be decidedly better than any forms of apparatus commonly in use.

On endospermic respiration in certain seeds, F. Stoward (*Ann. Bot. [London], 22 (1908), No. 87, pp. 415–448*).—Experiments with barley, maize, and castor beans have been carried on to determine whether or not the cells of the endosperm possess vitality. The view generally accepted is that endosperms of Gramineæ possess vitality and are endowed with the capacity of autodigestion.

The experiments, which are described at considerable length, lead to the conclusion that the pure endosperm tissue of both barley and maize is capable of manifesting a gaseous exchange of a respiratory character. Whether this manifestation of respiratory activity is wholly or in part due to the vital activity of living protoplasm, or to the agency of respiratory enzyms, is yet undecided.

The evidence of the possession of vitality by the aleurone layer, which has hitherto been based on cytological and enzymic data, is substantiated by the results of the author's investigations.

The vitality and self-digestion of the endosperm of some Gramineæ, Diana Bruschi (*Ann. [London], 22 (1908), No. 87, pp. 449–463*).—This paper, which is an abstract of several preceding papers by the author, gives briefly accounts of experiments with maize, barley, wheat, and rye, which indicate that the starch endosperm of the grains investigated can digest itself in the absence of the scutellum and other parts of the embryo, although in different degrees. The self-emptying of the cells can go on in the absence of any vitality in the amyliferous cells, because the starch hydrolysis is accelerated by a strong amylase which arises, little by little, from a pro-enzym existing in the endosperm of the resting seed. This becomes active even though every trace of vitality has been removed from the entire endosperm or seed by mechanical means. The investigations further indicate that vitality is possessed by the aleurone cells situated in the periphery of the endosperm, and it is also retained in one or several subaleuronic layers whence it lessens by degrees until it disappears toward the middle of the endosperm, as well as in the part near the scutellum.

The influence of the concentration of sugar solutions on respiration, A. Maige and G. Nicolas (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 2, pp. 139–142*).—Investigations were made on the effect of various concentrations of glucose, levulose, saccharose, maltose, and lactose on the respiration of young bean seedlings deprived of their cotyledons and of etiolated seedlings of broad beans. The normal respiration was determined by the quantity of oxygen observed, and the intramolecular respiration by the carbon dioxid given off by the plants.

The intensity of the normal respiration was found to increase with the increased concentration of all the sugars, except for lactose. Where this form of sugar was used, there was a gradual increase in the respiration activity up to a concentration of 1 per cent, after which the intensity of the respiration

slowly diminished. The respiratory quotient increased with the concentration, always remaining, however, less than 1. The rapidity of growth, both in its energy and respiratory quotient, varied with each kind of plant and sugar investigated.

The energy of the intramolecular respiration increased progressively with the concentration.

The effect of increased concentration of solutions is twofold: It decreases the turgescence of the cells as the strength of solution is increased; it increases the penetration of the solution into the cells, the penetrative power being more active with the stronger solutions.

A physiological study of the development of fruits and seeds, W. Lubimenko (*Compt. Rend. Acad. Sci. [Paris]*, *147 (1908), No. 8, pp. 435–437*).—Experiments with *Colutea arborescens* showed an atmospheric pressure within the pods that was 0.15 to 0.26 atmospheres greater than that of the surrounding air, and analyses showed that the contained gas differed from that of the air. The carbon dioxid found in the growing pods apparently diffuses very slowly, and there is a greater or less accumulation of that gas within them.

When sections of the pericarp of Colutea, peas, and Lathyrus were so made as to permit the free exchange of gases, the seed failed to develop any further, and the pods usually dropped off the plant in 6 to 8 days. If the pods after sectioning were protected against drying, there was no development of the seed.

The experiments seem to show that a confined atmosphere is necessary for the normal development of these seeds, and that one of the functions of the pericarp is to maintain within itself an atmosphere of fairly constant composition.

A chemical study of the ripening of tomatoes, F. M. Albahary (*Compt. Rend. Acad. Sci. [Paris]*, *147 (1908), No. 2, pp. 146, 147*).—A study was made of the chemical changes taking place during the ripening of tomatoes, analyses being made of green fruits before the development of the seeds, green fruits when the seeds were fully formed, and fully ripe fruits. The author calls attention to the necessity of avoiding all oxidation and fermentation in investigations of this kind.

Detailed analyses are given, from which it appears that there is a progressive increase in the organic acids, sugars, starch, and nonproteid nitrogen during the ripening of the tomato, and a falling off in the percentage of the proteid nitrogen and cellulose. The proportions of the other constituents remained practically unchanged.

The physiological rôle of fat in plants, Dubaquié (*Proc. Verb. Soc. Sci. Phys. et Nat. Bordeaux, 1906–7, pp. 92–96, dym. 1*).—The rôle of fat in plants has long been a subject of controversy, some investigators claiming that it is a form of reserve material, others that it is a product of elimination, etc. Experiments by the author with artificial cultures of *Aspergillus niger* and *Eurotiopsis gayoni* seem to indicate that fat is a reserve material which is drawn upon by the fungus at certain stages of development, particularly during spore formation. In experiments with Aspergillus, the maximum fat content was attained on the second day, after which it slowly decreased with the increasing dry weight of the mold. The occurrence of fat in plants is apparently not associated so much with the ternary compounds in the culture medium as it is with the age of the plant.

The effect of electricity upon plants, J. H. Priestley (*Proc. Bristol Nat. Soc., 4. ser., 1 (1906), pt. 3, pp. 192–203; abs. in Bot. Centbl., 108 (1908), No. 2, p. 36*).—An account is given of some experiments made by J. E. Newman in employing electricity as a stimulus to plant growth.

In experiments in 1904, 500 sq. yds. of kitchen garden were electrified by the overhead discharge system. The yields as compared with the control plats showed that cucumbers gave a gain of 17 per cent and strawberries from 36 to 80 per cent. Upon tomatoes there appeared to be no effect. An outbreak of a bacterial disease of cucumbers seemed much lighter upon the electrified plants.

In another experimental plat, carrots showed 50 per cent increase, and beets 30 per cent increase of crop with an increase of 1 per cent in sugar content.

In 1906, 20 acres of wheat were electrified with discharge wires at a considerable height and with a high tension current. In this case an increase of from 29 to 39 per cent over the control areas was recorded, and the electrified wheat is said to have given a better baking flour and commanded a higher price.

The author carried on some laboratory experiments to test the nature of the electrical acceleration of plant development, but no satisfactory clues were arrived at. There was nothing to indicate that the electric current enables a leaf to form starch in the dark, as is claimed by Pollacci.

Temperature and growth, W. L. Balls (*Ann. Bot.* [*London*], *22 (1908), No. 88, pp. 557–591, figs. 4, dgms. 7*).—The object of this paper was to analyze the effects produced upon the growth process by the temperature factor. The research was initiated by a casual observation, but it developed into an attempt to determine the chemical effects of the temperature factor by studying the pathological portion of the growth-temperature curve, and hence to demonstrate that the time factor is chemical in its nature and that its effects can be simulated immediately. After describing the methods of observation and tabulating the results of a large number of observations, the author arrives at the following conclusions:

"(1) The growth rate at various temperatures accords with the expectations of Van't Hoff's law.

"(2) The decrease, and ultimate cessation of growth at high temperatures, is due to the accumulation of catabolic products in the cells.

"(3) This cessation is distinct from the disorganization of the protoplasm by heat, which results on a further rise of temperature to the death point.

"(4) The same products are formed at low as at high temperatures, but with greater rapidity in the latter case.

"(5) To the rapid formation of these bodies is due the injurious effect of prolonged exposure to submaximal temperatures, commonly known as the time factor. This time factor is identical with the phenomenon of 'staleness' in rich cultures of fungi.

"(6) In the case of isolated cells these bodies diffuse out into the surrounding liquid. In multicellular organisms they have to be otherwise disposed of, probably by decomposition; since the conditions under which this decomposition takes place must be fairly uniform in the interior of a higher plant, these latter show in consequence a well-marked 'optimum,' which is the expression of the internal struggle between the increasing rapidity of chemical change with rise of temperature, and the inhibiting effects of the accumulating catabolic products."

As mentioned in the preliminary part of the work, this investigation was due to observed conditions in the infection of cotton seedlings with the sore-shin fungus. In a note appended to the paper, the author states that the artificial infection of cotton seedlings with the sore-shin fungus can be readily effected by placing the former on several layers of damp blotting paper in a Petri dish and then placing a fragment of rapidly growing mycelium from a cool culture in contact with it. If the dish is then stored at 20° C., within 24 hours the seedling will be found to have rotted at the point of inoculation. If the trial is repeated at a temperature of 33°, a brown superficial scar

is formed, but the fungus does not extend its attack into the inner layers of the cortex. At 38° no infection can be secured.

The influence of temperature on the action of poisons, L. Zehl (*Ztschr. Allg. Physiol., 8 (1908), pp. 140–190; abs. in Bot. Centbl., 108 (1908), No. 13, pp. 328, 329*).—A series of experiments with spores of *Aspergillus niger* and *Penicillium glaucum* were conducted to determine the poisonous action of a number of inorganic and organic compounds. Among the inorganic compounds used were aluminium sulphate, cobalt, copper, lithium, nickel, and zinc, as well as boracic acid and potassium chromate. Of the organic compounds, ethyl alcohol, amyl alcohol, chloral hydrate, acetanilid, antipyrin, phenol, picric acid, etc., were used.

The author found that raising the temperature increased the poisonous action of the inorganic compounds when used singly. In most cases the increase amounted to 3 times the initial toxicity, but for temperatures between 30 and 40° C. there was found to be no correlation between increased toxicity and increase in temperature, the toxicity increasing much more rapidly than the temperature. The organic poisons acted in a similar manner. No definite cause for this action could be determined, but the author believes that it can not be wholly explained by the increased ionization of the salts at the higher temperatures.

Where combinations of 2 inorganic salts were added to the culture media, the toxicity of the combined poisons was less than where the single salts were used. Where 2 organic or an organic and an inorganic poison were tested, the results were quite variable, the relative toxicity being increased in some cases while it was diminished in others.

Studies on germination and plant growth, S. U. Pickering (*Jour. Agr. Sci., 2 (1908), No. 4, pp. 411–434*).—According to the author, experiments have been in progress at the Woburn Experimental Fruit Farm on the effect of grass on trees, which have led to the conclusion that this effect can not be attributed to root competition, increased evaporation, differences in temperature, aeration, etc., but is due to some poisoning action exerted by the grass. Whether such action is a direct result of the growth of the grass, or an indirect one operating through the medium of soil bacteria, is the subject of the investigations here described.

The germination of a number of different kinds of seeds in heated soil seemed to indicate that the detrimental action of the grass can not be attributed to bacteria. Soils which were heated without drying to temperatures of from 60° to 150° behaved unfavorably toward the germination of seeds, retarding and in most cases decreasing the total germinations. Sterilized seeds with and without inoculation behaved in the same way as unsterilized ones, and, according to the author, the retarding effect of germination produced by heating the soil can not be explained by an alteration in the bacterial condition of the soil, for the alteration extends progressively at temperatures beyond that sufficient to destroy all bacteria.

By heating the soil an increase in the soluble constituents was found to occur, especially in the soluble organic and nitrogenous matter, and the increase of either of these was found to be directly proportional to the increase in the time required for germination. The increase in the soluble constituents appears to be due to the formation of a nitrogenous compound in the soil, which is inhibitory toward germination. This compound is sufficiently stable for extraction in solution, and it does not seem to be destroyed when the soil containing it is kept at a low atmospheric temperature for some months. The inhibitory substance is not of an acid nature, and the experiments do not settle definitely whether any of it is present in the soil before heating, but it

seems probable that such is the case. Preliminary experiments with apple trees under like conditions led to similar results.

The toxic property of bog water and bog soil, A. Dachnowski (*Bot. Gaz., 46 (1908), No. 2, pp. 130–143, figs. 6*).—During an ecological study of a small lake in Ohio, the author was led to give attention to the toxic character of bog water and bog soils. The lake in question is characterized by two well-marked plant zones, and investigations of water from each showed that it had marked toxic properties. The water from the central zone was decidedly more toxic than that from the other, but in both it could be corrected by aeration and by the use of calcium carbonate and carbon black.

Experiments were made on the germination of the gemmæ of *Marchantia polymorpha* and afterwards confirmed with water cultures of wheat, corn, beans, and elm and buckeye seedlings. The plants grown in the bog soil extract and in untreated bog water showed decided stunting in root growth, while the tops were more nearly alike. Marked differences in sensitiveness to the toxic action were shown by the different plants, the beans proving very plastic. The behavior of some of the plants was very similar to those grown in solutions containing strychnin, atropin, and similar substances.

The author believes that the inhibiting action of bog water and bog soils is due to plant substances that are soluble and which are probably the products of decomposition, plant excreta, etc. These substances by retarding oxidation, decrease transpiration and result in stunted growth, or even in the death of plants.

On plasmolysis, W. J. V. Osterhout (*Bot. Gaz., 46 (1908), No. 1, pp. 53–55*).—A discussion is given of the contraction of protoplasm within plant cells due to the chemical action of salts as distinguished from true plasmolysis. It is stated that the contraction of the protoplasm may often be prevented by the addition of substances to the nutrient solutions. Contraction caused by sodium chlorid may be prevented by the addition of a small quantity of calcium chlorid, although the osmotic pressure of the solution is greatly increased. Water distilled from a metal still was found to produce apparent plasmolysis within a few minutes, but this could be prevented by the addition of various inhibiting substances. It is believed by the author that many of the contradictory results attributed to plasmolysis are due to chemical action.

The concentration of green coloring matter in plants and photosynthesis, W. Lubimenko (*Rev. Gén. Bot., 20 (1908), Nos. 232, pp. 162–177, figs. 3; 233, pp. 217–238, fig. 1; 234, pp. 253–267, figs. 3; 235, pp. 285–297, pls. 2, fig. 1*).—Anatomical studies of leaves showed that the chloroplasts of shade-loving species of plants are larger than those of plants accustomed to grow in full light. The concentration of the chlorophyll was found to vary in different plants and in the same plant with the age of the leaves. In old leaves a greater absorption of light is possible, due to a considerable concentration of the coloring matter, and further it is probable that the limit of absorption for mature leaves is not reached under the usual conditions of illumination.

By means of spectroscopic analyses, the author was able to determine very accurately the variation in chlorophyll in the leaves of different species of plants at all stages of growth, and by a series of experiments he determined that the photosynthesis of the plant depends not only on the mass of the chloroplasts but on the concentration of the green coloring matter in the chlorophyll grains. In studies made with 9 species of plants at temperatures varying from 20 to 38° C. and at 3 different degrees of natural illumination, it was found that the maximum of photosynthesis does not coincide with the greatest concentration of the coloring matter in chloroplasts. The maximum assimila-

tion was found to correspond to a concentration of the pigment equaling that found in young leaves of shade-loving and old leaves of shade-shunning species. Adult leaves of tolerant species assimilate less energetically than adult leaves of those species which are intolerant of shade.

From a biological standpoint, the concentration of chlorophyll in the chloroplasts may be considered as a means for adapting plants to the different degrees of illumination found in their habitats. Tolerant species, by increasing the concentration of their pigment, are able to withstand a relatively feeble illumination, and a brightly lighted situation is injurious to intolerant species in so far as they are unable to vary the concentration of color in the chloroplasts. The intolerant species have a less concentrated chlorophyll in the natural state than the tolerant ones.

Does the chemical substance called chlorophyll exist? M. Tsvett (*Rev. Gén. Bot., 20 (1908), No. 236, pp. 328–331*).—The author presents arguments to show that what has been heretofore called chlorophyll is not a simple chemical substance, but is a mixture of 2 coloring materials, to which the names chlorophyllin α and chlorophyllin β are given. The first gives a blue color in a solution of ether and generally is 4 or 5 times as abundant as the second, which gives a green color when extracted with ether.

The influence of nutrition, water, and illumination on the development and organization of higher plants, Büngeр (*Naturw. Wchnschr., 23 (1908), No. 43, pp. 673–686*).—A summary and critical review is given of some of the more recent literature relating to the influence of nutrition, water, and light on plants.

FIELD CROPS.

Variety selection, seed culture, and plant breeding in Württemberg. C. Fruwirth (*Sorten, Saatfruchtbau und Pflanzenzüchtung in Württemberg. Plieningen, 1907, pp. 43*).—This publication in discussing varieties, selection, and dissemination touches upon the earliest work of this kind, the variety tests made before and after the establishment of the plant-breeding station, the distribution of the varieties in the country, and the varieties commonly grown. The history of seed production is reviewed, the promotion and direction of seed culture at the plant-breeding station is described, and notes on the different establishments making a specialty of seed and potato culture are given.

Under plant breeding the author discusses the development of breeding in Württemberg and other parts of Germany, and enumerates the farms which began plant breeding by themselves, as well as those which cooperated with the plant-breeding station. The methods of carrying on this work at the station are also outlined.

Report of the government agrostologist and botanist, J. Burtt-Davy, I. B. P. Evans, and H. G. Mundy (*Transvaal Dept. Agr. Ann. Rpt. 1907, pp. 132–148, 155–177*).—This report contains brief reviews of the different lines of work carried on during the year. Notes are given on veld or range improvement, the culture of a long list of miscellaneous crops, the prevalence of noxious weeds and poisonous plants, plant diseases and insect enemies, and the introduction of seeds and plants. In cultural tests with corn yields ranging from 1,200 to 4,000 lbs. per acre are reported.

Dry farming in Wyoming, V. T. Cooke (*Trans-Missouri Dry Farm. Cong. Bul. 1, pp. 13, pl. 1*).—A bulletin published by the State Dry Farming Commission and containing brief directions for farming dry lands in Wyoming.

Rules for the uniform seeding of grains for comparative botanical investigations (*Trudui Byuro Prikl. Bot., 1 (1908), No. 1–2, pp. 86–89*).—Rules are

given, through the application of which it is believed material for the study of morphological and biological varietal forms of grains may be secured.

Cereal and leguminous crops, M. P. CAVALCANTE (*O Brasil: Suas Riquezas Naturaes; Suas Industrias. Rio de Janeiro: Centro Indus. Brasil, 1908, Portuguese ed., vol. 2, pp. 277–319*).—The methods of culture practiced in Brazil and the general condition of the industry are described.

Report on tests with varieties of oats and barley at Garforth, 1907, R. S. SETON (*Univ. Leeds and Yorkshire Council Agr. Ed. [Pamphlet] 71, 1907, pp. 13*).—The best varieties of white oats as determined by tests since 1900 were Abundance, Waverley, Tartar King, and Storm King. For rich land Tartar King and Storm King, two stiff sorts, are recommended and for land in a lower state of fertility, Abundance and Waverley. Of black varieties, Excelsior proved the best.

Taking both yield and quality into account, Standwell barley has proved the best on the average for the past 7 years, being closely followed by Goldthorpe, Brewers Favorite, and Chevalier in the order stated.

The water requirement of beets, rye, and barley on loam soil in 1907, C. VON SEELHORST (*Jour. Landw., 56 (1908), No. 2, pp. 195–198, pl. 1; abs. in Chem. Zentbl., 1908, II, No. 7, p. 631*).—This is a continuation of observations on the amounts of water evaporated and used by plants during their period of growth (E. S. R., 18, p. 629). It was found that 1 gm. of dry matter in barley required 504.5 gm. of water, in rye 307 gm., beets 461.8 gm. For the production of 1 gm. of dry matter in grain 1,225.7 gm. of water was required in case of barley and 854.2 gm. in case of rye.

The water requirement of lupines in the fall of 1906 and of potatoes, summer barley, and rye in the summer of 1907 on sandy soil, C. VON SEELHORST (*Jour. Landw., 56 (1908), No. 2, pp. 199–207; abs. in Chem. Zentbl., 1908, II, No. 7, p. 631*).—For the production of 1 gm. of dry matter in lupines 402 to 424 gm. of water was required, in potatoes 491 to 829 gm., summer barley 562 to 583 gm., and rye 763 to 1,093 gm.

The water content of grain furnished the German army from the crop of 1906 (*Arch. Deut. Landw. Rats, 32 (1908), pp. 485–506, dgms. 4*).—Tables are given showing the extreme differences in the water content of rye, oats, and wheat for each month from October to March, inclusive.

Recent observations on the culture of serradella and lupines on heavy soils, B. HEINZE (*Jahresber. Ver. Angew. Bot., 5 (1907), pp. 161–199, pls. 4, fig. 1*).—It was found that serradella and lupines, although typical plants for sandy soils, developed well under certain conditions on heavy soils and gave yields only slightly less than crops grown on sandy lands. A high lime content in a friable loam did not act injuriously upon either crop. Both made a poor growth after potatoes, oats, mustard, peas, and beans, and apparently had not produced any root nodules. On the other hand, a very good development was obtained of lupines following serradella and of serradella after serradella. These results were secured without any inoculation of the seed or soil.

Pure cultures were very effective in inoculating serradella on Lauchstedt soil in pot experiments, and gave better results in this regard than inoculation with soil in field tests. Inoculation with pure cultures in field experiments became effective rather late in the growth of the crop when numerous nodules appeared on the roots, but no increase in yield as compared with uninoculated serradella was obtained. The same results were secured with lupines where these had not been preceded by any leguminous crop.

In one field test where serradella was grown for the first time and no leguminous crop had immediately preceded it, inoculation with soil from an old serradella field was most effective in causing the production of nodules on the roots

and giving a remarkably high yield. The soil used in this instance was the friable Lauchsted loam, while on another plat where inoculation with a sandy soil from another serradella field had been made the yield was not materially increased.

The results are believed to favor Hiltner's view that the nodule organisms may be divided into two groups, of which one includes the organisms of serradella, lupines, and soy beans. The author further regards the work as showing the close relationship, if not the identity, of serradella and lupine organisms and that these may be readily substituted the one for the other. It is stated that these organisms are present in the Lauchstedt soil in forms not as yet quite adapted to the two crops but that such adaptation is in progress.

Classification of brewing barleys from a technical standpoint as well as their nitrogen content (*Ann. Sci. Agron., 3. ser., 3 (1908), I, pp. 297–328*).—A review is here given of the papers and discussions on this subject by Prior, Hubert, Cluss, and Wahl presented at the Eighth International Congress of Agriculture held at Vienna in 1907.

Investigations on the physical characters of barley from an anatomic-physiological standpoint. H. T. Brown (*Ztschr. Gesam. Brauw., 30 (1907), No. 18, p. 241; abs. in Zentbl. Agr. Chem., 37 (1908), No. 12, pp. 819–822*).—The author found that the fineness of the hull is correlated with mealiness of the grain. The thousand-grain weight of rough kernels was always greater than that of the smooth grain. The rough grains also had a greater volume than those of the finer varieties. The nitrogen content was found in general to increase with the degree of roughness in the hulls.

The distinguishing characters of two-rowed barley varieties. J. Broili (*Jour. Landw., 56 (1908), No. 2, pp. 121–139*).—The author discusses the classification of two-rowed barley varieties by means of the scar, the smooth base, the basal beard, the serrated character of the pair of nerves next to the keel in the outer glume, and by means of the lodicules. Plants of each of 16 varieties were examined.

The construction of the base of the kernel is considered a good factor in the classification of two-rowed barleys. The smooth flat base of the grain is a character of the nutans type or the open-headed varieties, while the other forms of the base indicate the erectum type or compact-headed sorts. It is also regarded as probable that the hairiness of the basal beard can be used as a distinguishing character for practical purposes. The author regards these characters of greater value in practice than for use in scientific work. Serrations on the nerves are not considered a reliable factor, although this character may be used in describing a race. The difference in the form of the lodicules is looked upon as a definite character by which nutans and erectum types may be distinguished.

Smooth-awned barleys. R. Regel (*Trudui Byuro Prikl. Bot., 1 (1908), No. 1–2, pp. 5–85*).—This article is a monograph on smooth-awned barleys which form a much more satisfactory forage crop than the rough or sharp-awned varieties. Botanical descriptions of 16 forms of the smooth-awned group are presented.

Enzyms in stored barley (*Wchnschr. Brau., 25 (1908), No. 39, pp. 557–559*).—The results of the investigations reported show that stored barley contains a diastatic enzym having the power of liquefying starch paste and partly turning the same to sugar. An enzym capable of inverting sugar was also found. These two enzyms are not equally distributed in the barley grain but are confined largely to the germ end. It is believed that the enzyms in stored barley become active when germination begins.

[Analyses of barley] (*Wchnschr. Brau., 25 (1908), Nos. 34, pp. 489–492; 36, pp. 517, 518*).—Descriptions of 61 samples of barley, including 9 from Bohemia and Hungary, the rest being of German origin, are given and their analyses tabulated. The descriptions have reference to the kernel only. The analytical data include moisture content, protein content, 1,000-grain weight, and the percentages of three different grades of kernels separated with sieves of 2.8, 2.5, and 2.2 mm. mesh.

Breeding agricultural plants, C. Fruwirth (*Naturw. Ztschr. Forst u. Landw., 6 (1908), No. 9, pp. 449–468*).—This article, the fifth of a series on the breeding and improvement of certain agricultural plants, treats of the fodder beet and presents the results of breeding experiments conducted with this crop.

Covered single flower clusters and single branches of the flower-bearing parts set seed, but the seed bolls produced were lighter in weight than those grown under natural conditions on parts approximately of the same vigor. Covered flower clusters as compared with those developing in the open on the same part of the plant produced a smaller total weight of seed bolls, a smaller proportion as based on the number of flower clusters of well-developed seed bolls, and a larger proportion of poorly developed or dwarfed seed bolls. A number of well-developed fruits produced under cover yielded fewer plants than the same number produced in the open, and these plants under field culture also showed a lower average weight in the root and in the leaves. The weight of the seed bolls was found to increase rapidly from that part of any branch where blossoming begins and to decrease gradually toward the top where the bolls are light and small.

The heaviest seed boll on an upper branch was found to be lighter in weight than the heaviest boll produced on a lower branch. Selection of seed bolls according to their size gave in general the same results as selection according to weight. The largest seed boll, however, is not necessarily also the heaviest. The heavier bolls as a rule furnish the heavier seed. Culture experiments with light and heavy seed bolls did not show a definite relation between the weight of the seed boll and the weight of the beet produced, but it was ascertained that the heavier seed bolls produced a greater number of plants than an equal number of lighter seed bolls.

In crossing experiments the first generation in some instances showed variations in form and the influence of both parents was apparent. The spherical shape appeared dominant over the cylindrical form, pear shape over olive form, and scantiness of foliage over abundance of leaves.

Securing a stand of clover on the southern Iowa loess, E. B. Watson (*Proc. Iowa Acad. Sci., 14 (1907), pp. 177–186*).—A study was made of the influences governing the germination and early growth of clover on the loess and tilled soils of southern Iowa and of the action of manure on clover. The matter of securing a stand has been discussed in Bulletin 98 of the Iowa Station (E. S. R., 20, p. 230).

Experiments with horse, cattle, and mixed manures applied in pot culture tests in sterilized and unsterilized condition showed that sterilization had not lessened the benefit derived from the manure. Several tests of this kind were made, and from the results obtained it is concluded that the inoculation of this soil by means of manure is not necessary in alfalfa or clover growing. The results indicated that the bacteria in the manure had nothing to do with the growth of the clover, as this crop grew just as well without them.

In making a count of the number of bacteria in the soil treated in different ways it was found that the soil treated with manure contained a much greater number of bacteria than the check tests. It was thought that if the presence

of these bacteria is responsible for the better growth of the clover, the clover would suffer by their absence, and a series of experiments was carried on to throw light on this question. A summary of the conclusions drawn from the results secured is that bacteria were in no way responsible for the beneficial action of the manure on the growth of the clover because the sterile manure was as beneficial as the unsterilized, and further that when the whole pot was sterilized the crop did not suffer, but was even a little better than otherwise.

Mendelian studies of Egyptian cotton, W. L. Balls (*Jour. Agr. Sci., 2 (1908), No. 4, pp. 346–379, dgms. 3*).—The author concludes from his results that Mendel's law of heredity applies to all those characters of the cotton plant which have been critically investigated. No cases of coupling have yet been discovered which are likely to prevent the synthesis of the desired forms of cotton. Most of the characters of the plant fluctuate to some extent, but far less than has been commonly assumed. It is stated that the maximum length of the lint may be forced above the normal by special physiological conditions of the environment or the individual, but that it can not be depressed below that normal.

The cultivated varieties of cotton in Egypt are found to consist of innumerable different strains, and the deterioration which these undergo after a few years is due to this heterogeneity brought about by natural and unconscious artificial selection. The amount of cross fertilization in Egyptian cotton fields is given as not less than 5 per cent per annum nor more than 15 per cent. The accumulated effect of this annual crossing maintains the cotton crop as a mass of natural hybrids, and it aids in the depreciation of varieties when inferior strains are introduced by seed mixture. It was observed that many characters of cotton are intensified on crossing, but the causes of this phenomenon are as yet undetermined.

It is announced that the Khedivial Agricultural Society has founded the first official experiment station devoted to the utilization of Mendel's law for economic purposes.

Cotton, H. de Sá (*O Brasil: Suas Riquezas Naturaes; Suas Industrias. Rio de Janeiro: Centro Indus. Brasil, 1908, Portuguese ed., vol. 2, pp. 177–215*).—The methods of culture practiced in Brazil and the general condition of the industry are described.

Cotton growing and Nigeria, C. A. Birtwistle (*Proc. Roy. Colon. Inst., 39 (1907–8), pp. 80–104*).—This paper discusses the prospects of cotton culture in Nigeria and estimates that an area of 24,000,000 acres in that country is available for this crop. Labor, transportation, and market conditions are considered, and it is believed that an appreciable quantity of cotton will come out of Nigeria within 5 years of the opening of the Kano railway.

The effect of lime nitrogen on flax, C. Hoffmeister (*Flachs u. Leinen, 15 (1908), No. 170, pp. 3701–3703*).—The results of the experiments here reported indicate that lime nitrogen as a source of nitrogen for flax may be used with profit. It was found that not only the yield of seed was increased but that also the length of the stems and the yield of fiber were considerably augmented. With references to quality, lime nitrogen acted like other sources of nitrogen in that it increased the thickness of the fiber. The best results with this fertilizer are secured on a loose friable soil with the substance applied from 8 to 10 days before seeding.

[Varieties of oats on different types of soil and their composition], B. Sjollema and J. C. de Ruijter de Wildt (*Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], 1908, No. 4, pp. 1–43*).—In these experiments Probstei, Ligowo, Black President, Goldregen, Beseler II, Mesdag, and New Market oats were grown on marsh, moor, and newly broken heath soils.

On the heavy and sandy marsh soils about 2 bu. of seed was sown per acre, and on the moor and heath soils approximately 2.66 bu. The marsh soil was fertilized with superphosphate, and the low moor, sphagnum moor, and heath soils with Thomas slag, kainit, slaked oyster-shell lime, and nitrate of soda.

A heavy rain lodged the plats, and in this connection New Market, Beseler II, Goldregen, and Probstei were the most resistant sorts. On the sandy marsh as well as on the heath soil the crop lodged to a lesser extent than on the other soil types. Injuries from thrips were greatest on the heath plat, but Mesdag and Black President suffered little from this attack. Among the white varieties Goldregen was injured most and Probstei least. All sorts ripened latest on the heavy marsh soil and earliest on the heath soil.

The best results on the heavy marsh soil in the order of yield were secured from Goldregen, Probstei, and Beseler II. New Market gave the lowest yield of straw and the highest yield of grain, while Black President was one of the poorest yielders. On the sandy or light marsh soil the rank was New Market, Goldregen, and Ligowo, while on the low moor soil Probstei stood first, followed by Ligowo and New Market. On the sphagnum moor soil, which was quite sandy, Probstei led in yield, followed by Beseler II. The yield of grain for all varieties was low on the heath soil.

The heaviest weight per hectoliter on all soils was given by Black President and Goldregen. The different varieties, with the exception of Ligowo, showed a maximum difference in hectoliter weight of about 4 kg. (about 4.57 lbs. per bushel) on the different soil types. The highest average hectoliter weight was secured on the sandy marsh and heath soils, and the lowest on the heavy marsh and sphagnum moor soils.

The investigations on the weight of the different parts of the plants and their relation during different periods of growth seemed to have indicated that in different varieties grown under like conditions the relation of the weights of the different parts at maturity is constant. However, in the case of Probstei oats this constancy was not established.

A chemical study showed that relatively more organic nitrogen passes from the leaves than from the stems. The nitrogen content of the different varieties at maturity was practically the same for the stems, the leaves, and the heads. In early growth the differences between the nitrogen content of the 6 varieties was quite large, but from this period on there was a gradual approximation until later the difference was practically wiped out. The results further showed that the leaves and stems contributed a large part of their nitrogen content toward the development of the grain. On the sandy marsh and on the heath soil, the 2 types lowest in nitrogen, the development of the grain had drawn largely upon the nitrogen content of the leaves.

Beseler oats I, II, III, H. Dommes (*Mitt. Landw. Inst. Breslau, 4 (1908), No. 4, pp. 495–646, pls. 6, figs. 2, dgm. 1*).—This is a monograph on these varieties of oats. The history of their origin is related in detail, and the characters of the embryos of the 3 varieties are described. In addition the principal phases of growth with special reference to the morphological development of the parts of the plant above ground are discussed, and the yielding capacities of the varieties are compared.

Beseler I is adapted to mountain climates and matures rather late. The color of the straw and the grain is yellowish white. Beseler II may be profitably grown on rich valley soils in a high state of cultivation. It ripens early, stands up well, and is not injuriously influenced by heavy applications of nitrogenous fertilizers. The color of the straw and grain is a very clear white. Beseler III is a pronounced yellow variety, rather drought resistant, and well adapted to the continental climate of eastern Germany.

A list of 43 references to literature on oats culture and structure of the oat plant concludes the article.

Analysis of colonial oats, J. LEWIS (*Agr. Jour. Cape Good Hope, 33 (1908), No. 3, pp. 358–366*).—Tables are given showing the manner of treatment in culture tests and the yields per acre of 52 samples of oats obtained from various districts of Cape Colony. In addition, results of the chemical analyses of the samples are presented.

The peanut, J. ADAM (*Gouvt. Gén. Afrique Occident. Franç. Insp. Agr. 1908, pp. 206, figs. 46, dgms. 7, maps 3*).—This book devotes a chapter each to the origin and distribution of the peanut, varieties, culture and cultural requirements, products, commerce, growth of the industry, and economic importance of the plant.

Rice culture in Asiatic Russia, V. WALTA (*Tropenpflanzer, 12 (1908), No. 3, pp. 107–116*).—This article discusses in detail rice culture in the Russian Asiatic possessions, giving special prominence to lowland rice, although upland rice is also grown in some sections. It is estimated that the cost of producing an acre of rice amounts to about $14.61, and that with an average yield of about 1,923 lbs. of grain and 3,658 lbs. of straw per acre a profit of about $10.09 may be secured.

A report on experiments with potatoes, 1907, J. G. STEWART (*Unit. Leeds and Yorkshire Council Agr. Ed. [Pamphlet] 70, 1907, pp. 17, pls. 2*).—From the results of variety tests it is concluded that Midlothian Early and Ninetyfold are good early varieties, British Queen No. 2 and Dalmeny Radium medium varieties, and Up-to-Date, Dalmeny Regent, and Duchess of Cornwall good late varieties suited to cultivation in Yorkshire. Northern Star and Professor Maercker were the most disease-resistant varieties. Seed from Scotland and Ireland yielded much better than seed introduced from other parts of England, and the Irish seed gave a better return than the Scotch. The vigor of the potato has not been increased by growing the crop alternately on loamy and clay soils at Garforth. A dressing of wet sawdust over the sets at planting time apparently reduced the amount of scab. Sterilization of the soil prevented scab and greatly increased the yield.

Experiments with Solanum commersonii and S. commersonii violet, G. BOHUTINSKÝ-KRIŽEVCI (*Ztschr. Landw. Versuchsw. Osterr., 11 (1908), No. 7, pp. 655–662*).—The results of these experiments showed that *S. commersonii violet* is sensitive to large quantities of water in the soil and is no more adapted to wet soils than are the ordinary varieties of potatoes. It is also subject to plant diseases, being attacked by *Alternaria solani*. In quality it ranks with the ordinary potato, but it does not produce greater yields, the tubers are not larger, and they show a tendency to branch or to produce offsets. The author observed no character which differentiates this plant from the ordinary potato varieties.

The culture of Solanum commersonii violet, A. and P. ANDOUARD (*Bul. Sta. Agron. Loire-Inf., 1906–7, pp. 27–31*).—Two culture tests with this plant are reported, and the composition of the tubers is shown in tables. This crop grown in dry and humid soils in 1907 gave very small yields and the starch content of the tuber was comparatively low. The keeping quality also proved unsatisfactory.

The action of manganese on the potato and the beet, I. HENDRICK and E. CARPIAUX (*Bul. Inst. Chim. et Biol. Gembloux, 1908, No. 75, pp. 66–72*).—Soil relatively very rich was treated with superphosphate at the rate of 600 kg. per hectare (about 534 lbs. per acre), divided into 6 plats and planted with potatoes. Two plats served as check tests, two others received 10 kg. of sulphate of manganese per hectare (about 8.9 lbs. per acre), and the remaining two

50 kg. (about 44.5 lbs.). The results show that the application of 10 kg. of sulphate of manganese per hectare had no effect on the yield, while the use of 50 kg. increased the yield by 7 per cent.

A similar test was conducted on plats which had received no nitrogenous fertilizer and on others which had received 50,000 kg. of barnyard manure per hectare (about 44,500 lbs. per acre) two years before. Regarding the check test as 100, the yields of the plats without manure are represented by 104 where 10 kg. of sulphate of manganese was used and by 109 where 50 kg. were applied, while on the plats treated with barnyard manure these figures were, respectively, 105 and 111. From these results it is concluded that the action of the manganese on the yield can not be attributed entirely to the influence of this substance on the availability of the nitrogen of the soil.

On a number of plats of sugar beets receiving a general application of 500 kg. each of superphosphate, nitrate of soda, and kainit per hectare (about 445 lbs. per acre), several being treated with 10 and 50 gm. of sulphate of manganese per hectare, it was shown that this crop is not so favorably influenced by the application of manganese as the potato.

Plant food consumption of the beet during the first year of growth and its relation to the sugar content, K. Andrlík and J. Urban (*Ztschr. Zuckerindus. Böhmen, 32 (1908), No. 10, pp. 559–575*).—Attention is called to the fact that owing to the influence of soil, seed, fertilizing, and weather the potash consumption of the beet may vary greatly. As determined by the authors the minimum consumption amounted to 156.9 kg. for 400 quintals (about 3.92 lbs. for 1,000 lbs.) of beets. As a rule the consumption is much higher. The quantity of potash taken up by the plant was increased through fertilizing with potash salts and barnyard manure.

Potash consumption is influenced by the amount of available potash present in the soil. In dry weather the beet uses comparatively little potash, even if heavily fertilized with the substance. Different kinds of seed, as well as the same kind of seed grown on different soils and in different years, also affected the potash consumption of the plant.

A heavy consumption of potash indicates a large leaf growth rather than an increased yield in beets and sugar. The authors found in the samples examined that the quantity of potash used in the production of 100 parts of sugar in the beet ranged from 2.1 to 5.8 parts. It was further shown that the greater percentage of potash is deposited in the leaves, the quantities found in the root ranging from 32.1 to 41.5 per cent of the total used by the plant. It was observed that where 400 quintals of beets used 156.9 kg. of potash, 100 parts of sugar corresponded to 0.75 part of potash, where 177.5 kg. were used to 1.01 parts, and where the potash consumption rose to 303 kg. to 1.72 parts. Variations due to the kind of seed ranged from 0.2 to 0.7 part of potash used per 100 parts of sugar produced.

Fertilizer experiments with seed beets (*Centbl. Zuckerindus., 16 (1908), No. 49, pp. 1320, 1321*).—The following fertilizer applications were made in the experimental culture of seed beets: Well-rotted and pulverized chicken manure and air-dry sugarhouse refuse 690 kg., sodium superphosphate 230 kg., dry wood ashes 460 kg., and nitrate of soda 230 kg. per hectare. The increase in yield per hectare for the different substances was as follows: Chicken manure on one plat 660 kg., on another plat 750 kg., sugarhouse refuse 270 kg., sodium superphosphate 310 kg., dry wood ashes 470 kg., and nitrate of soda 550 kg. These experiments were carried on in southwest Russia where chicken manure and wood ashes may be obtained at a relatively low cost, and in view of this fact these two substances were very much more profitable than the higher priced commercial fertilizers.

Assuming that the value of 100 kg. of beet seed is only 50 marks, the use of the quantity of chicken manure applied resulted in a net profit per hectare of approximately 335 marks (about $32.50 per acre). As the manure could be applied at an expense of 18 marks per hectare, this represents a profit of 1,958 per cent on the money expended.

Abnormally large beets. K. ANDRLÍK and J. URBAN (*Zischr. Zuckerindus. Böhmen, 32 (1908), No. 9, pp. 493–496*).—Analyses of abnormally large sugar beets disclosed a characteristically low sugar content, a high percentage of nitrogen, sodium, and chlorin, and a low percentage of phosphoric acid and iron oxid. As compared with fodder beets they were richer in sugar, poorer in reducing sugars, and very high in nitrogen content.

The sugar-beet seed breeding station of Wohanka and Company, Prague, Austria. C. W. DE REKOWSKI (*Detroit, Mich., 1908, pp. 43, pls. 8, fig. 1, dgm. 1*).—This station is described and some of the results of investigations carried on by H. Briem, the director, are reported. The method of modern sugar-beet seed breeding and growing is discussed.

Annual report of the bureau of sugar experiment stations. W. MAXWELL (*Ann. Rpt. Bur. Sugar Expt. Stas. [Queensland], 1907, pp. 46*).—A brief statement for 1907 of the work of the sugar experimental station at Mackay, of two substations in sugar districts, and of the laboratories, together with an account of the economic and financial conditions of the sugar industry in Queensland, is presented.

The results show that the varieties New Guinea 8A, 15 or Badila, 24 or Goru, 24A, and 24B still maintain the lead in sugar production. The first rattoon crop of the 10 best varieties grown with and without irrigation and with and without manures show that the average of the irrigated and nonirrigated plats with manures gave an increase of 9.3 and 10.7 tons of cane per acre, respectively, apparently due to the fertilizer applied. The largest increase due to manure was on the nonirrigated plats of New Guinea 24B, the increase being 15.4 tons per acre. The smallest difference in yield occurred on the nonirrigated plats of Bois Rouge, the increase on the manured plat being only 5 tons greater per acre than on the plat receiving no manure.

Deep subsoiling between the rows, with subsequent cultivation of the rattoons, increased the yield by 11.9 tons of cane and 1.7 tons of sugar per acre. In this experiment the plats were neither manured nor irrigated.

The outcome of distance experiments indicates that 1 plant with 3 eyes, with 6 in. between the plants in the row, is the best way of planting seed in the row. Any increase exceeding 5 ft. between the rows is likely to result in a lower weight of cane and yield of sugar per acre, while less than 5 ft. between the rows can result in an increase of cane and sugar.

Experiments with new varieties have brought out the fact that the best sorts are deficient in arrowing. A description of the introduced canes is given.

The stripping of sugar cane in Formosa. T. MURAKAMI (*Internat. Sugar Jour., 10 (1908), No. 118, pp. 478–484*).—Results of experiments in the stripping of sugar cane in Formosa indicate that this method of treatment for imported canes causes a decrease in sucrose together with a lowering of the purity coefficient, while at the same time the glucose and fiber are increased. This the author interprets as due to a chemical activity by which the nonsucrose is transformed into sucrose and sucrose into glucose. This chemical activity may be influenced by the presence of a large amount of salt absorbed with the water. The fresh food material thus obtained is expended in the growth of all canes except the colored canes.

A long exposure to the hot sun was found to increase the fiber content, but exceptions to this rule were the Formosan varieties and the Striped Singapore,

which are all rather hard in rind. Different kinds of manures applied did not seem to affect the results. The juice obtained from all canes from which the dry leaves were not stripped was slightly higher in sucrose content and coefficient of purity than the juice from the stripped canes. Rose Bamboo has proved a very promising cane. The results secured with this variety show that by stripping 4,445.76 lbs. per acre of cane were gained but 229.68 lbs. of sugar were lost.

Sugar cane, A. DE MEDEIROS (*O Brasil: Suas Riquezas Naturaes; Suas Industrias. Rio de Janeiro: Centro Indus. Brasil, 1908. Portuguese ed., vol. 2, pp. 105–175*).—The methods of culture practiced in Brazil and the general condition of the industry are described.

Acclimatization experiments with sweet potatoes, L. BERNEGAU (*Jahresber. Ver. Angew. Bot., 5 (1907), pp. 96–99*).—The results of analyses of sweet potato meal are given, and cultural tests with this crop in Germany are briefly reported. The attempts at growing sweet potatoes in Germany have thus far not been very promising.

Fertilizer experiments with tobacco, P. WAGNER ET AL. (*Arb. Deut. Landw. Gesell., 1908, No. 138, pp. 99*).—The results of cooperative fertilizer experiments with tobacco are reported in detail and general conclusions are drawn.

Plants grown with insufficient potash contained from 0.51 to 0.70 per cent of potash in the dry matter of the leaves, while this factor in plants overfed with potash reached 16.15 per cent. The maximum yield showed a potash content in the leaves of 2.3 per cent. It is stated that 7 per cent of potash in the leaves is not to be regarded as extraordinarily high. In the average of all experiments the fire-holding capacity of fermented tobacco leaves grown without potash fertilization was 25 seconds, as compared with 46 seconds for those having received potash.

Analyses and tests of 19 different samples to determine the relation between fire-holding capacity and potash content showed an average of 6.9 per cent of potash in the sample, with little variation for all samples tested. This potash content is regarded as normal and sufficient to insure a good burn. The average chlorin content of these 19 samples was 0.553 per cent, and it is concluded that tobacco leaves should not contain more than 0.6 per cent of chlorin, as a higher percentage interferes with the burning of the leaf. This combination of potash and chlorin was apparently very good, for in all 19 samples the fire-holding capacity was so great that the leaves once ignited burned completely. It is stated that as a rule heavy potash fertilization under like conditions produces a tobacco of better burning quality than light potash fertilization. It is pointed out, however, that the chlorin content of the leaf must not be high if this result is to be obtained. It was observed that with the use of fertilizers containing little chlorin the chlorin content of the leaf may be reduced to 0.1 per cent, while on the other hand if fertilizers high in chlorin are used the chlorin content of the leaf may reach 4 per cent. The conclusion is drawn that for good burning qualities tobacco should contain from 5 to 6 per cent of potash and not more than 0.6 per cent of chlorin.

The potash requirement of the tobacco crop per hectare for a yield of 1,500 kg. of dry matter in the leaf, corresponding to about 1,800 kg. of air-dried leaves and stems, was found to be about 120 kg. (about 106.8 lbs. per acre). To supply this amount it is recommended that 40,000 kg. of barnyard manure and 100 kg. of potash in a readily available form be applied per hectare. Without the barnyard manure an average of about 200 kg. of readily available potash will supply this demand. The experiments show, however, that where barnyard manure was applied alone about the end of April the chlorin content of the leaf was increased and the burning quality reduced. It is advised to

apply the manure in the fall in order that the chlorin may leach out during the winter. Attention is called to the fact that stock fed with beet leaves produce a manure high in chlorin, while feeding molasses or hay heavily fertilized with potash produces a manure rich in potash, so that in a measure the chlorin and potash content of barnyard manure may be controlled.

A comparison between sulphate of potash and silicate of potash, or martellin, showed 4.4 per cent of potash, 3.2 per cent of chlorin, and a fire-holding capacity of 4 seconds in the leaf grown with sulphate of potash, and 6.6 per cent of potash, 1.2 per cent of chlorin, with a fire-holding capacity of 60 seconds for the tobacco grown with the martellin.

The use of ammonium sulphate produced in all cases a greater fire-holding capacity than ammonium nitrate, the average results in 3 different tests being 41 and 34 seconds, respectively.

The nature of tobacco fermentation, H. JENSEN (*Centbl. Bakt. [etc.], 2. Abt., 21 (1908), No. 15–16, pp. 469–483, dgms. 11*).—The results reported show that tobacco fermentation is not prevented by treating the leaf with corrosive sublimate, formol, or chloroform, and that fermentation is promoted by weighting down the mass and by fermenting in large bulks. Fermentation was found impossible in small quantities of tobacco, even though air was forced through them or they were inoculated with fermenting leaf. The effects of fermentation either in part or in their entirety were brought about by heating with steam from 10 minutes to 2 hours at a temperature from 90 to 100° C. Wet tobacco was brought to an active state of fermentation even when the bulk was small. Fermentation was impossible in tobacco which had been treated with steam as well as in leaf which had already gone through the process. Forcing oxygen through the tobacco to be fermented did not promote fermentation.

Tobacco, D. S. DE CARVALHO (*O. Brasil: Suas Riquezas Naturaes; Suas Industrias. Rio de Janeiro: Centro Indus. Brasil, 1908, Portuguese ed., vol. 2, pp. 231–275*).—The methods of culture practiced in Brazil and the general condition of the industry are described.

Observations on the breeding of Vicia faba, H. LANG (*Fühling's Landw. Ztg., 57 (1908), No. 14, pp. 481–497*).—The results of this work show that the most efficient factors on which selection in breeding may be based are the number of pods per plant, the length of the plant, and the size and light color of the seed. Selection according to the percentage of seed and the number of beans per pod produced remained without definite results. The weight of the beans per pod seemed quite constant and reliable, but the use of this factor is considered impracticable. It was further observed that progeny high in plant weight and yield of beans also ranked high in other important characters such as size and color of grain, number of pods per plant, yield of beans per pod, and length of plant.

Report on a test of varieties of wheat with notes on the weather at Garforth, 1907, R. S. SETON (*Univ. Leeds and Yorkshire Council Agr. Ed. [Pamphlet] 69, 1907, pp. 13*).—The results of variety tests here reported indicate that Standard Red and Squarehead Master proved to be the best red wheats. Browick Grey Chaff, although a good yielding variety, was not so good in quality as these two, but on account of its greater strength of straw it is better adapted for land in good condition than either. White Standup, the only white wheat grown, was not so remunerative as the best red wheats, although characterized by stiff straw of medium length and well adapted to land of good quality. Duluth wheat also gave promising results. Squarehead Master, now grown for 9 years without change of seed, has shown no falling off in yield or in quality.

Correlations in the wheat stem of importance in breeding varieties resistant to lodging, K. ALBRECHT (*Landw. Jahrb., 37 (1908), No. 3–4, pp. 617–672, fig. 1*).—The factors studied as being of value in this connection were weight of spike, length of internode, weight of internode, thickness or diameter of stem, resistance to cross bending, and the anatomical structure of the stem, including among other features the area occupied by the fibrovascular bundles in a cross section of the stem wall.

The author concludes from his results that the relative weight of the straw, which he determined by calculating the weight of a section of the stem 1 cm. in length, is the most reliable indication of the strength of the cell structure upon which resistance to lodging depends. The determination of the resistance in cross bending tests, which stands in absolute correlation with the relative straw weight, is not considered so valuable on account of the somewhat crude methods of measurement in use. In practice, however, the resistance of the stem as determined by cross bending is considered as sufficiently accurate for the selection of individual plants for breeding purposes. The determination of the relative weight of the straw is regarded as too tedious and difficult for the plant breeder. While the thickness and the length of the internodes are characters much less reliable in detecting the interior development of the cells, they are believed nevertheless to be of value in selecting plants resistant to lodging.

The book of wheat, P. T. DONDLINGER (*New York and London, 1908, pp. XI+369, pl. 1, figs. 65, dgm. 1, maps 2*).—In the treatment of his subject the author devotes a chapter of the book to each one of the following topics: Wheat grain and plant, improvement, natural environment, cultivation, harvesting, yield and cost of production, crop rotation and irrigation, fertilizers, diseases, insect enemies, transportation, storage, marketing, prices, milling, consumption, production and movement. The bibliography given occupies 27 pages.

A short wheat survey of Bengal, D. N. MOOKERJI (*Dept. Agr. Bengal, Dept. Rec., 1907, No. 2, pp. 19, pls. 2*).—The botanical relations of the wheats grown in Bengal, the names and relationships of the different races, the foremost important races of Bengal wheat, the distribution of varieties, the culture of the crop, the composition of the grain, and statistics with reference to production are discussed.

The content of important plant food ingredients in some common weeds, A. STUTZER and L. SEIDLER (*Fühling's Landw. Ztg., 57 (1908), No. 12, pp. 429, 430*).—The authors report the results as determined by analyses given in the following table:

Plant food contained in the dry matter of some common weeds.

Kind of weed.	Ash.	Nitrogen.	Phosphoric acid.	Potash.	Sodium.	Calcium.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Sonchus oleraceus	14.95	2.39	0.88	4.77	2.16	1.94
Centaurea cyanus	8.12	2.30	.78	1.94	1.07	3.13
Spergula arvensis	10.12	2.36	1.08	4.21	1.91	1.52
Serradula arvensis	9.68	1.91	.76	2.22	1.02	3.07
Raphanus raphanistrum	5.22	1.85	.78	1.30	.71	1.81
Polygonum persicaria	10.58	3.12	1.16	3.12	2.53	4.93
Achillea millefolium	9.61	2.30	.93	3.15	1.17	3.84

Testing seeds by means of electricity, T. JOHNSON (*Jahresber. Ver. Angew. Bot., (1907), pp. 102–112, figs. 3*).—A method to estimate the vitality of seeds by electricity, in which the blaze current is used as the indicating factor, is described in detail and the results of testing seeds of different grades of vitality are given.

HORTICULTURE.

Recent investigations on the grafting of herbaceous plants, E. Griffon (*Bul. Soc. Bot. France, 55 (1908), No. 5, pp. 397–405, pls. 2*).—In continuation of previous work (E. S. R., 19, p. 37) grafting experiments were conducted with the Solanums and other herbaceous plants to study the influence, if any, of the stock on the graft and vice versa.

As previously reported, grafting does not appear to exert any specific or unusual influence on the immediate fruit of the grafted plants, and, as indicated by one year's results with tomatoes, seedlings grown from fruits of grafted plants comport themselves in the same manner as those grown from fruits of ungrafted plants. The work is to be continued.

The culture of early vegetables: The rôle of glass sashes, G. Castet (*École Agr. Algér. Maison-Carrée, Inform. Agr. Bul. 6, pp. 52, figs. 60, map 1*).—A popular account of forcing methods used in growing early vegetables in southern France.

Climate, soil, and, fruit culture, A Bechtle (*Klima, Boden und Obstbau. Frankfurt, 1908, pp. XX+557*).—This book is designed as a reference work for the German fruit grower. It contains in concise form the knowledge gleaned from recent climatic and soil investigations which have a bearing on fruit culture. The numerous topics under which the subject-matter is treated are grouped under three general headings as follows: The climate, the soil, and phenology. The results secured in the fields of plant physiology and agricultural chemistry are also included as being closely related in fruit culture to many questions of a climatic nature.

The appendix deals with climatic and other conditions of North American orchard districts in comparison with German conditions. A bibliography of works consulted is given.

On fruit culture in Finland, B. W. Heikel (*Landthr. Styr. Meddel., 1907, No. 56, pp. 51, pls. 12*).—A report on the general condition of Finnish horticulture, together with discussions of varieties of apples, pears, cherries, and plums, grown in Finland.

Commercial apple culture in mountain regions, W. N. Hutt (*Bul. N. C. Dept. Agr., 29 (1908), No. 8, pp. 3–29, figs. 4, dgm. 1*).—A popular bulletin in which consideration is given to the adaptability of mountain regions to apple culture with reference to temperature and moisture conditions, atmospheric drainage, frost protection, etc., and discussing the various phases of apple culture, including selection of site, soils, planting operations, varieties, cultivation, fertilizers, cover crops, protection from mice and rabbits, and spraying.

Strawberry culture, F. A. Waugh (*Mass. Crop Rpt., 21 (1908), No. 6, pp. 30–39, figs. 4*).—A popular article on strawberry culture, treating of soils and localities, propagation, planting, general culture, mulching, methods of management, fertilizers, diseases, insects, varieties, and marketing of crops.

The influence of the color of soil on the growth and fruitfulness of grapes, L. Ravaz (*Ann. École Nat. Agr. Montpellier, n. ser., 8 (1908), No. 1, pp. 22–45, figs. 4*).—The author cites from several writers relative to the influence of the color of soil on the growth and fruit production of grapes and gives an account of investigations started along this line in 1906, with the results thus far secured.

An experimental plat containing 99 vines was covered with a concrete made up of water, lime, and basic slag from 4 to 7 cm. (about 1.6 to 2.8 in.) in depth, a small clear space being left at the base of each plant to insure the penetration of rain water. The covered portion was colored, ⅓ being white, ⅓ red and ⅓ black to correspond with different types of vineyard soils. The check

plat in each case was a grayish soil cultivated in the usual manner. The data secured show the vine growth to have been greatest on the black plat and least on the white plat. The growth started at the same time on all of the plats, but the growth on the red and black plats quickly surpassed that on the check plats. The growth on the white plat was slower than on the other colored plats and continued throughout a longer period. Measured by the yield of fruit, however, the white plat was first and the black plat third. The white plat appeared to have suffered least from a prevailing drought and the soil was found to contain a greater moisture content, from which the author advances the opinion that the drying out of soil may depend more upon the vegetative growth produced, which was least in the white plat, than upon the tilled or untilled condition of the soil.

In connection with this investigation the soil and air temperatures of the plats were taken almost daily from March 9 to November 30. The color of the soil did not appear to modify either the maximum or minimum air temperature. The soil temperature, however, at a depth of 10 cm. was much higher in the red and the black plats than in the check or in the white plats, and as far as this experiment is concerned the growth activity appeared to increase with the increase in soil temperature.

The reconstitution of limy soils, P. Sagourin (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 29 (1908), No. 45, pp. 555–562*).—The comparative results are given of tests of 2 grape hybrids, *Mourvèdre-Rupestris* 1202 and *Chasselas-Berlandieri* 41b, used as stocks on calcareous soils and upon which were grafted 6 varieties of grapes. Grapes grafted on the former had a much more vigorous growth than those grafted on the latter, which growth appeared, however, in some cases, to influence the quantity and quality of fruit unfavorably. Vines grafted on *Chasselas-Berlandieri* 41b matured quicker and the fruit attained as a rule a higher sugar content. This stock is especially recommended for plantations producing fine wines.

Recent investigations on the shallow culture of grapes, L. Ravaz (*Ann. École Nat. Agr. Montpellier, n. ser., 8 (1908), No. 1, pp. 5–21, figs. 6*).—In continuation of previous investigations on shallow culture (E. S. R., 17, p. 866), experiments were conducted in 1906–7 in which shallow culture was compared with deep culture in a vineyard in which the vines were stunted and suffering with short nodes.

The test plats had previously been fertilized and drained, but no considerable increase of vigor was noted either from the drainage or from any of the fertilizer ingredients, with the exception of nitrogen, which appeared to stimulate the growth somewhat. Shallow culture, however, had a decided beneficial influence on the vine growth and on the fruit production. The benefit is attributed chiefly to the encouragement and protection of surface-feeding roots. Similar results were secured at Geisenheim by the use of a mulch of basic slag. In the latter case the roots were not only protected, but the slag furnished a certain amount of plant food to the vines.

Investigations relative to the influence of the condition of the surface of the soil on the temperature of the air and of the soil showed the air to be warmer above level, shallow-tilled soil than above rough plowed soil. Newly plowed, moist soil cools the atmosphere to a considerable extent. The temperature at the base of the vines is higher than above the ridges between the rows. Level shallow culture starts vegetation earlier in the spring. Although the new growth is exposed for a longer time to spring frosts, these frosts are not so severe as on the cloddy soils. In order to lessen the danger from spring frosts it is suggested that soils should be left in a rough condition until growth starts,

and that when the buds begin to swell the surface of the soil should be either harrowed or rolled. Since grass and weeds play the same rôle as rough clods, they should not be cultivated out until the buds swell. Throwing the dirt away from the vines will also serve to retard growth.

The fertilizer requirements of grapes, G. Chiepaz (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, *29 (1908)*, *No. 44*, *pp. 517–522*).—The results are given of analytical studies made with grapevines and the fruit at six different periods during the growing season with a view of determining a suitable fertilizer for grapes as indicated by the amount of nitrogen, potash, phosphoric acid, and lime removed from the soil.

The data obtained show that about three-fourths of the total amount of nitrogen and five-eighths of the total amount of potash are taken up from the time growth starts to the flowering season. The absorption of these elements practically ceases when the fruits begin to show color. The phosphoric acid appears to be taken up almost entirely before the flowering season. Lime is taken up quite regularly throughout the growing season, the amount increasing as growth advances. It is estimated that a hectare (2.47 acres) of grapes removes from the soil annually from 40 to 80 kg. of nitrogen, 8 to 20 kg. of phosphoric acid, and 30 to 80 kg. of potash.

The origin of the red color in grapes, J. Laborde (*Bul. Assoc. Chim. Sucr. et Distill.*, *26 (1908)*, *No. 1–2*, *pp. 76–78*).—Red colors may be produced artificially in the leaves and fruits. The author has produced a red liquid from white grapes by heating in an autoclave at 120° for 30 minutes in a 2 per cent solution of hydrochloric acid.

The origin of red colored grapes, P. Malvezin (*Compt. Rend. Acad. Sci. [Paris]*, *147 (1908)*, *No. 7*, *pp. 384–386*).—Further experiments on the subject noted above. The author thinks the red coloring in nature is brought about by the combined action of air, light, heat, and diastase. In white grapes the diastase may be absent and the color can not be produced at ordinary temperatures, and therefore the red color may be produced from white grapes only when the temperature is raised artificially.

The transformation of the coloring matter in grapes during ripening, J. Laborde (*Compt. Rend. Acad. Sci. [Paris]*, *147 (1908)*, *No. 17*, *pp. 753–755*).—Determinations of the soluble, insoluble, and total coloring matter in grapes of different sorts at different stages of development are reported.

Tea on the Congo (*Bul. Off. Etat Indépend. Congo*, *24 (1908)*, *No. 10*, *Sup.*, *pp. 327–336*).—Data are given on experiments in growing and manufacturing tea at the Eala Botanic Garden. The results as a whole indicate that tea can be successfully grown in that region.

[Investigations in selecting and breeding opium poppies], J. M. Hayman (*Rpt. Cawnpore [India] Agr. Sta.*, *1907*, *pp. 14–17*).—Work is being conducted at the station in determining the extent to which the offspring of seed selected from highly productive opium poppies reproduces the same indications of high production. The results of the first year's work are presented in tabular form.

Seed was procured from selected parents producing from 4 to 6 grains of opium as against 2 and 3 grains in other cases. Comparing the average opium yield per plant of 1,120 seedlings with that of the average opium yield per plant of 14 parent plants, the progeny showed a decrease in yield of only about 1 grain. The work is to be continued.

The stability in type of different varieties of poppies was also tested, with special reference to the influence, if any, of cross-fertilization by bees. The results indicate that the types are distinct varieties and that bees have not thus far effected cross-fertilization. Studies of the growth of poppy plants lead

to the conclusion that the number of capsules per plant depends almost entirely on the condition of the land and the space allowed for the development of each plant.

FORESTRY.

The hardy conifers of Central Europe, E. SCHELLE (*Die Winterharten Nadelhölzer Mitteleuropas. Stuttgart, 1909, pp. VIII+356, figs. 171, pl. 1, map 1*).—This is a handbook for gardeners and garden lovers in which the author presents in concise form, aided by illustrations, the distinguishing characteristics of the native and exotic species and ornamental varieties of conifers adapted to the German climate. Consideration is also given to the habitat and morphology of conifers, together with cultural practices and methods of propagation.

Form and content of the fir, A. SCHIFFEL (*Mitt. Forstl. Versuchsw. Österr., 1908, No. 34, pp. 96*).—This is the fourth of a series of form and volume tables for conifers which the author has prepared by the form quotient method (E. S. R., 18, p. 1052). The tables for white pine have been noted (E. S. R., 19, p. 746), and similar tables for spruce and larch have been published.[a] The author is of the opinion that all other conifers can be cubed with sufficient accuracy by using the tables for one of the above-named kind. The form quotient method, however, can only be applied with safety to deciduous trees in computing the value of the bole up to where the crown starts.

Notes on the growth of pine trees at Greendale, T. W. ADAMS (*Canterbury Agr. and Pastoral Assoc. Jour., 10 (1908), No. 5, pp. 115–117*).—Brief notes are given on the growth of some 50 species of pine on the author's plantation in New Zealand. *Pinus laricio, P. coulteri, P. insignis,* and *P. ponderosa* are especially recommended for planting in that country.

Seeds of Lophira alata from Sierra Leone (*Bul. Imp. Inst., 6 (1908), No. 3, pp. 243–245*).—Analyses are given of the seeds of *L. alata*, a tree already known as one of the sources of the so-called African oak.

The seed was tested relative to its value as an oil seed. The fat content ranged from 31.19 per cent to 43 per cent, and the oil was valued by a soap manufacturer at about $5 to $10 per ton more than cotton-seed oil under ordinary market conditions. It has not as yet been determined at what price the seed can be marketed.

Timbers from Uganda (*Bul. Imp. Inst., 6 (1908), No. 3, pp. 227–239*).—Descriptions are given of over 50 Uganda timbers including several new species and genera relative to the wood structure and probable economic value of each.

On hardness tests of wood, G. JANKA (*Centbl. Gesam. Forstw., 34 (1908), No. 11, pp. 443–456, fig. 1*).—In a previous experiment the author determined the relative hardness of several kinds of wood by pressing into the wood, both radially and longitudinally, a small half-ball shaped iron die (E. S. R., 18, p. 341). A similar experiment is here reported, including the tabular results, in which the resistance of the wood of both conifers and hardwoods to the ball-shaped die was compared with its resistance to a cone-shaped die making the same sized impression at the surface of the wood.

As in the former experiment, an increase in the specific gravity of the wood was accompanied by an increased hardness. In all cases the hardness numbers with the ball-shaped die were greater than with the cone-shaped die, side impressions with the ball-shaped die giving the highest hardness numbers and end impressions with the cone-shaped die giving the lowest. The differences

[a] Mitt. Forstl. Versuchsw. Österr., 1899, No. 24; 1905, No. 31.

between the 2 dies, however, were quite variable even in the same species of wood. The author concludes that the cone-shaped die is best adapted to the testing of metals and homogeneous substances and that the ball-shaped die is more suitable for testing the hardness of wood. The author points out the simplicity of this impression method of testing the strength of wood as indicated by its hardness, and is of the opinion that it can largely take the place of the comprehensive bending and compression tests when suitable machinery is made for the purpose.

Tests of treated timbers (*Engin. News, 60 (1908), No. 13, p. 348*).—Extensive tests of the physical properties of timber that has been treated by preservative processes were conducted during the year by S. M. Rowe, and the results are to appear as a supplement to his Handbook of Timber Preservation (E. S. R., 17, p. 775). Two tables are here given which indicate the general results secured. Table 1 shows the ultimate crushing loads and other properties of some treated and untreated specimens, and Table 2 summarizes the results of tests on the absorptive properties of timber.

Report on the lumber industry in the Russian Far East, Hodgson (*Diplo. and Cons. Rpts. London, Misc. Ser., 1908, No. 670, pp. 12, map 1*).—This report contains a brief discussion of the forest areas of Eastern Siberia and Manchuria, the present status of the lumbering industry, the kinds of lumber, forest control and taxation, together with the regulations and scale of export duty in force in the Manchurian forest.

The estimated forest area in the Amur and Maritime Provinces is 509,000,000 acres, of which 19,000,000 acres belong to the Cossack administration.

Ceara rubber from Portuguese East Africa (*Bul. Imp. Inst., 6 (1908), No. 3, pp. 255–259*).—Analyses are given of 11 samples of plantation Ceara rubber from Portuguese East Africa, together with data on their preparation and notes on their commercial value. The results show that Ceara rubber of satisfactory quality and value can be produced in that country.

The length of the germinating period of Funtumia elastica seeds and method of preparing the fruits for shipment (*Bul. Off. État Indépend. Congo, 2½ (1908), No. 10, Sup., pp. 336, 337*).—When *F. elastica* fruits were stored at the Eala Botanic Garden for 8 months from the time of harvest, 45 per cent of the seed which was then sown germinated, whereas of seed which was decorticated and packed in charcoal, humus, sawdust, etc., only 12 per cent germinated at the end of one month after harvest. As a result of this investigation it is recommended that *F. elastica* seed be shipped in the whole thoroughly dried fruit either in tin cases or wooden boxes which should be left unsealed, in order to prevent sweating during the trip.

Rubber of Forsteronia floribunda from Jamaica (*Bul. Imp. Inst., 6 (1908), No. 3, pp. 259, 260*).—A sample of rubber of the *F. floribunda* vine, growing in the limestone districts of Jamaica, showed a crude rubber content of 79.3 per cent and a true rubber content in the dry rubber of 89 per cent.

Although the quality is good and the rubber readily salable the supply thus far has been irregular and small.

The science of Para rubber cultivation, II. Wright (*Colombo, Ceylon, 1907, pp. 97, pls. 4*).—This is a series of lectures with the discussions following, delivered by the author on various occasions in Ceylon and London. The following topics are included: Distance in planting and pruning (E. S. R., 18, p. 148); nature of the Para rubber tree and latex extraction; rubber cultivation and future production; rubber tapping demonstration; distance and interplanting (E. S. R., 18, p. 811); and rubber cultivation in the British Empire.

The International Rubber Exposition in London, September 14–26, 1908. S. Soskin (*Tropenflanzer Beihefte, 9 (1908), No. 6, pp. 285–336, pls. 3, chart*

1).—In addition to notes on the exhibits and sketches of the rubber industry in the several countries represented, consideration is given to the rubber industry as a whole relative to the total area planted to rubber and estimates of future production, the labor question and cost of planting operations, varieties, and methods and cost of harvesting and preparing rubber.

Reports of the superintendent of forests for 1904–1906, W. F. Fox (*N. Y. State Forest, Fish and Game Com. Ann. Rpts., 10–12 (1904–1906), pp. 35–112, pls. 7, fig. 1*).—These reports are similar in nature. The report for 1904 (E. S. R., 17, p. 871) and the report for 1906 (E. S. R., 19, p. 1147) have been noted as separates.

A statistical review of the forest administration of the Grand-Duchy of Baden for the year 1906 (*Statis. Nachr. Forstverw. Baden, 29 (1906), pp. XXI+135, dgms. 9*).—In addition to the statistical data for 1906 of forest areas, planting and cutting operations, yields, and revenue from various forest products comparative data are given for the period from 1878 to 1905.

Handbook for the Prussian forester, R. Radtke (*Handbuch für den Preussischen Förster. Neudamm, 1908, 4. ed., pp. XXXIV+999*).—This is a handbook of information relative to the state, communal, and private forest service of Prussia, the training and duties of foresters and forest guards, forest laws, regulations, etc.

Fire protection on the ticket-patrol system, D. N. Avasia (*Indian Forester, 34 (1908), No. 11, pp. 653–657, fig. 1*).—A brief description is given of the system of fire protection as carried out in the Allapilli teak forests in the Southern Circle of the Central Provinces, India.

DISEASES OF PLANTS.

Diseases and injuries to cultivated plants in 1905 (*Ber. Landw. Reichsamte Innern [Germany], No. 5, pp. VII+168*).—After reviewing the weather in relation to crop diseases and pests in Germany, a compilation is given of the diseases and insect injuries of cereals, root crops, forage plants, fiber plants, hops, tobacco, orchard fruits, grapes, vegetables, forest trees, etc. A tabular summary showing the distribution of the diseases, host plants, relative amount of injury, etc., concludes the report.

The potato black scab, T. Johnson (*Nature [London], 79 (1908), No. 2038, p. 67*).—The author reports that the abundant occurrence of the black scab of potatoes, due to *Chrysophlyctis endobiotica*, has enabled him to carry on some studies on the life history of the fungus. He has found that the so-called spores have proved to be zoosporangia and has studied the effects of temperature, nutrition, moisture, and light on their germination.

Soil sterilizing, Bordeaux mixture, and poisons for tobacco seed beds, W. T. Horne (*Estac. Cent. Agron. Cuba Circ. 30, pp. 11*).—Notes are given on hot-water sterilization of tobacco seed beds, the use of Bordeaux mixture for the control of the damping-off fungus, and poisonous baits for insects that affect tobacco plants in the seed bed.

Rust on wheat, J. M. Hayman (*Rpt. Cawnpore [India] Agr. Sta., 1907, pp. 54–57*).—For a number of years wheat has been grown in glass cages at the Cawnpore Station, the object of the investigation being to determine whether rust will appear on wheat grown under conditions which exclude the possibility of external infection. In all, 195 plants have been grown under protective conditions, and up to the end of the season of 1906 only negative results had been obtained. In 1907, however, a few pustules of rust were found occurring on the wheat plants in different glass cases. While there may have been some means for external infection, it is thought by the author to be

unlikely, as every precaution was taken to prevent the transmission of the disease in this way.

Studies were continued to determine the propagation of rust from season to season by volunteer wheat, but as yet no definite results have been obtained.

Experiments are in progress on the selection of rust-resistant varieties, in which a susceptible variety of wheat has been chosen and subjected to the conditions believed to favor the development of rust. While the past year was one favorable to rust, about 35 plants were secured that showed considerable resistance.

Peach leaf curl, yellows, rosette, and little peach, E. L. WORSHAM and W. V. REED (*Ga. Bd. Ent. Bul. 26, pp. 24, figs. 11*).—Descriptions are given of these diseases of the peach, with particular attention to the peach leaf curl.

From the results of a series of experiments for the control of the peach leaf curl, in which the trees were sprayed with Bordeaux mixture, copper-sulphate solution, lime-sulphur washes, Oregon wash, and soda Bordeaux, it appears that Bordeaux mixture, lime-sulphur wash, and Oregon wash, which is a modification of a lime-sulphur compound, were all effective in the control of the disease.

The other diseases are briefly described and, where known, suggestions given for their prevention.

Experiments for the control of Peronospora, H. SCHELLENBERG (*Landw. Jahrb. Schweiz, 22 (1908), No. 5, pp. 284–286*).—The results of experiments in spraying various fungicides on grapes for the control of downy mildew are given.

In one series of experiments the relative efficiency was tested of 0.5 and 1 per cent solutions of Bordeaux mixture and of different strengths of sulphur azurin and of Tenax, which is said to be a mixture of copper sulphate, aluminium sulphate, and soda. In these tests 4 and 5 applications of the fungicides were given at different periods during the season, and at the time of harvesting the average weight of grapes and the weight per vine were determined. In both instances the average weight of the individual grapes and the total production per vine were the highest where Bordeaux mixture had been used.

In a second series of experiments 2 per cent Bordeaux mixture, a sulphur-copper preparation, and 2 strengths of soda Bordeaux were compared. The best results were obtained with soda Bordeaux containing 2 kg. of copper sulphate and 0.9 kg. of soda to 100 liters of water.

The chestnut bark disease, E. A. STERLING (*Engin. News, 60 (1908), No. 13, pp. 332, 333*).—Attention is called to the disease popularly known as chestnut blight, which is due to the fungus *Diaporthe parasitica*. The commercial importance of the rapid spread of this disease is pointed out as threatening the existence of the chestnut tree as a factor in American forestry. The author states that the spread of the chestnut blight and the ultimate destruction of our chestnut forests will probably mean an annual loss to the United States of from $25,000,000 to $30,000,000.

The prompt removal and destruction of infected limbs and trees and the painting of wounds with tar paint will probably save individual specimens, but there appears to be little promise that the disease can be controlled in the extensive second-growth stands and merchantable timber throughout the range of the species.

The mildew of oaks, L. MANGIN (*Jour. Agr. Prat., n. ser., 16 (1908), No. 30, pp. 108–110, figs. 2*).—The mildew of oaks due to *Oïdium quercinum* is described. The author thinks that the fungus is the conidial phase of *Microsphæra alni*, and that while its attack could be prevented by the use of sulphur or some of the polysulphid sprays where only a few trees are to be treated, it will be found impracticable to attempt such means in forests or large plantations.

Epidemic of oak mildew, F. W. Neger (*Naturw. Ztschr. Forst u. Landw., 6 (1908), No. 11, pp. 539–542*).—An account is given showing the widespread epidemic of mildew of oaks in Europe during the summer of 1908, and the relation of the conidial stage of the mildew to the perfect form is discussed. A note by K. von Tubeuf describes briefly the occurrence of the mildew in Bavaria.

Notes on some new diseases of Coniferæ, A. W. Borthwick (*Trans. and Proc. Bot. Soc. Edinb., 23 (1907), pt. 3, pp. 232, 233*).—The author describes a new disease of *Picea pungens*, due to a fungus which attacks the buds and produces large black, conical swellings in which the fruiting bodies of the fungus occur. The bud is either immediately destroyed, or it may produce a much twisted cankered shoot which frequently dies at an early period. The characteristics of the fungus are said to resemble those of the various Cucurbitaria.

The second disease described is one of *Abies pectinata*. In this case the fungus belongs apparently to the Ascomycetes and it affects the leaves of the current year's growth. At first they become light brown in color and finally dark brown. At the maturity of the fungus the fructifications appear as small black, spherical swellings on the infested leaves. This fungus has caused considerable damage to the species mentioned above.

As yet neither of the fungi has been definitely determined and they are to be the subject of further investigation.

Annual report of the literature on plant diseases, M. Hollrung et al. (*Jahresber. Pflanzenkrank., 9 (1906), pp. VIII+298*).—This report, published in 1908, reviews the literature which appeared in 1906 relating to plant diseases and insect pests, about 1,800 papers being noted by title or abstract. The general groupings of the literature are general plant pathology and pathological anatomy, special pathology, plant hygiene, and methods for plant protection. The detailed arrangement and method of treatment of topics are similar to those in previous reports (E. S. R., 18, p. 746).

ECONOMIC ZOOLOGY—ENTOMOLOGY.

The zoological record, D. Sharp (*Zool. Rec., 43 (1906), pp. 1348*).—This volume contains the usual classified bibliographies covering the literature relating to all branches of zoology published during 1906, and in addition entries for 1901–1905 which were received too late for inclusion in the previous volume (E. S. R., 18, p. 1058).

A study of the pocket gopher, J. C. Dare (*Orchard and Farm, 8 (1908), No. 5, p. 11, fig. 1*).—A brief account of the habits and economic importance of the pocket gopher.

Rats and their animal parasites, A. E. Shipley (*Jour. Econ. Biol., 3 (1908), No. 3, pp. 61–83*).—Following a discussion of the habits and economic importance of rats, a complete list is given of all parasites, both ectoparasites and endoparasites, of which rats are known to serve as hosts.

The leprosy-like disease among rats on the Pacific coast, W. B. Wherry (*Jour. Amer. Med. Assoc., 50 (1908), No. 23, p. 1903*).—Out of over 30,000 rats examined 2 were found to be ill of a leprosy-like disease due to acid-fast bacilli. Both specimens were large female rats (*Mus decumanus*). A note is appended stating that since the above report was written a male and female of the same species have also been found affected with the disease. From the male was taken a single flea (*Ceratophyllus fasciatus*). This flea was ground up on a slide and stained by the tubercle method, but contained no acid-proof bacilli.

Experiments on rat extermination. R. O. Saigol (*Indian Med. Gaz., 43 (1908), No. 7, pp. 254–257*).—"Although hope had been extended from many quarters that rat extermination would be practicable by employing some microorganism which would not only produce a disease in the animals directly experimented upon, but an infectious fatal disease among the rat population as a whole through these diseased rats being let loose, this has not been borne out by the experiments given."

The warblers of North America. F. M. Chapman (*New York, 1907, pp. IX+306, pls. 32*).—This book has been prepared by the author in cooperation with other ornithologists to meet the demand for a fully illustrated work which will serve as an aid to the field identification of warblers and to the study of their life histories.

Our American flycatchers. B. S. Bowdish (*Sci. Amer. Sup., 66 (1908), No. 1710, pp. 226, 227, figs. 7*).—The habits, peculiarities, and economic importance of these birds are briefly described; photographs taken in the natural state accompany the article.

The midsummer bird life of Illinois: A statistical study. S. A. Forbes (*Amer. Nat., 42 (1908), No. 500, pp. 505–519*).—In continuation of earlier work (E. S. R., 18, p. 1143), observations were made in southern, central, and northern Illinois, 2 observers marching at a distance of 30 yards apart, covering a distance of 428 miles. Records were made of the number of each species of birds observed and of their ecological distribution. The number of native birds, European sparrows excluded, was found to be 527 to the square mile. A total of 7,740 individuals was observed, among which were recognized 85 species. Of these, 85 per cent belonged to the 21 most common species. The relative occurrence of bird life in crops, based on these data, is shown by the following table:

Birds observed in crops in midsummer, 1907.

Kind of crop.	Number.	Per cent.	Number per square mile.	Comparative densities. (Acreage for entire State=1.)
Pastures	2,107	27.2	878	1.36
Meadows	1,814	23.4	920	1.43
Grain	1,667	21.5	562	.87
Corn	1,169	15.1	300	.47
Other crops	983	12.8	.....	.....

A native bird destroying the sparrow. C. T. Musson (*Agr. Gaz. N. S. Wales, 19 (1908), No. 8, p. 680*).—The ground cuckoo-shrike (*Pteropodocys phasianella*) has appeared in one locality and is killing the sparrows though not attacking other birds.

The value of birds as insect destroyers. Mrs. W. F. Parrott (*Proc. Iowa Park and Forestry Assoc., 7 (1907), pp. 47–55*).—A brief account is given of birds as insect destroyers showing the importance of their protection.

Locusts birds. J. W. Gunning (*Transvaal Agr. Jour., 6 (1908), No. 24, pp. 527–530*).—A brief account is given of birds which feed upon locusts and are protected by law during certain seasons of the year.

Bufo fowleri in northern Georgia. H. A. Allard (*Science, n. ser., 28 (1908), No. 723, pp. 655, 656*).—Notes on the habits of Fowler's toad, which is shown to occur abundantly in much of the territory east of the Appalachian Mountains.

Report of scientific work in the field of entomology during 1906, G. SEIDLITZ (*Arch. Naturgesch., 73 (1907), II, No. 2, 1. half, pp. 448*).—A bibliography is presented of the literature on general entomology and the coleoptera published during the year 1906.

The new ideas on the origin of species by mutation, L. CUÉNOT (*Rev. Gén. Sci., 19 (1908), No. 21, pp. 860–871, figs. 8*).—The author discusses this subject at some length. A brief bibliography is given.

Notes on the value of introduced parasites or beneficial insects, W. W. FROGGATT (*West Indian Bul., 9 (1908), No. 3, pp. 262–264*).—A paper read at the meeting of the West Indian agricultural conference in which a brief account is given of an investigation of the value of parasitic insects in Hawaii and California.

Report of the entomologist, C. W. HOWARD (*Transvaal Dept. Agr. Ann. Rpt. 1906–7, pp. 193–217, maps 4*).—The greatest duty for the past 2 years has been that of combating the locusts, other work being considered secondary in view of the need of solving this question so that the farmers would have confidence in entering upon the work. A detailed account is given of the campaign against the brown and red locusts, together with maps showing the flights and areas infested by each species during 1906 and 1907.

Miscellaneous notes are included on the enemies of fruit trees and garden crops, and of insect parasites of man and domesticated animals.

Notes from Angola, F. C. WELLMAN (*Jour. Trop. Med. and Hyg. [London], 11 (1908) No. 8, pp. 117, 118, figs. 4*).—These notes are a continuation of a series which appeared in 1906. *Sarcopsylla penetrans* is mentioned as a factor in the ainhum disease. A list of 21 species of Tabanids is given. The effects of the sting of the common Angolan scorpion (*Uroplectes occidentalis*) and some other venomous arthropods are described.

Report of the State nursery inspector, A. E. STENE (*Ann. Rpt. Bd. Agr. R. I., 23 (1907), pp. 21–44, pls. 12, fig. 1*).—Among the injurious insects of the year here reported are the army worm, codling moth, apple maggot, frosted lightning hopper (*Ormenis pruinosa*), maple phenacoccus (*Phenacoccus acericola*), spruce gall louse (*Chermes abietes*), and rose scale (*Aulacaspis rosæ*). Various plant diseases are also reported.

Report of the superintendent for the suppression of the gipsy and brown-tail moths, for the year 1907, A. E. STENE (*Ann. Rpt. Bd. Agr. R. I., 23 (1907), App., pp. 1–52, pls. 9, figs. 2, map 1*).—A general account of these two pests and the work of suppression carried on in Rhode Island.

Notes on the work against the gipsy moth, E. P. FELT (*Jour. Econ. Ent., 1 (1908), No. 4, pp. 275, 276*).—This is a brief account of an examination made of the work being carried on in New England against the gipsy moth. Attention is called to a 10-horsepower gasoline engine manufactured for automobiles that is being used in place of a 6-horsepower engine weighing 1,800 lbs. formerly in use. A heavy 1½-in. hose from 400 to 800 ft. long with a smooth ¾-in. nozzle is used for work in woodlands, a pressure of 200 to 250 lbs. being maintained.

The machinery, which is mounted upon a stout wagon with a 400-gal. tank, is drawn by 4 horses. It is said to be capable of spraying 14 to 16 acres a day at a cost of about $10.20 per acre where the woodland is fairly clear of brush.

Description of new devices for rearing insects, A. F. BURGESS (*Jour. Econ. Ent., 1 (1908), No. 4, pp. 267–269, pls. 2*).—Several devices used at the Gipsy Moth Parasite Laboratory in Massachusetts are here described and illustrated.

Field tables of lepidoptera, W. T. M. FORBES (*Worcester, Mass., 1906, pp. 141*).—Tables based mainly upon color markings are here given for the adults

and for the larvæ. Data are also included on the food plants and dates of appearance.

Notes on the early stages of some Pamphila, P. LAURENT (*Ent. News, 19 (1908), No. 9, pp. 408–417*).—Notes are given on the life history of 17 species of butterflies belonging to the genus Pamphila. The larvæ seem to feed more readily on the coarser species of grasses.

Katra (hairy caterpillars) in Gujaret, C. U. PATEL (*Agr. Jour. India, 3 (1908), No. 2, pp. 152–160, dgm. 1*).—The species *Amsacta moorei, A. lactinea,* and *A. lineola* appear after the first fall of monsoon rain and attack and do great damage to newly grown crops, especially to millet. A general account is given of the life history, parasites, and enemies of this pest. Remedial experiments are reported.

On the Proctotrypid genus Antæon, with descriptions of the new species and a table of those occurring in Britain, A. J. CHITTY (*Ent. Mo. Mag., 2. ser., 19 (1908), Nos. 222, pp. 141–144; 223, pp. 145, 146; 225, pp. 209–215*).

Upon the aphis-feeding species of Aphelinus, L. O. HOWARD (*Ent. News, 19 (1908), No. 8, pp. 365–367*).—Four species of the genus Aphelinus are recorded as parasitic upon aphids, of which *Aphelinus semiflavus* and *A. nigritus* are here described as new. A table is given for the separation of these species.

Notes on the Coccinellidæ, T. L. CASEY (*Canad. Ent., 40 (1908), No. 11, pp. 393–421*).—Notes on the ladybirds with descriptions of one genus and several species and subspecies new to science.

On a collection of Coccidæ and other insects affecting some cultivated and wild plants in Java and in tropical western Africa, R. NEWSTEAD (*Jour. Econ. Biol., 3 (1908), No. 2, pp. 33–42, pls. 2*).—In addition to miscellaneous notes a genus, 6 species, and 2 varieties are described as new to science.

The present state of our knowledge of the Odonata of Mexico and Central America, P. P. CALVERT (*Science, n. ser., 28 (1908), No. 724, pp. 692–695*).—The author here presents a summary of the main results obtained from studies on the Odonata and a comparison with previous work done in this field.

An army worm in the Transvaal, F. THOMSEN (*Transvaal Agr. Jour., 6 (1908), No. 24, pp. 585–589*).—Army worms which may be *Caradrina exigua* or *C. orbicularis,* or both, are described as destroying the crop in one locality. A description is given of the stages, and also notes on the life history, habits, and food plants. Remedies are discussed.

The seventeen-year cicada on Staten Island in 1907, W. T. DAVIS (*Proc. Staten Isl. Assoc. Arts and Sci., 2 (1907–8), No. 1, pp. 1, 2*).—It is concluded that the individuals were sufficiently numerous to insure the insects' appearance in 1924.

A new predaceous enemy of the cotton boll weevil, W. NEWELL and R. C. TREHERNE (*Jour. Econ. Ent., 1 (1908), No. 4, p. 244*).—The carabid beetle, *Evarthrus sodalis,* and a second undetermined species of the same genus, are here reported as having been found to destroy *Anthonomus grandis.*

The first and last essential step in combating the boll weevil, W. E. HINDS (*Jour. Econ. Ent., 1 (1908), No. 4, pp. 233–243*).—This is a paper read at the meeting of the Association of Economic Entomologists, held in Chicago, in December, 1907. The author briefly reviews the results obtained in the investigation of the boll weevil, attention being called to both direct and indirect methods of combat. Particular attention is given to investigations conducted by W. W. Yothers and the author upon hibernation, a more detailed account of which is to be issued in bulletin form by the Bureau of Entomology of this Department. The following general conclusion is drawn:

"The destruction of stalks by some effective method and as long as may be possible before the normal time for weevils to enter hibernation constitutes

the most effective method now known of reducing the severity of the weevil attack upon the following crop and that it therefore deserves general recognition and adoption as the last step in the treatment of each season's crop and essentially the first step also in the production of a crop with the minimum weevil injury during the following season."

Notes on Transvaal tobacco pests, C. W. HOWARD (*Transvaal Agr. Jour., 6 (1908), No. 24, pp. 609–616, pls. 2, figs. 4*).—The only pests that the author considers at all serious are the cutworm, splitworm, and nematode. Notes are given upon the life history and habits of the splitworm (*Phthorimæa operculella*) gall worm (*Heterodera radicicola*), cutworm, bud worm (*Heliothis armiger*), pigweed caterpillar (*Caradrina exigua*), hornworms, aphis or green fly, green bug (*Nezara viridula*), and curculio beetles (*Peritelus ornatus* and *Strophosomus* sp.). Remedies are considered and directions are given for their application.

Insect pests of the mangel-wurzel, H. M. LEFROY (*Agr. Jour. India, 3 (1908), No. 2, pp. 161–163*).—The mangel-wurzel, while not one of the ordinary crop plants under cultivation in India, has been recommended as worthy to be made such. The insects which especially attack the plant are the surface weevil (*Tanymecus indicus*), which is followed by the surface caterpillar and later by the indigo caterpillar.

The earth flea, a common pest of winter vegetables, R. W. JACK (*Agr. Jour. Cape Good Hope, 32 (1908), No. 5, pp. 615–620, figs. 4*).—An account is given of a species of mite belonging to the family Enpodidæ which attacks nearly all commonly cultivated vegetables. It is stated that the injury can be largely prevented by clean cultivation and that the pest can be economically destroyed by spraying with the tobacco wash.

Grain weevils (*Bd. Agr. and Fisheries* [*London*], *Leaflet 206, pp. 4, fig. 1*).—An account is given of *Calandra granaria* and *C. oryzæ*, with remedial measures.

The diseases and enemies of useful and ornamental horticultural plants, F. KRÜGER and G. RÖRIG (*Krankheiten und Beschädigungen der Nutz und Zierpflanzen des Gartenbaues. Stuttgart, 1908, pp. VIII+212, pls. 4, figs. 224*).—In this book the author discusses the insect and other animal enemies as well as the plant diseases. Remedies are considered and indexes, of both plants and enemies, are given.

Experiments with remedies for insect enemies of fruit trees, TRUELLE (*Bul. Soc. Nat. Agr. France, 68 (1908), No. 7, pp. 507–513*).—A report is given of experiments with remedies for pests of fruit trees, particularly for *Hyponomeuta mainella*.

Massachusetts fruit trees and their insect foes, H. T. FERNALD (*Agr. of Mass., 1907, pp. 111–138, figs. 16*).—An address delivered before the meeting of the State board of agriculture in which the insect enemies of fruit trees of the State are discussed.

Gosford-Narara fruit fly and codling moth control experiment, W. B. GURNEY (*Agr. Gaz. N. S. Wales, 19 (1908), No. 7, pp. 581–584*).—The life history of *Ceratitis capitata*, the regulations in effect in November, 1907, with the penalty clause concerning care of fruit orchards, in connection with the codling moth and fruit fly, and an account of experiments to demonstrate to growers the practical value of carrying out the provisions of fruit fly regulations, are given.

The orchards were found badly infested with 3 species of fruit fly, the Mediterranean fly (*Ceratitis capitata*), the Queensland fly (*Dacus* (*Tephritis*) *tryoni*), and the Island fly (*Trypeta psidii*), the species first named being the more numerous. The 2 latter species have been bred from native plum or black apple (*Sideroxylon australe*), berries of white ash (*Schizoneria ovata*),

and wild black fig (*Ficus stephanocarpa*). It is thought, however, that reinfection from the wild fruit does not to any great extent annul the value of work done in orchards to check the fly.

Paraffin remedy v. poisoned bait [for the fruit fly], C. W. Mally (*Agr. Jour. Cape Good Hope, 32 (1908), No. 5, pp. 609–614*).—In experiments conducted it was found that *Ceratitis capitata* was not attracted to paraffin oil in comparison with pineapple juice and treacle (molasses). Bees were attracted to honey when sprayed on a hedge near a hive, but paid no attention to other sweets. This fact is of importance in connection with the application of poisoned bait for the fruit fly.

In a supplementary note, the government entomologist (C. P. Lounsbury) briefly reports additional experiments. He considers that the experiments here reported show that spraying the trees with poisoned baits, as previously recommended, affords greater protection against the pest than the exposure of vessels of paraffin oil.

Notes on a chalcid (Syntomaspis druparum) infesting apple seeds, C. R. Crosby (*Ann. Ent. Soc. Amer., 1 (1908), No. 1, p. 38*).—This species, previously known to infest the seeds of the wild apple in Crimea, has been found generally distributed in New York State where it infests the cultivated varieties as well as the wild apple (*Malus coronaria*).

The Smyrna fig and its pollinating insect, C. P. Lounsbury (*Agr. Jour. Cape Good Hope, 32 (1908), No. 5, pp. 561–568, fig. 1*).—An account is given of the rôle of *Blastophaga grossorum* in the fertilization of the flowers of the Smyrna fig. It is stated that the insect has been recently introduced into South Africa.

Report of the investigations of the olive fly in France in 1907, Chapelle (*Bul. Mens. Off. Renseig. Agr. [Paris], 7 (1908), No. 8, pp. 979–990*).—A description of *Dacus oleæ*, its life history, habits, and the nature of its injury is followed by an account of the work in combating it. The author concludes from researches in Italy and those here reported that the efficiency of the application of sweetened arsenicals is clearly demonstrated. The formulæ of insecticides used are given. Analyses of the oil from olives treated with these insecticides showed the presence of only traces of arsenic.

The fight against the olive fly, J. Chapelle (*Bul. Mens. Soc. Cent. Agr., Hort. et Acclim. Nice, 48 (1908), No. 8, pp. 239–247*).—A more extensive report of these experiments is noted above.

The pear-tree cephid, P. Passy (*Rev. Hort. [Paris], 80 (1908), No. 20, pp. 474–477, figs. 6*).—Pear trees are reported to be injured to a considerable extent and apple trees less so by *Cephus compressus* which, as a larva bores in the young twigs. The ichneumon, *Pimpla instigator*, plays an active rôle in the repression of the pest.

Isolation of orange groves and fumigation for the white fly, A. W. Morrill (*Fla. Fruit and Produce News, 1 (1908), No. 8, pp. 3, 7*).—A brief summary of results from fumigation experiments with hydrocyanic-acid gas which had been obtained since the preparation of Bulletin 76 of the Bureau of Entomology of this Department already noted (E. S. R., 20, p. 555). These show a wider applicability for the white fly than at first supposed. An isolation of 200 or 300 ft. will ordinarily insure immunity from the occurrence of the fly in injurious abundance for at least one season. The owner of a grove of 10 acres or more need not be deterred from fumigating on account of an infested grove of any size adjoining on one side. There are comparatively few groves that need be considered impracticable to fumigate on account of their location.

Observations upon the parasitism of an aphid that attacks citrus fruits, U. Pierantoni (*Atti R. Ist. Incoragg. Napoli, 6. ser., 59 (1907), pp. 1–7, pl. 1*).—

Aphidius aurantii, a brachonid attacking *Toxoptera aurantii*, is described as new to science. Observations upon the habits of the aphid and its parasite are accompanied by figures of both.

Cacao beetles and the use and application of lime, R. D. ANSTEAD (*Proc. Agr. Soc. Trinidad and Tobago, 8 (1908), No. 9, pp. 387–392*).—The cacao beetle (*Steirastoma depressum*) as a larva does great injury to the cacao trees, boring between the bark and the wood. Methods of preventing the injury are discussed.

Notes on Termes gestroi and other species of termites found on rubber estates in the Federated Malay States, H. E. PRATT (*Agr. Bul. Straits and Fed. Malay States, 6 (1908), No. 5, pp. 157–169*).—An account is given of injury by *Termes gestroi* to cultivated Para (*Hevea brasiliensis*) and Rambong (*Ficus elastica*) rubber trees. In order to distinguish this from other species a table is given for the separation of the common species met with on rubber plantations with descriptions of their various castes. Because of the damage to rubber trees of all ages and the difficulty in destroying it this white ant is considered to be the planter's most serious enemy. Methods to be employed in combating it are discussed.

The brown scale of the gooseberry and currant, R. NEWSTEAD (*Jour. Bd. Agr. [London], 15 (1908), No. 3, pp. 195–199, figs. 5*).—The scale *Lecanium persicæ ribis*, is said to be generally distributed throughout England but is less known in Wales, Scotland, and Ireland. An account of its life history is given and also the formulas and directions for applying the caustic-soda and paraffin-soda washes.

On an enchytraeid worm injurious to the seedlings of the larch, C. G. HEWITT (*Jour. Econ. Biol., 3 (1908), No. 2, pp. 43–45, pl. 1*).—A small white worm which was identified as *Fridericia bisetosa* is described as frequently attacking larch seedlings. Its presence is readily discernible by the dead and withered appearance of the plants. Injections of carbon bisulphid into the soil at a distance of 6 or 8 in. on each side of the row in doses of 0.25 to 0.50 oz. are recommended.

A new cecidomyiid on oak, H. M. RUSSELL and C. W. HOOKER (*Ent. News, 19 (1908), No. 8, pp. 349–352, pl. 1*).—A new species of gall fly which works on the leaves of the black oak is described as *Cecidomyia foliora*. Its life history and a description of the immature stages are given.

The life history of Syagrius intrudens, a destructive fern-eating weevil, J. MANGAN (*Jour. Econ. Biol., 3 (1908), No. 3, pp. 84–91, pls. 2*).—This weevil is reported as a persistent and exceedingly destructive pest of ferns at the Royal Botanical Gardens at Dublin. The larvæ burrow through the larger portions of the stems and even in the hardest parts of the rhizome. The ravages appear to be strictly confined to hothouse ferns. The most successful method of dealing with the pest is said to be that of soaking the roots in water. After a period of 15 minutes' immersion, all the weevils in the soil will have taken refuge in the stems, where they can be picked off by hand and destroyed.

A new species of tick from the Transvaal, L. G. NEUMANN (*Ann. Transvaal Mus., 1 (1908), No. 2, pp. 170–172*).—The author here describes *Rhipicentor ricinus*, a tick taken from *Erinaceus frontalis* at Pretoria, as a new species.

The structure, development, and bionomics of the house fly, II, C. G. HEWITT (*Quart. Jour. Micros. Sci. [London], n. ser., 52 (1908), No. 208, pp. 495–545, pls. 4*).—A second paper on the subject (E. S. R., 19, p. 664).

Temperature, character of food, moisture, and fermentation are shown to be the important factors in the development of the fly. Under favorable conditions, eggs may hatch as soon as 8 hours after deposition, while if kept at a temperature as low as 10° C., 2 or 3 days may elapse before the larvæ

emerge. The larval stage consisting of three instars may be passed in 5 days. The process of pupation may be completed in 6 hours and the pupal stage passed in 3 or 4 days, although it is usually 4 or 5 days.

The shortest period in which development took place was 8 days, when larvæ were incubated at a constant temperature of 35° C. Flies become sexually mature in 10 or 14 days after emergence and commence oviposition as soon as 4 days later. A bibliographical list is given.

Observations on the bionomics of fleas with special reference to Pulex cheopis (*Jour. Hyg. [Cambridge]*, *8 (1908)*, *No. 2, pp. 236–259*).—The life history, habits, dispersal, and collection and examination of fleas are here considered. Longevity and other experiments are reported.

The part played by insects in the epidemiology of plague, D. T. Verjbitski (*Jour. Hyg. [Cambridge]*, *8 (1908)*, *No. 2, pp. 162–208*).—Experiments were made by the author at Cronstadt and St. Petersburg with fleas and bugs with a view of determining the connection between human plague epidemics and plague epidemics among rats. Infected fleas were found to communicate plague to healthy animals for 3 days and bugs (*Cimex lectularius*) for 5 days after infection. The rat flea of Russia (*Typhlopsylla musculi*) does not bite man, but the fleas infesting man do bite rats and the fleas found on dogs and cats bite both human beings and rats. Fleas infesting man and fleas found on cats and dogs can live on rats as casual parasites and therefore can, under certain conditions, play a part in the transmission of plague from rats to human beings and vice versa.

Insect transmission of bubonic plague: A study of the San Francisco epidemic, M. B. Mitzmain (*Eut. News*, *19 (1908)*, *No. 8, pp. 353–359*).—An account is given of the fleas obtained in the examination of 1,800 rats. These examinations were made in an attempt to locate the source of the rat and flea introduction into the infected regions of California.

Preservation of the plague bacillus in the body of the bedbug, V. Jordansky and N. Kladnitsky (*Ann. Inst. Pasteur*, *22 (1908)*, *No. 5, pp. 455–462*).—The work of other investigators is briefly reviewed, and experiments with rats are reported. The authors find that the plague bacillus is preserved in virulent form in bedbugs for 10 days or longer, and conclude that in certain cases at least this insect may be an active agent in the transmission of the disease.

Report on the anatomy of the tsetse fly (Glossina palpalis), E. A. Minchin (*Rpts. Sleeping Sickness Com. Roy. Soc., 1907, No. 8, pp. 106–122, figs. 6*).—A description accompanied by drawings of the general anatomy of *Glossina palpalis* especially of its digestive tract. This is of importance in the study of the evolution of trypanosomes within the body of their arthropod hosts.

The reproduction and variations in the development of Glossina palpalis, E. Roubaud (*Compt. Rend. Acad. Sci. [Paris]*, *146 (1908)*, *No. 7, pp. 362–365; abs. in Bul. Inst. Pasteur*, *6 (1908)*, *No. 10, p. 480*).—The author has made life history studies of *G. palpalis*, the results of which are here reported.

Glossina palpalis in its relation to Trypanosoma gambiense and other trypanosomes, E. A. Minchin, A. C. H. Gray and F. M. G. Tulloch (*Rpts. Sleeping Sickness Com. Roy. Soc., 1907, No. 8, pp. 122–136, pls. 2, figs. 11, map 1*).—Experiments made to determine the exact mode of infection, particularly as to whether the fly becomes infectious at any definite period after having been fed on an infected animal, gave negative results, although positive proof was obtained that *G. palpalis* can convey trypanosomes by means of its proboscis from an infected to a healthy animal if it goes straight from one to the other. Infection was thus transmitted in 4 out of 5 experiments when *G. palpalis* was used as the transmitting agent and once out of 4 experiments when a Stomoxys was used. It is shown that the infection is conveyed by the con-

tamination of the proboscis and that if the fly be allowed to clean its proboscis by piercing the skin of one animal, it is no longer infectious to a second.

Experiments seem to show that the number of fly-bites required to produce infection is a very variable one, more than 1,000 flies having fed on a susceptible animal without infecting it. The smallest number of *G. palpalis* with which sleeping sickness was produced by the authors was 134.

"At 48 hours after feeding, the trypanosomes (*T. gambiense*) are still numerous in the intestine of the fly, and a type of more indifferent character begins to make its appearance. At 72 hours the trypanosomes are usually beginning to become more scanty and difficult to find in the digestive tract of the fly, although in some cases they are still numerous and chiefly of the indifferent type. At 96 hours, in almost every case, not a single trypanosome could be found even after the most careful searching." So far as conclusions could be drawn from the observation it appears that *T. gambiense* becomes extinct in the tsetse fly after the third day.

Two species of trypanosomes (*T. grayi* and *T. tullochii*) were found in freshly caught tsetse flies, the former in 1.47 per cent and the latter in 0.17 per cent of 3,000 flies examined. These 2 species were found to have nothing to do with sleeping sickness and are not developmental stages of *T. gambiense*.

Report on experiments to ascertain the ability of tsetse flies to convey Trypanosoma gambiense, P. H. Ross (*Rpts. Sleeping Sickness Com. Roy. Soc., 1907, No. 8, pp. 80–85*).—From experiments conducted with *Glossina fusca* and *G. pallidipes*, the author concludes that the former does not convey any species of trypanosoma, but that the latter evidently can. Having the work of Schaudinn in mind, the author searched but did not find an intracorpuscular stage of trypanosoma. *G. pallidipes* is said to attack as soon as one gets among them, while *G. fusca* shows no inclination to bite men. *G. longipennis* does not appear to bite during the day, but after 4 p. m. one is immediately bitten upon approach.

Descriptions and records of bees, T. D. A. Cockerell (*Ann. and Mag. Nat. Hist., 8. ser., 1 (1908), Nos. 3, pp. 259–267; 4, pp. 337–344*).—In the first article, in addition to descriptions of exotic species, 1 genus and 3 species from this country are described as new. In the second article 11 species from this country belonging to the genus Megachile are described as new.

Winter ventilation of hives, C. P. Dadant (*Amer. Bee Jour., 48 (1908), No. 11, pp. 333, 334*).—The author finds moisture absorbents over the cluster to be better than upper ventilation and that a slight amount of upper ventilation is better than a tight ceiling impervious to moisture. Entrance ventilation in a moderate degree is considered necessary.

[A digest and discussion of papers on bee keeping] (*Texas Dept. Agr. Bul. 3, pp. 119–135*).—A report and discussion of papers presented at the annual meeting of the Texas Bee Keepers' Association in which a number of subjects relating to apiculture, including varieties of bees, forms of hives, location and management of colonies, storing and marketing of honey, effect of pure food law, prices, etc., are presented and discussed.

Report of the State inspector of apiaries, M. E. Darby (*Ann. Rpt. Mo. Bd. Agr., 40 (1907), pp. 59–66, figs. 2*).—Out of 215 apiaries and 3,028 colonies inspected during 1907, 82 apiaries and 297 colonies were found infected with foul brood.

The Argentine ant, a possible pest of the apiary, R. Benton (*Gleanings Bee Cult., 36 (1908), No. 23, pp. 1432–1434*).—The author records observations on the Argentine ant made in the vicinity of a colony of bees in California. He believes that the ants become sufficiently troublesome to interfere seriously with the field work of the bees and so prove themselves the cause of almost

inestimable loss. In correspondence, it has been learned that Newell has found at Baton Rouge, Louisiana, that the ants vigorously attack the larvæ in the hives and also carry away stored honey. These colonies have, however, been protected by the use of a stand having four legs, each resting in a dish of water. Mention is made of an ant which the author has observed in Montana to attack and cut up live bees at the hive entrance.

The silk industry. E. L. Peñafiel (*Prácticas de Industria Sedera. Madrid: Govt., 1907. pp. 103, figs. 38*).—In this guide details are given of the raising of silkworms and of silk production.

FOODS—HUMAN NUTRITION.

Constituents of the urine and blood and the bearing of the metabolism of Bengalis on the problems of nutrition. D. McCay (*Sci. Mem. Med. and Sanit. Depts. India, n. ser., 1908, No. 34, pp. 67*).—This comprehensive investigation was undertaken particularly to study the relation of the native diet, low in nitrogen and high in nonnitrogenous constituents, to physical condition, body development, health and efficiency in comparison with the diet of Anglo-Indians and Eurasians in India.

As a part of the investigation, analyses were made on four or five consecutive days of the urine of 28 native students and assistants of the higher castes and of 16 natives of other castes, all of these being adult Hindus upon their ordinary diet. Observations were also made upon the blood of 170 Bengalis, two-thirds of them students and the remainder of different classes, but all apparently in good health and typical of the groups selected. The urine data showed that the average quantity of total nitrogen, urea, uric acid, and sulphates was lower than with Europeans according to the comparison made. Differences were also noted in the blood. As regards the observed low blood pressure of Bengalis in comparison with Europeans, the author believes that it must affect their vigor and energy. The observed differences in the chemical composition of the blood are ascribed to the use of a diet low in nitrogen, which prevents the nitrogenous tissues from drawing their nutritive material from so rich a source or from obtaining so free a supply of oxygen.

In the discussion of the daily metabolism of nitrogen it is pointed out that the value of 0.115 to 0.111 gm. per kilogram of body weight, which was noted in these studies, is essentially the quantity which is sometimes advocated as sufficient. Since this quantity represents the amount supplied by the usual diet of these native Indians, it confirms the conclusion that the body may be maintained in nitrogen equilibrium for a long time on a diet furnishing about one-third of that supplied by the commonly accepted dietary standards. From data summarized as to the body weight, height, and chest circumference of about 2,500 Bengali students, however, the author concludes that the Bengalis "do not reach the same standard of general physique as is attained by races of European origin; and yet from the evidence we can find no cause inherent in the Bengali as a race for this deficiency; on the contrary, we consider that there may be a very close relationship between the lower physical development of this people and the meager proteid constituent of the diet on which they subsist."

Studies are reported in detail of the nitrogen balance of 2 students living for 4 days on a diet consisting largely of rice and legumes. With the total computed intake 34.84 and 42.24 gm. nitrogen, respectively, there were gains of 0.80 and 0.51 gm. The nitrogen of the feces was very large, constituting from 23.86 to 25.42 per cent of that ingested. A similar set of investigations followed on 4 healthy prisoners for 35 days at hard labor on a diet in which

practically all the nitrogen was derived from rice and dhall (legumes). From 24.67 to 26.72 per cent of the nitrogen was excreted in the feces, but the nitrogen absorbed, averaging 0.185 gm. per kilogram daily, is believed to have been sufficient to meet all nitrogenous requirements. This large waste in the alimentary canal is deemed by the author exceedingly objectionable, not only from its economic aspects, but also in that it tends to permit excessive bacterial growth and the formation of toxic compounds, and he believes that it must be a factor in the prevalence of intestinal disorders and the causation of dysentery and kindred diseases.

From records extending over long periods the character and nutritive value of the diet of Bengali and Anglo-Indian and Eurasian students in Indian colleges are reported. The native diet in accordance with the usual food habits contained large proportions of carbohydrate foods, and little animal food, while that of the Anglo-Indian and Eurasian students was liberal as regards animal foods and other food constituents. Data of this character are summarized in the following table:

Nutrients in dietary of students in colleges in India.

[Quantity per man per day.]

Group studied.	Number of persons.	Protein.	Fat.	Carbohydrates.
		Gm.	*Gm.*	*Gm.*
Bengali students	568	67.1	71.6	548.7
Bengali students (more deficient dietary)	.....	43.6	33.9	200.3
Anglo-Indian and Eurasian students	.....	87.6	54.7	376.5
Do	126	94.97	56.2	467.0

Tabulated records extending over a large number of years were also available to the author as to the physical measurements of the 568 Bengali students included in the above table whose dietary provided a protein intake of 67.1 gm. per day of which 50.8 gm. was estimated to be digestible.

Although these students entered college at an average age of 17 or 18 years, the average increase in body weight from the first to the third year of their stay was but 2 lbs., only 15.3 per cent gaining continuously and 42.8 per cent showing a diminution. The chest girth also remained practically stationary, while the height increased from 1½ to 2½ in. It is concluded that "the metabolism of 0.148 gm. nitrogen per kilogram of body weight is not sufficient to meet the nitrogenous needs of the growing Bengali, and in from 30 to 40 per cent of the 568 examined was insufficient to prevent the loss of formed tissue proteid as the loss in body weight would appear to mean." Similar data for 126 Anglo-Indian and Eurasian students in the same college showed that on the diet furnished them, which supplied 0.203 gm. nitrogen per kilogram the students gained 14 lbs. in the first 3 years, only 2 per cent showing a diminution in weight. "The two classes enter college at about the same age, live in the same climate and under very similar conditions . . . but the results at the end of their college career are very different. The Anglo-Indian and Eurasian boys develop into strong, healthy men quite up to the average of European standards, while the Bengali students almost remain stationary as regards development."

Interesting statistics are given and comparisons made regarding the physical endurance of Bengali and European laborers, which, according to the author, show the decided superiority of the Europeans.

In discussing the effect of native diet on health, it is pointed out that the lowest insurance rate for native Indians is 33 per cent higher than that for Europeans in Europe and that there are many restrictions. Records of medical cases treated in the Medical College Hospital in Calcutta showed that the proportion of natives treated for kidney diseases was a little over twice that of Europeans. According to the author, it is surprising to find so great a prevalence of renal disease "in a country where scarlet fever is unknown," and in his opinion the observed facts do not indicate that "with a low proteid diet kidney function is less likely to become impaired. So far as the evidence goes, it would tend to show that, even with the exceedingly low nitrogenous intake of the population of Bengal, kidney disease is more common among natives than among Europeans."

Susceptibility to diabetes is also discussed. "Diabetes mellitus in Europeans is not accompanied in any very high percentage of cases by organic changes in the kidney—at least not in the earlier stages of the disease; whereas in the Bengali, albuminuria, even at the beginning of dietetic glycosuria, is fairly common. We are greatly inclined to think that the explanation of these differences rests largely with the nutritive power of the plasma in the two classes of people; the poor nitrogen content of the plasma in the Bengali starving the renal cells and causing them to lose their physiological property of preventing a filtration of the serum albumin of the blood into the tubules. . . . It would, therefore, appear that the large carbohydrate intake rendered necessary by a diet poor in nitrogen, and of course much more so the great quantities of sugar consumed by the Bengali, is even more likely to lead to injury and damage to the delicate tissues of glandular and other organs and to a diminution in the resisting power of the system than any excessive nitrogenous intake."

Parsimony in nutrition. J. CRICHTON-BROWNE (*Jour. Roy. Inst. Pub. Health, 16 (1908), Nos. 8, pp. 471–487; 9, pp. 527–552*).—A critical discussion of low proteid diet which the author does not regard as generally desirable.

Fads and feeding, C. S. READ (*London, 1908, pp. 163; rev. in Brit. Med. Jour., 1908, No. 2501, p. 1684*).—A popular discussion of different systems of diet.

Retail prices of food, 1890 to 1907 (*Bur. of Labor [U. S.] Bul. 77, pp. 181–332*).—A compilation of data regarding retail prices of food which on an average, it is stated, were higher in 1907 than in any other year of the 18-year period included, being 4.2 per cent higher than in 1906.

Cost of living of the working classes in the principal industrial towns of Great Britain (*Bur. of Labor [U. S.] Bul. 77, pp. 336–353*).—The data here reported were presented to Parliament in December, 1907, by the Labor Department of the British Board of Trade and represent the result of a comparative study of rents, prices paid for foods and other commodities and for fuel, and the standard rates of wages in certain selected localities.

Studies of the dinners served in Berlin restaurants, K. KIFSKALT (*Arch. Hyg., 66 (1908), No. 3, pp. 244–272*).—Detailed statistics are given of the kind and quantity of food served for dinners in a number of moderate-priced restaurants in Berlin and the nutritive value of the food. The results are discussed in comparison with those of earlier investigators and the author concludes that the nutritive value of such meals, owing to the higher cost of the portions served, is not greater than in 1895 when they were considered to furnish too little protein.

Food in Asiatic Turkey (*Daily Consular and Trade Rpts. [U. S.], 1908, No. 3297, pp. 8–10*).—Data supplied by E. L. Harris on diet and habits of the native population in Asia Minor and by T. R. Wallace on food and diet in Palestine are summarized.

The feeding of school children (*Pub. Health [London], 22 (1908), No. 3, pp. 97, 98*).—A review of a report by Hope published by the Liverpool Corporation on the subject of the insufficient or improper feeding of school children. A large amount of data is presented regarding existing conditions, the providing of meals for poor school children, and also regarding general food conditions.

"It will be seen that improper and injudicious feeding is exceedingly common, and by no means restricted to the poorer classes."

The feeding of the soldier (*Med. Rec. [N. Y.], 74 (1908), No. 15, p. 622*).—A discussion of recent information regarding the feeding of soldiers which led to the conclusion that a varied diet is best for the soldier as for the majority of individuals and "that a soldier on active duty benefits by a goodly proportion of meat in his rations."

Diets in tuberculosis, N. D. Bardsman and J. E. Chapman, *New York, 1908, pp. 184; rev. in Jour. Amer. Med. Assoc., 51 (1908), No. 13, pp. 1098, 1099*).—From their own observations and experience and the summary of results obtained by coworkers in Europe and America the authors have deduced some general principles regarding the diet of consumptives and the comparative value of different foodstuffs for the purpose.

Notes on scurvy in South Africa, D. M. Macrae (*Lancet [London], 1908, I, No. 26, pp. 1838–1840*).—In this discussion of a scurvy outbreak in South Africa, which the author attributes to the fact that the Kafirs, after having received the more generous rations supplied by the Government, were forced to subsist on a rather low diet largely of corn and with little meat, he states that marked success in treating scurvy has attended the use of a diet relatively rich in meat and that in cases where the recovery has been attributed to other food material it must be remembered that fresh meat has formed an important part of the ration. "It seems beyond doubt, however, that the elements necessary to maintain the equilibrium of bodily health belong to both fresh vegetables and animal food. Yet the facts of clinical experience have convinced the writer that the recent tendency to ascribe even the preponderance of merit in the treatment of scurvy to the use of fresh meat is not without considerable justification. In fresh raw meat or raw meat juice the physician possesses a remedy which he may use even in severe cases of scurvy."

How to cure spleens for food, E. T. Williams (*Amer. Med., n. ser., 2 (1907), No. 9, pp. 522, 523*).—Continuing work previously noted (E. S. R., 19, p. 459), the author on the basis of personal experience and other data discusses the palatibility and wholesomeness of spleens and their preparation for the table, and points out that although raw spleens do not keep well, the cooked material, particularly when boiled, has excellent keeping qualities. Attention is also directed to the high iron and phosphoric acid content of spleens.

The cooking of legumes (*Pure Products, 4 (1908), No. 6, pp. 252–254*).—A summary and discussion of reports by Kochs on the effects of different methods of cooking hulled peas, green peas, and lentils. Under all experimental conditions the largest amount of material was removed from hulled peas, as is natural, since the skin if present hinders extraction. More material was removed by combined soaking and boiling than by either process alone.

The book of fruit bottling, Editii Bradley and May Crooke (*London, 1907, pp. XVI+97, pls. 10, figs. 7*).—A large number of recipes are given for canning, preserving, and drying fruit, and on cider making. Some information on cookery in ancient times is also summarized.

Recipes for the preserving of fruit, vegetables, and meat, E. Wagner (*New York and London, 1908, pp. VIII+119, figs. 14*).—This work contains instructions for the beginner and the expert in preserving fruits and nuts in bottles and

tins, glazed and candied fruits, fruit juices, sirups and pulps, jellies, jams and marmalades, citron and orange peels, vegetables, mushrooms and truffles, pickles and piccalilli, meats and meat pastes.

The household gas-cookery book, Helen Edden and Mrs. Moser (*London, 1908; rev. in Epicure, 15 (1908), No. 180, p. 310*).—A cook book "with a considerable amount of practical information about the use of the gas cooking range."

The up-to-date home. Labor and money-saving appliances (*Bul. Amer. School Home Econ., Ser. 1, 1908, No. 11, pp. 47, figs. 5*).—Information is given regarding a number of labor-saving devices which have been tested at the American School of Home Economics. The desirability of labor-saving devices in the home is pointed out. "Any household appliance should save more time and labor than it takes to adjust it and clean it after use. . . . An appliance should be used sufficiently often to save more time and trouble than it gives."

Refrigeration on the homestead, H. V. Jackson and A. E. Lea (*Agr. Gaz. N. S. Wales, 19 (1908), No. 7, pp. 537–552, pl. 1, figs. 9*).—A description of refrigerating machines and directions for storing eggs, fruits, vegetables, rabbits, poultry, pork, ham, bacon, and fish.

Canned meats, A. McGill (*Lab. Inland Rev. Dept. [Canada] Bul. 16, pp. 11*).—Data are given regarding the examination of 76 samples of canned and potted poultry and meats. With the exception of a sample of potted pheasant the goods "have been found in perfect condition of preservation." Boracic acid, the only preservative found, was present in 28 samples or nearly 37 per cent of the total number examined. Examinations for starch in potted meats showed that 17 samples contained less than 1 per cent, 5 samples between 1 and 2 per cent, and 8 samples above 2 per cent, while no starch, or only traces, was found in 46 samples. As the author points out, all of the samples containing above 2 per cent of starch were sold as "loaf" meats, with the exception of a sample of sausage.

On the nature and causes of taint in miscured hams, E. Klein (*Lancet [London], 1908, I, No. 26, pp. 1832–1834, figs. 3*).—According to the author's observations, the taint occasionally found in miscured hams which have undergone dry curing is due to a micro-organism which he isolated and studied and for which the name *Bacillus fœdans* is proposed.

Drawn v. undrawn poultry, E. W. Burke (*Amer. Food Jour., 3 (1908), No. 9, pp. 7–10*).—A summary and discussion of data including legal enactments regarding drawn versus undrawn poultry. More extended legislation is recommended. According to the author, arguments are all in favor of drawing poultry. As he points out, it should be carefully drawn and kept as clean as larger animals "not only for keeping qualities but for healthfulness and flavor." The article was presented at the twelfth annual convention of the Association of State and National Food and Dairy Departments, 1908.

The water content of sausage, A. Röhrig (*Ber. Chem. Untersuch. Anst. Leipzig, 1907, p. 13; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 6, p. 360*).—Determinations of the water content of several sorts of sausage are reported.

Water content of sausage, H. Kreis (*Ber. Chem. Lab. Basel, 1907, pp. 21, 22; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 6, p. 360*).—Analytical data are reported.

Nut sausage, G. Kappeller and W. Theopold (*Ber. Nahrmtl. Untersuch. Amt. Magdeburg, 1907, p. 22; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 6, p. 361*).—An analysis is reported.

The origin, manufacture, and uses of extract of meat (*Lancet [London], 1908, II, No. 17, pp. 1233–1244, figs. 8, dgm. 1, maps 3*).—An illustrated, descriptive article on the Argentine meat extract industry.

Meat extract, A. Röhrig (*Ber. Chem. Untersuch. Anst. Leipzig, 1907, p. 11; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 6, p. 361*).—Analyses of 5 samples of meat extract are reported.

The food value of the herring, T. H. Milroy (*Ann. Rpt. Fishery Bd. Scot., 24 (1905), pt. 3, pp. 83–107; 25 (1906), pt. 3, pp. 197–208; Bio-Chem. Jour., 3 (1908), No. 6–8, pp. 366–390*).—The results of an extended series of analyses of herring taken on different parts of the Scotch coast are reported and discussed with reference to the changes which the herring undergoes before, during, and after the spawning period. Phosphoric acid was determined, as well as water, protein, and fat, and in later analyses determinations were also made of the coagulable muscle proteins.

Added preservatives in fish goods, M. Kozyn (*Vyestnīk Obshch. Hig., Sudeb. i Prakt. Med., 42 (1906), pp. 1439, 1440; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 6, p. 359*).—A study of the character of the preservatives and the extent to which they are used in canned fish and similar goods in Moscow.

The penguin egg (*Sci. Amer. Sup., 66 (1908), No. 1716, p. 330*).—An account of the collection and use of penguin eggs which are eaten in quantity in South Africa. The article states that the eggs are not very different in flavor from those of the common hen although the penguin feeds on fish. On cooking, the albumin does not become solidified but retains a jelly-like character and is of a bluish color. In size the egg approximates that of a goose. Successful shipments of these eggs have been made to Great Britain.

Preserved egg goods, A. Röhrig (*Ber. Chem. Untersuch. Anst. Leipzig, 1907, pp. 14, 15; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 6, p. 364*).—Data given regarding the composition of 3 sorts of preserved egg goods.

Preserved egg yolk, G. Benz (*Ber. Untersuch. Amt. Heilbronn, 23 (1907), pp. 14, 15; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 6, p. 364*).—In this account of commercial egg yolk preparations the author declares against the use of methyl alcohol as a preservative.

Experiments on bread fermentation, A. J. J. Vandevelde, L. Bosmans and A. Revijn (*Separate from Verslag. en Meded. K. Vlaam. Akad. Taal en Letterk., 1908, pp. 493–526*).—In continuation of work previously noted (E. S. R., 20, p. 463), the authors studied the factors which affect fermentation and quality of bread.

The use of sugar in bread making as a means for increasing the consumption of sugar, F. Dupont (*Ztschr. Ver. Deut. Zuckerindus., 1908, No. 634, II, pp. 992–994*).—The addition of sugar to bread is proposed as a desirable method of increasing sugar consumption.

A new type of bread for peasants, P. Gibelli and E. Grüner (*Ann. Ist. Agr. [Milan], 7 (1905–6), pp. 95–106*).—In view of danger from pellagra a special method of bread making is described and an analysis reported in comparison with maize bread.

Potentialities of plantain meal (*Indian Agr., 33 (1908), No. 8, p. 243*).—In an article quoted from the *Indian Trade Journal* the value of plantain or banana flour is discussed and an analysis by Hooper quoted.

How to prevent checking in biscuits and crackers, W. B. Crocker (*Rpt. Ann. Meeting Biscuit and Cracker Manfrs.' Assoc., 1908, pp. 16–18*).—On the basis of experience the author discusses the cause and prevention of checking in crackers and similar goods. The importance of flour of the right degree

of strength, proper mixing, baking, and similar features are insisted upon, and the flour used, it is stated, should be at least 70° F. in temperature.

The molecular weight of dextrin of honey from Coniferæ, H. Barschall (*Arb. K. Gsndhtsamt., 28 (1908), pp. 405–419; abs. in Chem. Zentbl., 1908, II, No. 1, p. 91*).—It is considered probable that the honey dextrin under consideration is a trisaccharid, though more data regarding its chemical nature are considered desirable.

The composition of pineapples, W. Bonewitz (*Chem. Ztg., 32 (1908), No. 15, pp. 176, 177; abs. in Chem. Abs., 2 (1908), No. 10, p. 1466*).—The data reported include proximate and ash analyses.

Spoiled plum jam, P. Köpcke (*Pharm. Zentralhalle, 49 (1908), pp. 376, 377; abs. in Chem. Zentbl., 1908, II, No. 1, pp. 91, 92*).—An analysis is reported of spoiled plum jam in comparison with analyses of 2 samples of normal taste and appearance.

Olive oil, A. McGill (*Lab. Inland Rev. Dept. [Canada] Bul. 159, pp. 10*).—Of 82 samples of olive oil examined 64 were found to be genuine and 15 adulterated, while 3 samples which were sold as salad oil without the use of the word "olive" were designated as doubtful.

New experiments on olive preservation, G. Frezzotti (*Bol. Uffic. Min. Agr., Indus. e Com. [Rome], 7 (1908), IV, No. 9, pp. 893–898*).—Experiments on different methods of preserving olives for oil making are reported and discussed.

Treatment of green olives which have undergone fermentation due to Bacterium coli commune, A. Kossowicz (*Ztschr. Landw. Versuchsw. Österr., 11 (1908), No. 9, pp. 725–727*).—According to the author, olives in which fermentation had been caused by *Bacterium coli commune*, and which possessed a disagreeable odor, became of good odor and appearance after treatment with a 2 per cent solution of common salt and sour milk.

Swedish berry and fruit wines, O. Hofman-Bang (*Pomol. Fören. Årsskr., 1908, Feb., Svensk Kem. Tidskr., 20 (1908), No. 5, pp. 90–93*).—Analyses of domestic wines are given, with discussions of the results obtained.

Some notes on claret, P. Schidrowitz (*Jour. Inst. Brew., 13 (1907), No. 4, pp. 302–319; Rev. Soc. Sci. Hyg. Aliment., 4 (1907), No. 2, pp. 52–64*).—The relations between quality and chemical composition were studied. Analyses of clarets at different stages indicated that as it grows older the amount of glycerin increases, the amount of alcohol, extract, ash, sugar, and tannin usually decreases, and the percentage of acidity is variable.

Analyses of malt liquors (*Mo. Bul. N. Y. State Dept. Health, 24 (1908), No. 8, pp. 213–216*).—The results of the examination of 219 samples of beers brewed in the State are reported with special reference to the use of hop substitutes and preservatives. Sulphites were found in the majority of the samples and salicylic acid, saccharin, or fluorids in a very few samples. No hop substitutes were noted.

Pickles, A. McGill (*Lab. Inland Rev. Dept. [Canada] Bul. 163, pp. 14*).—The author reports the results of the examination of 149 samples of pickles collected in Canada. With two exceptions the pickles were in good condition. Evidently both of the unsatisfactory samples were prepared with weak vinegar or the vegetables used contained so much water as to dilute the vinegar, the respective strengths being 1.02 and 0.61 per cent of acetic anhydrid.

To determine whether alum was used in making pickles, the goods were examined for soluble alumina and it was found to be present in 25 of the samples.

"It would not, however, be safe to infer the use of alum in every case in which a reaction for alumina was obtained. Owing to the prone habit of cucumbers, and the liability to take up, in the creases of the pericarp, minute

particles of clay, and further to the possibility of a slight solubility of such clay by prolonged contact with acetic acid, it may be that, where merely traces of alumina were found, these may be accounted for, as above suggested. It is, however, noteworthy that 124 samples gave no reaction with tests for alumina. This fact seems to warrant the conclusion that, where distinct traces of alumina are found in solution, the use of alum is indicated."

Twelve of the samples gave reactions for salicylic acid and an equal number for sulphurous acid. No other preservative (except vinegar) was found. In the greater part of the samples the strength of the vinegar ranged from 1.5 to 3 per cent acetic anhydrid.

Changes produced in mustard by proteus and the poisoning which follows, E. Bertarelli and M. Marchelli (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 6, pp. 353–359*).—An experimental study of the changes produced in mustard by the growth of micro-organisms.

Adulteration in red pepper, P. Grandmont (*Bul. Agr. Algérie et Tunisie, 14 (1908), No. 17, pp. 436–438*).—Data are given regarding the examination of adulterated red pepper in comparison with a sample of known quality.

Pepper adulterated with vetch seeds, Fleury (*Trav. Sci. Univ. Rennes, 6 (1907), No. 1, pp. 140–142*).—A summary and discussion of data on this topic.

Influence of preservatives and other substances added to foods upon health and metabolism, H. W. Wiley (*Proc. Amer. Phil. Soc., 47 (1908), No. 189, pp. 302–328, fig. 1*).—A summary of the results of the author's investigations with preservatives. His deduction is, that if the conclusions based upon experimental data are correct there can be no justification of the addition of chemical preservatives to human foods and, furthermore, "successful manufacturing establishments have demonstrated beyond peradventure that better, more wholesome, and more permanent forms of food products can be produced without the aid of any preservative whatever."

Nitrous acid as an antiseptic, J. H. Shepard (*Bul. Kans. Bd. Health, 4 (1908), No. 9, pp. 225–231; Pure Products, 4 (1908), No. 10, pp. 455–463; Amer. Food Jour., 3 (1908), No. 9, pp. 11–14, fig. 1*).—In a paper presented before the twelfth annual convention of the Association of State and National Food and Dairy Departments, 1908, the author reports the results of studies undertaken to determine whether nitrous acid hindered ferment action. Varying strengths were used in tests made with starch and diastase, with starch and ptyalin, with starch, pepsin, and egg albumin, and with starch and pancreatin, and it was found that even in high dilution digestion was retarded. "Any chemical in dilution of 1 part to 100,000 which will retard digestion nearly 25 per cent should not be permitted in any food product in any quantity whatever. And more especially is this true in the case of flour. . . . The addition of nitrous acid to flour is not only useless, it is dangerous."

If white bread is desired, the author suggests that it be secured by thoroughly aerating the dough and not by bleaching.

Benzoic acid, K. B. Lehmann (*Chem. Ztg., 32 (1908), No. 79, pp. 949–952*).—A digest of available data regarding the nature and hygienic effect of this preservative.

The influence of soaking on the boric acid content of canned goods, A. Röhrig (*Ber. Chem. Untersuch. Anst. Leipzig, 1907, p. 13; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 6, pp. 359, 360*).—The amount of boric acid in canned goods was found to be diminished by washing or soaking.

Food analysis No. 16, E. H. S. Bailey and H. L. Jackson (*Bul. Kans. Bd. Health, 4 (1908), No. 6, pp. 148–150*).—Data are given regarding the examination of beverages, extracts, vinegar, sugar, and baking powder.

Food analysis No. 18. J. T. Willard (*Bul. Kans. Bd. Health, 4 (1908), No. 9, pp. 212–221*).—Examinations made under the State pure food law are reported of a large number of samples of vinegar, milk and cream, ice cream, beverages, and miscellaneous food products.

In connection with the question of testing for sulphites in foods, samples of green sweet corn, raw and cooked in different ways, were distilled with dilute phosphoric acid. "The distillate was oxidized by bromin water and tested for sulphuric acid with barium chlorid in the usual way." In every case a precipitate was obtained, showing that some sulphur compound is cleaved from the fresh corn under the experimental conditions. The evolution of sulphur from vegetable substances was still further tested with fresh sweet potatoes, tomatoes, cucumbers, cabbage, string beans, peas, celery, and onions, and sulphur was found in the distillate in all cases except with cucumbers and peas.

Foodstuffs. D. Hooper (*Ann. Rpt. Indian Mus. Indus. Sect., 1907–8, pp. 19–21*).—An analysis of bark used as food is reported as well as data regarding the examination of samples of rice, ragi tailings, tamarind seed, castor meal, sugars, and a tea substitute.

The new Kentucky foods and drugs act. M. A. Scovell (*Amer. Food Jour., 3 (1908), No. 9, pp. 14, 15, 21*).—In this paper presented before the twelfth annual convention of the Association of State and National Food and Dairy Departments, 1908, the author discusses legislation recently enacted in Kentucky regarding foods and drugs.

Dairy and food laws of the State of Washington (*Olympia, Wash., 1907, pp. 34*).—A compilation of the dairy and food laws in the State of Washington enacted up to the close of the legislative session of 1907.

Legislation for the control of adulteration and falsification of food products. M. Toubeau (*La Législation Répressive des Fraudes et Falsifications sur les Produits Alimentaires. Thesis, Univ. Paris, 1908, pp. 275*).—An historical and critical digest of pure food legislation in France. In an appendix pure food legislation in some other countries is briefly summarized.

Progress in the chemistry of food and condiments in the year 1907. H. Kuttenkeuler (*Chem. Ztg., 32 (1908), Nos. 59, pp. 693–695; 60, pp. 709–711; 61, pp. 720, 721*).—A summary of investigations which have been reported along the principal lines of food chemistry.

Food and nutrition laboratory manual. Isabel Bevier and Susannah Usher (*Boston, 1908, pp. 75*).—In this revision results of investigations published since the first edition appeared (E. S. R., 18, p. 562) have been included.

On the assimilation of protein introduced parenterally. W. Cramer (*Jour. Physiol., 37 (1908), No. 2, pp. 146–157*).—The results obtained in the investigations show, according to the author, "that protein which has passed unchanged through the intestinal wall can be assimilated and evidence is adduced to show that this assimilation is brought about by the leucocytes ingesting the protein.

"This leads naturally to the question whether such an assimilation of unchanged protein takes place at all after a meal and whether the mechanism of the assimilation of the protein of the food from the intestinal canal is similar to the processes which regulate the assimilation of protein introduced into the peritoneal cavity.

"The fact that the mechanism of the assimilation of protein from the peritoneal cavity works under the most favorable conditions after a meal suggests that unchanged protein is absorbed and assimilated under normal conditions."

From the experimental evidence presented it follows, according to the author, that protein is "assimilated normally without being broken down in the intestine. Such a process takes place of course only to a limited extent and not

to the exclusion of other processes, such as the absorption and assimilation of the more advanced products of digestion of the protein of the food."

On the assimilation of protein introduced enterally, H. Pringle and W. Cramer (*Jour. Physiol., 37 (1908), No. 2, pp. 158–164*).—The results of the investigations show "that the intestinal mucous membrane of digesting animals is very much richer in incoagulable nitrogen than that of fasting animals. The most pronounced difference is found in the lymphoid nodules of the intestinal wall, where the residual nitrogen appears to be collected.

"The blood of digesting animals shows a small but distinct increase of residual nitrogen over the blood of fasting animals."

In general the results are analogous to those noted above "and allow the conclusion that the assimilation of protein from the intestinal canal is brought about partly at any rate by the agency of the leucocytes. Part of the nitrogenous material may be absorbed by a different path and undergo a different fate."

Studies of the precipitin reaction and heated proteins, W. A. Schmidt (*Biochem. Ztschr., 14 (1908), No. 3–4, pp. 294–348*).—From his studies of the precipitin reaction the author concludes that the animal body possesses the ability to regenerate proteids so that the original characteristics are apparent even if the proteids have been acted upon by heat, alkalis, and enzyms.

Assimilation of animal and vegetable fat by man, V. Gerlach (*Ztschr. Diätet. u. Phys. Ther., 12 (1907), p. 102; abs. in Biochem. Centbl., 7 (1908), No. 13, pp. 497, 498*).—From experiments of long duration of which he himself was the subject the author reached the conclusion that there was no difference in the digestibility of animal and vegetable fats. The materials used were butter and a commercial butter substitute prepared from cocoanut fat.

The uric acid excretion of normal man, P. J. Hanzlik and P. B. Hawk (*Jour. Biol. Chem., 5 (1908), No. 4, pp. 355–359*).—The conclusions drawn from the experiments reported follow:

"The average daily excretion of uric acid for 10 men, ranging in age from 19 to 29 years, and fed a normal mixed diet was 0.597 gm., a value somewhat lower than the generally accepted average of 0.7 gm. for such a period.

"The average daily protein ingestion for these same subjects, when permitted to select their diet, was 91.2 gm. or 1.33 gm. per kilogram of body weight."

Experiments on the daily variation in the work of the kidneys on a constant diet, M. Braeuner (*Ztschr. Klin. Med., 65 (1908), p. 438; abs. in Zentbl. Gesam. Physiol. u. Path Stoffwechsels, n. ser., 3 (1908), No. 20, p. 789*).—Wide variations were noted in the nitrogen and chlorin excretion and the molecular diuresis on diets with both a limited and a normal amount of common salt.

Increased body temperature of men working in hot climates, S. Kurita (*Arch. Schiffs u. Tropen Hyg., 11, (1907), No. 21, pp. 681–683*).—Observations made with stokers showed increased body temperature, pulse rate and rate of respiration as compared with engineers working at a somewhat lower temperature. After about 2 hours the body temperature again dropped to normal. The author concludes therefore that at least 2 hours' rest is essential after work has been performed where the air is excessively hot.

The minimum physiological energy requirement, J. Lefevre (*Jour. Physiol. et Path. Gén., 9 (1907), pp. 939–947; abs. in Bibliographia Physiol., 3. ser., 3 (1907), No. 3–4, p. 275*).

Direct calorimetric measurement of the minimum physiological energy requirement, J. Lefevre (*Jour. Physiol. et Path. Gén., 9 (1907), pp. 969–977; abs. in Bibliographia Physiol., 3. ser., 3 (1907), No. 3–4, p. 275*).—According to the author all heat in excess of 1,450 calories per day eliminated by the

human body is heat of thermo-genesis; that is, it is produced for maintaining the body temperature.

ANIMAL PRODUCTION.

The improvement of the Alpine region as a stock raising country (*Ann. Sci. Agron., 3. ser., 3 (1908), 1, pp. 114–133*).—A report by various authors to the Eighth International Congress, held at Vienna in May, 1907, which emphasizes the need of improving the pastures and other natural resources of the region adapted for stock raising.

Hays of southern Italy. F. Scurti and G. de Plato (*Staz. Sper. Agr. Ital., 41 (1908), No. 7, pp. 333–434*).—This contains tables showing the botanical and chemical analyses of 47 samples of hay collected from different localities in southern Italy. About 50 per cent of the plants which composed the hay were true grasses, 25 per cent legumes, and 25 per cent of different families. Samples with approximately this ratio of species contained from 7.09 to 13.89 per cent of protein, 10.16 to 22.59 carbohydrates, and 1.79 to 3.01 per cent of fat. A bibliography is included.

The available energy of red clover hay. H. P. Armsby and J. A. Fries (*Landw. Jahrb., 37 (1908), No. 3–4, pp. 423–495*).—A German translation of Bulletin 101 of the Bureau of Animal Industry of this Department, already noted (E. S. R., 19, p. 866).

Preservation of frozen turnips as ensilage. Fingerling (*Württemb. Wchnbl. Landw., 1908, No. 44, p. 739*).—The author recommends storing frozen turnips, which would otherwise be wasted, in pits and mixed with straw and chaff. The hole should be covered with a plank or a thick layer of straw and heavily weighted.

The grape as a feed for animals (*Indus. Latt. e Zootec., 6 (1908), No. 20, pp. 229, 230*).—A discussion of the nutritive value of different parts of the grapevine, with analyses.

The use of grapevine prunings as forage. K. Portele, trans. by E. Ottavi (*Coltivatore, 54 (1908), No. 41, pp. 459–462*).—The waste twigs cut from grapevines possess 55 to 60 per cent as much nutrient matter as meadow hay. They should be ground up and fed in moderate quantities.

Concentrated feeding stuffs. A. Maurizio (*Kraftfuttermittel. Hanover, 1908, pp. IV+112*).—A short treatise on animal feeding stuffs that have a higher nutritive value than hays. It includes grains, leguminous hay, molasses, meat meal, and factory by-products.

Feeding stuffs. H. E. Annett, F. V. Darbishire, and E. J. Russell (*Jour. Southeast. Agr. Col. Wye, 1907, No. 16, pp. 201–214*).—The substances analyzed are linseed cake, cocoanut cake, maize germ meal, rice meal, edible seaweed, and silage.

[Analyses of stock feeds]. H. Ingle (*Transvaal Dept. Agr. Ann. Rpt. 1907, pp. 249–263*).—This report contains analyses of forage crops and of the "joegee" bean, already noted (E. S. R., 19, p. 1166). In addition, analyses are given of peanuts, maraamas (*Bauhinia* sp.?), sugar beets, and chicory.

Residual products of oil factories as animal foods. A. Nardini (*Istria Agr., 1 (1908), No. 22, pp. 476–479*).—Analyses are given of the residues from the manufacture of linseed, sesame, peanut, and cocoanut oils.

Starch in feedstuffs. M. H. Davis (*Daily Consular and Trade Rpts. [U. S.], 1908, No. 3316, pp. 4, 5*).—American corn feeds may be imported to Germany free of duty if they contain less than 35 per cent of starch, but German methods of determining starch content are so different from American methods that a feed which passes in this country as containing 32 to 35 per cent of

starch yields, when subjected to German tests, about 50 to 55 per cent. The method of determination now used in Germany is described in detail. It is known as the diastase method and was first described in the fifth edition of Max Maercker's Handbuch des Spiritusfabrikation, in 1908.

Gluten feeds—artificially colored, E. GUDEMAN (*Jour. Amer. Chem. Soc., 30 (1908), No. 10, pp. 1623–1626*).—Examinations made during the past year of 90 samples of gluten feeds have shown that 68 samples, or over 75 per cent of those examined, have contained added coloring matter. "Of 6 samples received direct from manufacturers, only 1 showed a very slight amount of added color.

"Examinations made on different kinds of corn, ranging from white to dark red, and on the component parts of corn (bran, germ, and gluten), in all cases gave negative results for added color, tested under like conditions with the gluten feeds. The evaporated steep-water often gives a faint color reaction, similar to caramel (sugar) coloring, on the first wool samples. . . .

"The purpose of adding color to gluten feeds is only for deception, to make them appear better than they really are or to hide some inferiority, such as the use of rotten, burnt, or fermented corn."

The methods of examination are described in detail.

Cyclopedia of American agriculture.—Animals, L. H. BAILEY ET AL. (*New York, 1908, vol. 3, pp. XVI+708, pls. 25, figs. 681*).—As in the first two volumes of this cyclopedia (E. S. R., 18, p. 1088; 19, p. 733) the various topics are written by specialists.

This third volume is divided into three parts. Part 1, the animal and its relations, treats of the domestication, breeding, feeding, exhibiting and marketing of animals, the physiology of the animal body, diseases and management, and wild life in its relation to farming. Part 2 treats of dairy products, meat and meat products, including the tanning of hides, and an account of the leather industry. Part 3 takes up at length the North American farm animals, and discusses the origin and characteristics of the various breeds of live stock now found in the United States and Canada.

Heredity, J. A. THOMSON (*London, 1908, pp. XVI+605, pls. 15, figs. 34*).—This book, which is intended as an introduction to the study of heredity, includes 14 chapters, a representative bibliography of 48 pages arranged in alphabetical order, and a 20-page subject index to the bibliography. The subject is considered under the following chapter headings: Heredity and inheritance, defined and illustrated; the physical basis of inheritance; heredity and variation; common modes of inheritance; reversion and allied phenomena; telegony and other disputed questions; the transmission of acquired characters; heredity and disease; statistical study of inheritance; experimental study of inheritance; history of theories of heredity and inheritance; heredity and development; heredity and sex; and social aspects of biological results.

Inbreeding, Mendelism, and the elucidation of live stock history, J. WILSON (*Irish Nat., 17 (1908), No. 11, pp. 243, 244*).—This is an abstract of a paper read at the Dublin meeting of the British Association for the Advancement of Science.

The author emphasizes the advantages of inbreeding, and cites the deer as an example in nature. "The strongest male retains command of a flock until he is ousted by some other animal, who is in all probability a younger brother or a son of the previous master male." The various theories of the origin of the Dexter breed of cattle are reviewed and discarded. "Mendelism shows clearly that the Dexter is a hybrid breed, the original races being a slender black race and a stout red one like the Devon breed of cattle. . . . Mendelism is evidently going to be of great service to the historian of live stock."

Color of Shorthorn cattle (*Country Life [London]*, *24 (1908)*, *No. 618*, *pp. XLVIII, L*).—Brief notes on Mendelism in Shorthorn cattle. Offspring of white and roan ancestors reported as red generally prove to have more or less white hair. Mendel's law reveals the importance of more accurate descriptions in the herd book.

The cost of producing beef in winter, K. J. J. MACKENZIE (*Jour. Bd. Agr. [London]*, *15 (1908)*, *No. 4*, *pp. 253–260*).—A discussion of results previously noted (E. S. R., 10, p. 773; 18, p. 666).

Feeding experiments with mature oxen and sheep (*Landw. Wchnschr. Sachsen*, *10 (1908)*, *No. 38*, *pp. 332*, *333*).—A ration low in protein fed to 8 oxen for 3 months showed a total gain of 900 lbs., as compared to a similar gain of 720 lbs. on a ration high in protein. In the latter ration there was an actual loss of 60 lbs. during the last 20 days of the experiment. When similar rations were fed to sheep, however, there was a total gain of 1,014 lbs. at a cost of 8.9 cts. per pound on the ration poor in protein, and a similar gain of 1,268 lbs. at a cost of 7.8 cts. per pound on the ration rich in protein.

Breeding sheep for mutton, G. M. MCKEOWN (*Agr. Gaz. N. S. Wales*, *19 (1908)*, *No. 6*, *pp. 489–496*, *figs. 6*).—Various crosses have been tried to ascertain the most profitable sheep for the small land owner in New South Wales. A lamb that can be sold at 4 or 5 months of age is desired, and so far the best results have been obtained from a Shropshire ram and a Lincoln-merino ewe. The author discusses the best crops for mutton production.

Sheep raising for the production of wool in western Africa, Y. HENRY (*Agr. Prat. Pays Chauds*, *8 (1908)*, *No. 66*, *pp. 182–192*, *figs. 3*).—Methods of raising sheep and marketing wool as practiced in the Soudan are described.

Goats (*Jour. Jamaica Agr. Soc.*, *12 (1908)*, *Nos. 4*, *pp. 102–104*; *10*, *pp. 337–340*).—The types of goats kept on the island are the Maltese, Anglo-Nubian, and Swiss-Toggenburg for milk, the common Jamaica goat for mutton, and the Angora for mutton and hair. The keeping of pedigreed animals for milk and mutton is advocated. The subjects of breeding and management are discussed.

The value of potatoes for pig feeding in rations with different protein content, O. KELLNER ET AL. (*Bericht des Deutschen Landwirtschaftsrats an das Reichsamt des Innern betreffend Mästungsversuche mit Schweinen über die Verwertung der Kartoffeln bei Verschiedener Eiweisszufuhr. A. Allgemeiner Bericht*, *pp. 32*; *B. Berichte über die Einzelnen Versuche*, *pp. 215. Berlin*, *1908*).—That potatoes are the best home-grown substance for pig feeding is reported as the result of a cooperative series of experiments carried on at 17 different stations under the direction of the German Agricultural Society to estimate the value of potatoes when fed in varying proportion with supplementary protein feeds. Skim milk, meat meal, fish meal, bran of grains, husks of fruits, and oil cake were the supplements used. The normal ration proposed was 6.2 kg. protein per 1,000 kg. live weight for pigs weighing 20 kg., but the proportion of protein was decreased as the animals grew older, so that when animals had reached 130 kg. in weight they would receive for the normal ration only 2.4 kg. protein per 1,000 kg. live weight.

The experiments showed that steamed potatoes were an excellent food for fattening swine, this agreeing with practical experience. It is stated that potatoes can compose 50 to 60 per cent of the digestible carbohydrates of the ration and in some cases even more. An increase of protein above the normal amount was found to be of no advantage, a large increase producing lameness. A decrease of 15 to 20 per cent of normal protein diminished the live weight and increased the amount of carbohydrates consumed, yet where a slow fattening with cheap foods is desired it is believed that a slight decrease in protein may be allowed.

Specific favorable or unfavorable effects of the different protein supplements or mixtures were not observed either in the animal or in the slaughtered product. The average cost of producing 100 kg. live weight with proper food was 74 marks (about 8.1 cents per pound). The potatoes were estimated to be worth 3 marks per 100 kg. (about 19 cts. per bushel).

Pig feeding experiments with skim milk, Klein (*Milchw. Zentbl., 4 (1908), No. 8, pp. 362–370*).—Experiments previously reported (E. S. R., 19, p. 171) showed a gain proportional to the amount of skim milk when pigs were fed a wide ration. In continuing the work narrower rations were fed when it was found to be of no advantage to feed large amounts of skim milk. Four pairs of pigs about 15 weeks old, weighing 30 kg. each, were fed for 22 weeks, each lot receiving 272 kg. of ground barley. The pair fed in addition 770 kg. of skim milk, 432 kg. of potatoes, and 31 kg. of fish meal gained 0.687 kg. (about 1.51 lbs.) per head per day. The pair receiving 1,440 kg. skim milk and 402 kg. potatoes gained 0.646 kg. (about 1.42 lbs.) per day. The third pair, receiving 1,400 kg. skim milk, 370 kg. potatoes, and 31 kg. fish meal, gained 0.698 kg. (about 1.54 lbs.) per day, and the fourth which received 2,030 kg. skim milk, and 39 kg. potatoes, gained 0.659 kg. (about 1.45 lbs.) per day. There was little difference in percentage of dressed weight. Analyses of the feeding stuffs are given.

Feeding experiments with pigs, Klein (*Milchw. Zentbl., 4 (1908), No. 11, pp. 481–488*).—Continuing the feeding experiments noted above, 12 pigs were divided into 3 groups and fed for 56 days a basal ration of barley, dried potatoes, and skim milk. In the first group each pig received in addition cocoanut oil and made an average daily gain of 0.373 kg. (about 0.82 lb.). In group 2 the supplementary feeding stuff was potato starch inverted with diastasolin and the average daily gain per head 0.416 kg. (about 0.91 lb.). Group 3 was fed ordinary potato starch and gained an average of 0.374 kg. (about 0.82 lb.) per head per day.

Monographs on useful farm animals, VII. The East Friesian horse, H. Gross (*Monographien Landwirtshaftlicher Nutztiere VII. Das Ostfriesische Pferd. Hanover, 1908, pp. 117, pls. 5, figs. 95, dgm. 1, map 1*).—This monograph treats of East Friesland and its adaptability for the production of horses.

Much space is given to the origin and history of the East Friesian breed. This is often confounded with the Oldenburg, as the two breeds have many characteristics in common. Again, individuals of this breed are often seen in fine turnouts but erroneously supposed to be of English origin. The aim of the breeders is to produce a strongly built first-class roadster. The color varies from black to the various shades of brown, with white points. Improvement of the breed began at the beginning of the eighteenth century. A registry of merit was kept between 1708 and 1725, but is now lost. Stallions have been imported from various countries, but foreign blood is not in favor at the present time. The present stud book was begun in 1869. There are 28,318 horses in East Friesland. In 1907, 120 stallions of this breed were exported to the United States. The characteristics of the breed are fully described, including measurements of stallions.

Public measures for advancing the poultry industry in Germany, O. Knispel (*Arb. Deut. Landw. Gesell., 1908, No. 145, pp. XXVI+346, figs. 14, map 1*).—This is a collection of data on the breeds of poultry, methods of management, breeding stations, poultry schools, and associations for promoting the poultry industry in the several German states. With the text is a map showing the geographical distribution of the various breeds. Bavaria leads in the number of common fowl, in geese, and in the total of all kinds of poultry,

having 9,111,884 individuals. Posen, with 22,085 guinea hens and 44,854 turkeys, leads in these two species. Bremen, with 4.08 head per hectare (about 1.7 head per acre), has more poultry for its size than any other state. Oldenburg has 2.22 fowls per inhabitant and leads in this respect.

The most influential means for promoting the industry is considered to be through the establishment of breeding stations. There are 2,995 of these in the Empire, and 1,173 of them contain Italian breeds, these being most frequent in Bavaria. Next to these are the Wyandottes with 347 stations, Minorcas with 254, and Plymouth Rocks with 91. The Wyandotte and Plymouth Rock stations are more numerous in Posen than elsewhere.

Elementary analysis and distribution of nitrogen in eggshells of different sorts, H. Buchtala (*Ztschr. Physiol. Chem., 56 (1908), No. 1 pp. 11–17; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 549, II, p. 610*).—The membrane lining of hen's egg was examined in comparison with the shells or membranes of eggs of other sorts.

A review of investigations in animal nutrition by German investigators in the second half year of 1907, W. Zielstorff (*Chem. Ztschr., 7 (1908), No. 18, pp. 197–208*).

DAIRY FARMING—DAIRYING—AGROTECHNY.

Feeding experiments with milch cows, G. von Zweigbergk (*Östergöttlands Läns Hushåll. Sällsk. Handl., 1908, No. 2, pp. 156–163*).—Eight cows, separated into 2 lots of 4 each, were fed normal rations of hay, straw, mangels, mixed barley and oats, wheat bran, and oil cake, and during brief experimental periods the oil cake in the rations, amounting to 2 kg. per head per day, was replaced by an equal weight of gray or yellow peas. The quantity of milk produced did not appear to be influenced by the change, but the fat content of the milk was uniformly lower when peas were fed, and the butter made from the milk was of inferior quality. Even when only 0.5 kg. peas per head daily was fed the quality of the butter produced was not up to the standard. Trials with other legumes (horse beans and several vetches), gave similar results, but the horse beans were found less objectionable than the peas or vetches.

Report of Malmöhus County cow-testing association, 1907–8, L. Nanneson (*Malmö. Läns Hushåll. Sällsk. Kvrlsskr., 1908, No. 2, pp. 367–529*).—The report gives a detailed account of the work of 115 different test associations in existence in the county during the year. Twenty-five new associations were also formed, making 144 associations in operation at the close of the year, with over 2,000 herds and about 50,000 cows, or about one-third of the total number of cows in the county. The average yield per cow for the year for the 115 associations (1,590 herds, 38,237 cows) was 3,506 kg. (7,713 lbs.) milk, and 111.37 kg. (251.6 lbs.) butter fat, as compared with 3,377 kg. milk and 109.03 kg. butter fat for the preceding year (1,261 herds), and 2,849 and 91.3 kg. of milk and butter fat, respectively, for 1901–2 (327 herds). The average rations fed consisted of hay and straw 24 per cent, green feed and pasture 24 per cent, roots 12 per cent, bran and small grains 12 per cent, oil cakes 18 per cent, and miscellaneous feeds 10 per cent.

Cow-testing associations in Norway, 1906–7, L. Funder (*Aarsber. Offentl. Foranst. Landbr. Fremme, 1907, Statsforanstalt., pp. 563–638*).—During the year 132 associations comprising 22,764 cows were in operation. The average yield of milk for the year was 2,026 kg. (4,457 lbs.), and the average percentage of fat 3.48, equivalent to 70.5 kg. (155.1 lbs.) butter fat.

Milking appliances and milking machines, A. Rosam (*Österr. Molk. Ztg., 15 (1908), Nos. 18, pp. 241–243, figs. 14; 19, pp. 255–258, figs. 25; 20, pp. 269–271, figs. 8; 21, pp. 283–285, figs. 5*).—Descriptions and illustrations of various appliances for milking otherwise than by hand, including milking tubes, milking machines that force the milk out by pressure, and suction milking machines.

Milking machines, B. Böggild (*Mælkeritid., 21 (1908), No. 30, pp. 556–563*).—An address discussing the problem of machine milking, especially with the Vitula and the Lawrence-Kennedy-Gillies machines. The author concludes that it is too early as yet to recommend in general the installation of either machine on Danish dairy farms.

Dairying in southern Brazil, A. Redacção, B. Bernardino, and L. Granato (*Cent. Econ. Rio Grande do Sul Bol. 3, pp. 59, figs. 4*).—An account of the dairy industry and the methods employed in dairy husbandry in the State of Rio Grande do Sul. Analyses of milk are given.

Dairying in Finland, E. Konradi (*Mælkeritid., 21 (1908), No. 39, pp. 717–730*).—A general discussion of the conditions of the dairy industry in Finland.

Report of the experiment station and dairy institute at Kleinhof-Tapiau for the years 1907 and 1908, Hittcher (*Ber. Vers. Stat. u. Lehranst. Molkw. Kleinhof-Tapiau, 1907–8, pp. 27*).—This report contains analyses of human milk, records of the dairy herd, and related matters.

The lecithin content of milk, J. Nerking and E. Haensel (*Biochem. Ztschr., 13 (1908), No. 5–6, pp. 348–353; abs. in Analyst, 33 (1908), No. 393, pp. 470, 471*).—The lecithin content of various milks was estimated. Alcohol was added to the milk and the precipitate extracted with chloroform. The filtrate was evaporated, extracted with chloroform, and the two extractions united and evaporated. The residue, after the addition of sodium carbonate and potassium nitrate, was then ignited. The phosphoric acid in the ash was next separated with molybdic acid and weighed as magnesium pyrophosphate. The average percentage of lecithin and cephalin present in human milk was 0.05, cows' 0.063, asses' 0.16, sheep's 0.083, goats' 0.049, and mares' 0.011.

[Bacteriological studies of milk], W. G. Savage (*Ann. Rpt. Local Govt. Bd. [Gt. Brit.], 36 (1906–7), pp. 205–236, fig 1*).—Studies were made of leucocytes, streptococci, staphylococci, and a few pathogenic forms of bacteria found in milk.

The streptococci from individual cows differ from those of cow dung both in regard to their morphology and their action upon the different sugar alcohols. "The most frequently present group is a long chain form which ferments lactose, saccharose, and raffinose, coagulates milk, and usually ferments salicin. Twenty-two members of this group were located." These streptococci were not pathogenic when tested on mice.

The ordinary staphylococci were found in nearly all samples of milk, but as far as tested all were nonpathogenic. Staphylococci which form some translucent colonies were often present. Diptheroid bacilli and *Bacillus coli* were sometimes found. Streptococci were abundant but had no relationship to the number of leucocytes present. "An excess of leucocytes may be due to the conditions associated with a diminution of the milk in the later stages of pregnancy. It may be due to some old injury or inflammation, all traces of which have been removed when ordinary methods of examination are used. . . . On the other hand, the presence of streptococci is frequently a purely saprophytic phenomenon. In other cases it is probably associated with some local teat condition which does not affect the number of leucocytes, while only in certain cases is their presence in direct relationship to pathological conditions, causing a great increase in the number of leucocytes."

Studies of the so-called sterilized market milk, O. Knüsel (*Studien über die Sogenannte Sterilisierte Milch des Handels. Inaug. Diss., Univ. Zürich, 1908, pp. 79*).—The literature on the subject is reviewed at length and an account is given of the author's study of sterilized milk which he finds to be a very variable product.

Of 175 samples of "sterilized" milk 63 contained germs. A perfect sterilization is wellnigh impossible without cooking the milk, for the spores of anaerobic and proteolytic forms are very resistant to heat. The author follows Weber in dividing peptonizing bacteria into two groups, according to the rapidity of protein hydrolysis. A third group, however, is necessary, for a few species produce neither coagulation nor peptonization. The anaerobic bacteria are not of much importance in sterilized market milk.

The peptonizing bacteria produce a rennet ferment, a proteolytic ferment, a reductase, and a superoxydase. Arnold's test with guaiac and Storch's reaction both gave negative results for oxydase. Bacteria rennet is different from animal rennet. It coagulates sterilized milk and is active at 60° C. as well as at 37°, but ceases to act below 22°. The proteolytic ferment acts at a lower temperature than the rennet, hence milk may become bitter yet not coagulate. When proteolysis takes place at 8° no serum zone is found and the nutrient medium takes on a soapy appearance, which is not noticed when milk is kept in opaque receptacles. The superoxydase is united to the fat globules and is destroyed by boiling. To retard peptonization milk must be under 8°. The peptonizing bacteria form nitrates and nitrites on different nutrient media. They also form ammonia and hydrogen sulphid, but do not produce indol to any extent.

Milk and its relation to infectious diseases, J. W. Trask (*Jour. Amer. Med. Assoc., 51 (1908), No. 18, pp. 1491–1496*).—A review of investigations by different observers concerning milk and butter as carriers of typhoid fever, scarlet fever, diphtheria, and tuberculosis germs.

The supervision of the milk supply in towns and cities and the preparation of germ-free milk for children, Bettendorf and Stier (*Ztschr. Fleisch u. Milchhyg., 19 (1908), No. 2, pp. 64–75*).—A lecture before the German Society of Naturalists and Physicians at Cologne, September 20, 1908. The stringent supervision by physicians of the quality of the milk supply is insisted upon. The methods of detecting adulterants and estimating the bacterial content are reviewed. Directions are given for preparing milk for bottle-fed infants.

Chicago pasteurizing rules (*Pacific Dairy Rev., 12 (1908), No. 42, pp. 12, 13*).—Chicago is the first large American city to make pasteurization compulsory. Every pint of milk sold in that city must come from cows that have passed the tuberculin test or be subjected to pasteurization, and every pound of dairy products must come from such cows or made from pasteurized milk. The rules are given in full.

Process and apparatus for keeping milk sound, T. G. Mollinger and A. Romeijs (*English Pat. 25,393, Nov. 15, 1907. Jour. Soc. Chem. Indus., 28 (1909), No. 1, p. 36*).—A patented process is described by which milk is pasteurized and hermetically sealed in bottles.

The judging of milk with the aid of the fermentation test, F. Löhnis (*Milch Ztg., 37 (1908), No. 41, pp. 484, 485*).—The author advocates the use of the fermentation test as an aid in judging the purity of milk. His recent experiments indicate that 10 to 12° C. is the best temperature for keeping the milk. His methods are described in detail.

Investigations on the fatty acids of butter, M. Siegfeld (*Milchw. Zentbl., 3 (1907), No. 7, pp. 288–296; 4 (1908), No. 6, pp. 250–262; Chem. Ztg., 32 (1908), No. 42, pp. 505, 506*).—From an investigation of the properties of fatty acids the

author thinks there is little, if any, stearic acid in butter. The high melting point and the molecular weight of the fatty acids in butter would indicate a considerable amount of stearic acid, but it may be possible that this result is brought about by the formation of dioxystearic acid from the oxidation of oleic acid.

[The presence of acidity in cream starters], J. H. MONRAD (*N. Y. Produce Rev. and Amer. Cream., 26 (1908), No. 25, p. 936*).—The maximum acidity advocated by butter makers ranges from 48 to 60 cc. (Mann's test). This range in opinion is due, no doubt, to the fact that those who favor the lower figure are working with a different organism than are those who favor a higher degree of acidity.

On the influence of feed on milk and cheese, O. JENSEN (*Mælkeritid., 21 (1908), No. 38, pp. 665–689*).—The author concludes that "the quality of cheese can be influenced by the feed: this influence is, however, to a less degree a direct chemical than an indirect bacteriological one. The main factors in the manufacture of good cheese, besides expert knowledge, are healthy cows, proper cooling of the milk, and scrupulous cleanliness. These factors are of far greater importance in the manufacture of cheese than in butter making."

On the influence of feeding of root crops on Swiss cheese, BENTERUD and IVERSEN (*Aarsber. Offentl. Foranst. Landbr. Fremme, 1907, Statsforanstalt., pp. 514–539*).—Experiments conducted at three different cheese factories gave results showing that turnips fed either in moderate quantities with considerable hay and straw and but small quantities of grain, or fed heavily in connection with a variety of feeds and considerable amounts of grain, did not produce any deleterious effect on the quality of Swiss cheese. On the contrary, in most cases the quality was improved by the feeding of turnips, even when as much as 30 kg. per head were fed daily. A relatively small number of feeding trials with turnip leaves and potatoes gave results indicating a similar beneficial effect on the Swiss cheese produced.

The contradiction between common Swiss experience and these results is probably explained by differences in the quality of the milk used. Norwegian milk requires the use of more rennet and a longer stirring after having been set than Swiss milk, and the cheese is spongy and filled with fine holes. If a higher temperature is used in after-heating the cheese becomes dry. This peculiarity of the Norwegian milk appears to be partly overcome by the feeding of roots. Apparently Swiss cheese produced from milk of root-fed cows can more readily undergo the correct fermentation than is the case when roots are not fed.

On Norwegian whey and goat cheeses and their analyses, S. HALS and E. SUNDE (*Tidskr. Kemi Farm. og Ter., 5 (1908), Nos. 13, pp. 8; 16, pp. 10*).—Descriptions and analyses of the different kinds of Norwegian whey and goat cheeses are given. The authors studied methods of identification of goat-milk fat for the purpose of establishing adulterations of goat cheese with cows' milk. The most promising method of identification is the ratio between Polenske and Reichert-Meissl numbers, which appears to be narrower for goat-milk fat than for fat from cows' milk (1 : 5 as compared with 1 : 8 to 1 : 9), the Polenske number for goat-milk fat being as a general rule lower than for fat from cows' milk, while the saponification number is higher.

[Gorgonzola cheese], G. CORNALBA (*Coltivatore, 54 (1908), Nos. 40, pp. 426–429; 41, pp. 462–465; 42, pp. 485–490; 43, pp. 519–523; 49, pp. 720–724; 50, 752–755*).—A series of popular articles on the origin, importance, characteristics, and manufacture of Gorgonzola cheese.

[The use of baritine in cheese rind], W. B. CUTTING, Jr. (*Mo. Consular and Trade Rpts. [U. S.], 1908, No. 337, p. 144; Pract. Dairyman, 2 (1908), No. 7, p. 76*).—Baritine, which contains sulphate of barium, is sometimes applied to the rind of Gorgonzola cheese, being used principally on cheese exported during

the summer months. The importation of this cheese into France has recently been prohibited on account of the use of this material. A commission appointed by the Italian ministry of agriculture has reported that sulphate of barium is innocuous because of its insolubility, but also recommends that white clay, powdered talc, brick dust, or some other substitute be used in its stead in order to remove any hindrance with the development of this important export.

The preparation of rennet. S. Marisé (*Rev. Mens. Cám. Merc., 8 (1908), No. 93, pp. 299–303*).—Methods of procuring rennet from plants and animals and its preparation for use in powdered or liquid form is discussed.

Researches on the chemistry of milk and dairying in the first half year 1908. Grimmer (*Milchw. Zentbl., 4 (1908), No. 8, pp. 337–351*).—A review of literature, mostly German, on this subject.

Report on the progress of agrotechnic industries for the years 1904 and 1905. G. Bode (*Chem. Indus. [Berlin], 30 (1907), Nos. 23, pp. 631–637; 24, pp. 674–682; abs. in Vrtljschr. Bayer. Landw. Rat., 13 (1908), No. 2, Sup., pp. 269–278*).—A review of the scientific literature on storing grain, milling, and baking, the utilization of potatoes, and the manufacture of sugar and starch.

Annual report on the investigations and progress in the manufacture of sugar. J. Bock (*Jahresber. Zuckerfabrik. [Stammer], 47 (1907), pp. X+342, figs. 12*).—A review of the literature of all branches of sugar making for 1906, from the culture and growth of sugar-yielding plants to technical and chemical investigations of sugar products. There are also given descriptions of patents, tables of statistics, and texts of laws which concern the sugar industry of different countries.

The sugar industry: Its raw material, preparation, and its industrial significance. T. Grotewold (*Die Zuckerindustrie: Ihr Rohmaterial, ihre Technik und ihre Volkswirtschaftliche Bedeutung. Stuttgart [1907], pp. 176, figs. 43*).—A general treatise on this topic.

Metals in contact with wine. G. Bertoni (*Gior. Vin. Ital., 34 (1908), No. 46, pp. 726–729*).—A red wine was kept for several weeks in a vessel made of tin plate holding 25 liters. At the end of that time the wine which had deteriorated in quality was analyzed and found to contain 10 per cent alcohol, 26.6 per cent nitrogen-free extract, 4.90 per cent total acids, 0.577 per cent volatile acids, 1.62 per cent cream of tartar, 1.10 per cent tannin, and 2.294 per cent ash. The same kind of wine kept in glass analyzed as follows: Alcohol 10 per cent, nitrogen-free extract 27.4 per cent, total acids 5.55 per cent, volatile acids 0.72 per cent, cream of tartar 1.82 per cent, tannin 1.22 per cent, and ash 2.32 per cent.

VETERINARY MEDICINE.

Three diseases of animals which have recently assumed importance to the State sanitarian. J. R. Mohler (*Amer. Vet. Rev., 34 (1908), No. 2, pp. 198–208*).—Infectious anemia, mycotic lymphangitis, and chronic bacterial dysentery have recently been found to have a greater distribution in this country than has heretofore been known.

Infectious anemia, known also as swamp fever, and by several other names, has recently been investigated. An ultramicroscopic organism has been definitely determined as the cause of the disease. Formerly supposed to be confined to Manitoba and Minnesota, the disease now appears to be more or less prevalent in Kansas, Nebraska, Colorado, Wyoming, Montana, North Dakota, and Texas. A mortality of 75 per cent or higher has been estimated by veterinarians from sections where the disease is prevalent. Arsenic, quinin, silver, and other preparations have been used without uniform success. Symptomatic treatment appears to be the most dependable.

Mycotic lymphangitis is a chronic contagious disease, particularly of equines, caused by *Saccharomyces farciminosis*, which was first discovered in this country in Pennsylvania in 1907. Its presence has now been definitely established in Ohio, Iowa, California, and North Dakota. There is also a probability of its existence in Indiana and several western States. Treatment consists at the outset of extirpation of the nodules, lymph vessels, and neighboring lymph glands, in case the lesions are localized. Isolation of the animal and disinfection of the stable are necessary.

Chronic bacterial dysentery is due to an acid-fast bacillus simulating the tubercle bacillus. This disease has been reported in Pennyslvania, Minnesota, and Virginia. The infected animal should be isolated and the feces therefrom placed on cultivated soil where healthy cattle will not be exposed to the bacillus. The administration of medicine has been found unsatisfactory. Nutritious dry feed should be fed the diseased animals.

Report of the cattle bureau, A. PETERS (*Agr. of Mass., 1907, pp. 193–263*).—During the year under report there was an increase in the number of outbreaks of rabies and glanders. There were also several outbreaks of symptomatic anthrax or blackleg in young cattle and cases of actinomycosis in cows, verminous bronchitis in sheep, and calf dysentery. An account is given of these diseases and of the work with bovine tuberculosis.

Report of State veterinarian, D. F. LUCKEY (*Ann. Rpt. Mo. Bd. Agr., 40 (1907), pp. 41–55*).—The author reports that 25 shipments of sheep affected with scabies were made from the State during the year. Cattle ticks were found on stock in 5 counties. Of glanders 117 cases are recorded. The loss from hog cholera in Missouri for the past 5 years is estimated as at least $8,000,000. Of 702 head of cattle tested with tuberculin 4.5 per cent were found to be affected with tuberculosis.

Veterinary notes, T. W. CAVE (*Jour. Southeast. Agr. Col. Wye, 1907, No. 16, pp. 361–373*).—A report is given of experiments made in an attempt to immunize sheep against the disease commonly known as "struck" by the use of vaccines prepared for the protection of cattle against black quarter. It is the author's opinion that the bacilli producing these diseases are closely allied if not absolutely identical.

Investigations into the causes of outbreaks of disease among cattle and sheep have shown that *Strongylus ostertagi* and *S. cervicornis* infested the fourth stomach in enormous numbers and that they are responsible for the emaciation and extreme debility which occurred. It is stated that this is the first record of *S. ostertagi* having been found in Great Britain. Attention is called to the fact that in gid or pothery of lambs, severe loss may be experienced at the time of the invasion of the brain by the parasites and before the well-known hydatids have developed. The importance of destroying the heads of all pothery lambs is emphasized. A case of anthrax in a cow which was undergoing the tuberculin test is recorded.

Annual report on the civil veterinary department, United Provinces, for the year ending March 31, 1907, H. M. MAXWELL (*Ann. Rpt. Civ. Vet. Dept. United Prov., 1907 pp. 17*).—The work of the department is reported under the headings of veterinary instruction, treatment of disease, breeding operations, etc. According to reports received more deaths took place from contagious diseases than during the previous year, namely 4,477, as compared with 3,624. Brief accounts are given of the occurrence of glanders, dourine, surra, anthrax, rinderpest, foot-and-mouth disease, hemorrhagic septicemia, black quarter, and other contagious diseases, and of preventive inoculation.

Annual report of the Punjab veterinary college and civil veterinary department, Punjab, for the year 1907–8, W. RENOUF (*Ann. Rpt. Punjab*

Vet. Col. and Cir. Vet. Dept., 1907–8, pp. III+13+XIII).—Part 1 of this report is devoted to veterinary inspection, part 2 to the treatment of disease, and part 3 to breeding operations. Among the diseases mentioned as having occurred during the year are glanders, surra, rinderpest, hemorrhagic septicemia, foot-and-mouth disease, black quarter, anthrax, and rabies. Tables are appended showing the number of deaths from contagious diseases, results of preventive inoculations, number of animals treated, etc.

Report of the civil veterinary department, Eastern Bengal and Assam, for the year 1907–8. W. HARRIS ET AL. (*Rpt. Cir. Vet. Dept., East. Bengal and Assam, 1907–8, pp. 2+17+2*).—The work of the year is reported under the headings of veterinary instruction, treatment of disease, preventive inoculation, breeding operations, etc. Among the diseases reported are glanders, anthrax, surra, rinderpest, foot-and-mouth disease, hemorrhagic septicemia, and black quarter. The deaths from contagious diseases, results from preventive inoculation, number of animals treated, etc., are arranged in tabular form.

Report of the principal veterinary surgeon, C. E. GRAY (*Transvaal Dept. Agr. Ann. Rpt., 1906–7, pp. 70–84, map 1*).—During the 12 months under report East Coast fever, lung sickness, ulcerative lymphangitis, mange, and glanders decreased, while scab and swine fever increased in prevalence. A system of inspection of all dairy cows kept within municipal areas is recommended.

Report of the government veterinary bacteriologist, A. THEILER (*Transvaal Dept. Agr. Ann. Rpt., 1906–7, pp. 87–131*).—From inoculation and tick experiments it has been determined that *Piroplasma mutans* does not belong to the life cycle of *P. bigeminum* and that while the blue tick (*Rhipicephalus decoloratus*) carries *P. bigeminum* it does not carry *P. mutans*. Experiments with English redwater, which is probably due to *P. boris* of Europe, and South African redwater due to *P. bigeminum* are reviewed, from which it appears that the diseases are distinct. Further experiments with many variations were performed in the attempt to transmit East Coast fever by means other than through the medium of ticks. As these all failed there appears to be no way of artificially immunizing animals.

The Tzaneen virus used in the inoculation of mules against horse sickness, for some unaccountable reason became inert during the year and the ordinary strain was resorted to. Since 1905, 8,766 mules have been inoculated with a mortality of 329 or 3.7 per cent. From statistics at hand it is estimated that during the last season 6,783 horses and noninoculated mules died. Further investigations of horse sickness are reported.

Experiments made show that equines can be inoculated against piroplasmosis with a small risk of mortality providing certain precautions are observed. Virus obtained from the eleventh to eighteenth generations has been used successfully in inoculating against blue tongue in sheep. It is stated that the farmers are unanimous in testifying to the efficacy of this vaccine.

A disease of sheep known as gonw-ziekte which had appeared at repeated intervals from 1904 to 1906 was investigated and is believed to be a specific disease. A disease known as stiff sickness or the 3-days' sickness attacked cattle in several localities but was of ephemeral nature and did not cause serious damage. There was an unusual increase of *Strongylus contortus* in many parts of the Transvaal. Besides these wireworms, *Œsophagostoma columbianum* were present to a large extent. A detailed report is given of microscopic and anatomical examinations.

Animal diseases, TUCKER (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1907–8, pp. 14–18*).—A brief account is given of the diseases occurring during the year in sheep, calves, and young stock, adult cattle, horses, and pigs. Redwater

is reported to have spread during the year into uninfected territory, a heavy mortality resulting, small dairymen in some cases losing their entire herds. Small outbreaks of pleuro-pneumonia occurred throughout the state. The animal returns for the year show 4.6 per cent of the cows and 5.2 per cent of the pigs slaughtered to have been wholly or partially condemned for tuberculosis. Actinomycosis is said to be a very common disease and contagious abortion is becoming more evident in the dairying districts.

Common dangerous communicable diseases of domestic animals in the Philippine Islands, D. G. MOBERLY (*Philippine Agr. Rev. [English Ed.], 1 (1908), No. 3, pp. 110–135*).—Information is given in the form of questions and answers on rinderpest, surra, foot-and-mouth disease, anthrax, hog cholera, glanders, hemorrhagic septicemia, and ulcerative lymphangitis, with methods for disinfecting.

The influence of symbiosis upon the pathogenicity of micro-organisms, W. E. MUSGRAVE (*Philippine Jour. Sci., B, Med. Sci., 3 (1908), No. 2, pp. 77–88*).—Bacterial and animal symbiosis are discussed at length by the author. Many of the phenomena not now understood in the etiology and pathology of disease are said to be due to symbiotic combinations between micro-organisms. Variability in the virulence of bacteria is one of the most marked features and the reason for this variability is but partially understood. The author concludes that "the most promising field for laboratory research in the future will be the study of cause and effect, in the complex relations in which they occur in nature, of the interrelation and interaction of micro-organisms with each other and in their environment of complex symbiosis and the ever changing and multiple conditions found in hosts."

Protozoa and disease, J. J. CLARKE (*London, 1908, pt. 2, pp. XII+138, figs. 53*).—Attention is called to the great advance in our knowledge of the Sporozoa since the appearance of part 1 of this treatise (E. S. R., 15, p. 405). The causes and nature of several diseases of man make up the main part of this volume. The life histories of both nonparasitic and parasitic protozoa are followed by notes on tropical diseases, ticks, and piroplasmosis. In the concluding chapter the author considers the infective genital tumors of dogs.

The prevalence and distribution of the animal parasites of man in the Philippine Islands, with a consideration of their possible influence upon the public health, P. E. GARRISON (*Philippine Jour. Soc., B, Med. Sci., 3 (1908), No. 3, pp. 191–209*).—The results of examinations of feces of prisoners at Bilibid prison made in 1907, show the population of the islands to be almost universally infested with animal parasites. Of 4,106 prisoners examined, 3,447, or 84 per cent, were found to be infested. No particular part of the islands appeared to be subject to any excess of infection. The results are summarized as follows:

Prevalence of animal parasites in the feces of 4,106 prisoners in the Philippine Islands.

Kind of parasite.	Number of prisoners infected.	Per cent infected.	Kind of parasite.	Number of prisoners infected.	Per cent infected.
Whipworms (Trichuris)	2,426	59	"Japanese blood flukes" (Schistosoma)	16	0.4
Hookworms	2,135	52	"Japanese liver flukes" (Opisthorchis)	11	.3
Eelworms (Ascaris)	1,052	26	The "dwarf tapeworm" (Hymenolepis)	5	.1
Amœba	926	23			
Other intestinal protozoa (ciliates and flagellates)	853	21	Total infestations	7,636	
"Cochin China diarrhea worms" (Strongyloides)	132	3	Intestinal worms only	5,812	
Pinworms (Oxyuris)	32	.8	Flukes	45	1.1
Tænia	30	.7	All intestinal protozoa	1,779	43
"Japanese lung flukes" (Paragonimus)	18	.4			

The spirochetes and their relationship to other organisms, H. B. Ward (*Amer. Nat., 42 (1908), No. 498, pp. 374–387*).—A general account of spirochetes and their relation to other spiral micro-organisms is here given. Fifteen species are recognized as belonging to the genus Spirochæta.

The life history of Trypanosoma equiperdum, J. E. S. Moore and A. Breinl (*Proc. Roy. Soc. [London], Ser. B 80 (1908), No. B 540, pp. 288–298, pls. 2, figs. 2, dgm. 1*).—When *Trypanosoma equiperdum* is injected into rats the parasites multiply and kill the animal about 4 days after their first appearance in the blood, which occurs about 3 days after inoculation. A large number of slides were prepared at short intervals from the appearance of the trypanosomes up to death and for a short time afterwards. The results of prolonged investigations indicate that the transference takes place by means of the ordinary trypanosome encountered in the blood, possibly through the existence of slight abrasions on the animals that become infected, or more probably through the capacity of the trypanosomes to invade a mucous membrane even if it is intact.

The authors conclude that "during the infection of rats with dourine, that is to say, with a form of trypanosome which under normal circumstances is not related to two distinct hosts, there exists a life cycle among the parasites closely analogous to that occurring during the successive positive and negative periods of infection of the same animals with *T. gambiense*.

"The parasites, after introduction into a rat, multiply by longitudinal fission, accompanied by amitotic division of the nucleus. After this process an interaction takes place between the extra-nuclear centrosome and the nucleus (sexual stage?). Division again proceeds, and finally the trypanosomes are converted into round bodies, which correspond to the latent bodies of *T. gambiense*, but possess two long and delicate flagella."

The fixation, multiplication, and culture of pathogenic trypanosomes in the proboscis of tsetse flies, E. Roubaud (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 8, pp. 423–425*).—Experiments were conducted in which *Glossina palpalis* was fed upon animals infected with *Trypanosoma gambiense*, *T. dimorphon*, *T. brucei*, and *T. cazalboui*. It was found that immediately after this fly had fed upon the blood of an infected animal its proboscis contained blood in which trypanosomes were moving actively. In a short time the trypanosomes attached themselves to the wall of the proboscis and underwent changes of structure that were completed in about 5 minutes after ingestion of the blood. While conjugation was not observed the parasites multiplied actively. It is shown that the forms in the proboscis are not derived from trypanosomes regugitated from the digestive tract of the fly. The culture in the proboscis persisted for 48 hours in *T. brucei* and for 5 or 6 days in the other 3 species. Only about 10 per cent, however, of the flies that fed on infected animals developed a culture of the trypanosomes in the proboscis.

Histological observations on sleeping sickness and other trypanosome infections, F. W. Mott (*Rpts. Sleeping Sickness Com. Roy. Soc. 1906, No. 7, pp. 45, pls. 11*).—In addition to cases of *Trypanosoma gambiense* infection, the brains of 2 oxen with Jinga trypanosome and of a rabbit infected with surra were studied, the results of which are here given. A bibliographical list is appended.

Atoxyl and trypanosomiasis, R. Boyce and A. Breinl (*Ann. Trop. Med. and Par., 2 (1908), No. 1, pp. 1–32*).—The use of arsenic and its compounds, and the results of treatment with these and allied drugs is here reviewed.

Literary references—Trypanosomiasis and sleeping sickness (*Jour. Trop. Med. and Hyg. [London], 11 (1908), Nos. 9, pp. 146, 147; 10, p. 162; 11, pp. 179, 180; 12, p. 196*).—These references include literature issued during the year 1907.

Literary references—Plague (*Jour. Trop. Med. and Hyg.* [*London*], *11* (*1908*), *Nos. 7, p. 116; 8, pp. 130, 131*).—References to the literature issued during 1907 on plague are here given. Many of these give data upon rats and fleas.

The cause and prevention of the spread of plague in India, W. G. Liston (*Bombay Sanit. Assoc., 1907, Dec. 11, pp. 38, figs. 24; abs. in Bul. Inst. Pasteur, 6* (*1908*), *No. 11, p. 487*).—Included in this account are descriptions of different species of rats and fleas occurring in India. The author considers *Mus rattus* and *Pulex cheopis* as the species particularly concerned in the transmission of plague in India.

Report on experiments undertaken to discover whether the common domestic animals of India are affected by plague, W. B. Bannerman and R. J. Kápadía (*Jour. Hyg.* [*Cambridge*], *8* (*1908*), *No. 2, pp. 209–220*).—The experiments conducted appear to show that pigs, calves, fowls, turkeys, geese, and ducks are immune to the plague.

Filtration experiments with virus of cattle plague, E. H. Ruediger (*Philippine Jour. Sci., B, Med. Sci., 3* (*1908*), *No. 2, pp. 165–169, charts 25*).—The causative agent of cattle plague present in the bile and in the blood of an animal suffering with the disease apparently does not pass through the pores of Berkefeld filters marked V, N, or W. Physiological salt solution injected into the peritoneal cavity of an animal suffering from cattle plague and collected 1 or 2 hours later, appears to be infectious after having been passed through any one of these three Berkefeld filters. The peritoneal fluid thus prepared accordingly appears to be fully as virulent as the blood of the animal.

Recurrent fever in South Oran and Pediculus vestimenti, E. Sergent and H. Foley (*Bul. Soc. Path. Exot., 1* (*1908*), *pp. 174–176; abs. in Bul. Inst. Pasteur, 6* (*1908*), *No. 12, p. 553*).—The authors investigated an epidemic of recurrent fever in the natives of the Moroccan frontier from which it was concluded that *Argas persicus* and *P. vestimenti* are the species probably concerned in the transmission of the disease. Arthropods that had sucked blood from individuals sick with the disease were sent to Paris where they were ground in water and injected into monkeys. One monkey injected with the ground body of a louse was infected, while negative results were obtained from similar injections of 18 bugs and 22 ticks.

Abdominal hernia, O'Connor (*Vet. Rec., 21* (*1908*), *No. 1055, pp. 186–194, figs. 3*).—The etiology, symptoms, diagnosis, prognosis, and treatment of external abdominal hernia are discussed by the author.

The chronic arsenical poisoning of herbivorous animals, W. D. Harkins and R. E. Swain (*Jour. Amer. Chem. Soc., 30* (*1908*), *No. 6, pp. 928–946, fig. 1*).—Studies made in Montana on the effect of smelter smoke upon animals feeding on vegetation in the vicinity of smelters are reported.

While there is comparatively little sickness during the late spring and summer, by November a large number of animals are affected if allowed to run upon the pastures. A case is reported in which large numbers of sheep died after feeding for 1 week in October in a pasture 15 miles north from the smelter. Analyses were made of grass and moss taken from this pasture and in the grass 52 parts and in the moss 405 parts of arsenic trioxid in a million were found.

Autopsies of a large number of animals including horses, cattle, and sheep were made and many of the samples obtained were analyzed and the results of part of these are given in tabular form. It is shown that in one case a cow's liver contained 43 times the maximum amount of arsenic trioxid allowed in the recommendations made by the Royal Commission on Arsenical Poisoning. Flesh and also milk were found which likewise exceeded the limit prescribed by this commission.

Considerable data are given on the physiological action of arsenic. Experiments with sheep show that 46 mg. (0.7 grain) of arsenic trioxid per day, administered in the form of sodium arsenite per 100 lbs. of body weight is sufficient to cause the death of a sheep. Digestion experiments made to determine the amount of arsenic in plants that is soluble in the digestive juices of animals are reported. A detailed account is given showing the distribution of arsenic in the tissues, the milk, ulcers of the nose, and in the hair. Symptoms of the chronic arsenical poisoning caused by the vegetation of smelter regions are described.

A list of plants poisonous to stock, S. T. PARKINSON and E. J. RUSSELL (*Jour. Southeast. Agr. Col. Wye, 1907, No. 16, pp. 347–359*).—A table of the common wild plants found in Great Britain that are poisonous to stock is given. This includes common and botanical names, habitat, poisonous properties, and, when known, the chemical substances present.

The foot-and-mouth situation, L. PEARSON (*Nat. Stockman and Farmer, 32 (1908), No. 37, p. 876*).—Extracts from a letter in which an account of the work of eradication of this disease in Pennsylvania is described. Up to December 7, 94 infected herds had been found in the State. It is stated that all of the infection in Pennsylvania traces to Buffalo from which at least 9 infected carloads were sent into different localities about November 1.

Johne's disease in cattle, W. L. BEEBE (*Amer. Vet. Rev., 33 (1908), No. 6, pp. 709–716, figs. 3*).—Attention is called to the fact that chronic enteritis exists in the northwest, particularly in Minnesota. An account is given of several cases, of the symptoms, and of a post-mortem examination. The author concludes that there is very little room for doubt that the bacillus found so abundantly and so uniformly present is the cause of the disease, although attempts by the author and others to infect rabbits and guinea pigs have failed as have also attempts to cultivate the bacillus on artificial media. The disease is regarded as infectious and of grave importance. The author recommends that all affected animals be isolated, that the feces be deeply buried or burned, and that after a positive diagnosis has been made all animals be destroyed. References to the literature are given.

Experiments with English and South African redwater, A. THEILER (*Transvaal Agr. Jour., 6 (1908), No. 24, pp. 534–543*).—From experiments conducted with heifers in England and South Africa the author concludes that English redwater is not always inoculable, and that it differs in this respect from South African redwater.

An investigation in County Wexford, of a disease in young cattle, J. H. NORRIS (*Dept. Agr. and Tech. Instr. Ireland Jour., 8 (1908), No. 4, pp. 633, 634*).—This is a final report, previous reports having been noted (E. S. R., 18, p. 778). In these experiments 92 healthy calves were reared on 8 farms without a single loss, by keeping them from the other stock and on clean pasture. These farms in previous years had shown a death rate of 30 per cent.

Measures against animal tuberculosis in Denmark, B. BANG (*Amer. Vet. Rev., 34 (1908), No. 2, pp. 161–185; Jour. Compar. Path. and Ther., 21 (1908), No. 4, pp. 287–303*).—This article forms a report of the Danish International Committee submitted to the International Congress on Tuberculosis, at Washington, 1908. The tuberculosis acts of 1893 and 1904 and the amendment of 1898 are reported and discussed.

The passing of the State act of 1893 was chiefly due to the proposal of the author, who had been studying the efficacy of tuberculin for indicating the existence of tuberculosis among cattle and other domesticated animals, and who had worked out a system for the extermination of the disease in an in-

fected herd. An account is given of the so-called Bang method as carried out in Denmark and previously noted (E. S. R., 9, p. 991; 18, p. 81). In view of American experience, particular importance attaches to the requirement that only milk and buttermilk heated to a temperature of 80° C. can be returned from dairies to serve as food for cattle and pigs, and only such as is proved to have been heated to at least this temperature can be imported.

The blood of the horse, J. Sabrazès, L. Muratet, and P. Durroux (*Compt. Rend. Soc. Biol. [Paris], 65 (1908), No. 26, pp. 169–173; Gaz. Sci. Méd. Bordeaux, 29 (1908), Nos. 28, pp. 325–330; 29, pp. 339, 340*).—These contributions include a review of the literature and the report of investigations made by the authors. Studies were made of the density, corpuscular resistance, coagulation, etc., of blood from a large number of horses. The leucocytes were given particular attention and their variation under varying conditions including the influence of age, effect of digestion, management, fatigue, etc., was determined.

RURAL ENGINEERING.

Highway engineering, C. E. Morrison (*New York, 1908, pp. VI+315, figs. 60*).—This is intended for use as a text-book for the author's classes in Columbia University, and its purpose is stated to be "to emphasize the basic principles which are essential to good highways." The first chapter is devoted to an analysis of road resistance and the results of tests to determine it. There is about an equal amount of space devoted to country roads and city streets. Specifications form a considerable part of the text, those of New Jersey being given for country roads, those recommended by the National Paving Brick Manufacturers' Association for brick pavements, and those of the City of New York for other city pavements.

A new system of road making (*Surveyor, 35 (1909), No. 885, p. 12, figs. 3*).—A new system which has just been introduced in England is described. This comprises a concave subgrade of broken stone and a convex surface having a metal track for automobiles and traction engines laid in the center of the waterproof road material, and the sides of the road being paved with macadam for ordinary traffic. It is claimed that the advantages gained from its long life will offset the initial high cost of construction.

Effect of traction engine and heavy motor traffic upon road foundations, R. J. Thomas (*Surveyor, 34 (1908), No. 878, pp. 499–501*).—This is one of the papers presented to the First International Road Congress at Paris.

The author's observations on English country roads show that there is a concave cross section of the subsoil wherever the road has been subjected to heavy motor traffic. It is pointed out that the crossbars on the driving wheels are largely responsible for this condition, because of concentrating the weight on a small area with a consequent large unit pressure on the foundation. Concentration of traffic along the center of the road is also a serious factor in injuring the roadbed, largely because the weight of the engine is transmitted to the road by the inner edge of the broad tire when the surface is crowned.

Denatured alcohol in France, F. H. Mason (*Daily Consular and Trade Rpts. [U. S.], 1908, No. 3343, pp. 1, 2*).—This article contains statistics of the total production, the sources of distillation, and the various uses to which the supply of denatured alcohol has been put in France. It is noted that there is a large increase in consumption, due to its use for heating and lighting and for the manufacture of ether and explosives. In spite of this increase it is reported that the use of alcohol for motors has not attained its anticipated importance because of the high cost of denaturing material, the tendency to corrode the interior of cylinders, and the failure to explode with sufficient rapidity for automobile purposes.

RURAL ECONOMICS.

[Papers on rural economy]. R. Żeleński et al. (*S. Internat. Landw. Kong. Wien. 1 (1907), pp. 183–211, 322–333, 654–661; 2 (1907), Sec. I, Refs. 1–7, pp. 156; Sec. III, D, Refs. 1–6, pp. 168; summarized in Ann. Sci. Agron., 3. ser., 3 (1908), I, pp. 11–30*).—This is a report of the proceedings of the Eighth International Congress of Agriculture held at Vienna, May 21–25, 1907.

The papers are printed in full in Volume 2, and the topics discussed were: (1) The international regulation of dealing in futures; (2) the union of the International Congress of Agriculture with the International Institute of Agriculture at Rome; (3) the conservation of the agricultural class; (4) a comparative study of duties on agricultural produce; (5) the international labor problem with particular reference to agricultural laborers; (6) the reduction of taxes on land; (7) circulating capital in the agricultural industry; (8) the influence of farm management on net income; (9) book-keeping by an agricultural central organization; (10) the value of nonmarketable agricultural products; (11) the agricultural labor problem, etc.

Mother earth: A proposal for the permanent reconstruction of our country life. M. Fordham (*London, 1908, pp. 157*).—The author outlines a scheme for the rehabilitation of agriculture and rural social life in England as a remedy for rural depopulation and the unemployed in cities.

The administration of the small holdings act (*Bd. Agr. and Fisheries [London], Leaflet 216, pp. 8*).—The regulations issued by the Board of Agriculture and Fisheries for the acquisition, assignment, and control of land for small holdings under the acts of 1892 and 1907 are presented in this pamphlet.

Small holdings in England. F. Impey (*Rev. Econ. Internat., 5 (1908), IV, No. 8, pp. 519–548*).—A brief history of the modern small holdings movement in England, with a discussion of the chief provisions of the small holdings and allotments act of 1907 and the economic and social progress made since its operation.

Small holdings in Southwest Lancashire. J. O. Peet (*Jour. Bd. Agr. [London], 15 (1908), No. 8, pp. 561–567*).—A description of the size, operation, and returns of small holdings in Lancashire is presented. The size of the holdings range from about 6 to 40 acres, the latter being quite common, and rents range from £3 10s. to £5 per acre. While the rate of wages paid farm hands ranges from 18s. to 24s. per week, it is seldom that the laborers become small holders "though, with thrifty habits and high wages, they have a good chance of doing so if they desire."

In behalf of small proprietors. J. Aguet (*Coltivatore, 54 (1908), No. 46, pp. 609–612*).—This is an argument in favor of reducing the legal fees and government taxes on land transfers in Italy, with the view of enabling peasants to become the owners of small holdings. Relative to acquiring a piece of land under present conditions statistics are presented to show that the fees and taxes to effect the transfer amount to about one-third or even as high as one-half the purchase price, and this is regarded as too burdensome on the farm laboring class.

The sale of lands to peasants [in Russia] (*Bul. Mens. Off. Renseig. Agr. [Paris], 7 (1908), No. 10, pp. 1262–1271*).—This is a summary of the work of the agricultural commission during the year ended October 1, 1907, previously noted from another source (E. S. R., 20, p. 91).

The agrarian question in Bosnia. A. Raffalovich (*Econ. Européen, 34 (1908), No. 880, pp. 649, 650*).—Notes are given on the population, number and class of holdings, and land-tenure system in Bosnia, with a comparison of the

condition of the peasant class under the Turkish and Austrian régimes. The burdens on the agricultural class are regarded as the cause of the constant agitation in the province.

The economic relations of twenty-two farms near Offenburg, Baden, F. Bornemann (*Arb. Deut. Landw. Gesell., 1908, No. 148, Art. 13, pp. 41*).—The economic relations of these farms, including system of management, acreage and kind of crops, live stock, amount and kind of labor, use of machinery, financial returns, etc., are tabulated and discussed in this article.

The progressive farmer, T. P. Gill (*Irish Farming World, 21 (1908), No. 1081, pp. 1148, 1149*).—A discussion of agricultural conditions in Ireland and a presentation of facts regarding the farmer's need of studying markets and carrying on scientific agriculture with a view of improving his economic condition. The need of raising first-class products in competition with foreign trade is urged upon Irish farmers, and greater cooperation among farmers is advocated as a means toward greater economic and social development.

Cooperation for small holders, E. J. Cheney (*Jour. Bd. Agr. [London], 15 (1908), No. 8, pp. 579–585*).—The economic advantages of cooperation to small holders in England are discussed in this article, with suggestions as to the different lines along which the cooperative movement should be developed.

Annual report of the Agricultural Organization Society for the year ended December 31, 1907, R. A. Yerburgh and J. N. Harris (*Ann. Rpt. Agr. Organ. Soc. [London], 1907, pp. 86, dgm. 1, map 1*).—An account of the development of agricultural cooperation in Great Britain during 1907. The societies numbered 167, the membership 10,500, and the total business about £610,000. The purposes of this organization have already been noted (E. S. R., 18, p. 786).

Development of agricultural cooperative societies (*Bul. Mens. Off. Renscig. Agr. [Paris], 7 (1908), No. 10, pp. 1287–1289*).—On January 1, 1908, the cooperative dairies in Denmark numbered 1,101, with 160,000 members, the slaughterhouses 36, with 95,000 members, and the egg-collecting associations 792, with 58,140 members. See also a previous note (E. S. R., 19, p. 992).

Associations for the purchase of agricultural machines, M. Bérillon (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 29 (1908), No. 46, pp. 593–597*).—The author shows by statistics that more than half the land under cultivation in France is in small and moderate-size farms ranging from 2½ to 100 acres. The number and size of farms are as follows: From 2½ to 25 acres, 2,630,000 holdings; from 25 to 100 acres, 730,000 holdings; and above 100 acres in size 142,000 holdings.

The author presents a scheme whereby the owners and tenants on small farms can by forming cooperative associations procure modern machinery for exploiting their holdings. The effect of cooperation of this nature it is believed would be to improve the moral and economic welfare of small proprietors and bring about agricultural prosperity in France.

Agricultural credit in Belgium in 1906–7, Gilliéron-Duboux (*Chron. Agr. Vaud, 21 (1908), No. 22, pp. 465–470*).—Notes on the development of agricultural credit institutions in Belgium, the methods of procuring loans, the number and value of loans granted, and the number and location of the credit banks. On January 1, 1908, there were 7 central banks with 540 affiliated rural credit associations.

Agricultural legislation [in Portugal], compiled by A. G. Ramalho (*Legislação Agricola. Lisbon: Govt., 1907, Vol. II, No. 1, pp. 186*).—A chronological compilation of Portuguese laws, decrees, and other official documents of interest to agriculture from 1385 to 1446.

AGRICULTURAL EDUCATION.

Instruction in agriculture and forestry (*Ann. Sci. Agron., 3. ser., 3 (1908), I, pp. 31–72*).—Abstracts are given of the following addresses presented at the Eighth International Congress of Agriculture in Vienna in 1907: The More Practical Organization of Higher Agricultural Instruction, by H. Thiel; reports concerning The Supply and Demand of Specialists in the Promotion of Agriculture and Forestry, by V. Egger-Möllwald and Boettger; Is there Legal Authority for Demanding a Certificate of Proficiency from Directors of Agricultural and Forestry Enterprises, by H. de Haerdtl, R. von Guttenberg, and von Jaroschka; Experimental Work in Secondary Schools as a Method and Subject of Instruction, by F. Schindler; The Development of Agricultural and Forestry Instruction in Primary and Secondary Schools, by Rudolf Jugoviz; Instruction in Agriculture and Domestic Science, by P. de Vuyst; Agricultural Instruction for Soldiers, by Nazzari; How Chile Saltpeter May be Replaced in the Future, by A. Frank and K. Birkeland; What is the Best Organization of Agricultural Research, by A. C. True, Thomas Kosutány, and F. W. Dafert (E. S. R., 18, p. 1098); On the Effectiveness of Demonstration Trials in Pots or in the Field, by O. Reitmair; Statistics and Charts on Peat, by W. Bersch; and New Practice in Moor Culture, by B. Tacke.

Seventh annual general report of the Department of Agriculture and Technical Instruction for Ireland (*Dept. Agr. and Tech. Instr. Ireland, Ann. Gen. Rpt., 7 (1906–7), pp. VI+658*).—Along with administrative matters this report contains details of the department's work in agriculture, including agricultural instruction, and in technical instruction, including domestic science.

Under agricultural instruction an account is given of itinerant instruction and special courses, and of the instruction given at the Royal College of Science, Cirencester; Albert Agricultural College, Glasnevin; agricultural stations, agricultural classes and schools, Munster Institute, Cork; Ulster Dairy School, Loughry; and schools of rural domestic economy. The report on technical instruction includes the organization of a system of instruction in experimental science, drawing, manual instruction and domestic economy in day secondary schools, the organization of technical instruction under local authorities, the training of teachers in domestic economy, and the work of the Irish Training School of Domestic Economy and the Killarney School of Housewifery.

The appendixes include a table showing the 1907 apportionment of funds for educational and other purposes, schemes of instruction in agricultural subjects, prospectuses of agricultural colleges and stations and schools of rural economy, program of experimental science, drawing, and domestic economy for day secondary schools, programs of the institutions under the direct control of the department, examples of schemes of technical instruction in nonagricultural subjects, including domestic science, list of day secondary schools, showing grants paid for instruction in the subjects of the department's program during 1905–6, a list of home industries classes in receipt of aid during 1906–7, and a list of science, art, and technical schools and classes working in connection with the department or under local schemes.

[Agricultural and forestry instruction in Austria and Germany] (*Land u. Forstw. Unterrichts Ztg., 21 (1907), No. 3–4, pp. 175–307*).—This number is devoted to (1) the following special articles: Observations on Forestry Instruction, by A. Cieslar; The Development and Problems of Analytical Chemistry, by G. Vortmann; Observations on Methods of Instruction in Secondary Agricultural Schools, by A. Kullisz; and Itinerant Cooking and Housekeeping Courses for the Farming Community of Upper Austria; (2) present status and

organization of agricultural and forestry institutions in Prussia; (3) review of agricultural literature and book notices; and (4) notes from the annual reports of the agricultural and forestry schools for 1906–7.

[Agricultural and forestry education in Austria] (*Land u. Forstw. Unterrichts Ztg., 21 (1907), No. 1–2, pp. 174+LV*).—This report contains (1) special articles as follows: The Importance of Vocational Schools, by L. Fleischer; Vocational Instruction at the Eighth International Congress in Vienna, by E. Vital; Observations on Forestry Instruction, by A. Cieslar; and Suggestions For and Examples of Practical Experimental Work by Agricultural Schools, by F. Schindler; (2) statistical tables including date of organization, length of courses, number in faculties, attendance, graduates, occupations of 1906 graduates, stipends and special courses, of the agricultural and forestry institutions in Austria, and their geographical distribution; (3) Statistical Contributions to the History of Agricultural and Forestry Instruction: The Vocational Schools of Austria in 1903–4, by E. Vital; and (4) review of agricultural literature and book notices.

It is shown that in 1906–7 there were 195 agricultural and forestry schools in Austria, an increase of 6 over 1905–6. They included 3 high-school institutes, 3 agricultural academies, 9 agricultural high schools, 5 forestry high schools, 2 high schools for viticulture, fruit culture, and horticulture, 1 high school for the brewing industry, 43 farm schools or elementary agricultural schools with one-year courses, 75 agricultural winter schools, 10 elementary forestry schools, 17 dairy and housekeeping schools, 23 elementary special schools for horticulture, fruit culture, viticulture, hop culture, alpine farming, and apiculture, 2 brewing and 2 distillery schools.

[Agricultural and forestry instruction in Austria and other countries] (*Land u. Forstw. Unterrichts, Ztg., 22 (1908), No. 1–2, pp. 148+LV*).—This number is devoted to (1) the following special articles: Raising the Scientific Plane of Secondary Agricultural Schools, by A. Kulisz; Fostering a Taste for the Fine Arts in Secondary and Higher Agricultural and Forestry Schools, by J. Longo; and The Question of Text-books for Elementary Agricultural Schools, by H. Knesch; (2) an account of the present status and organization of agricultural and forestry institutions in the Kingdom of Saxony; (3) the organization of agricultural and forestry instruction in Switzerland; (4) itinerant housekeeping schools in France, and the poultry school at Gambais; (5) review of agricultural literature, and book notices; (6) notes from the annual reports of the agricultural and forestry schools for 1906–7; (7) miscellaneous notes; (8) an appendix containing a list of all the agricultural and forestry institutions in Austria and their boards of instruction, and (9) statistical data for 1907–8 of the agricultural and forestry institutions in Austria corresponding to those given for 1906–7 in the preceding abstract. These statistics show a net gain of 5 schools as compared with the previous year. This includes a decrease of 2 farm schools or elementary agricultural schools with one-year courses, and an increase of 5 agricultural winter schools, 1 elementary forestry school, and 1 elementary special school for horticulture, fruit culture, viticulture, hop culture, alpine farming, and apiculture.

Agricultural instruction in Saxony (*Jahresber. Landw. Königr. Sachs., 1907, pp. 83–103*).—This contains brief reports for 1907 of institutions in Saxony giving instruction in agriculture and domestic science, and of special courses in agriculture, together with tables showing the attendance, by provinces, for 1907–8 at the elementary agricultural schools and the total attendance from 1875 to 1908.

School training for the home duties of women. III. The domestic training of girls in Germany and Austria (*Bd. Ed. [London]. Spec. Rpts. Ed. Subjects, 19* (*1907*), *pp. 121+XVI*).—This is the third and concluding number of the special reports on the school training for home duties for women. It includes (1) introductory and concluding articles on the general education of girls, history of domestic training, and extent of domestic training in Germany and Austria; and discusses (2) the teaching of domestic subjects in elementary and continuation schools; (3) the teaching of domestic subjects in secondary schools; (4) domestic subjects in technical schools and classes; and (5) technical teachers in girls' schools. Twelve appendixes contain specimen accounts and lesson plans and extracts of syllabi and courses of study of individual schools, as well as summaries of regulations of several groups of schools.

MISCELLANEOUS.

Annual report of agricultural experiment station at Marburg for 1907–8. C. Haselhoff (*Jahresber. Landw. Vers. Stat. Marburg, 1907–8, pp. 22*).—This gives the organization of the station and an account of its work and publications during the year.

A brief review of the investigations conducted by the Government Agricultural Experiment Station, Groningen, from 1895 to 1907, B. Sjollema (*Kort Overzicht van de Onderzoekingen Verricht in het Rijkslandbouwproefstation te Groningen, in de Jaren 1895–1907. [Groningen]: Gov't., 1907, pp. 19*).

Agricultural report for the year 1906. Y. Henry (*Gouv. Gén. Afrique Occident. Franç., Rap. Agr. 1906, pp. 310, figs. 63, maps 11*).—This report describes the organization of the agricultural service, the experiment stations, and the agricultural resources and possibilities of western French-Africa.

Agricultural writers, 1200 to 1800. D. McDonald (*London, 1908, pp. 228, illus. 97*).—This consists of reproductions in facsimile and extracts from the writings of English agricultural writers from Sir Walter of Henley, 1200, to Arthur Young, 1800, together with brief biographies and explanatory notes. A chronological bibliography is appended.

Batten's agricultural directory (*New York, 1908, pp. 212*).—A directory of the agricultural press of the United States and Canada, with a discussion of agricultural conditions in these countries and statistics of farm products and values by States and Provinces.

Index to the first twenty volumes of bulletin de l'Association des Chimistes de Sucrerie et de Distillerie, L. Pellet (*Association des Chimistes de Sucrerie et de Distillerie. Table des Matières des Vingt Premiers Volumes, 1882–1902. Paris, 1907, pp. 203*).

General Index, Proceedings and Transactions of the Royal Society of Canada, first and second series, 1882–1906 (*Ottawa, Toronto, and London, 1908, pp. 133*).

NOTES.

Arizona Station.—The Territorial assembly has appropriated $13,100 for the station for the ensuing biennium. Of this $4,500 is for the maintenance of the date orchards at Tempe and Yuma, $2,500 for farmers' institutes, $3,100 for publications, and $3,000 for dry farming experiments in two locations to be selected by the station.

F. C. Kelton has been appointed assistant engineer and entered upon his duties January 15.

Connecticut State Station.—A. F. Hawes, station and State forester, has resigned to accept a similar position in Vermont.

Hawaii Federal Station.—D. L. Van Dine has been transferred to the Bureau of Entomology of this Department in connection with its investigations of sugar cane and rice insects.

Idaho University and Station.—A demonstration train similar to that sent out in northern Idaho last summer made an itinerary of about a month through southern Idaho, beginning February 15. The illustrative material comprised dairy apparatus, including a dairy cow and a milking machine; spraying apparatus; charts; exhibits of grains, grasses and agricultural products; and an agricultural library of about 100 volumes, made up in part of station and Department publications.

Indiana Station.—The State appropriation to the station of $25,000 per year was increased by the legislature at its recent session to $75,000 per year. Of this amount $15,000 is to be used for soil and crop improvement, $10,000 for dairying, $5,000 for poultry work, $10,000 for other live stock interests, $5,000 for the investigation of hog cholera and other animal diseases, and $10,000 for horticultural work. The advisory board, which with the director is given the power to determine the specific lines of work to be undertaken in each case, was enlarged to include, in addition to the State Corn Growers', Dairymen's and Live Stock associations, representatives of the State Horticultural Society and the State Poultry Fanciers' Association. Of the remainder of the appropriation, $10,000 is to be available for general expenses and $10,000 for extension work.

Louisiana Stations.—An arrangement has been effected whereby the secretary of the State Crop Pest Commission, Wilmon Newell, will become an active member of the station staff, devoting half his time to entomological investigations under the Adams Act.

Maryland College and Station.—George E. Gage, Ph. D. (Yale), assistant in the Yale biological laboratory, has been appointed assistant biologist in the station to pursue investigations in poultry diseases. Dr. Robert B. Mayo, assistant pathologist of the station, has resigned to engage in hospital work in Mississippi. Dr. Joseph R. Owens, treasurer of the college since 1890, died March 15, at the age of 70 years.

Massachusetts College.—Carroll D. Wright, a trustee of the college since 1906 and eminent for his contributions to statistics and sociology, died at Worcester, February 20, at the age of 68 years. Dr. Wright had been president of Clark

College since its establishment in 1902, a trustee of the Carnegie Institution of Washington, United States Commissioner of Labor from 1885 to 1905, president of the American Association for the Advancement of Science in 1904, and had held many other positions of prominence. He has been succeeded as trustee by Davis R. Dewey.

Montana College and Station.—The college and station have received increased appropriations from the legislature for the ensuing biennium. The college was granted $78,500 for maintenance, an increase of $12,500, and $50,000 for a woman's dormitory. The station received for maintenance $12,500 per year, an increase of $5,000 per year, in addition to a like amount for the maintenance of the substations. For improvements $10,000 was granted for a sheep and steer barn, an addition to the poultry plant, and sheds for young stock, together with $8,000 for the substations. Authority to purchase 160 acres from the college land grant was conferred, and $18,800 was also appropriated for the purchase of two blocks adjoining the college grounds.

The executive board was replaced by a new governing board, consisting of the president of the college and two members to be selected by the State board of education. The powers of the new board are restricted, supervisory control of the finances being vested in the State board of examiners. The change became effective April 15.

The farmers' institute work was also placed in charge of a new board, this consisting of the governor of the State, the president of the college, and the director of the station. The appropriation for farmers' institutes was increased from $7,500 per year to $8,000 per year.

E. T. Tannatt, professor of civil engineering in the college and engineer in the station, and R. W. Fisher, professor of horticulture and horticulturist, have resigned to engage in commercial work, their resignations becoming effective June 30.

North Dakota College.—According to *Breeders' Gazette*, a full collegiate course in veterinary science and surgery has been established.

Rhode Island College and Station.—C. H. Coggeshall, member of the board of managers since the establishment of the college, has been succeeded by Charles W. Estes, of Warren. The board has been reorganized by the election of Thomas G. Mathewson as vice-president, and Robert S. Burlingame as clerk and treasurer.

Vermont University.—The first annual farmers' week ever attempted in Vermont was held March 8–12, with a registration of 160. The program consisted of lectures and demonstrations by several speakers from various parts of New England as well as members of the university faculty.

Washington College and Station.—The State legislature, which has just adjourned, appropriated to the college and station for the ensuing biennium $487,256 for maintenance, general improvement, equipment, and experimental and extension work; $17,500 for farmers' institutes; and $29,600 for the Puyallup Substation.

A fruit demonstration train was operated in the Yakima Valley March 10–12. Demonstrations were given at 11 stops with a total attendance of 4,215. A new feature of this train was a flat car equipped with a model orchard in tubs, a large apple tree, and a power sprayer by means of which complete demonstrations of spraying and pruning were given.

The South African Veterinary Congress.—*The Veterinary Record* of February 20 and 27 contains a report of the first Pan-African Veterinary Congress which convened at Pretoria on January 13. This congress was initiated by the Transvaal Premier, General Botha, but in his absence was opened by the

Attorney-General, Hon. J. de Villiers, who described it as an epoch-making event. Other veterinary conferences have been held in British South Africa, but this is the first that has included delegates from other than British possessions. Representatives were present from Congo, Madagascar, Basutoland, German West Africa, Mozambique, Rhodesia, Natal Swaziland, Cape Colony, Bechuanaland, and the Transvaal, thus including South Africa nearly to the Equator.

Among the important questions considered were the veterinary laws in regard to stock diseases (including East coast fever, glanders, tuberculosis, lung sickness, rabies, epizootic lymphangitis, scab, and trypanosome affections), meat inspection, and veterinary surveys. Many resolutions were formulated to be submitted to the various African governments, and a subcommittee was appointed consisting of representatives of 6 colonies or states for the purpose of suggesting uniform regulations against animal diseases for the whole of Africa. Recommendations were also drafted in regard to veterinary surveys, with a view to protect the colonies from various unknown diseases from the interior. The importance of this conference is especially great, as the many contagious animal diseases have greatly crippled the agriculture of the colonies.

Innes Bequest to Horticultural Instruction and Research.—*The Gardeners' Chronicle* recently gave full details of a bequest made by the late John Innes, which bids fair to prove of lasting benefit to British horticulture. Under the terms of this bequest, a body of trustees is to administer a sum approximating £10,000 a year for the purposes of establishing and maintaining an institution to be known as the "John Innes Horticultural Institution," and which is to have for its object the promotion of horticultural instruction and research. The direct management of the institution, and such other matters as the trustees may determine, devolves upon a council of twelve persons, of whom the three trustees are ex-officio members, and the remainder selected from specified societies and universities in England. The house and a portion of the grounds of Manor Farm, Merton, England, have been bestowed for the purposes of the institution and for the establishment of a horticultural station which is to be efficiently equipped, including the provision of buildings and lecture rooms. The trustees are further empowered to establish and equip similar stations in other parts of the country or assist in such work.

The Gardeners' Chronicle points out the opportunity thus afforded for the development of a horticultural university, in which research and advanced teaching are the primary objects, and deprecates any possibility of the institution's becoming perverted into a school of elementary instruction.

Apicultural Station in Ontario.—A recent number of *Gleanings in Bee Culture* announces that an apicultural station is to be established under government auspices at Jordon, Ontario, where a fruit station is already in operation. The object of the station is stated to be to conduct experiments in the fertilization of flowers by bees, to carry on apicultural investigations, and to provide courses of instruction in apiculture.

LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS REVIEWED.

Stations in the United States.

Stations in the United States—Continued.

U. S. Department of Agriculture.

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau requests and remittances should be directed to the Chief of the Bureau. The price of *Experiment Station Record* is $1.50 per volume, or 15 cents per number. The prices of other technical publications are given above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XX. APRIL, 1909. No. 9.

For several years the widespread popular interest in the work of the National Department of Agriculture has been reflected in the extended consideration given by Congress to the act making appropriations for its support. As was pointed out by Chairman Scott of the Committee on Agriculture in presenting to the House of Representatives the bill for the next fiscal year, the act, "although one of the smallest of the great supply bills annually brought before the House, probably attracts more general interest in this Chamber than any other, and its provisions are more closely scrutinized and more carefully discussed. The reason for this is doubtless found in the fact that the activities of the Department are so widely extended and touch in a vital way the interests of so large a proportion of our people."

That this interest was fully maintained is indicated by the general participation in the subsequent debates upon the measure in both the House and the Senate, the discussion being prolonged to such an extent that it was not until March 4, the final day of the session, that the bill, originally reported on January 25, received the signature of the President.

As finally enacted the measure is substantially in the form in which it was submitted by the House committee. It also follows in a general way the corresponding laws of recent years, but it is even more completely a routine measure, inaugurating comparatively little new work and containing practically no matters of general legislation.

An innovation as to the lump-fund appropriations hitherto made to the various bureaus for their general expenses was adopted, under which in most cases these appropriations have been further subdivided by specifying the amount to be expended for each of the principal lines of work. Thus, the Bureau of Entomology, which last year received a lump fund of $158,800 for entomological investigations without further restrictions as to its division among the various projects under way, is by the new law granted in its stead $46,600 for investigations of insects affecting deciduous fruits,

$21,000 for insects affecting cereal and forage plants, $42,000 for insects affecting southern field crops, $12,000 for forest insects, $16,250 for insects affecting truck crops and stored products, $10,000 for bee culture, $16,500 for insects affecting citrus fruits, and $34,050 for other investigations. With a view to providing for exigencies due to unforeseen conditions, however, a provision was also added to the bill under which 10 per cent of the appropriation for the miscellaneous expenses of the work of any bureau is made available interchangeably for expenditure on the objects included within the general expenses of that bureau, "but no more than ten per centum shall be added to any one item of appropriation except in cases of extraordinary emergency, and then only upon the written order of the Secretary of Agriculture."

The total appropriation carried by the new law is $12,995,036. This is an increase of $1,322,930 over the previous act, or approximately 10 per cent. It makes provision for the continuance of nearly all the lines of work now under way, and in many cases their extension to meet the growing demands upon the Department.

The Weather Bureau receives a total appropriation of $1,508,260. This is a reduction of $154,000, which is due principally to the completion of the new buildings for the Mount Weather Observatory and the elimination of all appropriations for other buildings and equipment of new stations. The lines of work are essentially unchanged. The amount assigned to the investigations in climatology and meteorology is $125,000. The salary of the chief of the Bureau was increased from $5,000 to $6,000. An increase of $4,000 was allowed for contingent expenses, and the limit of cost of maintenance of the Bureau printing office was increased from $30,000 to $45,000.

The appropriation of the Bureau of Animal Industry was increased $97,000, making a total of $1,427,860. Among the items authorized are $250,000 for the eradication of the cattle tick in the South; $625,000 for inspection and quarantine work (other than the federal meat inspection, which is now provided for in the permanent law); $149,000 for the work of the Dairy Division; and $43,000 for the work in animal husbandry. For investigations of animal diseases and the maintenance of the Bureau experiment station, $109,000 was provided together with $25,000 for the purchase of additional land. The appropriation of $50,000 made last year for experiments in animal feeding and breeding in cooperation with the State experiment stations was continued, but the language was so altered as to permit independent investigations by the Bureau as well.

The Bureau of Plant Industry received one of the largest increases in the bill, $367,590, making its total $1,709,266. Of this $1,180,796 is for general expenses, which are further itemized to provide for

thirty-two lines of inquiry. Among these may be mentioned $225,000 for demonstration work against the boll weevil, $133,000 for farm-management investigations, and $71,360 for investigations of the methods of growing, packing, and marketing fruits and melons. An allotment of $76,680 was granted for cooperative demonstrations as to the utilization of arid and semiarid regions, and authority was granted to conduct cooperative work in conjuction with the Reclamation Service on its reclaimed lands. Authority to carry on breeding and testing work with fibrous plants suitable for paper making was also conferred, $10,000 being provided for the purpose. This was in addition to the paper-making tests of plants such as were authorized last year, these being continued in the new act as a special appropriation unassigned to any bureau and extended to include similar tests with woods.

The Bureau was given $12,250 for an investigation of the handling, grading, and baling of cotton and the establishment of standards for the different grades in accordance with previous legislation, and $52,440 was granted for similar work with grain. A clause providing for furnishing at cost to interested parties sets of cotton standards was reported by the Senate committee, but eliminated on a point of order, as was also a clause directing the Department, upon the request of grain growers, to grade their grain before shipment.

For the Congressional seed distribution, which was continued on the usual basis, an increase of $60,320 was granted, making a total of $262,320 for the purpose. The appropriation for the introduction of rare and valuable seeds from foreign countries was slightly decreased, and authority was given to expend not to exceed $10,000 of the amount in the testing and distribution of forage crops.

In the case of the Forest Service the act carries an apparent reduction of $84,100 for statutory salaries, but this is due to extensive transfers to the lump fund appropriation as a result of the recent establishment by the Service of six administrative districts or branch offices in the West, to which a considerable proportion of its Washington staff has been transferred. The net increase in the statutory and lump fund appropriations was $750,000, partly on account of this change, but principally to meet the increased use to which the National Forests are being put and the extension of their limits during the past year by some 17,000,000 acres. Authority to advise owners of woodlands as to their care, omitted last year, was restored, but permission was refused to arrange exchanges of private lands lying within forest reserves for stumpage of substantially equal value from the National Forests with a view to their unification. For permanent improvements the appropriation of last year, $600,000, was continued, making the total for the Forest Service $4,646,200, by far the largest carried in the bill.

The Bureau of Biological Survey was granted an increase of $25,420, of which $7,000 is for the maintenance of the Montana Bison Range and other reservations for mammals and birds. Authority was given for the expenditure of the balance remaining from the appropriation of the previous year for the purchase of land for the Montana Bison Range in completing its fencing, constructing sheds and other buildings, and extending its present area of 12,800 acres to 20,000 acres.

The total appropriation for the Office of Experiment Stations, including $720,000 for the experiment stations under the Hatch Act, is $1,069,220, an increase of $34,600. The allotment for statutory salaries was increased $4,640, this including an increase in the salary of the director from $3,500 to $4,000, and the lump fund for general expenses was increased $4,800, making $34,800 available for this purpose. The appropriations for the stations in Alaska, Hawaii, and Porto Rico were each increased $2,000 to correspond with the increase to the State stations under the Adams Act, and the allotment to the Guam Station was increased to $15,000, of which $1,500 was made available for the purchase of land. For the promotion of agricultural education through farmers' institutes and agricultural schools the appropriation of the previous year, $10,000, was continued. The lines of work assigned to the irrigation and drainage investigations remained unaltered, but in consequence of their recent separation as to organization the appropriation was divided, $75,000 being allotted to the irrigation investigations, and $81,160, a net increase of $6,160, to the drainage investigations.

Authority was granted to resume the nutrition investigations of the Office, which were suspended during the transfer to Washington and reconstruction of the respiration calorimeter and accessory apparatus, an appropriation of $10,000 being made to "investigate the nutritive value of agricultural products used for human food, with special suggestions of plans and methods for the more effective utilization of such products for this purpose, with the cooperation of other bureaus of the Department, and to disseminate useful information on this subject."

The work of the remaining bureaus of the Department was provided for substantially as at present. The appropriation for the Bureau of Chemistry was enlarged $53,840 in consequence of the increased business in connection with the enforcement of the federal food and drugs act. The Bureau of Entomology received a net increase of $92,720, of which $50,000 is for the extension of the gipsy and brown-tail moth campaign, making a total of $300,000 for that purpose. There was extended discussion of the soil surveys of the Department, and these were continued on the present basis. The

net appropriations for both the Bureau of Soils and the Bureau of Statistics showed a slight decrease on account of transfers of a portion of their clerical work, the former receiving $232,860 and the latter $220,920. The work of the Office of Public Roads was continued on the present basis, with an increase of $29,070 to meet growing demands. The salary of the director was increased from $2,750 to $3,000.

To provide for the increase in the general business of the Department as a result of that of the several bureaus, additional appropriations were granted of $41,670 for the Office of the Secretary, $14,800 for the Division of Accounts, $26,740 for the Division of Publications (of which $5,000 is for labor-saving machinery for addressing and mailing publications), and $2,240 for the Library. Owing to the completion of the new structure for stable, shop, and storage purposes, for which $25,000 was appropriated in the current act, there is an apparent decrease of $6,200 in the allotment for contingent expenses.

To the sums carried in this appropriation act should be added the appropriation of $460,000 for the Department printing and binding, which is carried in the appropriation act for sundry civil expenses. There are also permanent appropriations of $3,000,000 for the federal meat inspection, and $624,000 for the Adams fund, both of which are administered by the Department, making a grand total of $17,079,036. This is an imposing aggregate, indicating a substantial and gratifying recognition by Congress of the work of the Department and of the great industry it seeks to promote.

The appropriation act contains, as in previous years, a number of clauses specifically providing for cooperation between the Department and the agricultural colleges and experiment stations in a number of different lines of work, as for example, in animal feeding and breeding, and in general in the work of the Bureau of Plant Industry, but specifically in tests of rare and valuable introduced seeds and plants. In this way Congress indicates its recognition of the fact that the interests and purposes of these institutions are to a large extent identical and that they shall as far as practicable be mutually helpful.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

New determination of the mechanical equivalent of heat, V. Crémieu and L. Rispail (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 18, pp. 793–795, fig. 1*).—According to the authors' determinations, the mechanical equivalent of heat is $J = 4.1851 \times 10^7$ ergs with an experimental error of .0027 in the determined value which is less than 1/1500.

On the accumulation of the heat of the sun in various solutions, A. von Kalecsinszky (*Math. u. Naturw. Ber. Ungarn, 21 (1903) [pub. 1907], pp. 1–24*).—Experiments with fresh water, sea water, and other salt solutions are reported, showing that the storage of heat is decidedly influenced by the salts in solution as well as by the surface covering of the solution, as, for example, with fresh water, olive oil, or petroleum.

Investigations on the formation and decomposition of ammonia by silent electrical discharges in a Siemens tube, with especial reference to the validity of the law of mass action, J. H. Davies (*Ztschr. Phys. Chem., 64 (1908), No. 6, pp. 657–685, figs. 6*).—A somewhat detailed study of the effect of varying conditions of temperature, pressure, gas mixture, etc., is reported.

The volumetric composition of ammonia vapor and the atomic weight of nitrogen, P. A. Guye and A. Pintza (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 20, pp. 925–928, fig. 1; Mém. Soc. Phys. et Hist. Nat. Genève, 35 (1908), No. 4, pp. 594–614, pl. 1, figs. 2; abs. in Rev. Sci. [Paris], 5. ser., 10 (1908), No. 22, p. 699*).—The apparatus and methods employed by the authors in the volumetric analysis of ammonia vapor are described, the causes of error are discussed, and determinations are reported which give an atomic weight for nitrogen between 14 and 14.02, thus confirming the value which is now adopted, namely, 14.01. The volumetric method is considered by the authors too indirect as compared with the gravimetric method.

The modifications of the Kjeldahl method for the quantitative determination of nitrogen, J. S. Hepburn (*Jour. Franklin Inst., 166 (1908), No. 2, pp. 81–99; abs. in Chem. Abs., 2 (1908), No. 23, p. 3206*).—A historical review of tests of this method and its modifications, with 39 references to the literature. Determinations of nitrogen in antipyrin using various catalyzers with the sulphuric acid are reported, but in no case was the theoretical percentage obtained.

A modified Hüfner method for the volumetric determination of nitrogen, V. von Cordier (*Ztschr. Analyt. Chem., 47 (1908), No. 11, pp. 682–687, fig. 1; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 553, II, p. 983; Chem. Zentbl., 1908, II, No. 21, p. 1747, fig. 1*).—The method and apparatus (Victor Meyer vapor density apparatus) required are so modified that a larger amount of the material may be conveniently used for the determination, thus insuring more accurate measurement of the gas evolved by the action of the bromin solution. The method as modified is adapted particularly to the analysis of guanidin picrate and similar substances.

Electrolytic determination of nitric acid, O. L. Shinn (*Jour. Amer. Chem. Soc., 30 (1908), No. 9, pp. 1378–1381; abs. in Science, n. ser., 28 (1908), No. 711, pp. 219, 220; Sci. Abs., Sect. A—Phys., 10 (1908), No. 130, p. 608*).—"It was found that by keeping copper in solution, either by the addition of copper sulphate during reduction, or by retarding the speed at which the anode rotates, the nitric acid is completely reduced to ammonia. This may be determined either by distilling or by titrating excess of acid. Results are almost theoretical."

The determination of phosphoric acid as phosphomolybdic acid, P. Christensen (*Tidsskr. Landbr. Planteavl, 15 (1908), No. 3, pp. 454–466; Ztschr. Analyt. Chem., 47 (1908), No. 9–10, pp. 529–545; abs. in Chem. Ztg., 32 (1908), No. 93, Repert., p. 599; Chem. Zentbl., 1908, II, No. 16, p. 1379; Jour. Chem. Soc. [London], 94 (1908), No. 552, II, p. 895*).—A series of comparative tests of the complete molybdic method with the so-called direct method is reported. In the direct method the phosphoric acid is precipitated in nitric acid solution, freed from silica, with ammonium molybdate, and the precipitate ignited and weighed, the phosphoric acid being calculated by multiplying the weight of the residue after ignition by 0.0394. The relation of the results obtained by the direct method to the theoretical amounts was as 100 to 108. This relation is closer than that obtained in case of the complete method, and in the author's opinion indicates an accuracy which is sufficient for all practical purposes.

Application of the gasometric method to the exact determination of urea, A. Ronchèse (*Jour. Pharm. et Chim., 6. ser., 28 (1908), No. 10, pp. 444–452*).—A critical summary and discussion of methods.

A method for the determination of ammonia in barnyard manure, R. K. Kristensen (*Tidsskr. Landbr. Planteavl, 15 (1908), No. 1, p. 24; abs. in Chem. Ztg., 32 (1908), No. 93, Repert., p. 599*).—The method described is based upon distillation with a saturated solution of sodium hydroxid in a stream of air.

The volumetric-alkalimetric determination of alkaline earths in fertilizers and soils, O. Foerster (*Landw. Vers. Stat., 69 (1908), No. 3–4, pp. 235–243; abs. in Chem. Ztg., 32 (1908), No. 91, Repert., p. 581; Chem. Zentbl., 1908, II, No. 24, pp. 1894, 1895; Jour. Chem. Soc. [London], 94 (1908), No. 554, II, p. 1072*).—The use of hydrochloric acid for the titration of the basic substances is proposed in place of sulphuric acid commonly recommended. The use of this acid gives as a rule higher, and in the author's opinion, more accurate results. The details of the proposed method of titration are given.

Determination of the combined lime in humus, P. de Mondesir (*Jour. Agr. Prat., n. ser., 16 (1908), No. 44, pp. 554–557*).—This article discusses the importance of the lime combined with humus in soils and describes methods of determining what is termed the lime equivalent of soils. This determination is based upon the amount of calcium carbonate reduced when soils are treated with this substance.

On the determination of carbon dioxid in water, F. Guth (*Gesndhts. Ingen., 31 (1908), No. 17, pp. 737–742*).—Investigations on this subject are reviewed.

Hydrolysis of vignin of the cowpea, T. B. Osborne and F. W. Heyl (*Amer. Jour. Physiol., 22 (1908), No. 3, pp. 362–372*).—The hydrolysis of vignin of the cowpea (*Vigna sinensis*), a globulin which is the principal protein present, gave results "similar to those found for the proteins of other leguminous seeds, e. g., legumin, vicilin, phaseolin, and glycinin. Although these proteins are in many respects much alike, sufficiently positive differences, of one kind or another, exist between them to leave no doubt that each is a distinctly different protein.

"In conducting this hydrolysis, care was taken to keep account of the undetermined substance, in order to get a clearer idea of its approximate amount, and if possible to locate the large loss indicated by the low summation.

"The substances making up the total are stated as the free amino-acids, and, in addition, a small amount of ammonia. The amino-acids are doubtless united in the protein molecule with the elimination of a molecule of water for each molecule of acid, and it is not improbable that the ammonia is combined with one carboxyl group of the dibasic acids."

According to the authors' calculations, at least 30 per cent of the vignin is not accounted for after hydrolysis. "The substance obtained from the unesterified and ether insoluble part of the products of hydrolysis, which was examined for oxyprolin, weighed only 62.6 gm., equal to 12.26 per cent of the vignin. Of this, 7.58 per cent is included in the 20 per cent of unesterified amino acids, leaving only 4.68 per cent for unknown substances. It would seem from these figures that the losses which are practically unavoidable in carrying out these analyses may have a larger share in explaining the deficiency than has been heretofore supposed.

"It does not, however, seem probable that this apparently large deficiency consists to any considerable extent of products of decomposition already known. The amount of the substances that are determined directly, probably nearly represents the quantity in which they are produced by hydrolysis, for the determinations of glutaminic acid can be controlled to a certain extent by the results obtained by the ester method, and those of arginin, histidin, and lysin are, as will later be shown, accurately controlled by the nitrogen precipitated by phosphotungstic acid. The ammonia determinations are accurate.

"The known protein decomposition products which were not determined in this analysis can not be relied on to account for this difference."

An improvement in the technique in the hydrolysis of protein. The employment of hydrofluoric acid and its advantages, L. Hugounenq and A. Morel (*Journ. Pharm. et Chim., 6. ser., 28 (1908), No. 11, pp. 486–493*).—According to the authors, hydrofluoric acid possesses a number of advantages as a hydrolyzing agent. A smaller quantity of humic substance is produced than is the case with sulphuric or hydrochloric acid and the cleavage of protein to ammonia is smaller.

Concerning the identification of sugars, J. J. Blanksma and W. A. Van Ekenstein (*Chem. Weekbl., 5 (1908), No. 42, pp. 777–781*).—A summary and discussion of methods for the identification of sugars of different sorts.

Identification of δ-fructose in the presence of other natural sugars, J. Pieraerts (*Bul. Soc. Chim. France, 4. ser., 3 (1908), No. 18–19, pp. 966–984*).—A critical study of methods.

The rapid determination of sugar in scum, H. Pellet (*Betterave, 18 (1908), No. 465, pp. 402–404*).—The author describes a method which he has found satisfactory for use in beet-sugar factories.

The Fieh reaction for invert sugar in honey, Drawe (*Ztschr. Öffentl. Chem., 14 (1908), No. 18, p. 352*).—A controversial article.

Concerning the biological method for the examination of imported meat, M. Müller (*Ztschr. Fleisch u. Milchhyg., 19 (1908), No. 1, pp. 9–12*).—According to the author, the biological method may be satisfactorily used for the identification of dried intestines from different sorts of animals.

Sulphured fruit, H. Lührig (*Pharm. Centralhalle, 49 (1908), pp. 851–854; abs. in Chem. Centbl., 1908, II, No. 19, pp. 1622, 1623*).—The investigations carried on by the author indicate that the sulphur dioxid content of sulphured fruit varies so greatly in different portions that a large quantity should be available for inspection work rather than a small sample.

An electrical resistance method for the rapid determination of the moisture content of grain, L. J. Briggs (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 20, pp. 8, figs. 3*).—This circular describes an electrical method for determining the moisture content in wheat, to which the experiments have so far been confined. It was found that the electrical resistance of wheat containing 13 per cent of moisture is fifty times that of wheat containing 15 per cent. The temperature of the grain must be determined. The results show that the moisture content can be ascertained by this method with a probable error not exceeding 0.3 per cent. The measurements to be made require only 2 or 3 minutes. The apparatus is portable in character.

On fat determinations in feeding stuffs, A. G. Palmquist (*Svensk Kem. Tidskr., 20 (1908), No. 5, pp. 93–105, figs. 3; Landw. Vers. Stat., 69 (1908), No. 5–6, pp. 461–475; abst. in Analyst, 34 (1909), No. 396, pp. 101, 102*).—The author recommends a method similar to the Röse-Gottlieb method for determination of fat in feeding stuffs and perhaps other substances.

A 2 gm. sample of the finely ground material is heated direct on a water bath for 1 hour with 20 cc. 0.5 per cent hydrochloric acid in a flask the neck of which is graduated from 120 to 160 cc. The solution is then neutralized with 0.5 gm. of marble dust, cooled to about 50° C., and 20 cc. of 92 per cent alcohol added. When thoroughly mixed, 40 cc. of ether (specific gravity 0.72) is added and the mixture heated on a water bath at 45 to 50° for 30 minutes, the flask being connected with a reflux condenser inside of which a stirrer is rotated rapidly by means of a water turbine. After cooling in water to 17°, 60 cc. of petroleum ether (volatile below 75°) is added and shaken with the solution. After standing for an hour, 51 cc. of the ether-fat solution is pipetted off from the flask, placed in a 100 cc. Phillips beaker, evaporated at a low temperature, and weighed. The volume of the remaining portion of the fat solution is determined by inverting the stoppered flask and reading the volume on the graduated scale of the neck, and the total fat in the feeding stuff thus calculated.

A simple method for the quantitative separation of casein from human milk, Engel (*Biochem. Ztschr., 14 (1908), Nos. 3–4, pp. 234–237*).—The author added 500 cc. of water and 70 cc. of a 10 per cent normal solution of acetic acid to 100 cc. of milk. After standing for a few hours at a temperature of 3 to 4° C. the solution was placed in a water bath at 40° for a few minutes, when the casein separated completely from the whey in small flakes and was easily removed by filtration.

Estimation of the protein content of milk, A. A. Bonnema (*Pharm. Weekbl., 45 (1908), No. 41, pp. 1254–1259; abs. in Chem. Zentbl., 1908, II, No. 18, p. 1540*).—The protein in milk was found to contain an average of 14.3 per cent of nitrogen; hence, in estimating the protein content multiply the amount of nitrogen as shown by the Kjeldahl method by 6.99.

Estimation of sugar in cow's milk, C. Van Driel (*Pharm. Weekbl., 45 (1908), No. 42, pp. 1298–1305; abs. in Chem. Zentbl., 1908, II, No. 18, p. 1540*).—A comparison of the different methods indicates that the amount of lactose is not often accurately determined.

The estimation of inorganic compounds in milk, O. Allemann (*Landw. Jahrb. Schweiz, 22 (1908), No. 5, pp. 268–271*).—The loss of sulphur and chlorin by the customary methods of incinerating milk solids may be prevented by adding sodium peroxid. Analyses are given.

Characteristics of oils from certain expressed seeds, J. Kochs (*Chem. Rev. Fett u. Harz Indus., 15 (1908), No. 10, pp. 256, 257; abs. in Jour. Soc. Chem. Indus., 27 (1908), No. 21, p. 1072*).—The specific gravity, solidification point, butyro-refractometer numbers, and saponification, iodin and Reichert-Meissl

values of the oils extracted from the seeds of red currants, hips, tomatoes, raspberries, strawberries, and *Euonymus europæus* were determined, together with the melting point, iodin value, mean molecular weight, and percentage of unsaponifiable matter of the fatty acids obtained from these oils.

Characteristics of Japanese tea oil, M. Tsujimoto (*Chem. Rev. Fett u. Harz Indus., 15 (1908), No. 9, p. 224; abs. in Analyst, 33 (1908), No. 392, p. 424*).—"Two specimens of the seeds from the Japanese tea plant (*Thea sinensis*) yielded, respectively, 23.9 and 26.23 per cent of an orange-colored oil with a somewhat unpleasant odor and bitter taste. . . . The oil was readily soluble in the ordinary solvents for fats and it solidified at —10° C."

Color reactions of sesame oil with aromatic aldehydes and sugars, C. Fleig (*Bul. Soc. Chim. France, 4. ser., 3 (1908), No. 18–19, pp. 984–999; abs. in Jour. Soc. Chem. Indus., 27 (1908), No. 21, pp. 1072, 1073*).—The reactions with aromatic aldehydes are analogous with those obtained with furfurol in the Baudouin test. The intensity and stability of the color reactions may serve for the determination of sesame oil in mixtures with other oils.

Technical chemists' handbook, G. Lunge (*London, 1908, pp. XV+260*).—A revised edition of the Alkali Makers' Pocketbook, but enlarged to include chapters on feed-water for boilers, coal gas, calcium carbide and acetylene, fertilizers, aluminum salts, and alumina and calcareous cements.

Leather trades chemistry, S. R. Trotman (*London, 1908, pp. X+290, pls. 4, figs. 48*).—This work is intended to furnish data as to analytical details of modern processes most frequently met with in practice. The following topics are treated: Analysis of fuel, the estimation of nitrogen, preparation of standard solutions, water, effluents, depilation, deliming, qualitative recognition of tannins, analysis of tanning materials, common vegetable tannins, mineral tannage, analysis of spent liquors and tans, oils, soap, varnishes, skins, analysis of leather, fleshings and scutch, glue, benzine, dyestuffs, disinfectants, and antiseptics. A glossary of technical terms used in the tanning industry is appended.

METEOROLOGY—WATER.

Weather forecasts (*Lancet [London], 1908, II, No. 22, pp. 1613, 1614*).—This is a review of a paper by H. E. Rawson entitled A New Principle in Weather Forecasting and Its Importance in Naval and Military Operations, in which a method of forecasting based upon a 19-year cycle oscillation of the anticyclonic belts of the northern and southern hemispheres is proposed.

The occurrence of the foehn without subsequent precipitation, F. Mayr (*Ber. Naturw. Med. Ver. Innsbruck, 31 (1907–8), pp. 121–166*).—This article, which is based upon observations at the University of Innsbruck, 1897 to 1906, deals in considerable detail with the occurrence of foehns in Innsbruck; the meteorological behavior of foehns with and without precipitation, and the general distribution of air pressure in such cases; and northwest foehns. The fair weather foehn is a winter phenomenon. It is pointed out that the meteorological conditions connected with it are very different from those accompanying rain foehns, but in the author's opinion offer no safe basis for prediction.

A hailstorm following the course of an electric transmission-line, J. Violle (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 7, pp. 375–377; abs. in Sci. Abs., Sect. A—Phys., 11 (1908), No. 10, p. 555*).—A description is given of a hailstorm which followed closely the course of a 45,000-volt three-phase transmission-line for a distance of 8.7 miles. The observations indicate that the current had some effect in attracting and directing the storm.

The action of electric power lines on hailstorms, J. Violle (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 25, pp. 1371, 1372; Jour. Agr. Prat., n. ser.,*

17 (1909), No. 1, p. 14).—Referring to the above article, the author suggests the possibility of using this means for protecting vineyards and crops from damage by hailstorms.

Bulletin of the Mount Weather Observatory (*U. S. Dept. Agr., Bul. Mount Weather Observr., 1 (1908), pt. 4, pp. 207–277+IV, figs. 4, charts 6*).—This number contains the following articles: Pyrheliometer and Polarimeter Observations (illus.), by H. H. Kimball; Recent Auroral Displays and Magnetic Disturbances, by W. R. Gregg; Magnetic Declination, by E. R. Miller and W. R. Gregg; and Upper Air Temperatures for April, May, and June (illus.), by W. R. Blair.

Monthly Weather Review (*Mo. Weather Rev., 36 (1908), Nos. 9, pp. 275–324, figs. 12, charts 7; 10, pp. 325–356, figs. 4, charts 7*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of September and October, 1908, recent papers bearing on meteorology and seismology, recent additions to the Weather Bureau library, etc., these numbers contain the following articles and notes:

No. 9.—Résumé of Experiments in Aerodynamics, by A. F. Zahm; Hythers and the Comparison of Climates; The Relative Humidity of Our Houses in Winter; Scientific Ballooning and Weather Forecasts, by K. Bamler (trans. by A. G. McAdie); The Kite Station on Lake Constance (illus.), by E. Kleinschmidt (trans. by C. F. Talman); The Reflecting Power of Clouds (illus.); Early Meteorology at Harvard College, II, by B. M. Varney; Government Meteorological Work in Brazil (illus.), by R. DeC. Ward; Meteorology at the American Association for the Advancement of Science; The Isothermal Layer of the Atmosphere; Damages by Flood at Kansas City, Mo.; The Scientific Aspect of a Balloon Voyage (illus.), by H. H. Clayton; The Meteorological Work of the University of Jurjev (Dorpat), Russia, by E. Rosenthal; Prize Offered by the German Meteorological Society; A California Cloudburst, by J. S. Douglas; and A Mercurial Barograph of High Precision (illus.), by C. F. Marvin.

No. 10.—Deflecting Force Due to the Earth's Rotation, by R. A. Harris; Studies on the Vortices of the Atmosphere of the Earth (illus.), by F. H. Bigelow; Notes on Weather and Climate made during a Summer Trip to Brazil, 1908 (illus.), by R. DeC. Ward; Installation of Automatic River Stage Register at Hartford, Conn. (illus.), by W. W. Neifert; and The Meteorology of Mars, by S. Newcomb.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. Ostrander and R. C. Lindblad (*Massachusetts Sta. Met. Buls. 239, 240, pp. 4 each*).—Summaries of observation on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during November and December, 1908, are presented. The general character of the weather of each month is briefly discussed, and the December bulletin gives a summary for the year. The principal data in this summary are as follows:

Pressure, reduced to freezing and sea level (inches).—Maximum, 30.83, February 9; minimum, 28.86, January 8; mean, 30.044. *Air temperature*, in ground shelter (degrees F.).—Maximum, 96, July 12; Minimum, —12, February 5; mean, 47.6. *Humidity.*—Mean dew-point, 38.5; mean relative humidity, 75.8. *Precipitation.*—Total rainfall or melted snow, 30.68 in.; number of days on which 0.01 in. or more rain or melted snow fell, 109; total snowfall, 38.5 in. *Weather.*—Total cloudiness recorded by sun thermometer, 1,711 hours, or 39 per cent; number of clear days, 143. *Bright sunshine.*—Number of hours recorded, 2,743, or 61 per cent. *Wind.*—Prevailing direction, west-southwest; total movement, 63,571 miles; maximum daily movement, 594 miles, February 2; minimum daily movement, 10 miles, October 16; maximum pressure per square

foot, 30 lbs., April 11, north-northwest. *Dates of frost.*—Last, June 3; first, September 16. *Dates of snow.*—Last, April 20; first, November 3.

Meteorological summary for 1907, C. A. Patton (*Ohio Sta. Bul. 196, pp. 263–281*).—This summary includes as usual notes on the weather of each month and tabulated daily and monthly records of observations at the station at Wooster, Ohio, on temperature, precipitation, cloudiness, direction of the wind, etc., and for comparison, similar data for 20 previous years (1888–1907) at the station and for 25 years (1883–1907) in other parts of the State.

The mean temperature for the year at the station was 48.4° F.; for the State 49.6°; the highest temperature at the station 90°, August 12; for the State 98°, July 22; the lowest temperature at the station —14°, January 27; for the State —19°, February 6. The annual rainfall at the station was 40 in., for the State 42.9 in. The number of rainy days at the station was 138, for the State 129. The prevailing direction of the wind was north-southwest at the station and southwest for the State.

The climate of Innsbruck, A. Fessler (*Ber. Naturw. Med. Ver. Innsbruck, 31 (1907–8), pp. 3–96, charts 3; Appendix, pp. 67*).—Observations at the meteorological observatory of the University of Innsbruck on temperature, air, and vapor pressure, precipitation, humidity, winds, and cloudiness from 1891 to 1905 are summarized in text, tables, and charts.

The climate and meteorology of Australia, H. A. Hunt (*Off. Yearbook Aust. 1901–1907, pp. 115–141, dgms. 3, map 1; abs. in Nature [London], 78 (1908), No. 2034, p. 653*).—This is the first report of the Commonwealth Bureau of Meteorology of Australia, which was established something over a year ago. It gives a very brief general description of Australia from a meteorological standpoint, defines the meteorological advances of the country, and summarizes the results of observations on temperature, pressure, precipitation, evaporation, cyclones, storms, and winds. Special features are a comparison of the relative temperature and rainfall of different places and descriptions of certain characteristic storms. Attention is particularly called to forests as one of the more important factors affecting the climate.

Climate, R. DeC. Ward (*New York and London, 1908, pp. XVI+372; rev. in Science, n. ser., 28 (1908), No. 728, pp. 841, 842; Nature [London], 79 (1908), No. 2041, p. 155*).—In his review of this book in *Science*, Dr. O. L. Fassig says: "Ward's 'Climate' may be regarded as a supplement to the first volume of Hann's handbook, in which the author sets forth clearly and systematically some of the broader facts and relations of climate, primarily for the benefit of the general reader, although the needs of the teacher and student are not overlooked."

Geology and water resources of a portion of south-central Oregon, G. A. Waring (*U. S. Geol. Survey, Water-Supply Paper 220, pp. 86, pls. 10, fig. 1*).—The area reported upon in this paper lies mainly within and includes the greater part of Lake County. Data are given for geography, geology, hydrography, hydrology, reclamation projects, and soils.

The supply of available surface water in this region is not sufficient to irrigate all of the arable land. "The underground supply is as yet unknown, but on the whole, as has been shown, the indications seem favorable to the development of such water in the valleys of Silver, Christmas, and Summer lakes at least." The soils are very fertile and when irrigated become highly productive.

Geology and water resources of the Great Falls region, Montana, C. A. Fisher (*U. S. Geol. Survey, Water-Supply Paper 221, pp. 89, pls. 7*).—This report is based upon field work done during the season of 1906, covering an area of about 3,600 square miles in north-central Montana, mainly in Cascade and Teton counties, but including portions of Fergus, Chouteau, and Lewis and

Clark counties. It contains the usual summaries of data regarding geography, geology, and water resources, with notes on water power, irrigation, agriculture, climate, and possibilities of culture.

Preliminary report on the ground waters of San Joaquin Valley, California, W. C. MENDENHALL (*U. S. Geol. Survey, Water-Supply Paper No. 222, pp. 52, map 1*).—This paper contains a preliminary account of the geography and general geological conditions of the San Joaquin Valley and of the soils and surface waters, with a more detailed report on the nature, extent, distribution, availability, and development of underground waters for the whole area and for each county.

Ground waters and irrigation enterprises in the foothill belt, southern California, W. C. MENDENHALL (*U. S. Geol. Survey, Water-Supply Paper 219, pp. 180, pls. 9, figs. 16*).—This paper reports the results of a continuation of investigations begun in 1903 (E. S. R., 17, p. 708), covering the region lying along the south base of the San Gabriel Mountains from Cucamonga westward to Los Angeles. This area includes between 55,000 and 60,000 acres of irrigated land, largely in citrus fruits.

"In the same area there are about 40 flowing wells and nearly 400 pumping plants, representing an investment of at least $1,000,000 in wells and plants alone. There is, of course, an additional heavy investment in the connecting distributing systems. It is estimated that the pumping plants supply the equivalent of 80 to 100 second-feet of water, continuous flow, used largely for irrigation. This output is not regularly distributed throughout the year, but is largely concentrated in the dry months of July, August, and September, during which, after winters of light rainfall, the production of underground waters amounts to 300 second-feet or more."

The paper contains the usual data regarding geography, geological conditions, physiography, rainfall, and underground waters, with brief descriptions of the various irrigation enterprises.

Water conservation and irrigation (*Off. Yearbook Aust. 1901–1907, pp. 484–491*).—Brief accounts are given in this article of water-supply works, artesian wells, and irrigation plants in Australia.

The disinfection of drinking water with hydrogen peroxid, H. REICHEL (*Ztschr. Hyg. u. Infektionskrank., 61 (1908), No. 1, pp. 49–70, figs. 2; abs. in Chem. Zentbl., 1908, II, No. 18, p. 1544*).—Experiments are reported which indicate that ordinary drinking water can be thoroughly disinfected by 0.5 per cent of hydrogen peroxid in 24 hours, by 1.5 per cent in 6 hours, and by a 5 per cent solution in 3 to 4 hours. The latter is the shortest practicable time in which satisfactory disinfection can be secured.

The industrial uses of ozone, particularly for the purification of water, F. M. PERKIN (*Trans. Faraday Soc., 4 (1908), No. 2, pp. 81–94, pls. 2, figs. 6*).—The methods and appliances used for this purpose are quite fully described. It is stated that the use of ozone for the sterilization of water supplies for drinking purposes has the great advantages that it is extremely cheap, very efficient, and absolutely harmless.

The relative bacteriological contents of can, plate, and natural ice under various conditions, J. C. SPARKS (*Ice and Refrig., 35 (1908), No. 6, pp. 308–311*).—This article calls attention to conditions in a number of plants resulting in serious contamination of the ice produced.

Water supply and sewerage (*Ann. Rpt. Bd. Health Mass., 39 (1907), pp. 33–261*).—The subjects discussed in this report are as usual advice given to cities, towns, public institutions, and individuals regarding water and ice supply and sewerage, examination of public water supplies and rivers, water-supply statistics, and experiments on the purification of sewage and water at the Lawrence

Experiment Station in 1907, including purification of sewage and water filtration.

Sewage-grown crops (*Agr. Econ., 41 (1908), Nos. 467, pp. 289, 290; 468, pp. 317, 318*).—A general discussion of crops suited to sewage farming.

SOILS—FERTILIZERS.

The storage of winter precipitation in soils, J. A. WIDTSOE (*Utah Sta. Bul. 104, pp. 279–316, dgms. 4*).—This bulletin is based upon observations during several years on the variations in the moisture content of the soil, to a depth of 8 ft., on an irrigated farm and on several so-called dry farms. Detailed data are given for physical analyses of the soil and for their moisture content in fall and spring, with fall plowing and spring plowing of the land, with fall and winter irrigation, and with summer fallowing.

The results emphasize the fundamental importance of conserving the natural precipitation and making irrigation simply supplementary to it. "The natural precipitation over the larger portion of the Great Basin, if properly conserved by summer fallowing, is sufficient to produce crops without irrigation.

"The amount of moisture found in the soil in the fall depends on the crop grown, the total amount of water applied during the season, the summer precipitation, and, on an irrigated farm, on the date of the last irrigation. On an irrigated farm as high as 95.56 per cent and on nonirrigated farms as high as 93.17 per cent of the total winter precipitation were found in the upper 8 ft. of soil. The average of the maximum percentages of the winter precipitation found in the upper 8 ft. for 5 years on an irrigated farm was 82.13; for 3 years on nonirrigated farms, just reclaimed from the desert, was 61.85.

"The water capacity of soils under field conditions is low, usually not above 18 per cent. The drier the soil is in the fall the more of the winter precipitation is found in the first 8 ft. of soil." A comparatively small portion of the winter precipitation is lost from the soil by evaporation, but a considerable portion of it passes down through the soil below the eighth foot limit. "In the spring irrigated soils to a depth of 8 ft. are fully saturated and nonirrigated soils are usually so. . . . In the spring, less than 20 in. of precipitation are usually found in the upper 8 ft. of soil; that is, not more than the precipitation of one and one-half years is stored in the upper 8 ft. of soil.

"To make farming without irrigation successful, a considerable percentage of soil moisture must be carried over from year to year. Fall plowing tends to conserve the natural precipitation. Fall or winter irrigation is advisable on deep soils with good drainage. It should be practiced in moderation. . . . Summer fallowing conserves the soil moisture; the longer the fallow period, the higher the percentage of soil moisture. The reason why the beneficial effects of summer fallowing and fall plowing are not more evident in the soil moisture content is that the water capacity of most arid soils is small and that during the winter season a large portion of the water moves below the eighth foot limit reached by the soil augers.

"Lands may be water-logged even when only a small surplus of water is applied at each irrigation. The surplus moves to considerable depths until an impervious soil layer is reached, where the accumulation of water begins."

Quantity and composition of drainage water and a comparison of temperature, evaporation, and rainfall, J. H. NORTON (*Jour. Amer. Chem. Soc., 30 (1908), No. 7, pp. 1186–1190*).—The studies here reported were made in 1906 on the drainage basin of Richland Creek, covering an area of 84,954 acres in Madison and Washington counties, Arkansas, of purely agricultural lands on which no fertilizers had ever been used. The rainfall data were secured from

Weather Bureau stations near the boundary of the valley. Stream measurements were made approximately every 2 weeks from January 6 to December 23, and samples of water were taken for analysis at the same time. Determinations were made of chlorin, nitrogen, total solids, loss on ignition, and reaction. The drainage water per acre for the period covered was 59,470.92 cu. ft., the rainfall 202,520 cu. ft., the evaporation 143,049.08 cu. ft.

According to the analyses reported, the drainage water removed from 1 acre of the soil of this area in one year 794.638 lbs. of total solids, 349.296 lbs. of silica, 134.134 lbs. of organic and volatile matter (loss on ignition), 86.467 lbs. of alumina, 80.791 lbs. of lime, 17.728 lbs. of sulphur trioxid, 13.58 lbs. of chlorin, 10.065 lbs. of magnesia, 4.817 lbs. of potassium oxid, 4.012 lbs. of nitrogen, 3.01 lbs. of sodium oxid, 1.089 lbs. of ferric oxid, 0.953 lb. of manganous manganic oxid, and 0.657 lb. of phosphorus pentoxid.

The average composition of the surface 6 in. of soil of the region is given as follows: Water 5.53, silica 86.67, alumina 3.16, lime 0.20, sulphur trioxid 0.11, magnesia 0.16, potassium oxid 0.11, nitrogen 0.061, sodium oxid 0.16, ferric oxid 2.22, manganous manganic oxid 0.12, and phosphorus pentoxid 0.112 per cent.

"Taking the weight of 1 cu. ft. of soil at 70 lbs., this would mean that the drainage water removes 0.00313 in. of soil annually, or it would require about 300 years to remove 1 in. of soil by drainage water. . . .

"The annual loss per acre due to drainage water amounts to: Nitrogen, 60 cts.; potassium, 25 cts.; and phosphorus, about 4 cts. This would make an annual loss per acre of 89 cts.

"During the growing season the evaporation amounts to more than 90 per cent of the rainfall, while for the whole year the evaporation amounts to 70 per cent of the rainfall."

Distribution of water in the soil in furrow irrigation, R. H. Loughridge (*U. S. Dept. Agr., Office Expt., Stas. Bul. 203, pp. 63, figs. 19*).—This bulletin records the results of cooperative experiments carried on by this Office and the State of California to determine the extent in area and depth to which water percolates beneath furrows, as well as the proportion retained by the soil for the use of orchard trees. The experiments formed a part of a general study of the losses of water in irrigation and their prevention, investigations on evaporation having already been reported (E. S. R., 18, p. 1087).

The experiments were made mainly on sandy loam soils in citrus orchards near Riverside, Cal. The character of the soil and its moisture content to a depth of several feet were determined before the experiments were begun.

To ascertain the rate of movement of the irrigation water in the soil and the amount of moisture retained, trenches were dug across the irrigation furrows to a depth of 5 or 6 ft. and of convenient width. By means of these trenches it was possible to trace the rate and extent of percolation of the irrigation water and also to take samples at any desired depth for determination of moisture.

In view of the somewhat unusual character of the investigations, an important feature of the work was the development of methods suitable to the purpose. The experience gained indicates certain important improvements in methods, which are described in detail. The principal results of the percolation studies are summarized as follows:

"The preliminary examination of the land of the orchard before irrigation showed that the upper 2 ft. held only about 3.5 per cent of free water as the general average, while below this to the depth of 13 ft. the average was 6.16 per cent. The roots of the trees were mostly confined to the upper 4 ft., and in this depth there was an average of 4.68 per cent, an amount sufficient to

maintain a good appearance in the trees but not to produce new growth; the application of irrigation water caused increased growth.

"The unobstructed movement of water in loam soils is downward, with great irregularity in rate of progress and in the amount of water retained at various depths. The water beneath the surface does not move from the furrows toward the trees for more than 2 ft., and at a depth below 2 ft. the wet area is usually rapidly contracted to a cone shape. The soils in the tree rows, therefore, fail to receive any of the irrigation water, and the dry space increases in width and extent downward; the tree roots, which usually are confined to the upper 3 ft., are thus only partially supplied with needed moisture.

"The relative proportion of dry soil to that wetted by irrigation across 16 furrows and 4 tree rows in the sandy loam soil, was as 2 to 3 in a depth of 5 ft. As seen in the profiles, the proportions are as follows, taking the dry soil as the unit: Surface foot, 1 to 3.4; second foot, 1 to 4.3; third foot, 1 to 2.3; fourth foot, 1 to 0.8; fifth foot, 1 to 0.4; and sixth foot, 1 to 0.1.

"The depth reached by the percolation of irrigation water depends on the nature of the soils and length of time of flow; in the unobstructed loose soil it was 26 ft. near the head ditch, 4 ft. in the middle, and about the same at 30 ft. from the end, and many feet where the excess was received. In the compact, semiimpervious soil it reached a depth of 4 ft., while in the impervious hardpan soil the depth was but little more than 12 in. even after 3 days' application.

"The amount of water held by the soil when the downward movement ceased was always greatest in the upper 2 ft. and diminished in percentage to the bottom. [The general averages of 9 furrows were] 9.95 per cent in the first foot, 11.19 in the second, 9.14 in the third, and 8.27 per cent in the fourth foot.

"The presence of an impervious hardpan near the surface causes sidewise seepage of the water, a greater wetting of the surface, and consequent increased loss by evaporation and by accumulation and run-off at the lower end of the furrows.

"Shallow irrigation furrows do not give as good results as deep ones; they allow a large part of the water to rise by capillarity to the surface on either side and thence to escape into the air by evaporation, while deep furrows enable the soil to receive and retain nearly all of the water applied. The furrows in [the principal orchard experimented with] had an average depth of 3 or 4 in. and from these the lateral seepage was so great as to wet about 85 per cent of the space between the tree rows. During the 3 days of irrigation in which these soils were being kept wet the rate of evaporation was very high. After this the soil gradually dried out and the loss diminished.

"On loose sandy loams water percolates with such rapidity near the head ditch that a great part is lost by passing far below the roots and possibly into sand and gravel strata, through which it flows away. Thus on [one] orchard the depth of percolation was 26 ft. at a distance of 30 ft. from the ditch.

"It is extremely doubtful [whether] water at a depth of more than 5 ft. below the root systems will be of any benefit to the trees in times when needed, for the capillary rise is extremely slow, and especially so if the temperature of the soil be low. . . .

"In orchards with shallow mulches it was observed that the amount of water in the soil 6 weeks after irrigation was about the same as just previous to the application of water. . . .

"Percolation is influenced by the time that water is allowed to remain in the furrow. The water should be made to reach the end of the furrow as soon as possible, and then the flow so regulated that the whole line may receive prac-

tically the same amount and to depths of 8 or 10 ft. If the movement is slow and the soil conditions favorable to percolation, then in the soil near the head ditch there is danger of loss by the percolation of the water far beyond the reach of the root systems."

The physical condition of the soil in relation to agriculture. T. HALLISSY (*Irish Farming World, 21 (1908), No. 1081, pp. 1143, 1144; Farmers' Gaz., 67 (1908), Nos. 47, pp. 1013, 1014; 48, p. 1033*).—This is a report of a lecture in which the influence of the various physical factors on the fertility of the soil was discussed, but special emphasis was laid upon the relation of the soil to water.

While not minimizing the importance of the chemical and biological conditions of the soil, the author stated that "texture is what the farmer has always made the basis for his diagnosis as to its value, and modern science confirms his judgment."

Investigations on the composition of the air of cultivated soils. E. LAU (*Beiträge zur Kenntnis der Zusammensetzung der im Ackerboden befindlichen Luft. Inaug. Diss. Rostock, 1906, pp. 34, pl. 1, fig. 1; rev. in Zentbl. Agr. Chem., 37 (1908), No. 7, pp. 433, 434*).—A series of investigations on the conditions which influence the composition of the soil air is reported, from which the following conclusions are drawn:

The soil air is richest in carbon dioxid in summer and poorest in winter, the amount apparently varying with the temperature and the consequent intensity of the decomposition of the organic matter and the formation of carbon dioxid. The maximum carbon dioxid content was noted in the months of July and August, the minimum in February. The soil air is poorer in carbon dioxid at 2 o'clock at night than at 2 o'clock in the day.

The air of sandy soils contains the least carbon dioxid, that of moor soils the most, the air of loam soils being intermediate in this respect. The carbon dioxid content varies with the humus content as well as with the physical properties of the different soils. It is smallest at the surface and increases with the depth, the differences in this respect being greatest in case of moor soils and least in sandy soils.

The oxygen content stands in definite relation to the content of carbon dioxid, that is, the richer the soil air in carbon dioxid the poorer it is in oxygen, this being clearly due to the fact that the carbon dioxid results from the oxidation of humus.

Plant root respiration has a marked effect upon the carbon dioxid content of the soil air. The air of soils bearing plants is decidedly richer in carbon dioxid than that of bare soils, and the carbon dioxid content is greater in the vicinity of the plant roots than below them. The carbon dioxid content increases with the growth of the plants and with the rise of temperature. Soils bearing potatoes and lupines contain larger amounts of carbon dioxid than the same soils bearing other crops. This is attributed to the fact that potatoes and legumes have a higher rate of respiration than other plants.

The application of barnyard manure is equally as effective as the root action in increasing the carbon dioxid content of soil air.

The content of radio-active emanations in soil air. A. GOCKEL (*Phys. Ztschr., 9 (1908), No. 9, pp. 304–306*).—Measurements of the emanations in soil to a depth of 1 meter showed wide variations with different conditions of the soil and weather.

The absorptive power of a cultivated soil. J. ROSEN and C. HELLER (*Bot. Gaz., 46 (1908), No. 3, pp. 224–229, figs. 3*).—Experiments with wheat seedlings grown in solutions of different concentrations of disodium phosphate, potassium

chlorid, and sodium nitrate alone or combined with soil extract and soil gave results indicating that the increased tolerance of wheat seedlings to these salts when used in soil as compared with water solutions and soil extract solutions was due to the absorptive power of the soil for the salts. This conclusion is sustained by the facts that (1) the soil as shown by chemical analysis actually exerted considerable absorptive power for certain of the salts, (2) in case of the nitrate, upon which the soil exerted no absorptive power, there was no effect on the tolerance, and (3) tolerance increased with the increase of the absorptive power, both factors being lowest in the quartz, higher in the unmanured soil, and highest in the manured soil.

The colloids of cultivated soils, P. Ehrenberg (*Ztschr. Angew. Chem., 21 (1908) No. 41, p. 2122*).—This is an abstract of a paper read before the eightieth convention of the German Association of Naturalists and Physicians.

Soil colloids are classified and discussed with reference to their properties and behavior, particularly their flocculation or coagulation under the influence of low and high temperatures, drying, admixture of sand, alkali salts, lime compounds, physiological and biological processes, ether, and carbon bisulphid.

The article emphasizes the importance of the colloids in maintaining cultivated soils in proper condition.

Topographic mapping of bottom lands in Illinois, E. W. McCrary (*Engin. News, 60 (1908), No. 13, pp. 333, 334*).—This article explains briefly the methods pursued by the State Geological Survey in cooperation with the U. S. Geological Survey in the topographic mapping of portions of the drainage areas of the Kaskaskia, Big Muddy, and Embarras rivers.

Superficial and agricultural geology—Ireland, No. 2.—Soils, G. H. Kinahan (*Dublin, 1908; rev. in Chem. Trade Jour., 43 (1908), No. 1116, p. 333*).—This book contains in its introduction a discussion of agriculture in general and Irish agriculture in particular. Particular attention is also given to the bog soils and bog agriculture.

Soil analyses, A. Amos and E. J. Russell (*Jour. Southeast. Agr. Col. Wye, 1907, No. 16, pp. 215–240*).—As a part of a complete survey which is to be reported in full later, this article describes different classes of soils—sandy soils, loams, calcareous soils, and clay soils—as typified by soils of Surrey, Kent, and Lincolnshire, of which analyses are given.

Deli soils, J. G. C. Vriens (*Meded. Deli-Proefstat. Medan, 2 (1908), No. 3, pp. 175–236*).—Analyses of a large number of Deli tobacco soils are reported, the word Deli in this case being used to cover the whole of the east coast of Sumatra where the Deli tobacco is grown.

On the weathering of soils and the value of mineralogical-petrographic soil analysis, A. von 'Sigmond (*Földtani Közlöny, 38 (1908), No. 3–4, pp. 220–230*).—Mineralogical-petrographic studies of various Hungarian soils, the results of which confirm the conclusions of Delage and Lagatu (E. S. R., 17, p. 841) are reported. The importance of such studies is emphasized.

The alkali soils of the great Hungarian Alföld, P. Treitz (*Földtani Közlöny, 38 (1908), No. 1–2, pp. 106–131, pl. 1, fig. 1*).—These soils are described and their origin and composition are discussed.

The author concludes from his studies of these soils that the soluble salts found in them are derived from the ash constituents of the plants produced on the soil, and that the first and most necessary condition for the formation of sodium compounds, particularly the carbonate, is a calcareous subsoil, carbonates of the alkalis being formed by the action of calcium carbonate on the humates, sulphates, and chlorids of the alkalis. During the wet season of the year the carbonate of soda dissolved in the soil moisture of the upper layers of the

soil is carried down into the subsoil where it is brought into contact with gypsum and converted into sodium sulphate. In the warmer and drier portion of the year the water containing this sulphate rises to the surface soil and the sulphate is there again converted into carbonate. It thus happens that the composition of the alkali salts in the same soil is very variable at different seasons of the year.

Lime and phosphates in Rhodesian soils, J. Cameron (*Rhodesian Agr. Jour., 5 (1908), No. 3, pp. 155–159*).—It is stated that the most marked feature of Rhodesian soils is the low content of lime with a rather small supply of phosphates. Attention is also called to the calcareous and phosphatic deposits which are found in ant heaps occurring on the soils. The core-like material occurring in these heaps was found to contain 38 per cent of carbonate of lime, 3.5 per cent of phosphoric acid, 2 per cent of magnesia, and 3 per cent of iron. It is believed that this material has been formed at the expense of the lime and phosphoric acid of the surrounding soils. When these mounds are broken up and scattered over the soils their fertility is greatly increased.

Investigations on the fertility of noncalcareous soils, G. Paturel (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 29 (1908), No. 40, pp. 419–422*).—This article calls attention to certain soils which do not contain any calcium carbonate and yet are in many cases abundantly supplied with lime, generally in the form of humate, which is easily soluble and assimilable by the roots of plants.

Analyses of 5 samples of such soils, containing from 0.32 to 1.15 per cent of lime, are reported, as well as fertilizer experiments with one of the soils. A sample of one of the soils containing 0.49 per cent of lime yielded one-fifth of its lime on extraction with distilled water and 40 per cent on extraction with 1 per cent citric acid.

Experiments have shown that these soils are benefited by applications of lime to only a slight extent, but that applications of phosphates produce marked results. It is thought that superphosphates are likely to prove more efficient on these soils than Thomas slag.

The status of soil fertility investigations (*Illinois Sta. Circ. 123, pp. 3–56*).—This is a collection of documents relating to the controversy in connection with the theories of soil fertility of the Bureau of Soils of this Department.

Chemical principles of soil classification, C. G. Hopkins (*Science, n. ser., 28 (1908), No. 729, pp. 857–868*).—This is an address delivered before the American Society of Agronomists at Cornell University in July, 1908, discussing the theories of the Bureau of Soils of this Department regarding soil fertility.

Chemical principles of soil fertility, C. G. Hopkins (*Illinois Sta. Circ. 124, pp. 16*).—See abstract above.

Bacteria for enriching the soil and for increasing the production of crops, N. N. Banerjei (*Dept. Agr. Bengal, Quart. Jour., 1 (1908), No. 4, pp. 221–228*).—This is a brief account of experiments in inoculating seed and soil with dry cultures prepared by this Department and liquid cultures prepared in Germany for the production of cowpeas. The results, while not conclusive, indicate that in certain cases decided benefit was derived from the use of the inoculating material.

Notes on inoculation with Nitragin and inoculated soil in the culture of leguminous plants and its importance in fruit and garden culture, B. Heinze (*Proskau. Obstbau Ztg., 13 (1908), Nos. 6, pp. 87–92; 7, pp. 106–109*).—Inoculation by means of Nitragin or infected soil is considered advisable in many cases.

Inoculation of gram seed with the tubercle-forming bacteria, J. M. Hayman (*Rpt. Cawnpore [India] Agr. Sta., 1907, pp. 63, 64*).—Pot and field experiments

in which seed was inoculated with cultures prepared from root nodules of the gram and planted in sterilized and unsterilized soil are reported. The benefit of inoculation was marked in the pot experiments but not noticeable in the field experiments.

Protection of the soil in Hungary, R. Gonnard (*Rev. Écon. Internat., 5 (1908), IV, No. 1, pp. 67–98*).—This article explains what is being done by organization and government supervision to protect and improve the soils of Hungary, more particularly by forest management and control of waters.

Terracing of farm lands, W. W. Ashe (*N. C. Geol. and Econ. Survey Bul. 17, pp. 38, pls. 6, figs. 2*).—This bulletin briefly describes the coastal, Piedmont, and mountain regions of North Carolina and discusses in some detail the value and characteristics of the soils of the Piedmont region, the extent and cause of soil erosion and its effect on the quality of the soil, kinds of soils subject to erosion, and methods of lessening erosion with particular attention to the value and construction of terraces for this purpose in the Piedmont region of the State.

The advantages of terracing as a means of preventing erosion are stated to be in brief as follows: A reduction in the cost and labor of maintaining a tillable surface soil which is free from gullies, an increase in general fertility, and a corresponding increase in land values. Particular stress is laid upon the importance of using in connection with terracing a system of cropping and manuring which will increase the humus content of the soil.

Improvement and management of eastern Virginia lands, W. C. Stubbs (*South. Planter, 69 (1908), No. 10, pp. 866–869*).—The character of the soils of this region and the cultural management to which they have been subjected are discussed. A system of rotation and manuring based upon actual experiments on a typical soil of the region is described. This rotation includes first corn, followed by cowpeas or soy beans as a summer crop, wheat as a winter crop, and crimson clover as a spring and summer crop. Acid phosphate is used at the rate of 100 to 200 lbs. per acre with each crop.

Experiments with fertilizers showed that notwithstanding the fact that the soil had been cropped with tobacco for many years it did not respond to applications of potash fertilizers. Phosphoric acid was evidently the constituent most needed and nitrogen in combination with phosphoric acid gave profitable increase in yield. A sufficient amount of nitrogen, however, is supplied by the leguminous crops in the rotation described.

The study of the phosphoric acid and lime requirements of cultivated soils by means of field experiments on grass lands, P. Liechti (*Chem. Ztg., 32 (1908), No. 84, p. 1019*).—A report of the results of 3 years' cooperative experiments in different parts of Switzerland is reviewed. The method of organizing and conducting the experiments is also described. Of the single fertilizer elements, phosphoric acid gave the greatest increase in yield of forage. The addition of potash to the phosphoric acid gave a slightly larger increase.

Fertilizer experiments at the Biological Agricultural Institute of Amani, V. Lommel (*Pflanzer, 4 (1908), Nos. 9, pp. 140–144; 10, pp. 145–160; 11, pp. 161–170*).—Pot and field experiments with compost, barnyard manure, and commercial fertilizers on coffee, sisal, cotton, cocoanuts, and rubber plants are reported. The coffee did not grow normally in pot (cement cylinder) experiments and the field experiments have not yet been carried on long enough to give conclusive results.

Manuring experiment on flooded (rice) ground, J. E. van der Stok (*Teysmannia, 19 (1908), No. 6, pp. 389–399*).—This is a comparison of stable manure

with sulphate of ammonia for rice growing. The stable manure was applied at the rate of about 19 tons per acre and the sulphate of ammonia at the rate of 384 lbs. per acre. Two varieties of rice were used. The sulphate of ammonia gave the largest returns both in rice and straw with each variety; the percentage of increase of rice over the plats without manure was 26 and 31, of straw 72 and 40. With stable manure the increase over the unmanured plats was 12.5 and 15 per cent of rice and 21 and 9 per cent of straw, for the 2 varieties used.

Note on action of nitric acid in neutralizing alkaline soil, R. S. Symmonds (*Jour. and Proc. Roy. Soc. N. S. Wales, 41 (1907), pp. 46–48, pl. 1*).—Pot experiments with wheat in which an alkaline soil was treated with 0.2, 0.5, and 1 per cent of nitric acid are reported, the treated soil giving more than five times the yield of the untreated soil. It is suggested that the flow of artesian wells might be utilized to produce by electrochemical means the nitric acid required to correct alkalinity in soils and irrigation water. The probable cost of such an installation is briefly discussed.

Artesian waters (*Jour. Dept. Agr. So. Aust., 11 (1907), No. 4, pp. 362–370, figs. 3; 12 (1908), No. 2, pp. 132–136, figs. 2; Queensland Agr. Jour., 21 (1908), No. 3, pp. 148–151, figs. 3*).—These articles contain further discussion of the proposal of Symmonds, noted above, to use the power of flowing artesian wells to produce the nitric acid needed to neutralize alkaline soils and irrigation waters.

Artesian irrigation: An antidote for alkaline waters, R. S. Symmonds (*Agr. Gaz. N. S. Wales, 19 (1908), No. 8, pp. 609–627, figs. 8, map 1*).—This is a somewhat more detailed account of the experiments noted above.

The article calls attention to the frequent occurrence and injurious effect of alkali in artesian waters used for irrigation in New South Wales. The experiments reported show that this alkali can be neutralized successfully with nitric acid with great advantage in the growth of wheat. It was also found to be possible to manufacture successfully an efficient superphosphate by the use of nitric acid. It is suggested that the flow of the artesian wells may be made to furnish electric power for the production of the nitric acid needed, and data are given showing the power of flow of a number of such wells.

The most economical sources of nitrogen for plant food, L. A. Clinton (*Ann. Rpt. Conn. Bd. Agr., 40 (1906), pp. 153–164*).—This article discusses briefly the relative value and economy of different materials used to supply nitrogen in fertilizers, including nitrate of soda, ammonium sulphate, dried blood, fish and tankage, and farm manures. Conditions controlling the nitrification and availability of nitrogenous fertilizers in the soil are also briefly explained.

The behavior of lime nitrogen and nitrogen lime in storage and in soils, M. Popp (*Chem. Ztg., 32 (1908), No. 80, p. 972; Österr. Chem. Ztg., 11 (1908), No. 23, p. 317*).—It is stated that losses occur when the lime nitrogen is stored damp in thin layers. Decomposition in the soil depends upon the character and the bacterial activity of the soil. The conditions in loam soil seem more favorable than in sandy soil to the rapid rendering of the nitrogen available. Excessive water checks but does not stop this change. Small applications of the lime nitrogen are more rapidly transformed than large, and excessive amounts prevent bacterial action altogether and are poisonous to seeds and higher plants.

In pot experiments it was found that lime nitrogen was 90 per cent as effective as nitrate of soda and 95 per cent as effective as sulphate of ammonia. Twenty per cent of the effectiveness of the lime nitrogen may be lost by applying it

with the seed or entirely as a top-dressing to the growing crop. The best results followed application about 14 days before seeding, the material being deeply and thoroughly mixed with the soil. Dicyandiamid, although not affecting germination, has no fertilizing value, and plants taking it up make less growth than those without nitrogenous fertilizers.

Experiments on the use of calcium cyanamid as a fertilizer, A. Stutzer (*Ztschr. Angew. Chem., 21 (1908), No. 41, p. 2122; Chem. Ztg., 32 (1908), No. 80, p. 972; Österr. Chem. Ztg., 11 (1908), No. 22, p. 306*).—This paper, read before the eightieth convention of the Association of German Naturalists and Physicians, summarizes the results of experiments with lime nitrogen on various crops, showing that with proper precautions the material is as a rule an excellent fertilizer.

The influence of potash fertilizers on the relation of grain to straw, Clausen (*Deut. Landw. Presse, 35 (1908), No. 81, p. 851*).—The author found in pot and field experiments that in case both of leguminous plants (peas and beans) and of cereals (oats and rye) potash fertilizers (kainit) increased the proportion of seed to straw to a marked extent.

Silicate of potash as a fertilizer, E. Wein (*Deut. Landw. Presse, 35 (1908), No. 76, pp. 801, 802*).—This is a preliminary note on field experiments in which silicate of potash was compared with other common forms of potash fertilizers. It is stated that the results of 4 years' experiments have shown that the silicate is an efficient potash fertilizer and that it is less subject than other potash salts to loss from leaching of the soil when applied in large amounts.

Wood ashes as a fertilizer, A. M. Ten Eyck (*Market Growers' Jour., 3 (1908), No. 19, p. 11*).—The fertilizing value and the best methods of using ashes are briefly explained.

Experiments on methods of application of superphosphates, L. Malpeaux (*Jour. Agr. Prat., n. ser., 16 (1908), No. 39, pp. 396–398*).—On wheat and crimson clover superphosphate gave the best results when applied at a depth of 10 cm. as compared with application at the surface and at a depth of 20 cm. On barley the best results were obtained by applying in the fall and mixing well with the soil. On sugar beets also the superphosphate gave the best results when well mixed with the soil. The results in general were unfavorable to top-dressing and spring application.

The agricultural value of low-grade Thomas slag, M. de Molinari and O. Ligot (*Ann. Gembloux, 18 (1908), No. 10, pp. 555–558, pl. 1*).—Comparative pot tests of two low-grade slags containing, respectively, 4.76 and 3.94 per cent of phosphoric acid, on oats on sandy clay soil are reported. The results show that such slags even when used in amounts furnishing the same ration of total phosphoric acid as normal slags are much less effective than the latter, but that when reenforced with citric-acid soluble phosphoric acid they produce the same yield as normal slag.

The solubility of steamed bone meal in 2 per cent citric acid, J. Turk (*Chem. Ztg., 32 (1908), No. 85, pp. 1034, 1035*).—Tests are reported to show that the solubility in 2 per cent citric acid varies widely with the total amount of phosphoric acid in the sample used and that comparable results can be obtained only by using amounts of sample containing approximately the same amount of phosphoric acid. Because this fact is not taken account of in comparative tests of steamed bone and Thomas slag, the results in many cases are thought to be misleading.

The price and value of raw phosphates and so-called agricultural phosphates (*Deut. Landw. Presse, 35 (1908), No. 73, p. 772*).—This is in the main a warning against extravagant claims for these phosphates.

The action of gypsum as a fertilizer. M. Soave (*Staz. Sper. Agr. Ital., 41 (1908), No. 8, pp. 473–500, figs. 2; abs. in Chem. Zentbl., 1908, II, No. 19, p. 1627*).—This article contains a general discussion of this subject and reports a series of pot experiments to determine the chemical effect on soils of the application of gypsum and to compare the effect of gypsum with that of sulphate of potash on corn and beans. The effect of gypsum alone was insignificant. When combined with soluble potash, however, it seemed to produce a beneficial effect.

Manganese sulphate. M. de Molinari and O. Ligot (*Ann. Gembloux, 18 (1908), No. 11, pp. 609–611*).—Tests of this material as a fertilizer on oats and barley grown in pots on soil containing 0.12 per cent of manganese are reported. No benefit from its use was observed. The same was true in similar tests of the sulphates of iron, copper, and zinc.

The action of zinc in pot experiments. P. Ehrenberg (*Abs. in Chem. Ztg., 32 (1908), No. 78, p. 937*).—This is an abstract of a paper presented before the eightieth convention of the German Association of Naturalists and Physicians, which reported experiments to determine the effect of zinc in the soil on the physical and chemical properties of the soil and on the germination of seeds and growth of plants. Experiments were made with zinc plates buried in pots containing different kinds of soil and receiving different kinds of fertilizers. It was noted especially that the injurious effects were most marked in case of the use of ammonium salts as fertilizers. This is attributed to the corrosive action of ammonia set free by the reaction of the zinc on the ammonium salts.

Influence of the weather on the action of commercial fertilizers. W. von Sycianko (*Fühling's Landw. Ztg., 57 (1908), No. 20, pp. 698–701*).—Reference is made to a previous article by Grohmann (E. S. R., 20, p. 311) which maintained that the results of many of the experiments heretofore made do not permit of reliable conclusions because no exact account was taken of the influence of weather conditions, and an attempt is made to show the direct relation between varying conditions of moisture and temperature and the action of fertilizers as demonstrated by observations on fertilizer experiments with strawberries, carrots, kohl-rabi, peas, and other vegetables in which the results were carefully correlated with the weather conditions.

On the mixing of commercial fertilizers. B. Schulze (*Deut. Landw. Presse, 35 (1908), No. 76, p. 803, fig. 1*).—This article explains briefly in text and diagram what fertilizing materials can safely be mixed and which should not be mixed.

The use of peat in the preparation of fertilizers, ammonium salts, and nitrates. H. Rousset (*Rev. Gén. Chim., 11 (1908), No. 17, pp. 305–311, figs. 4; abs. in Chem. Ztg., 32 (1908), No. 84, Repert., p. 532; Ztschr. Angew. Chem., 22 (1909), No. 5, p. 207*).—This is a study of the methods of Rickmann, Woltereck, Müntz and Girard, and Gaillot and Brisset, which are based upon the conversion of peat nitrogen into ammonia and the formation of nitrates from the ammonia.

Obtaining ammonia from atmospheric nitrogen by means of peat. H. C. Woltereck (*Abs. in Chem. Ztg., 32 (1908), No. 78, p. 941; Chem. News, 98 (1908), No. 2549, p. 163; Jour. Bd. Agr. [London], 15 (1908), No. 12, p. 928*).—In this abstract of a paper presented at the recent Dublin meeting of the British Association for the advancement of Science, attention is called to a method now in use in Ireland (Carnlough) in which ammonia is produced by passing air and water vapor over peat at a low heat in especially devised furnaces. Besides sulphate of ammonia (amounting to 5 per cent of the dry peat), other products,

such as acetic acid, paraffin, tar, and ashes of considerable fertilizing value, are obtained.

Nitrogenous fertilizers prepared from peat, MAIZIÈRES (*Engrais, 23 (1908), No. 39, pp. 924–926*).—This is a brief review of methods which have recently been proposed for this purpose, especially those of Bazin and Woltereck (E. S. R., 19, p. 1124; 20, pp. 23, 523).

Nitrate from ammonia, K. W. JURISCH (*Chem. Ztg., 32 (1908), No. 67, pp. 791, 792*).—This is a review of investigations dealing with the oxidation of ammonia to nitric acid. The Ostwald method receives particular attention.

On lime nitrogen, G. BREDIG (*Chem. Ztg., 32 (1908), No. 69, pp. 810, 811*).—Studies on the rate of fixation of nitrogen by calcium carbonate with and without the addition of catalytic substances and with varying pressures are reviewed in this note.

Cyanamid or lime nitrogen (*Amer. Fert., 29 (1908), No. 5, pp. 18, 19, figs. 3*).—This is an illustrated description of works which are being built at Niagara Falls, Ontario, for the manufacture of calcium cyanamid. It is stated that these works are to have a capacity of 15,000 tons per annum.

Chilean nitrate fields, R. HANNA (*Amer. Fert., 29 (1908), No. 5, pp. 10–12; Jour. Indus. and Engin. Chem., 1 (1909), No. 1, pp. 45–47; Mo. Cons. and Trade Rpts. [U. S.], 1909, No. 340, pp. 181–185*).—This article explains briefly how the nitrate industry is conducted and discusses composition, shipping methods, and available deposits.

Nitrate of soda (*Amer. Fert., 30 (1909), No. 2, pp. 8, 9*).—This article gives in brief the official Chilean estimate of the extent of nitrate deposits in that country as reported by Consul R. Hanna. The estimate in 1906, confirming that of 1896, showed a possible production in the nitrate zone of 81,440,000 short tons.

Peruvian guano (*Mark Lane Express, 99 (1908), No. 4024, pp. 525, 527, figs. 3*).—This is a brief general account of the history, present supply, and characteristics of Peruvian guano, with suggestions as to soils and crops best suited to its use and methods of preparing and mixing the guano. Data are also given regarding the price and conditions of sale of the guano in England and its influence on British farming.

Phosphate deposits of Christmas Island, H. P. WOODWARD and E. S. SIMPSON (*Jour. Dept. Agr. West. Aust., 17 (1908), Nos. 1, pp. 552–556; 2, pp. 589–592*).—Explorations which indicate the occurrence of at least 50,000 cu. yds. of phosphatic shale and travertin limestone containing from 13.5 to 23.5 per cent of phosphoric acid are reported.

Deposits of phosphates in the Midland districts [of Western Australia] (*Jour. Dept. Agr. West. Aust., 17 (1908), No. 3, pp. 676–682*).—The discovery of deposits of low-grade phosphate is reported.

Natal mineral phosphates, A. PARDY (*Natal Agr. Jour., 11 (1908), No. 9, pp. 1090–1092*).—Analyses of 5 samples of these phosphates are given. The percentage of phosphoric acid varied from 10.98 to 36.35 per cent. The richer sample, however, contained a rather high percentage of fluorin, which would be a drawback in the case of the use of the phosphate in the manufacture of superphosphates.

Acetylene plant residue, A. PARDY (*Natal Agr. Jour., 11 (1908), No. 8, pp. 947, 948*).—An analysis of the lime residue from the generation of acetylene gas is reported and its value as a fertilizer briefly discussed. The material was found to contain 60.1 per cent of calcium carbonate, 29.5 per cent of calcium hydroxid, and 7.8 per cent of moisture, besides small amounts of magnesia,

silica, iron, alumina, etc. The material is considered a valuable lime fertilizer, but should be thoroughly saturated with water and aerated before crops are planted on land to which it is applied. This is best done by spreading on bare land in winter a considerable time before planting the crop.

Utilizing the dogfish. A. J. Fleming (*Daily Consular and Trade Rpts. [U. S.], 1908, No. 3339, pp. 13, 14*).—The methods and appliances used at Canso and Clarks Harbor, Nova Scotia, and at Shipegan, New Brunswick, for extracting oil from dogfish and making fertilizer from the residue are described. The Canso works are planned to reduce about 25 tons of fish in 24 hours, and the Clarks Harbor plant will reduce 30 tons of fish in 10 hours. The works have proved remunerative both to the operators and to fishermen.

Utilizing stock-yard waste (*Breeder's Gaz., 54 (1908), No. 20, pp. 905, 906*).—This article briefly discusses the increased demand for and improved methods of handling the large accumulations of stock-yard manure. It calls attention to the fact that a product that was formerly dumped into the streams or gotten rid of by some other simple means can now be completely disposed of as a fertilizer at prices of from $6 to $8 per carload of coarse manure and of $18 per ton for assorted pulverized manure in bags.

The disposal of sewage sludge (*Chem. Trade Jour., 43 (1908), No. 1115, p. 309*).—The Grossmann process in use at Manchester, England, is described. This consists essentially of mixing the pressed sludge with a small quantity of acid and subjecting it to the action of superheated steam. This removes fatty matter and leaves behind a dry, practically odorless material containing 2 per cent of ammonia and about 2 per cent each of phosphoric acid and potash.

Sewage sludge as a manure (*Times [London], 1908, Sept. 28; abs. in Jour Soc. Chem. Indus., 27 (1908), No. 19, p. 995*).—In this article reference is made to a report published in a parliamentary paper of experiments made by the British Board of Agriculture to test the fertilizing value of different kinds of sludge on mangels, turnips, and grass under ordinary farm conditions, and on wheat in pot experiments. None of the sludges showed any particular value as a fertilizer.

Chemicals and allied products, C. E. Munroe (*Bur. of the Census [U. S.], Manfrs. 1905, pt. 4, pp. 397–512*).—This report gives statistics of production, consumption, and imports up to and including 1905, the statistics of most interest from an agricultural standpoint being those relating to acids, ashes, and other fertilizers.

According to the statistics given the total value of the fertilizer output in the United States in 1905 was $56,632,853, an increase of 26.8 per cent over the value in 1900; the number of establishments was 400, a decrease of about 5 per cent since 1900. In the same time the capital invested ($69,023,264 in 1905) had increased about 14 per cent, the number of salaried officials had decreased 5.5 per cent, and salaries 8.7 per cent; the number of wage-earners had increased 22.6 per cent and wages 22.9 per cent. Of the total output, 1,670,978 tons, valued at $16,495,206, was superphosphate; 781,354 tons, valued at $13,020,825, was ammoniated superphosphate; 1,603,847 tons, valued at $31,305,057, was complete fertilizer; and 419,803 tons, valued at $4,826,656, miscellaneous. The largest increase (over 400 per cent) during 1900 to 1905 was in ammoniated superphosphate.

The South Atlantic States lead in both quantity and value of fertilizer products, the North Atlantic States being second, the South Central third, and the North Central fourth.

The amount and value of different kinds of fertilizing materials produced in 1905 as compared with 1900 are shown in the following table:

Amount and value of fertilizing materials produced in the United States, 1900 and 1905.

Kind of fertilizer.	Amount 1905.	Value 1905.	Increase in amount over 1900.	Increase in value over 1900.
	Tons.		*Per cent.*	*Per cent.*
Fish	923,305	$880,142	101	379
Kainit	190,493	1,891,073	248	263
Limestone	20,281	10,731	183	47

[a] Decrease. [b] Bushels.

Italy's production of chemical manures, A. Menozzi (*Abs. in Chem. Trade Jour., 43 (1908), No. 1108, p. 152*).—A report presented to the minister of agriculture on this subject is briefly reviewed.

Fertilizers in Australia (*Mark Lane Express, 99 (1908), No. 4023, p. 497*).—Attention is called to the rapid increase in the use of fertilizers in Australia, the imports in 1906 amounting to 150,360 tons valued at about $1,891,500.

Artificial fertilizers in China (*Chem. Trade Jour., 43 (1908), No. 1119, p. 398*).—A brief statement is given as to the extent to which fertilizers are used in China and the possibilities of developing the fertilizer trade there.

Report on commercial fertilizers, 1908, E. H. Jenkins and J. P. Street (*Connecticut State Sta. Rpt. 1907–8, pt. 8, pp. 453–570+VIII*).—Analyses of 632 samples of commercial fertilizers and manurial waste products examined during the year are reported and discussed with reference to variation in composition and commercial value. The fertilizers examined are classified as follows: Containing nitrogen as the chief active ingredient, 185 samples; phosphoric acid, 10 samples; potash, 23 samples; nitrogen and phosphoric acid, 53 samples; mixed fertilizers, 305 samples; and miscellaneous fertilizers and manures, 56 samples.

Inspection and analyses of cotton-seed meal on sale in Mississippi, W. F. Hand et al. (*Mississippi Sta. Bul. 114, pp. 3–35*).—Results of inspection of 414 samples of cotton-seed meal during the season of 1907–8 are summarized. Very few shipments of meal showed marked deficiencies in composition.

Analyses of commercial fertilizers, W. Frear (*Penn. Dept. Agr. Bul. 171, pp. 73*).—This is a report of inspection of fertilizers in the State from January 1 to August 1, 1908, and includes analyses of 625 samples of fertilizing materials.

Fertilizers as sold 1908, A. McGill et al. (*Lab. Inland Rev. Dept. Canada Bul. 161, pp. 23*).—Analyses of 119 samples of fertilizers collected in various districts of Canada are reported. Attention is especially called to the need of improvement in the Canadian fertilizer law with respect particularly to registration and identification of brands.

Manures, H. E. Annett, F. V. Darbishire, and E. J. Russell (*Jour. South-east. Agr. Col. Wye, 1907, No. 16, pp. 183–200*).—This article gives analyses with discussions of the fertilizing value of fish, meat, and other guanos, bone manures, potash salts, nitrate of soda, sulphate of ammonia, rape dust, pond muds, septic tank deposit, seaweeds, greaves, waste products, shoddy, mixed manures, sewage sludges, lime, phosphatic manures, mineral phosphates, superphosphate, and gypsum.

Ohio fertilizer law (*Off. Rpt. Ohio Dept. Agr. on Acreage and Condition of Crops, 1908, pp. 17–20*).—Various amendments of this law which took effect November 1, 1908, are given.

AGRICULTURAL BOTANY.

Solereder's Systematic Anatomy of Dicotyledons, trans. by L. A. Boodle and F. E. Fritsch, revised by D. H. Scott (*Oxford, 1908, vols. 1, pp. XII+644, figs. 153; 2, pp. VI+645–1183, figs. 36*).—After an introduction dealing chiefly with the value of anatomical characters, descriptions are given of the anatomical features of the individual dicotyledonous orders, the arrangement of the latter being the same as in Bentham and Hooker's Genera Plantarum. Under the description of each order, after a short review of the anatomical characters, detailed statements are given as to the structure of the leaf, structure of the axis, etc. Following the detailed descriptions a summary is given of the existing data regarding anatomical characters of plants.

The book, in addition to its value to students of plant anatomy, will be useful to those interested in applied botany, for the determination of raw vegetable products of unknown origin, and also to the physiologist who wishes to obtain information on the anatomy of the plants used in his experiments and on the distribution of certain anatomical features which are connected with special functions.

A text-book of general bacteriology, E. O. Jordan (*Philadelphia and London, 1908, pp. 557, figs. 163*).—This book, which is the outgrowth of a series of lectures given to the students of the University of Chicago, describes the fundamental principles and methods of laboratory work as fully as possible in a publication of its kind, an exhaustive treatise within ordinary limits being impossible. Following a description of methods of studying bacteria, chapters are given in which the biology of bacteria and their relations to organized life are discussed. The morphology, cultural characters, etc., of a number of groups of bacteria that cause disease in man are described at length. Chapters are given on dairy bacteriology, bacteria in the arts and industries, the bacteria of air, soil, and water, bacterial diseases of plants, etc.

A bibliography of mycological literature, G. Lindau and P. Sydow (*Thesaurus litteraturæ mycologicæ et lichenologicæ ratione habita præcipue omnium quæ adhuc scripta sunt de mycologia applicata. Leipsic, 1908, vol. 1, pt. 2, pp. 401–903*).—This publication is a continuation of the previous number (E. S. R., 19, p. 1027), the titles listed being those of authors as far as Lyon. The total number of papers to the conclusion of the present number is 16,142.

International catalogue of scientific literature. M—Botany (*Internat. Cat. Sci. Lit., 6 (1908), pp. VIII+330+843*).—This is an author and subject catalogue of the literature relating to botany, nearly 7,000 titles being listed. The method of treatment is similar to that described before (E. S. R., 20, p. 435). The literature indexed is mainly that of 1906.

The development of the Uredineæ and the origin of new forms, E. Fischer (*Mitt. Naturf. Gesell. Bern, 1907, No. 1629–1664, pp. 136–154*).—The author dis-

cusses the various generations of rusts and the relation of the uredo forms of some species to the other stages occurring in their life histories.

Field, garden, and orchard crops of the Bombay Presidency, G. A. GAMMIE (*Dept. Agr. Bombay Bul. 30, pp. IV+114*).—Botanical diagnoses are given of orders, genera, and species of the field, garden, and orchard crops of the Bombay Presidency, 38 orders of plants being represented. The different orders, genera, and species are described in more or less botanical terms, and economic notes are given on each species and variety.

Seeds and plants imported during the period from January 1 to March 31, 1908. Inventory No. 14 (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 137, pp. 64*).—This is the fourteenth inventory of seeds and plants imported through the Section of Seed and Plant Introduction and embraces 778 items, the introductions received between January 1 and March 31, 1908. Most of these introductions were from China, being a portion of the collection of F. N. Meyer, agricultural explorer.

The germination of some grass seed and a contribution to the study of aleurone grains, A. GUILLIERMOND (*Arch. Anat. Micros., 10 (1908), No. 2, pp. 141–226, pls. 4, figs. 13*).—A cytological study was made of the aleurone grains, and especially of the globoids, of certain grasses, and the author records various phenomena in the germination of seed of barley, wheat, and maize.

The aleurone grains of grasses are formed just as in the lupines from a fundamental mass of proteids by the inclusion of globoids whose number and size vary with the different species. The globoids by their reaction appear to be nitrogenous material and resemble volutin. Aleurone grains are to be found not only in the cotyledons and embryo of the seed but also in certain secretory cells of the epidermis. They are formed in the vacuoles, the globoids first appearing, and around these are deposited the proteids in the form of minute granules. During germination, the aleurone grains are transformed, the proteid granules disappearing first, and the globoids persisting for 5 or 6 days. The globoids are to be considered as reserve material. The epidermal cells of the cotyledons, believed by Brown and Morris to be the seat of diastatic secretion, also contain soluble starch, fat, and aleurone grains.

Chemical processes accompanying the germination of seeds, F. SCURTI and A. PARROZZANI (*Gaz. Chim. Ital., 38 (1908), I, No. 2, pp. 216–227; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 547, II, p. 417*).—A study was made of the proteolytic changes occurring in sunflower seeds, comparisons being made with the nitrogenous compounds found in etiolated shoots of the same seeds The authors identified xanthin, hypoxanthin, arginin, histidin, lysin, and cholin, in addition to which the seeds contained a small proportion of tyrosin. The conclusion is drawn that in so far as the proteids are concerned, natural germination consists of an ordinary proteolysis quite analogous to that produced by the action of the isolated enzyms on the isolated proteins.

In the authors' experiments, no asparagin was formed during the digestion of sunflower seeds, nor during the initial period of their natural germination, although it made its appearance during the more advanced stages of the germinative process. This confirms the view that asparagin is not a direct product of the resolution of proteids, but is a secondary product formed by special transformations at the expense of the primary products.

The production of dry matter and chlorophyll in the higher plants under the influence of different intensities of light, W. LUBIMENKO (*Ann. Sci. Nat. Bot., 9. ser., 7 (1908), No. 3–6, pp. 321–415, figs. 16*).—In previous publications (E. S. R., 19, pp. 831, 930), the author has discussed various phases of his investigations on the relation of light to chlorophyll, and in the present paper a

detailed account is given of his experiments which were carried on with 6 species of herbaceous plants and 8 species of trees.

From the author's conclusions it appears that the production of dry matter by green plants is determined by the energy of the light and varies with the illumination and the amount of chlorophyll in the leaves. The amount of chlorophyll in a given plant varies from time to time, the minimum being associated with full illumination in all the species studied. It increases rapidly with the diminution of illumination up to a maximum, after which there is a gradual diminution if the light is still more reduced. In general the maximum of chlorophyll production corresponds to an illumination considerably below that which induces the formation of the maximum dry weight of plants. The production of dry matter in plants increases with the increased light absorbed up to a certain point, after which it decreases with accompanied greater illumination. The optimum of energy absorbed for a given plant is constant for a given temperature, but diminishes when the temperature is increased.

The optimum intensity of light for the production of dry matter varies according to the quantity of chlorophyll contained in the leaves. Under natural conditions of light the maximum production of dry matter in plants poor in chlorophyll takes place in full sunlight, while on the contrary, with those species rich in green coloring matter the maximum production of dry weight corresponds to a considerable attenuation of light. In general the development of a plant following its illumination is in proportion to the dry matter produced. The growth of the stem and roots seems antagonistic, for while the rate of development of the stem increases with illumination, that of the roots decreases. The development of the leaves is affected in a manner similar to that of the roots.

With few exceptions, transpiration does not appear to have an appreciable effect on the total dry matter produced. The proportion of dry to fresh weight decreases with illumination, and the illumination appears to exert a specific influence upon the water contained in a plant, irrespective of transpiration.

All plants seem to be able to regulate the absorbed light energy and to protect themselves against the unfavorable influence of an excess of light. From a biological standpoint, plants growing in mass are at an advantage regarding an increase in dry matter, since they are able to secure a considerable reduction in the amount of total illumination.

The transpiration of evergreen plants, M. Puglisi (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 17 (1908), 1, No. 10, pp. 661–666*).—From a study made of a number of dicotyledonous plants with persistent foliage, the author found that among the Lauraceæ the energy of transpiration has a well-defined periodicity with a minimum stage during December and January, when cold weather and a minimum of illumination coincide, and an optimum in the spring of the year, when vegetative growth is actively renewed and the surrounding conditions are favorable. The curve of transpiration then decreases through the summer's heat and drought, and at length reaches the winter condition of minimum activity.

With Persea, Oreodaphne, and other plants the energy of transpiration is highest during midsummer, but is not always in proportion to the atmospheric conditions which favor the phenomena of transpiration. With the return of autumn rains, transpiration becomes irregular but finally reaches the level of the early spring condition.

The respiratory pigments of plants, W. Palladin (*Ber. Deut. Bot. Gesell., 26a (1908), No. 2, pp. 125–132; Ztschr. Physiol. Chem., 55 (1908), No. 2, pp. 207–222; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 547, II, pp. 416, 417*).—During the autolysis of germinating wheat, kept under chloroform

water, a chromogen is formed, which oxidizes at the surface of the liquid to a blackish-brown pigment. It is suggested that this pigment is formed from the anaerobic precursors by oxidation with molecular oxygen during respiration, and the name phytohæmatin is proposed for members of this class. According to this view, the process of respiration is primarily anaerobic and results in the production of alcohol and other substances and of carbon dioxid and water. The absorption of oxygen is merely due to a secondary oxidation of some of the products of fission.

The elimination of carbon dioxid from dead plants, A. J. Nabokich (*Ber. Deut. Bot. Gesell., 26a (1908), No. 4, pp. 324–332*).—A study was made of *Penicillium glaucum*, seedlings of *Lupinus luteus*, sunflowers, broad beans, peas, and of the fruiting bodies of *Agaricus campestris*, which showed that under the conditions of the experiment there was a considerable evolution of carbon dioxid when the plants were placed in a vacuum after they had been killed in various ways. This indicates an anaerobic respiration that was entirely independent of bacteria or enzyms.

The relation of the sugar and starch content of guard cells to the opening and closing of stomata, Margery S. Rosing (*Ber. Deut. Bot. Gesell., 26a (1908), No. 6, pp. 438–445*).—A study was made of a number of species of plants to determine whether there is any relation between the starch and sugar content of the guard cells and the opening and closing of the stomata, but while some of the preliminary results seemed to indicate a correlation, there was not sufficient harmony in them to warrant any generalization on the subject.

A study of amylolytic ferments in oats, P. Klempin (*Biochem. Ztschr., 19 (1908), No. 3, pp. 204–213, fig. 1*).—The author made a study of an amylolytic ferment separated from oats, and in the form of glycerin extract its optimum effect was secured in temperatures between 40 and 70° C. It was found able to withstand higher temperatures, 90 to 95° being necessary to render it inactive. Digestion experiments with the ferment showed it to be relatively active.

The relation between phosphorus and the formation of amino acids in the higher plants, F. Scurti (*Staz. Sper. Agr. Ital., 41 (1908), No. 7, pp. 456–470*).—The author reports a correlation between the presence of phosphorus and the formation of proteid substances in plants, and states that the correlation is also extended to amino acids, which are considered a stage in the synthesis of albuminoid materials, phosphorus in all probability having an important function in their formation.

Proteid formation in ripening seed, N. Wassilieff (*Ber. Deut. Bot. Gesell., 26a (1908), No. 7, pp. 454–467*).—A study was made of lupines and some other leguminous plants to determine the source of protein in their fruits and seeds.

When lupine fruits were separated from the plant the formation of proteids was found to continue both in light and darkness, and the increase in protein was accompanied by a decrease in the organic crystallized nitrogenous material in the pods. At first the increase in proteids was made at the expense of the asparagin, but later the synthesis of proteids was at the expense of amido acids, which are formed in darkness more abundantly than in the light. The author believes that the hypothesis that proteids are formed from asparagin is correct. It is thought probable that during the ripening process the amido acids are transformed into asparagin and this substance into protein. The rôle of the organic bases is similar to that of the amido acids, and their content diminishes with the increase of proteids. When the seeds were examined they were found to increase in their protein content with their development, part of the protein being derived from the amido compounds in the seeds themselves and part by translocation from the hulls. Seeds removed from the hulls increased in proteids at the expense of the asparagin and amido compounds.

Some chemical changes in the maturity of fruit, F. Scurti and G. De Plato (*Staz. Sper. Agr. Ital., 41 (1908), No. 7, pp. 435–455*).—A discussion is given of the changes in acidity, sugars, and nitrogenous constituents in oranges during the process of ripening of the fruits, and of the presence of asparagin and glutamin in the juice.

On the occurrence of zinc in plants, M. Javillier (*Thesis, Univ. Paris, 1908; Ann. Inst. Pasteur, 22 (1908), No. 9, pp. 720–727; rev. in Rev. Sci. [Paris], 5. ser., 10 (1908), No. 9, pp. 278, 279*).—In a study of about 45 species representing 27 families of plants, the author found zinc to be of quite common occurrence. The rôle of zinc in the plant was studied, and it is believed to have an important physiological function in the growth of many plants, probably acting as a catalytic agent in some of the more complex fertilizers, its behavior in this respect being similar to that of manganese. When added to cultures in which *Aspergillus niger* was grown, there was a decided increase in the dry weight of the fungus, and zinc appeared to actively stimulate the growth of a number of the vascular plants investigated.

Oleuropéine, a new glucosid isolated from the olive tree, E. Bourquelot and J. Vintilesco (*Jour. Pharm. et Chim., 6. ser., 28 (1908), No. 7, pp. 303–314*).—The authors have isolated from the olive a glucosid to which they have given the name oleuropéine. It is present in the bark, leaves, and fruit, the proportion varying with the part of the plant and the season of the year. It is most abundant in the young olives when the seed is forming, and it disappears in them toward the period of ripening. The method of isolation and properties of oleuropéine are described at length.

The abnormal development of wound tissues, T. Wulff (*Ark. Bot., 7 (1908), No. 3–4, Art. 14, pp. 32, pls. 7, fig. 1*).—In this article descriptions are given of abnormal callus-like tissues in raspberry canes, due to the development of corky tissues from the cambium layer injured by frost, and a somewhat similar affection the exact cause of which is not known. The primary injury in some cases seems to be due to the punctures of mites or other animal injuries.

Investigations on forest injury due to smoke and gas, Gerlach (*Ztschr. Forst u. Jagdw., 40 (1908), No. 7, pp. 429–437, figs. 2*).—A study has been made of two cases of smoke injury to forests in Germany. The author is convinced that the destruction of fir trees in two forest districts is due to the flue gases given off from some large industrial works. The presence of *Pissodes* spp. is attributed to the injury of the trees by gases. The twigs showed reddish discoloration which indicated gas injury, and analyses of samples of diseased twigs from the two localities showed 0.498 per cent sulphuric acid in 100 parts of dry matter in one instance and 0.465 per cent in the other.

The relation of the conformation of the land to air currents, and hence the direction of smoke dispersal, is discussed.

The injurious effect on plants and soils of flue dust, E. Haselhoff (*Fühling's Landw. Ztg., 57 (1908), No. 18, pp. 609–615*).—A discussion is given of the effect of smoke and fumes from blast furnaces, chemical works, etc., on the growth of various plants, together with data indicating the injury done by the components of smoke and flue dust on beans, rye, and grass. The effect of the accumulation of copper and other substances from chemical works in the soil is also discussed. Analyses, experiments, and observations with various plants are reported indicating that the injurious effect of the dust is due to sulphurous acid.

A registering photometer, E. A. Mitscherlich (*Landw. Vers. Stat., 68 (1908), No. 5–6, pp. 467–469, fig. 1*).—A description is given of a registering photometer which the author claims is especially adapted to experiments in connection with the light requirements of plants and similar work.

FIELD CROPS.

Report of the advisory committee on soil investigation, H. A. McKeene (*Springfield, Ill: State, 1908, pp. 32, dgms. 3*).—An act of the Illinois legislature provides for the investigation and study by the experiment station of the soils of the State, and it further provides that a committee of five, appointed by the State Farmers' Institute, is to advise with the director of the station on the ways and methods by which this investigation shall be conducted. This publication contains a report on the inspection of the soil experiment fields at nine different points in central Illinois, and gives briefly the results secured on the different fields, together with answers by C. G. Hopkins, in charge of the work, to questions by the committee.

Summary of results secured on the experimental field at Ploti in 1907, A. Winkler (*Ghodichnuĭ Otchet Ploty. Setsk. Khoz. Opuitn. Stantziĭ, 13 (1907), pp. 168–174*).—In a comparison of methods of fallowing, the best yields of rye and winter wheat during the dry season of 1907 were secured on black fallow. Spring wheat after timothy gave much smaller yields than after sainfoin, alfalfa, and clover. The yield of wheat after sainfoin was larger than after clover and alfalfa. It was also found that winter wheat after clover gave better results than spring wheat.

The results of experiments with barnyard manure showed that 18,000 kg. per hectare (about 8 tons per acre) were practically as effective as 36,000. The use of superphosphate in quantities furnishing 30 kg. of phosphoric acid per hectare (about 26.7 lbs. per acre) produced an increase in the yield of 240 kg. of grain.

Deep plowing gave better yields of spring wheat, sugar beets, and potatoes than shallow plowing, but corn produced the best crop on shallow plowing with frequent shallow surface cultivation. Determinations of soil moisture 10, 30, 50, 70, and 100 cm. below the surface indicated a lower moisture content in the corn field at a depth of 10 cm. (about 4 in.) than in a wheat field, while at all other depths the moisture content in the corn field was above that in the wheat field.

Report on the Cawnpore agricultural station for the year ending June 30, 1908, J. M. Hayman (*Rpt. Cawnpore [India] Agr. Sta., 1907, pp. 87*).—This report describes the situation, area, and soil of the station and presents the results of experiments with different crops and fertilizers.

The average results of fertilizer tests with corn show that the best yield was obtained where an application of poudrette, furnishing 100 lbs. of nitrogen per acre, was given. The best yield of wheat was secured from an application of sheep dung furnishing 50 lbs. of nitrogen. Cotton gave the best yield where barnyard manure was given in quantities furnishing 50 lbs. of nitrogen per acre and superphosphate in applications supplying 50 lbs. of phosphoric acid per acre. Potatoes led with a yield of 16,500 lbs. per acre on the plat fertilized with neem-cake furnishing 200 lbs. of nitrogen per acre, as compared with poudrette and cotton refuse supplying the same quantity of nitrogen. Hemp proved an effective green-manuring crop for wheat. Selection experiments with cotton are reported and the variations observed through different generations are recorded. Work with rice, leguminous forage crops, cacti, fiber plants, and crop rotations is briefly noted.

Cereal culture on the dry lands of central Tunis, E. Leloup (*Bul. Agr. Algérie et Tunisie, 14 (1908), Nos. 17, pp. 417–428; 18, pp. 441–448*).—This article describes the requirements and methods for dry farming in central Tunis, and gives directions for its improvement. The rainfall of the country for a number of years is tabulated, and it is pointed out that the rainfall alone

is not always sufficient in securing a profitable harvest. In 1898 a good crop was grown with a rainfall of 135 mm., while in 1908 with the same amount of rainfall the crop was an entire failure. In 1903, with a rainfall of 125 mm., and in 1905, with a rainfall of 110 mm., the yields were as satisfactory as in 1898. In 1904, when precipitation amounted to 115 mm. the harvest was poor, and in 1907, with a rainfall of 195 mm. it was very mediocre.

Alopecurus agrestis, C. Fruwirth (*Arb. Deut. Landw. Gesell., 1908, No. 136, pp. 20, pls. 6, figs. 2*).—This publication contains a botanical description of this grass, a discussion of the life of the plant, and notes on its growth requirements, distribution, influence on other crops, and uses.

The basis for judging brewing barley, E. Jalowetz (*Wiener Landw. Ztg., 58 (1908), No. 78, pp. 771–773*).—After discussing the subject and reviewing observations and experimental results with a bearing on the subject, the author concludes that the following points should be considered in judging brewing barley: Color, odor, broken and sprouted grains, sorting according to shape of the kernel, water content, nitrogen content in the sorted and unsorted portions of the quantity examined, the 1,000-kernel weight, fineness of the hull, mealiness or flintiness, germination, and foreign matter.

Comparison of plants of the field beet grown from seeds from the same seed boll, H. Briem (*Fühling's Landw. Ztg., 57 (1908), No. 20, pp. 694–698*).—The weight of the seeds taken from seed bolls containing 4 or 5 seeds are given, and the results of experiments with the different seeds from single seed bolls are reported. The weight of the beet and the sugar content of the same in each case are recorded. The results show in general that the heavier seeds produce the more vigorous and heavier plants.

Corn culture (*Texas Dept. Agr. Bul. 4, pp. 7–116, map 1*).—This bulletin contains a series of papers by different authors on the various phases of corn culture and the uses of the crop.

Experiments on the improvement of cotton by seed selection in the Leeward Islands, F. Watts and H. A. Tempany (*West Indian Bul., 9 (1908), No. 3, pp. 220–233*).—In the experiments reported selection of plants was based on strength and vigor of growth, freedom from disease, and yielding capacity, while the individual seeds were selected for the length, evenness, and strength of fiber. Of 100 plants grown from unselected seed of selected plants, 60 per cent produced a staple 1⅜ to 2 in. in length. Similar selections from high-grade and productive cotton gave in one instance 43 per cent of the fiber from 1⅜ to 2 in. long and 34 per cent of even fiber over 2 in. long. In another test 34 per cent of the fiber produced was over 2 in. long and quite even, while 29 per cent was over 2 in. long and very even. In a cooperative test seed classed under certain grades produced a crop of which 80 per cent came under the same grades as the original seed.

The methods of selection, including the examination of the lint, are described and the results of these and other tests, which in general show the influence of selection, are given in tables.

Hop experiments, A. Amos (*Jour. Southeast. Agr. Col. Wye, 1907, No. 16, pp. 333–345*).—The results of cooperative fertilizer and culture tests now in progress for a series of years are reported. The fertilizer experiments showed that the hop plant requires a normal mixture of all the elements of plant food and that it is not a special feeder on any one particular element in preference to another. From this it is concluded that the problem of manuring hops narrows down to a study of the soil and to the application of the elements found lacking.

In a culture test a plat given shallow cultivation for 12 years, simply for the purpose of keeping down weeds, produced throughout a crop greater than

the plat receiving deep cultivation each season. A plat given shallow cultivation for only 6 years did not produce as large yields as the one given shallow cultivation for 12 years.

Report from the select committee on the hop industry (*London, 1908, pp. LIV+591, dgms. 2*).—This report contains statistics and tables with regard to the acreage of land devoted to hops in England, the estimated yield per acre, and the total home production, together with similar data for different hop-growing counties of the country. The report further embodies the statements of 42 hop growers, dealers, consumers, and others heard by the committee. It deals mainly with the cultivation of the hop in England, but considerable attention is also devoted to the world's supply of hops and the international trade in the product.

The German hop crop of 1908 (*Allg. Brau. u. Hopfen Ztg., 48 (1908), No. 293, pp. 3159–3162*).—The acreage, average yield, and total yield of hops for the years 1878–1908, inclusive, are tabulated and data concerning the area and yields of the different hop-growing sections of the country in 1908 are reported.

Duty on hops (*San Francisco, Cal. [1908], pp. 20*).—This revised report of a hearing given before the Committee on Ways and Means, with reference to an increase in the duty on hops, includes statistics concerning the crop.

The ixtle and its relations, R. Endlich (*Tropenpflanzer, Beiheft e, 9 (1908), No. 5, pp. 221–283, pl. 1, figs. 6*).—The botanical relationships, culture, and uses of the following species of fiber plants are discussed: *Agave heteracantha*, *A. lophantha*, *A. univittata*, *A. falcata*, *A. striata*, *A. tequilana*, *Samuela carnerosana*, *Hesperaloë funifera*, *Yucca treculeana*, *Y. australis*, *Y. valida*, *Y. schottii*, *Y. elephantipes*, *Y. endlichiana*, and *Y. rostrata*.

The cultivation of ground nuts, H. C. Sampson (*Dept. Agr. Madras, Bul. 58, pp. 145–149*).—This is a popular bulletin on the culture of peanuts in India. The methods of irrigation practiced in connection with the culture of this crop are briefly noted.

Water culture method for experimenting with potatoes, J. J. Skinner (*Plant World, 11 (1908), No. 11, pp. 249–254, figs. 3*).—This article describes in detail the method used for growing potatoes under water culture for experimental purposes.

Commercial potato growing, A. G. Craig (*Washington Sta. Popular Bul. 11, pp. 7*).—This bulletin describes in a popular manner the culture of potatoes under the climatic and soil conditions of Washington. A list of varieties adapted to the State is given and the methods of growing potatoes in the irrigated districts are described.

The cultivation of tobacco in Kentucky and Tennessee, W. H. Scherffius, H. Woosley, and C. A. Mahan (*U. S. Dept. Agr., Farmers' Bul. 343, pp. 31, figs. 13*).—This bulletin gives general directions with reference to growing young tobacco plants in the seed bed, selecting and preparing ground for a tobacco crop, topping the plants, combating insects, selecting seed plants, harvesting, curing, stripping, grading, and marketing. The 4-year rotations and one 8-year rotation, practiced in the tobacco districts of these States, are outlined.

The production of cigar-wrapper tobacco under shade in the Connecticut Valley, J. B. Stewart (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 138, pp. 31, pls. 5*).—A general description of the culture, curing, packing, grading, and marketing of shade-grown tobacco is given, and the improvement of tobacco obtained by seed selection and the value of sterilizing the seed beds are discussed. A detailed account of expenditures connected with the production of 3 acres of shade tobacco in the Connecticut Valley is reported, together with the proceeds from the sale of the tobacco grown.

The results of actual experiments show that tobacco can be produced profitably in the Connecticut Valley under shade if a good strain of seed is secured and proper cultivation and handling of the crop is given. The best cloth to use for shade is one with 12 hard-twisted threads to the inch. This kind of cloth in an experiment produced a higher yield and a better quality of tobacco than cloth which contained only 8 threads to the inch. It has been found in experiments, and subsequently in general practice, that sterilized seed beds insure an abundance of good healthy plants.

Sumatra tobacco: Culture, curing, marketing, E. Mathieu (*Singapore, 1908, pp. 51, figs. 2*).—This publication briefly outlines the history and culture of the tobacco plant in Deli.

The yellow berry problem in Kansas hard winter wheats, H. F. Roberts and G. F. Freeman (*Kansas Sta. Bul. 156, pp. 35, dgm. 1*).—This bulletin reviews the results obtained by other investigators of the yellow berry problem and reports experiments conducted by the authors to determine the causes of this difficulty and means for their removal. The work of the Nebraska Station, partly reviewed here, has been previously noted (E. S. R., 17, p. 246).

By the term "yellow berry" is meant the appearance of grains of a light yellow color, opaque, soft, and starchy in hard winter wheats which normally produce a hard, flinty, translucent grain of medium size and of a clear, dark reddish amber color. Sometimes only a part of the kernel will show the yellow berry characteristics. It is pointed out that the data at hand indicate that the ordinary soft and starchy wheats of the Pacific Coast and the Middle and Southern States average somewhat higher in weight per bushel than the hard winter and spring wheats, and that the yellow berry in this respect does not resemble the soft wheats, the weight as well as the specific gravity falling below the flinty kernels of the same variety. This is considered as reducing the question to what extent the production of yellow berries is inherent in the variety and to what extent it is due to seasonal influences. In 21 varieties examined the average weight of the yellow berries per 100 was 2.596 gm., and that of the hard flinty grains 2.740 gm. The average specific gravity of the yellow berries was 1.304 and of the normal grains 1.336. It is known that the yellow berry contains less protein than the flinty kernel, and it is believed that the reduction in specific gravity is probably due to air cavities within the kernel and possibly to a reduced starch content.

To determine the relation between the amount of yellow berry produced under the climatic conditions of the particular season, 128 varieties of wheat were grown during 1905–6 and 1906–7. The heads were harvested when considered fully ripe and dried under cover, so that the existence of yellow berry could not be attributed to overripeness or exposure to the weather after cutting, but could only be ascribed to the influence of the weather before harvesting the heads or to inherent hereditary tendencies in the varieties themselves, or to both. Only clear kernels with a reddish amber color throughout were considered as normal grains, while those either wholly or in part yellowish, opaque, and starchy were classified as yellow berries.

The mean temperature during the wheat vegetative season, September to June, inclusive, in 1905–6 was 51.33° F., and in 1906–7, 49.10°, while the total precipitation for the corresponding periods was 25.72 and 21.11 in., respectively. The average total vegetative season made up of the fall vegetative period, or the number of days from planting to January 1, and the spring vegetative period, or the number of days from March 1 to maturity, was 267 days in 1906 and 279 days in 1907. The average percentage of yellow berry was 33 in 1906 and 39 in 1907. To interpret the results with regard to the relation of temperature,

light, air movements, and precipitation to the growth of the wheat plant, and the possible share of each factor in the production of yellow berry, was found to be extremely complex and intricate.

Relative to the influences of the autumn vegetative conditions on the production of yellow berry, the data for the 2 years show the same diminution in the percentage of yellow berry with the shortening of the fall vegetative period and a corresponding decline in the mean temperature for that period. The first year the planting season lasted over 19 days (from September 28 to October 16), corresponding with which there was a decrease in the average amount of yellow berry of from 53.80 per cent in the highest to 19.58 per cent in the lowest case. The second year, when the planting season covered a period of but 4 days (September 26–29), there was apparently a correspondingly lower range in the average percentage of yellow berry from the different plantings of from 44.33 per cent in the highest to 32.63 per cent in the lowest. Apparently the reduction in the total length of the growing period with the later plantings, the consequent lower mean temperature for the period of fall growth, and the necessarily retarded and diminished development of the plants is in direct correspondence with the subsequent development of yellow berry, in so far as the data here secured are concerned.

Vegetative spring conditions did not disclose any very definite relationships to the percentage of yellow berry. As the results were sometimes contradictory, and always complex and difficult of interpretation, it was concluded that hereditary tendencies in the varieties themselves might obscure results, and accordingly work was begun to demonstrate whether or not yellow berry is a heritable product.

Among the many cultures of wheats examined, which were planted side by side at the same time and which ripened on the same date, the percentages of yellow berry were found to vary widely. So-called commercial varieties, which were really mixtures of wheats, were grown under identically the same conditions in connection with this investigation. Among them strains of different type were found, which showed distinct physiological differences so far as the production of yellow berry was concerned. The varieties grown in 1906 were grouped into those wheats producing from 1 to 25 per cent, from 26 to 50 per cent, from 51 to 75 per cent, and from 76 to 100 per cent of yellow berry. The crop of 1907 from these groups showed in general that the averages of the amount of yellow berry for each had the same relative position that they occupied in 1906. The minimum range of yellow berry in the varieties lay in those groups of 1907 that came from the minimum groups of 1906. Although the varieties low in yellow berry had progeny in 1907 which averaged 12.25 per cent higher than the average of the corresponding parental groups for 1906, on the other hand the varieties high in yellow berry had progeny which averaged 27.41 per cent lower than the average of the corresponding parental groups for 1906. It was further found that the progeny from selected hard kernels from 8 apparently pure varieties planted in 1906 were much heavier than those from soft grains, and that as a rule the yields from the heavy hard grains were greater than those from the softer kernels.

The degree of inheritance of yellow berry in pure bred or pedigree wheats is discussed, and the results secured in work along that line are reported. In the first progeny group of the pedigree wheats in 1907 a little over one-third produced no yellow berry at all, and the average of all was but 3.9 per cent, whereas in the selections of spikes from the common commercial varieties, as well as in the selections of hard and soft grains from these varieties, there were no cases whatever where the offspring were free from yellow berry. The averages for the lowest groups in the case of the common commercial varieties

and of the selected hard and soft grains from the commercial varieties were 36.95 and 15.40 per cent, respectively.

It appears in general from the results that with the percentage increase of yellow berry in the parents a mean percentage increase of yellow berry in the offspring was observed, and it is considered as very evident that the pedigree culture method, so far as the elimination of the yellow berry is concerned, is superior to the other methods tried. The common commercial variety lots of parents all contained yellow berry, but there were 61 cases (46 per cent) in which the percentage ranged from 1 to 25. The progeny of these in 1907 showed a mean percentage of yellow berry of nearly 37, but among the pedigree cultures there were 38, or 36 per cent, which as parents fell into the 1 to 25 per cent class, but which in 1907 showed a mean percentage of yellow berry of only 7.9. The minimum or zero class of parents gave rise also to the minimum class of the offspring in the case of the pedigree wheats.

[Irrigation experiments with wheat, 1907–8], W. B. Gordon (*Punjab Irrig. Branch Papers, No. II, pt. 3 C, pp. 19*).—The results of these experiments, which were carried on in different parts of the country, show that in a dry year as a general rule four or five normal to heavy applications of water are required for a full yield. At one point, Guara, lighter waterings gave the best results, and at Lyallpur two good and well-timed applications were sufficient to produce almost a full crop. At Guara this result is ascribed to the high level of soil water in the spring, but the cause for the variation at Lyallpur is not known.

Varieties of wheat grown in the Central Provinces and Berar, G. Evans (*Dept. Agr. Cent. Prov. and Berar [India Bul.], pp. 29, pls. 2, map 1*).—Descriptions, together with the classification, of the different varieties of wheat grown in these provinces are given. Figures are presented on the estimated area in wheat for the years 1867 to 1907, inclusive.

The wheat of Tomsk, Siberia, C. Flaksberger (*Trudui Byuro Prikl. Bot., 1 (1908), No. 7–8, pp. 213–221*).—Botanical descriptions of varieties of *Triticum vulgare*, *T. compactum*, *T. turgidum*, and *T. durum* grown in the government of Tomsk are given, and the varieties grown in each of the 7 provinces of this government are pointed out.

HORTICULTURE.

The modern kitchen garden, V. A. Gressent (*Le Potager Moderne. Paris, 1907, 10. ed., pp. 936, figs. 176*).—A treatise on the intensive and extensive culture of vegetables in the various climatic sections of France. The aim of this work, which first appeared in 1864, is to furnish a practical knowledge of vegetable growing to the general public and institutions of various kinds rather than to serve as a guide to the professional market gardener.

Cabbages and cauliflowers: How to grow them, J. J. H. Gregory (*Boston, 1908, pp. 93, figs. 21*).—This is a revised edition of the author's practical treatise on growing, storing, and marketing cabbage. It also includes information relative to varieties, raising cabbage seed, originating new varieties, and cultural notes on other prominent members of the Brassica family, including cauliflower, broccoli, Brussels sprouts, kale, and sea kale.

The citron crop, A. S. Cheney (*Mo. Consular and Trade Rpts. [U. S.], 1909, No. 340, pp. 97, 98*).—Data are given on the production of citrons in the Mediterranean countries, together with a description of the method of preserving citrons in brine for future delivery. The estimated world's production of citrons for the season of 1908–9 is about 8,000 tons.

Mushrooms propagated from spores, M. C. Cooke (*Jour. Roy. Hort. Soc. [London], 34 (1908), No. 2, pp. 219–221, fig. 1*).—In view of the general failure

resulting from attempts to propagate mushrooms by spores, the author cites two instances in which the species *Agaricus elvcusis* was propagated from fragments thrown away on the naked soil and continued to flourish for many years. It is suggested that this species may prove of value to mushroom growers.

Inheritance in tomato hybrids, H. L. Price and A. W. Drinkard, Jr. (*Virginia Sta. Bul. 177, pp. 17–53, pls. 10, figs. 5*).—The experiments discussed in this bulletin were undertaken primarily for the purpose of testing for tomato characteristics Mendel's law of inheritance (E. S. R., 13, p. 744).

The work was begun in the spring of 1906, and the main problem consisted in determining what form of inheritance existed for each particular pair of characteristics. The plan as outlined included 21 distinct crosses, many of which differed with respect to more than one pair of character units. All character unit crosses of similar nature, regardless of parentage, are grouped together in a single series and discussed. The fruit characters studied include those having to do with shape, color, number of cells, pubescency, and smoothness. Of the plant characters, the potato leaf was compared with a normal cut leaf, green foliage with yellow foliage, and dwarf stature with standard stature.

From the data obtained the authors conclude that most character units for tomatoes when hybridized exhibit in the first hybrid generation the phenomenon of dominance and recessiveness, and are subject in the second hybrid generation to Mendelian splitting or segregation. These character units are independent in heredity, without respect to parentage. Reciprocal character unit crosses give similar results in the offspring. A list is given of 13 dominant and recessive unit character pairs as determined for the tomato. Certain individual crosses are discussed from the standpoint of di- and tri-hybrids as bearing upon their utility in the development of new varieties. The authors conclude relative to character unit polyhybrids that the different character units are usually independently heritable, and that the re-combinations of characters occurring in the second generation of hybrids conform with Mendel's law for polyhybrids. Extracted recessives and selected homozygous dominants breed true in subsequent generations. Inter- and intra-specific crosses of tomatoes gave similar results in the hybrids.

Of many desirable hybrids incidentally secured in this investigation the following are described: Beauty-Stone, Beauty-Golden Queen, and Potato Leaf-Red Currant.

On the influence of direct light on the chemical composition of fruits, G. Rivière and G. Bailhache (*Jour. Soc. Nat. Hort. France, 4. ser., 9 (1908), Nor., pp. 627–630*).—Analyses were made of the chemical composition of several varieties of pears, the sun-colored side of each specimen being compared with the unexposed side. In all cases the side of the fruit exposed to the sun showed a greater sugar content and a smaller acid content than the unexposed side.

Similar analyses are given for the Chasselas doré grape, in which comparisons were made between the colored and uncolored portions of the same berries, and between colored and uncolored berries taken from different bunches. The results confirm those secured with the pears.

California fruits and how to grow them, E. J. Wickson (*San Francisco, Cal., 1909, 4. ed., rev., pp. 433, pls. 25, figs. 228*).—This is the fourth edition of the author's work on fruit growing in California. The work has been enlarged and revised to embody the results of recent experience, observation, and research and is offered as a manual of methods which have yielded the greatest success, with lists of varieties best adapted to different districts of the State. The fruits discussed include deciduous and semitropical orchard fruits, grapes,

small fruits, and nuts. Consideration is also given to fruit preservation and protection and the utilization of fruit wastes.

Varieties of fruit for growing in North Carolina, W. N. Hutt and S. B. Shaw (*Bul. N. C. Dept. Agr., 29 (1908), No. 9, pp. 3–32*).—This is a popular bulletin containing lists of orchard and small fruits recommended for growing in the mountain, Piedmont, and coast regions of North Carolina. The lists were prepared especially to encourage commercial fruit culture, hence do not contain all of the varieties which will grow in the State. Each variety recommended is described relative to its characteristics and habits.

Fruit culture in Crimea, J. Barsaq (*Bul. Mens. Off. Renseig. Agr. [Paris], 7 (1908), No. 11, pp. 1348–1368*).—An account of the development and present status of the fruit industry in Crimea.

Nova Scotia apple industry (*Daily Consular and Trade Rpts. [U. S.], 1909, No. 3375, pp. 1–4*).—According to this consular report the apple industry in Nova Scotia has increased as indicated by the exports from 41,785 bbls. in 1880–1 to about 600,000 bbls. during the present season. Brief notes are given relative to handling the crop, varieties, evaporation process, location of factories, and extent of operations. Apple growing in Nova Scotia is confined to the Annapolis valley, a district about 100 miles long and ranging from 6 to 10 miles in width.

Dessert cherries in pots, J. Hudson (*Jour. Roy. Hort. Soc. [London], 34 (1908), No. 2, pp. 189–192*).—Brief practical directions are given for growing cherries in pots, together with a list of varieties best suited for forcing purposes.

A study of the biology and phylogeny of the fig (Ficus carica), and the classification of the figs of southern Italy, G. Celi (*Atti R. Ist. Incoragg. Napoli, 6. ser., 59 (1907), pp. 541–654, figs. 10*).—The author reviews the work of previous investigators relative to the life history, morphology and classification of the various races of the common fig (*F. carica*), and proposes new systems of classification both for domestic figs and capri figs. Sample schemes are given for the classification of the figs grown in southern Italy. An extensive bibliography of the fig is appended.

Notes on fig cultivation in southern India and peculiarities in viticulture in Penukonda in the Anantapur District, C. K. Subba Rao (*Dept. Agr. Madras Bul. 57, pp. 135–143*).—In addition to the notes on fig culture some unusual methods of pruning and treating grapevines are described.

On a process of forcing grapes, M. G. Bonnier (*Bul. Soc. Nat. Agr. France, 68 (1908), No. 8, pp. 653–657*).—The author gives an account of an experiment conducted by L. Pauchet in forcing grapes by causing vines to absorb a sugar solution. The method of procedure is described in detail. The grapes on the treated vines were 12 to 18 days earlier than on the untreated vines. It is believed that this method can be applied to advantage in forcing greenhouse grapes.

Commercial fertilizer experiments with grapevines, E. Zacharewicz (*Rev. Vit., 30 (1908), No. 785, pp. 746–751*).—The author continued for the season of 1908 his comparison of nonnitrogenous and nitrogenous fertilizers for grapes, with results which confirm those reported for previous years (E. S. R., 19, p. 946).

Annual report of the wine-making station of Haro for 1907, V. C. M. de Zúñiga (*Estación Enológica de Haro. Memoria Correspondiente al Año 1907. Haro, 1908, pp. 85, chart 1*).—This is a progress report on the work of the station for the year, including laboratory and field investigations, and is similar in character to that noted for the previous year (E. S. R., 19, p. 648).

Storage and transportation investigations with citrus fruits and grapes, A. V. Stubenrauch (*Ice and Refrig., 36 (1909), No. 1, pp. 8, 9*).—In the investigation reported, conducted by this Department during the summer of 1908, on the behavior of California Valencia oranges stored at different stages of maturity and held for different lengths of time at both 32° F. and at 40 to 42°, the oranges held in cold storage at these temperatures began to deteriorate from a month to 6 weeks after they were put in storage. Both the appearance and eating quality of the fruit were affected. The deterioration was slower and less marked, however, at the higher temperatures than at 32°. The fruit was affected by various skin troubles, the nature of which has not been determined, but which are believed to be connected with low temperatures in storage, since some lots of fruit held in cellar storage at about 60 to 65° showed no trace of these diseases.

Similar preliminary experiments in the cold storage of lemons showed that the fruit stored at 40 to 42° held in better condition longer than that stored at 32°, and indicated that when lemons are handled properly they will keep for a long time when held in common storage at ordinary temperatures.

Tabular data are given showing the results of 2 years' experience in the cold storage of table grapes in California. It was found possible to hold the grapes from 65 to 100 days in excellent condition when packed in fine ground cork, whereas similar fruit packed in the ordinary commercial way held but from 10 to 20 days. Shipping experiments with table grapes showed that the grapes rot least in transit and after arrival when the fruit has been picked and packed with great care and is shipped quickly after packing. The shipping quality of the grapes is improved by packing in cork dust, but tests made of various substitutes for cork dust indicate that redwood sawdust will prove entirely satisfactory. The results as a whole indicate, as in the previous work with citrus fruits (E. S. R., 20, p. 43), that much of the loss arising during storage and transportation is due primarily to improper methods of preparing the fruit for shipment.

The decay of Florida oranges while in transit and on the market, L. S. Tenny, G. W. Hosford, and H. M. White (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 19, pp. 8, figs. 2*).—During the season of 1906–7, the Bureau of Plant Industry commenced an investigation of the cause of decay in oranges shipped from Florida similar in nature to the investigation recently reported on California oranges (E. S. R., 20, p. 43). This circular summarizes the results secured for the past 2 seasons. So far as the investigation has gone the results appear to confirm those secured in California, and show that the decay of oranges is closely connected with rough methods of handling the fruit in the groves and packing houses. Numerous details of grove, packing-house, and transportation methods are to be given further attention.

Orange trees for Texas, H. M. Stringfellow (*Texas Farm and Ranch, 28 (1909), No. 2, pp. 10–12*).—The author discusses the possibilities of orange culture in south Texas, as indicated by past experience. It appears that this section has been visited by killing freezes of short duration at irregular intervals several years apart. Among the methods suggested for the protection of tree trunks the author advocates the trial of sheet asbestos to be wrapped around the trunk of the tree. The circulation of air from beneath the wrapping is prevented by drawing a small amount of earth around the bottom and stuffing a little cotton between the tree and the wrapping at the upper end.

A B C of lime cultivation, J. Jones et al. (*Imp. Dept. Agr. West Indies Pamphlet 53, 1908, pp. 48*).—This pamphlet is of a popular nature containing instructions on the various details of lime culture and the preparation for market of green and pickled limes, raw and concentrated lime juice, citrate of

lime, and hand-pressed and distilled lime oil. Brief trade notes relative to the future of the citrate of lime industry, notes on lime culture in Montserrat, and tables showing the exports of lime products from Dominica and Montserrat for the years 1892–1907, inclusive, together with a brief bibliography of available literature on the lime tree and its products, are appended.

Coffee in the State of São Paulo (Brazil), A. Lalière (*Le Café dans l'Etat de Saint-Paul (Brésil). Anvers, 1909, pp. 415, pls. 93, dgms. 5, maps 3; rev. in Ann. Gembloux, 19 (1909), No. 1, p. 50*).—The author discusses the statistics of coffee production in Brazil and elsewhere and gives a detailed account of the culture of coffee in São Paulo. The processes for preparing commercial coffee are also discussed, together with the economic factors of production, commerce, and valorization.

The fermentation of cacao and of coffee, O. Loew (*Philippine Agr. Rev. [English Ed.], 1 (1908), No. 9, pp. 351–364, pls. 2*).—This is a reprint of the author's report on this subject (E. S. R., 20, p. 45).

The future of cacao planting, H. H. Smith (*Jour. Roy. Hort. Soc. [London], 34 (1908), No. 2, pp. 193–218*).—This lecture, together with some supplementary notes on cacao culture, has been noted from another source (E. S. R., 20, p. 540).

Report of the inspector of cocoanut trees, Department of Agriculture, for the year 1907, L. C. Brown (*Agr. Bul. Straits and Fed. Malay States, 7 (1908), No. 12, pp. 590–596*).—The area planted to cocoanut trees in the different Malay states at the end of the year 1907 is estimated at approximately 112,500 acres, or an increase of more than 7 per cent over the previous year. Notes are given on the condition of the plantations, including areas, planting and cultural operations, the production of oil and copra, prices received, etc.

All about cinnamon, A. M. and J. Ferguson (*Colombo, Ceylon [1908], pp. 43*).—This pamphlet contains considerable information compiled from various sources relative to the history and botany of cinnamon, the importance of the cinnamon industry in Ceylon and elsewhere, cultivation and preparation for market, cinnamon substitutes, analysis of cinnamon and cassia oils, etc.

Course on care of trees, G. H. Allen (*Boston, [1908], pp. 45*).—This pamphlet presents a general discussion of the life and growth of trees, together with popular descriptions of the more common trees and methods of planting, pruning, tree surgery, and bolting. The common injuries of trees and their control are also discussed.

Buying nursery stock (*Wis. Hort. Soc. Bul. 14, pp. 3–23*).—This popular bulletin contains suggestions relative to the purchase and selection of nursery stock, together with lists of fruits and flowering and ornamental plants for culture in Wisconsin, and a statement of the aims and purposes of the Wisconsin State Horticultural Society.

The best climbers south and north, P. J. Berckmans (*Gard. Mag. [N. Y.], 8 (1908), No. 6, pp. 273–275, figs. 5*).—A popular discussion of the important characteristics and value for garden purposes of a large number of evergreen and deciduous vines.

Violet culture at Hyers and in the Mediterranean region, J. Foussat (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 29 (1908), Nos. 46, pp. 582–591, figs. 5; 47, pp. 621–628, figs. 4; Prog. Agr. et Vit., 25 (1908), No. 48, pp. 653–662, figs. 7*).—A detailed account is given of the culture of violets in the above-named regions, both for cut flowers and for the manufacture of perfume.

Manual of floriculture, P. L. de Vilmorin (*Manuel de Floriculture. Paris, 1908, pp. VIII+410, figs. 324*).—The purpose of this work is to meet the needs of the amateur in his desire to raise a few flowers in the house or garden. Part 1 deals with the general principles of gardening, and part 2 contains an alphabetical and descriptive list of the more interesting plants, which are also

for the most part illustrated. For details of culture, except in special cases, cross references are made to part 3, which contains lists of plants grouped together according to their treatment. The work concludes with a list of the principal species classed by colors and flowering seasons.

Gardening in California, landscape and flower, J. McLaren (*San Francisco, 1909, pp. XIII+399, pls. 29, figs. 114, dyms. 9*).—This handbook was prepared with special reference to California conditions, and is submitted to amateur and professional gardeners of that State as supplementary to authoritative treatises and encyclopedias on landscape and flower gardening. The first 6 chapters deal with the location of site for house and garden, planning and planting operations, lawn making, etc. In several succeeding chapters popular descriptions and cultural notes are given of a large number of trees and shrubs, climbers and twiners, bulbous and tuberous rooted plants, palms, ferns, bamboos, grasses, succulents, and herbaceous and bedding plants. Other chapters deal with the development of ponds, lakes, and the water garden, parlor gardening, the window box, the amateur's conservatory, diseases and insects injurious to plants, general cultural notes, and sand reclamation. The work concludes with a calendar of operations for the year.

Scottish gardens, H. Maxwell (*New York and London, 1908, pp. X+252, pls. 32*).—In this popular work illustrations and descriptions are given of a representative selection of different types of old and new Scottish gardens. The colored illustrations, by Miss M. G. W. Wilson, are a prominent feature of the book which is presented with a view of stimulating an interest in garden development. Lists are appended of rhododendrons suitable to the climate of the west of Scotland, together with other shrubs which have proved hardy in Scotland and decorative shrubs, herbs, and bulbs.

Some continental gardens and nurseries, W. J. Bean (*Roy. Bot. Gard. Kew, Bul. Misc. Inform., 1908, No. 9, pp. 387–406*).—Brief descriptive notes are given of several gardens and nurseries in Europe relative to the more interesting trees and shrubs growing there and the general landscape effects of the gardens.

FORESTRY.

Report on forestry, L. A. Thurston (*Hawaii. Planters' Mo., 27 (1908), No. 11, pp. 466–471*).—A review of forest conditions and operations in Hawaii presented before the Hawaiian Sugar Planters' Association.

In connection with the report an account is given of an experiment by L. von Tempsky in planting trees on cultivated versus uncultivated land. A 1-acre lot was planted to eucalypts by merely digging holes and planting 6 ft. each way, whereas a 3-acre lot was plowed and harrowed twice and thoroughly cleaned from weeds before planting. A crop of potatoes was also harvested from the 3-acre lot. Deducting the value of the potatoes which netted $69.19, the cost per acre of growing the trees on the cultivated land was $25.90 as against $18.40 for the uncultivated acre. One year from planting, however, the tallest tree in the uncultivated lot was 5 ft. 3 in. and the average height of the trees 3 ft., whereas on the cultivated lot the tallest tree measured 16 ft. and the average height was over 10 ft. These results appear to warrant systematic cultivation of the tree plantations in Hawaii wherever the location will render it possible.

Report of the superintendent of forestry, R. S. Hosmer (*Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 4 (1907), pp. 9–46*).—This is a report on the operations in the division of forestry for 1907 relative to the establishment and management of forest reserves, forest extension and miscellaneous forest work. Brief statements are included from many of the district foresters relative to

the work under their charge. Notes are also given on the forest fire service and Hawaiian forestry in general, together with an outline of future work.

One new forest reserve was added during the year, making a total of 13 reserves with a combined area of 397,687 acres of which 252,818 are Government land. The data of importance relative to these reserves are given in tabular form.

Report of the forest nurseryman, D. HAUGHS (*Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 4 (1907), pp. 47–54*).—This is a progress report on operations at the Government Nursery, the Nuuanu Station, and the Tantalus Forest for the year ending December 31, 1907, in continuation of lines of work previously noted (E. S. R., 18, p. 1050).

Schedule for forest description (*Forestry Quart., 6 (1908), No. 4, pp. 370–382*).—This is a full translation of an elaborate schedule of forest description compiled by Albert and Schwappach at the instance of the Association of German Experiment Stations, and with a view of securing uniform usage. The principal divisions under the description of site are location, climate, and soil, which are again redivided into many subdivisions and sections. The principal divisions under the description of stand are species, management forms or systems, origin, age, density, condition of stand and numerical data.

Particular attention is called to the soil description, especially the section on humus and peat soils, which is based upon the new classification by Potonié. Suggestions are invited in the article as to improvements in nomenclature for use in this country.

The basket willow, W. F. HUBBARD (*U. S. Dept. Agr., Farmers' Bul. 341, pp. 45, figs. 23*).—This is a condensation and revision of Bulletin 46 of the Forest Service of this Department (E. S. R., 16, p. 161). The important phases discussed are the distribution and characteristics of the willow, its present culture in America, suggestions for improvement in culture, expenditure and returns in American willow culture, systems of peeling, outline of the field experiments of the Forest Service, and varieties of willows for growing in America. An account is also given of the manufacture of willow ware in the United States, together with suggestions for basket makers. The bulletin concludes with a summary statement by C. D. Mell of the essential considerations pertaining to the basket willow industry.

Observations on the culture of Juglans nigra and Carya alba, SCHWAPPACH (*Ztschr. Forst. u. Jagdw., 40 (1908), No. 12, pp. 772–776*).—Data are given showing the growth of the black walnut and shellbark hickory in certain experimental plantations in Germany. It is believed that both of these trees are worthy of greater attention than has been given them in the past.

The silva of Colorado. II, The poplars, aspens, and cottonwoods, F. RAMALEY (*Univ. Colo. Studies, 4 (1907), No. 3, pp. 187–197, figs. 6*).—This is the second of a series of papers dealing with the trees and shrubs of Colorado. The poplars, aspens, and cottonwoods are here treated in a manner similar to the pine family in the paper previously noted (E. S. R., 19, p. 148).

Some rare or otherwise interesting trees recently observed in the western parts of Georgia, R. M. HARPER (*South. Woodlands, 2 (1908), No. 5, pp. 96–100*).—Descriptive notes are given of several trees recently observed in Georgia. The list of trees discussed is considered as supplementary to the catalogue of Georgia trees previously noted (E. S. R., 20, p. 339).

Forestry: Some practical notes on forestry suitable for New South Wales. Conifers, J. H. MAIDEN (*Dept. Agr. N. S. Wales, Misc. Pub. 1072, pp. 82, figs. 26*).—It is the purpose of the author to publish lists of plants suitable for cultivation in New South Wales, and the present publication contains a classified list of those coniferæ which it is believed will flourish in some part of that country.

Brief practical notes are given on their habitats, leading characteristics, present occurrence, and probable value in New South Wales.

Contribution to the knowledge of some timbers of the Eritrea Colony, L. SENNI (*Bol. R. Orto Bot. Palermo, 7 (1908), No. 1–3, pp. 37–58*).—Brief notes are given on the structure and other characteristics of the woods of several timber trees found in the Eritrea Colony, Africa.

An analysis of Canada's timber wealth, B. E. FERNOW (*Forestry Quart., 6 (1908), No. 4, pp. 337–353, figs. 6, maps 2*).—A preliminary survey of forest conditions, forest types, and timber areas in the Dominion of Canada, with estimates of the standing timber in the different provinces. The study is based partially upon the information available, but largely on a study of the geological and climatic conditions which predicate forest types and forest conditions. The author estimates the present supply of timber in the eastern provinces, under prevailing methods of lumbering, as 300,000,000,000 ft. and for the whole of Canada 600,000,000,000 ft., although it is believed that this estimate could be conservatively doubled with a closer utilization accompanied by adequate fire protection.

A compilation of the meager reports on timber conditions in northern Canada has been prepared by R. E. Young, Canadian Department of Interior, Ottawa, and as far as practicable the results have been mapped. By special arrangement this map accompanies the present article. The important features shown are the poor scattered timber, the fairly wooded and thickly wooded areas, the brule, the prairie, and the bare or treeless lands.

Wood preservation by the open-tank process, E. F. HARTMANN (*Engin. News, 60 (1908), No. 27, pp. 740–742, figs. 14*).—This is a general discussion of the subject of wood preservation with special reference to the open-tank process (E. S. R., 19, p. 150). Descriptions and illustrations are given of several open-tank systems in operation in this country.

Experiments in tapping Ceara rubber trees, E. V. WILCOX (*Hawaii. Forester and Agr., 5 (1908), No. 12, pp. 318–320, fig. 1*).—A brief summary of the rubber experiments which are being carried on by the Hawaii Station and the Territorial Board of Agriculture and Forestry in cooperation with private rubber-planting interests. The results obtained thus far in the experiments appear to indicate clearly that the Ceara rubber tree in Hawaii will not only grow and thrive but will also yield profitable returns. Further experiments will include tests of various tapping methods and trials of various species of rubber. A series of fertilizer experiments is also planned.

Report on the cultivation of rubber in Ceylon and the Federated Malay States and Johore, F. T. P. WATERHOUSE (*Hawaii. Forester and Agr., 5 (1908), No. 11, pp. 249–304, figs. 32*).—This is a report to the Hawaiian Board of Agriculture and Forestry and the Hawaiian Rubber Growers' Association, upon the status of the rubber industry in the above-named countries, together with the climatic and soil conditions, and the methods of planting, cultivation, tapping, and treatment of rubber in use. The various phases of the report are illustrated.

The rubber industry in the territories of Manica and Sofala, W. H. JOHNSON (*London, 1908, pp. 39*).—This is a report on the source, collection, and preparation of wild rubber, together with the present status of the rubber planting and experimental tapping operations in the above territories. The author concludes that, although Ceara rubber satisfactory in quality and value can be produced in Portuguese East Africa, it still remains to be determined whether the use of improved methods of tapping will increase the yield of rubber to the remunerative point.

On the rubber extracted from the latex of Euforbia candelabro, O. REBUFFAT (*Atti R. Ist. Incoragg. Napoli, 6. ser., 59 (1907), p. 89*).—According to analyses made by the author, the latex of *Euforbia candelabro*, which plant grows abundantly in Eritrea, Africa, contains from 40 to 50 per cent of dry rubber which compares favorably in quality with the best grades.

Packing Para rubber seed for export, T. W. MAIN (*Agr. Bul. Straits and Fed. Malay States, 7 (1908), No. 11, pp. 548, 549*).—The Botanic Gardens at Singapore have been highly successful in exporting large quantities of Para rubber seed packed in burnt rice husk. A layer of burnt rice husk is put in the bottom of a tin box and alternate layers of seed and husk are added until the box is full. The rice husk is slightly moistened before packing to keep the seeds in a fresh state. The box is not soldered for fear of excessive moisture collecting inside.

Of 10,800 Para seeds packed in this manner and shipped to British Guiana, 64.4 per cent germinated after being packed a little over 53 days. A much larger similar shipment later on gave a germination of approximately 80 per cent.

DISEASES OF PLANTS.

Report on economic mycology, E. S. SALMON (*Jour. Southeast. Agr. Col. Wye, 1907, No. 16, pp. 267–332, pls. 23*).—Notes are given on the gooseberry mildew (*Sphærotheca mors-uvæ*), brown rot of cherries (*Sclerotinia fructigena*), cherry leaf scorch (*Gnomonia erythrostoma*), apple scab (*Fusicladium dendriticum*), crown gall of alfalfa (*Urophlyctis alfalfæ*), and other diseases. The effect of the different fungi on the host plants is described, and, so far as known, preventive treatments are recommended.

In connection with the alfalfa disease, the author states that the disease was first observed in England in 1906. Experiments were carried on in which a number of badly diseased alfalfa plants covered with galls were obtained from the locality where the disease was first noticed, and these galls were kept dry in the laboratory through the winter. Later a number of the galls were soaked in water and ground in a mortar, and this material used for inoculating well-grown potted plants of alfalfa, beets, mangels, and potatoes. Control pots were kept of each kind of plant by the side of the inoculated ones. The test plants were inoculated twice during the season, first when the growth was beginning to be active and later when the plants had attained full growth for the season. In November, when all the plants were examined, 5 out of 6 of the inoculated alfalfa plants were infested with galls, and in 2 cases the attack of the fungus had been so active as to destroy the plants. No formation of galls was observed on the control plants, or on the inoculated or control plants of mangels, beets, or potatoes.

The report concludes with a discussion on the occurrence of the gooseberry mildew (*S. mors-uvæ*) in England and the need for legislation to prevent its spread.

On the occurrence of diseases and insect injuries on cultivated plants in 1907, R. SCHANDER (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 1 (1908), No. 1, pp. 122, pls. 5, figs. 10, maps 2*).—Descriptive notes are given on the diseases and insect injuries observed on cultivated plants in Posen and West Prussia during 1907, the data being grouped according to the host plants, as cereals, root crops, forage plants, orchard and small fruits, vegetables, and forest plants. In addition to fungus and insect pests and their injuries, the author describes the injurious action of various meteorological phenomena, paying particular attention to the injury following the wintering of cereals.

Troubles of alfalfa in New York, F. C. Stewart, G. T. French, and J. K. Wilson (*New York State Sta. Bul. 305, pp. 333–416, pls. 12, fig. 1*).—This bulletin gives an account of the various hindrances to the successful culture of alfalfa in New York, special attention being given to dodder, fungus diseases, and the impurities and adulteration of seed.

Among the more serious troubles, aside from impure seed and improper soil, are dodder and the leaf spot. Dodder may be prevented to a considerable extent by thoroughly sifting the alfalfa seed before sowing. Apparently the dodder seldom ripens its seed in New York. Moreover, it is found to be a perennial and not an annual plant, as generally believed. Where dodder has become well established, the infested areas should be cut over and burned and the crowns of the plants cut off and destroyed. After this is thoroughly done, the area may be reseeded with clean seed without much probability of reinfestation.

Among the fungus diseases noted, the leaf spot (*Pseudopeziza medicaginis*) is the most troublesome and is, in fact, practically the only fungus disease of real importance. The appearance of the fungus, methods of dissemination, etc., are described, and suggestions given for its control. The only practicable method known is mowing the plants, but if close mowing is followed by a period of dry weather the plants suffer severely. When the disease makes its appearance shortly before the hay crop is ready to harvest it is advised that the plants be cut early to avoid the loss of leaves, which is sure to follow if cutting is delayed.

Among other diseases described are wilt (*Sclerotinia libertiana*), anthracnose (*Colletotrichum trifolii*), root rot and damping off (*Rhizoctonia* sp. and *Pythium debaryanum*), downy mildew (*Peronospora trifoliorum*), Ascochyta leaf spot (*Ascochyta* sp.), Stagonospora leaf spot (*S. carpathica*(?)), Cercospora leaf spot (*C. medicaginis*), Alternaria disease of seed, and frost blisters on alfalfa leaves. Alfalfa is sometimes attacked by nematodes (*Heterodera radicicola*), causing the root knot. A number of diseases of unknown cause are briefly described.

A bibliography of more than 100 titles concludes the bulletin.

Alfalfa troubles, F. H. Hall (*New York State Sta. Bul. 305, popular ed., pp. 3–16, figs. 2*).—This is a popular edition of the above bulletin.

A new smut on Bromus secalinus, P. Magnus (*Hedwigia, 48 (1908), No. 3, pp. 145, 146, fig. 1*).—A technical description is given of *Tilletia belgradensis*, a parasite of *B. secalinus*, which the author thinks is specifically different from *T. caries*. The new species is believed to be widely disseminated in eastern Europe and Asia.

Dry rot of potato tubers, G. H. Pethybridge and E. H. Bowers (*Econ. Proc. Roy. Dublin Soc., 1 (1908), No. 14, pp. 547–558, pl. 1; abs. in Jour. Roy. Hort. Soc. [London], 34 (1908), No. 2, pp. 282, 283*).—A description is given of a dry rot of potato tubers. The authors have come to the conclusion that it is due to *Fusarium solani*, acting independently of any other organism, and that the fungus is a true parasite. Many of the tubers attacked failed to produce plants when used as sets, and others became shriveled to dry hard masses when kept in storage.

The results of numerous experiments with this fungus are given, and it is recommended as preventive measures that all suspicious-looking tubers should be rejected when the crop is dug and not stored. Stored potatoes should be examined from time to time and all affected tubers removed. Care should be taken to prevent wounding during the lifting and handling of the crop. No wounded tubers should be stored, and storehouses should be disinfected from time to time.

Potato rot, I. B. P. Evans (*Transvaal Agr. Jour., 7 (1908), No. 25, pp. 64, 65, pl. 1*).—A description is given of potato rot due to *Nectria solani* and the statement made that large quantities of seed potatoes consigned to the Transvaal from France and Germany were found to be affected by this fungus. Experiments carried on at the Botanical Experiment Station, Pretoria, showed that the disease was readily communicated through the planting of diseased tubers, and precautionary measures are suggested for its control.

The fruit spot of apples, C. Brooks (*New Hampshire Sta. Sci. Contrib. 2, pp. 423–456, pls. 7, figs. 2; Bul. Torrey Bot. Club, 35 (1908), No. 9, pp. 423–456, pls. 7, figs. 2*).—As a result of studies, the author reports two distinct fruit spots that occur on New Hampshire apples.

The first, to which he gives the name fruit pit, is characterized by numerous sunken areas from 2 to 6 mm. in diameter on the surface of the apple. These depressions are somewhat hemispherical in shape and have the appearance of bruises. At a later stage the tissues begin to take on a brown tint, and later the surface cells become dark brown. The author has been unable to detect a bitter taste in the browned tissue of the fruit pits. The surface spotting is often accompanied by browning of the tissue immediately surrounding the vascular bundles. The surface spots may, however, occur without the internal browning, or the internal browning may be unaccompanied by any surface indications. Microscopical examination of a large number of fruit pits has given no indication of the presence of either bacteria or fungi, and it is believed that this form of disease is not very common in New England.

The second form of fruit spot of apples is said to be very common in the New Hampshire and Boston markets, often from 50 to 90 per cent of the fruit being spotted. It occurs on almost every variety of apple, but is worst on Baldwins, and the disease has been frequently referred to as Baldwin spot. The disease makes its appearance about the middle of August, and at this time one may notice spots of a deeper red color on the colored surface of the apple and darker green on the lighter portions. Usually they occur at a lenticel, but are sometimes covered with a smooth and apparently unbroken epidermis. The red color gradually changes to brown or black, and on the green surfaces the spots may become sunken, but the depressions are due to a lack of growth and not to any shriveling of the flesh.

The development of the spots seems to depend upon seasonal and storage conditions. When the weather is damp and foggy during the last weeks before harvesting, the spots on the red fruit surfaces develop rapidly and become black and sunken before the fruit is gathered. After gathering, the spots develop most rapidly on apples placed in boxes and barrels in cellar storage. Where the apples are placed immediately in cold storage there is little or no further development of the fruit spot. On withered fruit the green spots often stand above the surrounding portions, forming elevations that are in marked contrast with the yellow withered skin.

The author has sectioned many hundred fruit spots and found a parasitic fungus constantly associated with them. By means of inoculations he has demonstrated that this fungus, the various characteristics of which he describes, and for which he proposes the name *Cylindrosporium pomi* n. sp., is the cause of the trouble. The fungus gains entrance to the apple in July or early August, and when it finds its way into the intercellular spaces, obtains its nourishment from the plant cells. If the fruit is attacked before the cells have lost their power to respond to external stimuli, the fungus is soon partially surrounded by a layer of brown, thick-walled cells which may serve as a

barrier to further growth. If, however, the fungus attacks the host cells when they are nearly mature, it finds conditions more favorable to its development and the result is a more vigorous growth of the fungus and a rapid browning and drying of the host tissue.

Spraying with Bordeaux mixture has been demonstrated as a preventive of the disease, and applications made in June or early in July are as effective as those made earlier in the season.

A brief bibliography of the literature of this disease is given.

The apple-tree canker or black-rot fungus in South Africa, I. B. P. Evans (*Transvaal Agr. Jour., 7 (1908), No. 25, pp. 62–64, pl. 1*).—Attention is called to the occurrence of *Sphæropsis malorum* on apples from a number of districts in Cape Colony. It is apparent that the fungus is rather widely distributed and is causing considerable loss. The destruction of all decayed fruit, pruning out of cankers, and spraying with Bordeaux mixture are recommended as preventive measures.

Die back of peach shoots, G. Massee (*Roy. Bot. Gard. Kew, Bul. Misc. Inform., 1908, No. 7, pp. 269–271, pl. 1; abs. in Jour. Roy. Hort. Soc. [London], 34 (1908), No. 2, p. 272*).—The author states that during the past few years numerous inquiries have been addressed to the Kew Gardens respecting the die back of peach shoots.

In the spring the leaf buds expand normally without any suggestion of the disease, but about the time when the blossom is fully expanded the young leaves wilt, turn brown, and die within a few days. At the same time the petals change to a rusty brown color and the flowers droop, but remain attached to the branches for some time, as do also the leaves. Finally the shoots assume a deep claret-red color and shrivel more or less as the season advances.

About midsummer, when the dead leaves and flowers have been removed by wind and rain, trees that have been badly diseased can be readily recognized by the appearance of naked shoots varying from 1 to 2 ft. in length. If these dead branches be examined during the months of May and June of the following year they will be found to be more or less thickly studded with minute, dull-orange-colored, tendril-like bodies, consisting of myriads of spores of a parasitic fungus. This parasite has so far failed to produce any other fruiting form than the conidia, and it has been identified as *Nænospora crocea*.

Investigations have shown that the shoots are capable of infection only when quite young, but that when the mycelium has gained entrance into the tissues it spreads rapidly and affects the entire growth of the season. Successful inoculation experiments have been made, but when branches more than 1 year old were inoculated no trace of disease was produced. The spores of the fungus do not appear to retain their germinating power for more than 3 months.

The citrus fruit rot, I. B. P. Evans (*Transvaal Agr. Jour., 7 (1908), No. 25, pp. 60–62, pl. 1*).—According to the author, considerable injury is being done to citrus fruits by the blue mold (*Penicillium digitatum*). A description is given of the fungus and its method of attacking the fruits, and, on the basis of information given in a bulletin of this Department (E. S. R., 20, p. 43), the author urges care in the management of orchards and in the handling of fruit in the course of preparation for market.

The diseases of the tea plant, C. Maublanc (*Agr. Prat. Pays Chauds, 8 (1908), Nos. 65, pp. 91–102, pl. 1; 66, pp. 227–241, pl. 1*).—A study is given of the various diseases to which the tea plant is subject, the information being largely drawn from notes of the late G. Delacroix.

Among the diseases of the foliage described the most destructive are the gray blight (*Pestalozzia guepini*), anthracnose (*Colletotrichum camelliæ*), blister

blight (*Exobasidium vexans*), brunissure (*Sorosphæra theæ*), and red rust (*Cephaleuros virescens*). In addition a number of other species of fungi that are found upon the leaves are described, but they are said to be seldom serious in their attack.

Among the most destructive diseases of the stem and roots of the trees are the thread blight (*Stilbum nanum*), canker (*Nectria ditissima*), a stem disease (*Massaria theicola*), horse-hair blight (*Marasmius sarmentosus*), root rots (*Rosellinia radiciperda* and *Trametes theæ*), nematodes, and phanerogamic parasites.

A root disease of Para rubber trees, W. J. Gallagher (*Agr. Bul. Straits and Fed. Malay States, 7 (1908), No. 11, pp. 515–522, dgm. 1*).—The author reports the rather common occurrence throughout the Malay Peninsula of a fungus which attacks the roots of the Para rubber trees (*Hevea brasiliensis*). The disease is seldom distributed over an entire estate, but is confined to limited areas which appear to serve as centers for its distribution.

The presence of the disease is not usually noticed until the tree is dead. The first symptoms are observed in the leaves becoming brown about the edges, and the entire leaf soon loses its natural color. Little or no latex will flow from wounds in the stem, and later the trees are blown down. This is apparently due to the destruction of the lateral roots of the trees. So far as the author has observed, the attack seems to be in the more superficial lateral roots, and on different occasions he has traced the mycelia of the fungus along the lateral roots to decaying jungle stumps.

Thus far, owing to a lack of fruiting bodies, the identification of the fungus has been impossible, but it is believed to be one of the higher fungi similar to the bracket fungi.

As remedial measures, the author suggests trenching about trees and destroying the fungus by exposure to the sun and the application of lime.

Recent investigations on the disease of fir trees caused by Phoma abietina, E. Mer (*Bul. Soc. Sci. Nancy, 3. ser., 9 (1908), No. 2, pp. 104–144*).—A discussion is given of the disease of firs due to *P. abietina*. The author protests against the name rust or reddening of firs, as he states that the reddish-brown color is due simply to the oxidation of the tannins in the leaves followed by their destruction by the fungus.

While there has doubtless been considerable loss in some regions due to the defoliation caused by this fungus, the author thinks it will seldom prove of a very serious nature. Where the fungus is abundant, it is recommended that the lower branches be cut from the trees and burned. This will not only improve the vigor of the trees, but through the removal of leaves weakened by lack of illumination, etc., the spread of the fungus will be checked.

The leaf rust of spruce, P. Delforge (*Bul. Soc. Cent. Forest. Belg., 15 (1908), No. 9; noted in Rev. Gén. Agron., n. ser., 3 (1908), No. 10, pp. 424–427*).—A description is given of a leaf rust of spruce due to the fungus *Chrysomyxa abietis*, which has proved rather destructive in a number of localities in Europe during the past season.

The microscopical character of the fungus and its effect on the plants are described, the injurious action being apparently due to the consumption by the fungus of the elaborated material in the leaves and the diminution of their assimilating surface. Later the fungus causes a premature falling of the leaves, the amount of injury varying with the intensity of the attack, and in different years, regions, etc.

As means for preventing the spread of the disease, the author recommends thinning out the trees, so that there will be a better circulation of air, thus re-

ducing the humidity. When possible the branches that are badly affected should be cut off and, if this is done late in the season, burned in order to prevent the germination of the teleutospores.

Yellow stripe in daffodils, H. R. Darlington (*Jour. Roy. Hort. Soc. [London], 34 (1908), No. 2, pp. 161–166*).—While daffodils are usually considered as exceptionally free from disease, the author calls attention to what is apparently a physiological disturbance which results in considerable injury to the plants.

This trouble, which is called yellow stripe, shows itself in a mild case as a scarcely perceptible discoloration or yellowing of the veins of the leaves, but in more serious cases distinct bands of yellow may be seen running lengthwise of the leaves. In bad cases no flowers at all will be produced, and the leaves wither before they are fully developed. Except in bad cases the yellow stripes seldom run the full length of the leaf.

The trouble is quite distinct from the yellowing of the leaf which takes place during the summer after the maturity of the bulb. The author believes that it is not a specific disease, but is a consequence of unsuitable conditions of soil, or inclement weather at the critical stage in the growth of the plant.

Parasitic rose canker, H. T. Güssow (*Jour. Roy. Hort. Soc. [London], 34 (1908), No. 2, pp. 222–230, figs. 4*).—A new disease of roses is described, which is said to be spreading in certain parts of Great Britain.

The disease apparently starts in the one-year-old wood, and is not noticed until far advanced. One of its principal characteristics is shown in the deep fissures covered with an abnormal growth, which have the appearance of canker spots. The bark bursts and the wound does not heal normally, but the callus continues to grow until badly cankered spots result. The author believes that the disease is identical with that described by Soraner (E. S. R., 18, p. 1143), in which case the disease was attributed to frost injury.

A study of material showed there was present a fungus that is believed to be identical with that described by Köck (E. S. R., 17, p. 674), but the author thinks that the species does not differ from the common *Coniothyrium fuckelii*, and he considers the latter fungus to be the cause of the rose canker described.

Notes are also given on a blackberry canker due to *C. tumæfaciens* n. sp. This fungus causes the development of excrescences on the stems from the size of a pea to that of a walnut, or even larger. A technical description of the fungus is given.

A new lilac leaf disease in England, H. T. Güssow (*Gard. Chron., 3. ser., 44 (1908), No. 1146, pp. 404, 405, figs. 2*).—A description is given of a leaf disease of lilac due to *Pseudomonas syringæ*. The affected leaves are greatly disfigured and the injury appears suddenly and seems to spread rapidly. In an early study of the disease a fungus was quite commonly observed, and the injury was believed to be due to *Cladosporium herbarum*. Subsequent studies, however, showed that the fungus is of secondary importance and that the primary trouble is due to bacteria. The organisms have been isolated, cultivated in various media, and successful inoculation experiments conducted, resulting in the production of typical forms of the disease. The organism is apparently that described by van Hall (E. S. R., 13, p. 1019), and it has also been shown to be capable of infecting a number of other plants, among them the apple, sour cherry, buckwheat, *Atriplex hortensis*, black poplar, etc.

On account of the nature of the disease, the author states that spraying would be futile against its spread, but that a careful lookout should be kept for spots upon the foliage and all diseased shoots cut out and burned.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

The decision of the Supreme Court of the United States on the sale of imported game. T. S. Palmer (*U. S. Dept. Agr., Bur. Biol. Survey Circ. 67, pp. 12*).—The author here reviews the so-called Silz case which is based upon the sale in New York during the closed season of English plover and Russian grouse and the possession of one golden plover from England and one blackcock from Russia. The decision rendered on November 2, 1908, by the Supreme Court of the United States, which is here published in full, sustains the right of the State to regulate the possession and sale of game taken outside its boundaries. This decision directly affects dealers in game, importers, and many persons engaged in the millinery trade.

A history is given of the question of the right of a State to regulate possession and sale of game taken outside its boundaries, with references to decisions on possession and sale of imported game and fish.

First report on the economic features of turtles of Pennsylvania, H. A. Surface (*Zool. Bul. Penn. Dept. Agr., 6 (1908), No. 4–5, pp. 107–195, pls. 9, figs. 16*).—A report of studies made of the turtles of the State with special reference to their food habits. Eighteen species are described as probably found in the State.

The snapping turtle (*Chelydra serpentina*) is reported to be more destructive than beneficial in its feeding habits, particularly as it is liable to be a very serious enemy of young ducks in ponds. The musk turtle (*Aromochelys odoratus*) apparently feeds almost wholly upon mollusks and insects, and is considered as being decidedly beneficial. The painted turtle (*Chrysemys picta*) appears to be almost equally herbivorous and carnivorous. Out of 86 examined 61 had eaten insects, 10 containing specimens of the rose bug. The author concludes that this species must be regarded as beneficial.

The speckled tortoise (*Clemmys guttatus*) was found to be particularly insectivorous and beneficial rather than obnoxious. Forty specimens of the common box turtle (*Terrapene carolina*) were examined, 62 per cent containing vegetable matter and 80 per cent animal tissue, including snails, slugs, millipedes, and insects.

A food table of the turtles examined and a bibliographical list are given.

The influence of minimum temperatures in limiting the northern distribution of insects, E. D. Sanderson (*New Hampshire Sta. Sci. Contrib. 1, pp. 245–262, maps 7; Jour. Econ. Ent., 1 (1908), No. 4, pp. 245–262, maps 7*).—This is a paper read before the section of economic zoology of the Seventh International Zoological Congress, held at Boston in 1907.

Examinations of the nests of the brown-tail moth collected in Maine and New Hampshire have shown that in those of average size 72 to 100 per cent of the larvæ have been killed by a temperature of —24° F. or lower. In large nests on oak, however, only 57 per cent were killed. Studies have been made of the minimum isotherms. When these are compared with the boundaries of the life zones as charted by the Biological Survey of this Department, many similarities become apparent, but also a number of important differences. "Upon comparing the distribution of several well-known injurious insects with the average annual minimum isotherms, they were found to define the northern limits in some instances rather better than the life zones."

Evidence is brought forward to show that the sum of positive temperatures [effective temperatures] for the season of growth and reproduction is not the only or the most important factor governing distribution northward, but that

the minimum temperature is perhaps the more important factor. Among the insects whose distribution is considered as more or less controlled by minimum temperatures are brown-tail moth, harlequin cabbage bug, cotton-boll worm or corn earworm, West Indian peach, San José and other scales, asparagus beetle, elm-leaf beetle, Morellos orange fruit worm (*Anastrepha ludens*), rose chafer, and the striped cucumber beetle. It is concluded that the present upper austral zone of the survey does not extend far enough to the northeast and extends too far to the northwest. Maps are given showing the isotherms for minimum temperatures in the United States and Europe and of the life zones and the distribution of San José scale in this country.

Observations on the social parasites and slavery of ants, E. WASMANN (*Biol. Centbl., 28 (1908), Nos. 8, pp. 257–271, fig. 1; 9, pp. 289–306, fig. 1; 10, pp. 321–333, fig. 1; 11–12, pp. 353–382; 13, pp. 417–441; abs. in Nature [London], 79 (1908), No. 2037, pp. 51, 52*).—A series of papers giving the results of recent elaborate observations and experiments respecting the behavior of different species of ants, living together in the same nest, toward each other and their treatment of small beetles and other parasites which live in ants' nests.

A preliminary list of the lepidoptera of western Pennsylvania collected in the vicinity of Pittsburg, II. ENGEL (*Ann. Carnegie Mus., 5 (1908), No. 1, pp. 27–136*).—A list prepared by the author in which the nomenclature and order given in Dyar's list is followed. Nearly 1,500 species and varieties are enumerated and it is stated that more than 100 additional species from this section still remain in collections awaiting determination.

A monographic catalogue of the Mymarid genus Alaptus of Haliday, with descriptions of three new North American forms and of A. iceryæ from type material, A. A. GIRAULT (*Ann. Ent. Soc. Amer., 1 (1908), No. 3, pp. 179–195, figs. 5*).—Of the 11 species here listed, the host relations of 4 are known, 3 having been reared from coccidæ and 1 from psocid eggs.

Locust plague in Panama, G. T. WEITZEL. (*Daily Consular and Trade Rpts. [U. S.], 1908, No. 335¼, p. 5*).—The plague of locusts against which the government of Panama has been fighting for several months has become a serious menace to the agricultural interests of the country, particularly in the district of Chepo, where great areas have been denuded of foliage and plants and crops almost totally destroyed. A commission appointed appropriated the sum of $475 per month to fight the pest.

"The method of extermination most generally adopted has been to dig a trench about 50 ft. in length, 2 ft. wide, and 1 ft. deep, with perpendicular sides, in which the locusts are driven by men beating the grass and trees with switches. In this way millions are collected and are destroyed with a solution of strong lye soapsuds. The trench is then refilled with earth so as to allay the odor."

Notes on grasshopper (or locust) swarms in New South Wales during 1907–8, W. B. GURNEY (*Agr. Gaz. N. S. Wales, 19 (1908), No. 5, pp 411–419, pl. 1, figs. 6*).—Besides *Chortoicetes terminifera* which is described as the most widespread and destructive, *C. pusilla*, *Oedalus senegalensis*, *Locusta danica*, and *Cyrtacanthacris exacta* are mentioned. *Sarcophaga pachytyli* and *S. aurifrons* are parasitic upon these pests.

In experiments with kerosene emulsion about 50 per cent were destroyed. Poisoned bait consisting of Paris green and bran mixed in the proportion of 1:10 and made into a mash with water sweetened with molasses destroyed many. An emulsion of a carbolic sheep wash was successfully used. Many of the larger hoppers were found eventually to recover from the effects of contact sprays.

Locust destruction work in the Transvaal. D. GUNN (*Transvaal Agr. Jour., 7 (1908), No. 25, pp. 75–80, maps 3*).—A report upon the work against the brown

and red locust during 1907–8 in the various districts of the Transvaal, accompanied by maps showing the areas infested.

Treatment of cotton pests in the West Indies in 1907, H. A. Ballou (*West Indian Bul., 9 (1908), No. 3, pp. 235–242, figs. 10*).—The attacks by *Alabama argillacea* were very severe during the year, except in St. Vincent, where it appeared for the first time. On this island the Jack Spaniard (*Polistes annularis*) proved a satisfactory check, while *Calosoma calidum* was also of considerable benefit. The smaller cotton worm (*Aletia luridula*) was the prevailing pest in certain fields in Barbados and was also found in Antigua. *Heliothis obsoleta* occurred in greater numbers than in previous years and threatened to become a serious pest on a few estates in Barbados and Antigua. The corn earworm (*Laphygma frugiperda*) attacked cotton bolls to some extent on a few estates.

Aphids were abundant in certain localities in Barbados. Ladybirds and the lace-wing fly, though abundant in most parts of the island, were lacking in others or not sufficiently abundant to prevent damage by this pest. Cutworms (*Prodenia* spp.) were less injurious than in previous years. Poison bait made of bran, Paris green, and molasses gave good results. Cotton stainers (*Dysdercus* spp.) were not a serious pest generally during the season, although very abundant and injurious on a few estates. The practice of collecting and killing them was a sufficient check.

The leaf blister-mite (*Eriophyes gossypii*) though present in nearly every cotton field in the island did not cause as much injury as formerly. Sulphur and lime gave good results. The red maggot (*Porrichondyla gossypii*) was not reported as doing great damage. The only remedy practiced is that of cutting out attacked stems and branches. The cotton black scale (*Saissetia nigra*) was a serious pest, but the native parasite, *Zalophothrix mirum*, has been increasing in abundance during the past 2 years and it is hoped that it may prove an efficient check.

The boll-weevil problem, with special reference to means of reducing damage, W. D. Hunter (*U. S. Dept. Agr., Farmers' Bul. 344, pp. 45, figs. 9*).—This is a summary account of the practical results obtained from investigations of the cotton boll weevil by the Bureau of Entomology of this Department and is intended to supersede Farmers' Bulletin 216, previously noted (E. S. R., 16, p. 991). Special attention is given to the life history and habits of the pest. The methods of control, which are described in detail, are summarized as follows:

"Destroy the vast majority of weevils in the fall by uprooting and burning the plants. This is the all-important step. It results in the death of millions of weevils. It insures a crop for the following season.

"Destroy also many weevils that have survived the preceding operation and are found in the cotton fields and along the hedgerows, fences, and buildings. This is done by clearing the places referred to thoroughly.

"As far as possible, locate the fields in situations where damage will be avoided. This can not be done in all cases but can frequently be done to good advantage.

"Prepare the land early and thoroughly in order to obtain an early crop. This means fall plowing and winter working of the land.

"Provide wide rows, and plenty of space between the rows and the plants in the drill, for the assistance of the natural enemies of the weevil, which do more against the pest than the farmer can do himself by any known means. Check-rowing, wherever practicable, is an excellent practice.

"Insure an early crop by early planting of early-maturing varieties, and by fertilizing where necessary.

"Continue the procuring of an early crop by early chopping to a stand and early and frequent cultivation. Do not lose the fruit the plants have set by cultivation too deep or too close to the rows.

"Where the labor is sufficient, pick the first-appearing weevils and the first-infested squares. Do not destroy the square but place them in screened cages. By this means the escape of the weevils will be prevented, while the parasites will be able to escape to continue their assistance on the side of the farmer.

"Use a crossbar of iron or wood, or some similar device, to cause the infested squares to fall early to the ground, so that they will be exposed to the important effects of heat and parasites.

"Do not poison for the leaf-worm unless its work begins at an abnormally early date in the summer."

The red cotton bug (Dysdercus cingulatus), H. M. LEFROY (*Mem. Dept. Agr. India, Ent. Ser., 2 (1908), No. 3, pp. 47–58, pl. 1*).—This pest is described as the source of considerable injury to cotton in reducing the vitality through sucking the juices of young shoots and bolls, producing small bolls containing bad fiber. Its natural enemies include a tachinid fly that is parasitic upon the adult bug, a reduviid (*Harpactor costalis*) and several birds, particularly the black-headed oriole (*Oriolus melanocephalus*).

The cotton leaf roller (Sylepta derogata), H. M. LEFROY (*Mem. Dept. Agr. India, Ent. Ser., 2 (1908), No. 6, pp. 95–110, pl. 1*).—The life history and habits of this moth are here described. It is a source of injury through stripping the leaves of the cotton plant. An undescribed hymenopterous parasite is stated to be an important factor in checking the increase of the pest. The destruction of the rolled leaves with the caterpillars from the beginning of the season is said to be effective. Spraying with lead arsenate is reported to control the pest.

The tobacco caterpillar (Prodenia littoralis), H. M. LEFROY (*Mem. Dept. Agr. India, Ent. Ser., 2 (1908), No. 5, pp. 79–93, pl. 1, fig. 1*).—A detailed account is given of the biology of this insect. In addition to the tobacco plant of which it is a serious pest, it is described as injuring a number of other crops including rice, corn, and grass, but attention is called to the fact that while in Egypt it has been described as attacking cotton it has not been found to do so to any extent in India.

Hand collection of the leaves within 3 days after hatching and the application of lead arsenate where spraying is possible are recommended. Where the caterpillar is so abundant that it moves in swarms, digging trenches to isolate it is recommended, the trenches preferably to be filled with water and kerosene poured thereon.

Attention is also called to the fact that the American boll worm (*Chloridea obsoleta*), while abundant on other food plants has in India only twice been observed feeding upon cotton.

Melon aphis, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope, 33 (1908), No. 4, pp. 491–496, figs. 2*).—*Aphis gossypii* by reason of its great destructiveness attracted attention in many districts during 1907. In the Cape Peninsula whole fields of watermelons and cucumbers were killed by it, and these and other cucurbitous plants including the calabash were seriously injured by it through the southwestern parts of the colony. The principal South African ladybird feeding on this pest is said to be *Chilomenes lunata*. Syrphus fly enemies of this insect are also said to be common and several species of internal parasites have been bred. Preventive and remedial measures are considered.

A few orchard plant lice, C. P. GILLETTE and E. P. TAYLOR (*Colorado Sta. Bul. 133, pp. 3–47, pls. 2, figs. 3*).—The authors report studies of the life his-

tories, habits, and nature of the injury to Colorado orchards caused by several species of plant lice with preventive and remedial measures.

The woolly apple aphis (*Schizoneura lanigera*) is considered as serious a pest in Colorado as the codling moth. The greatest injury to the tree is due to the root attack, but direct losses are greatest from injury to the branches and fruit. But little injury appears to be done to roots that are more than 10 in. below the surface of the soil, which fact should be taken advantage of in setting trees. Succulent and rapid growing parts, especially grafts, are said to be very susceptible. In Colorado the Missouri pippin seems to be worst infested while Northern Spy is practically exempt. Care should be taken that only clean stock be set out. Experiments were conducted with insecticides from which the following directions have been formulated as to the best methods of treatment:

"Just before the buds open in the spring, spray very thoroughly with a 7 per cent kerosene emulsion, black-leaf dip 1 lb. to 60 gal. of water (or some other strong tobacco decoction) or a good whale-oil soap, 1 lb. to 6 gal. of water. Spray the entire trunk and also the ground about the crown of the tree. Immediately after treatment apply a tanglefoot band over cotton so as to prevent the upward migration. If the lice become very numerous at any time upon the tops, spray them forcefully with the 7 per cent emulsion, or black leaf, 1 part in 70 parts of water. Root treatments are temporary in their effects. When the roots become very badly infested, treat as above described with 10 per cent kerosene emulsion, black leaf dip (1:50), 2 to 3 gal. to a tree, or, if the soil is quite open and porous, carbon bisulphid."

The green apple aphis (*Aphis pomi*), which is one of the worst orchard pests in Colorado, is the species most commonly brought into the State in the egg stage upon nursery stock. The Missouri pippin is said to be particularly attacked by this species while the Northern Spy is rarely so. Experiments have shown that oil emulsions destroy the eggs only at very high strengths. Lime-sulphur mixtures have proven quite successful, however. Kerosene emulsions one-fifteenth oil and black-leaf dip 1 part in 70 parts of water, are said to be the two sprays most favored at the present time.

The clover aphis (*Aphis bakeri*) ranks next to *A. pomi* in numbers as a leaf-infesting species of the apple. While it appears to have a tendency to accumulate in the apple blossoms, it is not as yet considered a serious pest in Colorado orchards.

The European grain aphis (*Aphis (Siphocoryne) avenæ*) has been found upon apple, pear, and quince trees in the State but not in sufficient numbers to do appreciable harm.

The rosy apple aphis (*Aphis pyri*) has appeared in orchards of the Grand Valley attacking the leaves and causing them to curl similarly to these affected by *A. pomi*.

The sweet-clover aphis (*Aphis medicaginis*) while preferring certain legumes, as sweet clovers, locos, black locust, and wild licorice, has been frequently found early in the season upon tender new shoots of the apple and other fruit trees. It is not likely, however, that the species will ever become a serious orchard pest.

Two peach plant lice, the green peach aphis (*Myzus persicæ*) and the black peach aphis (*Aphis persicæ-niger*) are considered. *M. persicæ* is said to be by far the most abundant peach louse in the State. This species is said to have been reported in this country upon the peach, plum, cherry, and many succulent plants under different names. *A. persicæ-niger* was first observed in Colorado in 1905. While at present known to occur only in a few localities on the west-

ern slope of the State it is expected that it will, in a few years, become distributed throughout nearly all the important peach sections.

Three important plum lice considered are the mealy plum louse (*Hyalopterus arundinis*) which is sometimes sufficiently numerous to completely cover the under surface of the leaves, the rusty brown plum louse (*Aphis setariæ*) which is found particularly upon red or American plums, and the hop plant louse (*Phorodon humuli*) which inhabits the plum as a winter host plant.

The black cherry louse (*Myzus cerasi*) is said to be generally distributed through the orchards of the eastern slope of the Rocky Mountains in Colorado.

Directions for the preparation of the insecticides recommended in the bulletin are appended.

Orchard plant lice and their remedies, C. P. Gillette and E. P. Taylor (*Colorado Sta. Bul. 134, pp. 3–16*).—An abbreviated edition of the above.

Control of leaf blister mite in apple orchards, P. J. Parrott (*New York State Sta. Bul. 306, pp. 417–438*).—This is a continuation of work previously noted (E. S. R., 18, p. 955).

The general spotting of apple foliage by this pest is said to have been an annual occurrence for several years, the pest having now become quite common throughout the apple-growing sections of western New York. It is also known to occur in Massachusetts, Pennsylvania, Illinois, and the province of Ontario.

It is concluded that the experiments reported show very conclusively that the blister mite is not a difficult pest to combat and that it can be efficiently controlled by sulphur sprays, miscible oils, and homemade oil emulsions. Orchards regularly sprayed with such mixtures are not subject to injury by the mite.

"Comparative tests of the boiled lime-sulphur wash, the homemade concentrated lime-sulphur wash, and two commercial preparations gave equally satisfactory results. One application of either of these sprays has practically prevented spotting of foliage by the mite.

"With the increased availability of the sulphur sprays these are now practicable remedies for the treatment of apple orchards for the blister mite. In employing these remedies for this purpose, a plan of spraying well adapted for the treatment of apple trees is an application of a sulphur wash as the buds are swelling and before the leaves appear, followed by the usual second and third applications of the Bordeaux mixture in their proper season."

Sulphur sprays for blister mite, F. H. Hall (*New York State Sta. Bul. 306, popular ed., pp. 3–7*).—This is a popular edition of the above bulletin.

A note on the fumigation of citrus trees with hydrocyanic-acid gas, F. Thomsen (*Transvaal Agr. Jour., 7 (1908), No. 25, p. 74, pl. 1*).—A description with illustrations of frame tents used in fumigating citrus trees. A table is given showing the quantities of materials to be used in the various sizes of of tents.

The castor semi-looper (Ophiusa melicerte), H. M. Lefroy (*Mem. Dept. Agr. India, Ent. Ser., 2 (1908), No. 4, pp. 59–77, pls. 2, fig. 1*).—A general account of the life history and habits of this insect, which is the source of considerable injury to the castor bean (*Ricinus communis*). In addition to several other plants, tea is occasionally attacked. A hymenopteron and a tachinid fly are reported as important enemies. Cultural methods, hand picking, and the application of arsenicals are described as remedial measures.

Pemphigus tessellata: Alternate host, migrants, and true sexes, Edith M. Patch (*Ent. News, 19 (1908), No. 10, pp. 484–488, pl. 1*).—From observations recorded by the author it appears that the maple is an alternate host plant of the alder blight (*Pemphigus tessellata*) and that the maple forms described by Riley as *P. acerifolii* are *P. tessellata* migrants.

Chrysomelid enemies of the osier and experiments with liquid insecticides, J. Feytaud (*Rev. Vit., 30 (1908), Nos. 771, pp. 344–348; 772, pp. 374–378; 773, pp. 404–409*).—The 2 species of willow largely grown in the department of Gironde (*Salix fragilis* and *S. viminalis*) are attacked by a number of leaf-eating beetles. These pests are said to reduce enormously at times the quantity and quality of this important crop. Species belonging to the genera Lina, Phratora, Phœdon, Plagiodera, etc., are the most injurious, particularly the species *Lina populi, L. tremulæ*, and *Phratora vulgatissima*. Many of the adult beetles, particularly of *L. populi*, are easily destroyed by burning litter, etc., in the vicinity of the osieries, into which they crawl to hibernate. Hand picking is said to be practiced to some extent, but experiments conducted appear to show that tobacco decoction mixed with soap is the most effective means of control. *L. populi* is said to be attacked by a tachinid fly (*Exorista dubia*), which deposits its eggs upon the larvæ. A tachinid is also reported to attack *P. vulgatissima*, a parasitism of 30 per cent having been recorded.

A brief account of the anatomy and classification of the Ixodoidea with special reference to the French fauna, A. Bonnet (*Arch. Par., 12 (1908), No. 2, pp. 224–267, figs. 44*).—The anatomy, biology, and classification of ticks are briefly considered. A table is given for the separation of the genera and species occurring in France, together with brief descriptions of each, and a bibliographical list.

A list of the ticks of South Africa, with descriptions and keys to all the forms known, C. W. Howard (*Ann. Transvaal Mus., 1 (1908), No. 2, pp. 73–169, pls. 16*).—An account of the ticks occurring in South Africa, their hosts and distribution, with descriptions and tables for their classification. A bibliographical list is given.

A new genus of the Siphonaptera, C. Fox (*Ent. News, 19 (1908), No. 10, pp. 452–455, fig. 1*).—A species of flea taken from *Scapanus californicus* in San Francisco is described as belonging to a new genus and species and named *Corypsylla ornatus*.

Some Irish experiments on warble flies, G. H. Carpenter (*Irish Nat., 17 (1908), No. 11, p. 245*).—Life history studies and investigations of the efficacy of commonly accepted means for checking the attacks of warble flies have been carried on during the past 4 years. Experiments have shown that the application of dressings such as carbolic dip, oil and tar smear, and paraffin emulsion are of but little value in preventing egg deposition on the animal.

In the spring of 1907 on one farm the maggots were systematically squeezed out and destroyed, 2,000 thus being obtained from 194 head of cattle or an average of over 10 per head. The effect was strikingly shown in the spring of 1908 when an examination made on this farm of 166 head of cattle resulted in the finding of but 694 maggots or an average of 4.2 per head. Two calves muzzled by day and tied between stakes at night during the summer of 1907 were the only ones on the farm entirely free from warbles in the spring of 1908.

Hypoderma bovis seems to be more common in Ireland than *H. lineata*. In both species the interval between the emergence of the maggot from the beast's skin and the appearance of the fly is about 7 weeks.

The extermination of mosquitoes, E. C. Levy (*Richmond, Va., Health Dept., 1908, pp. 14, figs. 3*).—The health department of the city of Richmond is carrying on an active campaign against mosquitoes. This article describes their breeding habits and methods of extermination through draining, filling in, or kerosening the breeding places.

Miscellaneous papers on apiculture. The relation of the etiology (cause) of bee diseases to the treatment, G. F. White (*U. S. Dept. Agr., Bur. Ent. Bul.*

75, *pl. 4, pp. 33–42*).—In this paper, which was presented at the meeting of the National Bee Keepers' Association, held at Detroit, October 14, 1908, the author discusses the relation of the etiology of bee diseases to their treatment. The predisposing causes of disease considered include age, sex, heredity, race, climate, and preexisting disease, while the exciting causes are found in food and micro-organisms. American foul brood, European foul brood, so-called "pickled brood," and paralysis are described and the importance of bee keepers becoming acquainted with their etiology is pointed out.

South African bee keeping. H. L. ATTRIDGE (*Agr. Jour. Cape Good Hope, 32 (1908), No. 6, pp. 692–704, figs. 9; 33 (1908), Nos. 1, pp. 46–56, figs. 11; 2, pp. 156–170, figs. 12; 3, pp. 307–317, figs. 6; 4, pp. 438–460, figs. 14*).—An extended account of bee keeping in South Africa, illustrated by many original photographs.

FOODS—HUMAN NUTRITION.

Digestibility of starch of different sorts as affected by cooking, EDNA D. DAY (*U. S. Dept. Agr., Office Expt. Stas. Bul. 202, pp. 42, figs. 6*).—Artificial digestion experiments, using malt diastase, taka diastase, and saliva, were made with raw starch, starch cooked below the boiling temperature, and starch cooked for different lengths of time and in different ways: Potato, arrowroot, tapioca, sago, wheat, corn, rice, and barley starches were used in the experiment. The report of experiments is preceded by a review of previous investigations on the subject, particular attention being given to the amyloses and related substances found in raw starch grains.

As the author points out, the starches used in the experiments had been separated from the other substances with which they are ordinarily combined in foods, and this and the further fact that artificial methods of digestion were used should be borne in mind in considering the results.

"Raw starch, as shown by the experiments reported, digests very much more slowly than the starch in the forms of a paste.

"Starch paste made below the boiling temperature of water is as easy to digest as that which has been boiled a few minutes, though it is not as homogeneous.

"Potato, arrowroot, and probably tapioca and sago starch pastes are not made more easily digestible by long-continued cooking. On the other hand, the cereal starches are made more easily digestible by long cooking, though the change occurs very slowly and perhaps the increased digestibility is not sufficiently great to justify the trouble, under ordinary circumstances at least, for separated starch such as is used in cookery. However, in the case of starch still inclosed in cellulose cells, as in many starchy foods, the long-continued cooking may be necessary. The commercial preparations of cornstarch require 30 to 40 minutes' cooking because of the improvement in flavor which results.

"Skin formation as well as lumps should be avoided in cooking starch—the latter contain raw starch, the former reverted amylodextrin, and both are very slow of digestion.

"The selection of potato starch instead of corn or wheat starch for thickening sauces, in accordance with the custom of French cooks, is rational, since it contains no rose amylose and so forms a clearer and more digestible sauce, and since it does not require 40 minutes' boiling for improvement in flavor, as is the case with cornstarch.

"Increasing the proportion of diastase to starch in artificial digestion experiments markedly hastens the digestion of both blue and red amylose. It would appear, therefore, that eating starchy foods slowly, which would of course increase the proportion of saliva and ptyalin to a given quantity of starch, would

be of more value from the standpoint of digestion than would any cooking of starch beyond the stage of paste formation."

Yeast, F. L. Ward (*Bakers' Helper, 22 (1908), No. 260, p. 1134*).—A summary of data on the conditions which are considered essential for satisfactory yeast development, together with information regarding a course in yeast at the University of California which, though designed primarily for vineyardists and wine makers, is in the author's opinion also applicable to the baking industry.

Changes in stored flour, H. G. Bell (*Oper. Miller, 13 (1908), No. 12, pp. 591, 592, figs. 4; Bakers' Helper, 22 (1908), No. 260, pp. 1132–1134, figs. 4*).—The acidity and baking qualities were studied of flours stored at high and low temperature with high and low humidity in each case.

"The warm, dry storeroom seems to be the most desirable for maintaining the quality of the flours. The next best condition of storage seems to be where the storeroom is cool and comparatively dry. The worst condition is where the storeroom is cool and very damp. In such a place, bacteria and fungi or molds grow most readily and work destruction on the flour stored there. Then, to bakers and flour merchants we would say—do not store your supply of flour in damp underground or partly underground storerooms. If stored there it will get sour and poor in quality in a very short time. Store supplies of flour in a warm, dry place or, if it can be kept dry, in a cool, dry place."

The character of old flours, L. Vuaflart (*Ann. Chim. Analyt., 13 (1908), No. 11, pp. 437, 438*).—Data are reported and discussed regarding the examination of 4 samples of new flour which in the character of their gluten and acid content resembled old flours.

Milling and baking test. Tests of flour sold in North Dakota, E. F. Ladd (*North Dakota Sta. Bul. 82, pp. 717–793*).—The investigations here reported were undertaken to determine the relative milling and bread making qualities of Fife and Bluestem wheats as compared with durum wheats and for the purpose of bringing together data regarding the range and composition of wheats and flours from local grown products. Examination was also made of commercial flours on sale in North Dakota with a view to determining their composition and bread making quality, and also to secure data regarding the extent to which bleaching of flour is practiced.

In the comparison of local grown wheats milling tests were made with 15 samples of Fife and Bluestem wheats and an equal number of samples of durum wheats.

In general, "the durum gave a rather larger percentage of flour than did the Fife and Bluestem, and the average weight per bushel for clean wheat was greater, yet the amount of high-grade flours were in favor of the Fife and Bluestem. . . .

"It takes slightly less durum to produce a barrel of flour than of Fife and Bluestem. The percentage of bran is less in the durum than in Fife and Bluestem, but the proportion of shorts is higher. The kernel of grain in the case of durum averages nearer than for the Fife and Bluestem."

As shown by the gluten tests, "the differences in expansive properties are particularly marked between the several grades of flour. The introduction of the first clear into the patent, or the lengthening out of the patent, as is often done, must necessarily result in decreasing the expansive properties. When the patent and first clear are united and sold as straight, or, as is more often done, bleached and sold as patent, or, at least, in place of patent, we can not wonder at the lowering of strength now generally recognized in many brands of flours.

"The expansive properties of the durum gluten are not equal to that from the Fife, as indicated in these tests, and this is further borne out in the baking

tests with the two flours. The physical properties of the gluten from a patent or first clear also differ in many other respects not clearly indicated by the above tests, but soon recognized by one who is engaged in washing out glutens."

The analyses of the flour samples showed in general that "the durum wheats have shown higher percentages of total protein than found in Fife and Bluestem wheats. The analyses of the flours do not average as high for the same grade of durum as for other wheats. On the other hand, analyses of previous years have shown the reverse order, but more markedly is this noticeable by comparing the analyses above given with the average for the section beyond on commercial flours as taken up in the markets of this State."

From the baking tests which were made with the flours ground at the station and the commercial samples it appeared, that "the volume of loaf for the commercial flours averages higher than for the experimental lots tested, but on the other hand the amount of flour used per loaf is greater for the commercial product and the number of loaves of bread per barrel is proportionately less than for the experimental flours. In making comparison it is essential that all this data be taken into consideration. . . .

"The commercial flours required a greater amount of flour to produce a dough of a given consistency and they made a less number of loaves of bread per barrel than any flour produced at the mill, including the first patent and the first clears. On the other hand the volume of the loaf, for the commercial flours, averaged quite a considerable above that of the test flours produced at the college. It should be said also that when several of the mill flours were blended better results were secured in bread production than where the individual samples were tested alone."

As regards the gluten tests made with the commercial flours, the results "show less of wet and of baked gluten for the commercial flour than either of the others and in expansion the gluten for the commercial flours is less than that produced from Dakota Fife and Bluestem wheats as a patent, but superior to that produced from the durum."

Analyses of the commercial flours are reported as well as determinations of the acidity and the nitrogen present as nitrites. The data indicate on an average 2.65 mg. nitrites per kilogram of flour. According to the author, the investigations are to be continued.

Chemically treated flours, E. F. Ladd (*North Dakota Sta. Spec. Bul. 9, pp. 1–14; Jour. Biol. Chem., 6 (1909), No. 1, pp. 75–86*).—From artificial digestion experiments and studies of the effect of bleaching on flour constituents and from earlier work on related topics, conclusions were drawn from which the following statements are quoted:

"Nitrous and nitric acid are two of the constituents formed from the bleaching of flour with nitrogen peroxid. The nitrites and nitrates, or nitrite and nitrate reacting material, are among the products formed in the flour. Bread as baked in the home by the domestic method will contain from one-third to one-half of the nitrite reacting material found in the flour.

"Oil properly extracted and purified from unbleached patent flour contains no nitrogen. Oil extracted from bleached flour and purified by the same methods gives a strong reaction for nitrogen, thus confirming the statement made by Lewkowitsch. . . . Artificial digestion experiments with pepsin solutions show that the gluten from the unbleached flour was digested in 4 hours and 57 minutes, while under the same conditions the gluten from the bleached flour was digested in 8 hours and 40 minutes.

"The baked gluten from the bleached and unbleached flours showed similar variations but not so wide, the time of digestion being much less; the same is true for the bread made from such flours. In pancreatic digestion the glutens

digested in 3.19 hours from bleached flour, and in 2.31 hours from unbleached flour. The time of digestion in pancreatic solutions of the baked gluten and of the bread was in favor of the unbleached product. The experiments made with the keeping quality of bread made from bleached and unbleached flour demonstrated the antiseptic effect of the bleaching agent.

"It has been demonstrated that when the diazo or like action took place, the acid acted upon the gluten of the flour changing its composition so that nitrogen gas was given off when the flour was treated with an acid."

Effect of bleached flour extracts on rabbits, E. F. Ladd and H. L. White (*North Dakota Sta. Spec. Bul. 9, pp. 15–26*).—The authors have tested the effects on rabbits of alcoholic and aqueous extracts of bleached and unbleached flour.

Quotations from their conclusions follow:

"There are produced in flour, as the results of artificial bleaching, toxic bodies. . . . Alcoholic extracts prepared from unbleached flour and fed to rabbits did not affect them. Alcoholic extracts prepared in the same manner from commercially bleached flour and fed to the rabbits in the same way caused their death within a few hours. Alcoholic extracts prepared from overbleached flour in the same manner and fed in the same way to rabbits caused their immediate collapse and death.

"Aqueous extracts prepared from overbleached flours when fed to rabbits caused their immediate collapse and death. Alcohol and aqueous extracts from overbleached flour, when neutralized with sodium bicarbonate, and fed to rabbits, caused the death of the rabbits in a short time, demonstrating that it was not the acidity that produced the death of the rabbits.

"In preparing aqueous extracts all nitrite reacting material disappeared; hence, the death of the rabbits, in this case, must have been due to the presence of other toxic material than that of nitrites."

Experiments on the spoilage of tomato ketchup, A. W. Bitting (*U. S. Dept. Agr., Bur. Chem. Bul. 119, pp. 37, pls. 2, figs. 5*).—Experiments on the manufacture of tomato ketchup without chemical preservatives under factory conditions and upon a commercial scale are reported. In addition, experiments with sodium benzoate and the household preservatives salt, sugar, spices, vinegar and acetic acid, and oil were also made, as well as studies of Penicillium in ketchup. It is stated that the product obtained when ketchup was made without preservatives was of excellent consistency, flavor, and color, and the results in the author's opinion prove "that such a ketchup can be made and delivered to the consumer in perfect condition; the product in question having already stood 10 months, unopened, without showing the slightest indications of spoilage. . . .

"The formula employed regularly in the factory where the experiment was conducted was used, but other recipes could be adapted without changing the character of special brands." The precautions observed in the manufacture of such a product are given in some detail. These were, in brief, the use of clean, whole, ripe fruit and high-grade salt, sugar, vinegar, and spices, thorough cooking, use of sterilized bottles, and care and cleanliness at every step.

While some of the condiments used had a limited antiseptic value, they are only of incidental value for this purpose.

"The spoilage of ketchup after opening depends more upon the temperature of the place in which it is kept than on any variation in the manner of processing. Fresh ketchup held, after opening, at a temperature of 95° F. kept for 5 days on an average without any trace of mold appearing; at 72° it kept for 6 days; at 67° for 8 days; about 46° (refrigerator), 14 days; and at from 30° to 60° for 27 days. These figures represent the time at which the first

trace of spoilage occurred in the neck of the bottle—had this been removed the figures would be much increased—and by no means represent the maximum time during which the ketchup could have been used, the maximum figures, even under these conditions of observation, varying from 8 to 58 days. The keeping of the ketchup in warm storage at 70° for 150 days before opening hastened the average time of spoilage after opening about one day. The advisability of using small containers, to get the best results with a first-class ketchup, is apparent.

"Sodium benzoate, even when used in the proportion of 0.1 per cent, is not always effective, and has an injurious effect upon the living matter of the molds, shown by the distortion and swelling of the filaments, which are filled with a coarse granular protoplasm containing much fat."

The use of the microscope to detect artificially colored ketchup and ketchup made from trimming stock, or from tomatoes that have been allowed to spoil is explained, and it is maintained that ketchup as ordinarily made from trimming stock should be so designated as to differentiate it from that made from sound fresh tomatoes, as the two products are radically different.

On the dietetic value of refrigerated foods, S. Rideal (*Cold Storage and Ice Trade Jour., 36 (1908), No. 4, pp. 32, 33*).—Various questions connected with the cold storage of meats and fish, dairy products, and fruit are discussed in the paper which is here summarized. According to the author's experiments on fermentation processes with reference to cold storage, the action of diastase is not entirely prevented by cold but is rendered very slow. The tenderness and maturing of refrigerated meat, according to the author, is attributable not only to the action of sarcolactic acid but also to the gradual and limited work of natural enzyms (pepsin and trypsin), which cause a certain amount of predigestion.

Preservatives in food, W. H. Collingridge (*Meat Trades' Jour., 28 (1908), No. 1075, p. 638*).—Data are reported on the detection of boric acid in samples of sausage in amounts varying from 0.2 to 0.9 per cent. The author points out that the amount taken in sausage might readily be greater than the medicinal dose and also objects to the use of boric acid as a preservative as it permits the utilization of meat for sausage in which putrefactive changes have begun.

Salicylic acid as a preservative, Christian (*Hyg. Rundschau, 18 (1908), No. 22, pp. 1321–1331*).—A summary and discussion of investigations on the use of salicylic acid as a preservative. In the author's opinion, this substance does not ordinarily produce very serious disturbances provided the daily dose is not greater than 1 gm. In the case of persons suffering with kidney disease it is very dangerous, but if the daily amount is very small, namely, under 0.1 gm., he believes that no effect on the normal functions of the body is noted. He points out, however, that there is danger in the use of this preservative, since the total amount obtained per day is unknown and may be harmful.

[Food inspection, etc.], J. Q. Emery (*Semiann. Bul. Dairy and Food Com. Wis., 1908, No. 13, pp. 152*).—In addition to summaries of papers on various pure food topics and legal enactments regarding adulteration, this bulletin reports results of the examination under the pure food law of a large number of samples of canned goods, catsups, cheese, flavoring extracts, sirups, flours, honey, drugs, medicines, etc. Data are also given regarding the creamery and other inspection work.

[Food analyses], J. McCrae (*Transvaal Govt. Labs. Ann. Rpt., 1906–7, pp. 13–15*).—Data are given regarding the examination of blown cans of condensed milk, corn meal, edible oils, and extract of malt. The extract of malt was found to contain 9.28 per cent of proof spirit.

Food analyses, C. F. Juritz (*Rpt. Senior Anal. Cape Good Hope, 1907, pp. 87–97*).—The materials analyzed under the food and drug law included milk and milk products, vinegar, brandy, whisky, etc. A number of general food analyses were also made including among others wines, spirits, lime juice, bush tea, "mealina," and American and colonial meal.

Food inspection decisions (*U. S. Dept. Agr., Food Insp. Decisions 97, pp. 2; 98, pp. 2; 99, pp. 2; 100, pp 2; 101, pp. 2; 102, pp. 2; 103, pp. 2*).—The subjects taken up are "soaked curd" cheese, the labeling of whisky compounds, change in form of guaranty legend, bleached flour, benzoate of soda, entry of vegetables greened with copper salts, and the labeling of turpentine.

Notices of judgment (*U. S. Dept. Agr., Notices of Judgment 28–35, pp. 13; 36, 37, pp. 7*).—The subjects included are the adulteration of milk, the adulteration and misbranding of pepper and buckwheat flour, and the misbranding of drug products, maple sirup, canned peaches and canned apples, and blackberries.

The revised food and drug regulations of the Louisiana State Board of Health, and food standards (*New Orleans: Board of Health, 1908, pp. 64*).—The full text of the food and drug law of Louisiana as revised to October 21, 1908.

Labels and rulings, E. F. Ladd (*North Dakota Sta. Spec. Bul. 8, pp. 3*).—The resolutions adopted September 29 and 30, 1908, by a conference representing several northwestern States and this Department are reported. The work of the conference was to secure "harmony of action as to rulings, standards and principles, and to promote the uniform enforcement of the food laws and cooperation among food officials of the States of the Middle West."

Model food law bill, E. F. Ladd (*North Dakota Sta. Spec. Bul. 10, pp. 11*).—A copy is presented of a draft of the pure food law suggested by a committee appointed at the meeting held at Mackinac Island, Mich., August 4–7, 1908, of the Association of State and National Food and Dairy Departments to draft a bill which could be used as a general law in the several States and Territories, and also a draft of a bill prepared by a similar committee providing for the sanitary inspection of all establishments or other places where food is prepared or distributed.

Proposed uniform food law for the States (*Amer. Food Jour., 3 (1908), No. 12, pp. 1–9*).—The text of a food law proposed by the committee referred to above.

Report of the proceedings of the twelfth annual convention of the Association of State and National Food and Dairy Departments (*Amer. Food Jour., 3 (1908), No. 8, pp. 1–12, figs. 17*).—This report contains a list of officers and an account of the proceedings of the 1908 meeting, the recommendations and resolutions, and similar data.

Meat inspection and legislation on this subject, H. Martel (*Rev. Soc. Sci. Hyg. Aliment., 6 (1908), No. 1, pp. 39*).—A summary of legislation on this subject at present in force in France and a plea for additional legislation which the author believes is needed.

Practical hygiene, Alice Ravenhill (*Leeds and Glasgow [1907], pp. VIII+744, figs. 139*).—This volume, which is designed for school use, contains chapters on the composition of foods, the effects of cooking, milk and the feeding of infants, tests for the quality of foodstuffs, methods of food preservation, personal hygiene, and a study of soils, building materials, ventilation, etc., with reference to dwellings, as well as chapters on the requirements of life and the human body, etc. Directions are given for experimental work in connection with the various chapters. A bibliography, glossary, and index are appended.

Investigations of foot racers and bicycle racers, W. Pfeiffer (*Berlin. Klin. Wchnschr., 45 (1908), No. 3, p. 93; abs. in Zentbl. Gesam. Physiol. u. Path.*

(*Stoffwechsels, n. ser., 3 (1908), No. 22, pp. 856, 857*).—According to the author's investigations, bicyclists endured a long race better than pedestrians. In the case of the pedestrians no differences were observed which could be attributed to vegetarian or to ordinary diet or to training or lack of it.

ANIMAL PRODUCTION.

The self-heating of hay. H. Miehe (*Die Selbsterhitzung des Heues. Jena, 1907, pp. 127, figs. 45; rev. in Zentbl. Physiol., 22 (1908), No. 17, p. 536*).—With a specially constructed apparatus the author conducted experiments which led him to conclude that the self-heating of hay is a bacteriological and not a chemical process as suggested by Boekout and De Vries (E. S. R., 17, p. 1001). The principal organisms concerned in raising the temperature to 40° are *Bacillus coli* and *Oïdium lactis*. Above 40° *B. calfactor* is most abundant and thrives the best at about 60° C. Other species present depend somewhat on the nature of the plants composing the hay. During the heating process many vegetative and spore forms of molds and bacteria are destroyed.

Analyses of [South American] food and forage plants. G. D'Utra (*Bol. Agr. [São Paulo], 9. ser., 1908, Nos. 7, pp. 521–541; 9, pp. 683–695; 10, pp. 786–797*).—Analyses are reported of 434 grasses, legumes, and other plants made between 1898 and 1907 from specimens collected about São Paulo. The analyses include the calculated digestible nutrients, and in most cases the manurial constituents.

Australian pasture herbs. F. Turner (*Sydney Morning Herald, 1907, July 11; Roy. Bot. Gard. Kew, Bul. Misc. Inform. 1909, No. 1, pp. 12–16*).—This article consists of brief notes on the economic value of Darling clover (*Trigonella suavissima*), *Erodium cygnorum*, *Geranium dissectum*, pigweed (*Boerhaavia diffusa*), mustard, nardoo (*Marsilea drummondii*), native carrot (*Daucus brachiatus*), native lucern (*Psoralea tenax*), native plantain or wild sago (*Plantago varia*), parakeelya (*Calandrinia balonensis*), and warrigal cabbage (*Tetragonia expansa*).

Commercial feeding stuffs. J. E. Halligan (*Louisiana Stas. Bul. 114, pp. 3–255*).—During the season of 1907–8 the station analyzed 8,615 samples of commercial feeding stuffs under the State feed-stuff law, comprising cotton-seed meal, cotton-seed feed, rice bran, rice polish, wheat bran, wheat products, molasses feeds, corn chops, corn and oat feeds, hominy feed, feed meals, brewers' grains, poultry feeds, beef scrap, blood meal, and commercial mixed feeds.

The samples of cotton-seed meal examined carried in general a high protein content, but this varied from 32.06 per cent to 50.88 per cent. The percentage of fat varied from 3.64 to 17.15. Of 800 samples examined, 103 were below guaranty in protein, 347 in fat, and 353 in carbohydrates.

The quality of rice bran seemed a little higher than the previous year. It is pointed out that many adulterated rice brans reach the guaranty yet may be injurious to the digestive organs of the animal to which they are fed if the percentage of hulls is high.

"There has been some trouble experienced with molasses feeds this past season, due to decomposition. Some of the samples contained lumps of molasses showing that they were not well mixed. Unground weed seeds were found in some shipments. These are objectionable, as they sometimes pass through the animal undigested and so they are a source of disseminating weeds. . . .

"Care should be exercised in keeping down the moisture content, as an excess of moisture tends to promote decomposition. The purchaser should avoid shipments that are not in good mechanical condition and feeds that smell rancid and contain over 12 per cent of moisture."

Many corn and oat feeds contained oat hulls and most of them showed the presence of salt. Of the 640 samples examined, 402 were below guaranty in fat.

Analyses of ground corncobs, corn bran, oat hulls, wheat screenings, cotton-seed hulls, and rice hulls, which are common adulterants of feeding stuffs, are also given. A method of figuring rebates on commercial feeding stuffs is described.

Investigations of feeding stuffs, H. IMMENDORFF (*Ber. Landw. Vers. Stat. Univ. Jena, 1907, pp. 10–14*).—This report contains analyses of 374 samples of cotton-seed meal, peanut meal, palm meal, linseed meal, rice feed meal, dried brewers' grains, and sesame meal.

Inspection and regulation of feeding stuffs, W. KINZEL (*Vrtljschr. Bayer. Landw. Rat., 13 (1908), No. 2, Sup., Beilage 3, pp. 35–59*).—There were inspected 2,526 samples of feeding stuffs, nearly double the number of the previous year. A large percentage were found to be adulterated.

St. John's bread, a competitor of molasses feed (*Deut. Zuckerindus., 33 (1908), No. 49, p. 956*).—A note on the increased use of this feed in Germany. Analyses are given.

The Roseworthy Agricultural College flock in 1907–8, A. J. PERKINS (*Jour. Dept. Agr. So. Aust., 12 (1908), Nos. 1, pp. 10–25; 2, pp. 111–128; 8, pp. 227–250. figs. 7*).—A report of experimental work to ascertain what number of live stock can be kept under average conditions, with a view to improving the yielding capacity of the land. The number of acres used, including buildings, yards, and roads, was 1,434, and the average stock kept for the year 43 horses, 70 cattle, 290 pigs, and 1,382 sheep. Pastures were used each month, and rotation of pastures is recommended. Rooted perennials like Golden Crown grass or perennial rye grass are recommended for green feed for early lambs. A field of 43 acres of rape carried an average of 3½ sheep to the acre for the year, and a field of 60 acres of barley stubble carried an average of 4⅓ sheep per acre. Properly managed it is believed that a 3-year rotation of bare fallow, wheat, and grazing should carry 1 sheep per acre for the year, and that only one-fifth of the total area need be thrown open to grazing.

"Catch crops will never involve us in much expense. For the most part they will call for no more than slight early autumn tillage of cereal stubbles and the broadcasting of such crops as rape, mustard, crimson clover, sulla, and perhaps vetches either alone or in combination with one of the cereals. Fallow crops, on the other hand, will always involve us in far greater preparatory expenditure, a portion of which, however, must be borne by the cereal crop that follows. Some of these fallow crops render necessary early autumn plowing, a heavy and laborious task when the land lies hard and dry; of such are kale, kohl-rabi, and perhaps turnips. . . . On the other hand, we have fallow crops that can be sown later in the season when wheat-seeding operations have been completed. For instance, such as peas, vetches, mustard, and perhaps turnips. . . . Fallow crops of this kind involve us in less expense than those previously referred to. Finally, we have the spring-sown summer crops such as sorghums, millets, maize, etc., of greater use on the whole for ensilage purposes and to dairy cattle than to a flock. . . . Whatever is done in this direction it is well to recollect that no forage crop can be raised to any advantage that does not dovetail in with the general economy of the farm practice of the district."

With various crosses of sheep it was found that the largest sheep did not make as good use of what pastures were available as the smaller, but more compact, Merino-Southdown. Slightly heavier fleeces were obtained, on an average, from 162 Merino-Shropshire ewes than from 502 pure Merinos. There was no pronounced difference in the weight of the fleece whether the ewe bore

a pure Merino or a half-bred lamb. Tables are submitted showing the development of lambs of the various crosses.

"It is not necessarily the lambs dropped earliest in the season that are heaviest in early spring. Particularly was this noticeable in 1907 in the case of half-bred Dorset-Horn lambs. Thus, with them we find the heaviest lambs of September 5 represented by those dropped between May 11 and 23 attaining at this time 78¾ lbs., while those dropped between April 21 and May 10 come second with an average weight of nearly 77 lbs., while those dropped between April 10 and 20 come third on the list with only 73¼ lbs. of average weight. With a half-bred Shropshire we find the lambs dropped in the second period about ¼ lb. ahead of those dropped in the first period, while lambs of the third period are a long way behind either of the former. With the half-bred Southdowns, on the other hand, the average weight of the lambs is always directly proportional to the length of their days. . . . Short-wool crosses, Merino crossed with Dorset-Horn, or Merino crossed with Shropshire, and perhaps the smaller Merino crossed with Southdown, give the best type of ewe for our conditions."

Steer-feeding experiments 1907–8, T. I. Mairs and W. H. Tomhave (*Pennsylvania Sta. Bul. 88, pp. 3–20, figs. 6, charts 2*).—To secure data as to the best ratio of total dry matter to digestible matter the authors compared, with 2 lots of 12 fattening steers, a limited grain ration with a full grain ration, each being fed in connection with corn silage, mixed hay, and corn stover for roughage. The experiment began October 30 and ended February 6.

"Both lots received the same kind of feed, consisting of broken ear corn and cotton-seed meal as concentrates, corn silage in the morning, and in the evening mixed hay to December 12, and corn stover from that time to the close of the experiment. Lot 1 received all the ear corn they would eat, while lot 2 received about two-thirds as much as lot 1. Lot 1 received 2 lbs. of cotton-seed meal per steer per day and lot 2, 2.25 lbs. It was the intention to feed lot 2 twice as much corn silage as was fed to lot 1 when on full feed. Lot 2 was given all the corn silage they would eat with a limited grain ration. Lot 1 was given all the corn they would eat with a limited silage ration. The intention was to so apportion the feed that the 2 lots would get the same amount of digestible matter, but lot 1 should receive the more concentrated ration—that is, lot 2 should receive the greater amount of dry matter."

The average daily gains per head were for lot 1 2.06 lbs., and for lot 2 1.87 lbs. The first 2 weeks lot 2 lost in weight, due to the change in feed. After that the gains of both lots were uniform.

"When corn silage forms a considerable portion of the ration of fattening steers more care is required in getting them on full feed than when a dry ration is fed exclusively, or silage is fed in small quantities.

"Slaughter tests failed to show any difference in the carcasses of the two lots that might be attributed to the difference in the feed.

"At the prices for feed named in this article the steers receiving the smaller amount of dry matter made the more economical gains."

Work on the effect of shelter was continued (E. S. R., 19, p. 674) with 2 lots of 12 steers each. Steers in an open shed made practically the same gain during the feeding period, November 13 to March 19, as those in a well-ventilated barn, but ate slightly more roughage.

Rolled oats as a substitute for milk in calf feeding, J. Michels (*North Carolina Sta. Bul. 199, pp. 12–16, fig. 1*).—An experiment lasting 13 weeks was made to compare cooked rolled oats with skim milk as a feed for calves. Nine calves fed the rolled oats made an average daily gain per head of 1.143 lbs., whereas 2 calves fed the skim milk made an average daily gain per head of 1.21 lbs. "On the basis that 1 lb. of rolled oats is equal to 1 gal. of whole milk,

and that whole milk is worth 8 cts. per quart to milkmen, the cost of the milk for a 13-weeks-old calf receiving no rolled oats is $26.96. When roller oats (which cost 4.4 cts. per pound delivered in barrel lots) are substituted for milk as shown above, the cost of the calf feed for the same period is only $12.46, a saving of $14.50 in favor of the rolled oats."

A summary of reports on feeding experiments with diastasolin (*Milch Ztg., 37 (1908), No. 47, pp. 553, 554*).—These results indicate that diastasolin may be used to provide a cheap substitute for whole milk in calf feeding.

Outlook for the beef industry in Canada, J. H. Grisdale (*Farmer's Advocate, 43 (1908), No. 846, pp. 1889, 1890, figs. 5*).—A general discussion of this subject. The increase in the dairy industry has led to the use of dairy sires and has retarded the beef industry. The possibilities of the business west of the Great Lakes are deemed enormous wherever there is a butter market. Packing plants in Montreal or Toronto would help the situation.

The wool industry and its improvement, H. Geldard (*Transvaal Agr. Jour., 7 (1908), No. 25, pp. 15–20, pl. 1, fig. 1*).—Suggestions are given as to improving the quality of Australian and South African wools.

Causes of the heavy loss of lambs in 1908, W. J. Quick and A. P. Spencer (*Virginia Sta. Bul. 178, pp. 57–74, figs. 7*).—This bulletin contains statistics of the sheep industry in Virginia and reports the results of an inquiry into the causes of a heavy loss of lambs during the lambing season of 1908.

"In 73 flocks visited 961 lambs were lost out of 5,252 dropped, or 19 per cent. In 65 flocks reported by letter, 1,478 lambs were lost out of 8,068 dropped, or 18 per cent. Figuring on this basis for the State as a whole, 70,147 lambs, valued at $350,375, were lost in Virginia during the lambing season of 1908. The estimated loss from natural and unpreventable causes was 14,029 lambs, valued at $70,145. The estimated loss from preventable causes was 56,118 lambs, valued at $280,590. . . .

"The losses were due to the following causes: Cold and exposure, 40 per cent; lack of milk, 31 per cent; weakness, 9 per cent; disease and accident, 3 per cent; worrying by dogs, 1 per cent; natural causes, 16 per cent."

Suggestions are also presented for the proper care of ewes before and after lambing and on the general management of sheep.

Goat breeding, E. Bödeker (*Ziegenzucht. Hanover, 1907, pp. VI–51, figs. 13*).—This is a brief treatise on the breeding, feeding, and management of goats.

Foods supplementary to corn in fattening pigs, E. A. Burnett (*Nebraska Sta. Bul. 107, pp. 3–10*).—A continuation of work previously noted (E. S. R., 18, p. 570).

In 1906–7 four lots of 4 Duroc-Jersey pigs, kept in a hog house, were fed a basal ration of corn meal. Lot 1 received no supplementary ration and made a daily gain per pig of 0.95 lb., at a cost of 4.66 cts. per pound. Lot 2, fed corn and shorts 3:1, made a daily gain per pig of 1 lb. at a cost of 4.43 cts. per pound. Lot 3, fed corn and tankage 9:1, made a daily gain per pig of 1.1 lbs., at a cost of 4.27 cts. per pound. Lot 4 was fed corn and ground bone 9:1 and gained per pig per day 0.95 lb., at a cost of 4.6 cts. per pound.

In 1907–8 the experiment was repeated, except that the pigs were kept in alfalfa pasture. The average daily gains per pig were, for lot 1 0.98 lb., lot 2 0.97 lb., lot 3 1.18 lbs., and lot 4 1.01 lbs. The average cost per pound of gain was, respectively, 2.38, 2.64, 3.19, and 2.72 cts. A fifth lot, fed corn meal and steamed ground bone 9:1, gained 0.97 lb. per pig per day, at a cost of 2.62 cts. per pound. When the same rations were fed to pigs in a dry lot, the average daily gains per pig were, respectively, 1.06 lbs., 1.09 lbs., 1.36 lbs., 1.19 lbs., and 1.09 lbs. The average cost per pound of gain was, respectively, 3.88, 4.18, 4.87, 4.10, and 4.17 cts.

"Corn is the cheapest ration fed, corn and shorts being second, corn and tankage third, corn and steamed ground bone fourth, and corn and skim milk fifth in cost of production at the prices for feed used in this bulletin. . . .

"It will be noted that where supplementary foods were used, the hogs generally made more rapid gains and reached heavier weights in a given length of time, so that they were ready for the market at an earlier age. This point is a distinct advantage, since it shortens the period of risk and increases the profit per day on each pig."

The effect of food on breaking strength of bones. E. A. BURNETT (*Nebraska Sta. Bul. 107, pp. 11–39, figs. 9*).—Using the pigs under test in the feeding trials noted above, a test was made to determine the effect of different rations on the breaking strength of bones in growing pigs. The average breaking strength of all the bones per 100 lbs. live weight at the time of slaughter of the 16 pigs used in the work of 1906–7 was for lot 1 281 lbs., lot 2 311.75 lbs., lot 3 413.75 lbs., and lot 4 467.75 lbs. The average breaking strength of all bones per 100 lbs. live weight for the 20 pigs used in 1907–8 was for lot 1 325 lbs., lot 2 396 lbs., lot 3 509 lbs., lot 4 580 lbs., and lot 5 681 lbs.

"The laboratory examination of these bones reveals a marked difference in fifth in cost of production at the prices for feed used in this bulletin. . . .

"The laboratory tests have also shown that there is no apparent increase in the external measurements of the bones resulting when protein or mineral matter is added to the food nutrients, but that these additional nutrients, so far as they are assimilated, have greatly added to the thickness of the bone walls by accretion on the inner surface of these walls, thereby reducing the marrow within the bones.

"The thickness of the bone wall increased about 50 per cent in those fed bone meal over those fed only corn. The percentage of mineral matter and the specific gravity in the green bones increased in nearly the same proportion as the thickness of the walls.

"That foods rich in phosphates and mineral matter will increase the strength of bone is conclusively proven.

"There can be no doubt about the advantage of feeding a sufficient amount of phosphates to build up strong, healthy bones, and a deficiency of phosphates during the growing period may materially effect the development of the growing animals. Bone meal and tankage may often be fed economically and the additional cost, if any, can profitably be incurred in the production of high-class breeding animals.

"That an excess of mineral matter in the food may cause mineral matter to be deposited in the bones in excess of that actually needed for the healthy growth of the animal is also quite possible, though not yet proven.

"That such food will cause the animal to stand up squarely on his pasterns is not yet proven. It would seem that the conformation of the pastern will have most to do with this. Strong-boned pigs with short, upright pasterns will be most likely to grow out with good feet, while pigs with long or oblique pasterns will generally go down. Excessive weight at early ages will affect all pigs unfavorably, and lack of exercise is also detrimental."

Weighings and measurements of a number of bones showed that the nature of the feed has no distinct effect upon the length, circumference, or volume of the bone. "The first two lots [in 1907–8], which were fed only corn or corn and shorts, had bones of less weight, of lower specific gravity, with thinner walls, and with a much lower content of mineral matter than those of the three other lots. These properties were characteristic of the entire bones as well as of the portions of the shafts where the fractures appeared when the strength was

being determined. . . . It is apparent that the strong bones have both thicker walls in the shaft and more mineral matter in the ends."

Comparative experiments with swine of different breeding (*Ber. K. Vet. og Landbohöjskoles Lab. Landökonom. Forsög* [*Copenhagen*], *64* (*1908*), *pp. 239*).—The experiments here reported were in continuation of work previously noted (E. S. R., 11, p. 68), and commenced in 1899 and continued for 7 years. The object was to compare the Yorkshire and Danish breeds and crosses between Danish sows and Yorkshire boars as to the period required to reach slaughterhouse weight and the utilization of the feed eaten by the swine. It was also the plan to study for these breeds the bodily conformation of the animals, the deposition of fat, and the quality of the pork as an export article. The report includes experiments with 1,083 different animals, separated into 202 lots, viz, 21 Yorkshire lots, 121 pure Danish lots, 56 first crosses, and 4 lots of mixed breeding.

The main results of the investigation may be briefly stated as follows: The Yorkshire pigs required a little more feed for the production of a pound of pork than the cross-bred pigs and these again slightly more than the Danish pigs. The Yorkshires gave a larger proportion of export pork than the Danish pigs for the same live weight and less shrinkage at slaughtering. They also scored higher in regard to deposition of fat, depth of body, form of hams, and fineness of bone and skin, the crosses coming second with regard to these points. Within the Danish breed there were considerable differences between the different lots as to thriftiness and quality, but by separating these into families it was found that for families where a sufficient number of different lots from each generation had been included in the experiments to enable one to judge of the thriftiness and quality of the separate generations, there was nearly always an indication that the feed consumption for a certain gain in live weight was increasing from generation to generation. In the same way the percentage of shrinkage at slaughtering was increasing, while the percentage of export pork was decreasing to the same extent with each generation. On the other hand, in the scores for the quality of bacon, depth of body, form of hams, and fineness of bone some progress was to be traced from one generation to another.

The feed consumption per pound of increase in live weight in the experiments here reported was found to average for lots weighing from 35 to 75 lbs. per pig, 3.4 lbs.; for lots weighing from 75 to 115 lbs., 3.8 lbs.; and for lots weighing from 115 to 155 lbs., 4.4 lbs. The lower consumption of feed per gain in live weight in the experiment here reported as compared with the earlier experiments is considered to be explained partly by the fact that nearly all of the former experiments were conducted during the summer and partly by an improvement in the average quality of the animals experimented with.

Pork production in Denmark (*Bul. Mens. Off. Renseig. Agr.* [*Paris*], *7* (*1908*), *No. 10, pp. 1254–1256*).—Statistical information on the recent development of the swine industry in that country.

The horse: Its selection and purchase, F. T. Barton (*London, 1907, pp. X+252, pls. 16*).—"The object of this book is to show buyers of horses what to select and what to reject when purchasing without professional guidance. . . . The chapter on conformation is intended to give the reader a general idea of the good and bad points of the horse." The characteristics of the Shire, Suffolk, and hackney horses are described. There are chapters on unsoundness, general hints relating to buying, and warranty, and examples are given of typical actions at law (English) relating to the sale and purchase of horses.

[The small hunter] (*Mark Lane Express, 99 (1908), No. 4024, pp. 531, 533, fig. 1*).—The author thinks that the short-legged, compact, powerful horse, standing from 15 hands to 15 hands 2½ in. is to be preferred to the larger horse in many places for hunting and for cavalry remounts. It is stated, however, that the economic value of the small hunter is not appreciated by many, as this class seems to be less numerous at shows than formerly.

Notes on horse feeding, A. Fredholm (*Proc. Agr. Soc. Trinidad and Tobago, 8 (1908), No. 2, pp. 477–501*).—A general discussion of the subject as applied to the local conditions. Analyses of feeds are given.

The use of African elephants for transport service (*Jour. Roy. Soc. Arts, 56 (1908), No. 2915, pp. 977, 978; Sci. Amer. Sup., 66 (1908), No. 1717, pp. 347, 348*).—Experiments at the elephant farm at Api, in the northern part of the Congo Free State, indicate that the African elephant, heretofore considered untamable and valuable only for ivory, may in the future become a valuable means of transportation in regions otherwise difficult of access. European stock does not survive in the tropical heat, and native carriers can be employed to only a limited extent. In the region of vast plains cut by rivers and swampy streams of the Uele district there is an abundance of native grasses to furnish cheap feed for the elephants.

Poultry fattening (*Jour. Nat. Poultry Organ. Soc., 2 (1908), No. 4, pp. 114, 115, pl. 1*).—A discussion of the conditions of this industry in Sussex, England. As a rule, poultry fatteners do not breed the birds themselves. The supply of suitable birds for fattening is inadequate. For a time this deficiency was made up by supplies from Ireland. It is hoped that the increase in the number of small holdings throughout the county will relieve the present shortage of fowls for the fattening pens.

The marketing of poultry (*Bd. Agr. and Fisheries [London], Leaflet 201, pp. 4*).—The methods of preparing poultry for the English markets are described.

Some ostrich food plants, J. Burtt-Davy (*Transvaal Agr. Jour., 7 (1908), No. 25, pp. 49–60, pl. 1*).—An account of methods of feeding ostriches as practiced in the eastern provinces of Cape Colony, with descriptions of native and introduced grasses and other food plants adapted for ostrich feeding.

The preservation of eggs in the Tropics, J. Vosseler (*Pflanzer, 4 (1908), No. 9, pp. 129–136*).—Eggs kept in plant materials such as chaff, straw, etc., had a musty odor and taste which develops rapidly in moist, tropical climates. Dry sand gave much better results. Lime-water made the shell brittle and the albumin disappeared so that the egg could not be whipped. Collodion, shellac, varnish, gum arabic, and glue were tried but were less satisfactory than potassium permanganate or a mixture of glycerin, alcohol, and water. The best results were obtained with water glass. Eggs so preserved kept for over a year.

Improved egg preservation, J. G. Stephens (*Daily Consular and Trade Rpts. [U. S.], 1909, No. 3377, p. 16*).—By immersing eggs in a vessel of hot paraffine wax in a vacuum the air in the shell is extracted and the hot wax pressed into the pores of the shell, thus hermetically sealing it. It is claimed that eggs so treated will retain their new-laid freshness for 6 months.

Insurance of live stock [in the different European countries] (*Jour. Bd. Agr. [London], 15 (1908), Nos. 1, pp. 32–44; 7, pp. 523–526; 8, pp. 572–579*).—General information on insuring stock and methods of establishing live stock insurance societies in Holland, Belgium, France, Switzerland, Germany, Sweden, Denmark, Norway, and Great Britain.

DAIRY FARMING—DAIRYING—AGROTECHNY.

[Feeding experiments with cows], J. MICHELS (*North Carolina Sta. Bul. 199, pp. 5–12*).—Corn stover of rather inferior quality was compared with cotton-seed hulls as a roughage for milk production when fed with a grain ration consisting of cotton-seed meal, dried brewers' grains, and linseed meal 4:2:1. Seven cows were used for the experiment and the feeding periods lasted 22 days, exclusive of the preliminary feeding.

"Averaging the results of the 2 stover periods, . . . the cows yielded 2,482 lbs. of milk during the stover period against 2,414.4 lbs. for the hull period. Similarly, the cows during the stover period yielded 116.2 lbs. of butter fat as against 116.5 lbs. for the average of the hull periods, showing in this experiment that cotton-seed hulls and corn stover had practically equal value as milk and butter fat producers. . . . On the whole it may be concluded that the cotton-seed hulls and corn stover used in the experiment had about equal value in maintaining the live weight of the cows. . . . Aside from their low nutritive value, cotton-seed hulls do not seem very well suited for dairy cows, on account of their low palatability and digestibility. With the cows used in these experiments it was found that a majority refused the hulls when they were offered them unmixed with concentrated feeds. When mixed with the concentrates the cows would eat them, largely because they were obliged to do so in order to get the concentrates. On general principles it can not be considered good feeding to thus force cows to swallow a lot of unpalatable material, especially when such material has such a low digestibility."

In another experiment 6 grade cows, from 3 to 4 weeks in lactation, were used to compare corn meal with a mixture of corn meal and dried brewers' grains in equal portions as a supplement to cotton-seed meal for milk production. The feeding periods were 21 days each. The average yield for the 2 periods in which corn meal alone was fed was 2,933.1 lbs. of milk, and for the period when the mixture of corn meal and brewers' grains was fed, 2,859.5 lbs.

The Canadian record of performance for pure-bred dairy cattle (*Canada Dept. Agr., Branch Live Stock Comr. Rpt. 1, pp. 32*).—This contains the rules and regulations of standards for registration of the Ayrshire, French-Canadian, Guernsey, Holstein-Friesian, and Jersey breeds. Details of yields of pure-bred Canadian cows, which have been admitted to the advance registry, are included.

Improvement in dairy herds, P. J. CARROLL (*Jour. Dept. Agr. Victoria, 6 (1908), No. 10, pp. 597–604*).—The author calls attention to the low yields of the average cows, and outlines a scheme for forming cow-testing associations.

The dairy institutes in Germany, WEIGMANN (*Illus. Landw. Ztg., 28 (1908), No. 87, pp. 749–751*).—A brief history of these institutions and their significance.

Milking machines, A. L. HAECKER and E. M. LITTLE (*Nebraska Sta. Bul. 108, pp. 3–73, pl. 1, figs. 4*).—The milking machine in use at the station is described and the results of various tests with the university herd are reported.

Tables are submitted which show the effect of the machine upon the yearly records of 20 cows. In at least one case the lactation period was shortened by the use of the machine. The amount of strippings left to be drawn by hand was very low, averaging about 3 per cent. Six cows milked out perfectly clean during the entire lactation period. "The average amount of strippings from the entire number of cows was only 220.7 lbs. This is less than 0.75 lb. each day per head. This item is significant only when we consider the performance of individual cows and when we learn that in almost every case the period when

strippings were obtained covered but a month or two during the entire lactation." In a few cases the amount of strippings was considerable. In one case there were 790.2 lbs. of strippings from one cow during 315 days. The machine was unable to draw the milk satisfactorily from another cow because of a peculiar shaped udder. The cost of repairs and supplies of the milking-machine equipment and 3 milkers for 2 years was $88.97.

The effect of alternate hand and machine milking was tried with 2 cows, but the results were not satisfactory. "When machine milking and hand milking are carried on irregularly and interchangeably the machine will not draw all the milk and in consequence more strippings are obtained. It is very evident that we can not make a comparison between two methods of milking by alternating these methods." In the case of hard milkers the sphincter muscle at the end of each teat was treated with a dilator until the milk could easily be drawn by hand, yet the machine was unable to remove the milk. The teat cups and mouthpieces need to be changed as the lactation period advances.

An average of 6 milkings required 67 minutes to milk 20 cows, producing 157.7 lbs. of milk, 29.5 of which was removed in the strippings, which required 24 minutes. In this case three machines were operated by one man. In another test 12 cows were milked in 92 minutes with one milker. The quantity of milk did not materially influence the time required in milking.

The bacterial content of milk drawn by hand was compared with that drawn by machine. "The average count in the case of the 3 samples of machine-drawn milk shows 37,090 bacteria per cubic centimeter of milk, while in the hand-drawn milk there are but 3,310 in each cubic centimeter." When the machine parts were thoroughly washed, scrubbed, and steamed for 20 minutes each morning and at night rinsed in three waters and submerged in limewater the bacterial content was slightly less in the machine-drawn milk than in the hand-drawn milk.

"The relief filters attached to the milkers when neglected are a continual source of contamination. Air rushes in through these openings to relieve the vacuum caused by each pulsation of the machine and unless protected each inflow of air will carry bacteria with it. This is especially true of the connector relief filters which are suspended but a few inches above the floor while the machine is in operation. During the time of the experiments cited here absorbent cotton was placed in each relief just before milking. The use of these wads of cotton checks contamination from this source entirely, as they stop and hold all bacteria.

"For soaking the tubing, lime has been used in every trial on account of its antiseptic properties and convenience. Other agents, such as formaldehyde, would have undoubtedly given better results as their germicidal properties would aid greatly in reducing the number of bacteria, but the use of a substance of this nature is questionable if not dangerous and could not be recommended for general use. The limewater used for this bath should be renewed every 4 or 5 days. If the antiseptic is to be of any benefit in preserving the rubber and in retarding bacterial growth it must come in contact with every part of the tubing. . . .

"Heifers in their first lactation apparently give better results by machine milking than do aged cows that have been accustomed to hand milking for one or more years.

"Some cows are not adapted to machine milking.

"Manipulation of the udder is absolutely necessary in some instances before all the milk can be drawn by the machine.

"Two men operating 4 machines can practically do the work of 3 men milking by hand.

"The man operating the milkers must thoroughly understand the care and management of dairy stock. He should also be persistent in the attention to details in order to obtain the best results.

"From these studies it would appear that the milking machine is fitted for large herds rather than small ones, and we believe it would be impracticable to install them where fewer than 30 cows are milked the year round."

Tables give the individual records of the different cows used in the experiments. From answers to questions received from 11 of the 13 milking plants in the State it is apparent that the milking machine is meeting with different degrees of success in the hands of practical dairymen and farmers. The reports are not enough alike to permit of a definite conclusion to fit all conditions, but they show what may be expected of the machine milkers under various conditions and in the hands of different men.

[The milk bottle question] (*Maritime Farmer, 14 (1908), No. 4, pp. 70, 71*).—The advantages and disadvantages of paper milk bottles are discussed. The author thinks that the use of paper bottles would reduce the cost of delivering milk and that there would also be less danger of spreading communicable diseases.

A note on the bacterial contamination of milk as illustrating the connection between flies and epidemic diarrhea, J. T. C. Nash (*Lancet [London], 1908, II, No. 23, pp. 1668, 1669*).—Milk exposed to flies for 5 hours on a warm day contained about 3,500,000 more of gas-forming bacteria per cubic centimeter than the same quality of milk when kept covered. The chemical changes produced by such large numbers of putrefactive bacteria "may conceivably be very prejudicial and excite acute diarrhea."

The bacterial flora of milk, G. Koestler (*Käsereitech. Rundschau, 1907, Oct.; abs. in Milchw. Zentbl., 4 (1908), No. 8, pp. 379–381*).—For practical purposes the author divides milk bacteria according to their ability to decompose lactose, casein, and fat. Those which attack lactose are subdivided according to the decomposition products, namely, acid-forming, gas-forming, and those which form other substances. For cheese makers the fermentation test is stated to be the only practical method for determining whether or not the desired kinds of bacteria are present.

The bacterial flora of Cheddar cheese, H. A. Harding and M. J. Prucha (*New York State Sta. Tech. Bul. 8, pp. 121–193, dgms. 11*).—This bulletin reviews recent studies of the bacterial flora of Cheddar cheese, and reports the results of a quantitative and qualitative study of the flora in 9 normal Cheddar cheeses during the ripening period.

"More than 300 pure cultures were isolated and finally reduced to 33 groups according to the classification of the Society of American Bacteriologists. Ten of these groups disappeared from the cheese at once; representatives of 9 other groups were found in but single cheeses, although each group persisted for some time in the cheese where found; the remaining 14 groups are the most important members of the cheese flora. The *Bacterium lactis acidi* of Leichmann, which includes 4 of these 14 groups, is the only species which was always found and it practically always included over 99 per cent of the total germ content.

"The initial flora of milk varies widely, depending upon its environment. When this milk is made into cheese the accompanying changes in temperature, moisture, and acidity induce a rapid shift in this flora, . . . and some of the forms which grow best in milk are lost before they can be observed, for they will not grow on any culture media now in use." As the whey is expelled from the coagulated mass it does not contain its volumetric proportion of the germs previously found in the milk. No data are given on the freshly coagulated curd.

The results obtained from a study of individual cheeses during ripening are presented in tabular form. "In different cheeses the rate of increase, the maximum germ content, and the age at which it is obtained, as well as the rate of decline after this point, varied greatly. The causes of these variations are only partly understood. . . . The lowest recorded maximum, 27,000,000, and the highest, 178,000,000 per gram are in the 2 cheeses having a very similar qualitative flora and ripening in a similar manner. The rate of ripening in these 2 cheeses was slightly different, the one with the highest maximum germ content ripening more slowly." The average germ content of all the cheese examined was 10,000,000 per gram at the end of 5 hours, 30,000,000 at the end of 1 day, 40,700,000 at the end of 10 days, 10,200,000 at the end of 50 days, 2,625,000 at the end of 100 days, and 500,000 at the end of 150 days.

"The type *B. lactis acidi* makes up 99 per cent or more of the flora of normal Cheddar cheese in practically all cases. The representatives of this type differ in their relation to air and in their ability to attack saccharose, so that they are found under 4 different group numbers. . . . *Streptococcus lacticus*, which includes 2 different group numbers, is occasionally found in much smaller numbers. These groups apparently agree with the corresponding groups of *B. lactis acidi* in everything except morphology. The position taken by Conn, that there is a distinct morphological basis for the separation of the cocci from the rod forms, appears to be well taken. Both the morphology and the physiology of these groups is easily influenced by their environment, and it is especially important that the cultures be brought to a vigorous condition before being subjected to detailed study.

"The acid liquefiers which are considered so important by Gorrini are represented by *Micrococcus lactis albidus* (2 groups), *M. lactis giganteus*, *M. lactis varians* (4 groups), and *M. lactis brevis*. *M. lactis albidus* and *M. lactis brevis* occurred sufficiently often to suggest that they might play some part in the ripening changes. Representatives of this group were found in all but [one cheese]. These forms grew well in the milk but made little headway in the cheese, although they survived there better than the nonacid-producing forms. Their number as compared to the total germ content of the cheese, was relatively insignificant.

"The gas-producing forms, like the preceding group, find the best conditions for their development in the milk and make little or no growth in the cheese. *Bacillus coli aerogenes* was found in the milk [for 2 cheeses]. In both cases it was not found in the cheese after the first day. The isolated cultures were slow gas producers and did not displace more than one-third of the closed arm in the fermentation tube.

"*Bacterium lactis aerogenes* was found in [4 cheeses. When present in considerable numbers] evidence of gas was noted in the vat during the early stages of the making process. These forms are very resistant to the acidity in the milk and cheese, but our data do not show that they multiply in the latter.

"The inert group, characterized by a lack of any apparent action upon milk, is represented by *Galactococcus versicolor* and *B. lactis connii*. They are fairly numerous at times in the milk and fresh curd. They usually disappear quickly. There is no evidence that they increase in the cheese.

"Very few specimens of yeasts have been found, although an effort was made to prepare plates especially suitable to their habits of growth. . . .

"The system of recording the reactions of cultures as proposed by the Society of American Bacteriologists is a marked advance in technique. By its aid the shifts in the cheese flora can be followed with more accuracy than was previously possible. The cultures isolated can readily be so characterized as to be

recognized by succeeding workers. Each investigator can thus build upon what has been done, and a satisfactory acquaintance with such of the flora as will grow on our culture media is possible at no very remote date.

"The quantitative changes observed in 9 normal cheeses, representing 4 commercial factories and our own dairy, agree closely with those previously found in Wisconsin and Canada. Emphasis should be laid upon the fact that first-class cheeses vary widely both in their total germ content and in the age at which the maximum number of bacteria is found. . . .

"The rate of the ripening process seems to be independent of the number of germs present, except that in certain cheeses a flora closely confined to acid-producing forms was coincident with a retarded rate of ripening.

"There is a lack of satisfactory evidence, either in the results from our studies or in those which have preceded them, that any of the forms thus far isolated play an important part in the later stages of the ripening of normal Cheddar cheese. This does not preclude the possibility that such evidence may be later produced nor that important forms may be found which do not appear upon our present culture media."

Stringiness in Emmenthal cheese, J. Hohl and R. Steinegger (*Landw. Jahrb. Schweiz, 22 (1908), No. 5, pp. 272–283*).—The authors have isolated and described a form of *Bacterium güntheri*, which apparently is the cause of stringiness.

Studies on fermented milk. I, Yoghourt and matzoon, W. Kuntze (*Centbl. Bakt. [etc.], 2. Abt., 21 (1908), No. 24–25, pp. 737–768, pls. 3*).—The author calls attention to the great variability of the bacteria found in yoghourt and matzoon by different observers. From his own researches he thinks that some, if not all, of these species described as new are only varieties of species previously known. A complete list of references is appended.

Alcohol industry in Germany, A. M. Thackara (*Mo. Consular and Trade Rpts. [U. S.], 1908, No. 339, pp. 179–182*).—Over 100,000,000 bu. of potatoes are used per year in the manufacture of alcohol in Germany, and in addition a large amount is made from cherries, plums, berries, grapes, currants, raisins, wine, wine lees, fruit and wine cake, rye, barley, wheat, corn, and sorghum. In northern Germany many of the distilleries are owned by the farmers. Few of the farmers' distilleries have rectifying plants, the crude alcohol being usually sold to dealers for rectifying purposes or for denaturing. In southern Germany a large number of small farmers distill alcohol with simple apparatus from fruit and berries that can not otherwise be marketed at a profit.

Micro-photographic atlas of industrially important fibers. I, Vegetable raw material, A. Herzog (*Mikrophotographischer Atlas der Technisch Wichtigen Faserstoffe. I, Pflanzliche Rohstoffe. München, 1908, pp. 80, pls. 46, figs. 14*).—This is a handbook for the microscopic investigations of materials used in the manufacture of textiles, paper, ropes, brushes, etc. The work is published in two parts, the one containing the discussions, descriptions, and bibliography, and the other the micro-photographs of the different fibers considered. The instruments, as well as the reagents, used in studying the fibers are enumerated and described. The classification of fibers is outlined. The different substances used in the manufacture of paper are also considered.

Paper-making materials and their conservation, F. P. Veitch (*U. S. Dept. Agr., Bur. Chem. Circ. 41, p. 20*).—This circular was prepared to furnish information as to the suitability of various products that may be used for paper stock, and contains many suggestions for utilizing waste products. Emphasis is laid on the fact that there are large quantities of waste textiles and paper which might with advantage be employed for paper making. It is estimated that 2,000,000 tons of such waste, worth approximately $30,000,000, can be

secured annually in this country, which would make approximately 1,700,000 tons of paper. Materials that may be used for paper making are classified into four groups; namely, seed hairs, bast fibers, stems and leaves of herbaceous plants, and wood, and the relative quantity and value of these different groups is discussed.

It is stated that the cheapest known raw material for medium grade paper which can be obtained in large quantities is wood. It is estimated that fully 12,000,000 cords of wood are available annually as waste from the lumber industry, besides large quantities from other sources which can doubtless be obtained at low cost for cheaper grades of the product. Straws from oat, wheat, rice, and other cereals make a good quality of paper, but are now being used only in small quantities.

"Malbón or *Malva castilla*, a plant which grows wild over large areas from southern California to southwestern Mexico, is used by the Indians in making cordage, ropes, and coarse fabrics. Examination of the fiber . . . indicates that it will yield about 60 per cent of pulp. The individual fibers are from 0.75 to 6 mm. long, averaging 2 mm., and are suitable for making a strong white paper. . . .

"One of the most striking points brought out . . . in the examination of paper is that the quality of any class is seldom as good as the materials and the technical skill of the maker can produce. . . .

"On the whole it is a conservative statement that the quantity of paper now used in this country can readily be reduced 25 per cent by making from the materials now employed better paper and by using no heavier paper than is required by the service to be performed. . . . Economic agricultural considerations indicate that the cultivated straws should only be employed [for paper making] when the woods and textile and paper wastes can no longer supply the demand or are too costly. Flax fiber, when it can not be put to more important uses, should be employed in paper making."

VETERINARY MEDICINE.

Annual report on the distribution of animal plagues in the German Empire (*Jahresber. Verbr. Tierseuch. Deut. Reiche, 22 (1907), pp. VI+97+176, maps 4*).—This is a report in which the extent and distribution of the important animal diseases occurring in the German Empire are considered, particularly anthrax, symptomatic anthrax, rabies, glanders, pleuro-pneumonia, hog cholera, swine erysipelas, chicken cholera, fowl plague, scab, and influenza of horses. Details concerning the distribution of these diseases in the Empire are also presented in tabular form. Maps are appended showing the occurrence of rabies, glanders, foot-and-mouth disease, and sheep scab in Germany. The meat inspection regulations of Germany are given as are also the laws of the various countries relative to animal diseases.

Veterinary department, 1907, A. Oliver (*Rpts. Finance, Admin., and Condition Sudan, 1907, pp. 837–843*).—The cattle plague which appeared to have been almost stamped out in the Sudan broke out again in the Kassala Province. Sarraja or contagious lymphangitis has become a serious problem over a great part of the Sudan. Trypanosomiasis of all classes of animals is said to be the most serious veterinary question in the province. Biliary fever of the horse and dog and a disease of fowls are transmitted by ticks, the latter causing great loss of poultry in Egypt. Horse sickness was not very prevalent while mange prevailed throughout the Sudan, particularly in baggage camels. Very little progress has as yet been made in the improvement of the local breeds of horses and donkeys.

Tuberculosis in animals and its relation to public health, W. Robertson (*Agr. Jour. Cape Good Hope, 33 (1908), No. 3, pp. 341–357, pls. 2*).—An account is given of the disease with directions for the use of tuberculin. The transmission of tuberculosis through the vehicle of meat and milk is discussed.

Tuberculosis of retropharyngeal lymphatic glands, W. Jowett (*Vet. Rec., 21 (1908), No. 1056, pp. 203, 204, pl. 1*).—Records are reported of 100 consecutive, post-mortem examinations made by the author of cattle which had reacted to tuberculin but which in the majority of cases gave no clinical indication of being the subject of tuberculosis. Thirty-nine of the animals were found to have well-marked lesions in the retropharyngeal glands and in 4 of the 39 animals, although careful examinations were made, no trace of tuberculosis could be detected in any other organ of the body.

The protection of cattle against tuberculosis, J. F. Heymans (*Wiener Klin. Wchnschr., 21 (1908), No. 25, pp. 893–895*).—The author describes a method which he calls the sac method that increases the resistant power of the animal to tubercle bacilli. The sac, made from a reed, is filled with 1 mg. of living tubercle bacilli, diluted with powder. The mouth of the sac is tied and collodionized and the sac is then introduced under the skin of the animal.

A tuberculous cow soon shows a typical reaction when a sac containing 0.5 cc. of raw tuberculin is inserted under the skin. When the sac contains live bacilli they thrive so long as they obtain the necessary nutrient substances by diffusion. The wound heals, the sac forming a nodule resembling a tubercle. Experience shows that an animal bearing one of these sacs is protected against experimental and spontaneous tuberculous infection to an extent hitherto unattained. This method has been applied by the author to 4,000 cattle during the last 3 years. References are given to articles published on the subject by the author.

A new contribution to the study of the vaccination of bovines against tuberculosis, A. Calmette and C. Guerin (*Ann. Inst. Pasteur, 22 (1908), No. 9, pp. 689–703*).—A continuation of experiments on vaccination against tuberculosis previously noted (E. S. R., 19, p. 577).

The authors conclude that by the ingestion of virulent or attenuated tubercle bacilli a relative immunity is produced that will protect from virulent bacilli for 6 months or longer. When from 8 to 12 months after having resisted a massive infection by the digestive tract and supposedly vaccinated, bovines received intravenously a dose of virulent bacilli, it was found that following a short period of discomfort they continued in perfect health for 6 or 8 months. They retain, however, in their bronchial and mediastinal glands, virulent bacilli that will cause tuberculosis in guinea pigs, but will not produce a reaction to tuberculin. After 6 to 8 months more the immunity disappears and the bacilli may produce tuberculous lesions. Tubercle bacilli from cultures introduced by ingestion are after a time resorbed in the mesenteric glands, but are not sufficiently numerous to produce lesions, while by intravenous injection they remained virulent in the lymphatic glands of the thoracic organs.

"Tuberculous animals or those sensibilized to tuberculin by 2 or 3 massive injections of that substance in the veins, offer a very great resistance to reinfections or to severe tuberculous infections, natural or artificial, even if these are made by the intravenous method. . . . Then it is not in any way a true immunity, because the animals, thus vaccinated, although not reacting to tuberculin, remain carriers of living and virulent bacilli which are able, when the resistance diminishes to create in the organism of these same animals serious lesions, and again because, as Roux and Vallée have demonstrated, vaccination by venous or subcutaneous methods does not protect against intestinal infection."

Economics as a positive factor in the dissemination of tuberculosis in animals, O. E. Dyson (*Nat. Provisioner, 39 (1908), No. 20, pp. 19, 37*).—A paper read by the author before the International Congress on Tuberculosis, in which which are discussed the factors that have prevented a more effectual work of eradication. The author considers eradication of the disease in this country to depend upon the enactment and rigid enforcement of Federal laws which will prevent the interstate shipment of any bovine intended for breeding or dairy purposes unless submitted to the tuberculin test and authoritatively certified as being free from the disease.

The control and prevention of bovine tuberculosis in individual herds, V. A. Moore (*Amer. Vet. Rev., 34 (1908), No. 1, pp. 22–29*).—This article forms part of the report of the committee on diseases of the American Veterinary Medical Association.

The author considers that past experience warrants the conclusion that tuberculosis can be practically eliminated from cattle, not by acts of legislation, but by the persistent application of an intelligent system of action that will prevent the further spread of the virus and eliminate as quickly as consistent the animals already infected. While laws will be of assistance, the real results must come from wise, conservative, and scientific advice given by the veterinarian and followed by the individual owner of cattle.

The struggle against tuberculosis in cattle in Denmark, B. Bang (*Vet. Rec., 21 (1908), Nos. 1046, pp. 63–65; 1047, pp. 82–85*).—This is a paper presented at the International Congress on Tuberculosis held in Paris, in 1905.

Suppression of tuberculosis among cattle on the Continent (*Jour. Bd. Agr. [London], 15 (1908), No. 7, pp. 494–502*).—A brief account is given of the work in Sweden, Norway, Denmark, Holland, Belgium, Germany, and France for the suppression of tuberculosis in cattle.

Bang's bacillus and its biology, J. Nowak (*Ann. Inst. Pasteur, 22 (1908), No. 6, pp. 541–556, pls. 3*).—The author here reports experiments carried on with the bacillus which Bang described as the specific agent of epizootic abortion in cows. A method of cultivating this bacillus which the author considers surer and easier to carry out is described. Development has been obtained in an atmosphere of oxygen and in compressed air. The bacillus has lived in a straight gelatin medium for more than 2 years. This viability explains the outbreaks of epidemics in certain stables. The death of the fetus resulted in guinea pigs and rabbits inoculated subcutaneously, intravenously, and intraperitoneally with the bacillus. Neither the ingestion nor the introduction of the bacillus into the vagina produced the disease in these animals. No experiments were made with cows.

A contribution to the study of red dysentery (coccidian enteritis) of cattle, E. Zublin (*Schweiz. Arch. Tierheilk., 50 (1908), No. 3, pp. 123–169, figs. 10; abs. in Vet. Rec., 21 (1909), No. 1072, pp. 487, 488*).—This is the report of an extensive study based upon the literature and the author's experience with the disease in Switzerland. The disease is a febrile epizootic of young cattle that is localized in the large intestine, particularly in the rectum. It is caused by a specific coccidia known as *Coccidium bovis*, which is not found in healthy animals. Though generally terminating in recovery it may cause the death of infected animals.

Three stages of the infection are recognized: (1) The congestive stage in which the feces contain blood coagula and a few coccidia; (2) the stage of hemorrhagic diarrhea accompanied by fever; and (3) the stage of regeneration and abatement and disappearance of the symptoms. Animals are probably infected through solid food or fluids which contain the spores. Direct transmission from animal to animal does not seem likely.

As the parasites are very resistant, treatment is purely symptomatic. The hyperemia is combated by repeated clysters of 1 per cent alum or ½ per cent tannin in solution. Afterwards astringents are given by mouth and cardiac weakness treated with stimulants and the system strengthened by the use of milk and eggs. The author has had recoveries in 95 per cent of the cases. It is said that the meat can usually be used for food.

The nodular disease of bovines an esophagostomiasis, G. Marotel (*Bul. Soc. Cent. Méd. Vét., 85 (1908), No. 18, pp. 457–461, figs. 3*).—Studies have been made of this disease through which it has been determined to be an esophagostomiasis and not an uncinariasis. The life cycle of the parasite has been followed and is here described.

Changes in the blood of parasite-infested sheep on an innutritious diet, W. Giltner (*Amer. Vet. Rev., 33 (1908), No. 5, pp. 557–561*).—Studies made of the blood of sheep infested with *Œsophagostoma columbianum* and *Hæmonchus contortus* are here reported. In the sheep studied the lesions produced by *O. columbianum*, together with the occurrence of the stomach worm in small numbers and a very coarse unbalanced innutritious ration, lessened the vitality of the sheep and led to a fatal issue after producing a marked alteration in the blood. A decided anemia, polynuclear leucocytosis and almost total absence of eosinophiles and mast cells are said to be the characterizing features. It is suggested that the change in the blood may be due to mechanical obstructions by the nodules of the absorption of digested nutrients or even the prevention of digestion.

Does lime and sulphur injure wools more than other dips? S. B. Hollings (*Agr. Jour. Cape Good Hope, 33 (1908), No. 3, pp. 377–382*).—Experiments were conducted with several dips in an attempt to ascertain to what extent if any the wool had been injured by dippings at different stages of growth. Under direction of an authority on wool each lot was scoured separately and treated up to and including the dyeing stage. The expert does not draw a conclusion, but from the detailed results reported, wool from sheep dipped in lime-sulphur appears to compare favorably with that from sheep dipped in Cooper's powder and tobacco extract.

The caustic soda and sulphur dip (*Natal Agr. Jour., 11 (1908), No. 8, pp. 982–985, pl. 1*).—Experiments here reported appear to show that the objection made to the use of this dip on the ground of injuries to the wool are not well founded.

Bovine piroplasmosis observed on the Ivory Coast, G. Bouet (*Bul. Soc. Path. Exot., 1 (1908), No. 4, p. 234*).—Piroplasmosis is reported on the Ivory Coast in cows from Senegal and in bovines, particularly zebus, which had recently arrived from various points of the Sudan or Sahel and which must have there contracted the disease. In all these cases the blood contained more or less abundantly either *Piroplasma bigeminum* or *P. mutans*. Blood from one of the oxen produced the disease when injected into a heifer. At the end of 15 days a Piroplasma of the *bigeminum* type and at the end of 24 days a Piroplasma of the *parvum* type appeared. The presence of *Trypanosoma cazalboui* prevented a report of the pathological effect of the Piroplasma being made. A heifer was also infected by the attachment of ticks, progeny of females taken on a bovine, and again *P. bigeminum* was found.

The value of the agglutination reaction and of bacteriological methods in the diagnosis of glanders, K. R. Collins (*Jour. Infect. Diseases, 5 (1908), No. 4, pp. 401–411*).—The application of this reaction was followed during a period of 2 years in which time 2,500 horses were tested. The results, in the author's opinion, are not sufficiently conclusive from a practical standpoint to make it a means of absolute diagnosis.

"The serum of horses reacting with *Bacillus malléi* in dilutions of 1:1,000 and above indicates a glanders infection which may be latent or active according to the accompanying symptoms and reaction to mallein.

"Horses giving a reaction of 1:500 to 1:1,000 are to be suspected and should be tested with mallein; if no reaction occurs and the horse is apparently in healthy condition, it may be considered free from glanders."

In connection with the experiments reported the author reviews the work of other investigators on the subject.

Lamziekte on the Kaap Plateau, J. Spreull (*Agr. Jour. Cape Good Hope, 32 (1908), No. 5, pp. 588–600*).—It is the author's opinion that the name lamziekte given to this disease by farmers should stand, sanctioned as it is by long usage in Cape Colony, although some writers have used the name pasteurellosis and, according to the type of the disease, it has also been called by several other names. The disease appears to be quite widespread in Cape Colony, being most severe in the coastal districts of the East Provinces, and it is the author's opinion that it must also occur in the Orange River Colony and western Transvaal.

The author has cultivated the organism on artificial media and has found it virulent on inoculation into healthy animals. It conforms in all respects except in its active motility with Lignières's description of the Pasteurella, a cocco-bacillus. The disease appears in a number of forms of which the three more common are the edematous or throat form, the thoracic form, and the paralytic form. An account is given of these forms, of susceptibility, plurality of attacks, post-mortem lesions, treatment, and prophylactic measures. Experiments conducted, including drenching and the injection of body fluids and artificial cultures, are also reported.

Report on swamp fever, J. R. Ballah (*Ann. Rpt. Dept. Agr. Prov. Saskatchewan, 1907, pp. 223–226, pl. 1*).—Attempts to transmit swamp fever by injection of blood, gland juice, or other fluid have been unsuccessful. In the cases examined the liver showed marked inflammatory changes leading in some cases to death of the tissue and formation of new connective tissue. In a considerable proportion of the cases examined special treatment of the tissue revealed bodies in the liver cells which the author believes to be protozoa and probably the specific cause of the disease.

Equine piroplasmosis in Sardegna, A. Baruchello and A. Pricolo (*Ann. Ist. Ig. Sper. Univ. Roma, 18 (1908), No. 2, pp. 307–313, pl. 1; abs. in Bul. Inst. Pasteur, 6 (1908), No. 17, p. 785*).—This disease which has been known in several provinces of Italy is here shown to occur on the Island of Sardinia. Studies made of the parasites are presented accompanied by illustrations.

Equine piroplasmosis, A. Pricolo (*Mod. Zooiatro, 1907, pp. 14; abs. in Bul. Inst. Pasteur, 6 (1908), No. 17, p. 785*).—A review of the literature on this disease.

Contributions to the study of Filaria irritans, the filaria of summer sores of horses, Fayet and Moreau (*Bul. Soc. Cent. Méd. Vét., 85 (1908), No. 18, pp. 462, 463*).—The authors have made biological studies of this nematode. Adults were recognized for the first time but sexes were not distinguished. The leucocytes of the affected horses were also studied.

A case of Sarcosporidia in the horse, Moussu and Coquot (*Bul. Soc. Cent Méd. Vét., 85 (1908), No. 18, pp. 445–456, figs. 3*).—An extensive report is given of a case of this affection including an account of a post-mortem examination.

A case of tuberculosis in a horse, J. Anderson (*Vet. Rec., 21 (1908), No. 1055, pp. 183, 184*).—The history, symptoms, and result of a post-mortem examination of a case of generalized tuberculosis is reported. The application of

tuberculin gave a positive reaction. The author considers the cervical vertebra to be a very common seat of tuberculosis in the horse.

Tuberculosis affecting the dorsal vertebra of a mare, W. Brown (*Vet. Rec., 21 (1908), No. 1052, pp. 145, 146, figs. 2*).—A case of this affection is reported accompanied by photographs.

Control of hog cholera by serum immunization, A. D. Melvin (*Amer. Vet. Rev., 34 (1908), No. 1, pp. 14–21*).—In this article, which was presented before the annual meeting of the American Veterinary Medical Association, an account is given of the methods of immunization that have been worked out by the biochemic division of the Bureau of Animal Industry of this Department and which have been patented in such manner as to insure to the people of the United States the right to a free use.

Up to the present time the filterable virus causing hog cholera has not been artificially cultivated. A protective serum is produced by hyperimmunization. With a standard serum of known potency susceptible pigs may be protected in two ways, by the so-called serum-simultaneous method and by the serum-alone method. The former, to be used in droves that have not been exposed to hog cholera, consists of injecting subcutaneously on one side of the body of the pig to be vaccinated a suitable quantity of serum and simultaneously on the other side of the body a small quantity of virulent blood taken from a hog sick with hog cholera. Experiments have shown that pigs are thereby given a firm immunity lasting at least 6 months and probably much longer. The serum-alone method which consists simply in injecting the protective serum appears to confer only a temporary immunity upon the treated pigs. This latter method is adapted to the treatment of hogs in a herd in which cholera has already broken out but which have not themselves shown visible symptoms of the disease. It is estimated that the cost of the serum per dose can be brought to 25 cts., as there seems to be no objection to the use for food purposes of the carcass of a hyperimmunized immune.

Experiments have been carried out upon farms under practical conditions. Some 2,000 hogs on 50 farms were thus treated during the fall of 1907 and the results show the efficiency of the method. The practical use is considered entirely feasible. Plans for the eradication of hog cholera by serum immunization are submitted.

Inoculation against hog cholera, J. W. Connaway (*Breeder's Gaz., 53 (1908), No. 20, pp. 1105–1107, figs. 7*).—Experiments conducted by the author in which virulent hog-cholera blood and hyperimmune serum were injected simultaneously are here reported. Out of 56 head that appeared healthy at the time of inoculation only 3 died. All of these are said to have been exposed as much as would ordinarily occur on the average stock farm. The injection of serum into sick hogs did not appear to modify the course of the disease.

Studies on hog cholera and preventive treatment, W. E. King (*Kansas Sta. Bul. 157, pp. 37–90, pls. 8, dgms. 34*).—The investigations here reported were conducted in cooperation with Dr. C. T. McClintock, following unsuccessful attempts to attenuate virulent hog-cholera blood by various physical and chemical means.

Negative results were obtained from attempts made to cultivate the filterable virus of hog cholera artificially in normal hog-serum broth in the abdominal cavity of the rabbit in collodium sacs.

As a large quantity of immune serum is required in the ordinary preventive treatment and since relatively small amounts are secured from individual hogs, experiments were made with other animals in view of producing a serum

at a moderate expense. As a result of experiments with sheep it was concluded that under some conditions the virus was attenuated in such a way as to successfully vaccinate healthy hogs, but these experiments were suspended since it was found impossible to obtain a definite degree of uniformity or standardization of the sheep-serum vaccine. Experiments with the donkey, in which more encouraging results were obtained, were followed by the use of the horse as a medium.

This work was directed particularly toward the production of a horse-serum hog-cholera vaccine and not toward the production of a hog-cholera antitoxin from the horse. The results obtained have been summarized by the author as follows:

"Virulent hog-cholera serum exerts a toxic influence upon a healthy horse when injected intravenously. Normal hog-cholera serum or virulent hog-cholera serum does not appear to produce an anaphylactic reaction when injected intravenously into the horse. The 2-hour horse serum (drawn from the horse 2 hours after the animal has received, intravenously, approximately 150 cc. of hog-cholera virus) when injected subcutaneously into the healthy hog in small quantities produces an acute form of the disease. The 4-hour horse serum when injected into healthy hogs intravenously produces acute hog cholera. The 4-hour horse serum, under certain conditions at least, when injected subcutaneously in small doses into healthy swine does not produce infection. The 5 to 7 hour horse serum when injected subcutaneously into the healthy hog does not produce the disease. The 24-hour horse serum in comparison with 4-hour horse serum, shows attenuated properties. The 24-hour horse-serum vaccine injected subcutaneously and intravenously, and 4-hour horse-serum vaccine when injected in small quantities subcutaneously, act as preventives against hog cholera. The 24-hour horse serum, however, is not constant in respect to its protective properties. A rough estimate shows that horse-serum vaccine can be prepared at a relatively low cost.

"Virulent hog-cholera serum in the liquid form becomes attenuated after a period of 9 months when kept at a temperature of approximately 10 to 15° C. Virulent hog-cholera serum dried under aseptic conditions at a temperature of 37° becomes attenuated after a period of 8 months. Horse-serum vaccine retains its protective properties for at least a period of 6 weeks when kept at an approximate temperature of 10 to 15°."

It is stated that experiments have shown that a hog once immunized to the disease will retain the protection for a period of from 3 to 8 months, or long enough to fatten and prepare the animal for market.

Tests of Bruschettini's hog-cholera vaccine and Bruschettini's hog cholera and swine plague serum, James Wilson (*U. S. Dept Agr., Office Sec. Circ. 27, pp. 2*).—In conformity with provisions made by Congress for the testing of samples of tuberculin, serums, antitoxin, and analogous products bought in the open market, tests were made of Bruschettini's hog-cholera vaccine and Bruschettini's hog cholera and swine plague serum. The results obtained indicate that neither are reliable agents for protecting hogs from hog cholera.

The dog in health, accident, and disease, F. T. Barton (*Philadelphia, [1908], pp. 197, pls. 12*).—A popular work largely devoted to a discussion of the characteristics of the various breeds of dogs, but also briefly considering the accidents and diseases to which dogs are subject.

Experimental studies of acute ankylostomiasis in dogs, J. Cuillé (*Rec. Vét. [Toulouse], 33 (1908), No. 10, pp. 613–618, fig. 1*).—Studies were made of

the symptoms and lesions produced by infecting dogs with *Anchylostomum trigonocephalum*. Only small dogs were found to contract the acute form. In these there is an acute enteritis resulting in dysentery. It is accompanied by a marked anemia and soon terminates in death.

New information on Kala-azar; cultures; inoculation of dogs; etiology, C. NICOLLE (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 9, pp. 498, 499*).—The author has experimentally reproduced Kala-azar in the dog. On September 21 and December 9, 1907, a young dog was inoculated in the liver and within the peritoneum with blood from the spleen of a child affected with the disease. On February 27, 1908, the dog was killed while still in a healthy condition. Numerous typical Leishman bodies were found in the spleen and bone marrow, and also, though more rarely, in the liver. These bodies appear to be identical with those found in the child. It is said that of 4 cases of the disease observed in children in Tunis, 2 had been frequently in contact with diseased dogs. The author is led to conclude that Kala-azar is a disease of the dog that is probably transmitted to man by ectoparasites.

Canine origin of Kala-azar, C. NICOLLE and C. COMTE (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 14, pp. 789–791*).—Of 40 dogs examined at the pound in Tunis, one was found with Leishman bodies in its spleen, bone marrow, and liver. The disease is said to be very difficult to diagnose, since the animals only occasionally appear sick and as it is difficult to detect the parasites in the peripheral blood.

A disease of fowls simulating in some respects fowl cholera, W. ROBERTSON (*Agr. Jour. Cape Good Hope, 32 (1908), No. 5, pp. 577–579, figs. 2*).—The author here reports an investigation made on a disease in which all classes of fowls are affected and in which the mortality is very high. It was found to be due to a bacillus different from fowl cholera. The culture and blood from affected animals remained in a virulent condition for a long period of time. The infection is not conveyed by feces direct, and cages, etc., do not seem to spread the disease.

A case of spirillosis of fowls in Bulgaria, G. GAREITSCHNOFF (*Vet. Sbirka, 1907, No. 7; abs. in Bul. Inst. Pasteur, 6 (1908), No. 12, p. 555*).—This is the report of an observation of the disease in Bulgaria.

Spirochetosis of Cypriote fowls, G. A. WILLIAMSON (*Jour. Trop. Med. and Hyg. [London], 11 (1908), No. 12, p. 181*).—The mortality as reported was very high, probably between 80 and 90 per cent in chickens, although less among older fowls. A spirochæte, probably *Spirochæta gallinarum*, was found in large numbers during the height of the disease. Ticks of the species *Argas reflexus* were found, the larvæ on the fowls and the adults in the crevices of the wood of the henhouse. Ducks on the same run with the fowls have been observed with similar symptoms of spirochetosis and the same species of tick was found upon them. It thus appears that *A. reflexus* as well as *A. persicus* transmits spirochetosis and suggests the possibility that *S. gallinarum* and *S. anserinum* are not true species.

Fowl spirochætiasis in Tunis (*Jour. Trop. Med. and Hyg. [London], 11 (1908), No. 15, pp. 239, 240.*)—Ticks of the species *Argas persicus* sent from a small place near Kairwan, Tunis, transmitted spirochetosis to fowls.

Animal parasites and parasitic diseases, B. F. KAUPP (*Chicago, 1908, pp. 207, figs. 73*).—An epitome of animal parasites intended for use by the student and busy practitioner. The subject is treated in four chapters under the headings ectozoa, entozoa, protozoa, and the preparation of specimens.

Endoglobular hematozoa, A. Lutz and C. Meyer (*Rev. Med. São Paulo, 1908, May 15; abs. in Bul. Inst. Pasteur, 6 (1908), No. 17, p. 769*).—The author has observed 3 types of parasites (Proteosoma, Haemoproteus, and Leucocytozoon) in the birds of Brazil. Of the 20 orders of birds recorded from the country representatives of 9 have been found with hematozoan parasites.

Coexistence of a Leptomonas (Herpetomonas) and a trypanosome in a nonpuncturing muscid (Drosophila confusa Staeger), E. Chatton and E. Alilaire (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 20, pp. 1004–1006, fig. 1*).—The authors found 2 Flagellates (a Herpetomonas and a Trypanosoma) occurring in *Drosophila confusa*, a fly very commonly met with in fermentation work at the Pasteur Institute. They consider this to be the first true trypanosome to be reported as occurring in an arthropod that does not suck blood and as an argument against the vertebrate origin and in favor of the arthropod origin of trypanosomes.

The government veterinary surgeon's report on the disease caused by the Strongylus parasite, J. D. Miller (*Proc. Agr. Soc. Trinidad and Tobago, 8 (1908), No. 9, pp. 373–375*).—A brief account is given of the Strongylus parasite as met with in the colony of Trinidad and Tobago. It is stated that the pure-bred zebu cattle resist the ravages of the parasite best and that sheep succumb more easily than other animals. Directions are given for the treatment necessary to prevent the ravages of the parasite.

Concerning Trypanosoma congolense, A. Laveran (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 9, pp. 452–455*).—Two goats inoculated with *T. congolense* acquired complete immunity. These animals were then inoculated with *T. dimorphon*, one having died and the other being seriously affected at the time of writing. The author concludes that the two trypanosomes are distinct species.

The transportation of live stock, N. S. Mayo (*Amer. Vet. Rev., 34 (1908), No. 1, pp. 30–34*).—An account read before the American Veterinary Medical Association in which directions are given for the treatment of live stock before and during transportation and after arrival at point of destination.

The Seabury cattle spraying machine, C. P. Lounsbury (*Agr. Jour. Cape Good Hope, 33 (1908), No. 3, pp. 336–340, fig. 1*).—A description is given of this machine for use in the destruction of ticks, mange, and lice, and it is announced that one has recently been imported into South Africa. Several hand-spraying tests are reported which indicate that in the application of dips power spraying must be greatly superior.

Apparatus of service in experimental pathology, F. P. Gay (*Jour. Med. Research, 19 (1908), No. 1, pp. 73–75, pl. 1*).—An autopsy board for animals and a self-regulating water bath maintaining a constant temperature are described and illustrated.

Some common disinfectants, M. Dorset (*U. S. Dept. Agr., Farmers' Bul. 345, pp. 12*).—This account has been prepared in order to correct much popular misconception in regard to the value and limitations of the various disinfectants sold in this country. Directions are given for the production of gas from formalin, from paraform, and from wood alcohol. The advantages and disadvantages in the use of formaldehyde, carbolic acid, and cresol are summarized for ready reference. Other disinfectants considered are compound solution of cresol, chlorid of lime, and bichlorid of mercury.

Filing system for bulletins, miscellaneous pamphlets, and clippings, M. H. Reynolds (*Amer. Vet. Rev., 33 (1908), No. 6, pp. 692–700*).—An account and key is given of a decimal system for the filing of bulletins and other literature of value to the veterinarian.

RURAL ENGINEERING.

Cost of pumping from wells for the irrigation of rice in Louisiana and Arkansas, W. B. GREGORY (*U. S. Dept. Agr., Office Expt. Stas. Bul. 201, pp. 39, figs. 2*).—In continuation of work previously noted (E. S. R., 19, p. 86), this bulletin gives the results of tests made to determine the relative cost as well as the efficiency of the methods and machinery used for irrigation pumping in Louisiana and Arkansas, with a view to supplying data to enable rice growers to decide whether to purchase water or to install individual plants.

The 18 plants tested are described in detail, with the results of each tabulated and peculiarities in conditions noted. The author notes that in certain plants having submerged centrifugal pumps the efficiency of engines, pumps, and wells could not be segregated because of the lack of a vacuum gauge attached to the suction pipe, and where there was a poor showing made the fault could not be assigned.

As a result of the tests the writer says, "it appears that under ordinary conditions there is a slight financial advantage in securing water from a canal."

Pumping for irrigation, E. RABETÉ (*Jour. Agr. Prat., n. ser., 16 (1908), No. 47, pp. 654–658*).—Two conventions were held recently at Cahors and Villeneuve-sur-Lot, to investigate the economic value and make tests of the various methods of pumping water in large quantities for irrigation. The conclusions from the convention at Cahors are briefly summarized in the article, among them being that machines furnishing the largest output show the least cost of renewal, and that, other conditions being equal, slow-speed motors are the most economical. The results of the Villeneuve convention are given fully.

At Villeneuve there were in all 16 pumping units tested. Of these 12 had motors of the explosive type and were operated in these tests on naphtha of specific gravity 0.7, 3 had electric motors operated by a continuous current of 230 volts, and 1 had a hot-air engine. In tables showing the experimental and calculated results three classes are observed: (1) Pumping units with an hourly output of more than 36 cu. meters of water lifted to a height of 5 meters; (2) between 5 and 36 cu. meters; and (3) less than 5 cu. meters of water. Many combinations of motors and pumps were tested, as, for example, in the first class were found stationary and movable motors with centrifugal pumps and electric motors belt-connected to centrifugal pumps. In the second class there were centrifugal, duplex, and triplex pumps with belt connections and also a diaphragm pump, all of which were operated by explosive motors. In the third class there were electric motors direct-connected and geared to centrifugal pumps, and also a hot-air engine operating a piston pump.

A table gives the results of cost and output by the hour, and by 100 kg. raised 5 meters. The costs in each class per horsepower per hour were approximately 9, 22, and 26 cts., respectively, with naphtha at 30 cts. per gallon and electric current at 5 cts. per kilowatt-hour.

The high economy of units of large output, the advantages of electric motors of small and average output, and the practical merits of hot-air engines are noted as conclusions from the tests.

Irrigation pumping, A. CHATTERTON (*Rpt. Dept. Agr. Madras, 1907–8, pp. 25–31*).—This report contains information on the installation of oil engines in that locality, the experiments made on government plants to determine the duty and a basis for the sale of water, and the governmental assistance rendered to irrigators in installing pumps. In a few cases the water is taken from streams, but mostly from driven wells. There is also a general account of well-boring operations as carried on in this district.

Irrigation in Victoria, H. G. McKINNEY (*Engin. Rec., 59 (1909), No. 3, pp. 62, 63*).—This is a brief historical review of irrigation in the State of Victoria, showing the causes of failure of many of the promoting companies and giving an account of the work of the commission appointed to investigate the subject of irrigation and rural water supply, and of its efforts to extend irrigation works in the State.

Experimental irrigation farm, W. J. ALLEN (*Agr. Gaz. N. S. Wales, 19 (1908), No. 11, pp. 927–937, figs. 17*).—The author describes the Yanco irrigation farm established by the government as the first to make use of the water provided by the Great Northern Murrumbidgee Scheme. The implements and methods used in preparing the land for water are described and illustrated.

An Egyptian steam cultivator (*Sci. Amer., 100 (1909), No. 7, p. 133, figs. 2*).—This machine is constructed with the idea of pulverizing the soil and stirring and aerating it at the same time that it is broken up. It is illustrated in this article and its mode of operation described.

The essential feature is a set of six disks rotating in a vertical plane transverse to the length of the machine, with curved cutting blades attached to the periphery of the disks at right angles to their plane. The disks are supported at the rear of the locomotive on a U-shaped frame, which can be raised or lowered, allowing the depth of cultivation to be varied up to 12 in. Official tests of the cultivator showed a working capacity of 1.58 acres per hour at an average depth of 9 in. in very dry and hard ground. The engine used was of the vertical type, but will be replaced in later models by a 2-cylinder horizontal type to give more room and better access to the engine parts.

New cotton picking machine (*Nat. Cooperator and Farm Jour., 30 (1909), No. 14, p. 9*).—There is described here a new machine which is reported to have been successfully operated under difficult conditions. It consists essentially of a large drum containing a fan operated by a 2½ horsepower gasoline engine. On the outside of the drum are connected 4 pieces of spiral rubber suction hose, tapering from 2¾ in. at the drum end to 1¾ in. at the nozzle. The cotton is drawn into the machine through these tubes and passes into a square exhaust pipe over the top of the machine and down to about 4 ft. from the base of the wagon carrying the machinery.

Destruction of concrete by alkali, W. P. HEADDEN (*Colorado Sta. Bul. 132, pp. 3–8*).—This contains chemical analyses, made by the author, of cement drain tile, which had disintegrated after only 8 or 9 months' use and also of river water which is assumed to be similar in composition to that which acted on the tile, with a discussion of the relative influence of the chemical constituents involved.

"The salient features in the composition of the salts present in the ground waters of this section are the large amount of sulphates and the presence of carbonates."

The action of a mixture of sodium sulphate and carbonate on coarsely ground concrete was also experimented with and found to yield rapidly a white decomposition product rich in carbon dioxid. The final conclusion from the results of the experiments is that "the action of the ground waters seems to have been one of chemical change converting the lime of the cement into a sulphate and carbonate, accompanied by the removal of silicic acid, alumina, and lime and totally destroying the cohesiveness of the concrete."

The construction and filling of silos, W. A. LINKLATER (*Washington Sta. Popular Bul. 10, pp. 8, figs. 11*).—There are described and illustrated silos of the following types: The King, a stave silo bound with iron hoops, a round silo with wooden hoops, and an eight-side silo of concrete. Practical suggestions

are also given regarding the location, size, and filling of silos, and notes on corn binders, racks, and cutters.

Greenhouse and conservatory construction and heating, P. N. Hasluck (*New York and London, 1907, pp. 160, figs. 238*).—This is stated to be a comprehensive digest of information contributed to the *Building World* (London) on methods and details of construction of various greenhouses and conservatories. The subjects treated are principles of greenhouse construction, horticultural glass and glazing, lean-to greenhouses and conservatories, span-roof greenhouses, dome-roof conservatories, conservatory and veranda, window conservatories, and heating greenhouses. The text is fully illustrated.

Ventilation for dwellings, rural schools, and stables, F. H. King (*Madison, Wis., 1908, pp. VI+128*).—In the introductory chapter of this brief treatise, which is intended especially for parents, teachers, and school officers and the owners and caretakers of live stock, the author discusses the requirements of man and of animals and gives specific examples of the evil effects of insufficient ventilation. There are also discussed the amount of air required, chemical changes and loss of sustaining power in respired air, and the influence and removal of moisture, and simple experiments bearing on these points are suggested.

The second chapter, treating of the principles of ventilation, takes up air movement, the motive power used, and the influence of the wind in this respect. Experiments illustrating air movement are suggested, and the relation of air movement to ventilator construction is discussed.

In chapter 3, on ventilating practice, are given designs of systems for dwellings, rural schoolhouses and churches, stables and poultry houses, showing the application of the principles involved.

RURAL ECONOMICS.

Better agriculture and how to get it, J. Hamilton (*Harrisburg, Pa., 1908, pp. 17*).—This is an address given before the meeting of the Pennsylvania State Board of Agriculture at Harrisburg, January 22 and 23, 1908. It presents a comparison of yields of staple agricultural products in this country and abroad and shows that the greater yields in foreign countries are due in part to the better facilities afforded for itinerant instruction in agriculture.

The latent forces of country life (*Jour. Soc. Agr. Brabant et Hainaut, 53 (1908), No. 52, pp. 1147–1149*).—This article is summarized from a recent work by Tibbaut dealing with the problem of the improvement of rural conditions in Belgium.

The natural healthfulness of the country, it is believed, is not a sufficient inducement to keep farm laborers on the land, and the improvement of the economic and social conditions of country life to counteract the so-called attractions of town life is recommended. Among the needs of the rural population at the present time, the lack of credit is believed to be the greatest. If easier facilities for securing credit could be arranged, together with the affording of opportunity to the laborer of becoming a small holder, it is thought the rural population would greatly increase in numbers and vigor of life.

Farmers' cooperative demonstration work in its relation to rural improvement, S. A. Knapp (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 21, pp. 20*).—The author discusses the necessity for improved rural conditions in the South and presents the remedy offered by the farmers' cooperative demonstration work conducted under the direction of the Bureau of Plant Industry of this Department, with some of the results thus far accomplished.

The demonstration work at present consists in practical field instruction to farmers in scientific agriculture by means of field agents, the instruction being confined to a few essential subjects. When the rudiments of good farming are mastered the farmer secures a greater income for his labor, and he is then taught that this greater income should be applied to the reduction of debt, the betterment of the family and the home, and the improvement of rural conditions. It is claimed that where cooperative demonstration farming has been carried on with sufficient intensity to influence public opinion there have resulted increased yields per acre, the purchase of more and better horses or mules, a great increase in the use of better implements, general interest in seed selection and the use of the best seed, home and school improvements, more months of schooling, better highways, increase of a healthy social life in the country, and intense interest in agriculture.

Cooperation true Americanism, W. M. HAYS (*Raleigh, N. C., 1908, pp. 11*).—This is an address by the Assistant Secretary of Agriculture of this Department read before the Southern States Association of the Commissioners of Agriculture and Other Agricultural Workers at Columbia, S. C., in November, 1907.

The author describes the methods and extent of business carried on by various cooperative dairy, fruit, grain, irrigation, drainage, meat, egg, breeding, and credit associations in the United States and foreign countries, points out the advantages of such organizations in encouraging farm life and promoting national welfare, and urges the appointment of a nonpartisan federal cooperative organization commission to supervise, encourage, and assist the formation of cooperative enterprises in the United States.

Agricultural organization, E. SMITHELLS (*Agr. Students' Gaz., n. ser., 14 (1908), No. 2, pp. 47–51*).—Notes are given on the general principles which govern in cooperation, and improvement in the agricultural industry in England is discussed from the following points of view: (1) That the cost of production must be reduced; (2) that the returns for produce sold must be increased; and (3) that the general conditions under which farming is carried on must be improved. Cooperation among farmers is believed to be the only means to the attainment of these ends.

Producers' associations and cooperative selling and credit societies in France to January 1, 1908 (*Bul. Off. Travail [France], 15 (1908), Nos. 8, pp. 730–741; 9, pp. 844–852; 10, pp. 978–985; 11, pp. 1109–1113*).—Complete returns for the year 1907 are presented and discussed.

The producers' associations numbered 414, as compared with 362 at the close of 1906; the selling associations numbered, respectively, 2,301 and 2,166 for the same periods; and the cooperative credit societies, including 17 district banks and 2,168 rural banks, numbered 2,185 at the close of 1907, a gain of 530 societies over the preceding year.

A serious menace to agricultural associations, HUBERT-VALLEROUX (*Écon. Franç., 36 (1908), II, No. 48, pp. 787–789*).—The author maintains in this article that the test cases made in the courts of France as to the legal standing and functions of agricultural associations must result in their disorganization unless the government so amends the law as to permit the cooperative purchase of supplies and sale of produce in bulk for the benefit of members.

The legality of the operations of agricultural associations, R. WORMS (*Bul. Soc. Nat. Agr. France, 68 (1908), No. 8, pp. 606–629*).—The author discusses the decisions of the courts of France with reference to agricultural associations, differentiates their functions from those of agricultural cooperative societies, summarizes the main points of the proposal made by the minister of agriculture relative to a law legalizing the operations of "economic agri-

cultural associations" designed to take the place of the present associations, and points out the defects in the proposal should it become law.

The agricultural associations (*Feuille Vin. Gironde, 34 (1909), No. 2, pp. 6, 7*).—A review of the development of these associations in France, together with the text of the proposed law and a discussion of its provisions.

Concerning agricultural credit in Rumania, D. Gociu (*Über den landwirtschaftlichen Kredit in Rumänien. Inaug. Diss., Univ. Erlangen, 1907, pp. IV+96*).—This deals with the history and economic significance of the different institutions concerned with agricultural credit in Rumania. Among the benefits to the rural classes as a result of the organization of cooperative credit have been to reduce the amount of mortgages, to increase farm values and farm rents, and to lower the rates of interest. Before the establishment of mutual credit and other agricultural banks annual interest rates ranged from 60 to 570 per cent, but farmers can now secure loans through their societies at from 4 to 7 per cent per annum.

The improvement of farm labor conditions in North Germany (*Deut. Landw. Presse, 35 (1908), No. 97, pp. 1015, 1016*).—This article contains the conclusions reached by Gerlach in his book entitled Ansiedlung von Landarbeitern in Norddeutschland, these being reprinted because of their important bearing on the farm labor problem in Germany. The results of the inquiry relate particularly to the improvement of the economic and social conditions surrounding the life of the farm laborer and include suggestions relating to the granting of land to farm laborers for the growing of their household supplies, the keeping of cows, pigs, and other live stock, regular hours of labor, better housing conditions, better schools for the children, etc. It is believed that the sense of proprietorship in land and other property on the part of farm laborers will be the strongest factor in retaining the most efficient workers on the land.

What influence has piecework upon the agricultural labor problem and how can its most important features be carried out? L. von der Heyde (*Illus. Landw. Ztg., 28 (1908), Nos. 94, pp. 805–807; 95, pp. 813, 814*).—The author shows from the operation of a large farm that there is little financial advantage to the farmer who hires help whether he pays by the year, day, or piecework, but that the moral effects upon the pieceworker and other laborers favor the last-mentioned method of employment. The modification of the conditions and pay of piecework, according to soil, weather, and other circumstances, is advocated for the mutual advantage of both farmer and laborer.

Farm laborers' wages (*Agr. Gaz. [London], 68 (1908), No. 1825, p. 389*).—The wages of farm laborers in Great Britain are discussed in this article. At present these range from 8s. 9d. (about $2.10) per week in County Mayo, Ireland, to 25s. 5d. (about $6.10) in Lancashire, England.

Cost of producing crops in the Hawkesbury district (*Agr. Gaz. N. S. Wales, 19 (1908), No. 9, pp. 732–734*).—From tests made in Australia, the cost of producing corn was about £4 per acre, the estimated profit being about £2 5s. The corresponding figures for the cost of wheat for hay and for grain were £2 11s. 7d. and £1 14s. 9d., the profits being estimated at about £1 8s. per acre for each crop.

Turkish land tenure (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 11 (1909), No. 2, pp. 15, 16*).—Notes are given on the chief systems of land tenure in Turkey, namely, government ownership, eleemosynary ownership, and freehold. The greater part of the land devoted to agriculture is owned by the State, the peasants working the land on shares called the "tithe," strictly tenderable in produce, although usually paid in money. The pasture land is held in common

for the use of the whole village without limitation as to the number of cattle that may be admitted by any one peasant. Instances of collective farming are also reported. Notes are also given on the methods of transferring land, taxation, and other economic features of the Turkish system.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 11 (1909), No. 2, pp. 9–16*).—Statistics on the number and value of farm animals in the United States, the stocks of potatoes on hand, the imports and exports of animals and animal products in 1907 and 1908, and other data on the condition of crops and live stock in foreign countries are reported, together with an article on the Turkish land tenure system noted above.

AGRICULTURAL EDUCATION.

The educational needs of country life, E. A. Bryan (*Pacific Homestead, 18 (1908), No. 18, p. 29*).—In this article the author advocates instruction in agriculture in the public schools, the consolidation of small schools, and the giving of agricultural instruction through extension work to the adult members of the community.

The work of the agricultural school in the scheme of State education, A. M. Soule (*South. Ed. Rev., 5 (1908), No. 7–8, pp. 176–186*).—A paper advocating the consolidation of rural schools and the establishment of Congressional district agricultural high schools.

Centralized schools in Ohio, A. B. Graham (*Agr. Col. Ext. Bul. [Ohio State Univ.], 4 (1909), No. 6, pp. 24, figs. 41, dgms. 6*).—This summarizes the present situation in Ohio with reference to centralized rural schools. It includes the State law under which consolidation has taken place, many illustrations of the schools and means of transportation to them, and a statement of the demonstrated advantages of the new system over the old.

Teaching agriculture in public schools, W. J. Spillman (*Wallaces' Farmer, 33 (1908), No. 52, p. 1601, fig. 1*).—Suggestions for teaching agriculture in public elementary schools without the use of a text-book.

Agricultural education with special reference to Ireland, J. R. Campbell (*Dept. Agr. and Tech. Instr. Ireland, Jour., 9 (1908), No. 1, pp. 3–18*).—In this address, delivered before the British Association for the Advancement of Science at Dublin, September, 1908, there are discussed (1) the want of harmony in methods of providing for and administering agricultural education in different countries, (2) science as an aid to agriculture, (3) the agricultural work and policy of the Department of Agriculture and Technical Instruction for Ireland, (4) the department and agricultural education, (5) agricultural education for women, (6) agriculture and elementary schools, and (7) agriculture and the universities.

Agricultural education, N. G. Mukerji (*Handbook of Indian Agr. Calcutta, 1907, 2. ed. rev., pp. 696–700*).—A brief statement of the present status and opportunities for development of agricultural education in India.

The College of Hawaii: Its work and outlook, J. W. Gilmore (*Hawaii. Forester and Agr., 6 (1909), No. 1, pp. 2–13*).—Brief reference is made to the agitation for colleges for the industrial classes and the Morrill acts of 1862 and 1890. The organization of the College of Hawaii, and the courses of study are outlined and described.

The State Agricultural Institute, Gembloux, H. Raquet (*Expansion Belge, 1 (1908), No. 11, pp. 469–475, figs. 12*).—A historical account of the organization, work, maintenance, etc., of the State Agricultural Institute at Gembloux.

College course for florists, C. N. Page (*Weekly Florists' Rev., 23 (1908), No. 577, pp. 10, 11*).—This paper, which was read at a meeting of the Society

of Iowa Florists, in Des Moines, December 9, 1908, suggests a college course for florists.

A course in agriculture for the public schools of Michigan, W. H. FRENCH (*Mich. Agr. Col., Dept. Agr. Ed. [Pamphlet], 1908, pp. 36*).—A brief outline for a course in agriculture for the elementary schools of Michigan is given, together with a similar outline for high schools, supplemented by more detailed directions for carrying on botanical work, lessons on farm crops, farm management, farm mechanics, horticulture, animal husbandry, and soils. Lists of books and bulletins suitable for the agricultural library of high schools are suggested.

Agriculture and school gardens, S. C. KELLERER (*Philippine Agr. Rev. [English Ed.], 1 (1908), No. 8, pp. 327–334, pls. 3*).—The writer gives reasons for teaching agriculture and school gardening and specific directions for preparing school gardens.

Suggestions for school gardens, J. R. WILLIAMS (*Jamaica, 1908, pp. 148, dgms. 3*).—This is a manual for teachers, dealing with garden processes rather than the principles of plant production. In the main part of the book the author takes up the selection and preparation of garden plats, the necessary tools, soils, seed beds, seedlings, care of plants, propagation of plants, rotations, and friends and enemies of the garden. This is followed by appendixes dealing with cultural directions for vegetables, cocoa, coffee, ginger, pineapples, tobacco, bananas, oranges, cotton, Guinea corn, sarsaparilla, pindars, vanilla, and flowers, with one chapter on insecticides.

Improvement of school grounds, H. L. HUTT (*Toronto: Ed. Dept. Ontario, 1908, pp. 35, pls. 12, dgms. 12*).—Plans and suggestions for the improvement of rural and urban school grounds.

Home nature-study course, ANNA B. COMSTOCK (*Home Nature-Study Course [Cornell Univ., State Col. Agr.], n. ser., 5 (1908), Nos. 1, pp. 40, figs. 14; 2, pp. 41–64, figs. 12; 3, pp. 65–88, figs. 13*).—Suggestions for the work of fourth and fifth year pupils as outlined in the Syllabus of Nature Study and Agriculture issued by the New York State Department of Education. There are given 3 lessons on the woodchuck, 3 on the brook, 2 on the kingfisher, 4 on the witch-hazel, 3 on the hickory, 7 on spiders and their webs, 2 on the moon, 2 on the crow, 2 on the beech, 4 on star study, 1 on wild carrot, 1 on a wasp nest, 3 on the muskrat, 5 on the honeybee, 1 on the walnut, and 1 on the sun.

Nature's craftsmen, H. C. MCCOOK (*New York and London, 1907, pp. XII+317, pl. 1, figs. 103*).—A collection of nature stories concerning ants, antlions, bees, spiders, birds, wasps, cicadas, water-striders, and caddis worms, with two chapters discussing insects and civilization and beneficial and injurious insects.

[Exercises in nature study] (*Agr. Col. Ext. Bul. [Ohio State Univ.], 4 (1908), Nos. 3, pp. 4–12, figs. 9; 4, pp. 4–14, figs. 14*).—These numbers contain the following articles: The Story of the Life of a Moth, by F. M. Webster; What Makes the Wind Blow, by J. W. Smith; and A Little Lesson in Studying Sheep, by C. S. Plumb.

Propagation of plants, V. H. DAVIS (*Agr. Col. Ext. Bul. [Ohio State Univ.], 4 (1909), No. 5, pp. 16, figs. 11*).—A study of the propagation of plants by (1) seeds or spores and (2) the vegetative method or division of the plant.

Tillage and cultivation, A. G. MCCALL (*Agr. Col. Ext. Bul. [Ohio State Univ.], 4 (1909), No. 7, pp. 4–11, figs. 7*).—This describes and illustrates the proper cultivation of the soil for water storage, aeration, and conservation of moisture, and suggests simple experiments for use in rural schools.

A corn primer, C. S. KNIGHT (*Agr. Ed. [Kans. Agr. Col.], Teachers' and Pupils' Ser., 1 (1908), No. 1, pp. 46, figs. 15*).—A guide for teachers in helping their students to become more familiar with the characteristics of corn. It

deals with the botany of the plant, its types or general classes, the types most commonly grown in this country and important varieties grown in Kansas, studies of the plant and the ear, and of the different parts of the kernel, and their mechanical separation, corn as food, commercial products of corn, its importance as a crop, its improvement by means of fertilizers, culture, and breeding, corn judging, and suggestions for corn experiments.

MISCELLANEOUS.

Twenty-first Annual Report of Illinois Station, 1908 (*Illinois Sta. Rpt. 1908, pp. 11*).—This contains lists of the publications of the station issued since its establishment and during the fiscal year, a brief statement concerning the principal lines of station work, and a financial statement for the fiscal year ended June 30, 1908.

Nineteenth Annual Report of Mississippi Station, 1906 (*Mississippi Sta. Rpt. 1906, pp. 12*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1906, and a report of the director on the work of the station during the year.

Twentieth Annual Report of Mississippi Station, 1907 (*Mississippi Sta. Rpt. 1907, pp. 12*).—Data corresponding to the above are presented for the fiscal year ended June 30, 1907.

Twenty-first Annual Report of Mississippi Station, 1908 (*Mississippi Sta. Rpt. 1908, pp. 1½*).—Data corresponding to the above are presented for the fiscal year ended June 30, 1908.

Twenty-seventh Annual Report of Ohio Station, 1908 (*Ohio Sta. Rpt. 1908, pp. XXIX, pl. 1*).—This contains an announcement concerning the work of the station, the organization list, a report of the board of control, a financial statement for the fiscal year ended June 30, 1908, and a report of the director summarizing the work of the station during the year.

Report of the Imperial Department of Agriculture for the years 1905–6 and 1906–7 (*Rpt. Imp. Dept. Agr. [India], 1905–1907, pp. IV+76*).—This includes the reports of the inspector-general of agriculture in India, the officiating director of the agricultural research institute, and the various heads of departments. An appendix contains a list of agricultural publications in India during 1905–6 and 1906–7.

Report of the work of the agricultural experiment station of the University of Jena for 1907 (*Ber. Landw. Vers. Stat. Univ. Jena, 1907, pp. 32*).—A summary of the work of this station for 1907 in fertilizer, feeding stuffs, and dairy products control, seed inspection, plant diseases, variety testing, fertilizer trials, veterinary science, and other lines.

Memorial of the celebration of the fiftieth anniversary of the agricultural experiment station at Pommritz (*Denkschrift zur Feier des 50 jährigen Bestehens der Agrikulturchemischen Versuchsstation für die Königl. Sächs. Oberlausitz zu Pommritz. Pommritz, [1907], pp. 69, figs. 3*).—This contains an account of the history and work of the station, the period from its establishment in 1856–1881 being discussed by E. Heiden, and the subsequent history to 1907 by G. Loges.

Note on agriculture in Japan, F. A. Nicholson (*Madras: Govt., 1907, pp. VII+122, pls. 2, fig. 1*).—Observations on agricultural practice in various parts of the southern districts of Japan, as based on a visit in 1906, are presented. The general conditions and characteristics of Japanese agriculture, the use of manures, and the forest conditions are set forth, with an account of new methods being introduced through education, the establishment of experiment

stations, agricultural associations including agricultural banks and cooperative associations, and the supervision of fertilizers.

Encyclopedia of agriculture, edited by C. E. GREEN and D. YOUNG (*Edinburgh and London, 1908, vol. 3, pp. VIII+633, pls. 17, figs. 157, map 1*).—This is the final volume of the general encyclopedia of agriculture and contains articles on topics arranged alphabetically from Kainit to Zelkova.

The British yearbook of agriculture and agricultural who's who, 1908–9 (*London, 1908, pp. VI+582*).—A handbook of information relative to British agriculture, the data being grouped under 10 heads, as follows: Societies and institutions of a national and general nature; county and local societies and institutions; agricultural, horticultural, and veterinary education and research; diseases of animals, including the regulations of the Board of Agriculture and Fisheries relating thereto; British foreign and colonial regulations relative to the importation and exportation of animals; lists of British agricultural publications, including official documents, books issued during 1907, publications of societies, agricultural colleges, county councils and similar bodies, and periodicals, as well as of official publications of the British colonies, India, and this country; markets, sales, and prices of agricultural products; statistical, legal, and general information, including data on small holdings, a list of shows in 1908; and an agricultural "who's who," which gives data regarding about 2,000 teachers, writers, and other persons prominently connected with agriculture in Great Britain.

American Agriculturist handbook for 1909 (*New York, Chicago, and Springfield, Mass., 1909, pp. 192, figs. 90*).—This is stated to be "a ready reference book for farm, home, and office." It contains statistical data with reference to crop yields and animal production for 1908; accounts of the work of the Forest Service and the Weather Bureau of this Department, and of the conservation movement; a glossary of terms used in agricultural science; brief discussions of various agricultural operations, including a spraying calendar, planting tables and feeding stuffs tables; and a directory of officers in charge of National and State agricultural work and of a large number of agricultural organizations, together with a variety of miscellaneous data.

The commercial products of India, G. WATT (*London, 1908, pp. VIII+1189*).—This is an abridgment of The Dictionary of the Economic Products of India, and constitutes an encyclopedia of Indian animal, vegetable, and mineral products of present or prospective commercial and industrial importance.

Press bulletins (*Ohio Sta. Bul. 196, pp. 283–285*).—Reprints of press bulletins on the following subjects: Yellow leaf in oats; late blight and rot fungus of potatoes now prevalent; the failure of the clover crop; seed corn for the season of 1908; how to fight the rose chafer; and the grape berry worm.

Experiment Station Work, XLIX (*U. S. Dept. Agr., Farmers' Bul. 342, pp. 32, figs. 3*).—This number contains articles on the following subjects: Conservation of soil resources, potato breeding, disk-harrowing alfalfa, the Montreal muskmelon, storage of Hubbard squash, fig culture in the South, mushroom growing, preserving wild mushrooms, cooking beans and other vegetables, and a model kitchen.

NOTES.

Colorado College and Station.—According to a note in *Minnesota Farm Review*, Fritz Knorr, assistant agronomist, has resigned to engage in commercial work.

Delaware College and Station.—The legislature has appropriated $10,000 for new buildings on the college and station farm and a like amount for repairs and maintenance of the college buildings.

Florida University and Station.—Dr. Andrew Sledd, president of the university for 4 years, has resigned to take effect July 1, and Dr. A. A. Murphree, president of the Florida Female College, has been chosen his successor. Thomas Hamilton, assistant plant pathologist, has resigned.

Hawaiian Sugar Planters' Station.—C. F. Eckart has returned from his leave of absence and resumed charge of the division of agriculture and chemistry.

Idaho University and Station.—H. T. French has resigned as director to take effect June 1. The establishment of three substations has been recently authorized, one of them to be located in either Bonner or Kootenai counties for work in connection with stump lands and swamp lands, another in Lincoln County for work with irrigation problems, and the third in Bingham County for work in dry farming.

In the university departments of veterinary science and forestry have been added, the latter to offer a regular 4-year course and a short winter course for forest rangers.

Purdue University and Station.—In addition to the increased appropriations to the station for maintenance, previously noted, the college of agriculture was granted $30,000 for a live stock judging pavilion and $20,000 for a farm mechanics building. A slight reduction was made as to the fees to be collected in the feeding stuffs inspection work of the station.

Iowa College and Station.—John Bower, assistant professor of dairying in the college and assistant dairyman in the station, and H. C. Horneman, in charge of the extension work in dairying, have resigned to engage in commercial work. E. T. Robbins has been succeeded as assistant in animal husbandry in the station by H. H. Kildee.

Kansas College and Station.—Appropriations aggregating $671,500 were granted by the last legislature for the ensuing biennium, together with $12,666.67 additional to restore endowment. Among the items authorized are $375,000 for current expenses, $35,000 for the purchase of land, $100,000 for an armory, gymnasium, and equipment, $5,000 for an athletic field, $10,000 for a greenhouse, $30,000 for the station, $52,500 for farmers' institutes, $25,000 for engineering equipment, $10,000 for a dairy herd and building, and $29,000 for heat and power equipment, repairs, and improvements to the grounds.

Kentucky Station.—W. H. Scherffius, head of the agricultural division, has resigned to take up work in South Africa, and L. A. Brown, of the North Dakota Station, has been added to the staff as chemist in the drug division.

Minnesota University.—*Science* announces a gift to the university by the Weyerhauser interests of St. Paul of 2,200 acres of land in Carlton County for experimental work in forestry.

Cornell University.—The exercises of Farmers' Week, held February 22–27, were very largely attended, the registration reaching 1,275. The programme included a general reunion of agricultural students resulting in the formation of a permanent association, meetings of the State Experimenters' League, Plant Breeders' Association, Poultry Association, the Cornell Horticultural Union, the Dairy Students' Association, the newly formed State Drainage Association, and other organizations, together with a corn congress, horse show, poultry institute, housekeepers' conference, the second annual agricultural stage, and a large number of lectures and demonstrations.

The total enrollment in the college of agriculture is 813, of whom 364 are in the three-months' winter course. The instruction in economic entomology, formerly given by the late Professor Slingerland, has been temporarily discontinued. A bequest made to the university by the late Dr. Charles A. Ring, of Niagara County, the interest of which is to be used in the advancement of horticultural science, is announced. The recent death is noted of Dr. C. H. Roberts, the donor of the 5 scholarships for aiding needy students in the college of agriculture.

A. R. Mann, formerly assistant professor in dairy industry, has been appointed secretary to the dean. Allan Ferguson, assistant in cheese making, has resigned to engage in commercial work.

North Carolina State Station.—I. O. Schaub, assistant in soils at the Iowa Station, has been appointed to carry on similar work at this station and has entered upon his duties.

Ohio University and Station.—The department of horticulture and forestry in the university has been divided, W. R. Lazenby retaining charge of the work in forestry. The first State poultry institute was held at the university March 9 and 10.

In the station, recent appointments include J. J. Crumley, Ph. D. (Johns Hopkins), of Antioch College, assistant forester; John S. Houser, whose resignation from the Cuban Experiment Station is noted elsewhere in this issue, and Leonard L. Scott, assistant entomologists; and W. A. Lloyd, assistant experimentalist.

Oregon College and Station.—The third demonstration train to be sent out was recently operated in southern Oregon, and in general interest and attendance was remarkably successful. Fully 30,000 people visited the train during the 4 days it was in operation, this representing two-thirds of the total population of the district traversed.

The special features emphasized were horticulture and poultry husbandry. The two horticultural cars were filled with educational material, including modern spraying devices, orchard tools and implements, specimens of correct and incorrect methods of grafting, pruning, budding, etc., frost-fighting apparatus, models of greenhouses and cold frames, seed-testing equipment, a large collection of the various types of soils, fertilizers, cover crops, and charts of special value to the orchardist and gardener.

In the poultry exhibit a flat car was inclosed with a portable poultry fence within which was a modern colony house and a flock of 20 Barred Plymouth Rocks. A baggage car contained further exhibits of 12 breeds of poultry, both live and dressed, various types of brooder houses in operation, incubators, trap nests, bone mills, spray devices, egg packers and other appliances, and numerous charts containing data as to the value of different rations for egg production, systems of housing, and other topics of interest.

Utah College and Station.—Appropriations to the college and station aggregating $202,100 have been made by the legislature. This is nearly double the

total amount granted 2 years ago, and represents the full amount requested. The college received $132,000 for maintenance, $20,000 for remodeling the women's building, $3,500 for a veterinary hospital, $2,500 for a stock-judging pavilion, and $600 for an incubator cellar. The grant for farmers' institutes was increased from $3,000 to $10,000. The station was given $5,000 for publications, $10,000 for dry-farming investigations, $11,000 for fruit investigations, and $7,500 for irrigation and drainage investigations. The various members of the board of trustees were reappointed, with the exception of A. S. Condon, who has been succeeded by Mathoniah Thomas of Salt Lake City. Under a new law the board is to be increased to 9 members, but the additional appointees have not as yet been announced.

Vermont University and Station.—*Science* announces that William Stuart, professor of horticulture and horticulturist, has accepted an appointment with the Bureau of Plant Industry of this Department, and will enter upon his duties at the close of the college year.

Wisconsin University and Station.—An experimental forestry laboratory is to be established at the university by the Forest Service of this Department. A building to cost $30,000 is to be erected for the purpose at an early date by the university, on a site adjacent to the college of agriculture. The Forest Service is to supply equipment and maintain a corps of investigators. It is expected that the laboratory will be available to the faculty and students of the university for research work, and that members of the staff will deliver lectures on forestry and related topics in the university courses as well as in a course for forest rangers to be established by the university. Among the lines of experimental work to be taken up in the laboratory are tests of various woods for paper pulp and for building materials, and the distillation of turpentine, alcohol, and resin from wood waste.

The new animal husbandry building and judging pavilion has been completed at a cost of about $75,000. The building is built of reinforced concrete and brick, with tile roofing, and contains offices for the departments of horse breeding and animal husbandry and the farm superintendent, veterinary demonstration and operating rooms, stables for breeding stock and sale animals, an isolation hospital, and an arena 165 by 65 ft., with a capacity of over 2,000.

County branches of the State Experiment Association are being organized with a view to closer supervision of experiments and greater specialization in planning tests to meet local conditons.

Wyoming University and Station.—The legislature has continued the biennial appropriation for farmers' institutes of $2,000 and has appropriated $15,000 to complete the wing of the residence hall for women, and $8,000 for the construction of barns on the station farms. V. J. Tidball, of Laramie, has been appointed on the board of trustees and the station committee, vice H. L. Stevens.

Cuban Experiment Station.—Following the change in administration, the resignations of the following members of the staff were called for: Dr. N. S. Mayo, chief, and J. S. Montgomery, assistant, department of animal industry; William T. Horne, chief, and J. S. Houser, assistant, department of vegetable pathology and entomology; R. S. Stark, chief, department of chemistry; Dr. H. Hasselbring, chief of the department of botany; and C. F. Austin, chief; C. F. Kinman, assistant, department of horticulture; Ricardo Villaescusa, assistant, department of agronomy; and Richard Hargrave, secretary. W. T. Horne was reappointed, and the department of botany was placed in his general charge.

County Demonstration Farms.—A bill has been passed by the Oklahoma legislature providing for the establishment of a demonstration farm of 40 acres in each county, under the general management of the State Board of Agriculture,

with the local supervision of the county farmers' institutes. An annual appropriation of $40,000 is provided for this work.

A similar law has been enacted by the Kansas legislature. Under this measure, however, the county commissioners are to make application to the board of regents of the Kansas College, and upon their approval the farms may be established and conducted under their supervision. The county is to provide the land necessary, which is not to exceed 40 acres. The cost of maintenance is limited to $1,500 for the first year and $500 thereafter, together with the receipts from farm products. A brief summary of each year's operations is to be distributed to each taxpayer of the county.

Under the Missouri law of 1907, the first county demonstration farm in that State is to be established in Jasper County in the near future under the joint supervision of the county court and the Missouri Station. The county contributes $500 annually for 5 years and the State assumes the remaining expense.

A New Government Dairy Farm in South Australia.—The South Australian government has purchased 1,600 acres at Turretfield, chiefly for the purpose of encouraging the keeping of improved breeds of milch cows and of demonstrating the best methods in up-to-date dairy practice. P. H. Suter, the government dairy expert, will make the farm his headquarters and will give a special course in dairying to a few students.

New Buildings of West Java Sugar Station.—An elaborate set of buildings for the sugar experiment station at Pekalongan, West Java, has recently been completed. The buildings include several laboratories and offices, a library, and a large museum.

First International Domestic Science Congress.—An account of this congress, which was held at Freiburg, Switzerland, September 29 to October 1, 1908, is given in a recent number of *Mittcilungen der Fachberichterstatter des K. K. Ackerbauministeriums*. The attendance reached nearly 700, and while the majority of those present were interested in the organization and development of domestic science instruction in city schools, agricultural instruction in the rural domestic science schools was not overlooked, and at the second session it was resolved that domestic science instruction in rural schools should be given an agricultural trend. Brief notes are also given in the number concerning agricultural domestic science instruction in Hungary, Germany, Switzerland, France, England, Sweden, Norway, and Belgium.

The Automobile in Agriculture.—A recent number of *L'Automobile Agricole*, a journal established two years ago to promote the use of mechanical motors in agriculture, announces that steps have been taken to organize an international congress of the agricultural automobile and the application of mechanical motors in agriculture.

Prospective Agricultural and Educational Meetings.—Meetings of the following organizations are announced: Association of American Agricultural Colleges and Experiment Stations at Portland, Oreg., August 18–20; American Association of Farmers' Institute Workers, at Portland, August 16 and 17; National Education Association, at Denver, Colo., July 5–9; Association of State and National Dairy and Food Departments, at Denver, August 9; and National Irrigation Congress, at Spokane, Wash., August 9–14. The National Corn Association is to hold its third show at Omaha, Nebr., December 6–18.

University of Virginia Summer School.—The University of Virginia offers a summer term from June 18 to July 31, the courses including educational psychology, rural school problems, history of education, agriculture, domestic economy, manual training, nature study, school gardening, teachers' training

work, and several other lines of study. A detailed description of all the courses appears in the April number of the *University of Virginia Record.*

Hampton Summer Session.—The Hampton Normal and Agricultural Institute, Hampton, Va., announces a four weeks' summer session for teachers, June 15 to July 13, with courses in cooking, dressmaking, manual training, nature study, poultry keeping, principles of teaching, and other academic subjects.

Louis Queiros School of Agriculture.—A letter received from the director of this institution, Mr. C. D. Smith, formerly director of the Michigan Station, gives numerous details regarding the school, which is located at Piracicaba, State of São Paulo, Brazil.

A definite organization has recently been effected, under which authority is concentrated almost entirely in the director, with the general supervision of the secretary of agriculture. The regular course of study is modeled in a general way after that at the Michigan College. It covers 3 years, with a preparatory year of arithmetic, Portuguese, French, geography, and history, and a subsequent year of special elective work in any of the sciences or in practical agriculture. The three-year course includes 3 semesters each of botany, chemistry and biology, and 1 semester each of stock judging, soils and plantations, harvests and seed selection, veterinary clinics, and carpenter and blacksmith work.

The equipment includes a farm of 800 acres of excellent land, large barns, and botanical, chemical, physical, and zoological laboratories. The faculty numbers about 10 at present, among them being J. W. Hart, formerly of the University of Illinois. The number of students is rapidly increasing and is expected shortly to reach the limit that can be accommodated under present conditions. For the maintenance of the school $274,000 is available for the present year in addition to the receipts from farm products, which amount to about $15,000.

Agricultural Instruction in Trinidad.—A recent number of *The Agricultural News* states that a course of lectures in agriculture is being given at the Port-of-Spain Training School and the San Fernando Training School. The course consists of thirty-six lectures, each of one hour's duration. One lecture is given weekly at each school, and an examination is held at the end of each twelve lectures.

Nature Study.—The *Nature-Study Review* began in May, 1908, a series of numbers, each of which is devoted to the nature-study work done in a particular State. The May number deals with California, the October number with New Jersey, the December number with Illinois, and the number for February, 1909, with Indiana. The California number presents the Place of Nature Study in the Normal School, Nature Study in the San Diego and Chico Normal Schools, the Present Needs and the Outlook for Nature Study in California, and a summary by H. W. Fairbanks. The New Jersey number contains a survey of nature study in the State, elementary science in the schools of Newark, nature study at home, practical experiments in the school room, a wild flower garden, school garden lessons at Montclair, and several other interesting articles, including A Demand for a Philosophy of Nature Study by C. H. Robison. The Illinois number includes articles on nature and other subjects of instruction, recent aspects of the nature-study movement, the nature-study situation in Illinois, school-room study of a robin's nest, and a review of the work of the John Swaney Consolidated School. The Indiana number includes articles on nature study in Indiana, the character, purpose, and extent of elementary agriculture in Indiana, nature-study work in Elkhart and East Chicago, school gardens at Delphi, corn contests in Hendricks County, and nature study in a museum by the director of the Fairbanks Museum, St. Johnsbury, Vt.

The January number is devoted largely to various phases of school industrial work. The topics are introduced with a note by O. W. Caldwell, of the University of Chicago, who argues for the inclusion of elementary industrial work in the regular school courses rather than the establishment of distinctive separate courses, because (1) efficiency in any line of industrial work requires a good general foundation in many subjects of study; and (2) general industrial education is needed to develop an understanding of the conditions of workers in other lines. "Industrial education should exist to make more efficient men and women. . . . We are in great danger of concluding that industrial education is for the work rather than for the worker." The value of poultry raising as a school occupation is illustrated by W. A. Baldwin, principal of the State Normal School, Hyannis, Mass., and C. H. Robison, of the State Normal School, Montclair, N. J., suggests "urbindustrial" and "agrindustrial" or "rurindustrial" as convenient terms for distinguishing the kind of industrial education proper to city and rural conditions.

Agricultural Legislation in Congress.—The principal agricultural legislation enacted at the final session of the Sixtieth Congress was embodied in the act making appropriations for this department, which is summarized elsewhere in this issue. In the diplomatic and consular appropriation act an appropriation of $4,800 was continued for the payment of the annual quota of the United States for the support of the International Institute of Agriculture. By a clause in the Indian appropriation act, the property of the Indian School at Morris, Minn., comprising 290 acres of land with buildings and equipment, was transferred to the State of Minnesota upon the condition that it be accepted by the State prior to July 1, 1910, for maintenance as an agricultural school to which Indian pupils are to be admitted without tuition and upon terms of equality with white pupils. By another act the University of Idaho was empowered to purchase 640 acres of land in the Coeur d'Alene Indian Reservation for use as a biological station, an encampment ground, and a forestry station. A joint resolution was passed authorizing the President of the United States to extend an invitation to the International Congress of Applied Chemistry to hold its eighth meeting in this country in 1912.

New Journals.—Société d'Études d'Agriculture Tropicale has established as its monthly organ *L'Agronomie Tropicale*. The initial number contains articles dealing with the cotton situation, stock raising in the Congo, the witch's broom disease of cacao, a list of German organizations engaged in the exploitation and culture of rubber, and abstracts of publications dealing with tropical agriculture and animal husbandry.

La Terre Vaudoise is being issued as a semimonthly by the Vaudoise Society of Agriculture and Viticulture, replacing *Chronique Agricole du Canton de Vaud* and *Bulletin de la Société Vaudoise d'Agriculture et de Viticulture*.

Wasser und Abwasser is a semimonthly journal devoted chiefly to abstracts of publications dealing with water supplies and the disposal of sewage and factory wastes. An original article also appears in each number.

Pomona Journal of Entomology is being published as a quarterly by the department of biology of Pomona College. The initial number contains articles on Aphididæ of Southern California and Notes on Coccidæ, by E. O. Essig; The Red Scale, by A. J. Cook; and Western Plant Louse Parasites, by C. F. Baker.

Fortschritte der Chemie, Physik und physikalischen Chemie is being published monthly as a new edition of *Physikalisch-chemischen Centralblattes*. Dr. Hermann Grossmann, of Berlin, is editor, and the staff includes Dr. H. Kappen, of Jena, in charge of agricultural chemistry; Dr. F. Ehrlich, of Berlin, in charge of the chemistry of the agricultural industries; and Dr. Hübner, of Berlin, in

charge of food chemistry. The initial number deals largely with physical chemistry, photochemistry, and electrochemistry.

The American Farm Review and Digest of the Agricultural Press is being issued monthly. As announced in the initial number, it is to contain original articles but its main purpose is to furnish a digest of articles appearing in the agricultural press of this country, with comment thereon by the various department editors. Among these are Bristow Adams, of the Forest Service of this department, in charge of forestry; J. C. Kendall, of the Kansas College and Station, in charge of crops in the West; Thomas Shaw, formerly of the Minnesota University Station, in charge of crops in the North; H. F. Hall, formerly of the New Hampshire College and Station, in charge of horticulture; and Frank Benton, formerly of the Bureau of Entomology of this department, in charge of bee keeping.

Horn and Hoof is being published monthly in the interest of dairy and stock farmers of the Northwest. The initial numbers contain numerous articles by experts from the agricultural colleges and this department.

The Illustrated Poultry Record is being published in London as a monthly. One of its sections is designated to education and experiments in which considerable attention is given in the opening numbers to work under way in North America. J. E. Rice, of Cornell University, is special correspondent from this country.

LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS REVIEWED.

Stations in the United States.

Stations in the United States—Continued.

U. S. Department of Agriculture.

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau requests and remittances should be directed to the Chief of the Bureau. The price of *Experiment Station Record* is $1.50 per volume, or 15 cents per number. The prices of other technical publications are given above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

Vol. XX. May, 1909. No. 10.

The extension of agricultural education work to its full development must depend largely on its capability of being coordinated with the general educational agencies already in operation. The number of such agencies is great, but they have not yet been brought into that harmony of purpose and action which can secure the largest educational results, and therefore none of them is now used to the best advantage. Consequently, any plan which has for its object the fuller realization of educational possibilities through the utilization and development of agricultural studies as an integral part of the general educational scheme deserves more than passing attention.

The University of Tennessee has recently inaugurated a unique plan of agricultural extension work in certain high schools of that State. The plan is designed to illustrate in its practical results the cultural value of instruction in agriculture to the general student in secondary schools, as well as its usefulness to those who may sometime follow the business of farming.

Briefly described, this plan provides for the monthly visitation of a limited number of high schools by the head of the university department of agricultural education, assistant professor Josiah Main, who gives at each visit a lesson and a demonstration, accompanied by an outline of work to be done the next month with suggested readings and reviews. He is also regarded as available for any popular lectures on education that may be arranged for in connection with these monthly visits. The university bears all the expenses of this visitation and supervision of the schools—unless the local community desires to provide entertainment for the visitor—but requires each school to assume responsibility for the success of the work by giving it a regular place in the school programme, providing a regular teacher for the class between visits, continuing the work from year to year so long as the university offers cooperation, and ultimately maintaining the work independently of the university connection as soon as financial support and other conditions justify. The expense for material equipment for the work will run from a minimum of $10 to whatever the school is willing to provide annually.

At present eleven county high schools in the State are taking advantage of this cooperative plan. Each lesson given by the visitor presupposes the mastery of all former lessons, thus making the work cumulative and capable of increasing technicality. The present series will be collected into a printed and illustrated form which can be taught to succeeding beginners' classes in each school without the necessity of much supervision. In this way the list of schools and trained teachers is developed together, and schools that drop out of the list are succeeded by new ones from the waiting list.

Several important advantages at once suggest themselves in this plan, considered as a whole, and the legislature has indicated its approval of the experiment by passing an act granting financial aid to high schools introducing agriculture, domestic science, and mechanic arts. Such a plan makes effective use of existing secondary schools. It takes these schools and teachers as they are, and develops the new work without displacing their present mechanisms or personnel. It gives opportunity for the demonstration of valuable results before calling for anything but nominal local expenditures in support of the work installed. In short, it seems perfectly adapted to existing conditions while affording the means of constantly surpassing them through the new impulse which must come with the wise introduction of agricultural instruction as a subject of general cultural value in secondary schools.

We know of no other State institution that has undertaken such a plan, and the experiment will be watched with much interest. The view-point which regards agriculture as a legitimate and valuable addition to cultural school subjects, in addition to its value for practical application in later life, seems to be gaining increasing adherence. It rests upon a much more secure foundation than do the arguments which support the importance of so-called manual training as a general school subject. Aside from its informational value for the student of whatever future calling, the purely practical aspect of agriculture includes much more than merely a vocation. And this view of the subject is clearly set forth in a quotation from an official announcement of the Tennessee plan: Agriculture "is not only a business but a mode of life, and no preparation for that mode of life could be complete that does not include not only farm husbandry, or agriculture in its strictest sense, but also much of the manual training peculiar to rural pursuits, hygiene and agricultural economics, and even rural society, education, and general culture."

The need of providing special assistance and instruction for teachers who have not heretofore appreciated the educational value of agriculture in the common schools, recognized in this Tennessee plan of agricultural extension work, is receiving increasing recognition in

a number of other States. Thus Louisiana, for example, has recently made provision for a chair of agricultural education with Prof. V. L. Roy, formerly parish superintendent of Avoyelles Parish, as the first incumbent. One-third of his salary is assumed by the State Board of Agriculture, one-third by the State Department of Education, and the remainder by the State university. He is expected to work under the coordinate direction of these three authorities in bringing agricultural instruction into the secondary and elementary schools of the State.

As a means of encouraging the establishment of agricultural courses in high schools, a system of recognition of certain high schools for State aid has also been established. Each of these schools receives $500 annually from the State treasury on condition of meeting certain specified requirements concerning laboratory equipment, the course of study, and the selection of a competent man to give the instruction in agriculture. Twenty-five schools have already applied for such recognition, and probably at least twelve, properly distributed over the State, will ultimately receive it. Last year the State superintendent held a number of summer normal courses for the benefit of new teachers of agriculture, and at least five such courses will be given this year.

A chair of rural education has also been established in the University of Missouri, with Prof. R. H. Emberson in charge. Professor Emberson's time will be given entirely to the rural school problem, and his business will be to bring the college of agriculture and the rural school into close touch and sympathy, to introduce agriculture into the curriculum, to assist teachers in making this work successful, and to interest the boys of the school in corn growing, corn judging, live-stock judging, and such other subjects as may be found feasible. His work will all be in the field.

Within a few weeks Minnesota has adopted a definite policy for the encouragement of vocational teaching in its public schools. A bill passed by the legislature appropriates $25,000 a year for the next two years to encourage the establishment of agricultural departments in State high schools and graded or consolidated rural schools. These agricultural departments must be provided with trained teachers of agriculture, manual training, and domestic science, and with not less than 5 acres of land for educational and experimental purposes. Schools which have met these requirements (not to exceed one in a county nor ten in the State in any one year), and have been designated by the State High School Board to receive State aid, will get an amount equal to two-thirds of their actual expenditures upon departments of agriculture, provided that State aid shall not exceed $2,500 a year for any one school.

Still another example tending in the same general direction is furnished by the State of Texas, whose legislature has voted $32,000 to

subsidize agricultural instruction in the public high schools, besides providing $5,000 for each of the three State normal schools with which to maintain courses in agriculture and manual training. In addition to this, agricultural instruction is also to be given in six summer normal courses for public school teachers, three of these courses being assigned to the three normal schools, one to the State university, one to the State College of Agriculture and the Mechanic Arts, and one to the College of Industrial Arts (for women) at Denton.

One other case is noteworthy in this connection, that of the establishment this year of Arkansas' first State normal school with a distinct department of agricultural instruction, supervised by an agricultural college graduate, Prof. L. A. Niven. And in anticipation of the competent teaching service which this department is to develop in its graduates, the legislature has also appropriated $160,000 for establishing at least four agricultural high schools in the State.

These new developments furnish additional evidence of a vigorous movement throughout the whole country for bringing agricultural teaching into all normal schools, as a means of spreading its introduction through their graduates into the common schools of the people. The following States, named in the chronological order of their action, have already crystallized this general tendency by appointing professors or assistant professors of agricultural education either in the State university or the State college: Illinois, Tennessee, Massachusetts, Oklahoma, Michigan, Indiana, and Louisiana. Mississippi has a professor of industrial pedagogy, supervising work in agriculture and mechanic arts, and several other States (as Iowa) have developed extension departments that aim to bring agricultural instruction into all the secondary schools as rapidly as practicable.

So it has come to pass that no single State can hope to gain or maintain a position of distinct precedence in agricultural education extension work; rather each must needs take heed lest it find itself already superseded in rank by one it had supposed to be far in the rear of the movement. And none are awaking sooner to the significance of this movement than the people who have not had superior educational advantages, who are not wont to be enthusiastic over the technics of education, but who are keenly alive to its practical (or impractical) tendencies and results. While these people have not been backward in asking for a type of education practically related to their own conceived needs, they have not usually assumed to formulate its requirements into a working course of study. This duty still remains to be done by men already experienced in the schools; but its real value will be pretty accurately and promptly gauged by the patrons for whom the schools in fact exist.

This consideration emphasizes the importance of spreading the work of educating teachers who shall be qualified both pedagogically and practically for shaping this new educational development to meet the prevailing needs in each State and locality. In some States the new work can probably best be done through the State university, in others by the agricultural college, the agricultural high schools, the State normal schools, or all of these in cooperation. In other States, like New York, Michigan, and Nebraska, it can be advantageously dealt with in the county normal training classes. And in still other conditions, as in Iowa, the movable institute school of instruction may prove most serviceable, especially in the earlier stages of extension development. In all these cases the essential desideratum is so to rationalize our methods of industrial and extension instruction as to bring them into effective coordination with the standard educational systems that have amply demonstrated an enduring value.

Recent remarks of King Edward in relation to the inclusion of applied science and agriculture in the scheme of university education are interesting as reflecting an attitude in England which is becoming more widespread. At the opening of the new buildings of the University of Leeds in July, 1908, he said:

"The high standard of moral and intellectual discipline for which our schools and universities have been distinguished has not been lowered, nor has the pursuit of literary and historical studies been checked, by the inclusion in the university curriculum of those scientific studies, and especially of those branches of applied science for which such ample provision has now been made. I rejoice to think that the opportunities open to the young men of our great industrial communities of acquiring a knowledge of subjects of commercial utility in an atmosphere of academic culture are being so greatly increased, and I find it difficult to express my appreciation of the manner in which the great responsibilities which rest with the authorities and teachers of a university such as this have been discharged. It is a source of pleasure to me to know that you have provided also for the study of the theory and practice of agriculture, for I am convinced that the best possible results can not be derived from the industry and natural ability of our farmers unless they are properly instructed in the scientific aspects of their work."

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

The rusting of iron, W. A. Tilden (*Jour. Chem. Soc. [London], 93 (1908), No. 549, pp. 1356–1364, fig. 1; abs. in Sci. Abs., Sect. A—Phys., 11 (1908), No. 131, p. 648*).—Experimental evidence is presented to support the following conclusions: "Commercial iron, liquid water, and oxygen are together sufficient for the production of rust. Carbon dioxid is not necessary, but when present hastens the action. Commercial iron is attacked by pure water in the absence of oxygen and carbon dioxid, the product being, not rust, but ferrous hydroxid. Iron rust always contains ferrous oxid. The process of rusting is due initially to electrolytic action resulting in the production of ferrous hydroxid or carbonate. This may be explained by the presence in all ordinary iron of various components which afford surfaces at different potentials in the presence of water, aqueous carbonic acid, or other electrolyte."

Rusting of iron, J. N. Friend (*Jour. Iron and Steel Inst., 77 (1908), pp. 5–32; abs. in Sci. Abs., Sect. A—Phys., 11 (1908), No. 131, pp. 648, 649*).—The electrolytic theory of corrosion of iron is held to be untenable. General rusting is held to be primarily acid attack due to the presence of carbon dioxid with moisture and oxygen. Cast iron only is attacked by pure cold or boiling water. The purer forms of iron are not attacked by pure water and air or steam and air at 100° C. The corrosive action of rust is dependent upon its hygroscopic nature, resulting in the absorption of moisture and carbon dioxid from the air which continue the corrosion.

Corrosion of iron, C. F. Burgess (*Trans. Amer. Electrochem. Soc., 13 (1908), pp. 17–54; abs. in Sci. Abs., Sect. A—Phys., 11 (1908), No. 131, p. 648*).—Strained parts of mild steel corrode more rapidly than unstrained. Annealing at 900° C. removes this difference. Oxygen in boiler water promotes corrosion more than carbon dioxid.

The principles and results of plant chemistry, I, II. Euler (*Grundlagen und Ergebnisse der Pflanzenchemie. Brunswick, 1908, pp. IX+238, dgm. 1*).—In this text-book, which it is stated is revised from the Swedish edition, present knowledge regarding plant chemistry is summarized and digested. The principal subdivisions are nitrogen-free aliphatic compounds, nitrogen-free cyclic compounds, and nitrogenous compounds. Full indexes add to the usefulness of the volume.

Concerning the value and synthesis of protein, F. Hofmeister (*Arch. Expt. Path. u. Pharmakol., 1908, Sup., pp. 273–281*).—A digest of data on the structure of the protein molecule.

Milk proteins, G. A. Olson (*Jour. Biol. Chem., 5 (1908), No. 2–3, pp. 261–281*).—Recent investigations on milk enzyms and proteolytic bacteria are reviewed. The author found in milk, cream, and butter a new protein, which contains 18.93 per cent of nitrogen, gives a biuret reaction, and is dissolved in weak sodium hydroxid solutions. It was first found in the filtrate of separator slime after the casein and albumin had been removed, and can be isolated by

the addition of one part concentrated hydrochloric acid to five parts of that filtrate.

"Physically the new protein possesses a brown varnish-like luster which when pulverized is changed into a whitish appearance. In water it swells and takes on a whitish appearance.

"When added to milk a part of the casein is digested in the same. Digestion is most favorable in neutral milks on prolonged standing.

"Physiologically the enzymic properties are most active at a temperature of 65° C. At 80° C. the ferment was destroyed.

"The filtrate obtained after the removal of the new protein also has digestive properties.

"The influence of chemicals and sterilization tend to slightly modify the soluble nitrogen compounds of the milk.

"The addition of digestive bacterial cultures to sterilized milk in the presence of chloroform caused proteolysis.

"The decomposition products formed in the presence of the new protein are similar to those formed in the presence of galactase and bacterial enzyms under the same conditions. From these facts it is believed that the characteristic digestion of the new protein and galactase are of bacterial origin.

"The enzymic property of the new protein is one of incorporation."

Hydrolysis of hordein, A. Kleinschmitt (*Hydrolyse des Hordeins. Inaug. Diss. Univ. Heidelberg, 1907, pp. 33; abs. in Biochem. Zentbl., 7 (1908), No. 21–22, p. 804*).—Hordein, the chief protein of barley, differs from other known products, according to the author's conclusions, but is closely related to both gliadin and zein, being midway between the two in its characteristics.

The article contains data on the cleavage products obtained from hordein by germination as compared with those of acid cleavage.

A reaction distinguishing phosphoprotein from nucleoprotein and the distribution of phosphoproteins in tissues, R. H. A. Plimmer and F. H. Scott (*Jour. Chem. Soc. [London], 93 (1908), No. 552, pp. 1699–1721*).—According to the authors the results of their experiments show that "phosphoproteins may be distinguished from nucleoproteins by the action of 1 per cent sodium hydroxid at 37° for 24 to 48 hours; the phosphorus is completely separated in this time as inorganic phosphoric acid.

"Phosphoproteins are present in milk, egg yolk, and in the ova of fishes, that is, in the substances which constitute the food stuffs of the embryo bird and fish and the young mammal.

"A small quantity of phosphoprotein is present in the pancreas."

A modification of the character of gluten in the presence of sulphurous acid, J. Dugast (*Compt. Rend. Acad. Sci. [Paris], 146 (1908), No. 24, pp. 1287, 1288*).—The author concludes that sulphurous-acid gas produces a great change in the character of gluten and modifies its baking qualities.

The constitution of starch, Z. Gatin-Gruzewska (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 4, pp. 178, 179; abs. in Biochem. Zentbl., 7 (1908), No. 21–22, p. 765*).—The addition of concentrated potassium hydroxid solution and a little alcohol to warm starch paste caused a precipitate which is identical with the amylopectin of other investigators. From the filtrate another body was isolated, called by the author amylon, which is soluble in water. The properties of these bodies were studied. Previous work has been noted (E. S. R., 20, p. 110).

Further studies on the forms of milk sugar, C. S. Hudson (*Jour. Amer. Chem. Soc., 30 (1908), No. 11, pp. 1767–1783, figs. 2*).—The solubility relations of milk sugar, the vapor pressures of saturated solutions of hydrated milk

sugar, the influence of concentration on the equilibrium between the forms of milk sugar, and other similar questions were studied.

On the sugar of colostrums, J. Seelien and E. Sunde (*Ztschr. Angew. Chem., 21 (1908), No. 50, pp. 2546–2551*).—Unlike the fats and proteids the carbohydrates of colostrum are similar to those of normal milk.

Preparation of a standard solution of litmus and the making of litmus media, C. W. Brown (*Michigan Sta. Rpt. 1908, pp. 127–129*).—A standard was prepared by dissolving 2.5 gm. of azolitmin in 100 cm. of distilled water. Litmus was then dissolved in distilled water, heated, filtered, and the filtrate compared with the standard. From experiments with different samples of litmus it appeared that there was a close correspondence between the solubility and the strength of the blue solution.

The determination of nitrogen, F. Taurke (*Chem. Ztg., 32 (1908), No. 97, p. 1176; abs. in Jour. Chem. Soc. [London], 96 (1909), No. 555, II, pp. 91, 92; Chem. Abs., 3 (1909), No. 7, p. 759*).—The author proposes to use in the Kjeldahl method a burette graduated as usual on one side from 0 to 50 cc. and on the other from 25 cc. at the top to 0 at the bottom. Using half-normal acid, fourth-normal alkali, and an aliquot of solution corresponding to 0.7 gm. of substance the readings of the latter scale give percentage of nitrogen directly.

Report of the committee on the analysis of phosphate rock, C. F. Hagedorn et al. (*Jour. Indus. and Engin. Chem., 1 (1909), No. 1, pp. 41–44*).—This is a summary of the report of the committee on this subject appointed by the National Fertilizer Association.

Comparative tests by a number of different analysts of the official gravimetric method, the so-called Pemberton volumetric method, the citrate method, and the Gladding method for phosphoric acid, and the Smith, Gladding, acetate, Glaser, and Wyatt methods for iron and alumnia are reported.

Good results with the volumetric and the Gladding methods are reported, but the conclusion reached is that "at this time there are not sufficient reasons for substituting either of these for the present official method.

"In the case of the methods for iron and alumina, the results indicate that the methods most generally used are those employing a KOH solution in the separation of the iron from the alumina, viz, the Smith and the Gladding methods. In the other methods, the iron and alumina was determined by weighing the combined phosphates. Of these the acetate and the Glaser methods are the most important, and it is our opinion that some modification of the acetate method could be worked out which would be extremely satisfactory, as it appeals to chemists on account of its simplicity as compared with other methods."

Volumetric determination of phosphoric acid in fertilizers, R. Williams (*Chem. Engin., 8 (1908), pp. 97–99; abs. in Analyst, 33 (1908), No. 393, p. 483*).—Objections to the American official volumetric molybdate method are stated and modifications of the method to overcome these objections are described.

In the modified method the total phosphate is precipitated in an aliquot part of the acid solution containing as slight an excess of acid as possible, by adding 1 cc. of mixed ferric and calcium chlorids (10 per cent of each in solution) and sufficient ammonia to render the solution slightly alkaline; 150 cc. of boiling water is then added, the liquid allowed to settle, and filtered. The precipitate is washed once with hot water, then dissolved in 100 to 125 cc. of hot dilute nitric acid (70 cc. of strong acid in 1 liter). The solution is nearly neutralized with ammonia, precipitated with 30 to 35 cc. of molybdate solution, added to the stirred hot liquid, and the process carried out as in the official method.

The determination of cotton-seed hulls in cotton-seed meal, G. S. Fraps (*Amer. Fert., 29 (1908), No. 6, pp. 30, 31*).—Noted from another source (E. S. R., 20, p. 510).

Detection and determination of nitric acid in water and sewage, KLUT (*Mitt. K. Prüfungsanst. Wasserver. u. Abwässer. Berlin, 1908, No. 10, pp. 85–101; abs. in Chem. Ztg., 32 (1908), No. 97, Report., p. 632; Brewers' Jour., 33 (1909), No. 3, p. 107; Gesundhts. Ingen., 32 (1909), No. 16, p. 271*).—As a qualitative test for nitric acid brucin is preferred to diphenylamin. For quantitative determination the Schulze-Tiemann method is recommended. The Ulsch method is considered the next best.

The determination of calcium carbonate in soils by the Bernard and Treitz method and its importance in the selection of vineyard soil, K. VOTRUBA (*Allg. Wein Ztg., 1908, No. 30, pp. 1–4; abs. in Chem. Zentbl., 1908, II, No. 12, pp. 1065, 1066; Jour. Chem. Soc. [London], 96 (1909), No. 555, II, p. 95*).—The Treitz method, which depends upon the determination of the calcium carbonate removed in suspension when soil is shaken with water, is preferred to that of Bernard as a means of selecting vineyard soils. The lime in fine soil is apparently of more importance than that in coarse lumps. Account must also be taken of other physical properties in selecting vineyard soils.

New method for the estimation of lactic acid in animal organs and fluids, E. JERUSALEM (*Biochem. Ztschr., 12 (1908), No. 5–6, pp. 361–389, figs. 2; abs. in Analyst, 33 (1908), No. 393, pp. 474, 475*).—The author extracted the lactic acid with ether and then oxidized by permanganate. The aldehyde formed is estimated by the iodoform method.

The quantitative estimation of creatinin in urine, G. EDLEFSEN (*München. Med. Wchnschr., 55 (1908), No. 49, pp. 2524–2527*).—A critical discussion of methods and a description of the procedure which the author recommends.

The determination of reducing sugars from the weight of cuprous oxid, C. A. BROWNE (*Internat. Sugar Jour., 10 (1908), No. 119, pp. 537–540*).—According to the author's experiments, it is more accurate to weigh copper in sugar determinations as CuO than as Cu_2O.

The precipitation of reducing sugars with basic lead acetate, A. H. BRYAN (*Internat. Sugar Jour., 10 (1908), No. 120, pp. 602–605*).—A contribution to the subject of methods.

Errors in the polarimetric determination of sucrose, when lead salts are used as clarifying agents (*Internat. Sugar Jour., 10 (1908), No. 120, pp. 581–583*).—A digest of recently published data on this subject.

Refractometer studies, F. G. WIECHMANN (*Internat. Sugar Jour., 10 (1908), No. 119, pp. 545–554*).—From the large number of determinations reported the author concludes that "if the refractometer is to find a permanent place in the sugar laboratory, it will be necessary to prepare a table of the refractive index values of chemically pure sucrose solutions, at some standard temperature, say at 20°."

The determination of nonsaccharin organic material in cane molasses, J. J. HAZEWINKEL (*Bul. Assoc. Chim. Sucr. et Distill., 26 (1908), No. 4, pp. 230–247*).—A study and comparison of methods. According to the author's observations, large quantities of mannose and glucose do not exist in defecation molasses.

The resorcin hydrochloric acid reaction and its value in honey analyses, RIECHEN and I. FIEHE (*Chem. Ztg., 32 (1908), No. 90, pp. 1090, 1091*).—The authors defend this reaction from the criticisms which have been made of it and state that their studies of the reaction are being continued.

The estimation of salt in imported pickled meat, G. GRÖNING (*Ztschr. Fleisch. u. Milchhyg., 19 (1908), No. 1, pp. 12–15, fig. 1*).—The author describes the apparatus and method which he has found convenient.

The detection of white corn flour in wheat flour products, E. CARLINFANTI and G. SALVATORI (*Arch. Farmacol. Sper. e Sci. Aff., 6 (1907), No. 8–9, pp. 458–*

468; abs. in Biochem. Zentbl., 8 (1908), No. 1–2, pp. 91, 92).—The method described depends upon the determination of the nitrogen content of the material extracted by iso-amyl alcohol.

An analysis of cloves, T. R. Hodgson (*Amer. Jour. Pharm., 81 (1909), No. 1, pp. 6–9*).—According to the author, the three determinations on which the greatest reliance can be placed in the analysis of cloves are ash, nitrogen, and oxygen equivalent. "The determination of the alcoholic extract is of no practical value, the determination of the crude fiber and moisture may in some cases be of considerable use, whereas in others it may be of no value whatsoever; the determination of the ether extract is advisable."

Judging black pepper, G. Graff (*Ztsch. Öffentl. Chem., 14 (1908), No. 22, pp. 425–447*).—According to the author's analytical studies and critical summary of the work of other investigators, the determination of crude fiber content, in addition to the ash and sand content, affords the best data for judging the quality of pepper. He recommends that 17 to 17.5 per cent crude fiber be adopted as a standard for whole and ground pepper.

The sanitary composition of cow's milk, M. Donsett (*Pure Products, 5 (1909), No. 1, pp. 7–10*).—The author insists that milk inspection not be confined to the content of nutrients, but should extend to the dirt content. The sedimentation and the Gerber filtration methods of estimating dirt content in milk are described.

The examination of milk for dirt and leucocytes, C. Revis (*Jour. Roy. Inst. Pub. Health, 16 (1908), No. 12, pp. 734–740*).—Methods now in use are described, together with a new method for estimating the dirt content which has been devised by the author. In this the sample of milk is centrifuged and treated with eau de Javelle to dissolve the leucocytes.

The determination of the Reichert-Meissl number by saponification with glycerin-potash, M. Siegfeld (*Chem. Ztg., 32 (1908), No. 93, p. 1128*).—The author prefers to saponify with potash rather than with soda. Comparative results with the two alkalis are given.

The analysis of cacao butter, G. Halphen (*Jour. Pharm. et Chim., 6. ser., 28 (1908), No. 8, pp. 345, 346; abs. in Analyst, 33 (1908), No. 393, p. 468*).—The author describes a method of detecting vegetable fats based on the difference in solubility of the respective bromin derivatives.

The estimation of cocoanut oil in butter, R. Ross (*Analyst, 33 (1908), No. 393, pp. 457–463*).—This article contains results of investigations on insoluble fatty acids. The variations in the composition of different butters and cocoanut oils are so great that the fixing of reliable constants is not deemed possible.

A method for detecting synthetic color in butter, R. W. Cornelison (*Jour. Amer. Chem. Soc., 30 (1908), No. 9, pp. 1478–1481*).—A new method is described by the author in which the clear dry fat is melted in glacial acetic acid. The clear acid is drawn off and tested with concentrated nitric acid, sulphuric acid, and sulphuric acid and ether. The results of the author's investigations are given.

The Rabild tube (*N. Y. Produce Rev. and Amer. Cream., 27 (1908), Nos. 5, p. 178; 7, p. 285*).—This tube is made for the purpose of making a rapid calculation of overrun in butter. Some butter makers use it for estimating the moisture content, but it is stated that as accurate results can not be obtained it can not be recommended for this purpose.

Some of the constituents of saffron and a method for the valuation of saffron, B. Pfyl and W. Scheitz (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 6, pp. 337–352; abs. in Analyst, 33 (1908), No. 393, pp. 472, 473*).—The authors isolated two sugars and a substance similar to the picrocrocin of Kayser from the petroleum spirit and the chloroform extracts of pure saffron.

The valuation of saffron may be estimated by the amount of reducing sugars present.

Composition of white lead and paints, G. S. FRAPS (*Texas Sta. Bul. 114, pp. 5–11*).—This bulletin describes standard pigments and oils and adulterant paint materials. Analytical data of paint materials are also reported.

"Eleven samples of so-called white lead were examined. Four were pure and 7 adulterated or substitutes. Two did not contain any white lead and 3 did not contain over 5 per cent.

"Fourteen samples of mixed paints were examined. Four were pure lead and zinc paints. Six samples contained 10 to 15 per cent carbonate of lime, 3 contained 36 to 58 per cent barium sulphate, and 1 contained 15 per cent carbonate of lime and 15 per cent clay.

"Two of these paints contained benzine as an inferior substitute for turpentine; some appeared to contain linseed oil adulterated with resin oil, and 1 contained linseed oil adulterated with a mineral oil."

Report of State chemist, H. G. KNIGHT (*Ann. Rpt. Dairy, Food and Oil Comr. Wyo., 4 (1908), pp. 36–85*).—During the fiscal year ending October 1, 1908, 651 samples of food, drugs, drinks, and illuminating oils were collected and examined. Of these 532 were passed and 119 declared adulterated or misbranded.

Extracts from the proceedings of the Association of Official Agricultural Chemists, 1908 (*U. S. Dept. Agr., Bur. Chem. Circ. 43, pp. 16*).—This contains the reports of the committees on recommendations of referees, with the action taken by the association in each case, together with resolutions adopted and a list of the officers, referees, and committees for the year 1909.

METEOROLOGY—WATER.

Relation of weather conditions to growth and development of cotton, J. B. MARBURY (*Cotton, 73 (1908), No. 2, pp. 51–53, figs. 5; 73 (1909), No. 3, pp. 88–90, figs. 3*).—It is stated that "cotton, though a sensitive plant, is of all summer-growing crops of the South about the least affected by ordinary changes in the weather. Its long period of growth, fruiting, and maturity affords it ample opportunity to recover from a number of temporary setbacks. During the protracted season from planting in April to the completion of its harvest in November it is exposed to many varieties of weather, and it seems to endure the bad as well as enjoy the good. Such a thing as 'half a crop' is unknown. Statistics show that the crop is seldom curtailed by more than one-fourth or one-third."

The relation between rainfall and temperature and the growth of cotton at different periods is explained in diagrams and in the text. Rainfall seems to be the stronger influence in the development of the cotton plant. "Well distributed showers during the spring months serve to keep the soil in a condition well suited for the best development of the young plant and to cause the roots to sink deep into the earth, thus enabling the plant to maintain itself against the dry periods of the following summer. A very wet spring causes the development of a large number of the surface roots to the sacrifice of those roots which naturally tend downward, and the droughty conditions which prevail frequently during the summer soon cause the plant to wilt and shed its foliage and fruit, since the dry surface soil does not furnish sufficient nourishment for its growth." Sunshine is also an important factor. The author states that "the normal conditions of temperature and rainfall throughout the cotton belt are, as a rule, most favorable for the proper development of this delicate plant. April and May, with less than 4 in. of rain each, cause the tap root to sink deep

into the soil, so that sufficient moisture is brought up from below to satisfy the demands of the plant later in the season, when the weather is dry and sunshine prevails. The temperature during June and July is also a very important factor, averaging about 78° for the former month and 80° for the latter. There is a marked uniformity in the average temperature among all the States in the cotton belt."

When the bolls begin to open (in August) "an abundance of light, well distributed showers and warm sunshine is needed. If too much rain falls, the results are peculiarly disastrous; the weed will begin to grow rapidly, to the detriment of the fruit; the plant will cease to make new blooms and the squares already formed will drop; the bolls will decay on account of the accumulated moisture which they absorb; the fiber in the open bolls will be either beaten out or discolored.

"September and October are the months for picking, and, of course, dry weather is needed. Only sufficient moisture is then required to nourish the growing bolls and opening flowers, and much of this can be secured through the roots, provided the weather early in the season has been such as to cause the roots to penetrate deep into the soil. Under normal conditions the rainfall is very light during the months of September and October throughout the major portion of the cotton belt, affording fine opportunity for securing the matured crop."

An analysis is given of weather conditions during years of greatest yield.

Periodical variations in climate, G. Meyer (*Gaea, 44 (1908), No. 10, pp. 588–591*).—This article attempts to show whether there is a relation between the moon and the weather. The general conclusion reached is that the phases of the moon have a greater and more certain influence upon variations in climate than the appearance of sunspots, at least for the region covered by the study reported.

Study of the results of hail shooting, L. Godinot (*Ann. Soc. Agr. Sci. et Indus. Lyon, 1907, pp. 82–92*).—This is a review of the present status of this subject based mainly upon official reports of government commissions appointed to investigate the matter.

Atmospheric humidity charts, A. Fröhlich (*Gsndhts. Ingen., 31 (1908), No. 50, pp. 790–792, charts 3*).—Charts showing the atmospheric humidity corresponding to different temperatures from —20 to 100° C. are given.

Report of the Chief of the Weather Bureau, 1906–7 (*U. S. Dept. Agr., Weather Bur. Rpt. 1906–7, pp. XLIII+402*).—As usual, part 1 of this document consists of an administrative report reviewing the operations of the Weather Bureau during the year and including statements regarding additions to equipment and extension of the work; part 2 gives a list of observing stations and changes therein during 1906, and twice-daily observations for 29 selected stations during 1906; part 3, monthly and annual meteorological summaries for 189 stations; part 4, monthly and annual means and annual extremes of temperature and dates of first and last killing frosts, 1906; part 5, monthly and annual precipitation, 1906, and monthly and seasonal snowfall, 1906–7; and part 6, miscellaneous meteorological tables and reports.

Among the more important subjects receiving attention during the year were research at Mount Weather, more particularly with reference to upper air investigations by means of kites, solar radiation, solar physics, and magnetism; forecasts and warnings; seismological observations; investigation of evaporation in connection with the Salton Sea (E. S. R., 19, p. 1112); river and flood service; climatological service; ocean meteorology; and wireless telegraphic weather service.

Meteorological observations (*Michigan Sta. Rpt. 1908, pp. 167–179*).—Tabulated daily and monthly summaries are given of observations during 1907 on temperature, pressure, precipitation, humidity, cloudiness, wind movement, etc.

Meteorological records for 1907 (*New York State Sta. Rpt. 1907, pt. 1, pp. 333–343*).—Tables are given showing daily readings of maximum and minimum thermometers at 5 p. m. for each month of 1907; tridaily readings of the standard air thermometer during each month of the year; a monthly summary of maximum, minimum, and standard thermometer readings; average monthly and yearly temperature since 1882; monthly and yearly maximum and minimum temperatures from 1883 to 1907, inclusive; and rainfall by months since 1882.

Some climatic features of the Territory of Hawaii, W. B. Stockman (*Honolulu Chamber Com. Ann., 1908, pp. 90–94*).—Data regarding temperature and rainfall are summarized, attention being called especially to the great diversity of climatic conditions in the Territory. These vary "from the eternal spring obtaining at sea level to the invigorating, ideal temperatures experienced at altitudes ranging from about 500 to 2,500 ft. on all the islands, and the freezing weather which obtains on the upper slopes of Mount Haleakala on Maui, and Mt. Mauna Loa and Mt. Mauna Kea on Hawaii; and from the torrential rains and moist atmosphere of the higher levels on the windward sides of all the islands to the light rainfalls and small percentage of relative humidity on the leeward sides.

"The topography and altitude of a place or district of these islands has a decided effect on its climatic conditions, but the controlling factor—other than latitude—is, perhaps, the directness with which the warm, moisture-laden trade winds pass over it, for any obstacle that deflects from their true course these winds—which here blow with great steadiness and considerable force—has a marked effect on the rainfall, and a modifying one on the temperature and humidity conditions."

Climatological data, J. N. Belfort de Mattos (*Sec. Agr. Com. e Obras Pub. Estado São Paulo, Secc. Met. [Pub.], Ser. 2, No. 4, pp. 6, pl. 1, charts 8*).—This is a record of climatological observations in the State of São Paulo, Brazil, during 1907.

Swedish meteorological observations, 1907, H. E. Hamberg (*Met. Iakttag. Sverige [Observr. Mét. Suéd.] K. Svenska Vetensk. Akad., 49 (1907), pp. X+159*).—This report is divided into 3 parts: (1) Daily observations at 18 stations of the second order, (2) monthly and annual summaries of all the meteorological elements furnished by 41 stations of the second order, and (3) 5-day means of temperature at the 41 stations included in part 2.

British rainfall, 1907, H. R. Mill (*London, 1908, pp. 100+280, pls. 5, figs. 25; rev. in Nature [London], 78 (1908), No. 2033, p. 604*).—This report is in the usual form and "deals with the distribution of rain in space and time over the British Isles during the year 1907, as recorded by more than 4,000 voluntary observers, and is supplemented by articles upon various branches relating to that subject."

Among the special articles are a discussion of the typical thunderstorms of July 21–22, "showing distinctly the linear arrangement of heavy rainfall in such storms and its disregard of the configuration of the land," and a note on mapping rainfalls (E. S. R., 20, p. 213). There are also discussions of droughts and rain spells.

Composition of Barbados rainfall (*Rpt. Agr. Work Barbados, Imp. Dept. Agr. West Indies, 1905–1907, pt. 1–2, p. 3*).—The amount and composition of the rainfall from December, 1905, to May, 1907, are given. "The total amount was

76.53 in. and supplied approximately 175 lbs. of chlorin and 9.5 lbs. of nitrogen per acre."

The chemistry of the River Nile, A. LUCAS (*Survey Dept., Egypt, Paper No. 7, pp. 78, dgm. 1, map. 1*).—This paper brings together what has already been published on the water of the Nile channels and the matter suspended in it (E. S. R., 18, pp. 421, 424; 19, p. 1013) as well as records of the results of further work recently done in the Survey Department laboratory of Egypt, and gives a brief outline of work on the water in the soil of the Nile Valley as a basis for future investigations. Appendixes give data on the following subjects: Bacteriology of the Nile water, preliminary microscopic examination of Nile silts, physical analyses of samples from well borings, chemical analyses of Nile water, and chemical analyses of water from desert wells. A bibliography containing 71 references to literature of the subject is given.

It is stated that "the whole body of underground water in the valley is simply a lateral continuation of that in the river and is in contact with it and supplied from it." Analyses of these underground waters show wide variations at different places. "This is only to be expected, since, owing to the varying nature of the soil through which the water percolates, it will naturally come into contact with, and will dissolve out, more salts in some places than in others."

Potable water and sewage (*Rev. Gén. Sci., 19 (1908), No. 22, pp. 905–908*).—This is a brief review of progress in methods of procuring pure water supplies and in disposing of sewage. Among the methods especially referred to are filtration through submerged and unsubmerged sand filters, rapid American filters, and sterilization by means of ozone and iron. The growing use, particularly in England, of the septic tank for disposing of sewage is also referred to.

On the rôle of bacteria in the biological methods of sewage purification, with special reference to the process of denitrification, W. MAIR (*Jour. Hyg. [Cambridge], 8 (1908), No. 5, pp. 609–653*).—The investigations reported in this paper were carried out in connection with an experimental plant built by the Corporation of Belfast for the purpose of discovering suitable methods of dealing with the sewage of that city. The investigations included "an examination of the experimental contact beds, and of the sprinkler, with reference to the disappearance of certain groups of bacteria," and a study of "the occurrence of denitrification in sewage with reference to the bacteria concerned in the process, with isolation in pure culture of certain of these bacteria and a study of their chemical effects upon nitrates."

The investigations on denitrification included more particularly the isolation and study of typical denitrifying bacteria, especially of the *Bacillus hyponitrosus* group, and the relation of the activities of these organisms to the purification of sewage.

It is thought probable "that in the contact beds a considerable proportion of the organic nitrogen disappears as gas as a result of alternate nitrification and denitrification. In the sprinkler the free exposure to air renders it unlikely that any appreciable amount of denitrification occurs." The general conclusion is reached "that the rôle of bacteria in the purification of sewage is a somewhat limited one, which by no means justifies the application of such terms as 'bacteria beds' and 'bacterial purification.' . . .

"There is, however, one other stage in the process which may with great probability be ascribed to bacterial action, the stage, namely, of nitrification," but the author finds it difficult in view of the results obtained in these investigations "to correlate the nitrification which occurs in nature, and in particular that which occurs in sewage purification, with the activity of" the nitrite and nitrate bacteria as isolated and studied by Winogradski.

SOILS—FERTILIZERS.

The mineral composition of soil particles, G. H. Failyer, J. G. Smith, and H. R. Wade (*U. S. Dept. Agr., Bur. Soils Bul. 54, pp. 36*).—This bulletin reports the results of chemical analyses of the soil separates of a number of soils covering all of the important agricultural areas of the United States, including soils of the Coastal Plains, soils from crystalline and metamorphic rocks, soils of glacial origin, derived from limestones and shales, and soils of the arid region.

The results obtained with the different groups of soils and with rocks, soils, and soil separates are compared.

The results are summarized as follows:

"As a general rule the smaller particles of soils are richer in potassium, calcium, magnesium, and phosphorus than the coarser particles.

"The concentration of these elements in the finer components is the more pronounced as the soils have undergone more extreme weathering.

"In glacial soils and others resulting largely from mechanical processes the coarser particles are relatively high in the percentage of potash, lime, and magnesia.

"The larger mechanical components contain these elements in forms which by protracted weathering will become more soluble, and they will ultimately be concentrated in the finer components.

"Calcium is often rather low in clay soils resulting from the weathering of hard, compact limestones. It is generally abundant in soils recently formed from easily broken down limestones. The sands of these latter soils may contain a high percentage of calcium, probably as lime sand or as coatings on other large mineral grains.

"A comparison of soils and soil separates with crystalline rocks indicates that in the process of the weathering of these rocks the phosphate remains of about the same proportion or slightly increases. The lime and potash seem to decrease in percentage, although minerals containing them are always present."

Contribution to the subject of kaolin formation, O. Hähnel (*Jour. Prakt. Chem., n. ser., 78 (1908), No. 17–18, pp. 280–284*).—The author concludes from his investigations that weathering and kaolinization are chemically distinct processes. The recent decomposition products of granite under humus were found to be very similar in composition to crude kaolin.

On the radioactivity of the soil, F. Bordas (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 20, pp. 924, 925; abs. in Rev. Sci. [Paris], 5. ser., 10 (1908), No. 22, p. 699; Jour. Chem. Soc. [London], 96 (1909), No. 555, II, p. 7; Chem. Zentbl., 1909, I, No. 3, p. 209*).—Observations are reported which show a decided radioactivity in soils of the Andean Plateau, and these observations suggest the possibility of a relation between this natural radioactivity and the formation of the large nitrate deposits in this part of Chile (Province of Aconcagua).

Soils of the United States, M. Whitney (*U. S. Dept. Agr., Bur. Soils Bul. 55, pp. 243, pls. 2, figs. 7*).—This bulletin contains a summary of recent soil investigations and a classification of the soils of the United States based upon the work of the Bureau of Soils to January 1, 1908.

"The first part consists of seven lectures covering the activities of the Bureau of Soils in the field and in the chemical and physical laboratories for the last nine years and discusses in a general way the most notable achievements during that period, coupled with suggestions for further research in the fundamental field of soil study." It sums up the more important of the conclusions of the Bureau, as in the main already published, regarding the nature

and properties, classification, and utilization of soils, fertilizers and manures, crop rotation, soil deterioration, and soil fertility as a national asset.

"Part II consists of descriptions of the soil provinces, soil series, and soil types, the last particularly from the standpoint of crop adaptation. The extent and the distribution of the soils of the United States are also shown, and the whole gives the complete classification of soils up to January 1, 1908."

The report is accompanied by a map showing the soil provinces in colors.

Soil investigations of the experimental fields at Aarslev Experiment Station, H. R. CHRISTENSEN (*Tidsskr. Landbr. Planteavl, 15 (1908), No. 3, pp. 383–406, dgms. 5*).—The investigations included mechanical and chemical analyses of 78 samples of surface soil and of 31 subsoil samples taken from three different fields. "Biological lime determinations," according to the Azotobacter method of the author (E. S. R., 18, p. 720), were also made in 30 samples of surface soil. The methods of sampling and analyses followed are described in detail in the report, and the results briefly discussed.

Data of analyses of some wet soils of lower Friuli and notes on their suitability for crop production, A. CARATTI and Z. BONOMI (*Ann. R. Staz. Sper. Agr. Udine, 9 (1908), pp. 57–72*).—A considerable area in the lower part of the province of Friuli is swampy and unfit for agricultural use. In connection with a project for draining this area, the authors took samples of soils at various points. The analyses of these samples are given, with some observations on the probable advance in value of the lands affected if the proposed drainage scheme is carried out.

Analyses of soils from the Eden district, F. B. GUTHRIE (*Agr. Gaz. N. S. Wales, 19 (1908), No. 10, pp. 838–844*).—Data regarding the physical and chemical properties of 9 samples of different kinds of soil from different parts of this district of New South Wales are reported and briefly discussed, particularly with reference to the improvement of the soils.

The meaning and value of the chemical analysis of soils, R. D. WATT (*Transvaal Agr. Jour., 7 (1908), No. 25, pp. 40–44*).—The terms used in stating soil analyses are defined and explained, and the average composition of 100 typical Transvaal soils examined during 1907 and 1908 is given as follows:

	Per cent.
Stones removed by 3 mm. sieve	2.59
Analysis of air-dry fine earth—	
Moisture	2.400
Loss on ignition (organic matter, etc.)	5.840
Insoluble matter (sand, etc.)	79.880
Oxid of iron and alumina	11.090
Lime	.240
Magnesia	.150
Potash	.190
Phosphoric acid	.055
Total	99.845
Nitrogen	0.1140
"Available" potash	.0113
"Available" phosphoric acid	.0069

The absorptive capacity of some Russian soils and of their finest particles as related to their composition, I. P. ZHOLTSINSKI (*Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 9 (1908), No. 2, pp. 129–225*).—The experiments were made with three kinds of soils—a chernozem, a red soil, and a podzol (bleisand).

The general conclusions of the author are as follows: (1) Soils differing strikingly in origin, morphology, and composition show in the majority of cases no less marked differences in their absorptive capacity. (2) The peculiarities of the absorptive capacity of each soil are reflected to a certain degree, and frequently very clearly, in its finest particles (clay). (3) The finest group of soil particles, the body of which presents a close combination of zeolitic clay with organic-mineral substances, possess a high absorptive capacity sometimes approaching the maximum limit. (4) The absorptive capacity of a soil does not show any parallelism with reference to ammonia, phosphoric acid, and lime. Soils absorbing much ammonia may take up little lime and phosphoric acid and inversely. A parallelism was observed only with reference to ammonia and potash. The fine particles and the soils deprived of them retain this peculiarity. (5) The maximum absorptive capacity with reference to potash and ammonia is possessed by soils richest in humus—chernozem; with reference to phosphoric acid, by soils rich in iron—red soils. The fine particles and soils deprived of part of the latter retain these peculiarities. With reference to lime the maximum absorption was shown by the red soils, but this phenomenon is not constant in its nature. (6) The presence of substances forming the ortstein (organic compounds of iron) in podzols considerably heighten the absorbing capacity of the podzol with reference to phosphoric acid; in the fine particles of the podzol this phenomenon is strongly accentuated. (7) The conclusion of Heiden, Krat, and others that no soil exhausts a solution completely is not correct with regard to weak solutions of phosphoric acid. (8) Between the amount of ammonia absorbed by the soils and clays and their contents of hygroscopic water there is a certain parallelism which is masked, however, by other factors in very poor soils (podzol) containing very little hygroscopic water. (9) Between the mechanical composition of the soils and their absorptive capacity there is a certain dependence which is the more marked the less it is masked by other factors. The clay and in general the mechanical fraction less than 0.01 mm. in diameter is of the greatest influence.

The pulverization and exhaustion of the soil in black fallow culture, S. Kulzhinski (*Khozyaystvo, 1906, No. 23; abs. in Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *9* (*1908*), *No. 2, p. 311*).—The author calls attention to the lowering of yields of winter cereals on black fallow as compared with the April fallow and even with the May fallow, on the unfertilized three-course rotation section of the Poltava Experiment Field.

This lowering began to be observed from the year 1900, when the third cycle of the rotation was commenced. Earlier, in the period 1895–1899, the winter cereals on the black fallow gave the highest yield. The data for moisture in the upper layer of the soil show that in the period 1895–1899 it was higher under the winter cereals on the black fallow than in the April fallow, while the reverse was the case in the period 1899–1904. The mechanical analysis of the soil in the later period gave in the black fallow more silt particles and considerably less clay particles than in the April fallow. The chemical analysis showed more humus, nitrogen, and phosphoric acid in the April fallow than in the black. It was found that at the time of the cultivation of the fallow nitrification was strongest in the black fallow but weakest in the spring.

On the basis of these data the author supposes the diminution of the yield of the winter cereals on the black fallow to be due to the fact that, owing to the intensified mellowing in the black fallow cultivation, the soil undergoes more weathering and pulverization. In consequence higher crops are at first obtained on black fallow than on other fallows. Then as the soil becomes exhausted by such high yields and its physical properties deteriorate (due to very fine pulverization), conditions arise which are unfavorable for the accumu-

lation and conservation of moisture and for the formation of nitrates, and the lowering of the yield is the result.

Productivity of the black fallow in the steppes as dependent upon precipitation and the fertility of the soil, L. P. Sokalski (*Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 9 (1908), No. 4, pp. 449–472*).—It has been well established that in the steppes with their dry climate black fallow cultivation is the safest means of insuring a satisfactory crop. The favorable influence of the black fallow has been generally ascribed to the circumstance that thereby moisture is best accumulated and conserved. This view the author subjects to a critical study, making use of the data accumulated during a number of years at the experiment stations of Kherson, Odessa, and the Don region.

He finds that there seems to be no connection between the crops of winter wheat and either the annual amounts of precipitation or the precipitation during the growing period. There is, however, a direct relation between the precipitation during the spring months and the crop of winter wheat. The ratio expressing this relation forms the coefficient of productivity. With the aid of this coefficient the size of the crop in a given locality can be predicted in May.

In the opinion of the author, the accumulation of moisture, if such a condition is brought about by the black fallow cultivation, does not affect the productiveness of the soil. He thinks that the favorable effect of the black fallow culture is due to the fact that this mode of culture increases the availability of the nutritive substances of the soil.

Brief report of the Poltava Experiment Field for 1907, S. Tret'yakov and Verbetski (*Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 9 (1908), No. 2, pp. 308–311*).—Data for 12 years show that larger yields were obtained on early fallow than on black fallow.

Brief report of the Kherson Experiment Field for 1906, F. Yanovchik (*Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 9 (1908), No. 2, pp. 306–308*).—Mean results for 15 years gave better crops of winter wheat and rye on early fallow than on black fallow. Experiments on different modes of cultivation, fertilizing, etc., are described.

Fertility of various horizons of the soil, V. Sazanov (*Trudui Ivanov Selsk. Khoz. Opuitn. Stantzii, 1907, No. 3, pp. 111–122; abs. in Zhur. Opuitn. Agron. [Russ. Jour. Expt. Landw.], 9 (1908), No. 2, pp. 302, 303*).—Vegetation experiments show that the fertility of the soil tested diminished from the upper to the lower layers.

Zeolites and similar compounds, their constitution and importance in technology and agriculture, R. Gans (*Jahrb. K. Preuss. Geol. Landesanst. u. Bergakad. Berlin, 26 (1905), No. 2, pp. 179–211; abs. in Chem. Abs., 2 (1908), No. 23, p. 3216; Jour. Soc. Chem. Indus., 28 (1909), No. 2, p. 102*).—The character of zeolitic silicates extracted from different kinds of soils are described and classified according to the substitution of their bases, as, for example, by ammonia. From a study of these and other changes the conclusion is reached that a fertilizer containing phosphates or carbonates is preferable to one containing sulphates and nitrates because with the former there is no unnecessary exchange of bases in the zeolitic compounds of the soil. Other results from exchange of bases due to addition of various fertilizing materials are given.

Soil moisture, A. Lehmann (*Dept. Agr. Mysore, Ann. Rpt. Agr. Chem., 8 (1906–7), pp. 25–30, 57, 58*).—The results of studies of the effect on soil moisture of different kinds and amount of cultivation are reported, and indicate that keeping the surface of the soil loose not only conserves the moisture of the soil but has other beneficial effects.

[Effect of soluble salts in the soil on the growth of sugar cane], J. B. HARRISON (*West Indian Bul., 9 (1908), No. 1, pp. 19–37; abs. in Internat. Sugar Jour., 10 (1908), No. 118, pp. 500–509; Chem. Ztg., 32 (1908), No. 87, Repert., p. 554*).—The author discusses, on the basis of experiments extending over a number of years, the effects of long-continued applications of sulphate of ammonia and nitrate of soda on the productiveness of the soil, the effects of cultivation and of manures on the composition of the soil waters of the sugar cane fields, the relation between temporary and permanent alkalinity of soil waters, the proportion of nitrogen in tropical soil waters, and the concentration of the subsoil water.

The general reaction of the fertile heavy clay soils of British Guiana is slightly alkaline, and a decided and comparatively rapid increase of the alkaline salts in the soils under experiment was observed. This concentration of salts exerts a decidedly injurious effect on the physical properties of the soil and on the growth of cane, but promotes the activity of nitrifying organisms. The alkalinity of the soil may explain why sulphate of ammonia gives better results than nitrate of soda when applied in large amounts. The remedies suggested by the author's experiments are deep drainage and the application of gypsum, calcium phosphates, and other neutralizing materials.

The isolation of harmful organic substances from soils, O. SCHREINER and E. C. SHOREY (*U. S. Dept. Agr., Bur. Soils Bul. 53, pp. 53, pls. 4*).—This bulletin presents briefly the evidence of the occurrence of harmful substances in the soil, reviews previous attempts to isolate the toxic compounds, and reports investigations relating to the isolation and toxic properties of a number of organic bodies, products of the decomposition of organic matter of vegetable and animal origin, in unproductive soils.

The isolation of four well-defined crystalline bodies is reported. The first of these, picolin carboxylic acid (E. S. R., 19, p. 419), possesses faint acid properties and also has the power of acting as a base toward strong acids. In experiments with wheat seedlings it was found to be harmful in concentrations of 100 parts per million, but like many poisons had a stimulating effect when present in small quantities.

A second body, dihydroxystearic acid, isolated from unproductive soils (E. S. R., 20, p. 704) "was injurious in all concentrations tested and ultimately caused death of the plants in concentrations of 100 parts per million."

The two other crystalline bodies isolated were agrosterol and agroceric acid (E. S. R., 20, p. 509). "Neither of these substances appears to be harmful to wheat and [they] are of interest in the study of soil fertility chiefly with regard to their possible connection with the generation or destruction of injurious or beneficial compounds, although it is not impossible that they may be themselves harmful to plants other than that tested."

The nitrogen problem, R. PEROTTI (*Bol. Quind. Soc. Agr. Ital., 13 (1908), No. 23, pp. 1186–1196; 14 (1909), Nos. 2, pp. 48–62; 3, pp. 84–100*).—This is a general discussion of the natural processes by which the soil acquires or loses nitrogen. Under the head of gain of nitrogen, bacteria, molds and algæ, and legumes are considered, and under loss volatilization of ammonia and denitrification are briefly treated.

Practical methods of promoting the natural processes of increasing and conserving the nitrogen supply of the soil are also discussed.

Leguminous plants as fixers of the nitrogen of the air, M. PASSON (*Bol. Inst. Agron. [São Paulo], 1 (1908), No. 10, pp. 345–349, fig. 1*).—Data are given for yields and nitrogen content of velvet bean, cowpea, and peanut, showing the amounts of nitrogen accumulated by crops of these plants.

[Inoculation for leguminous plants], H. A. HARDING (*New York State Sta. Rpt. 1907, pt. 3, pp. 116, 117, pl. 1*).—In a review of the bacteriological investigations of the New York State Station, the results of tests of commercial cultures for leguminous plants and of experiments in the use of inoculation and lime in the culture of alfalfa are briefly summarized.

As already noted (E. S. R., 17, p. 648; 18, p. 820), the commercial cultures examined were found "worthless for practical purposes" and the results of inoculation of alfalfa seed were found to be entirely negative. On the other hand, the application of soil from an alfalfa field at the rate of 100 to 200 lbs. per acre almost invariably gave good results. Applications of lime or ashes at the rate of 1,500 lbs. of stone lime or its equivalent per acre were found to be beneficial.

Fixation of atmospheric nitrogen by pure cultures of Azotobacter.—**Distribution of the organism**, M. W. BEIJERINCK (*K. Akad. Wetensch. Amsterdam, Proc. Sect. Sci., 11 (1908), pp. 67–74; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 553, II, pp. 975, 976*).—Contrary to the opinion formerly held by him, the author now finds, as a result of improved technique for the determination and study of the distribution of the organism, that Azotobacter fixes nitrogen, and that there is a distinct relation between the distribution of this organism and leguminous plants.

Investigations on the variation and the nitrogen fixing power of Bacillus asterosporus, G. BREDEMANN (*Centbl. Bakt. [etc.], 2. Abt., 22 (1908), No. 1–3, pp. 44–89, pls. 2, figs. 3*).—Studies made with 27 cultures of different origin are reported in detail. A bibliography of 24 references bearing upon the subject is also given.

The mineral nutrients of plants, P. VAGELER (*Die mineralischen Nährstoffe der Pflanze. Leipsic, 1908, pp. VI+130, figs. 3*).—This book, which gives a general survey of the subject, contains an introduction discussing briefly the general relation of animals and plants and chapters on the origin of the ash constituents of plants, the character of the ash constituents and their function in the plant organism, and the application of theories of plant nutrition in practice, that is, with reference to the function and use of mineral fertilizers.

Nature and use of commercial fertilizers, G. S. FRAPS (*Texas Sta. Bul. 112, pp. 5–35*).—This is a popular summary of information on this subject containing specific information as to the fertilizers required by cotton, corn, rice, potatoes, alfalfa, onions, peanuts, oats, and other crops.

The purchase and use of commercial fertilizers, R. MARÈS (*Bul. Agr. Algérie et Tunisie, 14 (1908), Nos. 20, pp. 485–502; 21, pp. 513–520*).—This subject is discussed primarily from the standpoint of Algerian and Tunisian conditions and crops. The legislation controlling the trade in fertilizers in these colonies is given.

Influence of the weather on the action of commercial fertilizers, W. VON SYCIANKO (*Fühling's Landw. Ztg., 57 (1908), No. 20, pp. 698–701*).—Reference is made to a previous article by Grohmann (E. S. R., 20, p. 311) which maintained that the results of many of the experiments heretofore made do not permit of reliable conclusions because no exact account was taken of the influence of weather conditions, and an attempt is made to show the direct relation between varying conditions of moisture and temperature and the action of fertilizers as demonstrated by observations on fertilizer experiments with strawberries, carrots, kohl-rabi, peas, and other vegetables in which the results were carefully correlated with the weather conditions.

The influence of precipitation on the efficiency of commercial fertilizers, GROHMANN (*Mitt. Landw. Inst. Leipzig, 1908, No. 9, pp. 1–76; abs. in Illus. Landw. Ztg., 28 (1908), No. 53, pp. 465, 466*).—This article is based upon obser-

vations on a number of farms in the region of Leipsic as to the effect of rainfall from the time of seeding to the time of blooming on the action of various fertilizers (nitrate of soda, potash salts, and superphosphate) on the growth of oats during the dry year of 1904. The rainfall during the growing period (38 days) of 1904 was 126.8 mm., or 118.2 mm. less than the normal for the region.

The broad general fact was brought out that the greater the rainfall during the growing period the smaller the action of the easily soluble and the greater the action of the difficultly soluble fertilizers. The distribution, as well as the amount of the rainfall, was of great importance. Difficultly soluble fertilizers gave best results when there were a few days of heavy rainfall rather than many days of light rainfall. Nitrate of soda was found to be effective as a fertilizer only when the average daily rainfall during the growing period was at least 2.5 mm. Potash salts and superphosphate required 3.5 mm. Since only about 40 per cent of rainfall is on the average used by plants, it is of great practical value to determine the limits of efficient rainfall for each locality. By application of the method of least squares the probable effect of the fertilizers under different rainfall conditions was calculated. These calculated results agreed quite well with those actually obtained in the field experiments.

Some results of the use of chemical fertilizers in Carnia, Z. Bonomi (*Ann. R. Staz. Sper. Agr. Udine, 9 (1908), pp. 27–30*).—A comparison on natural permanent meadow is here reported of mineral superphosphate alone and combined with nitrate of soda and with nitrate of soda and sulphate of potash. The superphosphate (12 to 14 per cent phosphoric acid) was used at the rate of 540 lbs. per acre, the nitrate of soda at the rate of 135 lbs. per acre, and the sulphate of potash at the rate of 180 lbs. per acre. Two plats were used for each combination and for check plats. The complete fertilizer gave the largest absolute gain, but the best result economically was obtained from the superphosphate and nitrate of soda.

Investigations on the composition of Peruvian guano, J. G. Maschhaupt (*Engrais, 23 (1908), No. 51, p. 1214*).—The results of 40 analyses of Peruvian guano are summarized, showing the variations in soluble potash, phosphoric acid, oxalic acid, uric acid, ammoniacal nitrogen, nitrogen in form of sulphate of ammonia, and total nitrogen in pure guano, leached and decomposed guano, and mixtures of guano and sulphate of ammonia. It is shown that the composition even of pure guano is so variable that it is impracticable to fix a standard for it.

Studies on the preparation of nitrate, J. Jörgensen (*Bol. Soc. Fomento Fabril [Chile], 25 (1908), No. 11, pp. 621–626*).—Studies of the solubility at different temperatures of caliche containing varying proportions of sodium nitrate, sulphate, and chlorid are reported. These caliches are divided into 3 general groups: (1) Those containing a large amount of sodium chlorid; (2) those containing a large amount of sodium sulphate; and (3) those containing carbonate (lei) in addition to chlorid and sulphate.

The first group presents no difficulties. For the second group the use of steam of low pressure is recommended. The preparation of the third group is complicated and not more than 50 per cent of the nitrate is usually recovered.

The author states that considerable nitrate is lost in the liquid remaining after the present processes of extraction are complete, and that much of this loss may be avoided by careful chemical analyses and improved methods.

Experiments on the action of nitrate of soda, ammonium salts, lime nitrogen, nitrogen lime, and the Norwegian lime niter, W. Schneidewind et al.

(*Arb. Deut. Landw. Gesell., 1908, No. 146, pp. 118; abs. in Mitt. Deut. Landw. Gesell., 23 (1908), No. 36, p. 300; Mark Lane Express, 99 (1908), No. 4021, p. 445; Chem. Ztg., 33 (1909), No. 18, Repert., p. 79*).—This report gives an account of laboratory, pot, and field experiments with these fertilizing materials during the years 1905 to 1907.

The laboratory experiments dealt with the study of losses of nitrogen when lime nitrogen was mixed with soil and with peat and other coarse materials, and when lime nitrogen and sulphate of ammonia were applied as top-dressing. The pot experiments were made in the ordinary way with oats, rye, and potatoes. In the field experiments the crops used were rye, wheat, barley, potatoes, and sugar beets.

Nitrate of soda in general produced the best results. Sulphate of ammonia was on the average about 90 per cent as effective as nitrate of soda in field experiments and 93 per cent as effective in pot experiments. In the field experiments ammonium sulphate was always used in combination with superphosphate in the belief that with such a combination there was no danger of loss of ammonia. The Norwegian basic lime nitrate gave practically the same results on most of the crops as nitrate of soda, although on wheat the latter was slightly superior. Calcium cyanamid did not give good results, especially with beets, on sandy and sandy loam soils. It gave good results except in case of beets on the better class of soils, although it did not prove equal to nitrate of soda. When used on wheat on good soil the efficiency of lime nitrogen was 80 per cent of that of nitrate of soda in field experiments and 85 per cent in pot experiments. Under the same conditions its efficiency was 92 per cent of that of ammonium salts in field experiments and 91 per cent in pot experiments.

In comparative tests of autumn and spring top-dressing nitrate of soda gave the best results when applied in the spring, but these were little better than those produced by fall application of sulphate of ammonia on good soils. On light soils, however, the results with spring application of nitrate of soda were much better than with fall application of sulphate of ammonia. The results indicate that on the light soils the sulphate of ammonia applied in the fall is converted into nitrates and lost from the soil during the winter. Late spring top-dressing with nitrate of soda reduced the sugar content of sugar beets.

The results indicate, therefore, that in general ammonium salts are not well suited to fall application, and suggest that lime nitrogen is probably better suited to this purpose.

The comparative fertilizing value of calcium cyanamid, calcium nitrate, ammonium sulphate, and sodium nitrate, V. Nazari (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 17 (1908), II, No. 7, pp. 334–342; abs. in Chem. Zentbl., 1908, II, No. 22, pp. 1785, 1786*).—This article gives the results of plat experiments with wheat on different kinds of soil to determine (1) the effect of humus on the action of cyanamid; (2) the best depth of application of cyanamid; (3) the effect of various phosphatic, potash, and calcareous fertilizers on the action of cyanamid; and (4) the comparative effect of cyanamid and the other nitrogenous fertilizers.

On sandy calcareous soils receiving applications of 4½, 13½, 27, and 45 tons per acre of stable manure spaded in to a depth of 10 in. 13 days before the planting of the crop the yields uniformly increased with the increase in the amount of manure added both when the manure was used with cyanamid (178 lbs. per acre) and without it. Cyanamid alone increased the yield of grain from 45 to 50 per cent.

The best results were obtained when the cyanamid was applied 10 days before the planting of the crop at a depth of 8 in., and the poorest at a depth of 2 in., on sandy calcareous and clayey calcareous soils.

The results of the experiments with various combinations of fertilizers were too complex for definite conclusions, but it was found that of the phosphates, including bone meal, mineral phosphate, and Thomas slag, the bone meal gave the best results, and of the potash fertilizers, including sulphate of potash, muriate of potash, and leucite, the sulphate and leucite were nearly equally efficient. Gypsum was less effective than lime. The greater efficiency of the bone meal is attributed to the fact that it furnished the most favorable conditions for the action of micro-organisms which render cyanamid available.

In the comparative tests of the different nitrogenous fertilizers on clayey calcareous soil applied in various ways the two nitrates gave very nearly the same result as sulphate of ammonia. In case of the latter the most favorable method of application was half at sowing and half as a top-dressing later. With the cyanamid, application shortly before sowing and thorough mixing with the soil gave best results.

Field experiments with lime nitrogen, sulphate of ammonia, and nitrate of soda, Tancré (*Landw. Wchnbl. Schles. Holst., 58 (1908), No. 51, pp. 870–873*).—Comparative tests of these fertilizers with rye, oats, barley, and beets are reported. The results in general were very favorable to the lime nitrogen, even in rainy seasons on heavy soils, the physical properties of which were injuriously affected by nitrate of soda.

Contribution to the ammonia question, I. P. Ehrenberg (*Landw. Vers. Stat., 69 (1908), No. 3–4, pp. 259–294, pl. 1; abs. in Chem. Ztg., 32 (1908), No. 93, Repert., p. 599; Chem. Zentbl., 1908, II, No. 24, p. 1893; Jour. Chem. Soc. [London], 94 (1908), No. 554, II, p. 1068; Chem. Abs., 3 (1909), No. 7, p. 817*).—This article reviews the work of other investigators on changes in the reaction of soils due to application of lime and nitrogenous fertilizers, and reports a series of pot experiments by the author in which white mustard, sorghum, buckwheat, corn, barley, and oats were grown in pure sand and in mixtures of sand and moor soil in small glass jars with various combinations of lime and other fertilizing materials furnishing physiologically acid or physiologically alkaline conditions in the soil.

The results were variable and did not in all cases confirm the conclusions of other investigators on this subject. It was apparent, however, that the difference in behavior in ammonium salts and nitrate combinations was due to difference in physiological reaction brought about by the use of these combinations. When nitrate was used the assimilation of the nitrogen set free the base, which tended to neutralize acid conditions in the soil and thus favored the growth of the crops. With ammonium salts the opposite effect was produced. Mustard and buckwheat are decidedly sensitive to acid conditions in the soil and were especially benefited by liming. Sorghum was less sensitive and less benefited by lime. Corn was the least sensitive of the crops experimented with.

The injurious effects of crude ammonia in vineyards, A. Berget (*Rev. Vit., 30 (1908), No. 768, pp. 257–259*).—Serious injury to grapes resulting from the use of 891 lbs. of this material per acre is reported, and 1,783 lbs. per acre should not be exceeded in any case.

Ammonium sulphate, F. J. Lloyd and U. Bonelli (*Chem. News, 98 (1908), No. 2549, pp. 172, 173; Chem. Trade Jour., 43 (1908), p. 362; abs. in Chem. Zentbl., 1908, II, No. 18, p. 1538; Analyst, 33 (1908), No. 393, p. 483*).—Attention is called to the fact that commercial ammonium sulphate may contain impurities (coal-tar derivatives) which unfit it for use as a fertilizer, since these impurities are injurious to higher plants and interfere with the action of the micro-organisms in the soil. The presence of these compounds is shown by a

violet coloration when strong ammonia is added to a solution of 1 gm. of the sample in 5 cc. of water.

The production of ammonium sulphate, C. G. ATWATER (*Amer. Fert., 29 (1908), No. 6, pp. 19–23*).—Statistics of production and consumption of sulphate of ammonia in this country and abroad are given. The total consumption in this country in 1907 is stated to have been 121,669 short tons, the imports 32,069 tons. The average price per ton was $61.93.

On the utilization of the atmospheric nitrogen in the production of calcium cyanamid, and its use in agriculture and chemistry, A. R. FRANK (*Trans. Faraday Soc., 4 (1908), No. 2, pp. 99–119, pls. 9, figs. 3*).—The more important facts contained in this paper have already been noted from another source (E. S. R., 20, p. 624).

The ammoniacal fermentation of cyanamid, C. ULPIANI (*Gaz. Chim. Ital., 38 (1908), II, No. 4, pp. 358–417; abs. in Chem. Zentbl., 1908, II, No. 19, pp. 1627, 1628; Jour. Soc. Chem. Indus., 27 (1908), No. 23, p. 1167*).—The author concludes from his investigations that contrary to the opinion of Löhnis, cyanimid is not ammonified by bacteria, but easily undergoes chemical change into dicyandiamid, urea, and other products. Dicyandiamid and urea are converted into ammonia, the first slowly, the second rapidly. Neither is injurious to vegetation, at least in amounts at which nitrogenous fertilizers are usually applied, and their formation completely destroys the poisonous properties of the cyanimid.

Experiments with calcium cyanamid, Z. BONOMI (*Ann. R. Staz. Sper. Agr. Udine, 9 (1908), pp. 31–41*).—Using natural permanent meadow which had been fertilized in December with 540 lbs. of Thomas slag and 180 lbs. of sulphate of potash per acre, three plats were in February given calcium cyanamid at the rate of 180 lbs. per acre and three sulphate of ammonia at the same rate. The results were in favor of calcium cyanamid. There were two tests of wheat, calcium cyanamid being compared in one with a mixture of sulphate of ammonia and nitrate of soda and in the other with sulphate of ammonia. The applications in each case were sufficient to give about 11 lbs. of nitrogen per acre. In both tests calcium cyanamid produced slightly larger results. With potatoes calcium cyanamid was compared with sulphate of ammonia, the fertilizers being applied as a top-dressing after being mixed with an equal amount of sand.

In a pot experiment with hemp, calcium cyanamid was compared with sulphate of ammonia; the latter was found to be inferior to the former. With corn calcium cyanamid was inferior to sulphate of ammonia in producing ears, but superior in the production of stalks. It was found that calcium cyanamid scorched the foliage of potatoes. This was due to the fact that the finely powdered fertilizer fell on the plant and adhered to it.

Lime nitrogen and its changes in the soil, E. DE KRUIJFF (*Teysmannia, 19 (1908), No. 6, pp. 357–362*).—The author briefly reviews the results of other investigations on this subject and reports experiments of his own on the rate of transformation of lime nitrogen into ammonia in culture solutions with and without glucose inoculated with 15 gm. of different kinds of soil, the object of which was to study the part played by soil bacteria in changing lime nitrogen into a form available for plant food.

The conclusions reached were as follows: (1) The change of lime nitrogen into forms suitable for plant life takes place only under the influence of microbic life. (2) The rapidity of these changes depends upon the composition of the soil. (3) The poisonous effect of lime nitrogen upon bacterial life, and in all probability, also upon plant growth, makes itself felt in a poor soil for a longer time than in a fertile soil. (4) Lime nitrogen, with good management, is equiva-

lent to nitrate of soda and sulphate of ammonia as an artificial fertilizer. (5) On some soils the use of lime nitrogen is not recommended.

Is it economically expedient to use potash fertilizers? Z. Bonomi (*Ann. R. Staz. Sper. Agr. Udine, 9 (1908), pp. 5–26*).—A report is given on tests of the effect of sulphate of potash on clover, medic, natural permanent meadow, and wheat and clover.

The amount of sulphate of potash used was 180 lbs. per acre on all the plats except one of clover and one of medic, which received 135 lbs. per acre, and one of clover, which received 225 lbs. per acre. Every plat showed an increased product. This increase was enough to give a profit over the cost of fertilizer in the first year on some of the plats of clover and medic, and on the wheat and clover. The second year showed enough increase to leave a profit except on one plat of natural permanent meadow, which was a special soil.

Raw rock phosphate (*Amer. Fert., 29 (1908), No. 2, pp. 5–9*).—This is a statement by the National Fertilizer Association summarizing conclusions reached from various experiments as to the relative efficiency of raw and dissolved phosphates. The general conclusion reached is that "the experience of the German experiment stations, combined with a majority in this country, show emphatically that raw rock phosphate has little or no fertilizing value, [and that] the method of applying followed by users of this material in this country is most extravagant and wasteful."

Statistics of the production of phosphates in 1908, Maizières (*Engrais, 23 (1908), No. 50, pp. 1189, 1190*).—Statistics are given of the production of American and Tunisian phosphates.

Withdrawal of western phosphate lands for protection of the industry (*Amer. Fert., 29 (1908), No. 6, pp. 12, 13; Tradesman, 60 (1909), No. 9, p. 458*).—This is a brief statement regarding the phosphate lands withdrawn from entry by the Secretary of the Interior in accordance with the President's order, in Morgan, Rich, and Cache counties, Utah; portions of Bear Lake, Bannock, Bingham, and Fremont counties, Idaho; and nearly all of Uinta County, Wyoming. The lands withdrawn were selected as a result of preliminary examinations by the U. S. Geological Survey, and comprise "in all about 7,500 square miles of land more or less underlain by phosphate rock and constituting the greatest known phosphate deposit of the world."

It is stated that 2,265,000 tons of phosphate rock was produced in the United States in 1907, of which 900,000 tons, or about 40 per cent, was exported. It is estimated that at the present rate of mining the known available supply of high-grade phosphate rock in the United States will last only 54 years, and if the increase in production shown during the last decade continues the supply will be exhausted in 25 years.

Florida phosphate deposits, E. H. Sellards (*Farmer and Fruit Grower, 43 (1908), Dec. 25, p. 1*).—The present state of development of these deposits is briefly reviewed in this article by the State geologist of Florida.

The phosphates of Tunis, Maizières (*Engrais, 23 (1908), No. 51, pp. 1213, 1214*).—This is a brief review of a recent report on the deposits of Djebel-Gouraya.

The manufacture of superphosphate, Grueber (*Die Superphosphatfabrikation. Halle, 1907, pp. 83; rev. in Osterr. Chem. Ztg., 11 (1908), No. 22, p. 307*).—One of a series of monographs on chemical-technical manufacturing methods.

A test of manganese as a fertilizer, Z. Bonomi (*Ann. R. Staz. Sper. Agr. Udine, 9 (1908), pp. 52–56*).—In an experiment with horse beans all the pots received Thomas slag supplying 56 lbs. soluble phosphoric acid per acre, sulphate of potash furnishing 66 lbs. oxid per acre, and nitrate of soda at the rate of 27 lbs. nitrogen per acre. In addition alternate pots received sulphate of

manganese at the rate of 65 lbs. per acre. The beans showed the action of the manganese to be quite favorable.

The fertilizing value of ashes. E. Pont (*Bul. Mens. Soc. Cent. Agr., Hort. et Acclim. Nice, 48 (1908), No. 11, pp. 348–353*).—This article briefly summarizes information regarding the composition and fertilizing value of leached and unleached wood ashes and coal ashes. The variation in the composition of the ashes of different kinds of wood, leaves, bark, tobacco, nut shells, and peat is also shown. The average composition of wood ashes is stated to be 6 to 7 per cent of potash and 3 to 5 per cent of phosphoric acid. It is stated that coal ashes may contain as high as 5 per cent of potash, but that the percentage is frequently much lower than this and that such ashes are always poor in phosphoric acid.

On the use of bracken as litter. E. J. Russell (*Jour. Bd. Agr. [London], 15 (1908), No. 7, pp. 481–487; abs. in Mark Lane Express, 99 (1908), No. 4025, p. 555*).—This article discusses briefly the suitability of bracken as bedding for animals and its fertilizing value, particularly as compared with straw. It is stated that bracken contains on the average 1.44 per cent of nitrogen, 0.2 per cent of phosphoric acid, and 0.11 per cent of potash, and is thus richer in fertilizing constituents, especially nitrogen, than wheat straw. It is a better absorbent than straw, but manure made with it decomposes less rapidly than straw-made manure.

A novel fertilizer industry. L. B. Judson (*Cornell Countryman, 6 (1908), No. 3, pp. 73–76, figs. 6*).—The machinery and methods employed at a place near Hackettstown, N. J., for preparing peaty soil for use as a fertilizer filler are described.

Fertilizer inspection. C. D. Woods and J. M. Bartlett (*Maine Sta. Bul. 160, pp. 275–310*).—This is a report in the usual form of results of analyses of fertilizers collected in the open market in the spring of 1908 by the station representative.

Analyses and valuations of commercial fertilizers and ground bone. C. S. Cathcart, V. J. Carberry, and C. L. Pfersch (*New Jersey Stas. Bul. 217, pp. 40*).—This bulletin supplements a previous bulletin on the same subject (E. S. R., 20, p. 625) and summarizes the complete data for fertilizer inspection during the year, which involved the examination of 735 samples of fertilizing materials.

Inspection of fertilizers. L. L. Van Slyke (*New York State Sta. Rpt. 1907, pt. 3, pp. 221–224*).—This is a historical review of fertilizer legislation in New York, including the main provisions of the present law and a brief summary of some of the direct results of fertilizer inspection.

Analyses of fertilizers, fall season, 1907, and spring season, 1908. B. W. Kilgore et al. (*Bul. N. C. Dept. Agr., 29 (1908), No. 7, pp. 76*).—The names and guaranteed composition of fertilizers registered for 1908, and analyses and valuations of about 560 samples of commercial fertilizers and 54 samples of cotton-seed meal, examined during the fall of 1907 and spring of 1908, are reported, with explanations regarding terms used in fertilizer analyses, freight rates, valuation, etc.

Complete report on commercial fertilizers for 1908. J. H. Stewart and B. H. Hite (*West Virginia Sta. Bul. 118, pp. 265–318*).—This report gives the results of examinations of 215 samples of fertilizers inspected during the year, with a discussion of the quality of the fertilizers sold in the State.

Fertilizer control laws. J. T. Welch (*Amer. Fert., 29 (1908), No. 6, pp. 7–10*).—This is a paper read before the Southern States Association of Commissioners of Agriculture and Other Agricultural Workers at Nashville in October, 1908, and discusses the basis for a general fertilizer law.

AGRICULTURAL BOTANY.

The heredity of acquired characters in plants, G. Henslow (*London, 1908, pp. XII+107, pls. 2*).—The object of this book is to prove that evolution, so far as plants are concerned, depends upon the inheritance of acquired characters. The author points out that Darwin supplemented his theory of the origin of species by means of natural selection by other interpretations of the methods of evolution. He considers that the present position of ecologists, in accepting the fact that evolution in plants is the result, not only of a natural response to the direct action of changed conditions of life by means of which they evolved new structures in adaptation to their new environments, but also of the heritability of these acquired characters is in exact accord with the alternative suggested by Darwin himself.

A laboratory course in plant physiology, W. F. Ganong (*New York, 1908, 2. ed., pp. VI+265, pls. 3, figs. 68*).—This edition of the laboratory guide has been rewritten and much extended from the first edition. The objects, as stated by the author, are to lead students through a good laboratory course in plant physiology, to provide a handbook of information upon all phases of plant physiology having an educational interest, and to serve as a guide to self-education by ambitious teachers or students who are unable to obtain regular instruction. The book is not designed as a compendium of physiological knowledge nor as a handbook of investigation, but rather as a guide to the acquisition of a physiological education.

An introduction to experimental plant morphology, K. Goebel (*Einleitung in die experimentelle Morphologie der Pflanzen. Leipsic and Berlin, 1908, pp. VIII+260, figs. 135*).—After discussing the general problems of experimental morphology, the author considers at length the influence of external and internal conditions on leaf formation, the conditions necessary for the formation of terminal and lateral axes, the regeneration of tissues, and the influence of polarity, etc., on plants, the book in its present form being an expansion of a course of lectures given by the author in 1906–7.

The absorption of rain and dew by the green parts of plants, G. Henslow (*Jour. Roy. Hort. Soc. [London], 34 (1908), No. 2, pp. 167–178*).—By a series of experiments with detached portions of various species of plants, the author is convinced that the power of absorption of water, either in the form of dew or rain, is possessed by the epidermis of the internodes of herbaceous plants and by attached and detached leaves. He claims that "there are ample reasons for believing that dew and rain are, when absorption has been deficient, absorbed and utilized to supplement the normal root supply."

Root development, N. O. Booth (*New York State Sta. Rpt. 1907, pt. 3, pp. 345–349*).—A summary is given of investigations carried on at the station, most of which have been printed in the earlier reports, showing the distribution of roots in vertical and horizontal directions in the soil, the variation of root distribution due to cultivation, etc.

Some chemical processes in the germination of seed, F. Scurti and A. Parrozzani (*Gaz. Chim. Ital., 38 (1908), I, No. 2, pp. 216–227*).—The authors describe some of the chemical changes which take place during the germination of sunflower seed, and the action of light and darkness upon the changes noted. The experiments were conducted principally to determine the transformation of proteid nitrogen.

The transformation of cyanogenetic glucosids during germination, L. Guignard (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 22, pp. 1023–1028*).—In order to determine the question of the transformation of cyanoge-

netic glucosids during germination, a study was made of the seeds of *Phaseolus lunatus*, in which seeds and seedlings were examined at regular intervals.

It was found that the total amount of glucosid in the seed diminished, fully ⅓ of it being used up during germination and growth of the seedlings for 30 days in the dark. In the seedlings ⅔ of the phaseolunatin was found within 15 days after germination. In the seedlings kept in the light the loss of the glucosid began to be restored in about 10 days through the synthesis of hydrocyanic acid under the action of chlorophyll, and this formation increased with the development of the leaves.

The question of the occurrence of free hydrocyanic acid in the seed was investigated, and the author states that if any free hydrocyanic acid is formed during germination through the action of the glucosid it immediately disappears to form other combinations.

Notes on plants containing hydrocyanic acid, E. Couperot (*Jour. Pharm. et Chim., 6. ser., 28 (1908), No. 12, p. 542*).—A list is given of 14 species of plants which the author has found to contain hydrocyanic acid, 8 of them being grasses. These species are in addition to those formerly reported by different authors.

On the action of some organic substances on plants, G. Ciamician and C. Ravenna (*Gaz. Chim. Ital., 38 (1908), I, No. 6, pp. 682–697*).—The authors describe experiments made with a view to studying the formation and biological significance of glucosids in plants. In cultures containing various aromatic compounds and glucosids, corn and beans were grown to ascertain how these substances would react upon the plants. Among the aromatic compounds used were benzoic aldehyde, salicylic aldehyde, hydrochinon, methyl salicylate, benzilic alcohol, and vanillin. The glucosids used were amygdalin, salicin, and arbutin.

The results show that the plants tolerated the glucosids much better than the aromatic substances. In some of the experiments with corn the glucosids were partially broken down and seemed to be utilized by the plants, as only a fraction of the original substance could be recovered after the experiment was concluded. In the case of amgydalin less than 0.1 was reclaimed at the end of the experiment.

The authors state that glucosids in the plant are to be considered as reserve materials, and in this form poisonous substances can accumulate that in the free state would not be tolerated by the plant.

The effect of alkaloids on regeneration in the scarlet runner bean, S. Morgulis (*Ohio Nat., 9 (1908), No. 2, pp. 404–412, figs. 5*).—Experiments are described in which the effect of the sulphates of atropin and strychnin, pilocarpine hydrochlorid, and digitalin on the regeneration of scarlet runner beans was studied. The seeds of the beans were germinated in sawdust, and the seedlings transferred to jars covered with black paper, in order to protect the roots from sunlight.

The plants were subjected to different strengths of the alkaloids, and after an interval of 2 days in the solutions were cut off just above the cotyledons and the rate and amount of growth, transpiration, etc., determined. The transpiration and fresh and dry weight of the plants are shown in tables. Seventeen days after the first mutilation of the plants, the stems were cut a second time near their ends, and the same factors of growth again determined.

It was found that the alkaloids exert a stimulating influence upon regenerating plants, increasing the rate of their regeneration. Comparisons were made with the effect of alkaloids on sea-urchin eggs, and with the single exception of the stronger solution of strychnin the beans were found able to live in concentrations which would prove fatal to animals.

The action of the alkaloids upon plants varies with the nature and strength of the solution, but on the whole there is a general rise and intensification of the vital processes, as seen in the increased transpiration and higher rate of regeneration. The rate of regeneration after consecutive operations shows that after the second operation there is a considerable decrease in the power of regeneration and, consequently, a slowing down of the process, as well as a lengthening of the period intervening between the operation and the first appearance of regenerated tissue.

Studies on solanin from sprouts and flowers of the potato, A. Colombano (*Gaz. Chim. Ital., 38 (1908), I, No. 1, pp. 19–37*).—A study is reported on the solanin occurring in the sprouts and flowers of the potato. The methods of isolation and characteristics of the alkaloid are described, and comparisons drawn between solanin obtained from the cultivated potato (*Solanum tuberosum*) and that isolated from *S. sodomæum*.

The influence of aluminum salts on protoplasm, M. Fluri (*Flora, 99 (1908), No. 2, pp. 81–126*).—Experiments with Spirogyra, Elodea, and Lemna in cultures containing sulphate, nitrate, chlorate, and bichromate of aluminum, yttrium nitrate, and lanthanium nitrate are described, which showed that there was a marked reduction of starch in plants grown in the light. While these substances in nearly every instance checked assimilation, the assimilatory processes were not wholly inhibited. These chemical compounds seemed to exercise a kind of plasmolysis on the protoplasm without any considerable contraction.

The action is not believed to be a chemical one, as the amount of the compounds present in the cells was very small. The aluminum salts apparently act upon the diastases, which will account in some degree for the reduction of starch.

If grape sugar, glycerin, or isodulcite is added to cultures containing aluminum compounds the injurious action of the chemical is inhibited.

Effects of the rays of radium on plants, C. S. Gager (*Mem. N. Y. Bot. Gard., 4 (1908), pp. VIII+278, pls. 14, figs. 73*).—After describing the discovery and nature of radioactivity, a review is given of previous investigations on plants and animals. From these investigations the conclusions are drawn that radium rays and Roentgen rays modify the life processes of plants and animals, the sensitiveness varying with the different species of plants and animals as well as with the strength of the rays. The younger and especially the embryonic tissues are more sensitive to the rays than the mature tissues, and with few exceptions cell activities are retarded or completely inhibited. The evidence for and against radiotropic response is conflicting, and internal changes appear profoundly modified by the presence of chlorophyll in the cell. The activity of enzyms is retarded by radium rays.

The author carried on extensive experiments with a number of species of plants to determine the effect of radium rays on the growth of seeds, on germination, synthesis of carbohydrates, respiration, alcoholic fermentation, tropistic response, histology, nuclear division, etc. The exposure to radium rays of lupine and buckwheat seeds previously soaked in water resulted in a retardation of growth, but an initial retardation of growth of white mustard was followed by acceleration. The effect of exposure to radium rays varied with the duration of exposure and the degree of activity of the radium. The effect of radium acting through the soil was to accelerate germination and subsequent growth of unsoaked oats in proportion to the distance from the radium, those plants farthest away being stimulated the most. The growth of lupine shoots under like conditions was retarded, although the root growth was 2 to 3 times as long as normal. Soaking seeds in water exposed to

radium had in general a stimulating effect on growth. Thorium rays from a Welsbach burner had practically the same effect as radium rays. The exposure of leaves to radium tubes resulted in a retardation of starch formation immediately under the radium coated rods. Anaerobic respiration was retarded and normal aerobic respiration accelerated by radium rays. Alcoholic fermentation was accelerated when radium tubes were placed in fermenting mixtures, and the budding of yeast cells was considerably increased.

In experiments on tropistic response the author found that neither roots nor shoots growing in air showed the slightest tendency to curvature to or from sealed tubes containing radium of various activities.

Where exposure to radium rays was followed by retardation of growth, histological examination showed a cessation of cell division, an acceleration of tissue differentiation, a decrease in the size of cells, and a lack of coordination in histogenesis.

Experiments with radioactive air indicated that radium acts as a stimulus to protoplasm. Where retardation of growth is observed, it is believed to be an expression of overstimulation. Acceleration of growth is held to indicate a stimulation between the minimum and optimum.

An extensive bibliography is included in this report.

Influencing the growth of plants by electricity, M. Breslauer and C. Schimidt (*Mitt. Deut. Landw. Gesell., 23 (1908), No. 50, pp. 441–445, figs. 3; Umschau, 13 (1909), No. 2, pp. 23–30, figs. 9; Deut. Landw. Presse, 35 (1908), No. 90, pp. 943, 944; abs. in Mark Lane Express, 99 (1908), No. 4031, p. 731; Chem. Abs., 3 (1909), No. 6, pp. 684, 685*).—These articles discuss experiments by Lemström and Lodge (E. S. R., 20, p. 630) and by one of the authors, Breslauer, of the Technical High School of Charlottenburg. They describe an installation similar to that of Lodge's, which was set up on a farm near Berlin with the object of testing the practical character of the method. It is estimated that the necessary apparatus may be installed and operated for about $21 per acre annually.

On wind injury to plants, F. Noll (*Sitzber. Naturhist. Ver. Preuss. Rheinlande u. Westfalens, 1907, No. 2, Sect. A, pp. 58–68, fig. 1*).—A preliminary account is given of some experimental investigations on the effect of prevailing winds on plants.

The formation of red wood in conifers, Jean White (*Proc. Roy. Soc. Victoria, n. ser., 20 (1907), No. 2, pp. 107–124*).—A study was made of a number of species of Australian and other conifers to determine the cause of the formation of red wood, which is sometimes conspicuous in parts of the trunks of these trees. It has been previously suggested that the formation of red wood is due to a morphogenic response to a gravitational stimulus, and the experiments described were conducted with plants so rotated on a klinostat as to remove the action of gravity.

So far as the author's investigations go, they seem to confirm the theory that the formation of red wood is due to the stimulus of gravity. Where the lesser thickness shown by the walls of the red wood tracheids was compared with similar tissues in the white wood, the stimulus seemed to be photomorphic, the response being somewhat similar to etiolation in character.

The distribution and occurrence of races of mistletoe in Bavaria, K. von Tubeuf (*Naturw. Ztschr. Forst u. Landw., 6 (1908), No. 12, pp. 561–599, figs. 28, map 1*).—A study was made on the occurrence and distribution of mistletoe (*Viscum album*) in Bavaria. The author claims that there are 3 biological races of this species, one occurring on the pine, a second on firs, and a third on deciduous trees. Among the latter species, much injury is done to the apple, poplar, willow, and maple.

In combating the mistletoe, consideration must be given to the fact that there are biological races of the parasite and attention paid to the trees liable to infection by the particular form present.

FIELD CROPS.

Agricultural experiments, R. Ward, S. H. Bayley, and W. R. Dunstan (*Rpt. Bot. Gard. and Onderneem. School Farm Brit. Guiana, 1906–7, pp. 1–13*).—In fertilizer experiments with sugar cane it was found that the substitution of nitrate of soda for sulphate of ammonia on unlimed land continuously manured with sulphate of ammonia reduced the increased yield from 12.1 tons to 10.3 tons per acre, while the substitution of sulphate of ammonia for nitrate of soda on the nitrate fields produced an increase from 8.6 tons to 9.2 tons. The apparent ill effects of the long-continued use of nitrogenous fertilizers were far more noticeable after nitrate of soda than after sulphate of ammonia. On the lighter lands manured continuously for 30 to 50 years with sulphate of ammonia the decreases in yield are considered as probably due to the action of this substance. This injurious effect is remedied by the use of lime and not by simply substituting nitrate of soda for the sulphate of ammonia.

The results of these experiments have also led to the conclusion that if heavy clay soil yields more than 0.008 per cent of phosphoric acid to 1 per cent citric acid solution under conditions of continuous shaking for 5 hours, it is probable that manuring with phosphates on that particular soil will not produce commensurately increased yields of sugar cane. Work with different varieties has shown that B. 208 is unsuitable for very heavy clay soils, although in all the tests on the experiment fields this variety has been characterized by a high sugar content and a high purity.

The results of fertilizer experiments with rice show that in 100 tests with and without applications of phosphates 63 were in favor of the use of phosphates. Basic superphosphate gave increased yields in 69 cases, superphosphate in 64, and slag phosphate in 52. Assuming that the plats were of equal fertility increases of 4.7, 7.3, and 9.6 per cent were due to the use of superphosphate, slag phosphates, and basic superphosphate, respectively.

A large number of varieties of cotton were tested and the results are briefly described. Brief notes on the quality of each variety are given, and it is stated that all the varieties of cotton submitted for examination can be most successfully cultivated in British Guiana.

Work with field crops, F. H. Hall (*New York State Sta. Rpt. 1907, pt. 3, pp. 267–291*).—A summary is here given of the work conducted with field crops at the station during the first 25 years of its existence. The crops entering into this work were alfalfa, barley, corn, oats, onions, potatoes, sugar beets, tobacco, wheat, and forage crops.

Report on field trials on the manuring of seeds hay, J. F. Blackshaw (*Midland Agr. and Dairy Col. Bul. 1, 1907–8, pp. 11*).—Fertilizer experiments with rye grass and clover are reported.

The results indicate that the use of commercial fertilizers in a favorable season and on good ground may be profitable and that it is better to apply a complete dressing than an incomplete one. Unit for unit, the nitrogen in sulphate of ammonia and nitrate of soda was of equal value to the crop. Muriate of potash was the only form of potash giving a profitable return, and then only when applied during the earlier part of March. The results indicate that 130 lbs. of sulphate of ammonia and 216 lbs. of superphosphate applied during the earlier part of April, and 105 lbs. of muriate of potash applied during the earlier part of March is likely to give the most profitable yields of the different fertilizer applications compared.

Dates of seeding winter grains, T. B. Hutcheson (*Virginia Sta. Circ. 3, pp. 8, figs. 2*).—Brief notes are given on work previously reported (E. S. R., 18, p. 927).

Report on a field trial with varieties of barley (*Midland Agr. and Dairy Col. Bul. 2, 1907–8, pp. 15–22*).—The trials here reported indicate that Chevalier varieties produce the heaviest yield of grain, but that on some soils and in unfavorable seasons the quality is not of the best. In general, barleys of the Goldthorpe type produce better grain than the Chevalier barleys.

The blue grass of southwest Virginia, W. B. Ellett (*Virginia Sta. Bul. 180, pp. 90–96*).—A chemical study of blue grass in the southwestern part of Virginia as compared with other localities is reported, with reference to the claim that the grass in this region is superior to any similar grass grown elsewhere for finishing cattle without grain for export trade.

The blue grass and the blue-grass hay from southwest Virginia averaged 15.85 per cent in protein content, samples from the Valley of Virginia 12.67, and those from eastern Virginia 13.42 per cent. The green grass from the southwest averaged 17.82 per cent, from the Valley 15.10 per cent, and from eastern Virginia 16.15 per cent of protein. The average of samples of hay from 7 other States was 11.54 per cent of protein as compared with 12.67 per cent for Virginia and 14.53 per cent for southwest Virginia. Samples of grass from New York, Pennsylvania, and Wisconsin averaged 16.54 per cent as compared with 16.36 per cent from Virginia and 17.82 per cent from southwest Virginia. The young grass from all parts of the State averaged 16.36 per cent of protein, while grass ready to cut averaged 12.67 per cent. Samples of grass taken from a grazed meadow at Blacksburg on different dates contained the following percentages of protein on a dry matter basis: May 26, 16.92; July 6, 17.09; July 13, 20.86; July 20, 20.27; August 3, 18.09; August 17, 14.95; August 24, 14.87; September 4, 17.93; and October 19, 17.45.

Selecting seed corn, L. Carrier (*Virginia Sta. Circ. 4, pp. 2–12, figs. 3*).—This circular contains brief directions with reference to time to select seed corn, the kind of plant and ear to select, and the care of seed corn after harvesting.

Cotton culture in Palembang, W. M. Gutteling (*Jaarb. Dept. Land. Nederland. Indië, 1907, pp. 170–178*).—A brief description of experimental work with cotton is given and brief notes on the culture of several tree cotton varieties are presented. The results with Caravonica cotton led to the conclusion that the climate is too wet and changeable for this variety. Rough Peruvian (*Gossypium peruvianum*) and Brazilian cotton (*G. brasiliense*) produced no seed. Bourbon cotton (*G. purpurascens*) and *G. mexicanum* were also cultivated, and their behavior during the season is described in detail.

Supply and distribution of cotton for the year ending August 31, 1908, D. C. Roper (*Bur. of the Census [U. S.] Bul. 97, pp. 40, pls. 2, dgms. 3*).—The total supply of cotton in the United States for this year is given as 13,358,707 running bales. The cotton consumed by manufacturers amounted to 4,539,090 bales, of which 2,187,096 bales were used in the cotton-growing States and 2,351,994 bales in all other States. The exports reached 7,573,349 bales.

The different topics treated in the bulletin are supply and distribution, different cotton stocks in the United States, the world's consumption of cotton, the trade in cotton and its manufactures for selected countries, the history and description of cotton manufacture, utilization of cotton mill waste, water power, future dealings in the staple, and the grading and classification of the fiber.

Report on field trials on the manuring of mangels, J. F. Blackshaw (*Midland Agr. and Dairy Col. Bul. 8, 1907–8, pp. 79–96*).—Experiments conducted in 1907 show that it did not pay to use more than 90 lbs. of phosphoric

acid, nor more than 60 lbs. of potash, per acre for mangels. Both phosphate and potash were better applied shortly before seeding rather than in March. It is recommended that 100 lbs. of sulphate of ammonia, 715 lbs. of superphosphate, and 127 lbs. of sulphate of potash be applied at seeding time, 130 lbs. of nitrate of soda when the crop is thinned, and 280 lbs. of common salt in March.

[Variety tests with oats], L. A. Moorhouse (*Oklahoma Sta. Rpt. 1908, pp. 44, 45, 75, 76*).—Four varieties of oats were tested in 1905 and 1906. The average yields per acre were as follows: Texas Red 42.35 bu., Kherson 41.37 bu., Lincoln 38.67 bu., and Culberson 33.54 bu. In 1906 imported Iowa seed oats gave a yield of 23.19 bu. per acre.

Culture tests with Panicum maximum and Paspalum dilatatum in Dutch East India (*Jaarb. Dept. Landb. Nederland. Indië, 1907, pp. 86, 87*).—Planting *Panicum maximum* at different distances resulted in the best yields where plants were placed 90 by 50 cm. (about 36 by 20 in.) apart. As this plant comes into bloom about every 2 months, cutting every 2 months instead of every month is recommended.

Paspalum dilatatum in field culture gave poor results, but where sown in beds and later transplanted satisfactory yields were secured. This grass, which is a good meadow plant when sown thickly, is ranked next in value to *Panicum maximum*.

Report on field trials with potatoes: English, Scotch, and Irish seed, J. F. Blackshaw (*Midland Agr. and Dairy Col. Bul. 3, 1907–8, pp. 23–25*).—Seed of Up-To-Date and British Queen were obtained from England, Scotland, and Ireland, and in practically every case the Irish seed gave the best results.

Report on field trials on the manuring of potatoes, T. Milburn (*Midland Agr. and Dairy Col. Bul. 5, 1907–8, pp. 43–50*).—Moderately heavy dressings of farmyard manure up to 20 tons per acre proved profitable. Commercial fertilizers alone also gave good profit when applied in moderately large dressings, but not so good as when given together with the barnyard manure. Sulphate of ammonia proved a better source of nitrogen for potatoes than nitrate of soda, and superphosphate a better source of phosphoric acid than dissolved bone. Sulphate of potash, according to the author, has a more beneficial effect upon the potato crop than either muriate of potash or kainit. Superphosphate at the rate of 4 cwt. proved more profitable than either 2 or 6 cwt. The most profitable application used with barnyard manure consisted of 1½ cwt. of sulphate of ammonia, 4 cwt. of superphosphate, and 1 to 1½ cwt. of sulphate of potash per acre.

The "spineless" prickly pears, D. Griffiths (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 140, pp. 24, pl. 1, map 1*).—This bulletin discusses the origin of spineless prickly pears, their habitat, and their characteristics, and gives directions for the treatment of cuttings, planting, cultivation, harvesting, and uses of the plant. Notes are given on the temperature and moisture requirements, and the necessity of investigations to increase hardiness is discussed. The nature and origin of the prickly pears to be distributed by this Department are briefly outlined.

Experiments made by the author in different seasons and in different regions have shown that under open-air conditions in the arid and semiarid States no wilting of the joints is necessary before planting the cuttings.

Tests of sorghums, W. P. Wheeler (*New York State Sta. Rpt. 1907, pt. 3, pp. 229, 230*).—This article is a brief review of the work done with sorghums at the station during the first 25 years of its existence.

In 1888 sorghums were grown from 162 samples of seed, including about 100 distinct varieties. This work was carried on for several years. It was found

that most of the best sugar-producing varieties came from South Africa and a few from India. After 5 years' test only 6 of the varieties were recommended as reliable sirup producers for the latitude of the station. But seldom was less than 12 per cent of total sugars in the juice found in the mature cane of any of the better varieties. The use of carbonate of lime as a fertilizer did not definitely show any differences in quality, yield, and maturity.

Report on experiments on the growing of sugar beets, T. Milburn, J. Golding, and S. G. Paine (*Midland Agr. and Dairy Col. Bul. 9, 1907–8, pp. 99–109*).—The results of sugar-beet trials conducted in 1907 indicate that with regard to distance between rows it is advisable to adopt the narrowest width possible down to 12 in. It is further shown that in a damp and cold season digging should be delayed as long as possible, for in every case roots dug in November contained a higher percentage of sugar than those dug in October.

Sugar beets in 1908, W. B. Ellett (*Virginia Sta. Circ. 5, pp. 11*).—Brief reports on the sugar content and purity secured in cooperative culture tests in different counties of the State are given. Of the samples analyzed the richest contained 16.4 per cent of sugar in the beet, with a purity of 90.4 per cent. The highest purity coefficient recorded is 92.7 per cent.

The composition and production of sugar beets (*New York State Sta. Rpt. 1907, pt. 3, pp. 230–232*).—A summary of experiments with Kleinwanzleben and Vilmorin Improved sugar beets conducted from 1897 to 1901. In 1897, about 140 samples of beets from different parts of the State varied from 12 to 18.5 per cent in sugar content, the general average being about 15.3 per cent. The next year beets from 16 different localities contained from 10.1 to 18.5 per cent of sugar, with an average of 15.5 per cent. In 1899, 1900, and 1901 the sugar content in beets grown at the station varied from 12.3 to 18.5 per cent, with an average of 15 per cent. In the several years of work the coefficient of purity varied from 72.5 to 90.2, averaging about 83 per cent.

Additional details as to these cultural tests and also of fertilizer trials have been previously noted (E. S. R., 11, p. 238; 13, p. 1042).

Potash consumption of the beet during its first season of growth, K. Andrlík and J. Urban (*Ztschr. Zuckerindus. Böhmen, 32 (1908), No. 10, pp. 559–575*).—In the series of experiments conducted with reference to this problem it was found that the quantity of potash taken up by the sugar beet in its first year of growth varies with the season, the soil, the fertilization, and the seed. The minimum quantity determined was 156.9 kg. in 400 quintals of beets (about 7.84 lbs. per ton of beets), but the consumption in general was much greater. The use of potash salts and barnyard manure increased the quantity of potash taken up, while dry seasons apparently reduced it, but the dry years also produced small yields of beets and sugar.

It was also observed that beets from different kinds of seed, grown under identical conditions, varied in potash consumption, and that beets from the same kind of seed but grown under different conditions also varied in this regard. A high potash consumption did not indicate a high yield of beets or of sugar, but was rather correlated with a heavy yield of leaves. The proportion of potash taken up to the quantity of sugar produced was not constant, the range determined being from 2.1 to 5.8 parts of potash to 100 parts of sugar. The roots contained from 32.1 to 41.5 per cent of the potash consumed, showing that the larger portion goes to the leaves. However, when the plants used large quantities of potash an increase in the potash content of the roots also took place.

In the beets showing the minimum content of potash the proportion of potash to sugar was 0.75 to 100, while in the beets containing on the average 177.5 kg. of potash per 400 quintals, the proportion of potash rose to 1.01 parts, and in the beets containing 303 kg. of potash per 400 quintals, to 1.72 parts per 100

parts of sugar. Some varieties of seed produced more potash and others less in the root. The differences observed ranged from 0.2 to 0.7 parts of potash per 100 parts of sugar.

Experiments with seedling and other varieties of canes, J. P. D'Albuquerque and J. R. Bovell (*Rpt. Agr. Work Barbados, Imp. Dept. Agr. West Indies, 1905–1907, pl. 3, pp. 99*).—This publication is the customary tabulated report, with brief comments, on this work carried on under the direction of the Imperial Department of Agriculture for the West Indies. The period covered is for the season between 1905 and 1907. The experiments were conducted in the same manner as previously noted (E. S. R., 19, p. 333).

On the black soils cane B. 3696 ranked first, with a yield of 2,045 lbs. of saccharose per acre in excess of that secured from White Transparent, the standard cane. B. 208 ranked second and B. 147 third, with increased yields of 1,494 lbs. and 922 lbs. of saccharose, respectively, over White Transparent. On the red soils, as plants and rattoons, B. 1566 stood first with 8,394 lbs. of saccharose per acre as plants and 6,645 lbs. as rattoons, while White Transparent as plant canes gave only 6,006 lbs. and as rattoons only 5,736 lbs. per acre. The average results from the best varieties during the past 4 seasons indicate that B. 3696, B. 1753, B. 1529, B. 147, and B. 208 are apparently the best varieties for the black soils, and B. 3405, B. 3412, B. 3390, B. 1566, B. 208, B. 1529, and B. 376 for the red soils. The seedling canes originated, selected, and tested in these experiments show a marked superiority in many instances. On the black soils the average results for 3 and 4 years, arranged according to saccharose yield, show that White Transparent stood last in a list of 90 with 6,670 lbs. of saccharose, while the seven best varieties gave an average of over 9,000 lbs.

[Variety tests with sweet potatoes], O. M. Morris (*Oklahoma Sta. Rpt. 1908, pp. 12, 13*).—The following varieties of sweet potatoes, with the yields per acre reported, were grown on thin upland soil of poor quality with a hardpan subsoil: Black Spanish 6,795 lbs., Blooming 5,094 lbs., Early Golden 17,771 lbs., Extra Early Carolina 9,460 lbs., Hanover Yam 11,585 lbs., Red Bermuda 15,309 lbs., Red Nancemond 4,807 lbs., Red Nose 9,889 lbs., Southern Queen 6,143 lbs., Vineless 981 lbs., Vineless Pumpkin Yam 10,371 lbs., Yellow Jersey 6,328 lbs.

Tobacco experiments, H. Jensen (*Jaarb. Dept. Landb. Nederland. Indië, 1907, pp. 199–247, pls. 3, dgm. 1*).—The results of experiments here described indicate that rubber solutions can not be used for combating phytophthora. In a plant breeding test it was found that the chances of securing a fixed broad leaf variety from an individual plant showing this characteristic were very small. It is believed that the plant with which the test was begun was a cross between a narrow and a broad leaf plant, and that for this reason the progeny broke up into many forms. A cross between Canary and Deli tobacco produced good plants practically free from mosaic disease, although the mother plants had been so attacked by this disease that they had improperly developed and were almost dwarfed.

Reciprocal crosses between White Burley and Peru followed Mendel's law in part only. Some of the individuals showed characters intermediate between the male and female parent in the first generation. The veins of the pure White Burley plants were light in color, which is regarded as a recessive character, while the veins of the crosses with Peru and Canary were normally green. With reference to the base of the leaf and the size of the plants the crosses were intermediate. The leaves in the hybrids had long stems, which is a character prevailing in Peru tobacco, and is therefore looked upon by the author as probably a dominant character derived from that variety.

After growing tobacco continuously for 5 years on the same soil green manuring gave good results, thus showing that fertility had declined. *Crotalaria retusa* as a green-manuring crop produced a good growth early enough in the season to be plowed under at the proper time. Irrigation increased the leaf surface of plants about 100 per cent.

The relation of nicotine to the quality of tobacco, W. W. Garner (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 141, pt. 1, pp. 16*).—The variation in the nicotine content and its relation to the quality of tobacco are discussed, and the results of experiments reported.

Extraction with petroleum ether of a sample of domestic filler tobacco possessing a peculiar pungency or harshness was found to remove the objectionable qualities. The ether extract, however, contained only a portion of the nicotine in the tobacco. The nicotine was apparently present in at least two forms, one of which is soluble in petroleum ether while the other is practically insoluble.

The total nicotine present in a sample of Connecticut wrapper-leaf tobacco before fermentation was 3.39 per cent and after fermentation 2.89 per cent, representing a loss of 0.5 per cent in the fermentation process. The nicotine soluble in petroleum ether before fermentation was 1.60 per cent, while that soluble after fermentation was 1.01 per cent. The loss of total nicotine in fermentation therefore corresponds very closely to the difference between the amount soluble in petroleum ether before and after fermentation.

The author concludes that "the undesirable sharpness or pungency contained in the smoke from certain types of cigar-filler tobacco and which constitutes one of the two factors included in the term 'strength,' as applied to the smoke, is due almost entirely to the volatile, easily soluble form of nicotine which acts as if it were in the free state. On the other hand, the true physiological effects of the smoke, as embodied in the term 'fullness,' are proportional to the total quantity of nicotine."

It was found that "the pungent, harsh quality of the smoke is partially, but not entirely, removed by protracted resweating and aging of the tobacco, whereby the easily volatile nicotine is largely expelled. This undesirable property is entirely removed by extracting the tobacco with petroleum ether, which simply dissolves out the volatile nicotine. Finally, the addition of sufficient citric acid to the tobacco to combine with all of this easily volatile nicotine efficiently overcomes the sharpness or pungency of the smoke."

Alaska wheat investigation, H. T. French and J. S. Jones (*Idaho Sta. Bul. 65, pp. 3–12*).—A classification of this wheat is given, the claims made for it are reviewed, and tests made at the station are reported.

Analyses made of the grain and the flour of Little Club and Alaska spring and Alaska winter wheat showed that in total protein and protein in the form of gliadin the Alaska wheat flour in both cases was somewhat higher than that from Little Club, which is described as a soft wheat, ranking probably about halfway between the best and the poorest milling varieties. The gluten in the Alaska spring wheat flour was rather hard to wash out, but when once obtained it seemed to be of practically the same quality as that secured from either of the other flours although somewhat less in amount. The water required to make a dough out of 340 gm. of flour for the different wheats was as follows: Little Club 180 cc., Alaska spring 182 cc., and Alaska winter 182 cc.

In baking tests both Alaska wheats gave noticeably whiter bread than did the Little Club. It was concluded from these tests that the gluten in the Little Club flour is somewhat stronger and quicker acting than that of the Alaska flours, but on the whole there was very little difference in the baking qualities of the flour obtained from the different wheats. The yield of Alaska wheat grown in

the vicinity of the station under field conditions is estimated at from 20 to 40 bu. per acre.

Seed studies (*New York State Sta. Rpt. 1907, pt. 3, pp. 330–344*).—This article is a review of the seed work of the station during the first 25 years of its existence. A description of the Geneva germinator is given, and the results secured in germination tests with field and garden seeds are tabulated, and the conclusions drawn from the investigation are pointed out.

The adulteration and misbranding of the seeds of alfalfa, red clover, orchard grass, and Kentucky blue grass, B. T. Galloway (*U. S. Dept. Agr., Office Sec. Circ. 28, pp. 5; Bur. Statis. Crop Reporter, 11 (1909), No. 3, pp. 21, 22*).—The number of seed samples secured and analyzed was 1,471 and analyses of the 102 samples which were found to be adulterated or misbranded are here reported. Of the 358 samples of alfalfa seed secured 86 contained seed of sweet clover, 76 seed of yellow trefoil, and in 107 dodder was present, ranging from a trace to a sufficient quantity to sow 3,600 seeds per square rod when seeding at the rate of 16 lbs. per acre. Only 8 samples contained yellow trefoil seed in sufficient quantity to be considered an adulterant.

Of the 413 samples of red clover secured only 2 were adulterated with yellow trefoil seed, though a trace of this seed was present in 164 samples. Dodder was found in 223 samples, and it was found that in seeding one lot at the rate of 8 lbs. of red clover seed per acre 679 dodder seeds would be sown per square rod. By the use of other lots more than 3,500 buckhorn and plantain seeds and 2,600 green foxtail seeds would be sown per square rod.

Of the 343 samples secured as orchard grass seed 2 contained no orchard grass seed, 2 were adulterated with chess, and 49 with seed of rye grass, meadow fescue, or both. Of the 357 samples obtained as Kentucky blue grass seed 25 contained Canada blue grass as an adulterant, 12 were practically all Canada blue grass, and 2 were meadow fescue.

It is stated that since this line of work reported here has begun, the importation of yellow trefoil seed and its use as an adulterant of red clover and alfalfa seed has practically ceased. Adulteration of orchard grass and Kentucky blue grass seed is also much less common now than a few years ago.

Feeds, seeds and weeds, E. H. Jenkins (*Connecticut State Sta. Bul. 161, pp. 3–6*).—This bulletin reports in tabular form, with brief discussion, the number and the vitality of weed seeds found in a pound of different proprietary feeding stuffs on sale in the State. The total number of weed seeds per pound in the 7 feeds examined ranged from 5,234 to 86,000. The seeds of Chætochloa, Chenopodium, Polygonum, Brassica, Ambrosia, Panicum, Rumex, and Silene were found in most of them. The number of Chenopodium seeds found in the feeds capable of germinating ranged from 27 to 13,814. The number of germinable Polygonum seeds was 453 in one feed and 522 in another, while from four samples none of these seeds grew. The vitality tests of the Chætochloa seeds showed that the number capable of germinating ranged from 0 to 13,118 per pound of feed. It is pointed out that of the feed mixtures examined in some instances 100 and in others more than 20,000 seeds were alive.

HORTICULTURE.

Horticultural investigations, N. O. Booth (*New York State Sta. Rpt. 1907, pt. 3, pp. 292–329, pls. 4*).—This is a summary of investigations which have been conducted with orchard and small fruits and vegetables at the station during the first 25 years since its establishment, including abstracts of the bulletins and other publications issued relative to the work.

Vegetable-fruit seed distribution for 1909, B. D. HALSTED (*New Jersey Stas. Bul. 218, pp. 3–28, pls. 4*).—The New Jersey stations have offered for distribution for 1909 to those willing to comply with the conditions several kinds of corn, tomato, eggplant, bean and squash seed, some 45 varieties in all, together with an ornamental, "White Star" phlox, which have been produced in connection with their plant-breeding investigations (E. S. R., 19, p. 1039). One variety of sweet corn, 2 of bush snap beans, and 2 of squash are also offered for home breeding purposes. The first part of this bulletin discusses the varieties offered for trial. Part 2 contains suggestions for the improvement and breeding of vegetables at home, together with notes on the varieties offered for breeding purposes. The general conditions of the seed distribution are also stated.

Mushroom culture, P. M. NÖVIK (*Norsk Havetidende, 24 (1908), No. 11, pp. 205–211, figs. 2*).—This article contains brief popular directions for growing mushrooms.

Fertilizer and irrigation experiments with onions, S. A. WASCHKA (*Texas Sta. Bul. 115, pp. 5–16*).—The results secured with comparative fertilizer and irrigation tests with Bermuda onions conducted through 4 seasons at the Beeville Substation are given, together with brief suggestions on the cultivation, harvesting, and marketing of onions.

The evidence secured from the 4 years' work with fertilizers indicates that soils similar to those at the Beeville station are not deficient in mineral elements and are more in need of humus than commercial fertilizers. Barnyard manure was the only fertilizer the use of which in large quantities justified the expense.

Comparative tests of the furrow and flooding methods of irrigation resulted in estimated gains in yield per acre by the flooding method of 4,200 to 7,000 lbs. of onions. The increased yields secured from irrigation as compared with dry culture indicate that irrigation is profitable even in seasons when the rainfall is sufficient to produce a good crop, but the work as a whole shows that by the use of cowpeas each year as a green manure and by watering the plants just after transplanting a profitable crop of onions can be grown in the Beeville section without other fertilizers or irrigation.

Data on the cost of irrigating onions and bunch crops have previously been reported (E. S. R., 17, p. 251).

Mendelian characters in tomatoes, U. P. HEDRICK and N. O. BOOTH (*Proc. Soc. Hort. Sci., 1907, pp. 19–24*).—This paper discusses the results secured from some hybridization experiments with tomatoes conducted by Hedrick in the seasons of 1903–1905, inclusive, and by the authors jointly in the years 1906–7. The work comprised a comparative study of the standard and dwarf characters of the tomato plant, and was pursued with the view of determining the practicability of originating new varieties of tomatoes by the Mendelian methods.

As a result of their work, the authors concluded that any 2 varieties of tomatoes differing in 2 or more characters may be crossed and forms secured which will contain any and all combinations of these characters. The work also indicated that it was actually necessary to raise 7 times as many tomatoes as are theoretically necessary, according to Mendel's work with peas (E. S. R., 13, p. 744), in order to secure any desired combination. There was a strong tendency for the second generation hybrids to revert to the same combinations of characters as the parents rather than to form new ones.

It was found that in raising tomatoes outdoors without the use of a greenhouse 3 years from the cross is sufficient time to form and fix any combination of characters, whereas it requires 8 to 10 years to fix types by the old method

of selection. By using a greenhouse for one generation a pear-shaped, yellow fruit was transferred from a standard to a dwarf vine in a year from the time the original cross was made. Since these characters were all recessive no further fixing was required.

Mendel's law applied in tomato breeding, A. G. CRAIG (*Proc. Soc. Hort. Sci., 1907, pp. 24–27*).—The results secured by the author in a test of Mendel's law as applied to tomatoes appear to have borne out the important features of the Mendelian theory, although the numerical proportions of the different character combinations secured as worked out by Mendel for peas (E. S. R., 13, p. 744) did not appear to hold for tomatoes. The author is of the opinion that unit characters and correlation of characters can be determined only by growing the hybrids resulting from any particular cross, except possibly where the pedigrees of both parents are known.

[A study relative to the influence of fertilizers on the structure of the tomato], O. M. MORRIS (*Oklahoma Sta. Rpt. 1908, pp. 13–15*).—Experiments were conducted for 3 successive years to determine whether different proportions of fertilizer ingredients applied to the soil would influence the relative amounts of seed pulp and solid flesh of the tomato. Several combinations of fertilizer and over 40 varieties of tomatoes were included in the work. The data secured indicate that there is practically no influence exerted by different fertilizers in increasing or decreasing the relative amount of solid flesh and seed pulp. The author also finds that the best varieties are not necessarily those that have the greatest proportion of solid flesh in the fruit.

Report of the South Haven Substation for 1907, L. R. TAFT and F. A. WILKEN (*Michigan Sta. Spec. Bul. 46, pp. 3–14*).—Notes are given in this report on the condition of the orchard and small fruits and nuts being tested at the substation (E. S. R., 20, p. 143), together with an outline of cultural and fertilizer tests and data on tests of some of the newer prepared scale-destroying mixtures, and a comparative test of the common arsenic compounds.

The season of 1907 was cold and backward. All of the peach trees at the station were winterkilled. Of the plums, only the Japanese varieties were affected, and Satsuma and Red June were the only varieties killed. All of the grapevines were killed back more or less, there being no difference noted in the resistance of varieties to the freeze. The Japanese walnuts, both the Sieboldiana and the Cordiformis, were seriously injured, the entire tops being killed except in limbs measuring 3 in. or more in diameter. The new growth of chestnuts was killed in most varieties, and the Japanese chestnuts were all killed. Hazelnuts and filberts, as well as the pecan, which is a southern tree, were not affected by the freeze. Generally speaking, the blossoms were 3 weeks behind their usual time and lasted for an unusually long period. Spring frosts did much damage to cherry and early strawberry blossoms.

New varieties of strawberries which fruited at the station are described, and lists are given of the gooseberries and currants showing the degree of freedom from cane borers, and of varieties of apples subject and not subject to injury from Bordeaux mixture. In the spraying tests none of the prepared scale-destroying mixtures were as satisfactory as the home-made lime-sulphur wash. Arsenate of lead was found to be superior to the other arsenic compounds in spraying for the prevention of wormy apples.

Fifth biennial report of the Montana State Board of Horticulture (*Bien. Rpt. Mont. Bd. Hort., 5 (1907–8), pp. 63, figs. 21*).—This report contains a review of the work done by the State board of horticulture, statistics showing the volume and character of the fruit industry in Montana, and other information

of practical value to fruit growers, relative to varieties, cultural methods, and insect pests and diseases and their control.

The small fruits: Information concerning their culture, J. TROOP (*Indiana Sta. Bul. 128, pp. 219–230*).—This bulletin contains popular directions for growing strawberries, raspberries, blackberries, currants and gooseberries.

Variety test of strawberries and cultural directions, O. M. TAYLOR (*New York State Sta. Bul. 309, pp. 507–557, pls. 8, figs. 2*).—This bulletin contains notes and descriptions of 89 varieties of strawberries tested at the station during the seasons of 1907 and 1908, many of which are recent introductions.

Lists are given of the varieties producing very many plants, those producing very few plants, those early and late as to season, those productive and unproductive, varieties having a desirable size throughout the season, early and late bloomers, and those possessing marked desirable characters. Brief general directions on strawberry culture are also given.

A large number of varieties fruited in midseason. Most of the early kinds produced only 1 or 2 satisfactory pickings, but Golden Gate and St. Louis were very productive. All of the 7 late varieties tested possessed marked desirable characters. Arnouts, a main season variety, was the most productive, yielding at the rate of 14,409 qt. per acre. Nineteen varieties gave a yield of 8,189 qt. and over. No insect injury occurred during the test, and 69 kinds were free from disease, or nearly so. Twenty varieties were strongly susceptible to attacks of leaf blight.

Some newer strawberries, O. M. TAYLOR (*New York State Sta. Bul. 309, popular ed., pp. 11*).—This is a popular edition of the above.

Culture v. nonculture with grapes, A. VIVIER (*Jour. Agr. Prat., n. ser., 17 (1909), No. 3, pp. 77, 78*).—In the autumn of 1902 the ground of one portion of a small grape vineyard was covered with a layer of basic slag about 4 in. thick. This part of the plat received no further cultivation, while the other portion of the plat has been cultivated in the usual manner. As indicated by the yields, the difference in favor of the mulched portion was 25 per cent in 1906 and 26 per cent in 1907. The experiment was repeated on other plats during the past season, the basic slag being applied in the autumn of 1907. The results for the first season, however, showed a yield of 13.5 per cent less grapes for the basic slag plat than for the plat receiving ordinary culture. The experiment is to be continued.

The grapes of New York, U. P. HEDRICK ET AL. (*New York State Sta. Rpt. 1907, pt. 2, pp. XV+564, pls. 101*).—This comprehensive work is a companion volume to The Apples of New York, previously noted (E. S. R., 17, pp. 559, 1157). Although its title implies that it is a local study, its real purpose is to record the state of development of American grapes, and the varietal descriptions contained therein are offered as its chief contribution to the pomology of the country. Brief historical narratives are given of Old World and New World grapes, as well as an account of the grape regions and of grape growing in New York, with statistics relating to the grape, wine and grape juice industries in that State. The species of American grapes are next discussed, the classification adopted being that used by Bailey in his monograph of the Vitaceæ in Gray's Synoptical Flora. The synonymy, bibliography, economic status, and full descriptions are then given of all the important varieties of American grapes. Life size color-plates are shown of varieties which from various standpoints are considered most important. The footnotes contain brief biographical sketches of those persons who have been prominently connected with the evolution of the grape and grape growing in America, together with some other historical and explanatory notes. The minor varieties of American grapes are

briefly described and a rather complete bibliography is given of grape literature in the United States.

Notes on the time of blossoming of fruit trees, C. H. HOOPER (*Jour. Bd. Agr. [London], 15 (1908), No. 9, pp. 678–687*).—Daily observations were made during the spring of 1908 on the condition of the blossoms of several varieties of fruit in the plantations of the Wye Agricultural College, with the view of ascertaining the period when the blossom is most susceptible to injury by frost.

With the exception of apricots and Japanese plums, little damage was done to the blossoms by frost in 1908. The present notes, however, contain considerable information relative to early and late blooming varieties of the various fruits, as well as on the duration of the blooming period.

The American apple orchard, F. A. WAUGH (*New York, 1908, pp. X+215, pl. 1, figs. 36*).—This work is designed as a sketch of the practice of apple growing in North America at the beginning of the 20th century. Consideration is given to all of the important phases of apple culture, including the geography of apple growing, soils, exposures, wind-breaks, winterkilling, planting operations, cultivation, cover crops, pruning, fertilizers, insect pests, fungus diseases and other orchard troubles, spraying machinery and spraying solutions, harvesting and marketing, the family orchard, renovation of old orchards, and selection of varieties. The work concludes with a list of the best-known varieties, with condensed descriptions.

Planting apple orchards in Idaho, J. R. SHINN (*Idaho Sta. Bul. 64, pp. 3–37, pls. 11, maps 2*).—This bulletin on the planting of apple orchards is designed to meet the needs of new settlers and other inexperienced growers. Practical suggestions are given relative to the selection of orchard sites and varieties, preparing the land, drainage, irrigation, various systems of planting, and care and protection from injurious vermin during the early life of the trees.

Orchard survey of Jackson County, C. I. LEWIS, S. L. BENNETT, and C. C. VINCENT (*Oregon Sta. Bul. 101, pp. 3–55, pls. 15*).—The character of the survey reported in this bulletin is similar to that previously noted for Wasco County (E. S. R., 20, p. 336). Studies were made of orchard sites, soils, cultivation, fertilizers, irrigation, drainage, planting systems, kinds and varieties of fruit, age of orchards, pruning, thinning, fungus diseases, insects, yields, harvesting, marketing, and prices received.

The total number of orchards in the county was found to be 473, containing 9,675.4 acres, of which 5,972.97 acres were planted to apples, 2,189.43 acres to pears, and the remainder to prunes, plums, cherries, apricots, almonds, and mixed orchards. Yellow Newton and Spitzenberg were the leading varieties of apples. Of the pears Bartlett was slightly in the lead, followed by Comice and Bosc. The orchard elevations varied from 1,200 to 2,600 ft.

A large percentage of the trees were under 6 years of age. The maximum yields were found in trees from 15 to 30 years of age. Older trees were declining in yield because of neglect. Practically 74 per cent of the orchards received good cultivation, however, and only 1½ per cent, largely home orchards, were totally neglected. Only 5 per cent of the growers used commercial fertilizer, 5 per cent cover crops, and 70 per cent stable compost in very limited quantities. Ten per cent of the growers were irrigating and others preparing to do so. Eighty-three per cent of the growers favor winter pruning and 11 per cent prune both winter and summer.

Anthracnose was the most noticeable fungus disease, being found in 61 orchards. Other diseases noted in lesser quantities were, blight, crown gall, shot-hole fungus, and apple scab. Of the insects the codling moth was noticeably present in 141 orchards. San José scale was found in 98 orchards, the

aphis in 58, and borers in 31 orchards. There was considerable difference of opinion as to the best date and number of applications to make in spraying for codling moth. Eighty per cent spray when the petals fall, 21 per cent wait until the moths appear, 85 per cent make 4 applications, and 12 per cent but 2 applications.

The practical culture of coffee trees, A. Fauchère (*Culture Pratique du Caféier et Préparation du Café. Paris, 1908, pp. 198, pls. 12, figs. 37, dgms. 4*).—This is a treatise on the culture and preparation of coffee for the market with special reference to the development of the industry in Madagascar. Consideration is given to the natural distribution, history, species and varieties of coffee, climate and soils, details of culture and management of coffee plantations, diseases and insects. The various processes in preparing coffee for the market, together with the equipment, are also described, and estimates are given on the cost of establishing and maintaining plantations. An appendix deals with the present importance and future possibilities of *Coffea arabica* as a variety for growing in Madagascar.

Some observations on modern coffee culture in Java, G. E. Schuurman (*Indische Mercuur, 32 (1909), No. 3, pp. 39–42*).—A paper on this subject presented to the Dutch section of the Dutch-Indes Agricultural Society, January, 1909.

Holly, yew and box, with chapters on other evergreens, W. Dallimore (*New York and London, 1908, pp. XIV+284, pls. 43*).—In this popular work the author describes the more important hollies, yews and boxes desirable for ornamental purposes, and gives notes on their culture and uses, together with extracts from various works on the superstitions, legends, poetry, etc., attached to each group. Brief cultural notes and descriptions are also given of several other useful evergreens.

The peony, J. E. Coit (*New York Cornell Sta. Bul. 259, pp. 73–145, pls. 20*).—This is the second progress report (E. S. R., 19, p. 342), on the peony investigations which are being cooperatively conducted by the American Peony Society and the Cornell Station, with a view to correct the confused nomenclature and establish the botanical status of all varieties of peonies, as well as to determine the commercial value of different kinds and to work out improved cultural methods. The station is testing an extensive number of varieties received from various sources.

The present report deals with the history, culture, and classification of peonies, together with descriptions of varieties which produced typical blooms at the station during the past season. The author outlines the history of the various species and discusses the early development of the peony as a popular flower. He has worked out an artificial key for classification purposes based upon the descriptions of species made by J. G. Baker in his Monograph of the Genus Paeonia. Other phases discussed include propagation and culture; evolution and horticultural classification; diseases and insects; and the methods of describing varieties. A chronological bibliography of peony literature is also given.

Dahlias and their cultivation, J. B. Wroe (*London, 1908, pp. 100, pl. 1, figs. 28*).—This work is offered as a practical treatise on the history, culture, and propagation of various types of dahlias for exhibition and garden decoration, with hints on staging and judging of flowers, as well as selections of varieties for all purposes.

Mesembryanthemum and portulacas, A. Berger (*Mesembrianthemen und Portulacaceen. Stuttgart, 1908, pp. V+328, figs. 67*).—This handbook contains descriptions and keys for classifying the important species of mesembryanthemum and portulacas, together with brief directions for their culture.

The perfect garden, W. P. WRIGHT (*London, 1908, pp. XII+408, pls. 30*).—In this popular work the author discusses garden making from æsthetic and cultural points of view and gives practical hints on economical management and the culture of all the principal flowers, fruits, and vegetables. The text is fully illustrated, and several plans for different types of gardens are appended.

Garden book, J. BIGGLE (*Philadelphia, 1908, pp. 184, pl. 1, figs. 81*).—This is a pocket handbook containing practical directions and hints for growing vegetables, small fruits, and flowers for pleasure and profit.

FORESTRY.

Silviculture based on natural principles, H. MAYR (*Waldbau auf naturgesetzlicher Grundlage. Berlin, 1909, pp. VII+568, figs. 27*).—In this treatise on silviculture the author has aimed to bring the observations and results of scientific investigations and silvicultural practice into harmonious unison. The subject-matter is treated under the general headings of the natural principles of silviculture, forest formation, and care and rearing of forests.

In part 1 consideration is given to the natural laws affecting forest distribution; the natural foundations of the forest regions of the Northern Hemisphere outside of the Tropics; the interior relations of these regions; the natural requirements of individual species; their silvicultural-physiological and silvicultural-biological properties; the scientific-silvicultural characteristics of the important forest trees and shrubs; the biology of forest stands; and alterations in natural forest conditions effected by man. Part 2 discusses the various systems of forest management; the factors influencing the choice of a system of management; natural and artificial regeneration methods; the culture of exotic species; and afforesting waste lands. Part 3 deals with the care and tending of forests.

In the concluding chapter the author advocates and describes a system of forest management, the small compartment woods (Kleinbestandswald), which system he believes will provide for forest development along both natural and economic lines. In the small compartment forests the districts and compartments may be based on technical considerations, but the subcompartments, which may vary from 0.3 hectare to 3 hectares (from 0.74 to 7.41 acres) in size, each consist of a different species. The whole forest is then composed of a large number of small, pure stands. In certain situations, such as mountains, high hills, and sandy and wet lands, it may be found desirable to increase the size of the subcompartments to 5 hectares and to grow the same species in neighboring compartments, although in the latter case the age-class of the adjoining stands should vary considerably.

The fundamental principles of forest management, A. HENZE (*Die Hauptgrundsätze des Forstbetriebes. Hanover, 1908, pp. 115, figs. 9*).—This is a popular book treating of the elements of silviculture and forest management. The work is designed primarily for farmers owning woodlands, and as a textbook for agricultural schools.

The range-officer system in the German state forest administration, O. VON BENTHEIM (*Das Oberförstersystem in den deutschen Staatsforstverwaltungen. Berlin, 1908, pp. 219*).—In this work the author traces the development of the range-officer system in German forestry, and presents evidence to show that, although great improvements have been brought about in forest management, the system has not been completely developed. He attributes many unfavorable existing forest conditions in Germany to this lack of completion, and concludes with suggestions for a more thorough development of the range-officer system.

The value of normal yield tables in forest management, E. Ostwald (*Ztschr. Forst. u. Jagdw., 41 (1909), No. 1, pp. 14–27*).—The author advances the opinion that most of the yield data which have been gathered in experimental work have been formulated to meet the needs of scientific investigators rather than practical foresters. With the view of illustrating a system of formulating the data which shall be of value to practical foresters, he presents and discusses a series of 8 yield tables which are based on the yield data secured by Schwappach in his work with the pine (E. S. R., 7, p. 961; 20, p. 644).

Report on forest conditions in Delaware and the forest policy for the State, W. D. Sterrett (*Delaware Sta. Bul. 82, pp. 3–58, figs. 10, map 1*).—Results are given of a cooperative study of forest conditions in Delaware made by the station and the Forest Service of this Department with the purpose of recommending practical measures for the management of the various classes of woodland and of formulating a definite forest policy for the State.

The two general lines of action recommended and discussed are the encouragement of forestry by private owners and the establishment of State forests. Lists are given of species indigenous to the State, grouped according to their commercial importance, together with remarks on their occurrence, and suggestions relative to the establishment and management of forest plantings.

Most of the land in the State was found to be too valuable for agricultural purposes to be used for growing forests. The author points out the desirability of the woodlot on the farm, however, and also advises the planting of trees to serve as wind-breaks and shelter belts. Since Delaware has a climate and soils well adapted to extremely rapid tree growth and a favorable market for forest products, it is concluded that timber growing, with careful treatment, can be made a profitable enterprise anywhere in the State on lands not valued at more than $15 per acre for agriculture.

Report of the State forester of Wisconsin for 1907–8, E. M. Griffith (*Rpt. State Forester Wis., 1907–8, pp. 5–133, pls. 11*).—This report discusses the condition of State forest operations for 1907–8, and contains suggestions for handling local forest problems of various kinds, such as reforestation, fire protection, timber trespass, forest taxation, and necessary legislation. An appendix contains the State forestry laws for the years 1905 and 1907.

Forest trees of the Pacific slope, G. B. Sudworth (*U. S. Dept. Agr., Forest Serv., 1908, pp. 441, pls. 2, figs. 207*).—This volume, now withdrawn from circulation, contains an account of the tree species, 150 in all, known to inhabit some part of the region including Alaska, British Columbia, Washington, Oregon, and California, many of which trees occur wholly within this region. Since the work is nontechnical in character, the artificial keys of families, genera, and species are omitted, and the many full-sized illustrations of the leaves, fruits and seeds have been made a special feature for the purpose of identification. Each species is considered relative to its distinguishing characteristics, longevity, range, occurrence, climatic conditions, tolerance, and reproduction.

The afforestation of poor agricultural soils, K. J. Möller (*Aufforstung Landwirtschaftlich Minderwertigen Bodens. Berlin, 1908, pp. IV+102*).—This work, which was given a prize by the department of the interior of Saxony, consists of a study of the expediency of afforesting lands which are either poor or of no value for agricultural purposes with special reference to small estates. The subject is discussed under 2 general headings. In part 1 the author considers to what extent the afforestation of these lands is advisable. In part 2 he discusses ways and means for afforesting such lands on small estates. An appendix contains regulations and sample statutes for the organization of forestry associations.

The afforestation of the infertile lands of small estates from the standpoints of agricultural and forest policy, R. Beck (*Die Aufforstung der unrentablen Flächen des Landwirtschaftlichen Kleinbesitzes vom Agrar- und Forstpolitischen Standpunkte aus betrachtet. Berlin, 1908, pp. 99*).—In this prize essay, which is similar in character to the one noted above, the author first considers the question as to what lands are suitable for afforestation purposes, and then discusses the ways and means for bringing about this afforestation.

Moss cover and natural regeneration, K. Böhmerle (*Centbl. Gesam. Forstw., 35 (1909), No. 1, pp. 22–27*).—An account with the data secured is given of investigations conducted at the Mariabrunn Forestry Station relative to the effect of moss covered ground on natural regeneration.

The results of this study indicate that a mossy cover, other conditions being equal, is not favorable for the germination of seeds falling on such ground. During periods of drought the mossy cover exerts a favorable influence as long as it remains moist by supplying the root systems with additional moisture. This influence is only temporary, however, and in the experimental areas the number of plants growing on moss-free ground was found to be considerably greater than that growing on mossy ground.

The plant biology of the Flemish dunes, C. De Bruyne (*Handel. Vlaamsch Natuur en Geneesk. Cong., 10 (1906), I, No. 1–2, pp. XXXVII–LXXX, figs. 50*).—In this paper the author discusses the various plant formations existing on Flemish sand dunes and their value for sand-binding purposes.

The future use of land in the United States, R. Zon (*U. S. Dept. Agr. Forest Serv., Circ. 159, pp. 15, map. 1*).—In this circular the author points out the importance of land as a natural resource and contrasts the present condition and extent of our agricultural, grazing, desert, forest, and intermediate lands with their probable condition and extent 50 years from now as influenced by the needs of an increased population. He shows that with an increasing demand for land for agricultural crops there is little hope of increasing the extent of forest land. He presents data drawn from forest conditions in our own and other countries to support the conclusion that the growing demand for wood material must be met by an increase in the productiveness of existing forest lands and a decrease in the waste.

Forests and reservoirs in their relation to stream flow with particular reference to navigable rivers, H. M. Chittenden (*Cong. Rec., 43 (1909), No. 47, pp. 2102–2121*).—An extensive paper on this subject which was prepared for discussion before the American Society of Civil Engineers.

The author takes exception to the rather commonly accepted opinion relative to the beneficial influence of forests on stream flow, and advocates the preservation of the forests independent of their relation to the rivers, which latter he believes can best be regulated by the establishment of reservoirs.

Wholesale lumber prices, 1886–1908 (*U. S. Dept. Agr., Forest Serv., 1908, folio*).—This is a schedule of market quotations for various species and grades of lumber based on figures quoted by the *New York Lumber Trade Journal*, the Redwood Association, and the Yellow Pine Manufacturers' Association. The figures in most instances are based on the January prices for each year.

DISEASES OF PLANTS.

The development of plant pathology during the past ten years, R. Solla (*Riv. Patol. Veg., 3 (1908), No. 1–3, pp. 1–36*).—A summary is given of the present status of plant pathology, and some of the more conspicuous discoveries and noted advances made during the past 10 years are described at some length.

In compiling the information the author has searched the literature quite extensively, and a list of more than 150 titles is given.

Report on plant protection (*S. Internat. Landw. Kong. Wien. 3 (1907), Sect. VII, Refs. 1, pp. 81; 2, pp. 33; 5, pp. 21*).—A series of papers is given that were presented to the International Agricultural Congress at its meeting in Vienna in 1907. The papers discuss the means adopted for the control of plant diseases, insect pests, nematodes, etc., and the organization and results obtained in some of the countries represented in the International Union for Plant Protection. Among the papers describing the status of the organization and work in different countries are the following: For Sweden, by J. Eriksson; Belgium, E. Marchal; Denmark, F. G. E. Rostrup; Germany, R. Aderhold; Holland, J. Ritzema Bos; Italy, B. Moreschi; Austria, K. Kornauth; Russia, A. Jaczewski; Switzerland, H. Müller-Thurgau; and Hungary, J. Jablonowsky. Summaries are given on the prevention of plant diseases through cultural methods and the utilization of individual and varietal resistance, by P. Sorauer, G. Pammer, and E. Zederbauer. Reports on nematode control are given by J. Ritzema Bos and J. Spiegler.

Botanical investigations. F. C. Stewart (*New York State Sta. Rpt. 1907, pt. 3, pp. 119–162, pls. 4, map 1*).—A summary is given of the work in the investigation of plant diseases and their treatment that has been carried on during the 25 years of the existence of the station. An account is presented of most of the important diseases of economic plants, together with suggestions for their control. The publications relating to fungicides and insecticides and spraying machinery, the work on weeds, and some miscellaneous investigations are also briefly summarized.

Diseases of field crops in Delaware in 1907. H. S. Jackson (*Delaware Sta. Bul. 83, pp. 3–25, figs. 12*).—A popular account is given of some of the more prevalent field-crop diseases observed during 1907 in Delaware, together with observations as to their prevention.

Among the diseases described at some length are clover dodder (*Cuscuta epithymum*), anthracnose of red clover (*Colletotrichum trifolii*), leaf blight of German millet (*Piricularia grisea*), oat smuts (*Ustilago avenæ* and *U. læris*), corn smut (*U. zeæ*), loose smut of wheat (*U. tritici*), powdery mildew of wheat (*Erysiphe graminis*), and leaf spot of cowpeas (*Cercospora cruenta*). In addition to the diseases mentioned above, the occurrence of a number of other fungi is reported.

Report of the acting botanist and plant pathologist. I. B. P. Evans (*Transvaal Dept. Agr. Ann. Rpt. 1907, pp. 155–172*).—After briefly reporting upon the botanical work carried on during the absence of the botanist, an account is given of the plant diseases which were investigated, the principal ones being the bitter pit affecting apples, rusts of cereals and other economic grasses, coffee rust with its allied fungi, and the South African locust fungus.

In the study of cereal rusts, the author has shown that oats, which seem to be free from rust in India, are readily infested from cultures of *Uredo coronifera* and *U. graminis*. Of the inoculated plants, those receiving spores of *U. coronifera* were much more severely attacked than those to which the other fungus was applied.

A study was made of the rust occurring on *Rhamnus prinoides* to ascertain whether it might not be connected with the crown rust of oats. As a result of inoculation experiments the author found that the æcidiospores did not germinate as ordinary æcidiospores but as teleutospores. A further examination of the fungus led the author to the conclusion that it is not *Puccinia coronata*, but belongs to the genus Endophyllum, and the name *E. macowanianum* n. sp. is

proposed for it. The inoculation experiments with this fungus on oats failed to develop any pustules.

A study was made of the coffee rust (*Hemileia vastatrix*), which is said to have practically ruined the coffee industry of the Colony within the last 10 years. It has been suggested that the species *H. woodii*, which occurs on native South African shrubs, might possibly affect coffee, but inoculation experiments have failed to show that this species would grow on coffee or that the coffee rust would infect the host plants of *H. woodii*. A new species of Hemileia, which is parasitic on another shrub, has been recently discovered, but inoculation experiments failed to infect the coffee plant with that rust.

Notes are given on the occurrence of the downy mildew of grapes, which threatens to become troublesome in Southern Africa; on the bitter pit of apples, upon which a report has been prepared, but which is withheld from publication until additional experiments are completed; and upon the locust fungus. Investigations on the locust fungus have shown that no fatal effects can be attributed to the fungus *Mucor exitiosus*, so far as locusts are concerned, the fungus probably being a purely saprophytic one that was not distinguished by the original cultivators from *Empusa grylli*, a true parasite.

Report of vegetable pathologist, H. Tryon (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1907–8, pp. 89–92*).—Notes are given on a number of diseases which have been under observation during the year covered by the report. Among those discussed are a rust of alfalfa, due to *Uromyces striatus*; a tobacco spot disease, caused by *Cercospora raciborskii*, which is said to impair the value of the tobacco crop, and so far as known occurs only in Australia and Java; a leaf blast of sisal hemp that is due to sudden meteorological changes; a disease of oranges caused by the fungus *Mycocopron* sp., which involves the rind of the fruit, causing it to be covered with minute black specks; and a disease of grapes caused by the fungus *Strumella vitis*.

An account of the inspection work carried on under the Diseases in Plants Act of 1896 completes the report.

Annual report of the government mycologist, 1907, W. J. Gallagher (*Agr. Bul. Straits and Fed. Malay States, 7 (1908), No. 12, pp. 588–590*).—Brief notes are given on the root disease of Para rubber trees due to *Fomes semitostus*; a bacterial disease of mangosteens, in which 25 per cent of the fruits were attacked; a disease of rice due to *Helminthosporium* sp., etc.

The wood-destroying fungi, J. Schorstein (*Separate from Ztschr. Österr. Ingen. u. Architekten Ver., 60 (1908), No. 45–46, pp. 7, figs. 22*).—An illustrated account is given of some of the more common wood-destroying fungi, 22 species being noted that occur on dead or living trees and 7 species which attack timber in houses and other structures.

The destruction of fungi by grain-drying apparatus, H. Lang (*Illus. Landw. Ztg., 28 (1908), No. 70, pp. 603, 604*).—A description is given of a modified seed treatment for the prevention of smut of cereals.

The seed after being soaked for 6 to 12 hours in water at ordinary temperature is plunged in hot water or subjected to air heated to 60° C. in a drying apparatus. This treatment is said to destroy the fungus spores, but in no way to injure the seed. Barley treated in this manner gave but 2.5 smutted plants as compared with 2,140 on an equal area the seed for which was treated with formalin and 2,735 smutted plants where no preliminary treatment was given the seed.

A successful experiment in combating the smut of barley, L. Kühle (*Illus. Landw. Ztg., 28 (1908), No. 67, pp. 578, 579*).—A description is given of experiments made to test the hot-air treatment for the prevention of smuts of wheat and barley.

It was found that an exposure of smut spores for 12 minutes to a temperature of 65° C. would destroy them. Further tests showed that barley would withstand a dry heat of 90° and wheat 110° without injury to germination. Where grain did not contain more than the average amount of moisture it was found to readiiy withstand a temperature of 65°, and field tests showed that barley smut was entirely absent from plats the seed for which had been treated with hot air. The experiments with wheat were less successful.

Potato diseases in San Joaquin County, California, W. A. Orton (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 23, pp. 14*).—A study was made as to the cause of the failure to produce successful crops of potatoes on the tule or peat lands in the deltas of the San Joaquin and Sacramento rivers. These lands are apparently very fertile and produce phenomenally large crops when first planted, but in a few years the yield diminishes and the tubers become so rough and scabby as to be practically worthless.

The principal cause of the trouble was found to be due to the potato wilt (*Fusarium oxysporum*). This disease, which has been previously noted (E. S. R., 15, p. 1088), is again described and suggestions offered for its control. A second cause of trouble is said to be the potato scab, due to *Oospora scabies*, while a third cause of considerable loss is a decay of potatoes locally known as "leak" or "melters." This is due to the invasion of the fungus *Rhizopus nigricans*. The affected potatoes turn a dull brown outside; the flesh is buff or brown and very soft and exudes a clear brown liquid.

For the wilt and the scab, rotation of crops, the use of resistant varieties, etc., are recommended, together with the disinfecting of the seed potatoes in the case of scab, while for the trouble caused by *R. nigricans* the author suggests care in handling the potatoes so as to prevent wounding, the practice of sanitary precautions to prevent infection, and the avoidance of placing newly dug potatoes in large piles where they will sweat.

Spraying potatoes against blight and the potato beetle, E. P. Sandsten and J. G. Milward (*Wisconsin Sta. Bul. 168, pp. 3–27, figs. 13*).—The Wisconsin Station has been carrying on spraying trials for the past 5 years in the leading potato-growing counties of the State to determine whether the early blight (*Alternaria solani*), which is the only form of blight prevalent in the State, can be controlled by the application of Bordeaux mixture, and also to determine whether spraying should be recommended as a profitable investment and insurance against blight. In all, over 200 acres have been under trial as described in the bulletin.

Directions are given for the preparation and application of fungicides and insecticides. A test was made of dry versus wet Bordeaux mixture, in which a gain due to spraying with dry Bordeaux mixture of 10 bu. per acre was obtained as compared to a gain for the standard Bordeaux mixture of 33 bu. per acre.

For the control of the potato beetle, the authors recommend various poisons. The results thus far obtained indicate that the spraying of standard late varieties can be followed with an assurance of profit. Substantial increases in yields were obtained from spraying early varieties which were planted late, but the spraying of early varieties planted early seldom proved profitable.

Potato spraying experiments in 1907, F. C. Stewart, G. T. Frencii, and F. A. Sirrine (*New York State Sta. Bul. 307, pp. 439–468*).—This bulletin gives the results of the sixth year's work in the 10-year series of potato spraying experiments which were begun in 1902. The experiments were conducted along the same lines as in previous years (E. S. R., 19, p. 447), 40 separate experiments being reported.

In the 10-year experiments at Geneva, 5 sprayings with Bordeaux mixture and Paris green or Bordeaux mixture alone increased the yield 73.7 bu. per acre and 3 sprayings increased it 44 bu. notwithstanding the fact that the amount of damage done by blight and insects was seemingly small. There was no potato rot found. At Riverhead the gain due to 6 sprayings was 31.25 bu. per acre and to 3 sprayings 18 bu.

In the cooperative experiments with farmers, which included 152.75 acres, the average gain due to spraying was 36.8 bu. per acre, yielding an average net profit of $17.07 per acre.

In experiments conducted by 24 volunteers, gains averaging 30.5 bu. per acre are reported.

Diseased potato seed (*Jour. Dept. Agr. West. Aust., 17 (1908), No. 5, p. 857, pl. 1*).—A brief note is given reporting the presence in seed potatoes of a disease known as the spindle disease, due to *Persola tomentosum*. Potatoes affected by this disease put out weak sprouts and their value for seed purposes is greatly reduced.

The Granville tobacco wilt, E. F. Smith (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 141, pt. 2, pp. 17–24*).—Attention was first called to this disease by publications of this Department and also of the North Carolina Station (E. S. R., 15, pp. 684, 685), and the author states that the diagnosis given in the North Carolina publication describing the disease and attributing it to bacteria is correct.

The bacterial origin of the disease is discussed and some recent experiments of the author's described, in which it is demonstrated that the disease is readily communicated to tomatoes through the root system. The cultural characters of the tobacco organism are the same as those of *Bacterium solanacearum* derived from tomato or potato, and there is no doubt but that the Granville wilt of tobacco and the brown rot of the potato, tomato, and eggplant are all due to the same organism. In the case of tobacco it seems probable that the main infection takes place through the root system. A very considerable extent of the destructive prevalence of the disease seems to be coincident with the abundant occurrence of root nematodes.

For the control of the disease, planting tobacco only on uninfected land, reducing the amount of infectious material as much as possible, avoiding the wounding of roots in transplanting, and breeding resistant varieties as far as possible are among the measures recommended.

The black rot of grapes, L. Ravaz (*Ann. Sci. Agron., 3. ser., 3 (1908), II, No. 2, pp. 179–182*).—This is a paper presented before the International Congress of Agriculture held at Vienna in 1907, in which the author gives an account of the black rot of grapes and discusses means for its control.

In France, it is said, the fungus has rather definite periods or cycles of appearance during the season. For its prevention vines should be sprayed with some of the fungicides containing copper compounds at intervals of 8 to 10 days during the early part of the season. Later applications are to be made whenever spots caused by the fungus are noticed on vines left unsprayed to serve as indicators of the presence of the disease.

The control of the gray rot of grapes, G. Istvanffi (*Ann. Sci. Agron., 3. ser., 3 (1908), II, No. 2, pp. 196–230*).—An account is given of studies on the control of the gray rot of grapes due to the fungus *Botrytis cinerea*, the conidial phase of *Sclerotinia fuckeliana*. The method of attack, development and biology of the fungus, varietal resistance of grapes to attack, etc., are described, after which the treatment by means of powders, liquid fungicides, etc., are discussed.

As precautionary and preventive measures the author recommends the collection and burning of leaves, dried grapes, etc.; the application of strong solutions of fungicides to the canes about 2 weeks before pruning; the reduction of humidity where possible; the avoidance of nitrogenous fertilizers; thinning of the grapes; and the use of liquid fungicides which are as adherent as possible and of powdered fungicides containing soluble copper and other materials which are readily decomposed. Among the solutions the best results were obtained with Bordeaux mixture containing gelatin or sugar, copper acetate solutions, and a solution of sulphate of nickel. Among the powders a mixture of copper acetate or copper sulphate and bisulphite of soda has given the best results.

A bibliography is appended.

The white rot of grapes. G. Istvanffi (*Ann. Sci. Agron., 3. ser., 3 (1908), II, No. 2, pp. 183–196*).—An account is given of the author's investigatons on the white rot of grapes due to *Coniothyrium diplodiella*, together with means for its control, based upon an extensive study of this subject, which has been previously noted (E. S. R., 15, p. 164). Some additional information has been gained regarding the disease and especially concerning its control. Spraying with a 3 or 4 per cent Bordeaux mixture and later dusting with a powder containing some form of copper and bisulphite of soda is recommended for application to the young shoots and the grapes. All diseased leaves, shoots, and grapes should be collected and burned as completely as possible. The application of the fungicides to the grape clusters should be begun immediately after flowering.

A brief bibliography is appended.

Lathræa squamaria as a parasite of the grape. H. Faes (*Rev. Vit., 30 (1908), No. 783, p. 700*).—In a brief note the author calls attention to the appearance of *L. squamaria* on the roots of grapes, previous investigators having considered it of rare occurrence. In one locality the vines are said to have suffered severely. As the upper part of the parasite annually dies to the ground, the injury has generally been attributed to phylloxera, but the author thinks that, at least in the instances described by him, the principal cause of injury is this phanerogamic parasite.

Apple scab or black spot. E. S. Salmon (*Jour. Bd. Agr. [London], 15 (1908), No. 3, pp. 182–195, figs. 9*).—An account is given of the scab or black spot of the apple, due to *Venturia pomi*, a disease which is said to be causing considerable damage in the orchards of England. Attention is called to the varying susceptibility of different varieties to attacks of this fungus.

For the prevention of the disease, thorough spraying with a Bordeaux mixture composed of copper sulphate 4 lbs., lime 4 lbs., and water 50 gal. is recommended. Where the disease appears late in the season, to avoid the discoloring due to Bordeaux mixture, ammoniacal copper carbonate solution is recommended. As additional treatment, the author suggests a winter washing of the trees with a rather strong copper sulphate solution.

Review of information relating to olive diseases. Cuboni (*Ann. Agr. [Italy], 1908, No. 256, pp. 83–91*).—In the report of the consulting commission on olive culture and oil making, an account is given of the diseases to which the olive tree is subject, particular attention being paid to those due to the fungi *Cycloconium oleaginum*, *Capnodium salicinum*, and *Stictis panizzei*, and suggestions are given for their control, as far as definite means are known.

[Spraying peaches and plums]. O. M. Morris (*Oklahoma Sta. Rpt. 1908, pp. 16, 17*).—A brief account is given of spraying peaches and plums with half-strength Bordeaux mixture for the purpose of protecting them from the attacks of brown rot. Four applications of the fungicide were given the trees, which

practically protected them from the disease. Trees not sprayed lost almost the entire crop.

Peach rot (*Oklahoma Sta. Rpt. 1908, pp. 78, 79*).—Directions are given for the prevention of peach rot by the use of applications of Bordeaux mixture or ammoniacal copper carbonate.

Studies in cacao disease, J. H. Hart (*Proc. Agr. Soc. Trinidad and Tobago, 8 (1908), No. 11, pp. 503–508*).—The author gives an account of an injury caused to cacao by the fungus *Diplodia cacaoicola*. This fungus, it is said, causes the brown rot of the pod and die back of the branches, and also affects the roots of the trees. Attention to plantations, pruning out and burning affected portions, and cultivation resulting in an active growth of the trees are recommended as preventive measures.

Inoculation experiments with Peridermium strobi from Pinus monticola, F. W. Neger (*Naturw. Ztschr. Forst u. Landw., 6 (1908), No. 12, p. 605*).—In order to determine the alternate host plant for the peridermium stage of *Peridermium strobi* from *Pinus monticola*, the author planted in 1905 a number of currant bushes among a vigorous stand of 18-year-old trees of *P. monticola*. The species of Ribes planted were *R. sanguineum*, *R. alpinum*, *R. rubrum*, *R. aureum*, and *R. grossularia*.

From 1905 to 1907 there was no trace of the uredo or teleuto forms on any of the plants. In 1908 the infection made its appearance but was found only on *R. sanguineum*. The investigations indicate that *R. alpinum* is not the alternate host for the peridermium of the species that occurs on *P. monticola*, but probably is the alternate host for the forms occurring on the stone pine (*P. cembra*).

The use of copper fungicides, K. von Tubeuf (*Naturw. Ztschr. Forst u. Landw., 6 (1908), Nos. 3, pp. 200–203, figs. 3; 4, pp. 229–235, figs. 3; 5, pp. 284–288, figs. 2*).—The action of various copper fungicides is described and notes given on their successful use in combating a number of plant diseases, particularly those of fruits, grapes, and potatoes. The fungi and the effect on their host plants are described, after which directions are given for the preparation and use of copper sulphate solutions, Bordeaux mixture, soda Bordeaux, etc.

Sulphur as a pest remedy, C. F. Juritz (*Agr. Jour. Cape Good Hope, 33 (1908), No. 6, pp. 719–730, figs. 5*).—On account of numerous inquiries regarding the kind of sulphur suitable for combating powdery mildew of grapes, sheep scab, and scale in orchards, the author has made a study of the different forms of sulphur found in commercial use to determine their value as remedies for these troubles.

As the form of sulphur is of most importance in combating powdery mildew, this phase formed the principal portion of the investigation. The action of sulphur when used as a fungicide is said to be due to the destructive effect on the mycelium and spores of the fumes which are given off when the weather is sufficiently warm. In order to have the proper effect it has been found that the sulphur must be evenly distributed and must be in actual contact with all the diseased parts of the vine. Studies were made of the fineness, purity, dampness, and presence of free sulphuric acid in the different samples, and it was found that sulphur, whether ground or in the form known as flowers of sulphur, to be effectual for destroying mildew must possess the following physical and chemical properties: Fineness, uniformity of fineness, absence of clogging tendency, purity, freedom from moisture, and freedom from hygroscopic substances. In testing the comparative adaptability of the different forms, it was found that fineness is not the only consideration, as a large proportion of the sulphur

applied to vines is wasted. At the same time, with good sulphur distributing machines, the superiority of the finer grades is distinctly manifest.

In considering sulphur to be used for scale washes and sheep dips, it was found that the cheaper and, within certain limits, the coarser and less-refined article answers all the purposes of the finer and more costly form.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Index-catalogue of medical and veterinary zoology, C. W. Stiles and A. Hassall (*U. S. Dept. Agr., Bur. Anim. Indus. Bul. 39, pts. 22, pp. III+1625–1718; 23, pp. III+1719–1805*).—A continuation of the index catalogue, part 22 containing the names of authors from Paaren to Pfeilsticker, and part 23, names from Pfender to Qvortrup.

The otter in Massachusetts, C. E. Gordon (*Science, n. ser., 28 (1908), No. 726, pp. 772–775, map 1*).—An account of the occurrence in Massachusetts of the North American otter (*Lutra canadensis*).

Investigations of the department of entomology, P. J. Parrott (*New York State Sta. Rpt. 1907, pt. 3, pp. 238–266, pls. 4*).—This is a summary of the entomological investigations conducted at the New York State Station since their commencement in 1894.

The garden insects which have received particular attention are the striped cucumber beetle, squash bug, squash borer, boreal lady beetle (*Epilachna borealis*), melon louse (*Aphis gossypii*), imported cabbage worm, cabbage looper, diamond-back moth (*Plutella maculipennis*), cabbage aphis, *Thrips tabaci*, and the harlequin cabbage bug. The fruit insects studied include the codling moth, San José scale, New York plum lecanium (*Eulecanium cerasifex*), pistol case bearer, plant lice, spring canker worm, grape flea beetle, tent caterpillar, forest tent caterpillar, raspberry sawfly, apple and pear mites (*Eriophyes* spp.), and others.

The insect enemies of field crops, etc., investigated, include the army worm, cottonwood leaf beetle (*Lina scripta*), onion cutworm (*Euxoa messoria*), and poplar and willow borer (*Cryptorhynchus lapathi*).

Report of the department of botany and entomology, J. F. Nicholson (*Oklahoma Sta. Rpt. 1908, pp. 19–42*).—The principal work of the department during the fiscal year 1907–8 under report was along entomological lines.

The green bug which appeared in January, 1907, destroyed 85 per cent of the oat crop and more than 75 per cent of the wheat crop. In experiments made to determine the effectiveness of natural enemies as many as 192 green bugs were consumed by a lady beetle in one day, while the parasite *Lysephlebus tritici* was observed to deposit eggs in 30 green bugs in 11 minutes. In some localities in 1908 fully 25 per cent of the fall wheat was destroyed by the Hessian fly.

The boll weevil appeared in sufficient numbers to become injurious and the webworm was especially destructive to alfalfa. Winter plowing of cotton ground, and clean cultivation in corn is reported to have given excellent results against the bollworm. The best results, however, were obtained by planting June corn in the cotton as a trap crop.

Spraying work against the codling moth showed that fully 95 per cent of the fruit could be saved by a thorough system of spraying. The San José scale is reported to be well scattered over the State. The black locust borer is said to threaten the destruction of the locust trees of the State.

A report of the nursery inspection work is also presented, 93 nurseries having been inspected during the year.

Notes from Connecticut. W. E. Britton (*Jour. Econ. Ent., 1 (1908), No. 5, pp. 313–315*).—The fall cankerworm (*Alsophila pometaria*) is said to have caused more damage in various portions of Connecticut than for several years, shade and woodland trees, including elm, maple, chestnut, hickory, California privet and oak as well as apple trees being fed upon. The peach sawfly (*Pamphilius persicum*) was greatly reduced in numbers by spraying with lead arsenate.

The common red spider. F. H. Chittenden (*U. S. Dept. Agr., Bur. Ent. Circ. 104, pp. 11, figs. 4*).—*Tetranychus bimaculatus*, commonly known as the red spider, is a species well distributed throughout the eastern United States which attacks a wide range of plants. Several predaceous enemies including *Scymnus punctum*, *Cecidomyia coccidarum*, *Chrysopa rufilabris*, and *Thrips sexmaculata* are reported.

The following remedies are advised:

"For the greenhouse and for general use, sulphur with neutral, whale-oil, and other soap solutions; kerosene-soap emulsion; and spraying with water.

"For the treatment of trees and shrubs, the same as the above, with the addition of resin wash and the lime-sulphur and lye-sulphur mixtures.

"For truck and garden plants, lye-sulphur wash and the same remedies as for the greenhouse, with the addition of clean gardening or farming, early fall plowing, keeping down weeds, and crop rotation where practicable."

The introduction of Iridomyrmex humilis into New Orleans. E. Foster (*Jour. Econ. Ent., 1 (1908), No. 5, pp. 289–293*).—The author discusses the probable manner and date of the introduction into this country of the Argentine ant. Since New Orleans has had no direct commercial intercourse with Argentina and cargoes of coffee have been coming from Brazil since the passage of the Compromise Act in 1833, it is considered more probable that the pest was introduced from the latter country.

[**Injurious beetles**], V. Mayet (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 29 (1908), No. 50, pp. 710–716, pl. 1*).—Five species of beetles (*Cetonia speciosissima*, *C. squalida*, *C. cinctella*, *Lethrus cephalotes*, and *Lucanus parallelipipedus*) and the nature of their injury to vines are here described.

Notes on some Cecropia cocoons and parasites. J. B. Smith (*Jour. Econ. Ent., 1 (1908), No. 5, pp. 293–297*).—Reports having come to the author in the fall and winter of 1907–8 of an unusual mortality in Cecropia cocoons, collections were made in New Jersey and on Long Island in order to determine the cause of death. Out of a total number of 1,062 cocoons examined 36 were found to be sound, adults had emerged from 34, 47 had died as pupæ, 295 were parasitized, and 650 were dead from disease. Two parasites, *Ophion macrurum* and an Ichneumonid form, were found. The hyperparasites *Spilocryptus extremis*, *Spilochalcis mariæ*, and *Dibrachys boucheanus* were reared in large numbers.

Some insects injurious to truck crops. The semitropical army worm, F. H. Chittenden and H. M. Russell (*U. S. Dept. Agr., Bur. Ent. Bul. 66, pt. 5, pp. 53–70, figs. 4*).—*Prodenia eridania* is reported as the source of considerable injury to garden truck in Florida, including tomato, potato, sweet potato, eggplant, pepper, okra, collards, and cowpeas. It feeds normally on weeds, such as the pokeweed, spiny amaranth, etc., and is confined to semitropical America as a pest. A description presented of its life history includes technical descriptions of the egg and 6 larval stages by H. G. Dyar.

"Experiments show that the egg period may be passed in a minimum of 4 days, the larval period in 17 days, and that the entire life cycle, in an outdoor summer temperature, would be about 35 days or 5 weeks; also, that there are

4 generations and possibly 5 produced in a year, the insect breeding practically continuously during the warm season."

Seven parasitic and six predaceous enemies are recorded, which are said to largely control the pests in ordinary years. A number of experiments with insecticides indicate that a spray of arsenate of lead used at the rate of 2 or 3 lbs. in 50 gals. of water, is the best remedy.

Notes on the lesser clover-leaf beetle, C. O. Houghton (*Jour. Econ. Ent., 1 (1908), No. 5, pp. 297–300*).—*Phytonomus nigrirostris* is said to be quite common in Delaware, where with *P. punctatus* it at times does considerable damage to clover. Biological notes are given.

Factors controlling parasitism with special reference to the cotton boll weevil. W. D. Pierce (*Jour. Econ. Ent., 1 (1908), No. 5, pp. 315–323*).—In the course of investigations made of the parasites of the boll weevil by the Bureau of Entomology of this Department the author has had opportunity to study the factors influencing parasitism in the weevils. Sixteen factors of importance are presented in addition to the eight considered by Marchal (E. S. R., 19, p. 1159).

A flea beetle attacking hops in British Columbia. H. J. Quayle (*Jour. Econ. Ent., 1 (1908), No. 5, p. 325*).—*Psylliodes punctulata* is reported to have been seriously injuring hops in British Columbia during the past year or two. The loss for 1908 in the Chilliwack and Agassiz valleys is estimated at about 80 per cent of the crop.

Some insects injurious to truck crops. The leafhoppers of the sugar beet and their relation to the "curly-leaf" condition. E. D. Ball (*U. S. Dept. Agr., Bur. Ent. Bul. 66, pt. 4, pp. 33–52, pls. 4*).—In cooperation with the Bureau of Entomology of this Department the author as entomologist of the Utah Station has investigated an affection of the sugar beet known as "curly leaf" or "blight," which occurs in the intermountain region, particularly in Utah and Colorado.

Until 1905 the condition had been supposed to be due to some fungus or bacterial disease, but in that year, when an estimated loss of a half million dollars resulted in Utah from the curly leaf, the beet leaf hopper (*Eutettix tenella*) was noticed present in large numbers.

The condition appears soon after an attack of the beet leaf hopper, a thickening of the smaller veins of the leaf taking place which gives the under surface a thickened appearance. This is followed by a curling of the edge and a final rolling up of the leaf, the upper surface always being rolled in. This results in the sending out of a large number of fibrous roots and in almost stopping the growth. In bad cases the beet shrivels and dies, while in a few instances there is a partial recovery and a new set of leaves, though the sugar content remains low.

Curly leaf appeared in cages in which beet leaf hoppers were introduced. Whether or not the condition is entirely the result of the attacks of this pest is said to be an open question. *E. tenella* is apparently a native of the southwestern part of the United States, having been collected in Colorado, New Mexico, Arizona, Utah, Idaho, California, and Oregon. Leaving hibernation, it appears in the fields about the time the beets are thinned and by the middle of June is well distributed. At Lehi, Utah, oviposition began late in June and continued until late in August, each female depositing about 80 eggs. In cage experiments the egg stage was between 13 and 15 days and the larval stage between 16 and 22 days. Nymphs that emerged from eggs the latter part of July are said to have changed to adults some 20 days later.

It is concluded that the severity of the condition is dependent upon the number of insects present, upon the time of their appearance, upon the size of

the beets, and upon the temperature of the surface soil, together with the temperature and moisture of the surrounding air. Proposed remedies include the use of kerosene emulsion (1 to 5), hopper-dozers, and other mechanical devices. Early planting and in some sections early and frequent irrigation are recommended. Seven other species of Eutettix are known to have definite food plants related to the sugar beet and several more the food plants of which are not known will probably be found to have similar habits. Brief notes are given on the species of this genus already known to occur on the beet, which, considered in order of their importance, are as follows: *E. strobi*, *E. scitula*, *E. seminuda*, *E. clarivida*, *E. insana*, and *E. stricta*. *Agallia sanguinolenta*, *A. cinerea*, *A. bigeloviæ*, *A. quadripunctata*, *A. novella*, and *Empoasca* sp. are also briefly noted.

A second kind of curly leaf, in which the leaves remain smooth but show numerous pale spots and the edges turn down, and in which the injury appears to be confined to the leaves attacked, is reported to have been found quite commonly in California. This injury appears to be due to the Empoascas.

The sugar-cane borers of Behar, M. Mackenzie and H. M. Lefroy (*Agr. Jour. India, 3 (1908), No. 2, pp. 104–124, pls. 3; Internat. Sugar Jour., 10 (1908), No. 119, pp. 540–544*).—Observations and biological data are given upon the lepidopterous borers of sugar cane. The white moth (*Scirpophaga auriflua*) and the black-spotted moth (*S. monostigma*) are described as shoot borers. The common moth borer (*Chilo simplex*), the gold-fringed moth borer (*C. auricilia*), the pink borer (*Nonagria uniformis*), and the green borer (*Anerastia ablutella*) are given as side borers, and *Polyocha saccharella* is described as a root borer.

Papers on deciduous fruit insects and insecticides. The grape-leaf skeletonizer, P. R. Jones (*U. S. Dept. Agr., Bur. Ent. Bul. 68, pt. 8, pp. 77–90, figs. 6*).—The author has studied *Harrisana americana* and here presents an account of its life history, including descriptions of its life stages, thus supplying many points which have been lacking.

The pest is considered a native species since it feeds upon the Virginia creeper and wild as well as domestic varieties of grapes. It appears to be widely distributed, having been reported from Canada and Mexico. Studies made at Washington, D. C., have shown that there are not 2 full generations in that vicinity. The moths from overwintering pupæ appear during the latter part of May or chiefly during the first 10 days of June. In 1908 eggs were first found on June 11, at which time a few had hatched. The average length of the egg stage was found to be 7.92 days, of the larval stage 40.5 days, of the pupal stage 14.8 days, and the life of the moth 3.5 days. The minimum length of the complete life cycle was found to be 53 days. The chalcidid *Perilampus platygaster*, a brachonid *Glyptapanteles* sp., and an ichneumon *Limneria* sp., are recorded as natural enemies. Handpicking or the application of an arsenical when the larvæ appear is recommended as a remedy.

A complete bibliography is appended.

Sawfly larvæ in apples, R. L. Webster (*Jour. Econ. Ent., 1 (1908), No. 5, pp. 310, 311*).—Larvæ of *Taxonus nigrisoma* are reported to have been found in apples shipped from New York State.

Papers on deciduous fruit insects and insecticides. The peach-tree bark-beetle, H. F. Wilson (*U. S. Dept. Agr., Bur. Ent. Bul. 68, pt. 9, pp. 91–108, pls. 2, figs. 3*).—The Bureau of Entomology of this Department has conducted, in cooperation with the Ohio Station, an investigation of *Phlœotribis liminaris*, a pest which has become a source of considerable injury in northern Ohio.

The author here reports the results of investigations made during 1908 at Lakeside, Ohio.

The adults are said to produce the primary injury to healthy trees, the work of the larvæ being secondary. Healthy trees by repeated attacks of the adults are reduced to a condition favorable to the formation of egg burrows. When the beetles are ready to hibernate in the fall they fly to the healthy trees and form their hibernation cells. These cells are injurious to the trees, since through each cell there is a flow of sap during the following season. When the beetles come out of hibernation they bore into the bark of healthy trees from ¼ to ½ in. either for food or to form egg burrows, many small channels being thus formed in the bark. It is estimated that in some instances from 1 to 3 or more gallons of sap flows from a single tree during a season.

A description is presented of the life history of the pest. No parasites have as yet been discovered. The details of experiments with remedies are reported. It is recommended that trees severely injured be pruned back and given an application of barnyard manure or commercial fertilizer. A thick coat of whitewash should be applied 3 times during the season, the first to be made the last week in March, the second the second week in July, and the third about the first of October. Healthy trees but slightly attacked should be painted with a thick coat of whitewash 3 times each season as prescribed for severely injured ones, the applications to be made to the trunk and larger limbs. The whitewash thus applied just prior to the emergence of the beetles acts as a repellant. The addition of table salt at the rate of ¼ lb. to a pail of whitewash makes the whitewash more adhesive. It is recommended that all dead or nearly dead limbs and trees be removed as fast as they appear in the orchard, thus destroying the breeding places.

A bibliography is appended.

The orange thrips. D. Moulton (*U. S. Dept. Agr., Bur. Ent. Bul. 12, tech. ser., pt. 7, pp. 119–122, pl. 1*).—The author presents a description of *Euthrips citri*, a species new to science which has become a very important orange pest in the southern San Joaquin Valley of California. Curled and thickened leaves and scab-like markings on the oranges have been known for from 10 to 15 years, but these injuries have only recently been attributed to the thrips. While the quality of the fruit does not appear to be affected, yet as oranges are graded and sold largely on appearance, many thousands of dollars have been lost annually.

There are apparently two broods of *E. citri*. "Adults of the first brood appear just before the blossoms in February, March, and April, and a second brood appears in July, August, September, and October. Adults and larvæ of the first brood feed on the small oranges just as the petals are being thrown off, the larvæ usually under the protection of the sepals, and on the first growths of the foliage. The second brood feeds on the nearly mature oranges and on the third and fourth growths of the foliage. All varieties of oranges and lemons are attacked, but the very noticeable scabbing on the fruit is common only on the navel orange; it is less conspicuous on the Valencia." That the thrips are not so prevalent on trees planted in sedimentary or loam soils as where the soil is of a clayey or adobe texture is explained in the protection afforded by the latter soil to the larval, pupal and early adult life stages, which are presumably passed in the soil.

A strong tobacco extract and the cheaper soap washes are suggested as remedies.

The citrus whitefly of Florida consists of two species. E. W. Berger (*Jour. Econ. Ent., 1 (1908), No. 5, pp. 324, 325*).—The author considers the citrus whitefly of Florida to represent two distinct and well-defined species.

The catalpa midge, H. A. Gossard (*Ohio Sta. Bul. 197, pp. 13, figs. 9*).—Terminal buds, leaves, and pods of the varieties of catalpa found in Ohio are said to be considerably injured by the attacks of *Cecidomyia catalpæ*. Hundreds of spots were often found on single leaves and large fruiting trees so badly attacked that from one-third to one-half of the leaves died from the injuries. The adults appear in May and in June larvæ are found in abundance on the leaves and in the terminal buds. The larvæ emerge in about 24 hours after the eggs are deposited. In midsummer from 3 to 4 weeks appear to be required for the completion of the life cycle. The larvæ are fed upon by lace wings and parasitized by the chalcid *Zatropis catalpæ*. As the larvæ drop to the ground and pupate near the surface of the soil, it is recommended that plowing be done in the late fall or early spring and that cultivation be carried on through the summer. The application of kainit beneath the trees or the drenching of the soil in early spring with kerosene emulsion (1 to 10) is also recommended.

The importation of Tetrastichus xanthomelænæ, L. O. Howard (*Jour. Econ. Ent., 1 (1908), No. 5, pp. 281–289, fig. 1*).—The author presents an account of the biological observations made by Marchal on an egg parasite which has apparently stopped the ravages of the elm-leaf beetle in France. This parasite (*T. xanthomelænæ*) was introduced from France in April, 1908, and bred at the gipsy-moth laboratory at Melrose Highlands, Mass., by W. F. Fiske, of the Bureau of Entomology of this Department, under the author's direction. The breeding notes are here presented. Adult parasites have been liberated in two localities near Boston, Mass., at New Brunswick, N. J., and at Washington, D. C.

Notes on maple mites, P. J. Parrott (*Jour. Econ. Ent., 1 (1908), No. 5, pp. 311–313*).—Fifteen species of mites that thrive on maples have been recognized, including the two Old World species *Phyllocoptes gymnaspis* and *Oxypleurites serratus*, which are recorded for the first time in this country. Descriptions are presented of the fusiform maple gall (*P. acris-crumena* [*Eriophyes acricola*]), and the bladder maple gall (*P.* [*E. quadripes*]), the two common and widely distributed species on the hard and soft maples.

A mosquito which breeds in salt and fresh water, C. S. Banks (*Philippine Jour. Sci., B. Med. Sci., 3 (1908), No. 4, pp. 335–339, pls. 2, maps 3*).—The author reports the results of an investigation made of an epidemic of æstivo-autumnal malaria in the mountain province of Lepanto-Bontoc. Adults of *Myzomyia ludlowii* were found at Bontoc in dwellings and the larvæ, previously known to develop only in sea water, were found breeding in the greatest abundance in rivers and streams of the vicinity. The water in that region, which is strongly impregnated with lime, is said to contain a high percentage of aluminum sulphate.

While larvæ of an undetermined culicine were found associated with those of *M. ludlowii* no other species of Anophelinæ was found. This is considered the first record of a species of mosquito developing naturally in both salt and fresh water.

The author concludes that altitude (up to 1,500 meters) has no appreciable influence upon the development of *M. ludlowii* and that there is little hope of ridding a community like Cervantes of this insect owing to the peculiar topographical features.

Mosquito comment, C. S. Ludlow (*Canad. Ent., 41 (1909), No. 1, pp. 21–24*).—The genus Calvertia, *Anopheles formosus*, and *Pseudoranolænia parangensis*, two species from the Philippines, are described as new.

The house mosquito, a city, town, and village problem, J. B. Smith (*New Jersey Stas. Bul. 216, pp. 3–21, pls. 2, figs. 7*).—The work done on the salt marshes of New Jersey since 1904 is said to have practically eliminated the

migratory species of mosquitoes from consideration. During the summer of 1908, the house mosquito (*Culex pipiens*) was present in the cities in great numbers. The author describes the life history and habits of this species and the many usual and unusual places in which it breeds. As many female mosquitoes pass the winter in cellars, it is recommended that such places be fumigated either with a mixture of equal parts of carbolic acid crystals and gum camphor or with Jimpson weed. In a municipal campaign all standing water should be located and removed by filling or draining. The standing water in sewer catch basins should be oiled frequently.

Remedies for the San José scale, E. P. TAYLOR (*Missouri Fruit Sta. Circ. 3, pp. 4*).—This circular contains formulas, methods of preparation, and directions for the use of standard and commercial lime-sulphur wash, oil emulsion, and miscible oil sprays.

Homemade soluble oils for use against the San José scale, J. L. PHILLIPS (*Virginia Sta. Bul. 179, pp. 78–88*).—The following conclusions have been drawn by the author from cooperative orchard tests:

"Homemade soluble oils are recommended for trial in place of the lime-sulphur wash, under certain conditions. Further tests must be made before we can recommend them unreservedly. For general orchard spraying the lime-sulphur is probably more satisfactory.

"The various prepared or patented brands of soluble oils cost about three times as much as the homemade product containing the same percentage of oil. Our tests indicate that the homemade oil is as effective as the prepared oil. The cost of the homemade oil is about the same as the cost of lime-sulphur.

"The homemade soluble oil is more practicable for the commercial orchardist than for the man who has only a few trees, unless one person will make the material for a neighborhood.

"It is not quite as troublesome and disagreeable to make soluble oil at home as it is to make lime-sulphur.

"Apply the soluble oil spray only in the dormant season. The trees should not be pruned before they are sprayed, as the oil may injure the cut surfaces, unless they are painted.

"The homemade soluble oil spray is recommended for trial against the San José scale, and the maple scale. It is not recommended for use against the scurfy scale."

Cooperative [spraying] experiments, L. R. TAFT (*Michigan Sta. Rpt. 1908, pp. 153–157*).—The author here discusses the general conclusions arrived at as the result of spraying experiments with insecticides and fungicides.

Spray calendar, C. E. SANBORN (*Texas Sta. Bul. 113, pp. 5–10, pl. 1*).—Spraying machinery, and formulas for, preparation, and use of insecticides and fungicides are briefly considered.

Spraying calendar, L. R. TAFT and R. S. SHAW (*Michigan Sta. Spec. Bul. 45, folio*).—In this wall calendar, directions are given for the preparation and application of insecticides and fungicides.

Homemade oil emulsion, E. P. TAYLOR (*Missouri Fruit Sta. Circ. 4, pp. 3*).—Directions for the preparation and use of kerosene emulsion.

Analysis of Paris green and other insecticides, L. L. VAN SLYKE (*New York State Sta. Rpt. 1907, pt. 3, pp. 225–227*).—This is a historical review of the legislation in New York relative to insecticides, including the main provisions of the present law, and a brief summary of the work of the New York State Station in the analysis of insecticides. During the years 1899 to 1902, 130 samples of Paris green were analyzed, the amount of arsenious oxid varying from 55.34 to 62.87 per cent, the copper oxid from 26.53 to 31.2 per cent, the arsenious oxid in combination with copper from 49.70 to 58.45 per cent, and the water

soluble arsenic from 0.61 to 2.24 per cent. Analyses of several proprietary insecticides and of Paris green-Bordeaux mixture are appended.

The danger in the use of arsenicals as insecticides, MESTREZAT (*Jour. Pharm. et Chim., 6. ser., 28 (1908), No. 9, pp. 393–397*).—After considering the results of analyses the author concludes that there is comparatively little danger from the use in viticulture of arsenical insecticides either in their application or in the consumption of the wine. The real and sole danger is in their simultaneous storage with other substances frequently used in agriculture, which resemble them so closely that they are easily mistaken.

Miscellaneous papers on apiculture. A brief survey of Hawaiian bee keeping. E. F. PHILLIPS (*U. S. Dept. Agr., Bur. Ent. Bul. 75, pt. 5, pp. 43–58, pls. 6*).—The author here reports an investigation made of the bee keeping industry in the Hawaiian Islands. While it is stated that the business can never become a leading industry it is believed that there is room for considerable expansion. An active and efficient bee keepers' association is said to have been in existence for 2 years. At the present time bee keeping is largely in the hands of 4 corporations, they owning and operating at least four-fifths of all the bees on the islands.

The number of colonies is estimated at 20,000 and the output of honey for 1908 as 1,000 tons. Most of the honey is shipped to the mainland or Europe. A list of honey plants furnished by D. L. Van Dine is presented. The introduced algeroba tree (*Prosopis juliflora*), which is the same or closely related to the mesquite of the Southwest is said to be one of the most important.

Two-thirds of the honey shipped annually from the islands is largely or entirely honeydew honey (E. S. R., 19, p. 1059; 20, p. 261). The greater part of this comes from the exudation of the sugar-cane leaf-hopper (*Perkinsiella saccharicida*), but possibly some of it from the sugar-cane aphis (*Aphis sacchari*).

As Hawaiian honey sells for low prices the bee keepers of the islands are desirous of producing wax instead. A method suggested by the author is described whereby wax secretion is stimulated by shaking the colonies on starters of foundation, the manipulation being identical with the shaking in treating for bee disease.

Careful examinations were made of apiaries in the islands but no trace of disease was found. Regulations have recently been passed which place restrictions on the importation of honey bees and honey.

Miscellaneous papers on apiculture. The status of apiculture in the United States. E. F. PHILLIPS (*U. S. Dept. Agr., Bur. Ent. Bul. 75, pt. 6, pp. 59–80*).—A discussion of the subject in which the notable growth of apiculture during the past half century is pointed out. It is stated that there are in the United States over 700,000 bee keepers producing annually $20,000,000 worth of honey and $2,000,000 worth of beeswax, and that the annual importation of honey amounts to about 2,500,000 lbs., and that of wax to about 700,000 lbs. Other topics discussed include the importance to American agriculture of the honey bee as a pollenizing agent, the present sources of loss in bee keeping due to swarming, winter losses, enemies, disease and waste of wax and nectar, and the need of further investigations in apiculture.

FOODS—HUMAN NUTRITION.

Thirteenth report on food products for 1908. J. P. STREET ET AL. (*Connecticut State Sta. Rpt. 1907–8, pt. 9, pp. 573–716*).—During the past year 625 samples collected by the station were examined, including among others arrowroot starch, cornstarch, diabetic preparations, ginger, infant and invalid foods, jams,

preserves and similar goods, meat extracts, meat juices and other preparations, yeast extracts, sirups, table salt, ammonia, and drugs. Of these samples 225 were found to be adulterated or below standard and 69 were compound. Of 771 samples collected by the dairy commissioner, including among other things spices, butter and butter substitutes, chocolate and cocoa, maple sirup, molasses, olive oil, vinegar and drugs, 233 were adulterated or below standard and 26 compound.

The part of the investigation which has to do with meat extracts and similar goods and yeast extracts constitutes an exhaustive study of such products and includes data on the manufacture, chemical composition and food value, as well as on the status of such products under the provisions of the pure food law. A bibliography is appended. In general, the comparative value of meat extract "is shown by determinations of water, total ash and its chief constituents, total nitrogen, and the meat bases. These data show the concentration of the extract, the amount and nature of its ash, and the proportion of true meat extractives which it contains. There are a number of preparations on the market sold as meat extracts, which are prepared wholly from yeast. These resemble meat extracts in taste and appearance, but show marked chemical differences. The important extractives, creatinin and creatin, are absent; on the other hand, the purin bases are comparatively abundant. The amount of creatinin and creatin found is, therefore, a valuable guide as to the source of an extract."

The data reported showed that certain of the meat extracts examined "satisfy the legal standards in all particulars, some are deficient in one or more respects, while others, because of false statements concerning them, must be considered as misbranded."

The physiological effects and nutritive value of meat extracts, as indicated by their chemical composition are discussed.

"The true value of a meat extract depends almost entirely upon the salts and extractives which it contains and upon its flavor.

"The characteristic salts of true meat extracts are potassium dihydrogen phosphate and potassium monohydrogen phosphate, the former predominating. Potassium chlorid is also present in considerable amount. . . .

"[The extractives] may be classed as nitrogenous and nonnitrogenous. . . . Most of [the nitrogenous extractives] are basic in character, some are amids, and all are classed under the somewhat loose term 'meat bases.' The most important physiologically are creatin, its anhydrid, creatinin, and the xanthin or purin bases. The purin bases most commonly found are xanthin, hypoxanthin, adenin and carnin.

"The nonnitrogenous extractive matters, in addition to the salts already considered, consist chiefly of lactic acid, lactates, and glycogen. Little is known as to the actual amounts of these ingredients present.

"Glycerol, glucose, and milk sugar are occasionally found in the extracts and must be considered as adulterants; preservatives are also sometimes employed, especially in fluid extracts."

The fluid meat extracts were found to contain on an average considerably more water than the paste-like goods, the other constituents being similar in character but lower in proportion. The meat powders examined contained less water and a larger amount of salt and other substances, the different brands showing considerable variation in composition owing to differences in the processes followed in their manufacture. When composed chiefly of ground meat they naturally resemble water-free meat in composition. It is claimed that sometimes blood is incorporated in these substances, and this would have an effect on composition and nutritive value.

"Ordinary meat contains about 25 per cent of solid matter; if all of the water were removed the residue would contain about 87 per cent of proteids and albuminoids, 8 per cent of extractives, and about 5 per cent of ash. This more or less complete removal of water is the practice followed in the preparation of meat powders. In some preparations, not only is the greater part of the water removed, but the proteid matter is treated by an appropriate ferment and a predigested or peptonized product results. Unlike meat extracts, meat powders, if properly prepared, are highly nutritious, and are the only means of securing the full nutritive value of meat in small bulk. Certain authorities have maintained that they are difficult of digestion, but later experiments have controverted this position, and they are now quite generally recommended as being readily digested and assimilated."

The proprietary meat articles, meat capsules, yeast extracts, and the other goods examined are also discussed.

Influence of food preservatives and artificial colors on digestion and health. V, Formaldehyde, H. W. WILEY, W. D. BIGELOW, F. C. WEBER, ET AL. (*U. S. Dept. Agr., Bur. Chem. Bul. 84, pt. 5, pp. VI+1295–1500, figs. 4*).—In continuation of work previously noted (E. S. R., 20, p. 464), similar experiments with healthy young men as subjects were undertaken to judge of the effects of formaldehyde on normal human beings.

Formaldehyde, as the author points out, "is one of those preservatives the use of which in foods has been almost universally condemned by experts, physicians, and the general public. Nevertheless, as formaldehyde has heretofore been used to quite an extent in certain foods, especially dairy products, and is still advertised under its own and other names for use in such products to a limited extent, it seemed wise to include this substance in the plan of investigation."

In the periods in which formaldehyde was added to the ration an aqueous solution was administered in milk. In the case of half of the subjects the preservative was added to the milk immediately before it was drunk, while with the other 6 subjects it was added to the milk 2 days before consumption in order that ample time might be given for any chemical union taking place between the formaldehyde and the protein constituents of the milk.

In the discussion of the experimental data such subjects as body weight, weight and water content of the feces, the urine, its volume, and the metabolism of nitrogen, phosphoric acid, and sulphur are considered. Quotations follow from the author's summary.

"The formaldehyde in the quantities administered did not produce any marked symptoms until the third preservative subperiod, a lapse of 10 days; then headache and pain in the stomach and intestines became general, in many cases producing cramps, and in a few cases attended by nausea and vomiting. Only two exceptions are noted. A burning sensation in the throat was reported in the majority of cases. In four cases out of eleven a well marked itching rash appeared on the chest and thighs, causing great discomfort, slight symptoms of this nature being reported in a fifth case. The general symptoms, therefore, are headache and abdominal pains, while a slight tendency to lower the temperature may be noted as a minor symptom, and the development of the rash, though marked, occurs in only about half of the cases.

"It is important to observe that in the case of healthy young men it requires some time for this drug to produce an effect noticeable in a symptomatic way, as above described. That no effect is produced, however, until after 10 days would not be a logical conclusion. It is evident that the system is able for some time to control the development of conditions which later become

pronounced, but that no ill effects are produced prior to that time is not probable. . . .

"A general study of all of the data leads to the conclusion that the admixture of formaldehyde with food is injurious to health, even in the case of healthy young men. It is fair to conclude, therefore, that in the case of infants and children the deleterious effects would be more pronounced. The metabolic functions are disturbed in a notable way, both by the retardation of the nitrogen and sulphur metabolism and the acceleration of phosphorus metabolism. There seems to be a tendency to an increased absorption from the alimentary canal, especially in the cases when the formaldehyde had stood in contact with the milk, and hence it is fair to presume that in so far as the digestive action in the intestinal canal is concerned, transforming solid food into soluble materials which may enter the circulation, there is evidently a stimulating effect produced.

"There are, however, many varying conditions which must be considered in properly interpreting the data. The uniformly increased absorption of the proteid elements of the food, and also of the sulphur and phosphoric acid, accompanied in the first two instances by a decrease in the metabolized elements excreted, and in the last instance, namely, phosphoric acid, by a pronounced increase in metabolism, makes the explanation of the data rather difficult. . . .

"The conditions which are noted in the case of the proteins would lead one to expect a gain in the body weight. This expectation, however, is not realized for either class of subjects, although the losses in weight are so slight as to be practically negligible. . . .

"The medical data indicate plainly that formaldehyde, even when given in small quantities, is an irritating substance to the mucous membrane, and therefore the normal organs are at first actively stimulated to rid themselves of the irritating foreign substance. It is not strange, therefore, that this preservative had a marked stimulative action on those organs and cells secreting the various digestive juices. It is evident that when the digestive and excretory organs of the body are excited to unusual activity by such an extraneous body having neither food nor condimental value, they act in self-defense, and it would be wholly illogical to conclude from this increased excitation that these bodies were helpful to digestion and conducive to health. The nature of the investigation made it impossible to determine whether any organic change took place in the various organs affected, but it may be assumed that any such change which these organs had undergone in the limited time was not sufficient to disturb in any notable way their normal functions, which they would perform until the continued administration of the drug produced disease due to the excessive stimulation.

"In the case of phosphoric acid, the increased katabolic activity is difficult of definite interpretation, though it is established beyond doubt that such an effect is produced. . . .

"The general tendency to produce a slight decrease in the temperature of the body, assuming for the moment that the data warrant the conclusions that such a condition of affairs existed, might well be due to the inhibition of cell activity shown by the retardation in the breaking down of tissues. The normal functions of the body would doubtless be disturbed by such a condition, aside from the irritating and other disturbing influences exerted by the ingested drug.

"The tendency of the preservative to produce albumin in the urine, while not well marked, is at least worthy of mention. The fact that only slight changes take place in the body weight is sufficiently explained by the data and can not be urged in favor of the exhibited preservative.

"The final conclusion, therefore, is that the addition of formaldehyde to foods tends to derange metabolism, disturb the normal functions, and produce irritation and undue stimulation of the secretory activities, and therefore it is never justifiable."

General results of the investigations showing the effect of formaldehyde upon digestion and health (*U. S. Dept. Agr., Bur. Chem. Circ. 42, pp. 16, figs. 4.*)—A general summary and discussion of investigations noted above.

A study of the methods of canning meats, with reference to the proper disposal of defective cans, C. N. McBryde (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 279–296, fig. 1*).—From an extended study of defective cans of meat goods the following conclusions were drawn:

"The majority of slow-leaking cans contain bacteria, which invariably set up putrefactive or fermentative changes in the contents of the cans.

"The majority of slow-leaking cans, when incubated for 10 days at a temperature of 100 to 110° F., will develop into 'swellers.'

"Short-vacuum, overstuffed, and collapsed cans will not swell upon incubation provided there are no breaks in the tins.

"The swelling of slow-leaking cans upon incubation is due to the formation of gases resulting from the growth of bacteria within the cans.

"The product contained in slow-leaking cans is not a safe article for food even though it be reprocessed."

Report of a commission on certain features of the Federal meat inspection regulations (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 361–374*).—A report of a committee appointed by the Secretary of Agriculture to express opinion upon "the disposition of carcasses affected with various diseases and abnormal conditions." In general, the commission considers that the regulation on this subject already in force fully safeguards the public health in so far as the points contained therein are concerned.

The quantity and distribution of phosphorus in certain foods, W. Heubner and M. Reeb (*Arch. Expt. Path. u. Pharmakol., 1908, Sup., pp. 265–272*).—The authors report and discuss determinations of the total phosphorus and its distribution in a number of food materials.

The analytical results are summarized in the following table:

Kind and amount of phosphorus in certain food materials.

Kind of food.	Total phosphorus.	Form of phosphorus.			
		Phosphatid.	Soluble phosphate.	Water soluble phosphate.	Nuclein and proteid phosphorus.
	Per ct.	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*
Horse flesh	0.192	0.039	0.114	0.010	0.026
Milk	.106	.006	.032	.006	.057
Egg white	.015	.....	.003	.003	.009
Bread	.098	.007	.035	.....	.049
Rice	.097	.004	.004	.....	.088
Bran	1.452	.020	.217	.346	.662
Carrots	.054	.004	.027	.015	.005
Beets	.028	.006	.012	.007	.003

White cabbage	.026	.005	.012	[a].006	.003

[a] Estimated.

The bacterial content of cooked fish. H. BRUNS (*Über das bakteriologische Verhalten des Fischfleisches nach der Zubereitung. Inaug. Diss., Univ. München, 1908, pp. 29; Arch. Hyg., 67 (1908), No. 3, pp. 209–236*).—The author studied the bacterial content of the surface and interior of raw fish and fish cooked and kept in different ways. According to the results which he obtained, the interior of the flesh and the surface of freshly cooked material are free from bacteria and remain so for some days provided the fish is properly handled and stored, as for instance by wrapping the fish in sterile paper and keeping at suitable temperature. It was also found that cooked fish imbedded in jelly remained free from bacteria for a number of days.

Edible fishes of New South Wales. D. G. STEAD (*Dept. Fisheries, N. S. Wales: 1908, pp. 123, pls. 81, map 1*).—A list of edible fishes of New South Wales is given, together with brief statements regarding each species. In the introductory chapter statistics are given of the character and extent of the New South Wales fishing industry.

Edible seaweed. H. E. ANNETT, F. V. DARBISHIRE, and E. J. RUSSELL (*Jour. Southeast. Agr. Col. Wye, 1907, No. 16, pp. 204, 205*).—An analysis of edible seaweed (a mixture of *Chondrus crispus* and *Gigartina mamillosa*) is reported and some data are quoted on the use of a jelly made from Irish moss (*Chondrus crispus*) with milk in calf feeding.

The water content of bread. O. MEZGER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 7, pp. 395–397*).—Analyses of both white and black bread are reported and discussed.

The behavior of ester compounds in the aging of wine. F. SCURTI and G. CORSO (*Staz. Sper. Agr. Ital., 41 (1908), No. 8, pp. 507–519; abs. in Chem. Zentbl., 1908, II, No. 19, p. 1622*).—The author does not believe in the theory that the total amount of esters in wine increases on aging. The article contains a critical discussion of methods.

Judging alcohol-free wine. J. M. KRASSER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 7, pp. 398–400*).—The author believes that the term "alcohol-free wine" should only be applied to such products as are made by removing alcohol from natural wines and that sterilized fruit juices should be designated as such and not called "alcohol-free wine." Analyses of so-called "alcohol-free wines" are reported.

Report on the physical, commercial, social and general conditions of Ichang and neighborhood. H. A. LITTLE (*Diplo. and Cons. Rpts. [London], Misc. Ser., 1908, No. 671, pp. 24, map 1*).—In addition to statistical and other data regarding schools, salaries and wages, land tenure, agriculture, fertilizers, the flora of the district, etc., this report contains considerable information regarding the character and cost of the food of Chinese laboring men.

[Diet in a reformatory for inebriates] (*Illus. London News [Amer. Ed.], 43 (1908), No. 1124, pp. 736, 737, figs. 13*).—In an article descriptive of the State Inebriates Reformatory at Aylesbury, a reformatory institution for women, data are given regarding the kind and amount of food supplied per woman per day.

The daily fare consists of white bread, butter, potatoes, meat, a green vegetable, a simple dessert, cereal porridge, tea, and cocoa. [From the quantities given the nutrients supplied per woman per day were calculated to be 115 gm. protein, 96 gm. fat, and 497 gm. carbohydrates, which would yield together 3,310 calories of available energy.]

Proposed ration for the agricultural school of Chile (*An. Agron. [Santiago de Chile], 2 (1907), No. 3, p. 283*).—The proposed ration per man per day consists of 250 gm. meat, 500 gm. bread, 56 gm. sugar, 200 gm. frejoles, 600 gm. navy beans, 25 gm. rice, 15 gm. fat, 150 gm. milk, 10 gm. coffee, with salad and

green vegetables. This ration would supply in round numbers 142 gm. protein, 52 gm. fat, 556 gm. carbohydrates, and 25 gm. ash, and 3,232 calories of available energy at a cost of 66 cents Chilean.

Ration for the technical school, J. FIGUEROA (*Bol. Min. Indus. i Obras Pub. [Chile]*, 7 (*1908*), *No. 1, p. 8*).—The ration proposed for the government technical school and its divisions is given. (See above.)

School luncheons. How and what to prepare for them, MRS. F. SCHOFF (*Nat. Cong. Mothers Mag., 3 (1908), No. 3, pp. 81–83*).—A discussion on preparing and packing school lunches and related matters.

The new housekeeping, C. BARNARD (*Housekeeping Expt. Sta. [Conn.] Bul. 4, pp. 4*).—A discussion of the use of alcohol as fuel and of preparing food with steam cookers and fireless cookers.

The importance of intestinal bacteria in nutrition, III, M. SCHOTTELIUS (*Arch. Hyg. 67 (1908), No. 3, pp. 177–208*).—The author concludes that intestinal bacteria are necessary for man and other vertebrates, and that normal intestinal bacteria assist in the preparation of nutrients so that they may be resorbed, induce peristalsis by stimulating the intestinal wall, diminish or destroy pathogenic bacteria in the intestine, and protect the body from bacterial poisons.

The absorption of proteins, W. D. HALLIBURTON (*Lancet [London], 1909, I, No. 1, pp. 21–23*).—A polemical article in which the author briefly summarizes present theories regarding protein cleavage in the body and metabolism.

The effect of adding meat to a vegetarian diet, P. ALBERTONI and F. ROSSI (*Arch. Expl. Path. u. Pharmakol., 1908, Sup., pp. 29–38*).—The authors briefly report the results of a series of investigations on the addition of meat to the diet of peasants of the Abruzzi region who have been users of an almost exclusively vegetarian diet for generations.

An increase in the power of assimilation and in body weight was noted as well as in physical strength and the hemoglobin content of the blood. Attention is directed especially to the increase in red blood corpuscles, a result which is similar to that observed in the treatment of anemia and underdeveloped individuals.

In discussing the results of their investigations in relation to the question of nitrogen minimum, the authors state that the distinction must be clearly drawn between a nitrogen minimum estimated on the basis of the balance of income and outgo and the practical minimum which enables the individual to carry on all the psychological and physical processes which are essential if he is to succeed in his environment.

Concerning the effect of maize diet, C. BEZZOLA (*Clin. Med. Ital., 46 (1907), No. 3, pp. 161–164; abs. in Biochem. Centbl., 7 (1908): No. 18–19, p. 699*).—In experiments with guinea pigs an exclusive maize diet did not prove adequate. When vegetables, etc., were added, better results were obtained. Long continued feeding of maize may be followed by serious consequences. Results were of the same character whether a good or bad quality of maize was used. The author does not consider that his results are applicable to the discussion of maize as an article of human food.

On the available alkali in the ash of human and cow's milk in its relation to infant nutrition, J. H. KASTLE (*Amer. Jour. Physiol., 22 (1908), No. 2, pp. 284–308*).—The essential points of resemblance and difference in the composition and properties of the ash of human and cow's milk are discussed in their relations to infant nutrition.

"In 35 out of 50 specimens of cow's milk, in which the alkalinity of the ash was determined, it ranged from 0.1193 cc. of tenth-normal sodium hydroxid to

0.1788 cc., the average being 0.1574 cc., and in 18 out of 26 specimens of human milk, in which the alkalinity of the ash was determined, it ranged from 0.1196 to 0.1799 cc. of tenth-normal sodium hydroxid, the average being 0.1513 cc., which numbers agree reasonably well with the average alkalinity of the ash of the two kinds of milk calculated from the complete analyses.

"It is evident, therefore, that while cow's milk contains from 2.5 to 3.5 times as much mineral matter as human milk, the ash of the two milks contains approximately the same amount of available alkali. . . . The salient points of difference between the two kinds of milk are: Human milk contains relatively more of its mineral matter in utilizable form than cow's milk; it can supply the organism of the child with relatively larger amounts of available alkali in proportion to the proteid than cow's milk; it contains much less proteid; and it contains a more readily absorbable variety of fat. . . . It is believed, therefore, that while the primary cause of gastro-intestinal disturbances following the use of cow's milk in infant feeding is due to the fact that the fat is not readily absorbed, the more remote and fundamental cause of these disorders in infants fed upon rich cow's milk is an excessive proteid metabolism and an insufficiency in available mineral matter in cow's milk as compared with human milk. . . . Some of the most valuable recommendations and practices relating to infant feeding, such as the feeding of skim milk and buttermilk, the addition of certain alkaline substances to the diet such as citrates, the dilution of cow's milk with barley broth, etc., or with water containing the white of egg as recommended by Lehmann, and the use of such substances as orange juice, as adjuncts to the infant diet, are in accord with the ideas herein set forth. Practically all of these aids to artificial infant feeding, based as they are upon the results of sound practical experience, have for their object either the reduction of the amount of fat in the milk or the addition thereto of mineral matter available for the neutralization of acids resulting from metabolism, or both. In this connection it is interesting to note that the ash of white of egg and orange juice both contain considerably more available alkali than cow's milk."

Tables of the alkalinity and the ash contents of milk are given.

Nutrition processes during the growth of the child, M. Rubner (*Arch. Hyg., 66 (1908), No. 1–2, pp. 81–126*).—In this theoretical discussion of diet during the period of growth the author emphasizes the importance of energy considerations and gives reasons for his belief that the proteid requirement has been sometimes overestimated. The article is a very important contribution to the theory of infant feeding.

Theory of nutrition after completion of growth, M. Rubner (*Arch. Hyg., 66 (1908), No. 1–2, pp. 1–80*).—This discussion of theories of nutrition is chiefly concerned with protein metabolism, and considers the functions of body protein, stored protein, protein as building material and protein as a source of energy, and related topics. Protein metabolism, the author states, varies according to the protein requirements of the cell, the cell with little protein retaining more of the protein supplied to it than one which is rich in this constituent. For this reason a large protein supply does not cause so great nitrogen excretion in the former case as in the latter.

The author discusses nitrogen metabolism and gain on a basis of the amount of nitrogen present in the body rather than on the usual basis of body weight. Cell function is the primary consideration in protein metabolism. The cleavage of protein accommodates itself to this factor, and there is a relationship between cell function and the size of the body. Within certain limits nitrogen metabolism is more rapid the more protein is supplied.

An excess of protein leads to a partial use of it to replace carbohydrates as a source of energy. In such cases the nutritive value is relatively less than when smaller amounts are supplied.

Problems of growth and length of life from the standpoint of energetics. M. RUBNER (*Arch. Hyg., 66 (1908), No. 1–2, pp. 127–208, charts 2; Sitzber. K. Preuss. Akad. Wiss., 1908, II, pp. 32–47*).—The author discusses rate of growth and duration of life of man and other mammals from the standpoint of energetics. With respect both to the amount of protein and energy required during the nursing period to double the body weight, man forms an exception to the other mammals included in the author's discussion in that on a uniform basis of comparison he requires smaller quantities of protein and about six times as much energy. According to the author's calculations, domestic mammals require on an average 4,808 calories for building a kilogram of body material.

A comparison is also made between man and other mammals with respect to the proportion of energy supplied during the nursing period, which is retained in the body. In this respect also man differs from the ordinary domestic animals, since he retains only 5.2 per cent of the net energy supplied in comparison with 34.3 in the case of domestic animals. This value is called by the author "quotient of growth." He estimates further that in domestic animals the ratio of food supply to maintenance is 202 to 100 and in man 120 to 100, so that in the case of domestic animals 69 per cent of the material supplied is retained in comparison with 6.2 per cent in the case of man.

According to the author's summary, the time required by the young animal for doubling the body weight is inversely proportional to the intensity of metabolism, and therefore the shorter the period of growth the greater the metabolism of energy. The intensity of energy metabolism is a function of surface area and therefore small animals show the more rapid growth.

In his discussion of the duration of life the author estimates that in the domestic animals each kilogram of body weight after growth is completed requires practically the same quantity of energy. Man forms an exception to this rule, in that he requires about four times as much as the other mammals. It follows, therefore, that man requires a greater proportional energy supply than other mammals.

The problem of duration of life and its relation to growth and nutrition. M. RUBNER (*Das Problem der Lebensdauer und seine Beziehungen zu Wachstum und Ernährung. München, 1908, pp. VIII+208; rev. in Biochem. Centbl., 7 (1908), No. 15–16, pp. 593, 594*).—A fuller discussion of problems considered in the article noted above.

ANIMAL PRODUCTION.

[Experiments in animal production]. W. H. JORDAN and W. P. WHEELER (*New York State Sta. Rpt. 1907, pt. 3, pp. 66–109, pls. 2*).—A summary of work done at this station during the first 25 years of its existence.

Some of the more important results obtained are as follows: Corn cut on September 29 contained a large increase in carbohydrate material over that cut September 11. From a number of experiments it was concluded that the German feeding standard called for a larger protein ration than is necessary. In 1901 it was demonstrated that the quality of the milk is determined by the individuality of the animal and not by the quality of the feed. It was also found that it was not possible to influence the amount of water in cow's milk through either the drinking water or watery food. Wet brewers' grains proved to be a valuable feed when given in the right proportions. Carbohydrates in the feed were found to furnish the raw material for the production of a large

proportion of the fat in the milk. The carcass of a corn-fed lamb contained a much larger proportion of fat than the carcass of a lamb fed upon cotton-seed meal.

Specific gravity methods for determining freshness of eggs were found unreliable. Small active breeds of poultry do better with a wide ration than large breeds. Hens fed linseed meal molted rapidly and earlier in the season than those receiving a large amount of tallow. Oyster shells were found to be utilized largely in the construction of the eggshell. Cockerels were found the most profitable when sold at about 6 lbs. weight, and capons when fed until about 9 lbs. in weight. Eleven per cent more eggs were obtained from hens when kept in pens without cockerels. From a number of experiments it was found that with growing stock ground grain gave on the whole better results than whole grain. Rations containing animal food were superior to those of vegetable origin for growing chicks, laying hens, and ducklings.

Of a number of coarse feeds fed to swine none were eaten without waste except mangels. With fresh forage crops better gains were made when salt was added to the ration. Corn silage, red clover, and sorghum proved to be good feeds when given in small amounts.

The computation of rations for farm animals by the use of energy values, H. P. Armsby (*U. S. Dept. Agr., Farmers' Bul. 346, pp. 32*).—The feed requirements for maintenance, growth, fattening, milk production, and work are treated in this bulletin from the standard of energy values instead of the balanced-ration method commonly used in popular works on feeding. The method for computing rations is presented in such form that it is intelligible to the practical farmer, though based on fundamental principles as revealed by scientific investigations.

Feeds and feeding, W. A. Henry, trans. by F. M. Draenert (*Forragem e Nutrição. São Paulo, 1907, pp. XIV+700*).—A Portuguese translation of this work (E. S. R., 10, p. 82).

Concentrated commercial feeding stuffs, W. J. Jones, O. C. Haworth, and J. B. Abbott (*Indiana Sta. Bul. 131, pp. 305–465*).—This bulletin contains the text of the Indiana feeding stuff law of 1907 and a discussion thereof, together with the results of analyses of 1,361 samples of feeding stuffs, including wheat bran and middlings, red-dog flour, mixed feeds, rye products, buckwheat bran and middlings, corn bran, hominy meal and chops, gluten feed, linseed meal, flax screenings, cotton-seed meal, dried brewers' grains, malt sprouts, proprietary and molasses feeds, poultry and scratch feeds, animal meals, and condimental stock feeds. There is also a list of brands and guaranties registered by manufacturers in compliance with the law.

"Since very few manufacturers had ever had their products analyzed it was to be expected that many would make their guaranties too high. In the majority of cases the guaranty was based on the average analysis of the products as given in Circular No. 7 published by this station [E. S. R., 19, p. 67], and while a large number of samples failed to meet the guaranty, and there is much room for improvement in the character of the feeding stuffs offered for sale, a decided increase in the number of samples meeting the guaranty is noted in those now being secured and in the case of many others the guaranty has been lowered to meet the inspection analysis."

The value of fodder plants at different stages of maturity and the proper time for harvesting the same, J. König and A. Fürstenberg (*Zentbl. Agr. Chem., 37 (1908), No. 11, pp. 745–749*).—Analyses were made of grass and of clover hays cut before, after, and at the time of blossoming. The results agreed with practical experience that hay should be cut when in blossom.

Tropical fodder plants, A. ZIMMERMANN (*Pflanzer, 4 (1908), Nos. 15, pp. 225–230; 16, pp. 250–256; 17, pp. 269, 270; 18, pp. 273–281; 19, pp. 300–303*).—Descriptions of grasses and other plants used for forage in the Tropics.

"Top feed" in Murchison and Gascoyne districts (*Jour. Dept. Agr. West. Aust., 17 (1908), No. 4, p. 753*).—Results of analyses of a sample of Wanyoo bush or "Sugar Brother" and of a broad-leaf wattle.

Defecation with a view to cattle feeding (*Sugar Beet, 30 (1909), No. 1, pp. 36, 37*).—This is an account of an old method which has recently been revived in Austria for use where the beets are to be fed to cattle. The beets are rasped, defecated with lime, and pressed. The pulp obtained has a higher nutritive value than that otherwise obtained, being drier and the sugar losses less than in diffusion pulps. The juices obtained are denser, and there follows also an economy of steam owing to the fact that the diffusion battery is done away with. The cost of the plant and its working is much less than with diffusion.

Digestibility of kale, vetch hay, steamed and unsteamed silage, J. WITHYCOMBE and C. E. BRADLEY (*Oregon Sta. Bul. 102, pp. 3–29, fig. 1*).—This bulletin reports 2 digestion experiments on fresh kale and 1 each on vetch hay, unsteamed corn silage, steamed corn silage, unsteamed vetch silage, and steamed vetch silage. Each experiment continued 7 days, in addition to a few days of preliminary feeding. The animals used were 2 dry cows, 1 a pure-bred Jersey and the other a Jersey-Shorthorn cross.

Chemical analysis showed the kale to be rich in protein, averaging about 2.5 per cent on the fresh sample and 21 per cent on the dry substance. The ash content was high, being 8.58 per cent in the stalks and 14.7 per cent in the leaves of the total dry matter. "Calculated to the acre yield of 30 tons, these values show that approximately 225 lbs. of potash and 115 lbs. of phosphoric acid enter into the composition of each acre of kale. This shows the plant to be a heavy feeder on these plant foods and proves the necessity of a rich soil for its successful growth." Analytical data on the other feeds are reported. Both cows lost in weight in each experiment except in the vetch hay and the unsteamed vetch silage periods.

Determinations were made of the energy values of the food and feces but not of the urine.

The following table shows the percentage of digestible nutrients and available energy of the different feeds:

Coefficients of digestible nutrients and available energy of kale, vetch hay, and silage.

Kind of feed.	Dry matter.	Protein.	Crude fiber.	Nitrogen-free extract.	Fat.	Ash.	Available energy.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Kale	68.01	80.63	58.99	75.83	65.85	38.81	71.76
Vetch hay	64.56	61.07	58.22	70.71	68.01	58.98	63.08
Unsteamed corn silage	63.24	56.38	62.94	66.85	77.34	47.28	76.70
Steamed corn silage	51.16	14.62	51.46	62.83	62.91	37.71	61.75
Unsteamed vetch silage	71.85	58.55	73.55	74.90	89.71	42.58	62.71
Steamed vetch silage	60.68	5.30	63.26	71.12	79.27	9.01	48.79

Experiments on the digestibility of prickly pear by cattle, R. F. HARE (*New Mexico Sta. Bul. 69, pp. 5–8, figs. 3*).—Noted from another source (E. S. R., 20, p. 171).

Steer feeding. II, Winter steer feeding, 1906–7, 1907–8, J. H. SKINNER and W. A. COCHEL (*Indiana Sta. Bul. 129, pp. 233–278*).—The object of the

experiments reported was to study the influences of the various factors which determine the profits from feeding beef cattle. The work extended over a period of 2 winters and has involved the use of 212 cattle. In calculating the cost of gain the value of the different feeds has been estimated at the following prices: Shelled corn 40 cts. per bushel, cotton-seed meal $28 per ton, and corn silage $2.50 per ton. In estimating the profit the value of the pork produced from hogs following the cattle is included.

The first series of experiments was to determine the influence of age on economy and profit in fattening cattle. A ration of shelled corn, cotton-seed meal, clover hay, and corn silage was fed to calves, yearlings, and 2-year-olds, with the results as shown in the following table:

Influence of age on economy and profit in fattening steers in winter.

Animals fed.	Year.	Initial cost per pound.	Initial weight.	Average daily gain.	Cost per pound.	Selling price per pound.	Final weight.	Profit per animal.
		Cts.	*Lbs.*	*Lbs.*	*Cts.*	*Cts.*	*Lbs.*	
19 calves	1906–7	4.50	508.8	2.08	5.35	5.35	883.0	$6.13
10 yearlings	do	4.15	922.0	2.38	7.62	5.60	1,351.6	9.24
10 2-year-olds	do	4.25	1,010.8	2.57	7.59	5.60	1,474.5	10.04
20 calves	1907–8	4.50	534.0	1.88	5.86	6.30	872.5	9.01
10 yearlings	do	4.15	853.6	2.21	7.85	6.50	1,252.1	13.80
2-years-olds	do	1.00	1,123.5	2.65	7.90	6.70	1,602.1	22.68

"The amount of feed consumed and the daily gain per steer increases with the age of the cattle."

"The amount of feed required to produce a pound of gain on calves was much less than with older cattle."

Two experiments were made with 2-year-old steers similar to those of the previous experiment to determine the feeding value of corn silage when fed with shelled corn and clover hay. In 1906–7 the experiment lasted 180 days. Ten steers fed shelled corn and clover hay made an average daily gain of 2.01 lbs., at a cost of 8.56 cts. per pound, and a similar lot receiving shelled corn, clover hay, and corn silage made a corresponding gain of 1.85 lbs., at a cost of 8.31 cts. per pound. In 1907–8 the experiment was repeated, lasting 150 days, when the steers fed the corn and clover ration made a gain of 1.9 lbs., at a cost of 9.13 cts. per pound, and those fed the corn, clover, and silage ration made a gain of 1.8 lbs., at a cost of 9.3 cts. per pound.

"In the financial statements of the two lots fed in 1906–7 it will be seen that the profit per steer was practically the same whether fed on corn and clover or on corn, clover, and silage. . . . The financial statements for the year 1907–8 show a profit of $18.41 in favor of the lot fed silage."

A second experiment was conducted to determine the value of a ration composed of shelled corn, cotton-seed meal, clover hay, and corn silage as compared with a similar ration without the silage. The initial value of these cattle was $4 per hundred in both lots. The initial weight was 1,123 lbs. in the silage-fed lot and 1,130 lbs. per steer in the lot fed no silage. At the end of the six months period, the lot receiving silage averaged 1,602 lbs., while that receiving no silage weighed 1,570 lbs. The 10 steers which received silage made an average daily gain of 2.66 lbs., at a cost of 7.91 cts. per pound. Those not receiving silage made an average daily gain of 2.44 lbs., at a cost of 8.75 cts. per pound.

The results indicate that corn silage may profitably be made a portion of the ration for finishing cattle.

Two tests were undertaken to determine the value of cotton-seed meal as a supplement in fattening 2-year-old steers. In the first experiment, which lasted 180 days, the basal ration consisted of shelled corn, clover hay, and corn silage. With cotton-seed meal as a supplement the average daily gain of 10 steers was 2.57 lbs., at a cost of 7.59 cts. per pound. Without the cotton-seed meal supplement the average daily gain of a similar lot was 1.85 lbs., at a cost of 8.31 cts. per pound.

"The addition of cotton-seed meal did not decrease the total amount of other feeds consumed, but seemed to stimulate the appetite of the steers to such an extent as to increase the daily feed consumed practically 3 lbs. per head."

In the second test, lasting 150 days, with cotton-seed meal as a supplement, the average daily gain was 2.7 lbs. at a cost of 7.83 cts. per pound. Without the cotton-seed meal the average daily gain was 1.8 lbs., at a cost of 9.3 cts. per pound.

In another test lasting 150 days no silage was fed. With cotton-seed meal as a supplement to corn and clover there was an average daily gain of 2.6 lbs., at a cost of 8.3 cts. per pound. Without the cotton-seed meal the average daily gain was 1.9 lbs. at a cost of 9.13 cts. per pound.

In another experiment clover hay was compared with timothy hay as a roughage. With the clover hay and shelled corn the average gain was 2.01 lbs., at a cost of 8.56 cts. per pound. With the shelled corn and timothy hay the average daily gain was 1.56 lbs., at a cost of 9.27 cts. per pound.

"The results of these experiments showed a much greater profit from fattening cattle in the winter of 1907–8 than in that of 1906–7.

"There is a marked difference in similar rations grown and fed in different seasons.

"High grade, blocky, early maturing beef calves showing both breeding and quality, are necessary in making yearling beef.

"Quality and type are not so essential in feeding aged steers as in feeding calves, provided the purchase price is proportionate. . . .

"The amount of pork produced from the droppings increases with the age of the cattle.

"When clover hay replaces timothy hay in the ration there is a greater amount of pork produced."

Steer feeding. III, Results of short v. long feeding periods, J. H. Skinner and W. A. Cochel (*Indiana Sta. Bul. 130, pp. 287–301*).—This bulletin reports the progress made at the station the past 2 years in securing data as to the rate and cost of gain, feed consumed, degree of finish obtained, and profits secured from feeding cattle through a long period of 180 days as contrasted with a short period of 90 days.

In both series of experiments reported two lots of 10 steers each were fed shelled corn, cotton-seed meal, clover hay, and corn silage. The corn was valued at 40 cts. per bushel. In the experiment in 1906–7, the average daily gains per head were for the long period 2.57 lbs., at a cost of 7.59 cts. per pound, and for the short period 3.16 lbs., at a cost of 6.98 cts. per pound. In 1907–8, the corresponding average daily gains of the long-fed steers were 2.66 lbs. per head, at a cost of 7.91 cts. per pound, and of the short-fed steers 2.85 lbs., at a cost of 7.83 cts. per pound.

In the first test the total amount of corn necessary to finish each steer was 34 bu. in the "short-fed" lot and 54.6 bu. in the "long-fed" lot; in the second test 42.5 bu. and 61.1 bu., respectively. In the "short-fed" lot it was necessary to put on 285 lbs. per head in the first test and 318 lbs. in the second test to

attain the marketable finish obtained from 464 lbs. and 479 lbs., respectively, in the "long-fed" lot.

During the period when both lots of cattle were in the feed lot there was a greater profit per head from feeding the heavier, fleshier steers. The gains were cheaper on the thinner cattle during the first 3 months of the test, but when fed to the same marketable finish the cost of gains was practically the same.

In 1906–7 the margin necessary to prevent loss on the "short-fed" cattle at the time of marketing was 48 cts. per hundred pounds; on the "long-fed" cattle at the same time, 50 cts.; and on the "long-fed" cattle at the time of marketing, $1.04. In 1907–8 the corresponding margins necessary were 92 cts., $1.01, and $1.54 per hundred pounds.

Details are given of the method of feeding the carload lot of steers which won the first prize in the 2-year-old champion class at the International Live Stock Show of 1907. These steers made an average daily gain of 3.25 lbs. per head, at a cost of 6.8 cts. per pound.

Feeding experiments with cattle and sheep, 1904–1908, D. A. GILCHRIST (*County Northumb., Ed. Com., Bul. 12, pp. 39; abs. in Irish Farming World, 22 (1909), No. 1088, p. 29*).—From Armstrong College, New Castle-on-Tyne, several feeding experiments for the past 4 years are reported.

It is concluded that a daily ration of 56 lbs. of sweet turnips per 800 lbs. live weight is suitable for fattening cattle. Egyptian and Indian-cotton cake have about the same feeding value. Delinting Indian cotton seed before the seed is crushed increases its feeding value. Peanut, sesame, and niger (*Guizotia oleifera*) cakes gave poor results and contained considerable amounts of sand. Analyses are given.

Cattle breeds of Morocco, G. DE GIRONCOURT (*Agr. Prat. Pays Chauds, 8 (1908), No. 68, pp. 390–399, figs. 4*).—Morocco contains much fertile land and there are vast pastures devoted to stock raising. From a zootechnical point of view it is more like Andalusia than Algeria. In northern Morocco the cattle may be divided into three types. The grayish-black cattle along the river Loukkos are brachycephalic, with lyre-formed horns, and are a good beef cattle. On the plains of the Sebou is a brachycephalic type, with short thick horns. These cattle are red or reddish-brown in color and are a good dairy breed. Farther south, among the tribes of Zemmour, is a general purpose breed of a dolichocephalic type, with long horns curving downward. The coat color varies, but is usually a mixture of black and gray.

The advantages of cattle raising in Guipuzcoa (*Prog. Agr. y Pecuario, 14 (1908), No. 591, pp. 471–475, figs. 7*).—An account of the native and introduced cattle breeds of this Spanish province.

Caracul sheep and broom meadows, VON LEPEL (*Illus. Landw. Ztg., 28 (1908), No. 101, pp. 861, 862*).—The author believes that caracul sheep may be successfully raised in Germany. Broom ought to be a good feed if small quantities are fed at first. Crosses with hornless native sheep give polled offspring, with pendent ears and coat characteristics of the caracul.

Lamb feeding (*Oklahoma Sta. Rpt. 1908, pp. 72, 73*).—Notes on feeding and handling lambs under Oklahoma conditions.

Market classes and grades of sheep, W. C. COFFEY (*Illinois Sta. Bul. 129, pp. 577–635, figs. 47*).—This bulletin, which defines and illustrates the classes and grades of sheep recognized in the Chicago and other large markets, is the result of a personal study of the subject at the Union Stock Yards at Chicago. The market classes enumerated are mutton, feeder, and breeding sheep. The subclasses of the mutton class are lambs, yearlings, wethers, ewes, bucks, and stags. Feeder sheep are almost exclusively western and the subclasses are

lambs, yearlings, wethers, and ewes. The subclasses of breeding sheep are bucks and ewes. Each subclass is divided into grades based on differences between the best and the less desirable animals. In the mutton class these differences are based on quality, condition, weight, and form; in the feeder class on quality, form, condition, and weight; and in the breeding class on age, constitution, form, breeding, quality, and condition. The characteristics of the different classes and grades are considered in detail.

Principles of modern swine breeding (*Landw. Wchnbl. Schles. Holst., 58 (1908). Nos. 48, pp. 827–829; 49, pp. 842–846; 50, pp. 857–859; 51, pp. 873–876; 52, pp. 886–889*).—A series of popular articles on the swine industry from the economic standpoint.

The preservation of our native types of horses, G. M. Rommel (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 85–143, figs. 19; Circ. 137, pp. 85–143, pl. 1, figs. 19*).—The author discusses the development of horse breeding in the United States, with special reference to the origin of types of light horses. Special topics discussed are the influence of Morgan blood on the saddle horse, "saddle" blood in American carriage horses, and the Standard bred as a carriage horse. It is stated that the classification of American carriage horses, formulated by this Department in cooperation with the American Association of Trotting Horse Breeders, has met with widespread adoption. The stud records of the breeding experiments in cooperation with the Colorado and Vermont stations, and the pedigrees of Department studs, are given in the article.

"In the Department's work the individuality of a horse is the point given greatest weight in his selection, and strict selection to type is the policy in view. Wherever possible (as in the last Kentucky purchase), the inheritance of type has been combined with the selection of type in the individual, and naturally an animal that inherits good individuality from his ancestors and is himself a good individual is much more valuable for the Department breeding establishments than one without such an inheritance."

Progress in Wisconsin horse breeding, A. S. Alexander (*Wisconsin Sta. Bul. 169, pp. 3–56*).—This bulletin reports the effects of the operation of the Wisconsin stallion law (E. S. R., 18, p. 764; 19, p. 774), upon the horse breeding industry of this State. As the result of this law 553 grade animals, many of which were unsound, have been retired from public service. The bulletin also contains a directory of owners of 225 pure-bred and 327 grade stallions and jacks licensed in 1908 and of the transfers of ownership of animals previously listed.

French breeds and poultry culture in Russia, De Gontcharoff (*Bul. Mens. Off. Renseig. Agr. [Paris], 7 (1908), No. 9, pp. 1113–1120*).—Houdan, Faverolle, La Flèche, Crèvecœur, Bresse, Mans, and Barbezieux breeds have been imported by Russian breeders. The Houdan is more common but the Faverolle is more easily acclimated. The Toulouse goose has produced excellent results when crossed with native breeds. Rouen ducks are superior to native stock. Pigeons and rabbits are not extensively raised for table use. French turkeys are not hardy enough for the Russian climate and the breeders are now importing the American Bronze.

The poultry work of the Bureau of Animal Industry, R. R. Slocum (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 353–360*).—This is a paper based on an address before the American Poultry Association at Niagara Falls, N. Y., August 11, 1907, and contains an account of the investigations on poultry husbandry and a list of publications on this subject by this Department, with suggestions as to future work.

Mrs. Basley's poultry book, Mrs. A. Basley (*Los Angeles, Cal., 1908, pp. 192, figs. 50*).—This is a general treatise for people who wish to raise poultry on the Pacific coast, and is in part a synopsis of a previous work on Woman's

Work in the Poultry Yard. Nearly half of the book is devoted to questions and answers of a practical nature.

Cost of rearing ducklings, E. and W. BROWN (*Jour. Bd. Agr. [London], 15 (1908), No. 9, pp. 664–671*).—This is a report of results of experiments on the poultry farm at the University College, Reading, to determine the cost of rearing ducklings conducted similarly to the previous experiments on the cost of raising chickens (E. S. R., 16, p. 297).

Forty Aylesbury ducklings were hatched April 28, 1908, in an incubator from 60 eggs. For 2 weeks they were fed a wet mash of bran, toppings, barley meal, linseed meal, and meat. Half of them were continued on this feed until 9 weeks old and made a total gain of 66 lbs. 10.88 oz. at a cost of 4.7d. per pound gain. The remainder after the first 2 weeks received the same mixture in a dry condition and made a total gain of 60 lbs. 2.88 oz. at a cost of 5.06d. per pound. The total cost of rearing a duckling 24 weeks was nearly 5s. The rearing of ducks for winter marketing was, therefore, less profitable than the breeding of spring ducklings.

Miscellaneous information concerning the live-stock industry, J. ROBERTS (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 375–417*).—This article consists mainly of statistics on the live-stock market of 1907, Federal meat inspection, our foreign trade of animals and animal products, home and foreign meat prices, registered live stock in the United States, certified pedigree record associations, standards for dairy products, and contagious diseases of animals in foreign countries.

The development of the export trade in pure bred live stock, G. M. ROMMEL (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 345–352*).—This is a paper presented at the meeting of the Missouri State Board of Agriculture at Columbia, January 7, 1908. The export trade of the United States in breeding animals is small. Among the obstacles in the way of foreign trade are the prevalence of disease in many foreign countries, inadequate means of transportation to some countries, especially South America, and inconvenient methods of exchanging money and credit. A government breeding farm is recommended where American types can be bred and advertised as such.

Experiments on the absorption of fat from an isolated loop of small intestine in healthy dogs, O. H. PLANT (*Amer. Jour. Physiol., 23 (1908), No. 2, pp. 65–80, fig. 1*).—Experiments were made on 3 half-grown female dogs. A loop of the small intestine was made in such a way as to eliminate the influence of the bile and pancreatic juices and yet not interfere with the blood supply of the loop or the general nutrition of the animal. The fats used were sweet cream, soap emulsion of neutral cotton-seed oil, soap solution of oleic acid and sodium hydroxid, oleic acid, and neutral cotton-seed oil. These substances separately, and also mixed with bile salts, were placed in the loop at different periods.

"Bile salts greatly increase the absorption of fats from a mixture that contains free fatty acid or soap. They only slightly increase the absorption of neutral oil.

"Solutions of soap, in the absence of other fat, are absorbed from a loop of intestine in greater percentage than emulsified fats; this is also true of fatty acid dissolved by bile salts.

"Neutral oil can be absorbed without the action of either bile or pancreatic juice from a loop of intestine where both these secretions are excluded. Under such conditions the neutral oil becomes markedly acid in reaction.

"Taken as a whole, the results of these experiments favor the theory that fats are absorbed in solution rather than as emulsified fats."

Arsenic in the animal body, W. H. Bloemendal (*Arch. Pharm., 246 (1908), No. 8, pp. 599–616*).—After administrations of arsenic, post-mortem examinations revealed its presence in all parts of the animal body, its relative predominance being as follows: Nails, hair, spleen, thyroid, skin, lungs, liver, kidney, heart, bones, muscles, sex organs, and brain. In the human body a larger portion of the acid was excreted than in cows, goats, or rabbits. But little arsenic was found in the milk of the cow or goat or in human milk and no traces were found in the fetal circulation of young rabbits.

DAIRY FARMING—DAIRYING—AGROTECHNY.

The influence of nonproteid nitrogenous compounds of feeding stuffs upon milk production, A. Morgen, C. Beger, and F. Westhausser (*Landw. Vers. Stat., 68 (1908), No. 5–6, pp. 333–432; abs. in Fühling's Landw. Ztg., 57 (1908), No. 21, pp. 734, 735*).—A continuation of experiments (E. S. R., 18, p. 978), in which sheep and goats were fed a basal ration supplying on an average about 2.5 kg. protein and 1 kg. fat per 1,000 kg. of live weight. At different periods a portion of the protein, about 09 kg. per day, was replaced by amids and by carbohydrates. The principal amid used was an extract from malt sprouts. The results are summarized as follows:

Yield of milk and milk solids with different protein substitutes as compared with the yield on a protein ration.

Kind of ration.	Milk.	Dry matter.	Nitrogen.	Fat.	Carbohydrates.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Amids	81.9	79.4	77.9	79.0	81.8
Carbohydrates	78.0	75.4	73.2	76.2	78.3
Asparagin	86.3	80.8	86.2	70.5	83.9
Ammonium acetate	93.7	98.9	96.7	.....	90.4

The largest amount of milk and milk solids was obtained with the protein ration. The amids of malt-sprout extract were much inferior in feeding value to those of the plant extract. The different rations had but a trifling effect on the quality of fat when tested with a refractometer.

The protein was better digested when no amids nor carbohydrates were substituted. With asparagin as a substitute the quantity of fat was reduced. During the amid period there was a larger amount of protein in the feces. The authors consider that the amids were changed into indigestible proteids and that this transformation probably took place in the upper part of the small intestine.

The absorption of drugs by milk in the mammary glands (*Arch. Pharm., 246 (1908), No. 8, pp. 593–598; Pharm. Weekbl., 45 (1908), No. 44, pp. 1357–1362; abs. in Chem. Zentbl., 1908, II, No. 21, p. 1742*).—Drugs were administered through the mouth and by hypodermic injections. L. Van Itallie found that physostigmin, pilocarpin, morphin, opium, sodium salicylate, salol, turpentine oil, phenolphthalein, and rhubarb did not appear in cow's milk, but that potassium iodid, arsenic, and fluorescein were present in small quantities. Arsenic, fluorescein, phenolphthalein, and oxymethylanthrachinone were found in the excreta. Mrs. A. Reijst-Scheffer found that when iodin was administered most of it was excreted. Of that portion appearing in the milk nearly all was found in the whey. There were traces in the casein but none in the fat.

A comparison of practical methods for determining the bacterial content of milk, P. G. HEINEMANN and T. H. GLENN (*Jour. Infect. Diseases, 5 (1908), No. 4, pp. 412–420, chart 1*).—Experiments were undertaken in order to promote uniformity in laboratory procedure for comparing the various methods now in use. Many workers favor an incubation temperature of 37° C. because it saves time, but the authors believe that incubation at 20° is superior because a higher count and a better differential count are obtained. At 37° acid formers, which are chiefly of fecal origin, are favored at the expense of the nonacid formers.

"Some milk bacteria of the *Bacterium aërogenes* type form red colonies at first and then later these colonies assume the blue color again. This phenomenon was not observed in dextrose agar. We conclude from this that dextrose is to be preferred as an addition to the medium to lactose.

"Official bacterial standards for milk should include a statement of the methods by which the bacteriological control is to be obtained. Since milk is usually consumed before the results of a bacteriological examination can possibly be reported, a gain of one or even two days is immaterial. The bacteriological and chemical examination of milk ought to be carried on chiefly with the object of improving the whole milk supply of a commonwealth rather than punishing individual offenders. To this end the most accurate and scientific method of examination is the preferable one."

A study of the determination of bacteria in milk in relation to the composition of the media, Z. NORTHRUP and BELL FARRAND (*Michigan Sta. Rpt. 1908, pp. 130–152*).—To determine the media most favorable to the growth of germs in milk, media were prepared of agar, peptone, and salt and divided into four portions, adjusting them to 5°, 10°, 15°, and 20° acid, respectively, with normal sodium hydroxid. Milk from 0 to 6 hours old was used for plating and the accounts were kept at 21° and 37° C. A bacterial count was taken at intervals to ascertain the degree of acidity, the percentage of lactose, and the percentage of peptone most conducive to the growth of the milk germs. The results are summarized in the following table:

Percentage of samples growing best under various conditions at 21° and 37° C.

Temperature.	Degree of acidity.				Lactose content.					Peptone content.					
										Lot 1.			Lot 2.		
	5°.	10°.	15°.	20°.	0°.	1°.	2°.	3°.	4°.	0°.	1°.	3°.	0°.	1°.	3°.
°C.	P. ct.	P. ct.	P. ct.	P. ct.	P. ct.	P. ct.	P. ct.	P. ct.	P. ct.	P. ct.	P. ct.	P. ct.	P. ct.	P. ct.	P. ct.
21.....	5	21	64	10	15	27	22	15	21	22	6	72	35	38	27
37.....	14	22	47	17	20	10	17½	17½	35	27	6⅔	66⅔	35	23	42

As regards temperature, 63 per cent of the samples were found to grow best at 21°, 9 per cent at 37°, and the remainder indeterminate.

"To check up the results obtained by plating the miscellaneous milk organisms, pure cultures of dairy germs (taken from butter), were grown on whey, ordinary and 4 per cent lactose agar.

"Four per cent lactose agar was used in this experiment as it was found to support the growth of the milk germs better than the ordinary (1 per cent) lactose agar, at 37° C. The explanation for this is that the media, in the percentage of lactose, reaches more nearly the composition of milk.

"All media was made according to standard methods, and adjusted to 15° acid. . . .

"The lactic germs grow equally well on ordinary and on lactose agar, while the associative germs prefer the ordinary agar. However, the results are not especially marked in either case."

Bacteria in milk, L. A. ROGERS (*U. S. Dept. Agr., Farmers' Bul. 348, pp. 24, figs. 6*).—This is a reprint from the Yearbook of this Department for 1907 (E. S. R., 20, p. 275).

Investigations on the bacterial content of dried milk, A. KOSSOWICZ (*Ztschr. Landw. Versuchsw. Österr., 11 (1908), No. 9, pp. 719–724; abs. in Chem. Zentbl., 1908, II, No. 18, p. 1531*).—Drying reduces the bacterial content to some extent. *Bacillus sinapivagus, B. prodigiosus,* and *B. fluorescens liquefaciens,* however, are not destroyed. Dried milks may become reinfected if not kept in closed vessels.

Milk and its products as carriers of tuberculosis infection, E. C. SCHROEDER (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 183–199; Circ. 143, pp. 183–199*).—This is a paper presented at a meeting of the New York Milk Committee, New York, April 11, 1908. The author presents evidence to show that tubercle bacilli are frequently present in milk delivered by dairymen to their city consumers; that the manner in which tubercle bacilli are eliminated from the bodies of tuberculous cattle offers a strong reason to suspect that they will contaminate milk; that the presence of tubercle bacilli certainly insures their presence in cream, ice cream, butter, and cheese made from it; and that we have no satisfactory reason for assuming that tubercle bacilli in milk and other dairy products are harmless to human beings. References to the literature of this subject are appended.

Some important factors in the production of sanitary milk, E. H. WEBSTER (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 161–178, figs. 12; Circ. 142, pp. 161–178, figs. 12*).—A popular article on this topic. The differences between a sanitary and unsanitary dairy equipment are illustrated. Other topics treated are the methods of caring for milk, the score-card system of dairy inspection, the health of the cows and the attendants, and the purity of the water supply in dairies.

The classification of milk, A. D. MELVIN (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 179–182*).—The substance of this article is contained in Circular 114 of the Bureau of Animal Industry previously noted (E. S. R., 19, p. 372).

The chemistry of milk and milk products in 1907, M. SIEGFELD (*Chem. Ztg., 32 (1908), Nos. 57, pp. 673–675; 58, pp. 686–688*).—A review of the literature of European investigations on the chemistry of milk for that year.

On the characteristics of butter, L. HOTON (*Rev. Internat. Falsif., 19 (1906), No. 4, pp. 115, 116; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 10, pp. 611, 612*).—Fats were compared with their fatty acids by means of an Abbé-Zeiss refractometer. The difference between the two figures in the case of butter was from 10 to 11, for oleomargarine 13 to 14, and for cocoa butter 15 to 16. The author reports a number of determinations on the liquid and semisolid portions of butter. The Reichert-Meissl number for the liquid portion was 31, for the semisolid 28.5. Similar tests were also made of fresh butter, of butter that had been preserved for several years, and of butter exposed to the air.

On the composition of Dutch butter made in the creameries placed under state control (*Gen. Dir. Agr. Min. Agr., Indus. and Trade [Netherlands]. [Circ.], 1908, Oct., pp. 3*).—A classification of 1,667 samples of butter, according to their Reichert-Meissl number.

Milled butter (*New Zeal. Dairyman, 14 (1908), No. 2, p. 69*).—Milled butter is a term used in New Zealand for butter that has been mixed or blended, as is practiced in Holland and Denmark. By mixing butters from different dairies the output is made more uniform.

The care and testing of Camembert cheese, C. THOM (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 339–343; Circ. 145, pp. 339–343*).—The topics treated in this article are the proper appearance of ripe Camembert cheese; the variations in flavor among really good cheeses, corresponding to the widely different tastes of consumers; how to test a cheese to determine its degree of ripeness without cutting it; and how cheeses not fully ripe should be handled by dealer and consumer to get the best results.

Methods of paying for milk at cheese factories, L. L. VAN SLYKE (*New York State Sta. Bul. 308, pp. 469–506*).—This bulletin discusses the different methods of paying for milk at cheese factories and, as in former bulletins (E. S. R., 9, p. 181), "the exclusive use of the milk-fat basis is advised, since it is the method which takes into consideration composition and quality of cheese in connection with yield of cheese, thus providing an equitable and simple system."

Paying for milk at Cheese factories, F. H. HALL (*New York State Sta. Bul. 308, popular ed., pp. 7*).—A popular edition of the above.

Creamery accounting, J. A. VYE (*Chicago Dairy Produce, 15 (1908), No. 28, pp. 20, 22, 23*).—The author outlines a plan for a uniform system of keeping accounts in cooperative creameries.

The cow-testing association in dairying, P. V. MARIS (*Pacific Homestead, 18 (1908), No. 17, pp. 1, 2, 19*).—The history of cow-testing associations is briefly reviewed. The author advocates their formation in all dairy communities because of their acknowledged value in improving the dairy herds wherever they have been formed.

The dairy industry in the South, B. H. RAWL, D. STUART, and G. M. WHITAKER (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 307–337, figs. 10; Farmers' Bul. 349, pp. 37, figs. 10*).—This is an account of the systematic field work by this Department to develop the dairy industry in the Southern States, which was begun in 1906, and is carried on in cooperation with the State experiment stations, agricultural colleges, and State departments of agriculture. D. Stuart discusses Southern Markets for Dairy Products, G. M. Whitaker The Milk Supply of Southern Cities, and B. H. Rawl Why Dairying is Undeveloped in the South. It is pointed out that although the demand for milk and milk products in the South is not supplied by home products, dairying has hitherto been unprofitable because too many dairymen keep inferior cows, feed them on purchased feeds, and produce an inferior grade of milk and butter.

[The dairy industry in foreign countries] (*Mo. Cons. and Trade Rpts. [U. S.], 1908, No. 339, pp. 103–110*).—In northern Spain the Cantabrian slopes are well suited for dairy farming, but the lack of capital is the leading obstacle to the development of the industry. Primitive methods are employed in dairying. Special kinds of cheese manufactured in this region, notably Cabrales, a kind similar to Roquefort, have a ready sale in Spain, such being equally the case with butter made in Asturias and Santander.

In Ireland, the yield of milk per cow is lower than in most other countries. Comparative statistics show that the value of dairy products in Canada is increasing. Vice-consul Doyle, of Colombo, Ceylon, thinks that the ravages of typhoid fever could be reduced if a sanitary milk bottle were used in the delivery of milk. In spite of its natural advantages for cattle raising, Brazil imports large quantities of dairy products. The dairying district has increased during the past few years and there is a good opening for American

dairy machinery. The greatest obstacles for further development are lack of transportation facilities and the prevalence of cattle diseases. Colombia is stated to be a wonderful cattle country, but the milk produced is simply for local consumption or made into a crude white cheese. Modern dairy apparatus is needed.

Dairy cattle in far away India, P. A. YODER (*Kimball's Dairy Farmer, 6 (1908), No. 23, pp. 24, 25, figs. 3*).—A popular account of dairying in that country. At the government dairy farm in Poona the Aden is considered the best breed of zebus. The Delhi breed of buffaloes is also liked for dairy purposes. Some are of large size and weigh a ton or more. The feeds consist of native hay, bran, oil cake, cotton seed, dahll (pigeon pea), and phool (husks from the dahll). Some of the black cows or buffaloes give 25 lbs. of milk per day.

The dairying industry, G. S. THOMSON (*London, 1907, pt. 1, pp. 263, pls. 53, figs. 3, dgms. 2*).—This is a general treatise on dairying, with special reference to the milk and cream supply as applied to the conditions in Queensland, Australia. In this, the first part of the work, the topics discussed are the composition and secretion of milk, metropolitan milk supply, dairy science for the practical farmer, and modern utensils used in dairying.

Milk booklet, R. OSTERTAG and T. HENKEL (*Schr. Deut. Milchw. Ver., 1908, No. 37, pp. 67, figs. 6½*).—This pamphlet treats in a popular manner of the structure of the udder, the excretion of milk, the methods of milking, and influences that affect milk secretion.

Tests of three devices for purifying milk, K. H. M. VAN DER ZANDE (*Off. Organ Alg. Nederland. Zuivelbond, III, No. 17; abs. in Milch. Ztg., 37 (1908), No. 47, pp. 554–556, figs. 3*).—Descriptions are given of a milk filter and two styles of milk sieves exhibited at the International Agricultural Exposition at The Hague, September 1907.

[Some appliances for use in dairy bacteriology], O. RAHN (*Michigan Sta. Rpt. 1908, pp. 125, 126, fig. 1*).—The author keeps tubes of media in large glass jars with covers, containing 70 to 150 test tubes. The bottom of the jar is covered with excelsior and is kept moist by ½ per cent mercury bichlorid solution, which stands about 1 cm. high in the jar.

A convenient Petri dish rack is described. It is made from strips of galvanized sheet iron, riveted together to stand the heat of the hot air sterilizer. One of the side strips may be opened by a hinge and may be fastened with a hook.

[Experiments in dairying and agrotechny], H. A. HARDING and L. L. VAN SLYKE (*New York State Sta. Rpt. 1907, pt. 3, pp. 110, 111, 114, 115, 117, 118, 163–220, 233–237*).—A summary of the more important results found at this station during the first 25 years of its work.

The best temperature at which to run milk through a continuous pasteurizer when tuberculous germs are suspected is 185°. The amount of protein in mottled butter is greater in the light portions and is the cause of the lighter color. Many experiments as to the composition of milk and its relation to the yields of cheese were made. In the process of cheese making the fat lost in the whey is independent of the percentage of fat in the milk. The casein is lost in the form of small particles of curd. Milk for cheese making should be paid for according to the percentage of fat in the milk. The beneficial effects of covering cheese with paraffin and curing at low temperatures were demonstrated. A number of factors influenced the amount of acid taken up by the casein during ripening. In ripening the insoluble proteid is eventually changed to a water-soluble form. A fishy flavor in cheese was found to be due to a physiological abnormality in one of the cows. A bitter flavor in Neufchâtel cheese

was caused by a germ. Sweet flavors in Cheddar cheese are due to yeasts. *Bacillus rudensis* is the cause of rusty spot.

The swelling of canned peas was due to a single species of bacteria. Studies were made on the chemistry of apple juice and homemade cider vinegar.

Process for transforming milk into a solid substance, G. V. Frye (*French Patent 389,835, May 2, 1908; abs. in Jour. Soc. Chem. Indus., 27 (1908), No. 20, p. 1026*).—By a process which is patented, milk is subjected to the action of an electric current, then oxidized, and molded into various shapes and dried. Collodion and oil may be added to produce elastic substances. The product is chiefly of use as an electrical insulator.

Preservation of unfermented fruit juice (*Oklahoma Sta. Rpt. 1908, p. 71*).—Directions are given for the preservation of the unfermented juice of apples and grapes.

Sulphurous acid in wine making, E. Dupont (*Rev. Vit., 30 (1908), Nos. 767, pp. 230–233; 768, pp. 253–257; 769, pp. 284–289; 770, pp. 309–312*).—A series of articles written for the use of the practical wine maker, and treating in a popular manner investigations previously reported (E. S. R., 19, p. 980).

Refrigeration in enology, B. Haas (*Rev. Vit., 30 (1908), No. 780, pp. 589–592*).—A popular article on the influence of temperature in wine making.

The preparation of wine in Algeria, J. Foussat (*Gouv. Gén. Algérie, Dir. Agr., Inform. Agr., Bul. 5, pp. 41, figs. 10*).—A popular account of wine making, with special reference to Algerian methods.

VETERINARY MEDICINE.

The effect of certain diseases and conditions of cattle upon the milk supply, J. R. Mohler (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 145–159*).—The diseases considered include tuberculosis, which is deemed probably the most important disease of cows from the standpoint of public health, actinomycosis, botryomycosis, foot-and-mouth disease, anthrax, cowpox, rabies, mammitis (mastitis or garget), gastro-enteritis, milk sickness, and septic or febrile conditions. Abnormal appearance and conditions of milk to be guarded against, such as slimy, stringy, or ropy milk, bitter milk, colored milk, poisonous milk, etc., are also considered.

The author makes the following recommendations as the basis for laws and for regulations by public health officers: "That all cows on dairy farms producing milk for market purposes be tagged, tattooed, or otherwise marked for identification.

"That all milk produced on such dairy farms shall either come from tuberculin-tested cattle, which shall be retested at least once a year, or be subjected to pasteurization under the supervision of the health authorities in case the herd is not tuberculin tested.

"That no additions to any herd, whether the herd has been tested or not, shall be made in the future without subjecting the additional cattle to the tuberculin test.

"That no license for the sale of milk shall in future be granted except to applicants having herds free of tuberculosis.

"That the milk of cattle showing any of the udder affections above mentioned, or anthrax, rabies, gastro-enteritis, septic conditions, or clinical symptoms of tuberculosis, shall not be utilized as human food, even though the milk be pasteurized. Milk from cows 15 days before and 5 days after parturition and that from animals receiving . . . deleterious medicaments or foodstuffs . . . shall likewise be excluded.

"That veterinary inspectors of the health department make frequent visits to dairies having untested herds, in order that they may discover all advanced cases of tuberculosis, or udder tuberculosis, as early as possible.

"That the various States pass laws granting an appropriate indemnity to all owners of tuberculous cattle which come under their respective jurisdiction, the said animals to be slaughtered in abattoirs having Federal inspection."

Foot-and-mouth disease, D. E. Salmon and T. Smith (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 141, pp. 8*).—This is a reprint with slight revision by D. E. Salmon and J. R. Mohler from the Special Report on Diseases of Cattle, previously noted (E. S. R., 16, p. 708).

Surra, R. J. Needham (*Jour. Dept. Agr. So. Aust., 12 (1908), No. 3, pp. 220–223*).—Attention is called to the importance of a strict inspection of all foreign vessels arriving at ports to prevent animals being landed from countries from which surra and other infectious diseases might be introduced.

The influence of heredity upon tuberculosis, A. Latham (*Lancet [London], 1908, II, No. 21, pp. 1512–1514*).—Some of the conclusions drawn by the author following a general survey of the subject are as follows: "The hereditary transmission of the germ is so infrequent that it is a negligible factor.

"The incidence of tuberculosis depends in the main on two factors—(a) exposure to infection, which in turn is governed by the dose received and the virulence of the particular strain of bacillus; and (b) the undermining of the resistance of the individual by insanitary conditions and by disease. . . .

"There is some evidence to suggest that the diminishing incidence and mortality of the disease may be in part due to a partial immunity inherited in the course of generations from tuberculous ancestors in whom the disease has been cured.

"The theory that there is an inherited predisposition to tuberculosis is based on insufficient evidence."

The eradication of tuberculosis in cattle, A. D. Melvin (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 209–214*).—This paper was presented at the annual convention of the American Veterinary Medical Association, held at Kansas City, Mo., in September, 1907, and has been previously abstracted (E. S. R., 19, p. 199).

The tuberculin test: Its method of application, value, and reliability, J. R. Mohler (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 201–207*).—This is a discussion of the tuberculin test, its origin, application, value, and reliability. It is stated that tuberculin is harmless for healthy animals and that it interferes in no way with the production of milk. The disposal of and indemnity for reacting animals is briefly considered, and a summary of directions for making the test is appended.

The tuberculin test of cattle for tuberculosis, J. R. Mohler (*U. S. Dept. Agr., Farmers' Bul. 351, pp. 8*).—This is a reprint of the above article.

The use of tuberculin in controlling tuberculosis in herds, C. J. Marshall (*Amer. Vet. Rev., 34 (1908), No. 2, pp. 220–227*).—A paper presented at the International Congress on Tuberculosis, held at Washington, in which a detailed account is given of the use of tuberculin. Attention is called to the importance of disinfection and sterilization of instruments, clothing, etc., before and during the time of making the test that contagious abortion, tuberculosis, and other contagious diseases may not be carried from animal to animal or from herd to herd.

The ophthalmo-reaction to tuberculin in cattle, K. Wölfel (*Berlin. Tierärztl. Wchnschr., 1908, No. 21, pp. 369–372; abs. in Vet. Rec., 21 (1908), No. 1058, p. 239*).—The author concludes that animals which react to the sub-

cutaneous injection of tuberculin do not always give the ocular reaction. The subcutaneous injection does not exercise any perceptible influence on a subsequent application of the opthalmic test. The congestion of the conjunctiva should take place 12 to 18 hours after the application of the tuberculin in the eye. It is not accompanied by a rise of temperature.

The epizootic diarrhea of calves and meat poisoning, V. Fally (*Rev. Gén. Méd. Vét., 11 (1908), No. 130, pp. 575–583*).—The author has studied the micro-organisms to determine the relations existing between epizootic diarrhea, a wide-spread affection of young cattle, and the poisoning that has frequently been observed to follow the consumption of veal. Calves affected with the disease were killed in extremis at the Brussels abattoir and the bacilli studied. When their cultural characters and agglutinin reactions were compared with those of the meat poisoning bacilli a close resemblance was found, it being impossible to distinguish the paracolon bacilli encountered in the calves from those belonging to the first enteritidis subgroup.

The dehorning of cattle, R. W. Hickman (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 297–306, figs. 6; Farmers' Bul. 350, pp. 14, figs. 6*).—The author here furnishes directions for the guidance of the dairy farmer or other cattle owner in the dehorning of cattle. Methods of dehorning as practiced on the range are briefly described, as is also the prevention of horn growth in young calves.

The inoculation of sheep against blue tongue and the results in practice, A Theiler (*Transvaal Agr. Jour., 7 (1908), No. 25, pp. 30–39*).—A report of the results of inoculation with virus obtained after the eleventh generation from sheep, a brief report of which has been previously noted (E. S. R., 20, p. 679). Between September, 1907, and February, 1908, over 90,000 doses of this vaccine were distributed in the Transvaal and over 100,000 doses among the other South African colonies. The absence of heavy rain during the season appeared to corroborate the theory that the carrier of the blue tongue micro-organism is a biting insect which requires water for its development. Detailed directions are given for the use of the vaccine, which has proved eminently successful.

Tuberculosis of hogs: Its cause and suppression, J. R. Mohler and H. J. Washburn (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 215–246, pls. 4; Circ. 144, pp. 215–246, pls. 4*).—This article has been substantially noted from another source (E. S. R., 19, p. 199).

Embryonal adenosarcoma of the kidney in swine, L. E. Day (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 247–257, figs. 8*).—The author reports the discovery of these neoplasms during the course of meat inspection work. They are said to usually escape notice until the post-mortem examination is made. "They appear as a large, encapsulated, irregular mass in the sublumbar region, extending perhaps from the diaphragm to the border of the pelvic cavity. Usually only one kidney is involved, but in some cases both are affected. When but one kidney is involved there is no predilection as to the side, the left kidney being affected as often as the right, and vice versa. These growths are comparatively rare and occur only in young hogs up to 18 months old. They grow very rapidly and may become very large. Recently one of these tumors weighing 60 lbs. was observed by the writer in a Chicago abattoir.

"The writer has never found such neoplasms in cattle or sheep and has no information that they have been observed in those animals by others."

The results of a histological study of these tumors are presented.

The leucocytes of the horse in health and disease, M. E. Tabusso (*Arch. Sci. R. Soc. Accad. Vet. Ital., 6 (1908), No. 3–4, pp. 33–49; abs. in Bul. Inst. Pasteur, 6 (1908), No. 17, p. 766*).—The original data here given include only investigations of the leucocytes of the well horse. In 1 cmm. of blood the author

found in the castrated male an average of 8,135 and in the female 7,140. The extremes were for the male 6,900 to 9,300 and for the female 6,200 to 7,900. The digestive period is accompanied by hyperleucocytosis.

Strangles and glanders, C. E. Gray (*Transvaal Agr. Jour.*, 7 (*1908*), *No. 25, pp. 25–30*).—Strangles or nieuwe ziekte and glanders are frequently confused in South Africa by horse owners. As such errors may lead to considerable loss and be attended by severe consequences, the two diseases are described the most marked points of difference indicated.

The colic of horses, S. Wall (*Die Kolik des Pferdes. Stockholm, 1908, pp. VII+179, figs. 47, charts 4*).—This study is based upon the records of cases at the clinic in Stockholm.

In 834 autopsies, the cause of death of 31.6 per cent was due to volvulus of the colon, 29.4 per cent to other displacements, including hernias, volvulus of the mesenteries, etc., and 23 per cent to ruptures of the stomach and intestines. During 15 years, 6,078 cases were recorded, of which 503 or 8 per cent resulted in death. The length of the attack in the cases which recovered was from 12 to 24 hours in 56 per cent and 36 to 48 hours in 40 per cent. In the fatal cases 61 per cent died in 12 to 24 hours.

The author classes colic under two heads—the first as chymostase or stoppage of the contents of the stomach and small intestines, and the second coprostase or stoppage in the colon, cecum, and rectum.

Influenza in horses, S. S. Cameron (*Jour. Dept. Agr. Victoria, 6 (1908), No. 10, pp. 619–624*).—Influenza of horses is reported as epidemic in Melbourne and its suburbs. The present visitation is apparently more marked both in the proportion of the horses attacked and in the severity of its effect than that of 1890.

Dermal mycosis associated with sarcoptic mange in horses, A. D. Melvin and J. R. Mohler (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 259–277, pl. 1, figs. 6*).—This paper was presented at the annual convention of the American Veterinary Medical Association held at Kansas City, Mo., September, 1907.

The disease here described was first noticed in 1901 among horses on the Umatilla Indian Reservation near Pendleton, Oreg., at which time 2,500 out of 6,000 horses kept on the reservation were more or less affected. A Fusarium causing the disease was grown on a potato medium and found to be the *Fusarium equinum*, described by Norgaard. "All ages and breeds of horses seem equally susceptible, as are both sexes, but there is considerable difference in the susceptibility of well and poorly nourished animals, since weak, impoverished, unclean, and neglected horses are more frequently attacked than horses in better condition. The animals stand around the rubbing post all day indifferent about eating, and finally become anemic and debilitated to such an extent that they die."

The morphology and cultural characteristics of the fungus are considered at length. Kerosene is said to have been used first as a remedy but later more satisfactory results have been obtained from coal tar dips. Experiments made by the Bureau of Animal Industry with a dip composed of sulphur and light dynamo oil in the proportion of 1 lb. of the former to 1 gal. of the latter have given good results.

Infectious anemia or swamp fever of horses, J. R. Mohler (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 138, pp. 4*).—In this circular the etiology, diagnosis, prognosis, post-mortem appearance, and treatment of infectious anemia are briefly considered.

The disease is due to an ultravisible virus which is transmissible to horses, mules, and asses by subcutaneous injection of blood serum. The incubation period following the inoculation of the virus is said to vary from 10 days to

1½ months. The virus has been found active in the carcass of an affected animal 24 hours after death. The probability of the disease being transmitted by flies, mosquitoes, internal parasites, etc., is receiving careful investigation. The prognosis of the disease is very unfavorable, veterinarians in different sections of the country where it is prevalent having reported a mortality of 75 per cent or higher.

Treatment thus far has been far from satisfactory. Investigations are now in progress with a view of producing a protective vaccine or serum.

Researches upon the piroplasmosis of horses in 1907, A. Belizer and Markinovski (*Abs. in Bul. Inst. Pasteur, 6 (1908), No. 17, p. 784*).—Investigations were pursued by the authors in the province of Riotan, Russia.

All of the horses attacked were found to be infested with the species of tick determined by Neumann as *Dermacentor reticulatus*. Native horses are immune while imported horses are very susceptible and often die with the disease. In experiments in which diseased animals were treated with different chemical products, the best results were obtained from injections of a solution of bichlorid of mercury and sodium. Atoxyl proved to be much less efficient. The authors found the different stages of Piroplasma described by Koch and Christophers in the blood and intestines of the tick, and a typical disease was produced by injections of blood from adult ticks. The inoculation of blood from immune horses gave good results and the authors state that immunity can be produced by the injection of small quantities of infected blood, which produce mild cases of the disease.

The administrative control of anthrax, F. W. Eurich (*Jour. Roy. Sanit. Inst., 29 (1908), No. 10, pp. 597–603*).—Examinations made of over 600 samples of dust derived from soil have failed to convince the author that this source is an important factor in the dissemination of the disease in man.

Anthrax has, however, been found in 15 per cent of the blood-stained wool and hair examined.

The theory and practice of antirabic immunization, W. F. Harvey and A. McKendrick (*Sci. Mem. Med. and Sanit. Depts. India, n. ser., 1907, No. 30, pp. 2+43, pls. 2*).—The authors have summarized their conclusions as follows: "(1) There is evidence of a direct proportion between infectivity and duration of desiccation of rabies nerve material; (2) there is no evidence for the existence of a rabies toxin; (3) the quantity of living fixed virus and the duration of time of administration are the only points which need be considered in making out a scheme of antirabic treatment; and (4) there is great advantage in using fresh material in antirabic immunization (as in Höyges' or Ferrans' methods) over dried or heated material, because the former method involves the introduction of less injurious foreign nerve substance and is more accurate as regards dosage than the latter."

The curative influence of extracts of leucocytes upon infections in animals, P. H. Hiss, Jr. (*Jour. Med. Research, 19 (1908), No. 3, pp. 323–397*).—Experiments were conducted in which the animals used for obtaining leucocytes and for most of the experiments were rabbits. The author concludes that "it does not seem unlikely that extracts of leucocytes (polymorphonuclear and mononuclear), and possibly of the blood-forming organs, furnish us with means of combating infections incited by those micro-organisms generally looked upon as giving rise to endotoxin poisonings, and which have steadily refused to yield to the action of immune sera alone."

Annual report on progress in the study of the pathogenic micro-organisms, P. von Baumgarten and F. Tangl (*Jahresber. Path. Mikroorgan., 22 (1906), pp. XII+964*).—The authors present in this work a review of the investigations made during the year 1906 of the pathogenic bacteria, fungi, and protozoa,

In this work they have been assisted by various specialists. Bibliographies are given with each division and complete author and subject indexes are appended.

A preliminary account of the Acanthocephales of mammals. A. Porta (*Arch. Par., 12 (1908), No. 2, pp. 268–282*).—Thirty-three species representing the genera Echinorhynchus, Chentrosoma, Corynosoma, Bolbosoma, and Gigantorhynchus are noted.

The trypanosomes of mosquitoes and their relations to the Hæmoproteus of birds. D. Mezincesco (*Compt. Rend. Soc. Biol. [Paris], 64 (1908), No. 19, pp. 975, 976*).—In the intestines of Culicidæ, particularly *Culex richardi* and *C. fasculus* taken in Roumania, the author found *Crithidia fasciculata* to be very common and probably sometimes pathogenic. *Trypanosoma culicis* was rarely found. The inoculation of cultures of this trypanosome into laboratory animals, wild pigeons, and turtle doves resulted negatively.

Further results of the experimental treatment of trypanosomiasis; being a progress report to a committee of the royal society. H. G. Plimmer and H. R. Bateman (*Proc. Roy. Soc. [London], Ser B, 80 (1908), No. B543, pp. 477–487*).—A continuation of experiments in which rats affected with nagana and surra and dogs with surra, were treated with compounds of arsenic, antimony, and mercury.

From examinations of rats which had been inoculated with nagana and treated with sodium antimony tartrate it appears that the bone marrow is the place where trypanosomes can live the longest and that the liver is also a place where they can find protection. This is stated to be borne out by experiments made by the authors upon trypanosomiasis in birds.

Plain facts about the hookworm disease (*Prog. Farmer, 23 (1908), No. 43, pp. 4, 5, 16*).—A popular account of the hookworm and the disease which it produces in man.

Rocky Mountain spotted fever. A. A. Robinson (*Med. Rec. [N. Y.], 74 (1908), No. 22, pp. 913–922, figs. 2, map 1, charts 6*).—A general review of the literature with a report of a case. This disease is shown to have been reported from Montana, Idaho, Wyoming, Nevada, Oregon, Washington, Utah, and Colorado. It is suggested that the mountain mosquito as well as *Dermacentor occidentalis* may transmit the disease obtaining the virus from the same source. A map is given showing the distribution of the disease and a bibliographical list is appended.

The development of the Leishman-Donovan parasite in Cimex rotundatus. W. S. Patton (*Sci. Mem. Med. and Sanit. Depts. India, n. ser., 1908, No. 31, pp. 2+25, pls. 2*).—"In the female as well as in the male bedbug (*C. rotundatus*) the parasites have by the third day passed through all the intermediate stages of development described up to the formation of the mature flagellates. Rapid multiplication by rosette formation is a characteristic feature of the development of the parasite in the bedbug. As the male bug sucks blood it probably plays as important a rôle in the transmission of the disease as the female bug.

"The infection acquired by the bug varies considerably, some ingesting large numbers of parasites, others only a few; and there is no evidence at present to show that the development in the bug depends on variations in the temperature.

"The tendency that the disease has to linger in a house for a long time is probably explained by the fact that the parasite may remain in the midgut of the bug for several days before beginning to develop, and, as the nymphs which take from 7 to 10 weeks to arrive at maturity, may ingest the parasites shortly after hatching, and as a rule feed only once between each molt, the

infection may remain for a considerable time in a house; there is no evidence at present to support the view that the infection is inherited by the bug."

Tenotomy of the perforatus in recidiving or incurable sprains of tendons, A. QUERRUAU (*Rec. Méd. Vét., 85 (1908), Nos. 11, pp. 349–357; 13, pp. 412–420; abs. in Amer. Vet. Rev., 34 (1908), No. 2, pp. 151–153*).—As a result of experiments continuing for 15 years, the author, an army veterinarian, concludes that the advantages that the tenotomy of the perforatus presents are such that it is the most radical and economical treatment to resort to in cases of recidiving or incurable sprains of the tendons, of the radial reinforcing band, and of the suspensory ligament and even in the relief of some incurable lameness due to traumatic synovitis of the great sesamoid sheath.

Plants poisonous to stock. The wallflower poison bush, J. C. BRÜNNICH (*Queensland Agr. Jour., 21 (1908), No. 2, pp. 89–91*).—Experiments made with alkaloidal extract of *Gastrolobium grandiflorum* which demonstrate the poisonous nature of the plant are reported.

Disinfection and commercial disinfectants, M. P. RAVENEL and K. W. SMITH (*Wisconsin Sta. Bul. 166, pp. 3–19, figs. 9*).—In this bulletin the author discusses various disinfectants and gives directions for their use. A number of commercial disinfectants were tested, organisms being exposed to different strengths at room temperature. They were then removed to fresh culture media and incubated at 37° C., the observations being kept up 72 hours.

"The results of these tests showed that a 2½ per cent solution of cresol, international dip, carboleum, chloro-naphtholeum disinfectant, zenoleum, germol, and daytholeum destroyed the germ causing pus and abscess (*Staphylococcus pyogenes aureus*), hog cholera, and the typhoid germ in 1 minute in every instance. A 10 per cent solution failed to destroy anthrax spores even after 3 hours exposure.

"Car-sul destroyed the germ causing pus and abscess, and hog-cholera germs in a 2½ per cent solution in 1 minute in every instance. A 10 per cent solution failed to destroy anthrax spores even after 3 hours exposure. A 1 per cent solution failed to kill the typhoid germ after 2 minutes exposure, destroyed it after 6 minutes exposure, but failed to kill anthrax spores.

"Dr. Robert's disinfectall killed the germ causing pus and abscess, and typhoid germs in a 2½ per cent solution in 1 minute. It failed to kill the hog-cholera germ in this strength in 1 minute, but killed it in 3 minutes. It failed to destroy anthrax spores after 24 hours exposure."

Antiformin, a disinfectant which dissolves bacteria, UHLENHUTH and XYLANDER (*Berlin. Klin. Wchnschr., 45 (1908), No. 29, pp. 1346–1349; abs. in Bul. Inst. Pasteur, 6 (1908), No. 20, p. 936*).—Antiformin is a trade name given to the alkaline liquid prepared by the addition of caustic soda to a solution of sodium hypochlorite (eau de Javelle). It has been used for some time as a disinfectant, especially in breweries for rapidly and thoroughly cleansing vats and pipes.

The authors have found that a solution of 2 to 5 per cent will destroy most bacteria including *Bacterium suisepticus* within 5 minutes. Spores of anthrax, however, resist its action. The disinfectant properties have remained for several months when kept in the laboratory. Even in dilute solutions antiformin was found to dissolve most of the bacteria without leaving a residue. The tubercle bacillus and other acid-proof bacteria show a remarkable resistance to its action even in concentrated solutions, and attempts have been made to utilize this fact in the isolation of a pure culture of the tubercle bacillus from sputum. Toxins and endotoxins have been destroyed by comparatively weak solutions. The authors recommend antiformin for disinfecting and deodorizing

excreta, and for disinfecting hands, wounds, and the skin for cutaneous diseases. It is also said to be of value in destroying the bacteria of potable water.

Cremating furnace, C. E. MARSHALL (*Michigan Sta. Rpt. 1908, pp. 122–125, dgms. 3*).—After having had grates of a cremating furnace burn out quite frequently it was found that 1¼ in. gas pipe could be used to support the material without such loss. Illustrations accompany the plans given of the cremating furnace.

RURAL ENGINEERING.

Irrigation in Wyoming, C. T. JOHNSTON (*U. S. Dept. Agr., Office Expt. Stas. Bul. 205, pp. 60, figs. 22, maps 3*).—The principal purpose of this bulletin is to present to parties contemplating settlement general information regarding the opportunities for settlement, the cost of land and water and of establishing homes on these lands, and regarding the crops grown. Much of the data deals with the geographic, economic, and climatic conditions.

It is stated that "probably no locality in the world is situated to control as many drainage basins as Wyoming," and these are discussed. Future development is deemed to be possible along every stream in the State where storage works may be provided. Approximately 1,000,000 acres of land are now irrigated, and with the total annual river discharge of 11,000,000 acre-feet this may be increased to 5,000,000 or 6,000,000 acres. The extent of irrigated lands and their products are discussed, reports from farmers relative to profits derived from various crops being given.

A large part of the bulletin is devoted to specific information regarding the irrigation enterprises affording opportunities for settlement. Following this suggestions are given as to the capital a settler should have, and the items of expense incidental to successful irrigation farming. In the latter connection estimates submitted by representatives of private projects are given.

The bulletin includes also a summary of the laws governing the use and control of water and their application, an account of the procedure under the Carey Act, and a few remarks as to the prospects for the future of irrigation farming in the State.

A report upon the drainage of agricultural lands in the Kankakee River Valley, Indiana, C. G. ELLIOTT (*U. S. Dept. Agr., Office Expt. Stas. Circ. 80, pp. 23, figs. 3*).—The problem presented here was to remedy the conditions in the lower Kankakee Valley arising from the isolated and localized attempts at improvement in the upper valley. The valley, its topography, the nature of the drainage problem, and the progress and methods pursued in attempting the improvement are briefly described, followed by a discussion of three possible plans for completing the reclamation. The one deemed to be best adapted to the situation is to straighten and enlarge the channel along the line of most direct and greatest slope. Descriptions of this line which was surveyed, of the Yellow River and a discussion of its influence on the overflow conditions, and other factors affecting the determination of the required size of channel are given, together with tabulated data pertaining to the plan and estimates of cost.

It is stated that no attempt has been made to discuss fully the engineering and economic features of the work, but rather "to bring before the owners of the valley lands the facts which are of most vital interest at this time, and to invite their consideration and criticism of the plan." . . .

Examples of large laterals and subdistricts which are necessary adjuncts to the scheme proposed are given at the end of the circular.

A report upon the drainage of the agricultural lands of Bolivar County, Mississippi, W. J. McEatiiron and S. H. McCrory (*U. S. Dept. Agr., Office Expt. Stns. Circ. 81, pp. 28, fig. 1*).—This report embodies the surveys, investigations, and plans for the drainage of 140,250 acres of land which is damaged by overflows from streams and bayous in the Yazoo Delta in Bolivar County, Miss.

The general topographic features and the soil and climatic conditions are discussed in their relation to the drainage of the locality. The plans, which contemplate the improvement of the natural drainage channels by cleaning, enlarging, and cutting off bends, are supplemented with estimates of quantities and costs and suggestions as to the manner of doing the work. The survey data given in the report include a list of bench marks established.

The reclamation of waste lands in the Netherlands (*Verslag. en Meded. Dir. Landb. Dept. Landb., Nijv. en Handel, 1908, No. 6, pp. 7–82*).—Detailed statistics of the reclamation of such lands are given. These show that from 1897 to 1907, 90,440 acres of waste land were reclaimed in the Netherlands, nearly one-third of which was wooded land and the remainder arable and grass land; 1,390,000 acres were still unreclaimed in 1907.

The principal causes of the awakened interest in the work of reclamation are the more extensive use of artificial manures, the extension of agricultural and silvicultural knowledge, the higher prices of agricultural products, and the greater interest in everything connected with agriculture and reclamation.

The economic effect of this reclamation work has been to increase the rate of wages and to reduce the number of unemployed in winter. Agriculture has benefited by the acquisition of more grass land.

The author takes up the various provinces and discusses the kinds of waste lands, the purposes for which reclamation is carried on, the manner of reclamation, the circumstances which help or hinder the work, the results and their influence.

The Netherlands Moor Society has had a large share in the work of reclamation.

Reservoirs for irrigation, water-power, and domestic supply, J. D. Schuyler (*New York and London, 1908, 2. ed., rev. and enl., pp. XXVI+573, pls. 7, figs. 381*).—This is a second edition (E. S. R., 13, p. 194) in which the contents have been revised and considerably augmented by new material. Hydraulic-fill dams are treated more fully, there being over 100 pages, including illustrations, devoted to the subject. There are two new chapters, one on reenforced concrete dams, and one on structural steel dams. Another addition is a set of profiles of the leading and better known masonry dams, drawn to a uniform scale for graphical comparison.

Farm methods of applying land plaster in western Oregon and western Washington, B. Hunter (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 22, pp. 14, figs. 10*).—This discusses briefly the quantity of plaster to apply for the best results and the saving effected by a careful and uniform distribution. The larger part of the circular is occupied by a description of three implements used by farmers for distributing plaster, showing the construction in detail, with drawings.

The value of land plaster in increasing the yield of leguminous crops in this section of the country, the benefits of uniform distribution, and the way to secure this by the use of implements are briefly discussed.

Trials of potato and beet harvesters, 1907, C. V. Birk and M. Dall (*Tidsskr. Landökonom., 1908, No. 6, pp. 337–350*).—Three potato harvesters, one potato plow, and three beet harvesters were included in the trials. Descrip-

tions of the machines with illustrations, and the conclusions of the judges with reference to their merits are given in the case of each machine.

Trials of self-binders and mowing machines at Constantinsborg, 1908, M. Dall (*Tidsskr. Landökonom., 1908, No. 12, pp. 585–615*).—Several machines of different manufacture were tested in cutting rye and oats and the amount of power required was determined. In addition, trials were made of five types of combined grain harvesters and mowing machines.

The repair of farm equipment, W. R. Beattie (*U. S. Dept. Agr., Farmers' Bul. 347, pp. 32, figs. 23*).—The tools, materials, and facilities required for making repairs on all parts of the farm equipment are listed and described, with practical suggestions as to selection and use of tools and materials, and arrangement of a workshop. A few practical suggestions are given with a view to emphasizing the increased efficiency resulting from keeping equipment in good repair.

Handbook of farm buildings, ponds, etc., T. Winder (*London, Sheffield, and Glasgow, 1908, pp. 171, figs. 111*).—This volume treats of farm buildings and their appurtenances according to English practice, with practical suggestions resulting from the author's experience. Data relative to the design, construction, repair, and maintenance of farm buildings form the nucleus of the book, with chapters on drainage, materials, houses for farm animals and implements, and yards, walks, and gates. There is also a chapter by J. W. Beauchamp on electricity as applied to agriculture, which discusses the various appliances which can be operated economically by electricity and the means of obtaining the power as suited to individual cases.

The King system of ventilation, C. A. Ocock (*Wisconsin Sta. Bul. 164, pp. 3–24, figs. 21*).—In this bulletin descriptions and detailed plans are presented which it is deemed are sufficient to enable farmers to install in barns this system of ventilation. The essential features of the system, which was proposed by King in 1889 (E. S. R., 2, p. 447), "are several inlet flues to distribute the pure air, and one or more foul air flues of adequate size to assure rapid removal of foul air."

The disposal problem in rural districts, S. B. Lake (*Mo. Bul. Ind. Bd. Health, 10 (1908), No. 10, pp. 120–124, figs. 2*).—In this paper the author points out the essential principles involved in the sanitary disposal of sewage and garbage, and presents a design for a garbage disposal plant with a description of its operation.

RURAL ECONOMICS.

Builders of an agricultural commonwealth, C. H. Poe (*So. Atlantic Quart., 8 (1909), No. 1, pp. 1–11*).—This article presents data relating to the economic development of the South by means of the growth of scientific agriculture, road improvement, and agricultural education.

The State agricultural committee of the Farmers' Union, W. L. Stallings (*South. Cult., 66 (1908), No. 24, pp. 14, 15*).—This article gives the membership and aims of the State agricultural committee of the Farmers' Union of Georgia.

The purpose of this committee is "to encourage among the membership of the union a greater interest in more scientific farming and the raising of home supplies on the farm, to the end that cotton and other money crops may be surplus crops." The committee proposes to disseminate information on scientific farming by means of bulletins, the holding of meetings similar to farmers' institutes, the preparation of newspaper articles, etc., to publish the results of a better system of farming as compared with those of former methods, and to

make Georgia farmers more self-sustaining and independent in order that they may cooperate in the marketing of their crops to greater advantage.

Some associations of agricultural importance, A. RAEYMAECKERS (*Ann. Gembloux, 19 (1909), No. 1, pp. 1–11*).—The author discusses the origin, development, objects, and present status of the most important agricultural associations and cooperative societies in Belgium with particular reference to their bearing on the nation's economic and social welfare. The following data show the status of these organizations at the close of 1907: Agricultural associations numbered 1,058 with 63,260 members; cooperative societies for the purchase of farm supplies 1,004, expending for this purpose about $4,615,120; cooperative dairies 497, doing a business valued at about $6,905,357; Raiffeisen credit banks 523, loaning about $657,970; and assurance societies 1,591, insuring live stock valued at about $26,870,752.

The cooperative principle in the organization of agriculture in Denmark, T. BRINKMANN (*Fühling's Landw. Ztg., 57 (1908), No. 20, pp. 678–694*).—The author discusses the position of Denmark with regard to the world's markets, its agricultural possibilities and conditions, the number and size of its holdings, and other features of its economic life which have had a bearing on the development of the cooperative organization of agriculture in that country. The cooperative production and marketing of products are almost entirely limited to three fields—milk products, eggs, and bacon. The bulk of these products are shown to be raised on small holdings where marketing with profit would be impossible without cooperation, and the growth of the movement among the small farmers has resulted not only in developing the highest forms of agricultural cooperation to be found in Europe, but also has contributed to the economic welfare and independence of the Danish peasant class.

Jubilee of the Imperial Union of German Agricultural Cooperative Societies (*Dept. Agr. and Tech. Instr. Ireland Jour., 9 (1908), No. 1, pp. 37–42; Natal Agr. Jour., 12 (1909), No. 1, pp. 44, 45*).—A summarized account of the history of agricultural cooperation in Germany and of the above organization in particular.

Statistics of the development and business of the cooperative societies are presented, from which it appears that on June 1, 1908, there were 21,959 in Germany, of which the credit societies numbered 14,675, agricultural societies 2,138, creameries 3,132, and miscellaneous 2,014. Of the entire number, 17,627 belong to the imperial union.

Farming on shares in the present system of rural economy, A. SERPIERI (*Bol. Quind. Soc. Agr. Ital., 13 (1908), No. 22, pp. 1028–1057*).—This paper describes the different forms of share farming in various sections of Italy, points out under what circumstances and conditions of land and labor this system offers the best economic and social results, and discusses the economic limitations of farming on shares in Italy. The transformation of share farming into the tenant system, it is believed, will probably be intensified in the future and will be to the advantage of the tenant class.

The paper is followed by detailed explanatory notes and a discussion.

Agriculture and the tariff in England, O. BÜHLER (*Landw. Jahrb., 37 (1908), No. 6, pp. 961–1050*).—This article discusses the governmental inquiry into the agricultural conditions of England in 1906 and the significance of the land laws passed in 1907 for their improvement.

The agricultural holdings act, 1908 (*Gard. Chron., 3. ser., 45 (1909), Nos. 1149, pp. 11, 12; 1150, pp. 27, 28*).—This is a discussion of the act which took effect January 1, 1909, regulating the relations between landlord and tenant in England. The act repeals the market gardeners' compensation act of 1895, and the agricultural holdings acts of 1883, 1900, and 1906. The provisions relate to

compensation for improvements, arbitration, damage by game, freedom of cropping, compensation for disturbance, repairs to buildings, and record of condition at the time of commencing a tenancy. The text of the act has been previously noted (E. S. R., 20, p. 588).

Interim report of proceedings under the small holdings and allotments acts for the six months ending June 30, 1908, T. H. ELLIOTT (*Bd. Agr. and Fisheries [London]. Interim Rpt. Proc. Small Hold. and Allot. Acts, June 30, 1908, pp. 92*).

Holdings of farm laborers, DELIUS (*Landw. Wchnbl. Schles. Holst., 58 (1908), No. 52, pp. 890, 891*).—As a means of preventing rural depopulation, the author believes that the farm laborer must be established on the land, and that this can be done by the erection of suitable houses on land not less than ¼ hectare (about 0.31 acre) in extent, which property the laborer should have the privilege of purchasing. The cost of such holdings, the furnishing of funds by government and cooperative associations, and the moral and economic effects of ownership upon the laborer are briefly discussed.

Propositions regarding the improvement of the farm laborer, STIEGER (*Mitt. Deut. Landw. Gesell., 23 (1908), No. 45, pp. 391–394*).—This is a series of 36 propositions dealing with the conditions which should be put in operation for the educational, economic, and social improvement of the farm laborer and his family and their bearing upon the farm labor problem in Germany. The propositions relating to the moral and economic significance of piecework in agriculture have been previously noted (E. S. R., 20, p. 389).

Measures to be taken in the organization and management of farms to offset the lack of farm help, DYHRENFURTH (*Illus. Landw. Ztg., 28 (1908), No. 97, pp. 829–831*).—In addition to advocating the laying down of arable land to pasture and the raising of live stock in districts where farm labor is scarce, the author discusses from personal experience his method of farm management. This consists in the winter utilization of men and animals for work usually performed in the spring, the planting of winter crops and crops which follow each other in order of maturity, the greater use of machinery, the performance of many kinds of farm labor by piecework, etc. In this way his 4 farms have been operated with a less number of laborers and horses than would be possible under conditions which usually prevail throughout Germany.

The rights of employers when farm laborers break their contracts, SCHUMACHER (*Deut. Landw. Presse, 35 (1908), No. 98, pp. 1021, 1022*).—The rights of farmers according to the laws of Prussia and the Rhine Provinces, in cases where farm laborers break their contracts, are presented and discussed.

[Mexican farm laborers in the United States], V. S. CLARK (*Bur. of Labor [U. S.] Bul. 78, pp. 482–485*).—Notes are given on the number, distribution, kinds of labor in which employed, wages, mode of life, and social habits of Mexican farm laborers in the United States.

"The main value of the Mexican in agriculture is as a temporary worker in crops where the season is short, especially in harvesting cotton, grain, and sugar beets. Mexicans are not likely to be employed the year round by small farmers, because they are not entertained in the family like American, German, Scandinavian, or Irish laborers of the North. Yet they do not occupy a position analogous to that of the negro in the South. They are not permanent, do not acquire land or establish themselves in little cabin homesteads, but remain nomadic and outside of American civilization."

Agricultural imports of the Netherlands (*U. S. Dept. Agr., Bur. Statis. Bul. 72, pp. 53*).—Tabulated data of the imports of the Netherlands for the 10-year period 1897–1906, with special attention to agricultural imports and the proportion of these products furnished by the United States, are reported. The

total imports from the United States in 1906 were valued at $126,620,800, of which $72,791,316, or 57.5 per cent, were agricultural products, as compared with an average for the 10-year period of 62.2 per cent.

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 11 (1909), No. 3, pp. 17–24*).—Statistics on the condition, value, yields, and prices of principal crops in the United States and foreign countries are tabulated and discussed, together with articles on the adulteration and misbranding of the seeds of alfalfa, red clover, orchard grass, and Kentucky bluegrass (noted elsewhere in this issue), and on the quantity and value of the imports of tobacco into England from the thirteen American colonies 200 years ago.

AGRICULTURAL EDUCATION.

Annual report Winnebago County schools, 1908, O. J. Kern (*Rockford, Ill., 1908, pp. 96, figs. 92, dgms. 2*).—This report classifies and describes the "forces at work" in country life under the heads of better physical conditions of the farm home, better farm management, transportation and communication for the farm, farmers' organizations and civic associations, the printing press, the country church, and the country school. There follows a chapter on outdoor art for country life, including directions for school gardening and a synopsis of such work done in the county in 1908, and a chapter on indoor art for country life similarly exemplified. One important division of the report is a classified list of the books available in the Rockford (Ill.) Public Library on country life interests, including the farm and home, country schools, industrial training, the studying and teaching of agriculture, and occupations and amusements. Such a classification of the books in local libraries would make them much more useful to teachers, and this report will be found helpful and suggestive to any planning for such classification. Seven pages are devoted to a review of the development of country high school work in Winnebago County, and some examples of recent consolidation in Ohio, and several pages on the Babcock milk tester as an educational and economic factor in a school are offered to illustrate "some ways a city high school may enrich country life."

The farmers' school, A. B. Graham (*Ann. Rpt. Ohio Bd. Agr., 62 (1907), pp. 412–421*).—This address reviews the history of rural school supervision in Ohio and dwells upon the provision made in recent years for the promotion of rural children to the opportunity for secondary training. The author also suggests many agricultural applications of the facts and principles learned in science study and points out the opportunities for making school work the center of social interest and activity in each community. Special emphasis is laid upon the importance of securing the best possible teachers for the rural schools.

The successful farmer's education, W. G. Owens (*Ann. Rpt. Penn. Dept. Agr., 13 (1907), pp. 224–228*).—The needs of the modern farmer for instruction concerning up-to-date machinery and other special features of agriculture are pointed out, the importance of agriculture as an industry is emphasized, and the need of starting instruction in agriculture in the public schools is insisted upon.

Higher education for the farmer's wife, Mrs. F. M. Jones (*Ann. Rpt. Ohio Bd. Agr., 62 (1907), pp. 456, 457*).—This paper makes an earnest plea for the introduction into the rural home of domestic time-and-labor-saving conveniences comparable in value with those which the farmer commonly provides himself with for the out-door work of the farm, that the energy thus saved to the wife may be utilized in the better organization of the entire home life and in assist-

ing her to wholesome social leadership for the betterment of the whole community.

One woman's work for farm women, JENNIE BUELL (*Boston, 1908, pp. 78*).—This is a biographical sketch of the late Mary A. Mayo, dealing with her work in rural social movements, especially through the grange and in the women's sessions of farmers' institutes in Michigan. In the latter work Mrs. Mayo was the first woman leader.

Agriculture in rural schools, A. M. DUNTON (*Northwest. Agr., 24 (1909), Nos. 6, pp. 7, 8, figs. 7; 7, p. 3*).—An article on the development and influence of the agricultural high school at McIntosh, Minn.

The Home Gardening Association (*Ann. Rpt. Home Gard. Assoc. [Cleveland], 9 (1908), pp. 34, figs. 19*).—A report of the year's activities of this association laying special emphasis upon the work of the "training garden" begun experimentally in 1906. This aims to give boys "practical experience in the preparation of the soil, the selection and planting of seed, the rotation of crops, and the sale of the produce" of school gardens. An important educational feature of this plan is the keeping of an individual "garden diary" of all work done and produce sold. Such a diary, with experiments performed, is presented.

School gardening and nature study in English rural schools and in London, SUSAN B. SIPE (*U. S. Dept. Agr., Office Expt. Stas. Bul. 204, pp. 37, figs. 15*).—This is a report upon some studies of methods of teaching nature study and school gardening in England conducted by the author in connection with a recent visit to Europe. An account is given of the nature-study book in the schools of Whitechapel, London, including a roof garden, nature-study museum, country-in-town exhibition, and a school nature-study union; nature study at the Kentish Town Road School, London; rural school gardens, including the work of agricultural inspectors, and evening and day school gardens; and teachers' courses and examinations, including summer courses, at the Horticultural College, Swanley, Kent.

A manual for high schools with special reference to science and agriculture, J. MAIN (*Knoxville, Tenn., 1909, pp. 32, figs. 6, map 1, dgm. 1*).—This is a tentative scheme for working out a practical and pedagogical correlation between agriculture and the other subjects commonly included in a good high school curriculum, with special reference to the work in natural and physical science. One of the leading aims in the plan is to bring forward each successive phase of agriculture at the season when it may be both of the highest psychological interest and greatest practical value. The manual includes an elaborate course of study, detailed plans for an agricultural school library, and a list of required laboratory equipment.

Teachers' manual of elementary agriculture, nature study, and domestic science (*Boston and London, 1908, pp. 117, pl. 1, figs. 5*).—This manual has been prepared under the direction of the Colorado Teachers' Association, and is introduced in a foreword by F. E. Thompson, of the Colorado State University, which contains a statement of the teacher's problem in the rural schools, with general and specific suggestions toward its solution. There follow brief chapters on soils, plant life, school gardening, field crops, insects and birds, live stock, and domestic science, each prepared by a specialist. The manual closes with a bibliography for agricultural and nature-study work.

Public school agriculture, 1909 (*Mass. Agr. Col., Dept. Agr. Ed. [Pamphlet], 1909, pp. 32*).—This pamphlet is the work of a committee appointed at the close of a conference on agricultural science at Amherst, Mass., in 1908, to prepare a series of teachable exercises on elementary agriculture. The exercises proposed number 54, distributed over the study of soils, capillarity, drainage, evaporation,

earthworms, plant transpiration, fertilizers, leguminous forage plants, seed selection, corn germination, plant variation, propagation, grafting, pruning, Bordeaux mixture, milk bacteria, milk testing, etc. Twenty-four additional exercises are suggested, with a list of helpful bulletins and books.

Course in nature study and elementary agriculture for the ungraded schools of California, R. O. Johnson (*[Chico, Cal., 1909], pp. 6*).—This is an outline for work in the ungraded schools, and includes some suggestions concerning the administration of a course in nature study and elementary agriculture, together with a specimen lesson concerning the cow.

The study of the evergreens in the public schools, C. M. Weed (*Boston: State Forester, 1908, pp. 30, figs. 8*).—A brief manual for teachers who wish to use the common evergreens for nature-study work at a season when deciduous plants are not available. It furnishes detailed and practical directions as to methods of study in the public school, a suggested list of trees appropriate for consecutive grades, the preparation of solar prints, and feasible correlations with other lines of grade work.

Syllabus of illustrated lecture on the production and marketing of eggs and fowls, J. Dryden (*U. S. Dept. Agr., Office Expt. Stas., Farmers' Inst. Lecture 10, pp. 20*).—This lecture deals with egg production, housing of fowls, feeding of fowls, poultry in the orchard, incubation, fattening chickens, marketing product, and insect pests. Forty-four lantern slides have been prepared to illustrate the lecture, and a list of references to poultry literature is given.

Annual report of farmers' institutes, 1908, T. Butler (*Bul. N. C. Dept. Agr., 29 (1908), No. 10, pp. 71, figs. 2*).—In addition to the report on the work of the men's and women's institutes, the bulletin contains lectures delivered at women's institutes, the programme of the Farmers' State Convention, lectures delivered at the women's meeting of that convention, and an account of the development of the dairy interests in the State under the influences of the National and State departments of agriculture, the State Dairymen's Association, the dairy department of the North Carolina College of Agriculture and Mechanic Arts, and the individual efforts of dairymen.

Organization lists of the agricultural colleges and experiment stations, Mary A. Agnew (*U. S. Dept. Agr., Office Expt. Stas. Bul. 206, pp. 114*).

MISCELLANEOUS.

Annual report of the director for the fiscal year ending June 30, 1908 (*Delaware Sta. Bul. 84, pp. 3–12*).—This contains the organization list of the station, a report of the director discussing the function, personnel, work, equipment, and needs of the station, and a financial statement for the fiscal year ended June 30, 1908.

Biennial Report of Iowa Station, 1902–3 (*Iowa State Col. Agr. Rpt. 1902–3, pp. 22, 23, 25, 26, 33, 34, 36–38, 54–60, 68, 73, 88, 92, 117*).—Extracts from the reports of the president of the college, the treasurer, and secretary pertaining to the station are given, including notes on its work and publications, and a financial statement for the fiscal years ended June 30, 1902, and June 30, 1903.

Biennial Report of Iowa Station, 1904–5 (*Iowa State Col. Agr. Rpt. 1904–5, pp. 54–57, 64–67, 90–95, 104*).—This contains a report of the director of the station, a financial statement for the fiscal years ended June 30, 1904 and June 30, 1905, and a summary of the bulletins issued during that period.

Annual Report of Iowa Station, 1906 (*Iowa State Col. Agr. Rpt. 1906, pp. 60–65, 68*).—This contains a report of the director on the work of the station, and a financial statement for the fiscal year ended June 30, 1906.

Twenty-first Annual Report of Michigan Station, 1908 (*Michigan Sta. Rpt. 1908, pp. 115–410*).—This contains a financial statement for the fiscal year ended June 30, 1908; reports of the director and heads of departments on the work of the station during the year, the experimental features of which, together with several special articles and reprints of Special Bulletins 45 and 46, are noted elsewhere in this issue; and reprints of Bulletins 248–251, and of Special Bulletins 38, 39, 42, and 43, previously noted.

Twenty-sixth Annual Report of New York State Station, 1907 (*New York State Sta. Rpt. 1907, pts. 1, pp. IX+456; 2, pp. XV+564; 3, pp. VII+362*).—This report is issued in 3 volumes. Part 1 contains the organization list of the station, a financial statement for the Federal funds for the fiscal year ended June 30, 1907, and for the State funds for the fiscal year ended September 30, 1907, a list of the periodicals received by the station, meteorological observations noted on page 913 of this issue, reprints of Bulletins 286–290, 292, 293, and 295, Technical Bulletins 4–6, and Circular 8, all of which have been previously noted, and an index to the first 25 annual reports of the station. Part 2 is made up of The Grapes of New York, and is noted on page 940 of this issue. Part 3 contains an extended review of the work of the station for the first 25 years, including an account of the twenty-fifth anniversary exercises. The summaries of the experimental work are noted elsewhere in this issue.

Director's report for 1908, W. H. Jordan (*New York State Sta. Bul. 310, pp. 559–579*).—This contains the organization list and a review of the work and publications of the station for the year.

Seventeenth Annual Report of Oklahoma Station, 1908 (*Oklahoma Sta. Rpt. 1908, pp. 80*).—This contains the organization list, a report of the acting director and heads of departments on the work of the station, a list of the station publications available for distribution, a brief digest of the station publications issued during the year, and a financial statement for the fiscal year ended June 30, 1908.

The press bulletins summarized are in part a repetition of matter published in the regular bulletins of the station. Those not noted elsewhere in this issue are entitled Protecting Trees from Rabbits, Setting Trees, Vaccinate for Blackleg, and Bee Culture in Oklahoma.

Twenty-fourth Annual Report of the Bureau of Animal Industry, 1907 (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1907, pp. 486*).—This includes a report of the Chief of the Bureau for the fiscal year ended June 30, 1907, numerous articles abstracted elsewhere in this issue or previously noted, and a list of the publications of the Bureau during 1907. An appendix contains the rules and regulations of the Secretary of Agriculture relating to animal industry issued in 1907.

Report of committee on station organization and policy, H. J. Wheeler et al. (*U. S. Dept. Agr., Office Expt. Stas. Circ. 82, pp. 10*).—This report was presented to the Association of American Agricultural Colleges and Experiment Stations at the convention held at Washington, D. C., November 18–20, 1908, and has been noted editorially (E. S. R., 20, p. 303).

Index to the Yearbooks of the United States Department of Agriculture, 1901–1905, C. H. Greathouse (*U. S. Dept. Agr., Div. Pubs. Bul. 9, pp. 166*).—This is a combined subject and author index in continuation of work previously noted (E. S. R., 14, p. 509).

NOTES.

Colorado College and Station.—The legislature has appropriated $119,000 for the ensuing biennium, of which $40,000 is for the completion and equipment of a building for instruction in civil and irrigation engineering, and the remainder for farmers' institutes and station work. A bill was also passed establishing a substation at Cheyenne Wells.

L. M. Taylor has been elected secretary of the State board of agriculture, vice A. M. Hawley.

Connecticut College.—The eighth annual session of the summer school will be held during the four weeks beginning June 29. Courses in nature study, domestic science, agriculture and methods of teaching elementary agriculture have been planned to meet the needs of teachers, especially those in rural schools, as well as of others interested in nature and country life. Special practical courses in poultry husbandry and fruit growing will also be given.

Hawaii Federal Station.—The special agent in charge has been appointed by the governor of Hawaii a member of two special boards provided for at the recent session of the legislature. One of them is on the allotment of a special tax known as the Natural Resources Conservation Tax, and the other a commission to investigate fruit growing and truck farming in that Territory.

An exhibit of station work was made at the recent poultry exhibition, special prominence being given to the work under way with cotton, tobacco, rubber, and rice, and to bee keeping.

Iowa College and Station.—A single board of education has been established by the legislature to control the college and station, the State university, and the State normal school, which have hitherto been governed by separate boards. This board consists of nine members appointed by the governor for terms of six years each, its personnel being as follows: A. B. Funk, Spirit Lake; James E. Trewin, Cedar Rapids; P. K. Holbrook, Onawa; Roger Leavitt, Cedar Falls; C. R. Brenton, Dallas Center; T. D. Foster, Ottumwa; E. T. Schoentgen, Council Bluffs; D. D. Murphy, Elkader; and George T. Baker, Davenport. Of these, C. R. Brenton was a member of the former board of trustees of the college. A finance committee is to be selected by the board from outside its own membership, which will give its entire time to the business management of the institutions.

Kansas College and Station.—W. A. Harris, of Lawrence, Arthur Capper, of Topeka, and W. J. Todd, of Maple Hill, have been appointed to the board of regents, vice J. S. McDowell, A. M. Story, and G. P. Griffith. At a recent meeting of the board the horticulturist was appointed to the newly established office of State forester. The purchase of two quarter sections of land northwest of the college farm was authorized.

Maine Station.—An act has been passed by the legislature requiring the station to conduct investigations in orcharding and the growing of corn and other farm crops, and appropriating $10,000 for the purchase and equipment of a suitable farm for such work.

Michigan College and Station.—Extension work in animal husbandry, begun by the college about a year ago through the appointment of F. W. Raven as field agent, has met with encouraging success. Efforts have been directed mainly toward the organization of cooperative breeders' associations, with a view to the stimulation of live-stock improvement. During the first 6 months 10 associations were formed, representing 2,100 cows, and 51 registered sires were purchased. O. K. White has recently been appointed field agent in horticultural extension work, and A. R. Potts for similar work with soils and field crops.

William S. Sayer, assistant in bacteriology in the college and research assistant in bacteriology in the station since 1907, was drowned while canoeing April 30. He was graduated from Beloit College in 1899, and engaged in graduate work in the University of Chicago for the two years following. He had served as chemist and bacteriologist to the Chicago Sanitary Commission, and later was in commercial work. He was 33 years of age.

Maryland College and Station.—Frank Kent has been appointed registrar and treasurer of the college and treasurer of the station, vice the late Dr. J. R. Owens.

Mississippi College.—The corner stone of the new administration building, to cost approximately $100,000, was laid April 16, with appropriate exercises. The principal address was delivered by President W. O. Thompson, of the Ohio University, who took for his subject Industrial Education.

Nebraska University and Station.—According to a note in *Science*, the charter of the university has been amended by the legislature to allow a reorganization into seven colleges, namely: The graduate college, the college of arts and sciences, the college of agriculture, the college of engineering, the teachers' college, the college of law, and the college of medicine. Of these the graduate college has hitherto been known as the graduate school, and the colleges of agriculture and engineering have constituted what was known as the industrial college.

An appropriation was made by the legislature of $45,000 for substations, $20,000 for farmers' institutes, and $100,000 for permanent improvements, the purchase of additional land, and other purposes.

Cornell University.—*The Rural New Yorker* announces that the College of Agriculture is to cooperate with the Chautauqua Institution in holding a country life week at Chautauqua, August 23 and 24. This will take the form of a general conference of all persons interested in country life with a symposium on its problems, both by men in close touch with country life and those prominent in other activities. It is expected that many of the agricultural colleges and schools of the country will be represented.

New York State Station.—A State appropriation of $10,000 has been granted for a study of grape production in Chautauqua County. The investigations are to include methods of culture and the ravages of insect pests and fungi.

Ohio University and Station.—The legislature has appropriated $20,000 to amplify the extension work of the university through the holding of traveling schools of agriculture. These schools are restricted in duration to one week, and not more than one school may be held in a county during a given year. Instruction is to be offered in soil fertility, stock raising, crop production, dairying, horticulture, domestic science, and kindred subjects. An agricultural train was sent out March 23, which made a 5-day trip through the southwestern part of the State.

Arrangements are being made to supplement the variety tests of wheat under way at the station with milling and baking tests, and C. G. Evans has been appointed assistant agronomist to have charge of this work.

The vestry of a church in Boardman, Mahoning County, has offered to the station the use of a tract of 10 acres for a test field, and the county commissioners and county agricultural society of Hancock County have made a similar offer of a tract of 20 acres. These offers have been accepted and work on the fields has been begun.

The calls for the station's fair exhibit from county fair associations have become so urgent that two exhibits will be put in the field during the coming fair season, the routing of the exhibits being placed in the hands of a committee of the fair associations.

The State appropriations to the station aggregate $118,990, besides $1,000 for stationery and an unrestricted amount for paper for publications. The appropriations include $28,500 for administrative purposes, $9,500 for agronomy, $15,150 for animal husbandry, $5,000 for botany, $15,600 for cooperative experiments, $6,950 for entomology, $8,000 for forestry, $8,000 for soils, $3,650 for chemistry, $9,640 for horticulture, $8,000 for nutrition, and $1,000 for equipment.

Oklahoma College and Station.—A very successful week's short course was held at the college in January. About 400 farmers were in attendance, and 50 women attended the course in domestic economy. The subjects presented included cotton, corn, and alfalfa growing, seed selection, road building, farm management, horse and swine judging, dairying, tuberculosis, Texas fever and its eradication, the silo and its uses, care of farm horses, orchard pests and spraying, fruit growing and storage, and tree planting. A special feature of the week was a meat-cutting demonstration, conducted under a large tent in which all the retail cuts of beef, pork, and mutton were shown and their relative value explained.

The State Dairymen's Association held its annual meeting during the week, and a corn growers' association was organized with over a hundred charter members.

Extension work is contemplated through a boys' and girls' agricultural club and cooperative experimental work among former students of the college. Several new buildings for the college and station are to be erected.

John F. Nicholson, professor of botany, entomology, and geology in the college and entomologist in the station, resigned February 10 and is engaged in commercial work.

Pennsylvania College and Station.—The Pennsylvania Railroad recently arranged a special trip to the college for a company of 23 of its local station agents, for a day's study of agricultural matters of benefit to the farmers in the districts tributary to their stations. H. P. Baker, forester, has been granted leave of absence for 18 months, beginning July 1, to be spent in study and travel in Europe and the Orient.

Rhode Island College and Station.—By a recent act of the general assembly, the board of managers has been increased by the addition of the State commissioner of education and a representative to be elected from the State board of agriculture. It is expected that this change will bring the institution into closer touch with the general agricultural work of the State, and that it will tend to promote cordial relations between the board and the State board of agriculture.

Tennessee University and Station.—The legislature has passed a bill giving 25 per cent of the State's revenues for education. Of this amount 7 per cent will go to the university and experiment station—$10,000 being set aside for the support of the substation at Jackson, $5,000 for crop experiments in middle Tennessee, $7,500 for the station at Knoxville, and the remainder, at present about $40,000, for instruction at the university.

W. K. Hunter has been appointed fertilizer and food chemist, vice W. E. Grainger. J. E. Hite, assistant in cooperative experiments at Gallatin, is no longer connected with the station.

Virginia College and Station.—Since November 1 five agricultural trains have been sent out over as many different railroads, with an aggregate attendance of about 25,000 people or about 100 at each stop. At least two more trains are contemplated before June 1. The college and station are to furnish speakers and experts for two cars, one of which will be for live stock. In return the railroads have agreed to run farmers' excursion trains along their lines to the college during the summer.

The dairy division is now installed in its new quarters in the basement of the new agricultural building. Its equipment is considered second to none in the South. There is a commercial creamery room 90 by 90 feet, with complete equipment, especially for the production of high-grade cream; a farm dairy and butter-making room 90 by 90 feet, with most of the standard separators and churns; a pasteurizing room 30 by 20 feet, containing a duplex pasteurizer driven direct by motor; a bottling outfit; a wash room isolated from the creamery, with sterilizing apparatus; a room 20 by 20 feet, containing a brine tank with freezing capacity of 1¾ tons of ice in 36 hours; 4 cold storage rooms, 2 for bottling, 1 for cream, and 1 for cheese, insulated with cork and refrigerated with the ammonia absorption system; a laboratory for dairy bacteriology 15 by 20 feet; a milk-testing laboratory and lecture room 90 by 90 feet, completely equipped for 32 students, with room for 70; and a cheese room 90 by 90 feet. All the rooms have cement floors with center drain, and all machinery is run by electric motor.

E. B. Fred, assistant bacteriologist in the station, has been granted a year's leave of absence to be spent in the study of soil bacteriology in Germany.

Virginia Truck Station.—Recent changes in the governing board include the appointment thereto of J. M. Barker, of Axton, vice J. W. Churchman, deceased, and of N. W. Nock, of Onancock, vice C. W. Heater, and the selection of President P. B. Barringer, of the Virginia College, as president of the board.

Wisconsin University and Station.—In addition to the editing of all publications of the college and station, the new editorial office is to serve as a press bureau for the preparation of data to be sent out to newspapers of the State and the agricultural press of the country. A press bulletin containing news notes and articles on work of the college and station is being issued weekly by the university.

Recent appointments in the college of agriculture include Ward M. Totman as assistant in dairy husbandry, and Fred L. Musback as assistant in soils, vice M. I. Tuttle and Roy R. Marshall, resigned.

The station is again preparing to conduct spraying demonstrations for potato blight and cranberry diseases in cooperation with farmers in the State.

New York Conference on Secondary Agricultural Schools and Branch Experiment Stations.—At a conference of deans of the various State agricultural schools, held at Cornell University during Farmers' Week, the function and scope of the secondary agricultural schools was discussed. The consensus of opinion favored so conducting such schools as to fit their graduates primarily for practical farm work and secondarily for teaching agriculture. The correlation of all such work into a general State system was advocated as was also the passage of legislation providing for the establishment of agricultural instruction in the public schools on a basis similar to the trade schools founded in 1908.

With reference to branch experiment stations, for which there is considerable agitation in the State, the decision reached was adverse to the establish-

ment of such stations as regards the buying of land and erecting permanent buildings. It was agreed that field laboratories and temporary stations might be established to solve individual problems and maintained until a solution of these problems was reached.

Alfred University State School of Agriculture.—The *Buffalo* (N. Y.) *News* of April 7 announces that the legislature has appropriated $40,000 for the buildings and equipment of the New York State School of Agriculture at Alfred University, Alfred, N. Y. Of this sum $5,000 is immediately available for the purchase of live stock, dairy supplies, and improvements on the State farm.

Agriculture in Public Schools.—The *Fairmont West Virginian* of March 31, 1909, states that the legislature has passed a bill requiring West Virginia teachers to pass an examination in agriculture for any grade of certificate.

Michigan Farmers' Short Course.—The second annual farmers' short course conducted by the Menominee (Mich.) County Agricultural School, March 16 to 19 was remarkably successful, no less than 2,500 persons being enrolled from adjacent counties in Michigan and Wisconsin.

Traveling Stock-judging Schools in Canada.—A new feature in farmers' institute work was attempted last year in the Province of Alberta, viz, traveling stock-judging schools. Two cars with about 50 head of improved stock, loaned by the Lacombe Agricultural Society and leading stockmen of the province, were carried from place to place throughout the province and used for demonstration purposes. In selecting the stock the object was to have the popular breeds of horses, cattle, sheep, and swine represented. Owing to the risk in carrying the animals on the train for 3 months they were insured, and at each place were stabled in livery barns. A hostler and two herdsmen accompanied the stock.

Nine schools, of 1 or 2 weeks' duration, were held in comfortable class rooms, and from 4 to 6 speakers took part in the program at each place. At the close of each school a judging contest, open only to the members of the school, was held and prizes were offered. A membership fee of $1 was charged, the money being used for fitting up the class room and for prize money. The scheme is reported to have been highly successful.

New Journals.—*Zeitschrift für biologische Technik und Methodik* is being issued at regular intervals under the direction of Dr. Martin Gildemeister, of Strassburg. It is to contain short original articles in the German language and original descriptions, notes, and abstracts of articles dealing with biological apparatus and methods. Special attention is to be given to plant and animal physiology, physiological chemistry, bacteriology, fermentation chemistry, pharmacology, and experimental pathology, psychology, and morphology.

The American Pure Food and Drug Journal, "devoted to the enforcement of the National and State pure food and drug laws," is being issued as a monthly. The initial number contains the text of the National food and drug act and of the West Virginia pure-food law, inspection rulings by State authorities in Ohio and Kentucky, an account of legal cases arising in the enforcement of the National act, articles discussing various pure-food questions, and other data.

LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS REVIEWED.

Stations in the United States.

Stations in the United States—Continued.

U. S. Department of Agriculture.

NOTE.—The publications of the United States Department of Agriculture, except those of the Weather Bureau, may be purchased from the Superintendent of Documents, Washington, D. C. For the publications of the Weather Bureau requests and remittances should be directed to the Chief of the Bureau. The price of *Experiment Station Record* is $1.50 per volume, or 15 cents per number. The prices of other technical publications are given above. The publications of the State experiment stations are distributed from the stations and not from the Department.

EXPERIMENT STATION RECORD.

VOL. XX. JUNE, 1909. No. 11.

The list of projects conducted by the experiment stations under the Adams fund includes sixty-three which fall under the head of investigations in breeding. This relatively large number indicates the popularity of the subject, and an evident feeling that it not only presents large research possibility but is a line in which investigation is greatly needed.

The attention which is being given to breeding is encouraging, and the number of enterprises suggests the possibility of material additions to the general understanding of its various phases. As the Adams fund is known to be for work of research character, this expectation seems a reasonable one, for it implies a grade of work which is systematic and thoroughgoing, and will be continued to a definite conclusion. The men who have enlisted under that fund therefore have a certain responsibility resting upon them for the maintenance of a high standard of investigation, and for the character of the results which they secure. Like all Adams fund workers, their scientific reputation is at stake, and their conceptions of research as well as their ability in that line will be judged by the direction which their work takes. This will depend ultimately upon the attitude in which the man in charge approaches the subject, and the direction in which his real interest lies. It may be modified for a time by external influences, but in the end it will, like all investigation, be the product of the man.

Quite wide differences still exist in the conception of research and original investigation as applied to breeding. The subject is alluring on account of the practical possibilities it presents. Popular interest in the results of selection and breeding has led some men into it whose main interest apparently centers around the thing to be produced rather than the method or the phenomena involved. There is a failure to distinguish between the scientific or research phases and the practical phases of plant breeding—between the search for truth and the production of a material thing.

The subject of breeding presents many excellent opportunities for research, but the breeding of plants and animals by experiment stations or by practical breeders is not necessarily of that grade. The study of principles and the broadening of knowledge as to how desired results may be secured is one thing, and the intelligent application of such knowledge in the improvement of existing varieties is another. It is for the worker to determine which line he will undertake. Not all of the breeding work is necessarily confined to the research fund—in fact, only such as involves actual research features is appropriate to it. There is a place for the more practical kinds of breeding work, provided it is not merely commercial and contains experimental features.

In a comparatively few cases does the breeding work of the stations actually deal primarily with underlying principles or methods: in some others it involves the more or less systematic study of phenomena observed in connection with the attempt to secure improvement, but in many cases the primary aim and the one largely influencing the conduct of the work is improvement in some particular by well-known methods, usually depending on the chance of favorable variation.

There is danger, therefore, that the expectations aroused by the number of undertakings in breeding may not be fully realized in the scientific output. This seems quite likely to be the case unless more scientific features are introduced. This emphasizes the necessity of recognizing the proper distinction between various kinds of effort, and applying the proper terminology. The terms "investigation" and "original research" have been used too loosely in reference to station work, and that practice is likely to bring a reflection on the scientific work in agriculture. These terms are not easily defined, being largely a matter of feeling and spirit, but they stand for fairly definite grades of work in the minds of scientific men.

Of the 63 breeding projects of the experiment stations, only 11 relate to the breeding of animals. The small number of the latter is perhaps natural, both from the cost of animal experiments and the number of men who are especially interested in that phase of breeding studies. The subject is more complex because animals are more highly organized than plants and greater time is necessary to secure results. It is believed, however, that more investigation could profitably be undertaken in that line, but investigations of insufficient extent and thoroughness are to be discouraged.

There are several quite large projects being carried on by the stations, and in addition to these there are a number conducted under other auspices, notably by Davenport, under the Carnegie Institution, and by Castle, at Harvard. The field is a most appropriate one to the agricultural experiment stations and to the Adams fund,

especially if this fund can be supplemented by State funds so as to insure the conduct of the investigation on a sufficiently large scale. It affords excellent opportunity for the exercise of research ability and for investigation of the first rank. The results are needed not only for their practical application but as a basis for teaching. Breeding studies must go on in connection with the attempt to secure economy of production through the development and perpetuation of more efficient machines for converting food into products and the securing of greater special adaptation.

From being largely a matter of good judgment of animals, successful breeding has come to have a more substantial basis in science. Bakewell's good judgment of stock enabled him to develop the Dishley breed of sheep and the Longhorn breed of cattle. Every feeder knows that the individuality of the animal is an important factor in feeding problems. The characteristics of animals of the same species are subject to so great variations that it is necessary for the successful stockman to be a good judge as to what animals will make the most economical use of feeds. The past century has witnessed a great increase in the number of good judges of stock. Under the present training in our agricultural colleges the average student after a reasonable amount of experience can pick out the fit from the unfit. Good judges of stock are becoming more common. But given a pen of good animals, the problem before the breeder is how to perpetuate the good qualities—how can the ability to make an economical use of feed be carried over to the next generation?

Modern scientific investigation has contributed considerable light upon this point. Microscopic study of the germ cells and embryonic tissue has revealed the inner structure and the conditions which may influence the incipient organism. Biometric treatment of the phenomena of heredity indicates the degree to which in the long run a continuous variation may be inherited; and above all the discovery of Mendel's principles has made it possible to predict with a reasonable degree of certainty what characters may be inherited.

Experimental evidence has shown that the unit characters of which each individual being is composed may be inherited independently; that some of these units are dominant over others; that the recessive characters can be inherited as a rule only when mated with recessive; that all ancestors of the same degree do not contribute equally to the hereditary qualities of the offspring. Mendel and other investigators have proved that each character of an animal may be broken up into its separate factors by experimental work, and that definite knowledge may be obtained as to which characters blend and which are alternative; which are dominant and which are recessive.

Once these facts have been ascertained, the breeder is no longer working in a haphazard way. When Hurst can predict the difference between the result of mating two pairs of rabbits, externally identical, because he knows the difference between their gametic constitution, or Castle can prophesy a new variety of guinea pigs, as reported on another page of this issue, the breeder has it in his hands to accomplish his object more intelligently and with greater certainty.

Davenport, Hurst, Bateson, and others have found that poultry exhibits numerous unit characteristics which are inherited in alternative fashion, many of which when correlated easily separate as a result of hybridization. Davenport has recently found that the crest of canaries behaves in Mendelian fashion, as in the case of poultry and pigeons. Spillman has indicated how a knowledge of Mendelian characters may assist in fixing the white band and in eliminating the white feet of Hampshire swine without using black breeding animals. From a study of stud books Harper found that in Percheron horses the gray color is dominant over black, and the dam dominant over the sire in the ratio of five to four; and Hurst that the bay and brown colors of thoroughbred horses are Mendelian dominant over chestnut.

Most of the work done in the determination of Mendelian principles has been applied to morphological characters, but the practical man has more concern with physiological qualifications. If morphological characters behave in Mendelian fashion, there is reason to suppose that the physiological characters do likewise, although this has been determined in but few cases. For instance, normal mice are dominant over waltzing mice; and Hurst has found that, at least in some cases, broodiness in hens is dominant over nonbroodiness.

It has been the common opinion among farmers and stockmen that an acquired modification is inherited, but the study of cell division under the microscope indicates that functional variations are rarely if ever inherited, and that injuries and mutilations are not passed on. The lecture before the American Association for the Advancement of Science, at Baltimore, by Professor Wilson, reported on page 1071, is an illustration of how microscopic studies of germ cells may throw light upon the vexed problem of the determination of sex.

Results of applying the statistical methods, as elaborated by Quetelet, Galton, Pearson, and their followers, to the problems of heredity are too well known to be described here, but as yet their value seems to have been less appreciated by station workers in animal breeding than in plant breeding. The breeding of the larger domestic animals is slow and costly, but fundamental principles remain the same throughout the animal kingdom, and much can be done, at least in a preliminary way, by working with small animals which reach maturity in a few weeks or months. Though the primary interest may

be with horses and cows and the information sought is to be applied to their breeding, much time may be saved by experimental work with mice, guinea pigs, rabbits, and other prolific mammals.

The discovery of a dominant character in the color pattern of a rabbit may require many generations of rabbits but only a comparatively short space of time. Once discovered, the observations may be transferred to the horse to determine if the same character is dominant there, with a saving of much time. Such questions as the regulation of sex, telegony, maternal impression, and inheritance of acquired characters are of great interest to biologists and practical breeders alike. Small animals lend themselves to studies of this kind, and may give both theoretical results and practical indications. Recently much light has been thrown on the subject of the determination of sex by studies with moths, grasshoppers, the cherry bug, and other insects.

Conditions at some of the stations have been too unsettled to warrant the inauguration of a work which may take many years before appreciable results can be secured. The more stable conditions which now prevail, and the special research fund, offer many inducements for men who have the proper training and are content to work industriously and continuously along one line for a term of years.

With our present knowledge there seem to be three main lines which offer great opportunities: (a) Experimental breeding with discontinuous variations; (b) statistical study of continuous variations; and (c) microscopic study of the minute constituents of germ cells. Eventually we shall have to seek explanations for the phenomena of heredity in physiological chemistry and molecular physics, but for the present there is abundant opportunity for studying experimentally the problems which bear more directly upon the practical work of the breeder.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

Agricultural chemistry, A. Morgen and G. Fingerling (*Jahrb. Chem., 17 (1907), pp. 285–299*).—This is a review for the year 1907, and, as usual, contains biographical notes, references to important discoveries in analytical methods, and a review of chemical investigations relating to air and water, soils, fertilizers, and plant and animal physiology.

Chemical industry in relation to agriculture, A. Frank (*Jour. Soc. Chem. Indus., 27 (1908), No. 22, pp. 1093–1100*).—This article shows the close relation between chemical industry and agriculture, particularly in the production of phosphates, potash salts, and nitrogen compounds. Especial attention is given to the progress and present status of the manufacture of nitrogen compounds from the air by electric processes.

The behavior of metallic aluminum in contact with milk, wine, and some salt solutions, F. von Fillinger (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 4, pp. 232–234*).—An investigation undertaken with reference to the use of aluminum for cooking utensils showed that fresh milk did not dissolve an appreciable quantity of it, while the serum of very sour milk dissolved only traces. When wine was cooked in aluminum none of the metal was dissolved.

On the precipitation of magnesium as ammonium-magnesium phosphate, E. Raffa (*Gaz. Chim. Ital., 38 (1908), II, No. 6, pp. 556–566; abs. in Analyst, 34 (1909), No. 395, p. 73; Ztschr. Angew. Chem., 22 (1909), No. 9, pp. 397, 398; Jour. Chem. Soc. [London], 96 (1909), No. 556, II, pp. 183, 184*).—The author discusses conditions affecting the accuracy of the determination of magnesium by precipitation with sodium-ammonium phosphate.

A volumetric method is proposed as follows: To 40 cc. of half-normal sodium-ammonium phosphate in a wide-mouthed flask add rapidly 10 cc. of the solution in which magnesium (0.3 to 0.5 gm.) is to be determined; shake the mixture and allow to stand until precipitation is complete; filter through a dry filter or remove the clear liquid with a pipette. To an aliquot part of the solution add 1 to 2 cc. of concentrated acetic acid and determine excess of phosphoric acid by means of uranyl acetate in the usual way.

If a gravimetric procedure is preferred, the precipitated ammonium-magnesium phosphate (using 20 to 25 cc. of sodium-ammonium phosphate) may be collected on a filter, washed with 2.5 per cent ammonium solution, ignited, and weighed in the usual way.

The theory of the titrametric determination of phosphoric acid (*Pharm. Zentralhalle, 49 (1908), No. 51, pp. 1035–1037*).—The theory and calculation of results of precipitation as ammonium phosphomolybdate and ammonium magnesium phosphate weighed as magnesium pyrophosphate are briefly explained.

Volumetric determination of water-soluble phosphoric acid in superphosphates, L. Schucht (*Chem. Ztg., 32 (1908), No. 99, pp. 1201, 1202; abs. in*

Jour. Chem. Soc. [*London*], *96* (*1909*), *No. 555, II, p. 92; Chem. Zentbl., 1909, I, No. 3, p. 216; Chem. Abs., 3* (*1909*), *No. 7, p. 763*).—The perfected method proposed by the author is in brief as follows: In 500 cc. of a superphosphate solution containing 20 gm. to the liter, precipitate the lime with exactly the amount of normal potassium oxalate required (this is determined by previous titration of an aliquot of the solution), heat to about 70° C. until the granular precipitate falls to the bottom, cool in a stream of water, make the volume to 550 cc., filter, and titrate 110 cc. of the filtrate with one-half-normal alkali solution, using methyl orange or indigo methyl orange as indicator. To another portion of 110 cc. of the filtrate add 25 cc. of normal oxalate solution and titrate with the same alkali solution, using phenolphthalein as indicator. The difference between the number of cubic centimeters obtained in the two titrations multiplied by 0.0355 and by 50 gives the percentage of water-soluble phosphoric acid. The number of cubic centimeters obtained in the first titration multiplied by the same factors gives the percentage of free acid.

The determination of nitrogen in calcium cyanamid, D. Girasoli (*Atti R. Ist. Incoragg. Napoli, 6. ser., 59* (*1907*), *pp. 13, 14*).—The author reports a new method, easily executed, sufficiently exact, and time saving.

The calcium cyanamid is put into a glass tube connected on one side with a flask in which steam is produced and on the other side with a condenser. The tube is heated with a Bunsen lamp while steam is forced through and the distillate is collected in a flask containing a known quantity of tenth-normal sulphuric acid. The reaction is complete when the distillate no longer gives an alkaline reaction. The excess of sulphuric acid is titrated with a tenth-normal ammonia solution, using phenolphthalein as an indicator. A table is appended comparing the results obtained with 3 samples by this and the Kjeldahl method. A maximum difference of 0.13 per cent is shown.

Comparative determinations of hardness in water, Klut (*Mitt. K. Prüfungsanst. Wasserver. u. Abwässer. Berlin, 1908, No. 10, pp. 74–85; abs. in Chem. Ztg., 32* (*1908*), *No. 97, Repert., p. 632; Chem. Zentbl., 1908, II, No. 25, p. 1953; Jour. Chem. Soc.* [*London*], *96* (*1909*), *No. 556, II, p. 183; Gesndhts. Ingen., 32* (*1909*), *No. 16, pp. 270, 271*).—Gravimetric analysis is considered the only absolutely accurate method of determining hardness. For quick determination Clark's soap method has value. The methods of Pfeiffer, Wartha, and Lunge are considered unreliable. For temporary hardness the author titrates with tenth-normal acid and methyl orange. "Carbonate" and "mineral-acid" hardness are suggested as substitute terms for temporary and permanent hardness.

The determination of the clay content of soils, C. C. Fletcher (*Science, n. ser., 28* (*1908*), *No. 730, p. 930*).—In the method described the amount of clay is determined, after removing the coarser particles by centrifuging, by evaporating the clay water to dryness in enameled-ware cups having a capacity of about 300 cc. and weighing about 180 gm. The possibility of still further shortening the process by determining the percentage of clay by difference is suggested.

Shaking as a means of preparing soils for mechanical analysis, P. Kashinski (*Zhur. Opuitn. Agron.* [*Russ. Jour. Expt. Landw.*], *9* (*1908*), *No. 4, pp. 488–493*).—The effect of shaking as compared with boiling was studied in the mechanical analyses of three soils (one podzol, one alkali, and one chernozem). The results are summed up as follows: (1) Shaking gives less particles with the diameter less than 0.01 mm. and more particles of the diameter 0.25 to 0.05 than boiling does; (2) by increasing the volume of water in shaking these differences grew less; (3) for alkali and podzol soils the values obtained by shaking and boiling are practically equal. The values differ strikingly in the case of chernozem soils.

Methods of testing the efficiency of ventilation, Ellen H. Richards et al. (*Technol. Quart., 21 (1908), No. 3, pp. 321–331, figs. 3; abs. in Chem. Abs., 3 (1909), No. 1, p. 90*).—Simple methods and apparatus for the collection of samples of air in occupied rooms and for the determination of carbon dioxid are described.

From the observations recorded the conclusion is drawn that when in a crowded hall the temperature is less than 70° F., humidity less than 70 per cent, carbon dioxid less than 7 parts in 10,000, and there is no appreciable odor, the air is satisfactory. When the temperature rises to 80°, humidity to about 83 per cent, and carbon dioxid to 8 parts per 10,000, with a close odor, steps should be taken at once to improve ventilation.

Improvement in the technique of protein hydrolysis. The employment of hydrofluoric acid and its advantages, L. Hugounenq and A. Morel (*Bul. Soc. Chim. France, 4. ser., 3–4 (1908), No. 23, pp. 1146–1151*).—The authors conclude that hydrofluoric acid possesses many advantages for the hydrolysis of proteids in experimental studies of their cleavage products and structure.

The hydrolysis of fish muscle, T. B. Osborne and F. W. Heyl (*Amer. Jour. Physiol., 23 (1908), No. 2, pp. 81–89*).—Out of a total of 16.40 per cent nitrogen yielded by hydrolyzing halibut muscle, according to the method outlined, the different forms of nitrogen yielded the following portions: Nitrogen as ammonia 1.10 per cent, basic nitrogen 4.95 per cent, nonbasic nitrogen 9.96 per cent, and nitrogen in magnesium oxid precipitate 0.39 per cent.

"The nitrogen contained in the histidin, arginin, and lysin is equal to 4.16 per cent, or 0.79 per cent less than the basic nitrogen precipitated by phosphotungstic acid. This difference is nearly the same as that similarly found for chicken muscle, and is probably largely caused by basic substances of nonprotein origin contained in the muscle substance."

Concerning the constitution of phytin, C. Neuberg (*Biochem. Ztschr., 9 (1908), No. 5–6, pp. 557–560; 16 (1909), No. 4–5, pp. 406–410*).—According to the results of the author's investigations phytin is to be regarded as an inosit-phosphoric-acid ester.

Extending the use of the precipitin reaction, J. Fiehe (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 9, pp. 512–515, fig. 1*).—Filtering and handling the serum used in this reaction, and similar questions of laboratory technique, are discussed and some notes are given regarding the use of the method for identifying fat by means of the muscular tissue present in it.

Concerning the identification of starch, W. H. Bloemendal (*Pharm. Weekbl., 43 (1906), pp. 1249–1265; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 11, p. 691*).—The author endeavored to determine whether starches of different sorts showed differences in composition similar to those noted with cellulose, the general preference for arrowroot starch instead of potato starch as food, and the behavior of different starches to the iodin reaction and as regards paste formation indicating that such might be the case.

Determinations of the specific gravity, carbon hydrogen, and water content and heat of combustion of potato, rice, wheat, and maranta starches gave identical results, or results which differed only within the limits of error. Judging by the ease with which β-amylose (amylogranulose), for instance, is changed into α-amylose (amylocellulose) by simply drying, the author concludes that the difference between these substances is simply one of water content. He does not believe that α-amylose exists as such in the original starch grain.

The polarimetric determination of starch, C. J. Lintner (*Ztschr. Untersuch. Nahr. u. Genussmtl., 14 (1907), No. 3, pp. 205–208; 16 (1908), No. 9, pp. 509–512*).—Data are given regarding a method devised by the author.

The alkalinity of meat ash and the ash of some casein preparations determined by Farnstein precipitation method, A. Kickton (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 10, pp. 561–574*).—A large number of determinations are reported and discussed.

The identification of horse meat by the biological method, R. Schüller (*Ztschr. Fleisch u. Milchhyg., 19 (1908), No. 2, pp. 41–48*).—A study of methods.

Examination of sausage, H. Kreis (*Chem. Ztg., 32 (1908), No. 86, pp. 1042–1045*).—A digest of data and a study of methods.

The identification of artificial and natural honeys and the detection of cane sugar and its decomposition products, I. Fiehe (*Chem. Ztg., 32 (1908), No. 86, pp. 1045, 1046*).—A contribution to the question of the resorcin-hydrochloric-acid method for judging honey.

The detection of formic acid in honey, T. Merl (*Ztschr. Untersuch. Nahr u. Genussmtl., 16 (1908), No. 7, pp. 385–389*).—A critical study of methods and progress report.

An important source of error in the estimation of caffein by the Juckenack-Hilger method, K. Lendrich and R. Murdfield (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 11, pp. 647–658*).—A critical study of methods.

The theobromin content of coco and a new method for estimating it quantitively, A. Kreutz (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 10, pp. 579–584*).—A progress report of methods for determining quantitatively the theobromin present in the free state and as a glucosid.

Judging alcohol-free wine, J. M. Krasser (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 7, pp. 398–400*).—The author considers that only those goods should be called alcohol-free wine which have been prepared by removing the alcohol of natural wine. The term, he believes, should not be applied to sterilized musts.

The use of Fiehe's resorcin-hydrochloric-acid reaction for identifying artificial invert sugar in wine, A. Kickton (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 10, pp. 574–579*).—A critical study of this method.

With what exactness can the analytical data of wine examinations be represented? (*Ber. K. Lehranst. Wein. Obst. u. Gartenbau Geisenheim, 1907, pp. 219–230*).—A summary and discussion of analytical data.

Participation of reductase in the process of alcohol fermentation, V. I. Palladin (*Izv. Imp. Akad. Nauk [Bul. Acad. Imp. Sci. St. Pétersb.], 6. ser., 1908, No. 8, pp. 667–672*).—This article gives the results of the author's experiments, which indicate that reductases participate in the process of alcohol fermentation. The reductases used were common zymin (yeast killed by acetone) and zymin poor in glycogen. When zymin was treated with an aqueous solution of sodium selenite and a few drops of toluene, metallic selenium was precipitated. A similarly treated portion when boiled showed no change. Other experiments showed that reductase participates in the process of decomposition of glucose into alcohol and carbon dioxid.

Color reactions as tests for heated milk, B. Herholz (*Beiträge zu bisher bekannten Reaktionen zur Unterscheidung von roher und erhitzter Milch mit besonderer Berücksichtigung der Guajakproben. Inaug. Diss., Univ. Braunsberg, 1908, pp. 102; Milchw. Zentbl., 4 (1908), No. 10, pp. 445–472; abs. in Chem. Zentbl., 1908, II, No. 18, p. 1540*).—The author made tests of a large number of methods used for detecting heated milk, and thinks that paraphenylendiamin, ursol, and guaiacol are trustworthy reagents for this purpose. The guaiac ring test is preferred, as it is simple and inexpensive and the reagent can be kept for some time without losing its characteristic properties. The intensity and duration of the blue zone that is formed is a test of the temperature to which the milk has been heated.

The differentiation of the enzyms in milk by hydrogen dioxid and its tests, C. H. Lawall (*Amer. Jour. Pharm., 81 (1909), No. 2, pp. 57–59*).—Milk which was suspected of having been preserved with hydrogen dioxid was tested by Dupouy's method and by the benzidin test of Wilkinson and Peters.

With both methods the preservative could be detected when present in varying amounts down to 0.5 of 1 per cent. The author considers these methods superior to the use of potassium chromate and diluted sulphuric acid. Small amounts could be detected only within a few hours after the hydrogen dioxid was added. The author also found that hydrogen dioxid inhibits or destroys the action of the enzym reacting with the Wilkinson-Peters test much more rapidly than it affects the enzym reacting with the Dupouy test, and that eventually it destroys the action of both of these enzyms and causes the milk to react the same as boiled or sterilized milk.

On the biological differentiation of milk, J. Bauer (*München. Med. Wchnschr., 55 (1908), No. 16, pp. 847, 848; abs. in Hyg. Rundschau, 19 (1909), No. 1, p. 33*).—The author used the "deviation of complement" process as a test for adulterated milk but found that it is unreliable, since unadulterated milk can retard hemolysis. The amount of water present can be approximately estimated, however, with a titrated serum.

On recent rapid methods for estimating the fat content of cream, Rusche (*Milchw. Zentbl., 4 (1908), No. 9, pp. 385–409*).—Methods of Gerber, Siegfeld, Sichler, and other investigators are reviewed and criticised.

The estimation of the fat content in cream, Grimmer (*Milchw. Zentbl., 4 (1908), No. 10, pp. 433–439*).—A discussion of the article noted above, relating chiefly to the correct formula when estimating fat with the Gerber butyrometer.

Butter and its adulterations under the microscope, W. Morres (*Österr. Molk. Ztg., 15 (1908), No. 23, pp. 312–314, figs. 12*).—The author believes that a microscopical examination of butter is an easy and reliable means for detecting butter adulterants.

On the estimation of sugar in bagasse, H. Pellet (*Internat. Sugar Jour., 10 (1908), No. 119, pp. 554, 555*).—A discussion of the determination of sugar with the Zameron apparatus. Correct results are not obtained unless precautions are taken to avoid the inversion of sugar. A single extraction always gives low results.

Explanation of the occasional abnormally high quotient of purity of some sugar-cane juices, H. Pellet (*Internat. Sugar Jour., 10 (1908), No. 119, pp. 558, 559*).—The author explains the abnormally high quotient of some sugar juices as follows: According to the quality of the cane and the manner in which it has been treated the juices obtained are in a more or less viscous condition, and consequently the air which has become entangled in the juice during the process of extraction is held by the liquid in a state of an emulsion and is incapable of escaping even after having stood for a comparatively long time. The Brix reading will, therefore, be more or less influenced by the presence of this emulsified air. It will, however, pass to its normal value when the air is expelled by heating or by other suitable means.

Determination of sugar in molasses cattle feeds and denatured sugar products, L. Vuaflart (*Bul. Assoc. Chim. Sucr. et Distill., 26 (1908), No. 5, pp. 339–341; Internat. Sugar Jour., 11 (1909), No. 121, pp. 38, 39; abs. in Jour. Soc. Chem. Indus., 27 (1908), No. 24, p. 1215*).—The author states that polarimetric methods are untrustworthy for determining sugar in these products, as there are optically active substances other than sucrose which are not precipitated by basic lead acetate. He recommends a method for determining sugar

in molasses feeds and one for denatured sugar mixtures containing linseed meal.

Application of the gasometric method to the exact determination of urea, A. Ronchèse (*Bul. Soc. Chim. France, 4. ser., 3–4 (1908), No. 23, pp. 1135–1141*).—Noted from another source (E. S. R., 20, p. 807).

Wood products, distillates and extracts, P. Dumesny and J. Noyer, trans. by D. Grant (*London, 1908, pp. XVI+320, figs. 107*).—A translation of a technical treatise on the industrial chemistry of wood and its preservatives. The special subjects treated are the carbonizing or "coaling" of wood, the manufacture of acetic acid and secondary products of wood distillation, analysis of raw materials and finished products, the destructive distillation of olive oil residuals, and the manufacture and testing of tan wood extracts and their utilization in modern tanneries.

Leather industries laboratory book, H. R. Procter (*London and New York, 1908, 2. ed., rev. and enl., pp. XX+460, pls. 3, figs. 46*).—This is the second edition of a work which "is occupied mainly with the practical details of analytical processes and makes no attempt to teach either chemical theories or the principles of leather manufacture." The chemical, microscopical, and bacteriological methods described have been tested in the laboratory and include processes used in the examination of tanning material. The work is intended as a supplement to the ordinary chemical text-book.

A new mercury azotometer, C. A. Garcia (*Bul. Soc. Chim. France, 4. ser., 3–4 (1908), No. 23, pp. 1111–1114, fig. 1; abs. in Analyst, 34 (1909), No. 395, p. 78, fig. 1; Jour. Chem. Soc. [London], 96 (1909), No. 555, II, p. 92*).—An apparatus in which the air space is reduced to a minimum with a view to thus increasing the accuracy of measurement is described.

A simple apparatus for the estimation of catalase, G. Koestler (*Milchw. Zentbl., 4 (1908), No. 12, pp. 532–535, figs. 3; abs. in Rev. Gén. Lait, 7 (1909), No. 9, p. 214*).—The apparatus described consists of a graduated tube provided with an agar cork, which is forced upward as gas is formed.

An apparatus adapted to a number of analytical purposes, M. E. Pozzi-Escot (*Bul. Assoc. Chim. Sucr. et Distill., 26 (1908), No. 4, pp. 267–271, fig. 1*).—The apparatus described is a small flask with accessory devices, which, as explained by the author, is adapted to use in a number of analytical determinations, including the determination of carbon dioxid in carbonates, amid, ammoniacal and nitrous nitrogen, oxygen in water, analysis of persulphates, perborates, percarbonates, and peroxids, hydrazin, and copper.

METEOROLOGY—WATER.

Wireless telegraphy in the service of modern meteorology, P. Polis (*Hansa, 45 (1908), No. 38, pp. 937, 938*).—This is a brief account of the use of wireless telegraphy to secure a series of weather observations on a trip on a large ocean liner from Hamburg to New York and return in August, 1908, and of the preparation of daily synoptic weather charts, with suggestions as to the aid a system of such observations would give in general weather predictions on sea and land.

Wireless telegraphy in the service of modern meteorology, E. Herrmann (*Hansa, 45 (1908), No. 39, pp. 962–964*).—The author questions whether weather reports from ships by means of wireless telegraphy, as suggested by Polis (see above), will prove of very great value in determining the laws controlling the distribution of variation in atmospheric pressure over wide areas, upon which accurate weather forecasting on land and sea depends.

Monthly Weather Review (*Mo. Weather Rev., 36 (1908), Nos. 11, pp. 357–394, figs. 2, charts 8; 12, pp. 395–434, figs. 3, charts 9*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of November and December, 1908, recent papers bearing on meteorology and seismology, recent additions to the Weather Bureau library, notes from the Weather Bureau library, etc., these numbers contain the following articles and notes:

No. 11.—The Climate of the Historic Past (illus.), by E. Huntington; Notes on the Climate of Eastern Asia, by A. J. Henry; An Elementary Method of Deriving the Deflecting Force due to the Earth's Rotation for West-east Motion (illus.), by W. H. Jackson; Titles of Papers Read Before the German Meteorological Association; Relation Between the Range of Air Temperature and the Distribution of Land and Water, by M. Tsutsui; A Comparison of the Changes in the Temperature of the Waters of the North Atlantic and in the Strength of the Trade Winds, by W. C. Hepworth; Kassner's Meteorological Globes, by R. DeC. Ward; Luminous Fog; Brilliant Gulf Waters; New System of Storm Signals for Norway, by F. S. S. Johnson; Recent Progress in California; Suggested Reform in Meteorological Methods, by A. G. McAdie; and An Annotated Bibliography of Evaporation, by Mrs. G. J. Livingston.

No. 12.—Studies on the Vortices of the Atmosphere of the Earth (illus.), by F. H. Bigelow; Deficient Humidity Indoors, by F. H. Day; Wireless Telegraphy in the Service of Modern Meteorology, by P. Polis, trans. by C. F. Talman (see p. 1011); Remarkable Snowstorm at Grand Haven, Mich., by C. H. Eshleman; Tornadoes in Wisconsin, November 25, 1908; Severe Windstorms in Ohio, August 12 and 17, 1908, by J. W. Smith; Severe Windstorms in New Mexico and Oklahoma; A Luminous Meteor Cloud Observed at Urbana, Ill. (illus.), by C. J. Kullmer; The Training School at Tokyo, Japan, for Meteorological Observers; The Class under Instruction at Washington; Formation of Dew at Tree Tops; Hurricanes Affected by Mountain Ranges; Is the Earth Drying Up?; Tasmania and the Total Solar Eclipse; Driest Year at Portland, Me., by E. B. Jones; Address to the Mathematical and Physical Section of the British Association for the Advancement of Science, Dublin, September, 1908, by W. N. Shaw; The Baltimore Meeting of the American Association for the Advancement of Science, by W. R. Blair; The Baltimore Meeting of the Association of American Geographers; and Tornadoes in Arkansas during November, 1908 (illus.).

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. Ostrander and R. C. Lindblad (*Massachusetts Sta. Met. Buls. 241, 242, pp. 4 each*).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during January and February, 1909. The data are briefly discussed in general notes on the weather of each month.

Meteorological report, 1907, F. H. Auld (*Ann. Rpt. Dept. Agr. Prov. Saskatchewan, 1907, pp. 92–106*).—This is a summary of observations on temperature and precipitation at 40 meteorological stations in Saskatchewan during the year 1907. The weather of each month is described.

Weather at Rothamsted in 1908, J. J. Willis (*Gard. Chron., 3. ser., 45 (1909), No. 1153, pp. 66, 67*).—Observations on temperature, precipitation, and general weather conditions are briefly summarized in this article. The year was characterized by a deficiency of rainfall, the total being 25.31 in., as against an average of 28.12 in. for the past 55 years. The mean temperature of the year, 48.2° F., was slightly, 0.3°, in excess of the average.

Danish meteorological conditions in 1907–8, V. Willaume-Jantzen (*Tidsskr. Landökonomi, 1908, No. 13, pp. 660–689*).—Conditions for each month from October, 1907, to September, 1908, inclusive, are summarized.

Meteorology (*New Zeal. Off. Yearbook 1908, pp. 618–623*).—Tabular summaries are given of observations on temperature, rainfall, atmospheric pressure, and wind at 14 stations in New Zealand during the year 1907.

Handbook of climatology, J. Hann (*Handbuch der Klimatologie. Stuttgart, 1908, 3. ed., rev. and enl., pp. XIV+394; rev. in Nature [London], 79 (1909), No. 2048, p. 363*).—This is the third revised and enlarged edition of this handbook. The most important revision is in connection with the sections on radiation, cyclical changes of climate, methods of computing averages for temperature and rainfall from incomplete or short series observations, and climatic zones of the globe.

Variations in climate, H. Arctowski (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 25, pp. 1438–1440; abs. in Rev. Sci. [Paris], 47 (1909), I, No. 1, p. 27; Sci. Abs., Sect. A—Phys., 12 (1909), No. 134, p. 72*).—On the basis of observations on temperature recorded during more than 50 years in different parts of the earth, but particularly from 1891 to 1900 in France, the author concludes that there are exceptionally warm or exceptionally cold years.

Temperature differences are not alike in size and magnitude at different places, but in many cases the variations at one place are the opposite of those at another. The amount of compensation between different stations is apparently insufficient to permit of the assumption of a constant mean temperature at the earth's surface. It is suggested that this is due to variations in intensity of solar radiation.

Public water supplies, F. E. Turneaure and H. L. Russell (*New York and London, 1908, 2. ed., rev. and enl., pp. XV+808, figs. 231*).—This is the second revised and enlarged edition of this standard work.

"The chapters relating to the purification of water have been thoroughly revised, that on mechanical or rapid filtration being rewritten and greatly enlarged. . . . Besides the matter relating to purification many other changes and additions have been made in nearly every chapter. The most important of these relate to methods of bacterial examination of water, the investigation of ground water and the construction of collecting works, data on the use of water, data on rainfall and flow of streams, the construction of dams, and the application of reenforced concrete to conduits, dams, filters, reservoirs, and tanks. The literature of each chapter has also been extended and brought up to date."

Chemical and biological survey of the waters of Illinois, E. Bartow et al. (*Univ. Ill. Bul., 6 (1908), No. 4, pp. 80, figs. 13*).—This report gives "a detailed description of the work accomplished during the 16 months ending December 31, 1907, with a summary, by years, of the analyses made since the foundation of the survey to that time, and a summary, by months, of the analyses made during the last two years. The new quarters into which the survey moved during the summer of 1907 are described.

"The progress of the cooperative work with the State board of health, and with the engineering experiment station of the University of Illinois, the State geological survey, and the Water Resources Branch of the United States Geological Survey, is reported.

"There are included the descriptions of several experiments or investigations carried on by the survey." Among these are Sanitary Chemical Examination of Water Bacteria, by A. W. Sellards; Stand for Fermentation Tubes, by W. G. Bain; Laboratory Experiments in Water Treatment, by E. Bartow and J. M. Lindgren; Normal Waters of Illinois; Investigation of Manufacturing Waste at Waukegan; and Character of the Underground Waters of Normal.

From the study of normal waters of Illinois, the conclusion is drawn "that waters from deep rock wells though varying in composition at different depths

and in different sections show an increase of mineral residue from north to south. This variation is shown at least from the northern border of the State to a line drawn from Quincy to Ottawa and probably to the southeast of the above line as indicated by isolated cases.

"The deep drift waters are so very variable that such tests as free ammonia and consumed oxygen have little value as means for judging their purity. Waters containing more sodium than is required to unite with the nitrate, chlorin, and sulphate ions predominate.

"The streams are all turbid and impure. The turbidity is more persistent to the south. All must be treated before being used for drinking purposes."

Bacteria in water, A. Koch (*Jahresber. Gärungs-Organismen, 16 (1905), pp. 154–171*).—The literature of this subject appearing during 1905 is reviewed.

Some features of the fifth report of the Royal Commission on Sewage Disposal, H. Lemmoin-Cannon (*Jour. Roy. Sanit. Inst., 30 (1909), No. 1, pp. 58–63*).—This is a brief summary of some of the chief features of this report, which has been previously noted (E. S. R., 20, p. 617), relating to sewage farming, processes in artificial systems, including preliminary treatment, chemical precipitation, septic tank treatment, and preparation and utilization of sludge, comparative cost of treatment by land and by artificial processes, and standards for sewage effluents. The conclusions of the report do not indicate any decided advantage of artificial treatment over land treatment either as regards efficiency or economy provided soil and other conditions are favorable to land treatment.

Purification and disposal of town and factory sewage, A. Reich (*Reinigung und Beseitigung städtlicher und gewerblicher Abwässer. Hanover, 1907, pp. 139, pl. 1, figs. 30*).—This is a concise summary of information regarding the nature of town and factory sewage, the collection and examination of water samples, the self-purification of streams, and methods of purification of sewage, including mechanical and mechanical-chemical methods, irrigation, biological processes, and electrical methods.

SOILS—FERTILIZERS.

The agricultural soils of Cape Colony, C. F. Juritz (*Agr. Jour. Cape Good Hope, 33 (1908), Nos. 1, pp. 33–45; 2, pp. 171–187, map 1; 3, pp. 318–335, figs. 2; 4, pp. 473–490; 5, pp. 599–613, figs. 3; 6, pp. 743–759, figs. 3; 34 (1909), Nos 1, pp. 64–90, figs. 3; 2, pp. 166–184, figs. 3; 3, pp. 277–294, figs. 2*).—This article discusses the value of chemical analysis as a means of determining the fertility of soils, describes methods commonly employed for such analysis, especially those used by the author in the examination of Cape Colony soils, presents an argument in favor of systematic soil surveys and investigation in the colony, and reports results of analyses of about 800 samples of soil from different parts of the colony, of which 442 were collected in pursuance of a systematic soil survey and represented 27,000 square miles, or one-tenth of the total area.

Most of the soils were analyzed by the standard method based on extraction with hydrochloric acid of 1.115 sp. gr. A considerable number, however, were examined by the German official method and a few by the Maercker, Hilgard, and Dyer methods for comparative purposes.

The humus deposits in the limestone Alps, Wilhelm Graf zu Leiningen (*Naturw. Ztschr. Forst u. Landw., 6 (1908), No. 11, pp. 529–538, pls. 2; 7 (1909), Nos. 1, pp. 8–32; 3, pp. 160–173; 5, pp. 249–273*).—This article discusses Alpine peat deposits in general; the terminology of forms of humus; peat formation in wet and dry places; relation of animal life, lower organisms and wind-borne matter, character of plants, character of decomposition, and pres-

ence or absence of lime to the nature of the humus; nature of subsoils underlying peat deposits; plant food and free acids in peat; and classification of types of soil, vegetation, and humus in peat deposits.

Contribution to the study of the humus matter of peat, L. Roger and E. Vulquin (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 25, pp. 1404–1406*).—Studies of the humus matter obtained by extracting fibrous peat with 10 per cent soda solution are reported which indicate that the process of peat formation results in the accumulation of nitrogen and carbon in the products of decomposition of vegetable matter. Neither pentosans nor hexosans were found in the peat. A new fact observed was that the humus of peat has decidedly acid properties.

Recent results of investigations in soil bacteriology and their value for agricultural practice, J. Simon (*Neuere Ergebnisse bodenbakteriologischer Forschungen, ihr Wert für die landwirtschaftliche Praxis. Dippoldiswalde, [1908], pp. 27, dgms. 2*).—The author discusses the bearing of recent bacteriological investigations on the nitrogen cycle in the soil, soil inoculation, and the accumulation of nitrogen in the soil, and the best practical means of increasing the activity of beneficial soil organisms.

Legume bacteria, S. F. Edwards and B. Barlow (*Ontario Dept. Agr. Bul. 169, pp. 32, figs. 45*).—Studies on nitrogen assimilation by legumes which have been going on about 5 years are summarized. Previous accounts of this work have been noted (E. S. R., 19, p. 528). The results of practical tests of inoculating material prepared and distributed by the authors are also summarized. See also a previous note (E. S. R., 19, p. 1121). During 1908 "2,113 cultures were distributed, and reports were returned from 634, or 31.7 per cent. Of these, positive beneficial results were stated in 397, or 62.6 per cent, and no benefit was apparent in 237, or 37.4 per cent."

Investigations on the process of denitrification, M. Cingolani (*Staz. Sper. Agr. Ital., 41 (1908), No. 8, pp. 530–540; Ann. R. Staz. Chim. Agr. Sper. Roma, 2. ser., 2 (1907–8), pp. 274–284; abs. in Chem. Ztg., 32 (1908), No. 77, pp. 922, 923; Chem. Zentbl., 1908, II, No. 19, pp. 1626, 1627; Jour. Chem. Soc. [London], 96 (1909), No. 556, II, p. 171*).—The author reports investigations in which he isolated from fresh calf manure 2 new denitrifying organisms which he has named *Bacterium porticensis denitrificans α* and *B. porticensis denitrificans β*. The morphological and cultural characters of these organisms are fully described. When cultures were kept at a temperature of 97° F., intense fermentation developed in from 12 to 48 hours and in 2 to 6 days the nitric acid (0.3 per cent) had entirely disappeared.

The action of heat and antiseptics on soils, S. U. Pickering (*Jour. Agr. Sci., 3 (1908), No. 1, pp. 32–54; abs. in Jour. Soc. Chem. Indus., 28 (1909), No. 4, p. 212*).—In continuation of previous work on the effect of moist heat on the soluble constituents of soil (E. S. R., 20, p. 737), the author compared the effect of moist heat and various volatile antiseptics on the productiveness of soils.

The experiments were made with kilogram samples not only of the Rothamsted soil used in previous experiments, but also with various other kinds of soils, including a sample of unproductive soil from Takoma Park, D. C. The effect of the different treatments on solubility of the soil constituents and on the germination of seeds of wheat, rye, clover, mustard, rye grass, and fescue was determined. The results are summarized as follows:

"When soils are treated with antiseptics, such as carbon disulphid, chloroform, benzene, ether, or paraffin oil, they undergo chemical change, and the soluble organic matter in them is increased, just as in case of their being heated; they also exhibit the same inhibitory effect on the germination of seeds that heated soils do.

"The different antiseptics differ in the intensity of their action, but the inhibitory substance formed is probably the same in all cases, and also the same as that formed by heat, for the quantity formed has the same effect on seeds, whether produced by antiseptics or by heat.

"On keeping treated soils for a few weeks at a summer temperature, some of the organic matter which was rendered soluble becomes insoluble, and the inhibitory action is reduced. This is also the case with heated soils, especially when repeatedly watered; though with unheated soils under similar conditions the soluble matter increases.

"The treatment of soils with antiseptics induces a change equivalent to that obtained by heating the soil to 60° to 75°, and this may be sufficient to account for the increased growth observed in plants grown in them.

"The production by heat of a substance inhibitory to germination appears to be a property common to all soils, twelve instances having been examined. The proportion of it formed depends on the increase in the amount of organic matter rendered soluble by heating; but the actual amount of the soluble organic matter in the heated soil is not always a criterion as to the intensity of its inhibitory action, and still less is the amount of soluble organic matter originally present in the unheated soil, though in the majority of cases it may be so. There appears to be no connection between the fertility of a soil and the extent to which it is altered by heating.

"Soils in their natural state appear generally to contain a certain amount of this inhibitory substance, as they act less favorably towards germination than pure water does. Whether in any cases soils can act more favorably than water—as the earlier experiments had indicated they could—is open to doubt, but the probability is in favor of their doing so. So far as the instances now examined are concerned, the richer soils, and those containing most soluble organic matter, as slightly less favorable to germination than the poorer soils."

The rôle of oxidation in soil fertility, O. Schreiner and H. S. Reed (*U. S. Dept. Agr., Bur. Soils Bul. 56, pp. 52*).—A series of experiments is reported in which the oxidizing power of roots of wheat seedlings grown in water extracts of soils of different kinds was studied by means of soluble chromogens such as alpha-naphthylamin, benzidin, vanillin, vanillic acid, and esculin, which yield upon oxidation by the plant roots insoluble colored compounds which are to a large extent deposited upon the surface of the roots, and chromogens such as phenolphthalein, aloin, and leucorosolic acid, which are converted into soluble coloring matters in the solutions.

The authors conclude from the results obtained in these experiments that wheat roots have an extracellular oxidizing power due chiefly to the enzyms which they secrete, and that oxidation is most active in the newer regions of the roots. It was found to be more pronounced in plants grown in extracts of productive soils than in those grown in extracts of unproductive soils.

"Treating the soil extracts with an absorbing agent is usually beneficial to oxidation.

"The distillate of a poor soil extract which contains volatile toxic compounds was less favorable to oxidation than the residue remaining from distillation.

"The process of oxidation is usually accelerated by the addition of nitrates to an aqueous soil extract. The addition of ammonium sulphate is less beneficial to oxidation than the addition of an equal amount of nitrogen in the form of nitrate.

"Calcium salts were found to increase the amount of oxidation in cultures to which they were added.

"The addition of potassium salts was not generally beneficial to the processes of oxidation. In some cases their presence caused a material retardation

of the oxidation. The most of the retardation was due to the action of the potassium itself and not to the formation of acid conditions in the solution. Sodium or ammonium salts of the same acid were more favorable to oxidation than the corresponding potassium salt.

"Phosphates usually produced material increases in the oxidation in solutions to which they were added.

"Chlorids and sulphates, when combined with a suitable base, like sodium, are somewhat beneficial to oxidation, but are not as favorable as the corresponding nitrate would be.

"The presence of toxic organic substances in solution was extremely deleterious to the oxidizing power of plants. The oxidizing power of the plants, especially in the presence of nitrates, was able to alleviate the toxicity of such solutions.

"The process of oxidation by roots is largely, if not entirely, due to the activity of a peroxidase produced by the roots. This oxidizing enzym is most active in neutral or slightly alkaline solutions. The activity of the enzym may be inhibited by the presence of acid and also by the conditions in solutions where putrefaction processes occur."

Soil improvement work, S. D. Conner (*Indiana Sta. Rpt. 1908, pp. 39–42*).—A brief statement is made regarding the cooperative soil improvement experiments which have been conducted in 45 different localities in 33 counties of the State, and a fuller account is given of two such experiments on peat soil in Newton and Henry counties and one on a clay soil in Scott County. The peat soils have been found to be greatly benefited by applications of potash, while in the clay and loam soils phosphorus appears to be the element most needed. These soils are also much benefited by ground limestone and slaked lime.

Soil fertility, T. F. Hunt (*Pennsylvania Sta. Bul. 90, pp. 26, charts 7*).—This is a summary of the results of a series of fertilizer experiments on a clay loam soil of limestone origin which have been carried on for 25 years at this station.

The more important facts brought out by the results are that phosphoric acid is the only fertilizing constituent which produced an increase in yield when used alone. A larger increase, however, was obtained when both phosphoric acid and potash were used. The productive power of the soil was maintained during the 25 years by applying in alternate years 48 lbs. of phosphoric acid and 100 lbs. of potash per acre in a rotation in which clover occurred once in 4 years, but a material increase in yield resulted from the addition of 24 lbs. of nitrogen per acre to the mineral fertilizers. Nitrate of soda gave better results as a source of nitrogen than either dried blood or sulphate of ammonia. An acid condition, proving especially injurious in later years to corn and clover, resulted from the continued application of sulphate of ammonia.

The crop producing power of the soil was maintained during the 25 years without the use of any yard manure. "Without the addition of any organic matter to the soil, except the roots and stubble of the crops raised, the fertility has been fully maintained. In other words, a complete commercial fertilizer and yard manure having maintained the crop producing power equally well in a 4 years' rotation containing clover. Comparatively small quantities of yard manure applied on alternate years, viz, to the corn and wheat, have produced marked increase in yield compared with plats receiving no fertilizer. . . . The addition of 4,000 lbs. of quick lime applied once in 4 years to plats receiving no fertilizer has caused the decrease in yield, but when applied in connection with 6 tons of yard manure the products produced were equal to those produced by an application of 10 tons of manure without lime."

The general conclusion arrived at is that economic farm management under the conditions obtaining in these experiments requires the use of yard manure

supplemented by commercial fertilizers, and "that the best results can be obtained only by a continuous and systematic use of fertilizers in connection with a well ordered method of cropping."

Theories of manure and fertilizer action, A. D. Hall (*Science, n. ser., 28 (1908), No. 723, pp. 617–628, fig. 1; Amer. Fert., 30 (1909), No. 3, pp. 23–30*).—This is a lecture given at the Graduate School of Agriculture at Cornell University in July, 1908, and discusses at some length the various theories which have been advanced to explain the action of manures and fertilizers, the discussion being based mainly upon Liebig's generalizations and conclusions from the results of experiments at Rothamsted and of investigations of the Bureau of Soils of this Department.

The author concludes that there is no direct proof of the supposition "that all soils give rise to soil solutions sufficiently rich in the elements of plant food to nourish a full crop did not some other factor come into play," nor convincing evidence "of the excretion of toxic substances from plants past the autotrophic seedling stage. . . .

"If, however, we give the theory a wider form, and, instead of excretions from the plant, understand débris of any kind left behind by the plant and the results of the bacterial action upon it, we may thereby obtain a clue to certain phenomena at present imperfectly understood. . . .

"Assuming that the persistence in the soil of obscure diseases appropriate to the particular plant can be neglected as the cause of these phenomena, there still remains some unexplained factor arising from a plant's growth which is injurious to a succeeding crop, and this may either be the excreted toxins of Whitney's theory or may be some secondary effects due to the competition of injurious products of the bacteria and other microflora accumulating in the particular soil layer in which the roots of the crop chiefly reside."

[Miscellaneous fertilizer notes] (*Sugar Beet, 30 (1909), No. 1, pp. 18–21*).—Brief notes are given on European investigations on the acclimatization of nitrifying organisms, the use of manganese as a fertilizer, the physiological function of potash in plants, the importance of soda in the growth of sugar beets, Thomas slag as a fertilizer for sugar beets, and toxic substances in soils. The investigations on which these notes are based have already been noted.

Experiments with chemical fertilizers in 1908, E. Chuard and C. Dusserre (*Bul. Soc. Vaud. Agr. et Vit., 1909, No. 225, pp. 303–308*).—Cooperative experiments with 10 farmers in 5 different localities in the Canton of Vaud to determine the profitableness of applying superphosphate, nitrate of soda, and potash salts on well manured soils of good productive capacity are reported. The results show that the chemical fertilizers gave profitable returns on wheat, oats, and maslin (mixed grain).

Cooperative fertilized experiments in Sweden, 1907, P. Bolin (*K. Landtbr. Akad. Handl. och Tidskr., 47 (1908), No. 4, pp. 177–265, dgms. 5*).—The experiments, similar in plan to those of previous years, were conducted with spring grains, root crops, meadows, and lupines. Comparative trials with nitrate of soda and calcium cyanamid, and variety tests were also conducted.

Results obtained with different forms of nitrogen, Clausen (*Landw. Wchnbl. Schles. Holst., 59 (1909), No. 4, pp. 47–50*).—Comparative tests of nitrate of soda, lime nitrogen, Norwegian nitrate, and ammonium salts with rye, barley, oats, and potatoes are reported.

The Norwegian nitrate was fully as effective as the better known nitrate of soda and sulphate of ammonia. The lime nitrogen was especially effective on potatoes and rye, but less so on summer grain. The high absorptive power of the Norwegian nitrate for moisture and the very finely powdered condition of the lime nitrogen interfere somewhat with their handling.

Recent investigations of the nitrogenous fertilizers, C. Schreiber (*Rev. Gén. Agron., n. ser., 3 (1908), Nos. 11, pp. 433–440; figs. 2; 12, pp. 481–486; 4 (1909), No. 1, pp. 4–9, fig. 1*).—Pot experiments with oats are reported which had for their object the study of the loss of nitrate of soda from sandy soils in the drainage. Previous experiments had shown that there was very little loss of nitrate of soda from loam soil in good condition thoroughly cultivated, even when the nitrate was applied two or three weeks before planting. The losses were but little larger in the sandy soil notwithstanding abundant rainfall during the season.

Pot experiments with lime nitrate and lime nitrogen (calcium cyanamid) on oats on clayey and sandy soils showed that the first was about equal to nitrate of soda as a fertilizer, but that the second was decidedly less efficient (53 to 73 per cent). Lime nitrogen applied as a top-dressing at the time of seeding retarded germination and prevented growth of plants. When incorporated with the soil the day of seeding it produced less increase of yield than when cultivated in 15 days before seeding. The use of lime (carbonate) with the lime nitrogen produced an injurious effect. See also a previous note (E. S. R., 20, p. 428).

In pot experiments with oats to determine the effect of calcium carbonate on ammonium sulphate used as a fertilizer it was found that decided losses of ammonia occurred when ammonium sulphate was applied as a top-dressing on soils rich in lime.

On the loss of nitrogen in drainage waters, J. Graftiau (*Ann. Gembloux, 19 (1909), No. 2, pp. 69–75*).—This article points out that the conclusions recently reported by Schreiber (see above) were drawn from experiments in which very large crops were grown and the drainage was very small. It is believed that the conclusions are not applicable to normal conditions of field culture.

Loss of nitrogen by leaching of nitrate of soda, C. Schreiber (*Ann. Gembloux, 19 (1909), No. 3, pp. 160–165*).—This is a reply to Graftiau's criticism of the author's experiments noted above, presenting further data from field experiments in support of the author's conclusions.

Further note on the loss of nitrogen in drainage waters, J. Graftiau (*Ann. Gembloux, 19 (1909), No. 4, pp. 214–222*).—This is a further contribution to the discussion of the above report on this subject by C. Schreiber. The author insists that neither Schreiber's experiments nor those of other investigators cited by him justify practical generalizations.

The loss of nitrogen by seepage of nitrate of soda, C. Schreiber (*Ann. Gembloux, 19 (1909), No. 5, pp. 327–332*).—This is a further reply to Graftiau's criticism of the author's conclusions regarding this subject.

Action of sulphate of ammonia containing 3 per cent of sulphuric acid on the growth of plants, O. Lemmermann and A. Einecke (*Fühling's Landw. Ztg., 57 (1908), No. 23, pp. 787–791*).—In continuation of previous experiments (E. S. R., 20, p. 429), the effect of the sulphate of ammonia alone and combined with acid phosphate was tested in pot experiments with barley, with the result that nearly as good yields were obtained with the sulphate containing 3 per cent acid, even with the addition of acid phosphate, as with the acid-free sulphate.

The agricultural use of calcium cyanamid, A. Müntz and P. Nottin (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 20, pp. 902–906; Bul. Soc. Agr. France, 1908, Dec. 15, pp. 375–379; Prog. Agr. et Vit. (Ed. l'Est-Centre), 29 (1908), No. 50, pp. 718–721; Jour. Agr. Prat., n. ser., 16 (1908), No. 49, pp. 718–720; Jour. Chem. Soc. [London], 96 (1909), No. 555, II, p. 88; Chem. Abs., 3 (1909), No. 4, p. 468*).—Comparative tests of the rate of nitrification of calcium cyanamid,

ammonium sulphate, blood, and roasted leather are reported, showing that taking the rate of nitrification of sulphate of ammonia during 5 months as 100, that of calcium cyanamid was 88, dried blood 66, and roasted leather 26. When as in these experiments the cyanamid was employed in amounts 10 to 20 times greater than those ordinarily used in practice, the nitrifying organisms were paralyzed at first and even a small amount of denitrification occurred, but in a short time the organisms apparently adapted themselves to the medium and normal nitrification was restored. This retardation is due to the cyanamid and not to the excess of caustic lime present. Amounts of the material furnishing 35.7 lbs. of nitrogen per acre may be applied without any retardation of nitrification. Very large amounts may be applied to humus soils in a very active state of nitrification without retarding this process, and still larger amounts may be used (60 times that employed in intensive culture) if added in successive applications extending over a considerable period (4 months).

Comparative field tests on different kinds of soil confirm in general the laboratory results. In only one case were unfavorable results obtained in the application of the cyanamid at the time of planting. Nevertheless, as a precautionary measure it is advised to apply the material shortly in advance of planting. The cyanamid was applied in amounts furnishing 35.7 lbs. of nitrogen per acre in March and April on wheat and oats, and in amounts furnishing 41.95 lbs. of nitrogen per acre on grapes and natural grass lands. In damp weather there was no injury from such application. In dry weather the grain and grass were slightly burned, but soon recovered from the bad effects and the final yield was not reduced. The authors advise, however, that the cyanamid should not be applied as a top-dressing except in wet weather.

The general conclusion from these investigations is that calcium cyanamid is substantially analogous to sulphate of ammonia as a fertilizer.

On the decomposition of lime nitrogen in soils, H. Immendorff (*Chem. Ztg., 32 (1908), No. 80, pp. 971, 972; Umschau, 12 (1908), No. 44, pp. 874–876; Österr. Chem. Ztg., 11 (1908), No. 23, pp. 315, 316*).—Investigations on this subject are reviewed.

Physiological action of dicyandiamid, O. Loew (*Chem. Ztg., 32 (1908), No. 57, pp. 676, 677; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 551, II, p. 775; Chem. Abs., 3 (1909), No. 2, p. 221*).—Observations are reported which led to the conclusion that dicyandiamid is not a good source of nitrogen for many kinds of soil bacteria, the growth being much less rapid in media containing small amounts of this substance than in those containing ammonium sulphate.

When young barley plants were placed in a 5 per cent solution of the substance an injurious effect was noticed after 2 days. Lathyrus plants withstood the injurious action of dicyandiamid somewhat longer. With 0.05 to 0.1 per cent solutions only the points of the leaves were affected. Twigs of Tradescantia in 0.1 per cent solution and Elodea in 0.2 per cent solution showed no injurious effects, and Elodea apparently utilized the dicyandiamid as a source of nitrogen. Threads of Spirogyra remained intact for several days in 1 per cent solutions of dicyandiamid, and worms lived for more than 4 days in 0.5 per cent solution. Bacteria were not injured in the least in broth containing 0.5 per cent of the substance.

The structural formula of the dicyandiamid is discussed.

The importance of nitrogen, H. Steinmetz (*Ber. Naturw. Ver. Regensburg, 1905–6, No. 11, pp. 108–119*).—The importance of nitrogen in relation to industry and plant and animal life, and the possibilities of developing the manufacture of

nitrogen compounds from the free nitrogen of the air are discussed. The dependence of the manufacture of such compounds upon cheap sources of power is explained as well as the sources of water power for this purpose in Germany.

The nitrogen question and its solution, N. Caro (*Österr. Chem. Ztg., 12 (1909), No. 1, pp. 3–5*).—This article reviews briefly various methods which have been proposed in recent years for increasing the supply of combined nitrogen, such as the preparation of ammonium sulphate by the dry distillation of coal, the Mond gas process, the utilization of peat, and the manufacture of calcium cyanamid.

Sulphate of ammonia in 1908, Maizières (*Engrais, 24 (1909), No. 5, pp. 124–127; abs. in Mark Lane Express, 100 (1909), No. 4035, p. 89*).—Statistics of production and consumption of ammonium sulphate are given.

The synthesis of ammonia by means of peat, H. Woltereck (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 25, pp. 1402, 1403; abs. in Jour. Chem. Soc. [London], 96 (1909), No. 556, II, p. 138*).—Further tests of Woltereck's process, which has been previously noted (E. S. R., 19, p. 1124), showed that the products obtained contained much more nitrogen than would be yielded by the amount of peat employed.

The oxidation of the nitrogen of the air, O. Schönherr (*Ztschr. Angew. Chem., 21 (1908), No. 31, pp. 1633–1637; trans. in Jour. Indus. and Engin. Chem., 1 (1909), No. 2, pp. 120, 121; abs. in Amer. Chem. Jour., 41 (1909), No. 1 pp. 75, 76*).—This article deals especially with a method employed by a Baden firm for the manufacture of nitrate, but discusses incidentally other processes proposed for this purpose. The method especially referred to is an electrical process similar to that of Birkeland and Eyde, the essential difference being that the air is carried along a quietly burning arc of great length instead of being forced through the electric flame.

A future substitute for nitrate of soda, K. Birkeland and A. Frank (*8. Internat. Landw. Kong. Wien, 1 (1907), pp. 230–234; 2 (1907), Sect. IIB, Ref. 1, pp. 27+7*).—This is a discussion of the present status and future possibilities of the manufacture of basic lime nitrate by the Birkeland and Eyde process and of calcium cyanamid by the Frank and Caro process.

Calcium cyanamid (*Mark Lane Express, 100 (1909), No. 4034, pp. 59, 61, figs. 3*).—This article discusses the characteristic qualities, storage and mixing, sources, price, use, and methods of application of lime nitrogen.

Calcium cyanamid (*Engin. and Min. Jour., 87 (1909), No. 2, p. 138*).—This is a brief note on the progress in the establishment of factories for the manufacture of this product, attention being called particularly to the plant in course of construction at Niagara Falls, Ontario. It is expected that this plant will begin operation early in the spring of 1909. The calcium cyanamid to be produced will contain about 10 per cent of nitrogen and no free lime.

New Canadian industry, W. H. H. Webster (*Mo. Cons. and Trade Rpts. [U. S.], 1908, No. 338, p. 125*).—This is a brief account of the calcium cyanamid factory which is being built at Niagara Falls, Ontario.

Potash silicate, P. Krische (*Illus. Landw. Ztg., 28 (1908), No. 79, pp. 685, 686; abs. in Chem. Abs., 3 (1909), No. 1, p. 94*).—This article reviews briefly several unsuccessful attempts to use ground rock as a fertilizer, and calls attention to a proprietary potash silicate (a fine-ground eruptive rock, phonolith) which is now being put on the German market. The objections to the use of silicate of potash as fertilizer are stated to be low percentage of soluble potash, high cost as compared with soluble potash salts, and lack of water-holding power.

Potash silicate (ground phonolith) as a potash fertilizer, P. Wagner (*Deut. Landw. Presse, 36 (1909), No. 1, pp. 1–3; abs. in Landw. Ztschr. Rheinprovinz, 10 (1909), No. 7, p. 85*).—Comparative tests of sulphate of potash and of a fine-ground eruptive rock known as phonolith, containing about 50 per cent of silica, 9 to 10 per cent of potash, and 8 per cent of soda, on Italian rye grass, tomatoes, and mustard, are reported.

The results show that the potash of the ground phonolith is very resistant to the solvent action of acids and of soils and roots. The potash is so firmly combined with silicic acid that scarcely one-half of it is dissolved by 10 per cent hydrochloric acid and very little by the roots of plants.

Soil fertility and phosphoric acid, G. S. Fraps (*Trans. Texas Acad. Sci., 10 (1907), pp. 40–44; Amer. Fert., 30 (1909), No. 2, pp. 5–7*).—This article is based largely upon results of experiments reported in a bulletin of the Texas Station (E. S. R., 19, p. 919), which have shown that the soils of Texas are especially in need of phosphoric acid; that soils may contain phosphates which are equally soluble, but are assimilated with unequal readiness by plants; that two soils may contain equal quantities of phosphoric acid of equal value to plants and yet on account of variation in absorbing powers of the soil the amounts of phosphoric acid dissolved from the two soils may be widely different; and that the same compounds of phosphoric acid may have different values for the same plant in different soils. The author is of the opinion that soils deficient in phosphoric acid are widely distributed in the South.

Shall we use natural rock phosphate or manufactured acid phosphate for the permanent improvement of Illinois soils? C. G. Hopkins (*Illinois Sta. Circ. 127, pp. 23*).—This is a reply to a pamphlet issued by a large packing house opposing the use of untreated rock phosphate. The results of experiments by a number of stations are quoted to show that under certain conditions such phosphate may be profitably used.

Phosphoric acid of varying solubility in citric acid as a fertilizer for meadows, H. Svoboda (*Ztschr. Landw. Versuchsw. Österr., 11 (1908), No. 10, pp. 733–774; abs. in Chem. Ztg., 32 (1908), No. 103, Repert., p. 674; Chem. Centbl., 1908, II, No. 24, p. 1893; Jour. Chem. Soc. [London], 96 (1909), No. 556, II, p. 177*).—Comparative tests, extending over a series of years, with Thomas slag of varying solubility in citric acid, bone meal, and rock phosphate are reported. The results show in general that while phosphates having a high degree of solubility in citric acid act more quickly, they are more rapidly exhausted and on this account are not so well suited to the fertilizing of meadows as less soluble phosphates.

Modern land-pebble phosphate-mining plants in Florida, H. D. Mendenhall (*Engin. News, 60 (1908), No. 16, pp. 410–414, figs. 7*).—This is an account of a modern phosphate-mining plant, of which there are about 20 in the land pebble district of Florida, each turning out from 50,000 to 500,000 tons of phosphate a year.

Phosphate industry in Tennessee, H. D. Ruhm (*Engin. and Min. Jour., 87 (1909), No. 2, pp. 139, 140*).—The situation in the Tennessee phosphate field during 1908 is briefly reviewed.

Agricultural lime, E. H. Jenkins and E. M. East (*Connecticut State Sta. Bul. 163, pp. 3–18*).—This bulletin discusses, on the basis of examinations of samples collected in Connecticut, the sources, composition, and prices of agricultural lime in that State, as well as its action in the soil.

Lime, J. P. Rowe (*Univ. Mont. Bul. 50, pp. 40–42, pls. 6*).—The limestone deposits of Montana and their utilization in the preparation of lime are briefly discussed.

Gypsum deposits, J. P. Rowe (*Univ. Mont. Bul. 50, pp. 31–39, pls. 3, figs. 3*).—Economic deposits of gypsum in what are termed the north, middle, and south fields of Montana are briefly described.

Lime and marl examinations in Jutland, 1908, M. K. Kristensen (*Tidsskr. Landbr. Plantcarl, 15 (1908), No. 5, pp. 621–644*).—Analyses of a large number of samples of lime and marl are given, and the results discussed.

Magnesia, its function and use in agriculture, F. Rigaux (*Bul. Assoc. Chim. Sucr. et Distill., 26 (1908), No. 6, pp. 444–448*).—From analyses of a number of Belgian soils the conclusion is drawn that many soils naturally contain so little magnesia or are so reduced in this constituent by the methods of cropping pursued that they are unable on this account to produce maximum yields. Analyses are given which indicate that magnesia is an important constituent of crops. It is shown from experiments by Pellet on various Belgian soils that as a rule the yield and quality of cereals, potatoes, sugar beets, and leguminous plants were improved by application of magnesia, and by Lawes and Gilbert, Stutzer, and others that the fertilizing value of ammonia salts is increased by the use of magnesia in connection with them.

Manurial value of sewage and sewage sludge (*Jour. Bd. Agr. [London], 15 (1908), No. 9, pp. 690–696*).—This is a brief discussion based mainly upon the fifth report of the Royal Commission on Sewage Disposal (E. S. R., 20, p. 617).

Attention is called to the loss of nitrogen in ordinary methods of sewage disposal and the method of preparing sewage sludge is described. The sludge is mixed with 0.5 to 1 per cent of lime in the form of milk-of-lime and pressed by means of compressed air into cakes containing from 50 to 65 per cent of water and from 0.89 to 1.28 per cent of nitrogen. The cost of the process is estimated at from 50 cts. to $1.25 per ton of pressed cake. The calculated fertilizing value of the material is stated to be from $1.50 to $1.75 per ton, "but the actual market value is insignificant, owing to the relatively high cost of carriage upon a mixture containing of necessity a large proportion of water, grit, and carbonaceous matter."

Tests of the fertilizing value of the sludge on mangel-wurzels, beets, swedes, wheat, and grass at Woburn and at several agricultural colleges in England indicate "that unit for unit the nitrogen and the phosphoric acid of sludge seem to be of less value manurially than the nitrogen and phosphoric acid of artificial manures; at any rate so far as the first year of application is concerned. It also appears that sewage sludge is not a suitable dressing for quickly growing plants, unless it is applied in very large quantities per acre."

Analyses of the ashes discharged during the eruption of Vesuvius in April, 1906, D. Girasoli (*Atti R. Ist. Incoragg. Napoli, 6. ser., 59 (1907), pp. 239–243*).—The rain of ashes lasted from April 4 to 21. During the first days the ashes had the appearance of coarse black sand, the next were much finer and gray in color, and at the last there was an almost impalpable dust of a reddish color. A physical separation by means of electrical currents of different strengths showed an abundance of magnetite with fragments of lava, vitreous substance, augite, leucite, feldspar, and olivin, with some scales of mica. Chemical analyses of the different separates are given.

Consumption of fertilizers (*Amer. Fert., 30 (1909), No. 1, p. 6*).—A table is given showing the consumption of commercial fertilizers in various States during 1907. The total is given as 4,451,523 tons.

Fertilizers in South Australia, W. L. Summers (*Jour. Dept. Agr. So. Aust., 11 (1908), No. 12, pp. 1113–1115, fig. 1*).—Statistics of the use of fertilizers since 1897 are given.

AGRICULTURAL BOTANY.

A statistical criterion for species and genera among the bacteria, C. E. A. WINSLOW (*Bul. Torrey Bot. Club, 36 (1909), No. 1, pp. 31–39*).—Attention is called to the almost infinite number of variations in different groups of bacteria and the difficulty of their classification. The author has attempted their classification by the statistical method and has devoted several years to work on the classification of the family Coccaceæ (see p. 1079). He has found that others are pursuing the same method for limiting the species of other groups of bacteria, and he concludes that in groups like bacteria and perhaps in some classes of fungi, which have differentiated along physiological rather than morphological lines, differences in metabolism may have the same systematic importance that is given to gross structural differences in other groups.

The characters vary in each particular group and their value for classification must be determined by a survey of their relationships. The most satisfactory method of studying the systematic relations of these simple and variable forms is by obtaining quantitative measurements of a number of characteristic properties in a large series of individuals and by statistical analysis of the results.

The author believes that generic names may be given to the larger groups of organisms which have several apparently independent properties in common, and specific names may be reserved for the smaller groups, characterized by variations in single uncorrelated properties.

Studies on bacterial enzyms, II. ZIKES (*Wchnschr. Brau., 25 (1908), No. 24, pp. 361–366*).—A summary is given of information regarding the occurrence and function of bacterial enzyms.

The proteases of plants, VI, S. H VINES (*Ann. Bot. [London], 23 (1909), No. 89, pp. 1–18*).—This is the sixth contribution of the author's on this subject, those previous having been noted (E. S. R., 19, p. 931). From his studies the author is led to reject the hypothesis of the occurrence of trypsin in plants, and he proposes in its stead the theory that the proteases of plants belong to two groups, the peptases and the ereptases, and claims that this view is supported by considerable direct and indirect evidence.

The ereptases are enzyms which are readily soluble in water and in alcohol up to about 65 per cent. Their digestive activity seems to be exclusively peptolytic and to be especially associated with acid media. Thus far the author has been unable to give an approximate reaction range for plant ereptase.

The peptases are proteases the digestive activity of which is limited to the peptonization of the more complex proteins. There appears to be some ground for believing that there are two kinds of peptases, which differ from each other in the mode of their occurrence and in the relation between their respective digestive activities and the reaction of the medium. The first kind exists in the tissues of plants, fruits, seeds, latex, etc., and to this is given the name endopeptase. The other kind is found in the excretions of plants, as in the pitcher liquid of Nepenthes, and is designated as ectopeptase.

The author concludes the series of papers by calling attention to the analogies between proteolytic enzyms of plants and those of animals. The enzym which he has called ectopeptase agrees in all essential properties with animal pepsin. It is not so easy to find an animal analogue for endopeptase, but it appears to correspond fairly well with the peptonizing factor in trypsin.

Concerning fungus desamidase, II. PRINGSHEIM (*Biochem. Ztschr., 12 (1908), No. 1–2, pp. 15–25*).—According to the investigations of the author and others, various fungi, especially yeasts and *Aspergillus niger*, have the ability of splitting off ammonia from nitrogen-containing substances, particularly from amino acids. The action is essentially enzymic, and the name desamidase has been

given the enzym. It retains its active properties to a limited degree when the fungi are treated with acetone and ether, but loses them entirely if expressed under pressure. Material which has been acted upon by desamidase may be further transformed into alcohols through the action of yeasts and the splitting off of carbon dioxid.

Concerning hydrating ferments in various gums, V. Boucher (*Compt. Rend. Soc. Biol.* [*Paris*], *64* (*1908*), *No. 20, pp. 1003, 1004*).—A brief account is given of investigations on the presence of hydrating ferments in various gums. The occurrence of such bodies was first announced in 1885, and this led to the belief that enzyms may play an important part in the formation of gums by plants.

The author has attempted to ascertain the forms of the enzym, and his experiments were conducted with reference to the occurrence of emulsin. An examination of 30 different kinds of gums representing resin gums, tannin gums, and some true resins showed, with one exception, a kino from *Pterocarpus marsupium*, the presence of emulsin capable of splitting up amygdalin. The failure in this case is attributed to the relatively large amount of tannin in the gum.

Preliminary investigations on the oxidizing diastases of plant latex, V. Cayla (*Compt. Rend. Soc. Biol.* [*Paris*], *65* (*1908*), *No. 26, pp. 128–130*).—A preliminary report is given of a study of 18 species of plants, among them many of the best known rubber-producing plants, to determine the occurrence of oxidizing enzyms in their latex.

The results thus far obtained indicate that the latex of all the plants contains oxidizing diastases, and in most of the species studied the form present was oxygenase. In some of the species peroxidase was found, while in a few catalase was recognized. The reactions observed indicate the presence of the same diastase in a given species, no matter what the source of the plant, although the oxidizing ferment was found to differ in a number of very closely related species.

The influence of agitation on the growth of some of the lower fungi, A. Sartory (*Etudes Expérimentales de l'Influence de l'Agitation sur les Champignons Inférieurs. Thesis, Paris, 1908, pp. 142, pls. 20; rev. in Rev. Sci.* [*Paris*], *47* (*1909*), *1, No. 4, pp. 114–116*).—A study was made in liquid and solid media of a number of the lower fungi to determine the effect of shaking on their growth and development. A form of apparatus was devised that would violently shake the vessel containing the cultures at regular intervals.

When subjected to relatively infrequent shakings, 10 to 20 times a minute, the species of Oomycetes, Ascomycetes, and molds developed with little change from the normal growth. When agitated at the rates of from 60 to 120 times per minute marked changes occurred. The thallus-like growth usually formed by the filaments became spherical, a supporting structure was developed, and important changes were induced in the reproductive organs of the fungi. The alcoholic fermentation of yeasts was favored by the agitation.

The influence of light on the growth of Rhizopus nigricans, L. Raybaud (*Compt. Rend. Soc. Biol.* [*Paris*], *64* (*1908*), *No. 23, pp. 1172–1174*).—As a preliminary to a general study of the effect of light on the lower fungi, the author reports the results of investigations on the effect of different colors of light on the growth and development of *R. nigricans*, which, according to Van Tieghem, is neither geotropic nor heliotropic in its growth.

Cultures of the fungus were placed under clear glass and colored screens and the growth noted. Under clear glass phototropism was indicated after about 48 hours, and heliotropism under yellow glass in 4 days. Red rays appeared to exert a peculiar effect. They retarded growth for a short time, but after development began the filaments assumed oblique positions and at the end of

about 3 days they curved downward on to the substratum, over which they spread in their subsequent development. Under no other kind of radiation was such behavior noted. Violet colored light stimulated the production of more and larger sporangia, while the final vegetative growth was greatest under the blue and yellow screens. Growth under the green screens was retarded, the mycelium was less developed, and the sporangia were very small.

The effect of light on germination, W. KINZEL (*Ber. Deut. Bot. Gesell., 26a (1908), No. 9, pp. 655–665*).—A study is reported on the effect of light on the germination of seeds of over 100 species of plants. The seeds were placed to germinate under different degrees of illumination and the effect of light in retarding or hastening the germination is shown. A bibliography of about 80 titles concludes the report.

The chemistry of chlorophyll, S. B. SCHRYVER (*Sci. Prog. Twentieth Cent., 3 (1909), No. 11, pp. 425–449*).—A summary is given of the present state of information regarding the chemistry of chlorophyll, and in the general conclusions the author states that chlorophyll is a magnesium derivative, from which the metal is eliminated readily by means of acid but with great difficulty by alkalis. The green pigment consists in most plants apparently of a mixture of magnesium derivatives, a crystalline chlorophyll, and another chlorophyll or mixture of chlorophylls which are esters of the unsaturated alcohol phytol. The statement is made that there is a considerable amount of evidence which tends to show that an intimate chemical relationship exists between the green pigments of plants and the red pigments of blood.

Studies in chlorophylls, L. MARCHLEWSKI (*Biochem. Ztschr., 10 (1908), No. 1–2, pp. 131–166, pls. 3, dgms. 2*).—Spectroscopic studies have been made of chlorophylls from various sources and their behavior toward acids noted.

The author concludes that chlorophyll, phæophyl, and phyllogen are identical substances, differing in all probability only in the methods of their isolation. He thinks that Hoppe-Seyler's name, chlorophyllan, should be adopted, and if distinctions between the two prominent groups are to be maintained, Tsvett's names, chlorophyllin α and β (E. S. R., 20, p. 739), should be used, or they may be designated as chlorophyllan and allochlorophyllan.

The photodynamic work of chlorophyll extracts, W. HAUSMANN (*Biochem. Ztschr., 12 (1908), No. 3–4, pp. 331–334*).—The author shows that a methyl alcoholic extract of green plants has a marked effect on the red corpuscles of the blood. He experimented with extracts made from leaves of cabbage, maize, wheat, grass, beans, oak, clover, etc., and found that while comparatively inactive in the dark, the extracts induced complete hemolysis within an hour when brought into sunlight.

From these experiments the author concludes that chlorophyll must have a marked photodynamic effect on the assimilation processes of the plant.

The protein changes taking place in green plants when kept in the dark, W. BUTKEWITSCH (*Biochem. Ztschr., 12 (1908), No. 3–4, pp. 314–330, dgm. 1; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 552, II, p. 884*).—Experiments were conducted with beans and oats, in which the protein changes were noted, the total nitrogen, proteid nitrogen, aspartic acid, and ammonia nitrogen being determined. In the case of beans the indigestible and other forms of nitrogen were estimated. The analyses were made of samples of the original material and also of samples which had remained for different lengths of time in the dark.

It was found that there was a decrease of proteid nitrogen and an increase in aspartic acid nitrogen. The nitrogen which was due neither to aspartic acid nor protein first increased and then diminished. The conclusion is drawn that

part of the aspartic acid was formed by secondary changes from products of protein degradation, which include leucin and tyrosin.

Chemical changes due to the wounding of plants, R. Friedrich (*Centbl. Bakt.* [*etc.*], *2. Abt., 21 (1908), No. 10–12, pp. 330–347, fig. 1; abs. in Jour. Chem. Soc.* [*London*], *94 (1908), No. 551, II, p. 774*).—After giving a résumé of previous investigations dealing with the increased evolution of carbon dioxid and the increased production of protein, the author describes experiments with potato tubers, oak leaves, onion bulbs, pear fruits, and other parts of plants, which indicate that a fall in the carbohydrate content is correlated with increased respiration in the portion of the plant under investigation. It was found that the protein produced in wounded potatoes, onions, and pears depended on the presence of a large amount of carbohydrates. In the case of oak leaves there was a decrease in the total nitrogen and an increase in the proteid and amid nitrogen following mutilation of the leaves, and in this respect the fruits of the Japanese quince and the leaves of *Clivia gardneri* behaved in a similar manner.

The observations of the author tend to support the view that protein is formed from plants by a reaction between carbohydrate and amid material.

The action of sulphur dioxid on plants, A. Wieler (*Naturw. Rundschau, 22 (1907), No. 18, p. 229; abs. in Zentbl. Agr. Chem., 37 (1908), No. 8, pp. 572, 573; Jour. Chem. Soc.* [*London*], *94 (1908), No. 552, II, p. 887*).—The author shows that assimilation of carbon dioxid is profoundly influenced by the presence of sulphur dioxid, but respiration is not affected. An examination made of leaves from districts where sulphur dioxid caused injury showed that this substance was present in the leaf, although only in small quantities. When the leaves were collected close to the source of the gas larger amounts were found. The sulphur dioxid apparently enters through the stomata and causes greater injury in wet than in dry weather.

There is some evidence that other factors come into play besides the direct action of sulphur dioxid in the leaf. As the soils in the district where the injury arises are decidedly acid, it is believed that the injury could be overcome to a considerable extent by the use of suitable fertilizers and in particular by liming the soil.

A new group of plants containing hydrocyanic acid, M. Greshoff (*Pharm. Weekbl., 45 (1908), pp. 1165–1169; abs. in Jour. Pharm. et Chim., 6. ser., 28 (1908), No. 12, pp. 554, 555*).—Investigations made with *Triglochin maritimum*, *T. palustre*, and *Scheuchzeria palustris*, plants belonging to the natural order Juncaginaceæ, have shown that they contain hydrocyanic acid. The investigations indicate that probably it exists in the form of a glucosid analogous to linamarin.

Centaurea aspera, a plant containing hydrocyanic acid, C. Gerber and J. Cotte (*Compt. Rend. Soc. Biol.* [*Paris*], *65 (1908), No. 26, pp. 185, 186*).—While making a distillate from *C. aspera*, the authors were struck with the odor of hydrocyanic acid, and an investigation showed the presence in different parts of the plant of a glucosid yielding it. The glucosid was found principally in the green part of the plant, and in the basal leaves, which were dead and dry. The amount varied from 0.842 gm. per thousand in the green leaves, 0.610 in entire young plants, and 0.252 in the dead basal leaves, to traces in the old stems and roots. The glucosid is probably identical with amygdalin.

Seeds and plants imported during the period from April 1 to June 30, 1908. Inventory No. 15 (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 142, pp. 81*).—This is the fifteenth inventory of seeds and plants imported by the Office of Foreign Seed and Plant Introduction, comprising 812 numbers imported between the

dates of April 1 and June 30, 1908, and consisting mainly of material collected by F. N. Meyer, agricultural explorer in northern and central China.

FIELD CROPS.

Dry farming investigations in Montana, A. Atkinson and J. B. Nelson (*Montana Sta. Bul. 74, pp. 65–89, pls. 10, map 1*).—This bulletin presents data gathered during the past 4 years at several substations located in different parts of the State. Data regarding precipitation, given in a table, were taken from observations made either at the substations or by the nearest Weather Bureau station. General directions for dry-land farming are given.

It is concluded from the results thus far secured that dry farming can be profitably practiced in many parts of the State. Turkey Red wheat sown in the fall gave the best yields of all crops grown. Yields of 55 and 58 bu. per acre are recorded. Fall-sown rye also gave very good yields, over 40 bu. per acre being secured in some instances. Satisfactory yields of potatoes were obtained, the average being about 124 bu. per acre. Brome grass was the most promising forage crop tested.

Other experimental results indicate that using from 3 to 5 pk. of seed per acre in growing the different grains is better than using larger amounts. Planting grain crops to permit intertillage reduced the yield as compared with planting sufficiently deep with the ordinary seed drill. Alternating grain with a properly cultivated summer fallow gave decidedly more profitable returns than continuous grain culture on the same land. The importance of keeping the summer fallow well cultivated was also plainly brought out by these experiments.

Alfalfa in cultivated rows for seed production in semiarid regions, C. J. Brand and J. M. Westgate (*U. S. Dept. Agr., Bur. Plant Indus. Circ. 24, pp. 23, figs. 3*).—Historical notes with reference to this method of culture are given, the principles underlying alfalfa seed production are considered, and directions for growing alfalfa in cultivated rows for seed are presented.

It has been observed that isolation of alfalfa plants increases seed production, and this is considered due largely to the increased amount of sunlight available when the plants shade each other but little or not at all. At the Arlington Experimental Farm, plants secured from cuttings taken from a heavy-seeding plant produced a maximum of 38 pods when the area per plant was equivalent to a 7-in. square, and 96 pods when the space was equal to an 11-in. square, while the highest number of pods on plants in rows 39 in. apart and 18 in. apart in the row was 505.

The authors and other investigators have found that alfalfa flowers tripped by any form of manipulation set seed much more readily than unexploded blossoms. In an experiment at the Arlington Experimental Farm, plants the flowers of which were tripped by exerting pressure successively over the whole plant showed an increase of 25.5 per cent in the yield of pods over adjoining untreated rows. At Chico, Cal., an increase of 129 per cent in the number of pods is recorded. The results of two experiments have shown that the proportion of increase in the number of seeds is not so high as in the number of pods.

Growing alfalfa for seed in cultivated rows promises to be more successful in sections with an annual rainfall of 14 to 20 in. than elsewhere. "The results obtained in the experiments thus far conducted indicate that it gives especial promise in Utah, in eastern Colorado, and in the western portions of Kansas, Nebraska, and South Dakota. Yields of seed at the rate of 5 bu. to the acre have been obtained." A number of methods used in the preparation of the seed bed, the seeding in rows, and the cultivation and harvesting of the crop

are described. The yields per acre when alfalfa is grown by this method are estimated as follows:

Estimated yield of hay and seed to the acre when alfalfa is grown in cultivated rows.

Variety.	Green weight of hay.	Dry weight of hay.	Weight of seed.
	Pounds.	*Pounds.*	*Pounds.*
Dry-land alfalfa (Brotts)	2,672	1,154	167
Commercial sand lucern (S. P. I. No. 20451)	3,463	1,359	143
Turkestan alfalfa (S. P. I. No. 18751)	2,141	908	62

It is stated that heavy seed crops are to a large extent dependent upon a certain amount of dry weather and heat when the seed is setting. At this stage the plant requires but a small supply of moisture.

Alfalfa yields, 1908, F. D. Stevens (*Alabama Canebrake Sta. Bul. 26, pp. 18–20*).—In 1908 the following quantities of well-cured hay were secured from a field of 6.3 acres at the five different cuttings: April 9, 13,600 lbs.; May 28, 13,305 lbs.; June 29, 7,547 lbs.; August 5, 11,689 lbs.; and September 10, 3,110 lbs.

Comparative variety tests with fodder beets, J. J. Vaňha and O. Kyas (*Ztschr. Landw. Versuchsw. Osterr., 11 (1908), No. 12, pp. 864–887*).—Experiments were conducted with 8 varieties for 2 years. The results are tabulated and discussed at length and each of the different varieties is described. In summarizing the results with reference to both yield and quality the varieties ranked in the following order: Vauriak, Erfurt, Leutewitz, Mamut, Oberndorf, Chrestensen, Eckendorf, and Askania-Eckendorf.

The general conclusion is drawn that the influence of weather and soil fertility is much greater than that of variety characteristics.

Comparative culture tests with varieties of fodder beets and a study of the Mauthner treatment of beet seed, O. Kyas, J. Bukovanský, and J. J. Vaňha (*Ztschr. Landw. Versuchsw. Österr., 11 (1908), No. 12, pp. 888–893.*—The Mauthner treatment consists in subjecting the seed to chlorin and sulphuric acid fumes. Results secured under field conditions did not indicate a definite favorable influence due to this method. It was shown that the leaf spot disease of the beet has no connection with the seed and this method of treatment. The injuries resulting from *Uromyces betæ* were generally reduced in the beets grown from treated seed, and the same was true of dry rot.

In decreasing order of yield the varieties grown ranked as follows: Mamut, Red Eckendorf, Oberndorf, and Mauthner Olive Form. The dry matter content was found to be in positive correlation with the sugar content of the beet. The protein content showed no connection with these factors and was practically the same for all varieties.

The sugar-beet crop in the principal European countries from 1898–1908, G. Dureau (*Jour. Fabric. Sucr., 50 (1909), Nos. 4, p. 1, charts 2; 5, p. 1, charts 2; 6, p. 1, charts 2; 7, p. 1, chart 1*).—The production of sugar beets in the principal beet sugar producing countries of Europe for the 10 years, 1898–1908, is discussed and statistics comparing the different countries with each other are presented.

The American sugar-beet growers annual, edited by F. Roderus (*Chicago, Ill., 1908, pp. 100, figs. 115*).—This publication contains a series of articles with reference to the beet-sugar industry in this country and presents numerous statistics concerning the production of sugar beets and beet sugar, together

with data regarding the commerce of this staple and its production throughout the world.

Score cards for dent corn (*Ohio Sta. Circ. 86, pp. 3*).—This circular presents the score cards for use in the final selection of seed ears, in the plant selection for seed corn, and in judging varieties of corn at husking time as adopted by the Ohio Corn Improvement Association November 24, 1908. Explanatory notes on all the points are given.

Fertilizer tests with cotton. F. D. STEVENS (*Alabama Canebrake Sta. Bul. 26, pp. 3–18*).—A computation is presented showing that by disposing of the lint and seed of 18 bales of cotton produced on the station farm in 1907 there was removed from the land 574.2 lbs. of nitrogen, 188.1 lbs. of acid phosphate, and 276.1 lbs. of potash, representing $107.92, $10.72, and $16.20 in money value, respectively.

A comparative fertilizer test on poor red prairie land indicated a net gain in value of lint of 58 cts. per acre from the use of 200 lbs. of cotton-seed meal, $3.56 from 240 lbs. of acid phosphate, and $3.70 from a combination of these two applications. The results of a more extended trial show the greatest net gain from using 160 lbs. of cotton-seed meal and 240 lbs. of acid phosphate. In this case the net profit was $4.52 per acre, while the use of 160 lbs. of kainit in addition to this application resulted in a loss of $3.67. The use of the kainit alone produced a net gain of $1.53 per acre.

The results of a third experiment reported again show the value of applying cotton-seed meal with acid phosphate. An application of 230 lbs. of cotton-seed meal and 320 lbs. of acid phosphate was used at a profit of $5.75 per acre, which was surpassed only by the use of 100 lbs. of nitrate of soda giving a net profit of $11.57.

On dark prairie soil the best net gain per acre was also made by using nitrate of soda alone, but it amounted to only $5.32. Applying the nitrate with acid phosphate in the scooter furrow before planting and using acid phosphate alone resulted in losses. In another test on this black calcareous prairie soil the largest net gain, $12.48 per acre, was secured where 200 lbs. of nitrate of soda and 200 lbs. of cotton-seed meal per acre had been given. The addition of 200 lbs. each of kainit and acid phosphate reduced this gain to $6.02. When the cotton-seed meal was omitted a loss of $7.97 was sustained, and when nitrate of soda was replaced by cotton-seed meal a loss of $9.21 per acre. The least profitable application consisted of 200 lbs. each of kainit and acid phosphate, which resulted in a loss of $10.60.

Heavy annual applications of commercial fertilizers on land growing cotton for five consecutive years gave the largest increase in yield during the first 2 years, the returns being more than doubled as compared with the yields on untreated land. A comparative test of alfalfa and cotton showed that alfalfa was much more profitable. Alfalfa turned under apparently increased the yield of seed cotton of the following cotton crop by 622 lbs.

Among a series of winter cover crops crimson clover seemed most efficient in increasing the cotton yield. Crushed lime rock on poor red prairie upland reduced the yield. The cowpea sown broadcast in standing corn alternated with cotton was found efficient in maintaining the fertility of the soil.

Recent experiments with oats. C. G. WILLIAMS (*Ohio Sta. Circ. 88, pp. 8*).—Among the 25 best varieties of oats grown at the Ohio Station, Siberian, Sixty Day, Improved American, Illinois German, Joanette, Green Mountain, and Big Four led in productive capacity, the range in yield of grain being on the average for the 5 years from 68.34 bu. for the last mentioned variety to 70.46 bu. for the first mentioned.

In 1908 a number of new varieties were introduced from abroad. White Ligowa and Hvitling gave promising results. The seed of these selections tested above 40 lbs. per bushel and that of Gartons Regenerated Swedish Select 46 lbs., but 1 year's growth in Ohio brought the weight per bushel down to that of normal Ohio oats. Seed of Siberian and Joanette oats was introduced from Canada in 1904 and these varieties have been grown each season to 1908, inclusive. The results showed that this northern-grown seed gave about as satisfactory results as similar native varieties and they did about as well the first year as they did in succeeding seasons.

The general average results of experiments with different rates of seeding showed that 11 pk. of seed per acre gave the highest yield of grain, the increase being a little more than needed to pay for the extra seed. Wideawake and Seizure produced the most straw in proportion to grain of any of the varieties reported.

Barley and other spring grains were grown for the purpose of finding a substitute for oats or winter wheat, and of the different crops so tested Oderbruck barley was apparently a close competitor of oats. A variety of winter oats has been developed by the station from self-sown plants of a spring crop and which went through the winter of 1905–6. In 1907 this strain of winter oats yielded at the rate of 46.41 bu. per acre, as compared with 44.24 bu. for spring oats. In 1908 the yield was 66.56 bu. per acre, while the average of all the spring varieties tested was 61.51 bu. The first year the bushel weight exceeded that of the spring varieties by 3.08 lbs. and the second year by 8.92 lbs. The variety also ripens from 8 to 10 days earlier than the average of the spring varieties. The variety will be tested further before it is recommended.

Varieties of potatoes grown in the Central Provinces, G. Evans (*Dept. Agr. Cent. Prov. and Berar [India Bul.], pp. 13, pls. 2*).—The four common varieties, Italian, Patna, Naini Tal, and Deshi or Moolkhi, grown in the Central Provinces, are described and the methods of potato culture practiced are discussed.

Culture and preparation of sisal, A. Marquès (*Culture et Préparation du Sisal. Paris, 1909, pp. 97, pls. 11, figs. 4*).—This book contains a description of the sisal plant (*Agave sisalana*), together with its culture and the preparation of the fiber, as observed by the author in the Hawaiian Islands.

The soy bean: A comparison with the cowpea, C. A. Mooers (*Tennessee Sta. Bul. 82, pp. 75–104, figs. 14*).—In comparing the two plants the author enumerates the prominent qualities of each and points out that the cowpea is preferable for planting either with corn or sorghum and generally for seeding broadcast, while the soy bean appears the more valuable of the two crops when grown as a grain producer, as an intensive farm crop, and as an early grain or hay crop.

The best varieties of soy beans are more certain to produce high yields of seed than any of the cowpeas. In 1907, Mammoth Yellow soy bean planted June 17 yielded 28.4 bu., and planted June 29, 26.6 bu. of seed per acre. Medium Yellow soy bean planted July 15 produced 20.2 bu. On the other hand, Whippoorwill cowpea produced 27.7 bu. of seed per acre from the planting made June 17, 18.8 bu. from the planting June 29, and no seed from the one made July 15.

Soy beans at the station have proved more resistant to light frosts than the cowpea and also less sensitive to cool weather in the spring. Other points of comparison favorable to the soy bean are a higher protein and fat content, freedom from weevil attacks in the seed, the ripening of the seed at one time, and the ease of harvesting and thrashing the crop.

Analyses made at the station show an average protein content of 35.40 per cent and a fat content of 20.35 per cent for soy-bean seed, as compared with 25.28 per cent of protein and 1.72 per cent of fat for the cowpea.

A stand of cowpeas is more certain than a stand of soy beans because a soil crust offers but little resistance to the cowpea and the seed is also surer of germination. For sowing broadcast the cowpea is therefore superior to the soy bean, especially on land likely to bake or poorly prepared. A variety test of soy beans showed Butterball to be a good early variety, B. P. I. No. 1299 the best variety in the test for August planting and for an extra early seed crop, Ito San about the best early variety, B. P. I. No. 1194 about the best of the mid-season varieties, and Mammoth Yellow about the best late variety.

Variations in length of season required for full maturity, as observed in 1907, were as follows: "Mammoth Yellow, 186 and 113 days, yielding 21.5 and 26.6 bu. of seed, respectively; Ito San, 129 and 81 days, yielding 11 and 16.5 bu. of seed, respectively; Medium Yellow, 164 and 86 days, yielding 18.3 and 20.2 bu. of seed respectively." Varieties of cowpeas also showed marked variations in length of season, but the difference between the two plants is that late-sown soy beans make only a small growth, while late-sown cowpeas grow with the usual vigor until arrested by frost or other untoward conditions.

Cultural directions with reference to the soy bean are given and varieties of special merit are enumerated. The construction of curing racks for hay is described and illustrated and the results with soy beans in cooperative experiments in middle Tennessee are briefly reported.

The plant food consumption of the beet during the first year of growth and its relation to the sugar content, K. Andrlík and J Urban (*Ztschr. Zuckerindus. Böhmen, 33 (1909), No. 4, pp. 221–240*).—The results of experiments showed that the plant food consumption varied with different varieties or strains. The plants of one kind of seed took up more phosphoric acid and potash than those grown from another kind, while in nitrogen consumption there was no difference. Disregarding this difference and basing conclusions on average results, the authors estimate the plant food consumption of a crop of 400 quintals of beets per hectare (about 17.8 tons per acre) as 65.1 kg. (about 143.2 lbs.) of phosphoric acid, 139.8 kg. (about 307.6 lbs.) of nitrogen, and 168.6 kg. (about 370.9 lbs.) of potash. Attention is called to the fact that aside from the difference in seed, conditions of soil and season have a marked influence and that the deductions are based on the assumption that weather conditions are favorable.

Experiments with varieties of sugar cane, F. Watts et al. (*Imp. Dept. Agr. West Indies, Sugar-Cane Expts. Leeward Isl., 1906–7, pt. 1, pp. 74*).—Noted from another source (E. S. R., 20, p. 639).

Manurial experiments, F. Watts et al. (*Imp. Dept. Agr. West Indies, Sugar-Cane Expts. Leeward Isl., 1906–7, pt. 2, pp. 37, dgms. 5*).—Noted from another source (E. S. R., 20, p. 639).

Shelter-tent experiment with Sumatra-type tobacco, W. Frear (*Pennsylvania Sta. Bul. 89, pp. 3–14, figs. 2*).—Sumatra leaf was grown under shelter in 1905 at two locations on Penn sandy loam soil. Plants from commercial seed showed great diversity of type, while those from self-fertilized seed grown in Pennsylvania in 1904 showed a marked uniformity. Crops of cured leaf weighing 1,200 and 1,700 lbs. per acre were secured at Milton Grove and Cocalico, respectively.

Sweating and assorting caused a loss of 21.7 per cent. "The tobacco was bulked on February 16, 1906; the temperature rose from 70° F., at the beginning, to 100° on February 25, and then fell to 96° on March 2. On March 3 the bulk was turned; on the 4th the temperature was 84°; on the 12th, 100°;

and on the 17th, 92°. On March 18, 30 days after the beginning of the sweat, the bulk was taken up and assorted."

The cured leaf consisted of about 75 per cent of wrappers and 25 per cent "seconds." Of the wrappers 45 per cent were light, 30 per cent medium, and 27 per cent dark. Sixty per cent of the leaves were over 16 in. long. In capacity, life, and burning quality the 1905 crop was superior to the crop of 1904, and showed a general rating above all domestic Sumatra-type tobacco except the better Georgia and Florida grades. The cured leaf was produced at Cocalico at a cost of 45 cts. per pound. It is believed that the cost per pound of producing the sweated and sorted leaf will not be over 65 to 70 cts. The items of expense are given in a table.

Principles and practical methods of curing tobacco, W. W. Garner (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 143, pp. 54, figs. 10*).—This bulletin discusses the principles of curing tobacco and presents practical methods of curing as applied to the various types. The discussion of the principles of curing includes a description of the air-curing and flue-curing processes, as well as of the method of curing with open fires. The different types of tobacco considered are cigar tobaccos, shade-grown cigar-wrapper leaf, Burley, sun-cured, yellow, heavy export, and Perique tobaccos.

Outlines of tobacco barn construction are given and appliances used in harvesting, handling, and curing tobacco are described.

Foreign tobaccos, L. P. de Bussy (*Meded. Deli-Proefstat. Medan, 3 (1909), No. 4, pp. 122–151*).—Brief reports are given on culture tests with varieties of tobacco secured from different countries, including the United States. Among varieties from the United States, Cooley hybrid gave a much better product than Brewer hybrid.

The production of wheat in the British Empire, A. E. Humphries (*Jour. Roy. Soc. Arts, 57 (1909), No. 2934, pp. 230–253*).—This article discusses the production of wheat in the United Kingdom, Australia, Canada, India, New Zealand, South Africa, and British East Africa, and presents statistics for a number of years with reference to acreage, yield, and exports and imports of wheat.

Wheat and other cereals, D. Zolla (*Le Blé et les Céréales. Paris, 1909, pp. VII+298, dgms. 18*).—This book discusses the wheat industry of France from the standpoint of rural and national economics and considers in this connection the imports and exports of wheat, the profits in wheat culture, variations in price, and the influence of agricultural organizations on the price. A chapter each is devoted to a special study of the Paris grain market and its commercial organization.

Wheat fields and markets of the world, R. E. Smith (*St. Louis, Mo., 1908, pp. 418, dgms. 2*).—Part 1 of this book treats of what in the world's commerce and the possibility of increasing the world's wheat crop and reviews the conditions with reference to the production and commerce of wheat in different wheat importing and exporting countries. Part 2 describes the principal wheat markets of the world, such as the Chicago Board of Trade and the grain markets of London, Berlin, and Paris. Descriptions of the London, Berlin, and Paris stock exchanges are given in an appendix.

The grain production of the world in 1908 (*Veröffentl. K. Ung. Ackerb. Min., 1908, No. 15, pp. 108*).—Estimates of the production of different grain crops in 16 grain importing countries and 21 grain exporting countries are presented.

Cereal culture, F. Schindler (*Der Getreidebau. Berlin, 1909, pp. XII+466, figs. 80*).—This book contains a general discussion of the cereals, with special reference to their botanical and agricultural characteristics, and gives descrip-

tions of rye, wheat, barley, oats, corn, millet, and rice. Detailed cultural directions for each crop are presented.

Principal crops of the world, O. Warburg and J. E. Van Someren Brand (*Kulturpflanzen der Weltwirtschaft. Leipsic [1908], pp. XIV+411, pls. 12, figs. 653*).—Discussions of the following crops are presented: Rice, wheat, maize, sugar, grapes, coffee, tea, cacao, tobacco, and cotton.

HORTICULTURE.

Ninth report of the Woburn Experimental Fruit Farm, Duke of Bedford and S. U. Pickering (*Woburn Expl. Fruit Farm Rpt., 9 (1908), pp. 95+XLVII, pls. 6*).—An account is given of an extensive series of experiments on methods of planting fruit trees which were conducted with the view of verifying the results secured by the authors along this line for the 10 years prior to 1905 (E. S. R., 17, p. 559), and in which the majority of the evidence went to show that trees which were carelessly planted, that is, planted with the roots just as they happened to come, into holes too small for them, filling in the dirt without working it around the roots and severely packing it, gave a more vigorous tree growth at the end of 3 or 4 years than trees carefully planted according to accepted methods. With the view of making the experiments sufficiently numerous to render the results accurate, 2,000 trees, planted by some 10 different hands in 17 different localities and in 8 different counties, were included in the work. The trees were for the most part dwarf apples, though some plums and bush fruits were used. The results secured in the various experiments are tabulated and fully discussed.

An appendix to this report consists of the following papers by S. U. Pickering, which are elsewhere noted from another source: Studies on Germination and Plant Growth (E. S. R., 20, p. 737); The Action of Heat and Antiseptics on Soils (p. 1015).

In the comparative test of orthodox and careless methods of planting the trees the ramming process was very severe. The tree, with the roots just as they happened to come, was set in a shallow hole. The hole was then filled up and the earth thoroughly puddled with a heavy rammer until the whole mass "shook like jelly at each stroke." A shovelful of loose earth was thrown over the surface so as to render hoeing possible. Both rammed and unrammed trees were hoed and kept free from weeds. The ground about the rammed trees remained quite hard for the 12 months following the planting and could be distinguished even during the second and third years.

Summing up the evidence obtained during the first 2 years from these recent experiments, it was found that although the ramming appeared to check the growth of the tree during the early part of the first season about 40 per cent more new wood was formed with the rammed trees during the first year after planting than when the trees were planted carefully. There was a still greater increase of new wood during the second year, but with some of the trees examined during the third season the excess rate of growth appeared to be slackening. The excess of branch formation is attributed to a similar excess of root formation. The actual shoots on the rammed trees were thicker than on the unrammed trees.

The authors advance the opinion that the form of planting which aims at avoiding all injury to the roots is really the one which should be designated as bad practice, since the object to be sought in planting a tree is to secure the development of fresh rootlets from the main roots rather than to preserve existing fibrous roots, which, having lost their tips, are of little value to the tree. Ramming the soil hastens the development of adventitious roots by

creating an intimate contact between the roots and the soil. Although soil which has been puddled so severely is in an unsuitable condition for vegetation, the ramming takes place only over the roots themselves, and before the end of the first season the new roots are found to have penetrated beyond the puddled earth. Trimming the roots back ¼ to ⅓ of their length was found to be advantageous since it stimulated the development of fibrous roots. It is conceded that rammed trees may fruit somewhat less during the first few years in consequence of the more vigorous growth, although no such reduction was noted in some cases under observation. Ramming can have little or no effect in light, sandy soils.

Unsuccessful attempts were made to secure beneficial effects similar to those which resulted from ramming the tree by both plastering the roots with various substances and by surrounding the roots with very fine sand.

From the results thus far secured, the authors are of the opinion that trenching or deep cultivation will benefit trees only where it materially improves the drainage and where the subsoil is sufficiently rich to encourage fruit development.

Autumn was found to be the best time to plant trees during the dormant season. In such early plantings the adventitious roots were in most cases formed before the following January. The formation of adventitious roots was greatest in cases where the roots had been most damaged in the lifting and where they had not been trimmed. The authors are at a loss to explain the benefit to be derived from not trimming the injured roots, and advise that they be trimmed, owing to the danger from penetration of fungi.

Comparative tests of the hexagonal, square, and rectangular planting systems resulted only slightly in favor of the hexagonal arrangement and were not sufficient to counterbalance the disadvantage of the narrower alleys between the trees. No material advantage was found in running the rows of trees north to south and east to west as compared with running them northeast, southwest, etc.

Contribution to the study of the injection of nutrients into fruit trees, G. Fron (*Jour. Soc. Nat. Hort. France, 4. ser., 10 (1909), pp. 54–59, figs. 2*).—The author reports on some experiments conducted during the past 2 seasons in the injection of nutritive fluids into the stems of fruit trees according to the method used by J. M. Simon (E. S. R., 18, p. 636). He gives a detailed account of the work as conducted with some pear trees, in which sulphate of iron was used as a nutrient in one case and nitrate of lime in the other. Both solutions appear to have increased the vigor of the trees. In most of the experiments, however, the improvement was confined to a small portion of the tree. The author is of the opinion that although this method of treating trees is of little value in practical fruit culture it might, if carried on for several years, serve as a guide for determining which elements should be added to the soil. His experiments are to be continued.

A radical change in the method of determining fruit varieties, A. Janson (*Gartenwelt, 12 (1908), No. 63, pp. 746–748*).—The author points out the difficulties of correctly identifying little known varieties of fruits, and discusses the possibilities of classifying fruits by means of their specific weights.

Preliminary tests of this method lead the author to conclude that, as soon as sufficient data have been gathered relative to the specific weights of the known varieties of fruit, specimens can be easily identified by a comparison of their specific and molecular weights. The desirability of further comparison with the pomological descriptions is pointed out, since there might be a similarity of weight between certain hybrids or little known fruits and some of the varieties which had previously been determined. The method is to be tested further.

The specific weight of fruit varieties, H. Zimmerman (*Gartenwelt, 13 (1909), No. 4, pp. 39–41*).—The author, having tested the value of the specific gravity of apples as a means of determining varieties, in accordance with the method noted (see p. 1035), arrives at the conclusion that the specific densities of various heavy fruits of the same variety are not sufficiently constant to be used as a distinguishing character.

In order to determine whether the differences in the size of the air spaces in the core influence the specific weight, several apples were quartered and the core removed. The specific density was then determined for each quarter. From the data secured it is concluded that the specific density is not affected by the air spaces in the core, but is influenced by the general structure and composition of the apple.

Papers read at the summer meeting of the Ohio State Horticultural Society (*Ohio Sta. Circ. 87, pp. 13*).—This circular contains the full text of the various addresses and papers delivered at the summer meeting of the Ohio State Horticultural Society, as follows: Orchard Renewal, by S. R. Gill; Spraying for Apple Scab in 1908, and Proposed Spray Mixtures for Orchard Use, by A. D. Selby; two papers on Control of Pear Blight in Northern Ohio, by R. A. Hunt and W. Miller, respectively; and Experimental Notes of the Season, by H. A. Gossard. The last-named paper deals with spraying experiments with fruit trees.

French gardening, or intensive cultivation on the French system, T. Newsome (*London, 1908, pp. 83, pls. 4, figs. 27*).—A popular work on this subject in which the author discusses the principles involved in intensive French vegetable gardening, and gives the history of French gardens in England, together with the details of the equipment required for such work, and its cost.

Sugar corn and tomatoes, T. H. McHatton (*Georgia Sta. Bul. 82, pp. 175–207, figs. 14*).—The station inaugurated in 1908 a series of culture experiments to determine the possibilities of growing the ordinary vegetables under Georgia conditions. Sugar corn and tomatoes were the crops tested during the past season. This bulletin contains an account of the experiments, including the notes and data secured. It is stated that the work has not been continued sufficiently long to warrant definite conclusions.

In the work with sweet corn special study was made of the relation between the time of planting and the subsequent crop, as indicated by the yield, sugar content, percentage of smut, and injury by corn ear-worm. Five varieties were grown and plantings were made one week apart from May 6 to June 10, inclusive. Different varieties behaved differently, but the results as a whole for the season, which was an unusually dry one, indicate the third week in May is the best time for planting sugar corn. Smut and the corn ear-worm were the prevalent troubles, the smut affecting from 2.33 per cent to 37.57 per cent of the crop and the corn ear-worm from 60.7 per cent to 100 per cent of the crop. The early plantings were injured most by smut and the late plantings by the corn ear-worm.

In the tomato work a comparative test was made of barnyard manure, acid phosphate, muriate of potash, nitrate of soda, and a complete chemical fertilizer, relative to their influence on the yield and quality of the crop. A test was also made of the mulched, unmulched, and staked systems of culture. The results for 1908 indicate that either barnyard manure or a complete chemical fertilizer gives better yields than any of the chemicals used alone. The acid phosphate plat showed the smallest percentage of diseased plants, and the nitrate of soda plat the highest. The complete fertilizer plat gave the best quality fruit, followed by that fertilized with nitrate of soda. The best yields were secured

on the mulched plat and the poorest on the staked plat. Fruits grown on the staked plat showed the greater percentage of disease. There was very little difference between the mulched and unmulched plats as to disease. On the whole the vines were free from insect pests and comparatively so from disease.

In addition to the discussion of the experimental work, descriptive notes are given on the principal diseases and pests affecting sweet corn and tomatoes, including directions for their control.

[The selection of tomatoes for a higher yield], J. Troop and C. G. Woodbury (*Indiana Sta. Rpt. 1908, pp. 27–28*).—The station is studying the influence on the yield of selecting seed from the heaviest yielding individual plants. The previous season's results showed a variation of about 600 per cent in total yield between the best and poorest plants. About 200 plants were used in this season's work, and records were kept of the yield of each plant at each picking. The highest yield per single plant was 15.06 lbs., and the lowest 1.68 lbs., or a difference of nearly 900 per cent. The highest number of fruits per single plant was 91, and the lowest, 18. No definite conclusions are drawn, but from the season's results Hummer, Chalk Early Jewel, and Stone, in the order named, were the most profitable varieties to grow.

Raspberries, blackberries, and loganberries in Washington, W. S. Thornber (*Washington Sta. Bul. 87, pp. 3–32, figs. 17*).—This bulletin contains practical suggestions for growing, harvesting and shipping raspberries, blackberries and loganberries, together with descriptive notes on the most promising varieties.

Factors affecting the keeping quality of table grapes while in transit and in storage (*U. S. Dept. Agr., Bur. Plant Indus. Doc. 392, pp. 3*).—This circular contains some of the more important results secured in the cold storage experiments with table grapes in California conducted by the Bureau of Plant Industry in 1906–7, and was issued to call to the special attention of grape growers and shippers the value of careful handling, and quick shipment and cooling. The data have been noted from another source (E. S. R., 20, p. 840).

The Rixford: A new type of Smyrna fig, W. T. Swingle (*Pacific Rural Press, 77 (1909), No. 9, pp. 161, 170, figs. 2*).—A popular description is given of a new type of drying fig recently discovered in California which it is believed may prove of value in climates too moist for the successful curing of figs of the ordinary Smyrna type.

These new figs, of which two varieties have been discovered, are designated as self-sealed figs, since the narrow mouth of the fruit, when it matures, is found to be sealed with a drop of pellucid gum. As the figs dry and shrivel on the tree the drop of gum hardens and hermetically seals the mouth, thus preventing the entrance of beetles, pomace flies, and other insects. Since the fermentation germs are unable to enter the fig it does not readily sour. One of the varieties was found to withstand soaking rains uninjured, whereas the figs on the adjoining trees which were not sealed were ruined.

Notes are also given on other promising varieties of figs for California.

The first season with the peach orchard, M. A. Blake (*New Jersey Stas. Bul. 219, pp. 3–27, pls. 10, dgm. 1*).—The stations have 2 young experimental peach orchards which were established for the purpose of investigating various problems which arise in connection with the industry and to assist in placing the peach industry of the State on a firmer basis. Accurate accounts are being kept of the expense of the various cultural operations, some data on which have been previously reported (E. S. R., 19, p. 1037).

This bulletin discusses the details of planting and caring for young peach trees, including the selection of site, soil, purchase and cost of trees, varieties,

fall and spring planting, treatment previous to planting, preparation of land, laying out the orchard, planting operations, fertilizers, intercropping, summer pruning, growth of the trees, and expenses of the first season.

Report of progress with citrus fruits, S. A. Wasciika (*Texas Sta. Bul. 118, pp. 3–11, figs. 6*).—This bulletin was prepared with the view of meeting the numerous requests for information concerning citrus fruit culture in south and southwest Texas, and is based upon the experience gained from recently established experimental plantings at the Beeville Substation, as well as upon information gathered from other sources. Although the advice given is not considered conclusive, the belief is expressed that it will prove of value to prospective planters.

Oranges, grape fruit, lemons, and kumquats have made satisfactory growth. Winter temperatures along the coast belt have been too mild for the most part during the past 5 years to test the endurance of the citrus trees. During the past January, however, they withstood a temperature of from 20 to 24° F. Brief notes are given on the preparation of the land, planting operations, varieties, stock for citrus trees, notes on the behavior of the different citrus fruits at the station, cultivation, cover crops, winter protection, pruning, insects, and diseases. The Satsuma orange is the hardiest orange and will resist more cold than any other orange. The Dugat appears to be the next hardiest. Both varieties are young and heavy bearers. On account of its hardiness *Citrus trifoliata* is preferred as a stock for oranges, lemons, and grape fruit. Several varieties of grape fruit tested at the station proved to be heavy bearers the third year after planting. One-year-old lemon trees planted in February, 1904, bore as high as 164 lemons of excellent quality in 1908. The kumquats also are very young and prolific bearers, setting a crop of fruit the first year after planting.

Cacao culture in West Africa, A. Chevalier (*Vég. Utiles Afrique Trop. Franç., 1908, No. 1, pp. 245, pl. 1, figs. 8*).—This is a treatise on cacao culture with special reference to the development of the industry in French West Africa. In part 1 general consideration is given to the botany, geographic distribution, production and consumption of cacao. Part 2 consists of a detailed account of cacao culture in the islands of St. Thomas and Principe. Part 3 discusses cacao culture in other countries of West Africa. In part 4 the author presents his conclusions relative to the best means of developing the cacao industry in the French colonies of West Africa.

Relationship and classification of the Italian varieties of the almond (Amygdalus communis). A. Biasco (*Separate from Ann. R. Scuola Sup. Agr. Portici, 2. ser., 8 (1908), pp. 40*).—The author discusses the opinions of several writers relative to the relationship of the almonds, and proposes a new scheme for classification, according to which he has arranged the Italian varieties of almonds.

List of herbaceous perennials tested in the arboretum and botanic garden Central Experimental Farm, Ottawa, Canada, with descriptions of flowers, and other notes, W. T. Macoun (*Canada Cent. Expt. Farm Bul. 5, 2. ser., pp. 112, pls. 6*).—The purposes of this bulletin are to assist in the correct naming of varieties, and to bring into greater prominence such useful and hardy species as are worthy of general cultivation. The species and varieties are arranged alphabetically under their scientific names. Common names are given wherever known, as well as the native habitat of the plants. Other data presented are the year when planted, the height to which the plant grows, degree of hardiness, time of blooming and the color of flowers. Introductory notes deal with the planting and care of herbaceous perennials.

Sweet peas and their cultivation for home and exhibition. C. H. CURTIS (*London, 1908, pp. 90, pl. 1, figs. 14*).—A popular treatise dealing with the history and development of sweet peas and their cultivation for garden decoration, home use, and exhibition.

FORESTRY.

Second report of the Royal Commission appointed to inquire into and to report on certain questions affecting coast erosion, the reclamation of tidal lands, and afforestation in the United Kingdom (*Roy. Com. Coast Erosion and Afforest. [Gt. Brit.] Rpt., 2 (1909), pt. 1, pp. X+48*).—A Royal Commission was appointed in July, 1906, to inquire as to the encroachment of the sea on various parts of the United Kingdom and to report on the best means of preventing this encroachment, and the reclamation of tidal lands. Subsequently the commission was directed to determine the advisability of establishing afforestation experiments on these waste lands as a means of increasing employment during periods of depression in the labor market.

This report deals with the afforestation phase alone. Section 1 discusses the present unsatisfactory condition of British woodlands, the causes thereof, the natural conditions in the United Kingdom favorable to the growth of trees, and instances of successful results of British forestry. Some lessons are drawn from German methods and results, and considerable data from various sources are given relative to the scarcity of timber, and rise of price.

The succeeding sections of the report discuss in detail unemployed labor in relation to afforestation, the nature and extent of lands suitable for this work, administration, finance, and a summary of the principal conclusions and recommendations.

The commissioners conclude that the soil and climate in the islands are favorable to the production of high-class timber if scientific methods of afforestation be pursued, and that silviculture should prove a safe and remunerative investment. The amount of land suitable for afforestation not now under timber is estimated at about 9,000,000 acres, somewhat irregularly distributed throughout the United Kingdom. It is recommended that a special board of commissioners be appointed to carry out a national scheme of afforestation for this land. The annual sum required for the full scheme as outlined is £2,000,000, the interest on the loan to be defrayed by taxation. It is calculated that the net deficit will be £90,000 in the first year and will rise progressively to £3,131,250 in the fortieth year, after which period the forest will become more than self-supporting. The net revenue from the forest after 80 years, based upon present prices, is estimated at £17,500,000. The best rotation to secure sustained timber yields requires 150,000 acres to be afforested annually. This will provide temporary employment to 18,000 men during the winter months, and permanent employment to 1 man per each 100 acres afforested, in addition to a large number employed in the incidental and subsidiary occupations connected with forestry.

Investigations of the N. C. Geological and Economic Survey relating to forestry problems along the North Carolina banks, J. H. PRATT (*Jour. Elisha Mitchell Sci. Soc., 24 (1908), No. 4, pp. 125–138*).—The author describes the conditions along the North Carolina banks and presents a report of a brief examination of the banks made by J. F. Bond of the Forest Service of this Department. The report includes a discussion of the damage being done by drifting sands on the areas examined and suggests a definite plan by which these lands can be protected.

Second annual report on forest conditions in Ohio, W. J. Green (*Ohio Sta. Bul. 200, pp. 107–126, map 1*).—This is a report on the progress made by the station in forestry work during 1908, together with a general discussion of forest problems to be met in Ohio. The two principal lines of work conducted during the year were the propagation and distribution of forest tree seedlings and the making of a preliminary forest survey through portions of some of the central counties of the State. During 1907 and 1908, 1,287 woodlots aggregating 101,088 acres were examined and suggestions made for improvement.

Forest survey of Litchfield and New Haven counties, Connecticut, A. F. Hawes and R. C. Hawley (*Connecticut State Sta. Bul. 162, pp. 3–47, pls. 6*).—The surveys here reported were made with the chief object of arousing interest in the forest lands of Litchfield and New Haven counties with a view to lead to the adoption of better methods of treatment. The counties are described relative to their location and physiographic features, agricultural and forest lands, forest types, estimates of timber consumption and production, and local market conditions.

Notes are also given showing the forest conditions of the individual towns of each county. Three principal forest types are recognized in the survey: The mixed hardwoods, white pine, and abandoned field types. General suggestions are given for the management of each of these types, as well as for protection against fire and grazing.

Seventh report of the forest commissioner of the State of Maine, E. E. Ring (*Rpt. Forest Comr. Maine, 7 (1908), pp. 103, pls. 6*).—This report includes a résumé of the forest fires of 1907–8, with conclusions and recommendations for future control, an article on white pine blight in Maine, by W. J. Morse, which is noted on page 1047 of this issue, the text of a decision of the State supreme court to regulate the cutting of trees, and a historical account of the wild lands of Maine relative to their acquisition and disposal. The report concludes with an extensive list of Maine islands conveyed by Maine and earlier by Massachusetts, showing the name of the island, situation, and date of conveyance to private parties.

Fifth annual report of the State forester of Massachusetts, F. W. Rane (*Ann. Rpt. State Forester Mass., 5 (1908), pp. 46, pls. 8*).—This is a progress report on forest operations in Massachusetts for 1908. It contains the text of recent forest legislation in Massachusetts, information on the examination of woodlands, and the practical assistance given owners, distribution of nursery stock, activities along forest educational lines, fire protection, publications issued, etc. Data are also given on the forestry work done by the Metropolitan Water and Sewerage Board in connection with the construction of the Wachusett reservoir.

This work was begun in 1898. In all, 1,330 acres were planted to coniferous and deciduous trees up to January 1, 1909. The cost of raising the trees from seed, preparing, planting, and protecting the lands planted until the trees were planted in the field, was $14.92 per thousand trees, or $18.98 per acre (1,390 trees per acre). The annual charge for maintaining efficient fire protection is estimated at 31 cts. per acre. The cost of an improvement thinning is $6 per acre, and it is calculated that such a thinning must be made twice during the first 10 years, after which time the trees should care for themselves.

Annual progress report upon state forest administration in South Australia for the year 1907–8, W. Gill (*Ann. Rpt. State Forest Admin. So. Aust., 1907–8, pp. 11, pls. 6*).—A brief review is given of the year's planting and other forest operations conducted by the woods and forest departments for the year ending June 30, 1908. The data given are similar in character to that contained in previous reports (E. S. R., 19, p. 1148).

Report on forest statistics of Alsace-Lorraine (*Beitr. Forststatis. Elsass-Lothringen, 1909, No. 26, pp. 125*).—This work consists of a statistical account of forest areas, products, revenues, expenditures, etc., for the year 1907, together with a comparative summary for each year since 1870.

The timber industry in north Germany, J. Marchet (*Der Holzhandel Norddeutschlands. Leipsic and Vienna, 1908, pp. VII+227, figs. 19, maps 2*).—A study of the timber industry in various sections of north Germany, with considerable data on production, commerce, prices, etc.

Researches on the woods of different species of African leguminous trees, E. Perrot and G. Gérard (*Vég. Utiles Afrique Trop. Franç., 1907, No. 3, pp. 155, pls. 10, figs. 24*).—This work, which consists of a botanical, scientific, and economic study of different species of African leguminous trees, was undertaken with the view of establishing scientific characters for the identification of the different species by an examination of the woods. The microscopic study of these woods was the important feature of the investigation.

In part 1 consideration is given to the anatomy of the ligneous tissue in its relation to the diagnosis of wood. In part 2 the individual species are considered relative to their botany, wood structure and composition, and economic value. In part 3 the author compares and discusses the important facts brought out in the studies.

An extensive bibliography on the study of woods is given and a series of schedules are appended showing the important data obtained by the microscopical examination of each species.

A Philippine substitute for lignum-vitæ, W. I. Hutchinson ([*Philippine*] *Bur. Forestry Bul. 9, pp. 3–8*).—In view of the rapidly decreasing supply of lignum-vitæ (*Guajacum officinale*) of the West Indies, the Philippine Bureau of Forestry conducted an investigation for the purpose of finding a wood capable of replacing it. As a result of this work, mancono (*Xanthostemon verdugonianus*), the hardest and heaviest of Philippine woods, is recommended as having enough good qualities to serve as a substitute for lignum-vitæ. It is urged that the wood be tried by all hardwood manufacturers, since the species is found in merchantable sizes and quantity and can be cheaply exploited.

The two species are described and compared, and the mancono is discussed relative to its distribution and occurrence, logging operations, cost of labor and transportation. One official test of this wood was made by the U. S. Naval Station at Cavite, in which it was installed in a launch as a bearing for journals rotating in salt water, and was found to be but little worn at the end of 7 months. It is considered to be the equal of lignum-vitæ when both woods are used for bearings on side grain.

Physiological principles involved in the tapping of rubber trees; based on experiments conducted with Hevea brasiliensis, H. Fitting (*Tropenpflanzer. Beihefte, 10 (1909), No. 1, pp. 4–17*).—The author reports on a physiological investigation of various methods of tapping rubber trees, conducted in Java. Various tapping methods were studied relative to their influence on the life of the tree in general and upon the subsequent formation of latex and rubber, and the results of this study are compared with the experience of practical rubber growers. The author recommends and discusses the use of a somewhat modified herring-bone tapping system.

On the plantation, cultivation, and curing of Para Indian rubber (Hevea brasiliensis), H. A. Wickham (*London, 1908, pp. 78, pls. 7, figs. 5, map 1*).—This is a collection of notes on the above topics based upon the author's experience in the tropical region of South America. An account is also given of the introduction of Para rubber from South America to the eastern tropics.

DISEASES OF PLANTS.

Examples of the use of the microscope in investigating plant diseases, O. Appel (*Beispiele zur mikroskopischen Untersuchung von Pflanzenkrankheiten. Berlin, 1908, 2. ed., rev. and enl., pp. 54, figs. 63*).—This is a second edition of the author's contribution on the use of the microscope in the study of plant diseases, and is issued as a separate from Hager and Mez's Das Mikroskop und seine Anwendung.

In this publication the author describes the principal microscopic characters of a number of common and destructive diseases, among them the bacterial rot of potatoes, the bacterial disease of cherries, club root of Cruciferæ, the Phytophthora disease of potatoes, grape mildew, leaf spot of clover, cereal mildews, smuts and rusts of grain, etc. In addition notes are given on a number of insects that cause diseases of plants, such as nematodes, plant lice, scale insects, etc.

Two little known Myxosporiums, C. W. Edgerton (*Ann. Mycol., 6 (1908), No. 1, pp. 48–53, figs. 2*).—During a study of fungi which have a Gloeosporium-like fructification, the author noted two parasites which should be placed in the genus Myxosporium. One of these occurs on the branches of the tulip tree (*Liriodendron tulipifera*), while the other is found on the living branches of apple and pear trees. The latter produces a canker on the old bark and has been frequently confused with another fungus, *Sphæropsis malorum*.

After a careful study of the bark canker and that caused by the black rot fungus, the author concludes that the two forms may be readily distinguished. The bark canker is produced, as indicated above, by a species of Myxosporium, and the name *M. corticolum* n. sp. is given it. The fungus is perennial, living from year to year in the bark, and forming a new ring of growth each year. It grows rapidly in the direction of the main axis, causing the formation of a long narrow canker. It does not penetrate deeply into the host, the mycelium extending only about one-third to the cambium zone. The outer portion of the cortex is killed and dries out much faster than the healthier tissues, and, as a result, this area becomes slightly sunken. During the second year the fungus grows out into the unaffected bark surrounding the canker and this region becomes the spore-bearing one for that season.

Notes are given on the relation of this fungus to others, with a discussion of its synonymy, and a technical description concludes the study of this species.

The second species, which attacks the tulip tree in a somewhat similar manner, is also due to a new species, *M. longisporum*, which is technically described.

Investigations on diseases of cereals in 1908, K. Störmer (*Landw. Wchnschr. Sachsen, 10 (1908), Nos. 35, pp. 306–309; 38, pp. 331, 332; 39, pp. 340, 341; 40, pp. 347–349*).—A report is given of studies carried on at the plant pathology station on the occurrence of cereal diseases in Saxony in 1908. The most important diseases were the smuts of barley and wheat (*Ustilago hordei* and *U. tritici*), the stinking smut (*Tilletia caries*), the stem disease due to *Ophiobolus herpotrichus*, and the leaf and stem disease caused by *Helminthosporium gramineum*.

Different treatments for the prevention of these diseases were tested. The modified hot-water treatment for smut prevention as well as the treatment by means of dry hot air recommended by Kühle (E. S. R., 20, p. 947), which consists of a preliminary soaking of the seed in cold water for several hours, followed by drying in a drying machine heated to 60° C. or more, are recommended as the most efficient treatments for smut.

Notes are given on other diseases, among them rust, mildew, etc.

Formalin for oat smut. A. Goss (*Indiana Sta. Rpt. 1908, pp. 17, 18*).—Attention is called to the value of formalin for treatment of seed oats for the prevention of smut.

The rust of timothy. F. D. Kern (*Torreya, 9 (1909), No. 1, pp. 3–5*).—The occurrence of rust on timothy is said to have been reported in this country as early as 1881 or 1882, but it is only in recent years that it has been found in sufficient abundance to attract attention. In 1906 timothy rust was found fairly abundant in several localities in New York and in 1907 it was also reported from Delaware, West Virginia, and Canada. In 1908 it was also reported from Michigan and Wisconsin.

A study of the rust indicates that it is a physiological species of the common *Puccinia graminis* or *P. poculiformis*, as the author considers the species, and it is believed that there is little danger of the rust transferring to timothy from other cereals and grasses. It is thought probable that the disease will become more general in its distribution and may locally do considerable injury, but in spreading it will be limited to passing the summer spore stages on timothy alone.

The browning of the bracts of hops due to lime nitrogen. Wagner (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 6 (1908), No. 11, pp. 126–129*).—A description is given of a browning of the bracts of hop strobiles following fertilizer experiments with lime nitrogen that has caused considerable injury. The injury was observed to be confined almost wholly to plants grown in light soils that had received applications of lime nitrogen in the spring of the year. Autumn applications were followed with no injury, and the author advises the use of this fertilizer in autumn only. The quality of spring fertilized hops was a little better than where the application was made in the fall of the year, but the risk from the browning is believed to be too great to warrant the use of the fertilizer in the spring. The cause of the unfavorable action when applied in the spring is to be investigated.

Varieties of potato scab (*Jour. Bd. Agr. [London], 15 (1909), No. 10, pp. 749–751, pls. 2*).—Descriptions are given of various forms of scab occurring on potatoes, among them the scab due to mechanical injury, the wart disease or black scab caused by *Chrysophlyctis endobiotica*, the scab caused by millipeles or false wireworms, the Oospora scab of potatoes, and the form of scab caused by *Spongospora scabies*.

Dry scab of potatoes. G. Massee (*Roy. Bot. Gard. Kew, Bul. Misc. Inform., 1909, No. 1, pp. 16–18, fig. 1*).—A description is given of the dry scab of potatoes, due to *Spondylocladium atrovirens*. The injury is confined to the tubers, and no indication of its presence is suggested by the foliage, which remains unaffected. The fungus causes disfigurement of the tuber, followed by local areas of a dry rot. The presence of the fungus is revealed by the occurrence of blackish-olive patches, which soon become depressed below the general surface of the tuber, due to the drying and breaking up of the tissues. Frequently only one or two areas are present on a tuber, varying from half an inch to an inch in diameter.

As the mycelium penetrates a considerable portion of the tuber, it is recommended that tubers showing signs of disease should not be used for planting, even if the portion obviously infected has been cut away.

This disease has been known for a number of years, having previously been attributed to *Phellomyces sclerotiophorus*.

Potato spraying experiments in 1908. F. C. Stewart, G. T. French, and F. A. Sirrine (*New York State Sta. Bul. 311, pp. 38*).—This bulletin gives the results of the seventh year's work in potato spraying in continuation of the experiments begun in 1902. Twenty-seven separate experiments are reported upon.

At Geneva, 6 sprayings with Bordeaux mixture resulted in an increased yield of 39 bu. per acre, while 3 sprayings gave an increase of 29.5 bu., although both early and late blight were wholly absent and there were but few flea beetles. The chief trouble in 1908 was tip burn. There was no rot observed. At Riverhead the gain due to 5 sprayings was 15.3 bu. per acre and to 3 sprayings 10.75 bu.

In the farmers' business experiments, including 200 acres, the average gain due to spraying was 18.5 bu. per acre, with a net profit of $8.53. In 5 of the experiments, spraying was unprofitable.

Eleven volunteer experimenters reported gains averaging 66.3 bu. per acre.

Potato spraying in dry seasons, F. H. Hall (*New York State Sta. Buls. 307, 311, popular ed., pp. 10*).—This is a popular edition of Bulletin 307 of the station previously noted (E. S. R., 20, p. 948) and of Bulletin 311, noted above.

Treatment for scab and early blight on potatoes and mildew on cucumbers and cantaloups, T. C. Johnson (*Virginia Truck Sta. Circ. 1, pp. 2–8*).—The corrosive sublimate and formalin methods of treating seed potatoes for scab, and the use of Bordeaux mixture for preventing the early blight of potatoes and for spraying cantaloups and cucumbers for the prevention of mildew are described.

[Spraying experiments with cantaloups], J. Troop and C. G. Woodbury (*Indiana Sta. Rpt. 1908, pp. 35–37*).—The results of spraying cantaloups with a 5:5:50 Bordeaux mixture for the prevention of rust are given. In these experiments 3.54 acres of cantaloups received 5 applications of the fungicide, the first being made about the time the rust spots began to appear, which was a few days subsequent to the setting of the fruit. The other applications followed at intervals of 1 to 2 weeks. As a result of the spraying, a net profit of $11.49 per acre was obtained.

Melon wilt, J. Troop and C. G. Woodbury (*Indiana Sta. Rpt. 1908, pp. 30, 31*).—An account is given of an attempt to discover the means by which the bacterial wilt of cucurbits (*Bacillus tracheiphilus*) is carried from plant to plant. Forty hills of cantaloups were grown in pots sunken in the ground. The soil for half of the pots was sterilized, while in the others it was unsterilized, and half of the hills of both sterilized and unsterilized soil were covered with screens.

From the results of the experiments, it seems probable that soil sterilization had but little effect and that the disease is largely spread by insects.

The gooseberry mildew, J. Eriksson (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 6 (1908), No. 11, pp. 121–126*).—An account is given of the introduction and distribution of the gooseberry mildew (*Sphærotheca mors-uvæ*) into Europe and attention called to its destructiveness, the various host plants, the time and periods of infestation, and the results of spraying experiments. The author suggests the cutting out and burning of all diseased plants, so far as possible.

Exosmosis in the roots of plants and combating chlorosis, G. Truffaut (*Jour. Soc. Nat. Hort. France, 4. ser., 9 (1908), Dec., pp. 709–713*).—By means of hyacinth bulbs the author has been able to demonstrate the exosmosis of the sulphates of iron, potash, and magnesia placed in cavities of the bulbs. The sulphuric acid found its way into the distilled water in which the bulbs were grown through the roots developed by the plants. Acting upon this suggestion some fruit trees suffering with chlorosis due to an excess of lime were bored into and sulphate of iron placed within the trunks. The sulphuric acid in the iron compound was found to attack the lime deposits within the trees and apparently to permit the absorption of other elements needed by the plant.

Apple blotch, a serious disease of southern orchards, W. M. Scott and J. B. Rorer (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 144, pp. 28, pls. 6*).—As a

result of demonstration experiments conducted in the Middle West in 1906, the authors determined that apple blotch was far more destructive than apple scab and bitter rot combined, and their attention was turned to an investigation of the disease.

This disease is well distributed over the eastern half of the United States, occurring in some regions to such an extent that fully 50 per cent of the fruit is rendered unfit for packing.

The disease, which is of a fungus origin, was first described as occurring on the fruit in a bulletin of the Illinois Station (E. S. R., 13, p. 1059) and later its occurrence was noted by a number of investigators. In 1907 the authors pointed out the relation between certain cankers and leaf spots to the blotch on the fruit. About the same time similar observations were reported by Sheldon (E. S. R., 19, p. 348), who identified the fungus as *Phyllosticta solitaria*.

Apple blotch occurs on the fruit, branches, and leaves, the form on the fruit being by far the most important from an economic standpoint. On the fruit, the first evidence of the disease is shown in small, inconspicuous, light brown blotches, which spread rapidly with an irregular, jagged, advancing margin. Where the spots are numerous they often coalesce and form large blotches, which may cover half the apple or more. The fungus kills only the superficial cells, so that continued growth results in the cracking of the fruits.

Characteristic cankers are formed by the fungus on fruit spurs, twigs, and rapidly growing shoots. At first these cankers are rather small and inconspicuous, appearing as small purple or black blotches. As they increase in size they become brown in the center, retaining a purple margin, but may finally become gray. The bark soon cracks around the cankers, especially along the lateral edges.

On the leaves the spots are irregular, light brown, yellowish, or whitish, small, and are of comparatively minor importance.

The fungus is believed to pass the winter in the twig cankers, these furnishing the chief source of infection. As in the case of other fungus diseases, the apple blotch is dependent more or less upon weather conditions, although it develops in cool as well as in warm weather.

A wide range in susceptibility of different varieties of apples to this disease is noted. An account of the life history of the fungus, a description of its cultural characters, and the results of inoculation experiments are given.

It was shown in 1906 that spraying with Bordeaux mixture was successful in preventing the disease, and in 1907 the experiments were repeated to determine the number and times of application. In most of the experiments a 5:5:50 Bordeaux mixture was employed, but it is thought that probably a weaker solution or one containing a greater amount of lime might be advantageously employed. For the prevention of codling moth and other insect injuries, the addition of 2 lbs. of arsenate of lead or 6 oz. of Paris green is recommended.

The principal period of infection comes usually from 4 to 6 weeks after the petals have fallen, and 4 applications of Bordeaux mixture, the first 3 or 4 weeks after the petals have fallen, will ordinarily be found sufficient. By combining the treatments for insect enemies, bitter rot, blotch, leaf spot and scab, 6 applications, the first when the cluster buds are beginning to show conspicuously and the last about the first of August, would be found advantageous for the control of all of the more important apple troubles.

Scaly bark of citrus, H. S. Fawcett (*Florida Sta. Bul. 98, pp. 75–80, figs. 3*).—This is a preliminary report of investigations on scaly bark, which has been

found quite destructive to sweet orange trees in one of the most important citrus-growing sections of Florida.

The disease is primarily one of bark and rind, the wood being affected only secondarily. The bark of the trunk and of branches of all sizes may be affected, but the greatest injury is done to the younger branches and twigs up to about ½ in. in diameter and to the fruit. On the branches and twigs, more or less circular spots ⅛ in. or more in diameter are developed, the bark becomes brittle, cracks, and forms small flakes or scales. This may continue for several years until the branch is finally girdled and killed. The formation of rough scaly bark also occurs on the trunks of the badly diseased trees, and the exudation of gum is usually an accompaniment of the trouble.

The disease is apparently infectious, and it is believed that it may be spread from tree to tree and from grove to grove.

Studies in the laboratory and field have so far failed to reveal any organism within the diseased tissue, except *Colletotrichum glœosporioides*, the fungus which causes the wither tip.

Experiments have been carried on for the control of the disease, and the author recommends top-working affected trees, heading back, pruning out, and thorough spraying with Bordeaux mixture.

Fungus diseases of cacao and sanitation of cacao orchards, F. A. Stockdale (*Imp. Dept. Agr. West Indies Pamphlet 54, 1908, pp. 47*).—In this pamphlet brief descriptions are given of the principal diseases of cacao and of the remedial measures that have proved to be most successful in dealing with these diseases. It appears that the fungus diseases of cacao are quite amenable to treatment, and as the recommendations are simple and practical in character, there should be no difficulty in carrying them out.

Among the diseases described are the root disease, canker, die back, Lasiodiplodia, thread blight, witches' broom disease, brown rot of pods, and black rot of pods.

The publication concludes with suggestions for the proper sanitation of cacao orchards.

Bud rot of the coconut, E. B. Copeland (*Philippine Agr. Rev.* [*English Ed.*], *1 (1908), No. 5, pp. 210–220, pl. 1*).—An account is given of investigations by the author on the occurrence of the bud rot of the coconut in the Philippines. The disease is reported to be very prevalent in 3 districts and present but doing less damage in several others. The disease is described, and, as a tree once affected is practically valueless, the author recommends that in order to prevent the spread of the disease to other trees all those infected should be burned. A synopsis is given of reports on the occurrence of bud rot in other countries.

The blue rot of coniferous timber, E. Münch (*Naturw. Ztschr. Forst u. Landw., 5 (1907), No. 11, pp. 531–573, figs. 28; 6 (1908), Nos. 1, pp. 32–47, figs. 3; 6, pp. 297–333, figs. 2*).—A study was made of the cause of the so-called blue rot of the wood of various species of coniferous trees and the effect produced by the fungus on the tensile strength of infected timber.

The author found the trouble to be due principally to what has been called *Ceratostomella pilifera*, but instead of there being a definite species under that name, it is really a group of allied forms, which have been separated and studied in detail. Three forms are recognized as new species, *C. piceæ*, *C. cana*, and *C. cærulea*. The first two species are associated with certain species of Graphium in their life cycles.

In addition to the foregoing fungi, the author found *Endoconidiophora cærulea*, a new genus of fungus, attacking pine, fir, and hemlock trees.

The most injury is said to be due to attacks of *C. pini* and *C. cærulea*. The mycelium of the fungi was found to be able to attack and destroy the living tissues of conifers, growing much more rapidly in moist than in dry timber. The specific gravity and strength of timber was found to be decidedly reduced, due to the presence of the fungus.

A fir disease in Saxony, F. W. Neger (*Tharand. Forstl. Jahrb., 58 (1908), No. 2, pp. 201–225, pls. 3, figs. 2*).—For a number of years the fir trees of Saxony and other parts of Germany have been subject to a disease which the author was commissioned in 1905 to study and report upon.

The disease is manifested upon the trees in the thinning of the leaves and the dying of the branches, the top of the tree being usually first to show the trouble, and by a water-soaked appearance of the heart wood. An investigation showed that the disease was due to *Agaricus mellcus* attacking the trees through their taproots. No parasite of any kind was found on the leaves or in the injured twigs. The mycelium of the mushroom forms a dense network of rhizomorphs about the taproot and later enters the tissues, finally causing a rotting of the roots. Later the horizontal roots are invaded and the tree dies.

The attack of the fungus is favored by anything that weakens the vitality of the tree, such as smelter fumes, checking the transpiration stream, resulting in a water-logged condition of the stem and main roots, lack of light, etc. Correcting these conditions will to a great degree diminish the spread and injury due to the parasite.

The white-pine blight in Maine, W. J. Morse (*Rpt. Forest Comr. Maine, 7 (1907–8), pp. 20–25, pl. 1*).—On account of the recent interest in the blight of white pine, the author was led to investigate during the past summer the injury to white pine in a number of localities in Maine. He found that there is no connection between the so-called white-pine blight and that recently described in a pamphlet of the Forest Service of this Department (E. S. R., 20, p. 549). Practically all of the so-called pine blight in Maine in 1907 and 1908 is believed to have been due to adverse weather conditions during the past two winters.

The infectious chlorosis of the Japanese euonymus, E. Baur (*Ber. Deut. Bot. Gesell., 26a (1908), No. 9, pp. 711–713*).—In continuation of previous experiments (E. S. R., 18, p. 648), the author has made a study of the chlorotic forms of the Japanese euonymus and of variegated forms of privet. In some cases he has been able to transfer the infection by means of inoculation experiments, while in others he failed. On this account he is led to the conclusion that there may be an infectious and a noninfectious form of chlorosis. In a previous report he stated his belief that the infectious virus could be isolated, but thus far he has failed to do so.

The destruction of wood by fungi, A. H. R. Buller (*Sci. Prog. Twentieth Cent., 3 (1909), No. 11, pp. 361–378, figs. 3*).—A discussion is given of the destruction of wood by fungi and attention called to a number of the more common species of fungi that attack structural timber, decaying trees, etc.

North American rose rusts, J. C. Arthur (*Torreya, 9 (1909), No. 2, pp. 21–28, figs. 3*).—According to the author practically all rose rusts in North America have been hitherto placed under two species, *Phragmidium speciosum* and *P. subcorticium*. Subsequent studies, however, have shown that there are a number of distinct species, and 6 are recognized, all of which are indigenous but one. The distribution of these species throughout the United States is indicated. The species recognized are *P. americanum*, *P. rosæ-setigeræ*, *P. rosæ-californicæ*, *P. rosæ-arkansanæ*, *P. montivagum*, and *P. disciflorum*.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Spring practice in economic zoology, H. A. Gossard (*Ohio Sta. Bul. 198, pp. 15–88+VIII, figs. 10*).—This is the second of a series of manuals of economic zoology to be issued in 4 numbers corresponding with the seasons of the year. The winter number has been previously noted (E. S. R., 17, p. 675).

Under farm management the rotation of crops, fertilizers, and clean farming are discussed. Under natural friends and enemies domesticated animals, rats, mice, rabbits, moles, shrews, skunks, woodchucks, toads, and various species of birds, and methods of attraction or destruction, as the case may be, are briefly considered. The insects attacking grasses, grains, and fruits are described and methods of treatment discussed. Similar data for the insects of the vegetable garden are presented in tabular form. Records of bird migration made at Wooster by S. Harry and A. I. Good are appended.

Eighth report of the State entomologist, 1908, W. E. Britton (*Connecticut State Sta. Rpt. 1907–8, pt. II, pp. VIII+763–848, pls. 18, figs. 12*).—A résumé of the entomological features for 1908 and a report of the nursery inspection work are first presented. In the report of the progress in suppressing the gipsy moth in Connecticut it is stated that the actual size of the area infested by the pest has been considerably reduced during the year. The spring and the fall cankerworms which were more abundant than in 1907 are considered at some length. The San José scale did not spread as much as usual due to the preceding severe winter. From further tests of gases for the destruction of this pest on nursery stock, in which carbon disulphid, carbon tetrachlorid, and acetylene were used, it is concluded that hydrocyanic-acid gas is to be preferred.

A report of an investigation of the mosquito breeding problem at the State Rifle Range at East Haven, and of the Beaver Swamp region, near New Haven, is presented in which it is concluded that for a few thousand dollars the entire region could be put in a salutary condition. Notes are also given on mosquito breeding places in the vicinity of Stamford.

Under insects attacking cucurbitaceous plants in Connecticut the squash borer, striped cucumber beetle (*Diabrotica vittata*), corn root-worm, squash lady-beetle (*Epilachna borealis*), squash bug, melon aphis, squash aphis (*Nectarophora cucurbitæ*), and greenhouse whitefly are considered. The elm-leaf beetle is said to have been the source of more injury to elm trees than for several years. The fungus *Sporotrichum globuliferum* (*entomophilum*) which attacks the pupæ and adults in late summer is one of the most important of its natural enemies. The green clover worm (*Plathypena scabra*) was the source of injury in June and July to bush and pole beans. In experiments made to determine the value of various substances and devices in the prevention of injury to cabbages by the cabbage maggot, the best results were obtained from the use of tarred paper disks. Tests of homemade soluble oil has led the author to advise orchardists to purchase a prepared mixture.

Under insect notes the author reports the snow-white linden moth to have been very abundant in July. The hickory tussock caterpillar (*Halisidota caryæ*) which was abundant during the summer was killed in large numbers in September and October by a fungus disease. Caterpillars of *H. tessellaris* and probably *Estigmene acræa* were also killed by this or a similar disease. Lead arsenate was found to give better results than Paris green when used against the potato beetle. The three-lined leaf-beetle (*Lema trilineata*) which was more than usually abundant on potatoes was fed upon by the predaceous beetles *Lebia grandis* and *Pterostichus lucublandus*. The marsh golden-rod was eaten up in one or more localities by the beetles *Trirhabda canadensis* and *Microrophala vittata*. The chrysomelid beetle *Nodonota puncticollis* was destruc-

tive to young chestnut trees at Stamford. The New York weevil (*Ithycerus noveboracensis*) injured young pear trees in one locality by eating out the base of the new growth. Other insects noted as a source of injury are *Otiorhynchus sulcatus* by eating the leaves of palms, lemon trees, etc., the strawberry weevil (*Anthonomus signatus*), the raspberry sawfly (*Monophadnoides rubi*), apple leaf-folder (*Ancylus nubeculana*), the leopard moth (*Zeuzera pyrina*), the boll worm, and the pyramid caterpillar (*Pyrophila pyramidoides*).

Insect notes for 1908, Edith M. Patch (*Maine Sta. Bul. 162, pp. 351–368, pls. 9*).—This bulletin contains brief accounts of the more important insects of the year 1908.

Nymphs of a predaceous bug, probably *Podisus modestus*, are reported as occurring in the nests and feeding upon young brown-tail moth caterpillars. The greatest amount of damage caused by any single species was due to *Heterocampa guttivitta*. Associated with *H. guttivitta* were the rosy-striped oak-worm (*Anisota virginiensis* [*pellucida*]) and the green-striped maple-worm (*A.* [*Dryocampa*] *rubicunda*), the former particularly on oak and the latter upon maple. The white tipped moth (*Symmerista* [*Edema*] *albifrons*) was very prominent on oak, birch, and other trees. *Argyroploce abietana* injured spruce in one locality by eating out the inside of the leaves. *Acrobasis* (*Phycis*) *rubrifasciella* was injurious to sweet fern and white birch. *Galium verum* was found to be a much preferred food plant of *Deilephila galli* which also feeds upon fireweed, strawberry leaves, etc. *Datana major* was numerous upon deerberry, while gall mites (*Eriophyes fraxiniphila* and *E. fraxini*) are said to have attacked red ash in the vicinity of Orono. Other insects reported include the bean worm (*Ogdoconta cinereola*), *Alcothoe caudata* on the blossoms of Virgin's bower, *Estigmene acræa*, *Diacrisia* (*Spilosoma*) *virginica*, *Basilona imperialis*, the pine hawk moth (*Lapara bombycoides*), *Dibolia borealis*, the raspberry cane borer (*Oberea bimaculata*), *Osmoderma scabra*, *Dermestes vulpinus* in tankage and curd from dried buttermilk, *Corticaria ferruginea*, *Brachys aerosa*, *Dendroctonus terebrans*, *Monohammus titillator* and *M. scutellatus*, *Cryptorhynchus lapathi*, *Conotrachelus nenuphar*, *Aphrophora parallela*, *Eriopeltis festucæ*, *Leptoterna dolobrata*, *Canthophorus cinctus*, *Anasa tristis*, *Lygus pratensis*, *Nematus erichsonii*, *Lophyrus abietis*, plant lice and several species of grasshoppers. *Tiphia inornata*, a parasite upon the white grub, was very numerous.

The apple leaf-hopper and other injurious insects of 1907 and 1908, F. L. Washburn (*Minnesota Sta. Bul. 112, pp. 145–254, pl. 1, figs. 67*).—Studies made of *Empoasca mali* have shown it to be at least two-brooded in Minnesota. The eggs of the summer brood are deposited in the petiole of the clover, apple, and probably other plants. There are said to be 5 nymphal stages, a period of 22 days elapsing after hatching before the adults appear. Adults live 14 days or longer. The presence of the winter egg is denoted by a blister-like swelling on the bark of the apple. The pest does not seriously injure orchard trees but retards the growth of nursery stock and also occurs on a large number of other plants, including alfalfa. It appears desirable that nursery stock be grown at some distance from the apple orchard. The best results as regards remedial measures have been obtained from the use of screens smeared with tangle-foot. Fish-oil soap 1 lb. to 10 gal. of water was found to kill adults and young if they were not too well protected by the curled leaves. Among the destructive shade-tree pests briefly considered are the oak primer (*Elaphidion villosum*), Ægeriid ash borer (*Podosesia* [*Ægeria*] *fraxini*), stalk borer (*Papaipema furcata*), locust borer (*Cyllene robiniæ*), box elder maple borer, bronze birch borer (*Agrilus anxius*), white pine louse (*Chermes pinicortis*), alder aphis (*Pemphigus tesselatus*), cottony maple scale, fall webworm, poplar leaf

beetle (*Melasoma scripta*), Curtis scale (*Aspidiotus ostreæformis*), scurfy scale, white-marked tussock moth (*Hemerocampa leucostigma*), forest tent caterpillar, *Cimbex americana*, *Euvanessa antiopa*, and the elm-leaf beetle.

Further experiments conducted in 1907 with remedies for the cabbage maggot are reported. The best results were obtained by treating cauliflower with a decoction of white hellebore prepared by steeping 2 oz. of the powder for an hour in 1 qt. of water and then diluting with water to make 1 gal. This was applied with a watering pot (from which the rose had been removed) a few days after the plants were set out, with a second application 5 days later, followed by a third 5 days after the second. Holland cabbage appears to be exempt from attack but red cabbage is not. Cabbage maggots were found to emerge from pupæ which were buried 5 in. deep in the soil. *Pseudocucoila gillettei* was the most common parasite that emerged from the puparia, other parasites, including *Homotropus bicapillaris albopictus*, *Aphæreta pegomyiæ*, and *Megaspilus striatipes*.

From the results obtained with the work with the pest during 1908 and previous years it is concluded that "radishes grown in the open are apparently benefited by several applications of hellebore decoction (4 oz. of white hellebore steeped in 2 gal. of water) applied with a watering pot, first when plants are 1.5 in. high, and 3 or 4 later applications at 5 days' intervals; or by the use of tobacco dust with equal frequency in the same way."

Spraying experiments for pests of the orchard and garden are reported and discussed. "Spraying plum trees with arsenate of lead and Bordeaux mixture (3:4:50) two or three times at beginning of curculio season, at intervals of a week or ten days will prevent at least 50 per cent loss of fruit from curculio injury, to which must be added whatever injury from fungi is saved by the use of Bordeaux mixture."

Attention is called to the occurrence of crown gall on raspberries and that such comes under the Minnesota law relating to contagious diseases of plants. The irritating harvest mite or jigger is described and preventive remedies suggested. White grubs (*Lachnosterna rugosa* and *L. fusca*) are said to have been more destructive to lawns in the State in 1908 than ever before. The bee moth (*Galleria mellonella*) is now under investigation. Foul brood is described and remedies briefly considered.

Reports of orchard inspectors (*Zool. Bul. Penn. Dept. Agr., 6 (1908), Nos. 8, pp. 271–300; 9, pp. 303–332*).—A report by counties of the orchard inspection work.

A European ant (Myrmica levinodis) introduced into Massachusetts, W. M. Wheeler (*Jour. Econ. Ent., 1 (1908), No. 6, pp. 337–339*).—The author reports the discovery of *M. levinodis* at Forest Hills and Jamaica Plain, Mass. This species and the variety previously described as *brucsi* with *Tetramorium cespitum* are the only species known to have been introduced into this country from Europe. As *M. levinodis* is very fond of attending aphids and prefers to nest in cultivated soil, it is suggested that it may become of economic importance.

Notes on Tenthredinoidea, with descriptions of new species, I, S. A. Rohwer (*Canad. Ent., 40 (1908), No. 6, pp. 175–180*).—A first paper in which 6 species from Colorado representing the genera Enura, Cephaleia, Emphytus, Hoplocampa, and Lycasta are described as new to science.

A list of parasites known to attack American Rhynchophora, W. D. Pierce (*Jour. Econ. Ent., 1 (1908), No. 6, pp. 380–396*).—This list contains important data that have been recorded since the preliminary list was published (E. S. R., 19, p. 757). The sources of the records are indicated and a bibliography is appended.

Notes on the life history of Nonagria oblonga, W. R. WALTON (*Ent. News, 19 (1908), No. 7, pp. 295–299, pl. 1*).—Infestation by this moth in 75 per cent of the stalks of the common cat-tail rush (*Typha* sp.) is reported as having been found near Harrisburg, Pa. The tachinid (*Masicera myoidæa*) has been reared from the larvæ.

A bit of contemporary history, ANNIE T. SLOSSON (*Canad. Ent., 40 (1908), No. 7, pp. 213–219, pl. 1, figs. 3*).—A description is given of *Ignotus anigmaticus*. This species has been recognized as a pest among the collections of the public museum in Milwaukee, Wis.

Miscellaneous papers. Biological studies on three species of Aphididæ, J. J. DAVIS (*U. S. Dept. Agr., Bur. Ent. Bul. 12, tech. ser., pt. 8, pp. 123–168, figs. 4*).—The author here reports studies made of the biology of the corn root-aphis, corn leaf-aphis (*Aphis maidis*), and sorghum aphis (*Sipha [Chaitophorus] flava*). Technical descriptions are given of the different forms in their various stages and a complete bibliography of each species is appended.

Notes and descriptions of some orchard plant lice of the family Aphididæ, C. P. GILLETTE (*Jour. Econ. Ent., 1 (1908), Nos. 5, pp. 302–310, pls. 2; 6, pp. 359–369, pls. 2*).—In this paper, which is supplemental to Bulletin 133 of the Colorado Station previously noted (E. S. R., 20, p. 854), the author describes the various stages and habits of *Schizoneura lanigera, Aphis pomi, A. persicæ-niger, A. bakeri, Myzus persicæ*, and *M. cerasi*. *Hippodamia convergens* is said to be the most abundant destroyer of the woolly aphis in Colorado. Various other lady beetles are mentioned as feeding upon, and *Aphelinus mali* as having been observed ovipositing in, the woolly aphis.

The army worm at Durham, North Carolina, Z. P. METCALF (*Jour. Econ. Ent., 1 (1908), No. 6, pp. 354, 355*).—The author reports the occurrence of *Heliophila unipuncta* in August, 1908. In order to determine the percentage of infestation by tachinid flies (*Winthemia quadripustulata*), 491 larvæ were collected and observed. Of these 442, or 90 per cent, were infested with eggs of the parasite. Only 7 adult moths emerged, showing a total mortality of 98.6 per cent. The 442 infested larvæ yielded 709 parasitic puparia from which 556 adult flies emerged.

Experiments for the control of the red spider in Florida (Tetranychus bimaculatus), H. M. RUSSELL (*Jour. Econ. Ent., 1 (1908), No. 6, pp. 377–380*).—The red spider was the source of considerable injury to truck, general crops, and citrus trees in Florida during the spring of 1908. Experiments made with lime sulphur, lye sulphur, sulphur, and kerosene emulsion, here reported, show that the pest can be controlled by spraying with any one of the four insecticides.

Notes on the grass mite, Pediculopsis graminum, H. E. HODGKISS (*Jour. Econ. Ent., 1 (1908), No. 6, pp. 375–377*).—A brief account of the distribution of this mite and the injury which it produces. The condition known in grass as "silver top" is said to be the result of the attack upon the stem by this pest. A parasitic fungus (*Sporotrichum poæ*) is said to gain entrance into the stems of grass and buds of carnations with or following the entrance of this mite.

Dimples in apples from oviposition of Lygus pratensis, E. P. TAYLOR (*Jour. Econ. Ent., 1 (1908), No. 6, pp. 370–375, pls. 2*).—The author has found that an injury to apples resembling that of the plum and apple curculio is due to egg punctures made in the very early development of the apple by the common tarnished plant bug. Many peach blossoms were also observed late in March which had apparently been blasted as a result of their having been fed upon by this insect. Out of 110 apples picked from Blue Pearmain trees on April 10, 45, or 40 per cent bore egg punctures. No freshly laid eggs were found after the apples were more than one-third of an inch in diameter. The eggs were

found to hatch in about 8 days. The author has been unable to find any previous report of the deposition of eggs in fruit by this insect.

Crocigrapha normani, EDITH M. PATCH (*Ent. News, 19 (1908), No. 7, pp. 321, 322, pl. 1*).—Notes are given on the life history of this noctuid. Eggs were taken from a leaf of the wild cherry. The larvæ were found to feed readily upon leaves and the small green fruit of the apple.

The tussock moth in orchards, W. J. SCHOENE (*New York State Sta. Bul. 312, pp. 39–49, pls. 3*).—The white-marked tussock-moth (*Hemerocampa leucostigma*) is said to have appeared in destructive numbers in the vicinity of Lockport, New York, during the summer of 1908. A description is presented of the biology of the pest. Cocoons collected or examined at Lockport were found infested by the hymenopterous parasites *Pimpla inquisitor* and *P. conquisitor* and by tachinid flies (*Tachina clisiocampæ* and *Sisyropa* n. sp.). The insect may be efficiently controlled by collecting and destroying the egg masses and by the use of arsenical sprays.

Orchards injured by tussock moth, F. H. HALL (*New York State Sta. Bul. 312, popular ed., pp. 5, figs. 6*).—A popular edition of the above.

Must the calyx cup be filled? M. V. SLINGERLAND (*Jour. Econ. Ent., 1 (1908), No. 6, pp. 352–354, pl. 1*).—The author made investigations of the feeding habits of young codling moth larvæ to determine whether they feed in the upper calyx cavity after squeezing through between the calyx lobes, or go on down through the closely-set row of stems into the lower calyx cavity for their first meal. It was found that in every case where the young larva had entered the apple at the calyx end it had fed for several days, or through the first larval stage, in the outer calyx cavity.

Proprietary and homemade miscible oils for the control of the San José scale, C. D. JARVIS (*Connecticut Storrs Sta. Bul. 54, pp. 169–197, fig. 1*).—This bulletin supersedes Bulletin 49 of the station previously noted (E. S. R., 19, p. 662). It furnishes additional information in regard to the home manufacture of miscible oil, throws some light on the various commercial soluble oils, and reports the results of experiments with oil spraying in various sections of the State. As compared with lime-sulphur wash miscible oils are found to be more convenient, more pleasant to handle, less destructive on spraying equipment, and more efficient, especially with large apple trees.

"From the results of these experiments it seems safe to conclude that when used at the rate of 1:15, the commercial and homemade miscible oils may be depended upon to control the scale without injury to the tree. Their predominating weakness lies in their failure to leave a mark on the tree. This lack of a mark makes it difficult to determine the thoroughness of the application. It is believed that in most cases of failure to secure good results from oil spraying, the cause may be attributed to the failure of the operator to wet the tree completely with the spray. That miscible oil at the proper strength will kill every scale with which it comes in contact is clearly demonstrated by the experiment in dipping nursery stock. No injury to the tree has been observed in any of the experiments, while, on the contrary, a decided benefit from the fungicidal properties of the various miscible oils has been apparent. . . .

"The most important factor in the home manufacture of miscible oil is the securing of the proper materials for the purpose. As a rule they can not be obtained from the local dealer and must be purchased directly from the producer.

"In view of the difficulty in securing the proper materials and since commercial preparations may now be obtained at a reasonable price, fruit growers are advised not to make up their own miscible oil, unless they require enough

to warrant the purchase of materials in barrel lots directly from the producer. . . .

"Miscible oil may be applied any time during the dormant season, so long as the temperature is above the freezing point."

Miscellaneous treatment for San José scale, T. B. Symons (*Maryland Sta. Bul. 131, pp. 129–149*).—A number of new patent washes including Niagara brand concentrated lime-sulphur, orchard brand lime-sulphur, Rex lime-sulphur, San-u-zay, Target Brand scale emulsion, Orchard Brand soluble oil, and avenarius carbolineum were tested.

From these tests it appears that all the stronger solutions employed with the exception of San-u-zay and avenarius carbolineum gave good results. From further experiments with hydrocyanic-acid gas it was determined that the excessive amount of 0.50 gm. of cyanid per cubic foot will not injure peach buds under ordinary conditions of fumigation. At 0.30 gm. per cubic foot, 30 minutes was not sufficient to kill all the scales and 45 minutes exposure is recommended. Dipping experiments in which dormant nursery trees were dipped in several insecticides including lime-sulphur, Scalecide, Target Brand, soluble oil, Kill-o-scale, and San-u-zay indicate that the treatment is effective in combating San José scale. Further experimentation is considered necessary, however, before such treatment can be recommended.

Notes on Aspidiotus destructor and its chalcid parasite in Tahiti, R. W. Doane (*Jour. Econ. Ent., 1 (1908), No. 6, pp. 341, 342*).—The author visited the Society Islands during the summer of 1908 to study the conditions that control the appearance and disappearance of the transparent coconut scale. In some of the islands this scale has killed many of the trees and affected others so badly that no nuts are borne. The pest attacks all parts of the tree, except the roots and old trunk, and in all stages of its growth.

In Tahiti on most of the plantations the scale was found to be disappearing at a very rapid rate, due to the work of the parasite *Aspidiotiphagus citrinus*. On some of the trees 50 to 75 per cent of the scale were found to be dead. Specimens of the scale more or less badly parasitized from 6 islands of the group were seen by the author, and it is thought that under normal conditions the parasite will soon have the scale so well under control that it will no longer be a menace to the trees.

Care of scale-infested trees, H. A. Surface (*Zool. Bul. Penn. Dept. Agr., 6 (1909), No. 11, pp. 367–396*).—Directions for the care of trees infested with San José and other scales. The angoumois grain moth is also briefly considered.

Whitefly studies in 1908, E. W. Berger (*Florida Sta. Bul. 97, pp. 43–71, figs. 18*).—This is a revision of Bulletin 88 of the station previously noted (E. S. R., 18, p. 850), together with a report of progress.

Six fungus parasites are now known to infect the larvæ of the whitefly and a seventh infects both larvæ and adults. Methods for introducing whitefly fungi are considered at some length. The writer is of the opinion that by following the recommendations here made regarding parasitic fungi that their efficacy can be doubled and a clean fruit produced two years out of three.

Two fungus hyperparasites *Cladosporium* sp. and *Coniothyrium* sp. are reported. The former frequently overruns and destroys red and yellow Aschersonias, while the latter occasionally overruns pustules of the brown fungus, chiefly after the latter has become old or weakened from drought or cold weather.

The food plants preferred by the whitefly include two native species, prickly ash (*Fagara clava-herculis*) and the wild persimmon (*Diospyros virginiana*), and several introduced species, namely, all varieties of citrus, chinaberry, umbrella tree, cape jessamine, privets, and Japanese persimmon. The author

lists 18 additional species of food plants which the whitefly sometimes infests. Chinaberry and umbrella trees are considered as the food plants most to be feared by citrus-growing communities. Investigation has shown that whitefly larvæ and pupæ can continue to live on leaves which have dropped from trees during winter if protected against complete drying up and that these insects may mature sufficiently late in the spring to infest the new leaves. Defoliation is not recommended as a means of checking the whitefly in a grove except when the defoliation has already been in a great measure accomplished by a freeze.

The author has found the citrus whitefly in Florida to consist of two distinct species and here presents a description of the second, a new species to which he has given the name *Aleyrodes nubifera*. The eggs of the new species are reticulated instead of smooth like the eggs of *A. citri*. Distinct differences also exist in the first and fourth larval stages and in the pupæ. The adults of *A. citri* have immaculate wings while those of *A. nubifera* have a smoky colored area near the end of the wing easily visible in the living insect with the aid of a lens.

The saddled prominent (Heterocampa guttivitta), Edith M. Patch (*Maine Sta. Bul. 161, pp. 311–350, pls. 8, fig. 1*).—The author reports *H. guttivitta* to have denuded vast areas of hard wood forests in Maine in 1907 and 1908. Studies made of the life history and habits and descriptions of the several stages are presented, with suggested means of control.

But one generation occurs in Maine. In 1908 moths emerged in greatest numbers in May and early June, oviposition soon commenced and eggs hatched in about 9 days. The larvæ become full grown in about 5 weeks, during which time 4 molts are passed, then enter the ground to pupate. The eggs are said to be deposited singly upon the leaves, the moths apparently preferring to oviposit upon the upper leaves of trees. Beech leaves were the favorite food of the species but other trees and succulent plants were also fed upon.

Pimpla pedatis and *Ichneumon sublatus* were bred from pupæ, the latter species in large numbers. Of the predaceous wasps species of the Ammophilas were particularly abundant. The adults and larvæ of Calosoma were numerous in the infested woodlands, the larvæ being particularly fond of fresh pupæ. *Pterostichus lucublandus* was abundant in the spring of 1907 under beech trees where the pupæ were hibernating. *Podisus modestus* was the most active of the predaceous bugs in feeding upon the caterpillars. Late in July and early in August various species of caterpillars were attacked by a fungus disease and in some instances practically the whole infestation of saddled prominents was wiped out. It is considered probable that *P. modestus* was an important agent in the transfer of the spores of this fungus. A list is given of 53 species of birds that are supposed to feed upon the pest in Maine.

Arsenicals are recommended for use against the pest in fruit orchards. The caterpillars are readily shaken from the branches, which fact has been made use of in some instances, the trees afterward being protected by sticky bands on the trunk.

A new species of the Tortricidæ, C. H. Fernald (*Canad. Ent., 40 (1908), No. 10, pp. 349, 350*).—The species here described (*Argyroploce abictana*) is reported as injuring small spruce trees in Maine.

Work of the Bureau of Entomology against forest insects, A. D. Hopkins (*Jour. Econ. Ent., 1 (1908), No. 6, pp. 343–348*).—A brief account of the investigations made of forest insects in this country.

Tick eradication, E. C. Cotton (*Tennessee Sta. Bul. 81, pp. 53–71, figs. 7*).—The author has conducted an investigation of the cattle tick and here furnishes information regarding its life history and habits and their relation to exterminative measures.

The life cycle is illustrated graphically and shows the time required at Knoxville to starve seed ticks that hatch from eggs laid by the engorged ticks which drop on April 15 and September 15. "After the ticks drop to the ground on April 15, 10 days will elapse before egg laying begins. The ticks will continue November 13, a period of 4 months and 21 days (141 days). . . . For ticks laying until May 28, or 33 days, the eggs will begin hatching on June 25, an incubation period of 60 days, and the seed ticks will not all be dead until dropping from the host animal on September 15, the time elapsing before egg laying will be but 4 days and the tick will cease laying on October 15, an egg-laying period of 26 days. The eggs will not hatch, however, until March 17 of the following spring, or an incubation period of 6 months (180 days), and the seed ticks will not all be dead until July 28, a period of 4 months and 3 days (123 days). . . . Engorged ticks dropping from the host animals during [December, January, and February] will usually freeze to death before laying any eggs."

The author considers pasture rotation as the most effective method of control under general farm conditions, particularly where a rotation of crops is practiced. Examples of two rotation systems requiring 4 and 5 years are given as applicable to tick eradication. The feed-lot method is also explained. For those sections of Tennessee where the pasture rotation method can not be applied, dipping and oiling are recommended. Life histories and habits of the cattle tick and dog tick are compared in diagrammatic and tabular form.

Another chalcidoid parasite of a tick, L. O. Howard (*Canad. Ent., 40 (1908), No. 7, pp. 239–241, fig. 1*).—A second chalcidoid parasite of a tick is here described as *Hunterellus hookeri*. This species has been bred from engorged nymphs of the brown dog tick, *Rhipicephalus texanus*, collected at Corpus Christi, Tex.

Notes on fleas collected on rat and human hosts in San Francisco and elsewhere, R. W. Doane (*Canad. Ent., 40 (1908), No. 8, pp. 303, 304*).—Out of 1,300 fleas collected upon rats (*Mus norvegicus*) in California, *Ceratophyllus fasciatus* was represented by 863 specimens, *Pulex irritans* by 163, *Leemopsylla cheopis* by 139, and *Ctenopsyllus musculi* by 118. Out of 684 fleas collected on man *P. irritans* was represented by 680.

Notes on the hen flea (Xestopsylla gallinacea), G. W. Herrick (*Jour. Econ. Ent., 1 (1908), No. 6, pp. 355–358*).—The author reports observing more than 325 specimens of *X. gallinacea* on a single fowl at Agricultural College, Miss. Engorged females were found to deposit all of their eggs on the day following their placement in vials. An average of 3 eggs were deposited by 15 fleas thus isolated, 7 being the maximum number deposited. The eggs were found to hatch within 48 hours after deposition.

The foul brood of bees and the foul-brood law, G. W. Herrick and E. E. Scholl (*Texas Sta. Bul. 116, pp. 3–10*).—An account of the American and European foul brood with directions for treatment, to which is appended the Texas foul-brood law.

Calendar for the treatment of plant diseases and insect pests, W. J. Green, A. D. Selby, and H. A. Gossard (*Ohio Sta. Bul. 199, pp. 89–102*).—This is a revised edition of Bulletin 147 of the station (E. S. R., 16, p. 77). Formulas are given with directions for the use of insecticides and fungicides.

Treatment of plant diseases and injurious insects in South Carolina, H. W. Barre and A. F. Conradi (*South Carolina Sta. Bul. 141, pp. 3–52, fig. 1*).—In this bulletin the authors describe spraying machinery, insecticides, and fungicides, and their use in combating the more important insect enemies and plant diseases of fruit trees, shrubs, vegetables, and field crops.

Washington State College spraying calendar for 1909, R. K. Beattie and A. L. Melander (*Washington Sta. Popular Bul. 13, folio*).—Directions for the preparation and use of several insecticides and fungicides for the treatment of the more important insect fungus enemies of plants are given in calendar form.

Cyanid as an insecticide, R. S. Woglum and W. Wood (*Jour. Econ. Ent., 1 (1908), No. 6, pp. 348–350*).—The authors report that a solution of potassium cyanid at the rate of 1 oz. to a gallon of water when poured into a small pit at the exit of a burrow destroys ants to a depth of 1½ ft. below the surface of the soil. This solution can be prepared at a cost of from 1½ to 2 cts. per gallon. It appears, however, to be injurious to plant life.

Preliminary report on results of analysis of Paris green, F. D. Fuller (*Penn. Dept. Agr. Bul. 166, pp. 6*).—Thirty-six samples of Paris green bought in the open market were analyzed and the results are here reported. These samples represent the product of 36 manufacturing concerns. The amount of arsenic calculated as arsenious oxid varied from 55.24 to 59.47 per cent with an average of 56.82 per cent. The amount of arsenic in water soluble form calculated as arsenious oxid varied from 0.7 to 2.52 per cent with an average of 1.48 per cent.

The economic entomologist in business, H. L. Frost (*Jour. Econ. Ent., 1 (1908), No. 6, pp. 350–352*).—The author calls attention to the great need of commercial economic entomologists. While the business of caring for trees has made tremendous advancement in the last 10 years, there are still many problems to be solved that require the attention of the economic entomologist.

FOODS—HUMAN NUTRITION.

Report upon the chemical examination of drawn and undrawn poultry kept in cold storage, W. F. Boos (*Ann. Rpt. Bd. Health Mass., 39 (1907), pp. 263–283*).—The author summarizes as follows the results of his studies on drawn and undrawn cold storage poultry:

"In cold storage itself no chemical changes occur. This is shown by:

"(a) The absence, after nine months and more of cold storage, in both drawn and undrawn cold storage fowl of ptomaines and decomposition products in general, except such as are formed by bacteria and autolytic changes occurring before the birds are placed in cold storage and after they are thawed.

"(b) The negative results of animal inoculations with extracts obtained from the two kinds of poultry.

"When fowl are taken out of cold storage and exposed to a temperature of 68° F., the conditions of exposure being the same, the undrawn birds show better keeping qualities [than those drawn by the usual method].

"When freshly killed fowl are exposed at 68° F. under conditions constant for all the birds exposed, the birds drawn according to the [improved] method described . . . show perfect keeping qualities, while the undrawn fowl undergo a rapid process of decomposition. Under these conditions the ordinarily drawn birds show fair keeping qualities, although they are not free from bacterial decomposition.

"It may be concluded, therefore, from these results that it is best to draw fowl in a different manner from that usually followed, before they are placed in cold storage. After removal from cold storage, the fowl should never be contaminated by soaking in water, but should thaw in the air. Ordinary drawing is worse by far than no drawing at all."

Report upon the bacteriological examination of drawn and undrawn poultry kept in cold storage, H. R. Brown (*Ann. Rpt. Bd. Health Mass., 39*

(*1907*), *pp. 285–336*).—An extended series of bacteriological investigations of drawn and undrawn cold storage poultry led to the following general conclusions:

"Poultry kept at temperatures ranging from +5° to —14° F. undergoes no decomposition as a result of bacterial activity.

"Freezing destroys the red and some of the white blood corpuscles.

"Freezing temperatures as low as —14° F. destroy a large percentage of the bacteria present, but do not affect the more resistant ones.

"When the tissues are thawed, they become moistened by the melting ice crystals, and in this condition bacterial growth is facilitated and decomposition of the tissues and contents of the cells is promoted.

"In the drawn chickens placed in cold storage aerobic conditions prevailed throughout the pleuro-peritoneal cavities. The undrawn chickens showed much smaller numbers of bacteria in the pleuro-peritoneal cavities. On account of the closed cavity, partial anaerobic conditions prevailed in these birds.

"In decomposing meats, putrefactive aerobic bacteria may possibly produce the primary stages and prepare the way for anaerobes which possibly control the intermediate stages of decomposition. By the combined action of both, decay is brought about, but it is probably finished by aerobic bacteria.

"From these facts it appears that, given the aerobic conditions and the larger numbers of bacteria growing on the moist surfaces and tissues of a thawed drawn chicken, decomposition will proceed at a more rapid rate than with an undrawn one containing fewer bacteria existing under partial anaerobic conditions.

"In freshly killed, unfrozen drawn chickens, the surfaces and tissues become dry within a very short time, and, although aerobic conditions prevail, the bacteria can not grow because of lack of moisture.

"In freshly killed, unfrozen and undrawn chickens, on account of the closed pleuro-peritoneal cavities there is no drying of the tissues and surfaces, and facultative aerobic and anaerobic bacteria from the intestines rapidly cause decomposition.

"By the removal of the viscera without the spilling of the contents of the alimentary tract decomposition can be prevented absolutely. The operation requires about two minutes.

"Briefly stated, decomposition depends largely upon the presence of moisture in the tissues, for moisture is absolutely essential to bacterial growth. In freshly killed birds, ordinarily or properly drawn, the surfaces quickly become dry. In cold storage birds, no matter how they are drawn, the tissues will be moist, because of the melting of the crystals of ice. If properly drawn, there would be but few bacteria present capable of causing decomposition."

Cold storage and its relation to food preservation, M. Bureau (*Ann. Soc. Agr. Sci. et Indus. Lyon, 1907, pp. 351–381, figs. 15; 394–396*).—Methods of producing low temperature, the application of such processes to food preservation, and general topics connected with the cold storage industry in France and elsewhere, are considered. The paper is followed by a discussion.

The oyster question (*Mo. Bul. Ind. Bd. Health, 10 (1908), No. 11, pp. 134–136, fig. 1*).—Analyses of shell and solid pack oysters are reported in comparison with similar data obtained with watered and iced stock. On an average the weight of meat in solid pack oysters was 397.4 gm. in a pint as compared with 268.5 gm. in watered oysters.

"It is contended by oyster packers who have been accustomed to shipping iced and watered stock and who wish to continue to do so, that icing does not increase the volume of oysters appreciably if at all. This contention can not be correct, for by comparison the percentage of solids in the meat is in one

instance 17.06 and in the watered stock 13.31, a difference of 22.05 per cent in favor of the solid pack, and while the solid pack contains 26.76 per cent of water in the sample, the watered stock contains 43.50 per cent. The solid pack contains 73.24 per cent of meat and the watered stock 56.50 per cent, here again showing a very decided advantage in favor of the solid pack. The average solid content of the solid pack oysters is 13.40, and of the watered stock 8.59, a difference in favor of the solid pack amounting to 35.9 per cent."

On the basis of the analytical work the question of pecuniary loss to the consumer, legislation, and similar topics are discussed.

Concerning changes in egg pastes when stored, G. Popp (*Ztschr. Öffentl. Chem., 14 (1908), No. 23, pp. 453–463*).—The analytical data reported and discussed have to do with changes in the quality of egg pastes. The author concludes that a knowledge of the composition of the raw materials used in making such goods is absolutely essential for a perfectly trustworthy opinion. When this is known it is possible to estimate the amount of egg per pound with considerable accuracy. The amount used in the noodles is very small, perhaps one-third of one egg per pound. In judging the quality of egg pastes the author considers a complete analysis essential in addition to date regarding cholesterin.

Analysis of gases contained in swollen canned goods, F. O. Tonney and J. B. Gooken (*Amer. Food Jour., 3 (1908), No. 6, pp. 20–23, figs. 3*).—The methods followed in analyzing gases from swollen cans are described. The presence of carbon dioxid together with alcohol in a large number of samples indicates that in many cases the swelling is due to alcoholic fermentation which results from imperfect sterilization of the canned contents. Nitrogen occurred in most of the swollen cans, and its significance, aside from the small amounts due to the entrance of air, lies, the authors believe, in the fact that it may be regarded roughly as an index to the amount of proteid decomposition which has taken place. "In general it may be said that nitrogen indicates putrefaction and carbon dioxid indicates fermentation. The two processes, however, were not often found to be distinct from each other.

"The presence of hydrogen, which was found in quantities varying from 0 to 58 per cent, is believed by the writers to be an especially valuable indication of ptomaine producing processes. . . .

"Marsh gas was occasionally found in small amounts associated with hydrogen. Its significance is probably similar.

"Carbon monoxid, which was found in a few cases, probably owed its presence to the reduction of carbon dioxid by nascent hydrogen.

"Oxygen in negligible traces was thought to be due to the entrance of small amounts of air.

"One of the most noticeable facts brought out in the course of the analyses was the extreme variation in the amount and kind of constituent gases in the same type of goods. One can out of a lot may show simple alcoholic fermentation, while its neighbor in the same box presents marked evidences of putrefaction. It is evident, therefore, that a favorable analysis of one or two cans can not properly be taken as a criterion for the safety of the lot."

The question of the treatment of such goods and of swollen cans and their subsequent sale is considered. "The possibility, or rather the likelihood of danger to a large number of persons, should be sufficient to exclude such products from sale. And in the absence of any unfailing chemical tests for the toxic bodies themselves, the presence of conditions favorable to their formation and the presence of substances commonly associated with them must be considered adequate grounds for condemnation."

The manufacture of preserved meat goods, W. Dosquet (*Die Fabrikation von Fleischkonserven. Brunswick, 1908, pp. 37, figs. 2; reprint from Deut.*

Vrtljschr. Offentl. Gsandhtspflege, 39, No. 4, pt. 2).—A digest of data on the technique of meat canning, with special reference to hygienic requirements, preservation of aroma and quality, in which the author has embodied the results of his experience and investigations.

"Vapor," a preparation for smoking meat, A. Juckenack (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 12, pp. 731, 732*).—A preparation tested in Germany for smoking meat, sausage, etc., was found to consist of 92 per cent sulphur with oxid of iron and organic material, probably dried juniper berries.

A new preservative for fruit juice, A. Juckenack (*Ztschr. Untersuch. Nahr. u. Genussmtl., (1908), No. 12, pp. 730, 731*).—A new commercial preservative on the market in Germany was found to consist of a mixture of benzoic acid and potassium sodium tartrate.

Contribution to the fruit juice statistics of 1907–8, A. Juckenack (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 12, pp. 742, 743*).—Analyses of raspberry, cherry, strawberry, and currant juices are reported.

Fruit statistics 1908. H. Lührig, P. Bohrisch and A. Hepner (*Pharm. Centralhalle, 49 (1908), No. 43, pp. 869–873*).—Data are given regarding the examination of a considerable number of samples of raspberry, blackberry, and currant juices.

Supplement to fruit juice statistics for 1908, A. Beihe, F. Grosse, and G. Schmidt (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 12, pp. 734–737*).—Analyses of raspberry juice, blueberry juice, and red bilberry juice are reported.

Note on fruit juice statistics, F. Härtel, P. Hase, and W. Mueller (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 12, pp. 744, 745*).—Analyses of apricots, raspberries, and raspberry juice are reported.

Note on fruit juice statistics, A. Gronover (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 12, p. 745*).—Analyses of wild raspberry juice are reported.

The composition of berries with special reference to the alkalinity of the ash, K. Fischer and K. Alpers (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 12, pp. 738–741*).—Currants, cherries, and berries of different sorts are included in this analytical study.

Examination and judging of lemon juice, E. Frisch (*Arch. Pharm., 246 (1908), Nos. 6, pp. 472–480; 7, pp. 481–484*).—Analytical and other data are reported in this critical study of the analysis and valuation of lemon juice.

Composition of a number of natural wines from southern France, I. Fiehe (*Chem. Ztg., 32 (1908), No. 91, pp. 1105, 1106*).—Analyses of 17 red, white, and half white wines are reported.

Swiss wine statistics for the year 1907 (*Ann. Agr. Suisse, 9 (1908), No. 4, pp. 169–191*).—Results of the examination of Swiss wines are reported.

Food and drug inspection (*Ann. Rpt. Bd. Health Mass., 39 (1907), pp. 337–355*).—A summary of the character and extent of the inspection work of the State board of health for the year ending November 30, 1907.

Report of the analyst, H. C. Lythgoe (*Ann. Rpt. Bd. Health Mass., 39 (1907), pp. 357–386*).—During the year a total of 5,684 samples of milk and other foods and drugs were examined. Of these 1,546 were found to be adulterated and 4,138 were genuine. The report contains the usual data regarding the different groups of products examined.

[State food and dairy commission report] J. Q. Emery (*Semiann. Bul. Dairy and Food Com. Wis., 1907, No. 11–12, pp. 242*).—This volume contains a summary of the State laws, the report of the chemist, results of inspection of

cheese factories and creameries, milk inspection, an account of prosecutions under the law, and similar data.

Chemist's analyses, R. FISCHER (*Semiann. Bul. Dairy and Food Com. Wis., 1907, No. 11–12, pp. 9–103*).—During the year ending December 31, 1907, it is stated that 2,157 samples of food and drugs were analyzed, of which 1,097 were pronounced unlawful by reason of being adulterated or misbranded.

"It should be emphasized that these figures and those given in the appended summary do not by any means represent the true condition of the Wisconsin market. In most instances only such samples were sent to the laboratory for analysis as were suspected of being adulterated. This was particularly true of butter, cheese, cream, milk, oleomargarine and canned goods, where the ratios of unlawful to lawful samples are very much higher than the actual figures. For example, while the actual number of samples of milk collected by our inspectors from creameries and cheese factories was 4,470, only 143 were sent to the laboratory as suspicious. Of these 143 samples, 123, or 2.75 per cent of the total number, were found adulterated. In the case of drugs, however, the figures in most cases show the actual conditions of the Wisconsin market in respect to the kinds of drugs analyzed."

[Report of the dairy, food, and oil commissioner of Wyoming], E. W. BURKE (*Ann. Rpt. Dairy, Food and Oil Comr. Wyo., 4 (1908), pp. 1–34*).—A general account of the work of the Wyoming State Dairy, Food, and Oil Commissioner. Summaries of information on a variety of topics connected with pure food are included, as well as a discussion of conditions in meat markets and slaughterhouses, hotels and restaurants, and dairies. The author recommends that hotels and restaurants should be under the same supervision and by the same authorities as meat markets and slaughterhouses.

Food inspection decisions (*U. S. Dept. Agr., Food Insp. Decisions 104, pp. 3; 105, pp. 2; 106, pp. 2*).—These decisions have to do with the amendment to Food Inspection Decisions 76 and 89, relating to the use in foods of benzoate of soda, the labeling of canned salmon and whitefish, and the amendment of Food Inspection Decision 77, particularly with reference to the definition of the terms "batch" and "mixtures."

Food Inspection Decision 104 contains the report of the Referee Board of Consulting Scientific Experts, appointed by the President of the United States, to consider the use of benzoic acid.

"The main general conclusions reached by the Referee Board are as follows:

"First. Sodium benzoate in small doses (under 0.5 gm. per day) mixed with the food is without deleterious or poisonous action and is not injurious to health.

"Second. Sodium benzoate in large doses (up to 4 gm. per day) mixed with the food has not been found to exert any deleterious effect on the general health, nor to act as a poison in the general acceptation of the term. In some directions there were slight modifications in certain physiological processes, the exact significance of which modifications is not known.

"Third. The admixture of sodium benzoate with food in small or large doses has not been found to injuriously affect or impair the quality or nutritive value of such food."

Notices of judgment (*U. S. Dept. Agr., Notices of Judgment 38, pp. 2; 39–42, pp. 7; 43–47, pp. 11; 48–49, pp. 4*).—These notices of judgment have to do with the misbranding of canned corn, corn and beans, canned peas, butter, meal, maple sirup, and coffee, and the adulteration of water and eggs, and the adulteration and misbranding of whisky and vanilla extract.

Food legislation during the year ended June 30, 1908, W. D. BIGELOW and N. A. PARKINSON (*U. S. Department Agr., Bur. Chem. Bul. 121, pp. 85*).—This bulletin is a compilation of the food legislation enacted in the United States

and Canada during the year ended June 30, 1908, and supplements Bulletin 112 of the Bureau previously noted (E. S. R., 19, p. 1163).

Ohio food and drug laws. R. W. DUNLAP (*Columbus, 1908, pp. 41*).—This compilation of Ohio State food and drug laws was prepared by the State dairy and food commissioner.

Regulations under the public health (regulations as to food) act, 1907, S. B. PROVIS (*Local Govt. Bd. [Gt. Brit.] Circ. (Foreign Meat No. 2), pp. 7*).—The regulations which are included have to do with boneless meat and boxed meat, tripe, tongue, and kidneys, and other meat and meat products imported into Great Britain.

Food inspection at ports of entry. W. F. DEARDEN (*Jour. Roy. Sanit. Inst., 29 (1908), No. 11, pp. 681–688*).—The author discusses the provisions of the bill which received royal assent in September, 1908, providing for the inspection by port sanitary authorities of foodstuffs imported into England and Wales.

The importance of pure-food laws for fruit and vegetable products with special reference to nutrition problems. T. ECHTERMEYER (*Sehr. Volksw. Ver. Obst. u. Gemüseverwert. Deut., 1908, No. 4, pp. 16*).—A general discussion of the subject presented at the Eighth International Congress of Agriculture in Vienna, 1907.

The paper is preceded by an introductory statement by J. Kochs.

Essentials of diet in health and disease. AMY E. POPE and MARY L. CARPENTER (*New York, 1908, pp. 250; rev. in Dietet. and Hyg. Gaz., 23 (1909), No. 1, p. 44*).—A discussion of food, digestion, and diet in health and disease, with a number of recipes for the preparation of food for the sick and convalescent. The volume is intended for use in nurses' training schools and in the home.

The baby. D. R. BROWN (*Boston, 1908, pp. VI+200*).—In this general treatise on infants there are chapters on the elements of food and digestion, lactation, substitute foods, and substitute feeding.

Carrot soup for infants. E. MORO (*München. Med. Wchnschr., 55 (1908), No. 31, pp. 1637–1640, figs. 4; abs. in Biochem. Zentbl., 7 (1908), No. 21–22, p. 83*).—Soup made from carrots and beef seasoned with salt caused a rapid retention of water in the body and diminished intestinal flora when fed to sick infants.

Dietary conditions in Java. J. J. MATIGNON and J. SALM (*Rev. Hyg. et Pol. Sanit., 30 (1908), No. 6, pp. 471–484*).—General dietary conditions in Java, the character of the rations of different groups of the native and foreign population, the preparation of food, and related questions are discussed. The data regarding the nutritive value of rations and portions of food digested are given on the authority of Eyckman.

[Food of Dundee mill operatives]. W. A. G. CLARK (*Daily Cons. and Trade Rpts. [U. S.], 1908, No. 3330, pp. 1–8*).—In an article on the Dundee jute industry the author gives considerable data regarding the food supply and cost of food of Dundee factory operatives, housing conditions, and related topics.

[The new army ration, fireless cookers, etc.] (*Rpt. Commis. Gen. [U. S. Army], 1908, pp. 10–13*).—Information is given regarding the new U. S. Army ration, bake ovens and ranges, kitchen cars, army training schools for bakers and cooks, the ration for officers and civilians serving in the field, and related questions.

As regards the use of fireless cookers, the author states that 100 specially constructed cookers have been tested. "They were tried out on the march, on bivouac, and in maneuver camps, and so far as reports have been received have proved highly satisfactory, with the addition of slight changes suggested by actual experience, and which can be readily made. Some criticism has been made on the subject of adopting the fireless cooker, on account of its weight, as a part of the company field outfit.

"These cookers designed by the Subsistence Department combine lightness of weight with stability of construction, and are intended to stand long travel on rough roads and assure the perfection of the contents at the end of the journey. This method of cooking will insure hot meals of excellent quality on the march, on bivouac, or on the firing line, save expense and labor, and largely contribute to the health and comfort of the troops."

The up-to-date home. Money and labor saving appliances, M. Le Bosquet (*Bul. Amer. School Home Econ., Ser. 1., 1908, No. 11, pp. 48, figs. 54*).—Kitchen appliances and labor-saving devices, alcohol as fuel, electric cooking, gas, laundry appliances, and other similar questions are discussed in this summary of data which is based on tests made and information collected by the author.

Experiments with an ash-free diet, H. W. Goodall and E. P. Joslin (*Trans. Assoc. Amer. Physicians, 23 (1908), pp. 92–106*).—The ash-free diet used in the experiments reported consisted of specially prepared egg albumin, olive oil, and sugar. Two healthy individuals were subjects of the experiments, which were continued for periods of 13 and 9 days, respectively.

According to the authors, the results obtained indicate no marked changes in metabolism ascribable to the ash-free diet. The experimental data "simply represent the withdrawal of accessory salts from the body. They confirm the views of earlier writers, that it is practically impossible to diminish the chlorin of the body by more than 10 to 14 per cent, and that the loss is proportionate to this. No remarkable symptoms appeared, and those that occurred were rather less than would be expected from such a diet, even though it contained a normal quantity of salts. We do not feel that they afford a basis for any far-reaching deductions as to changes in metabolism, and they certainly give no support to the view that the withdrawal of salts from the diet will cause an acidosis of the acetone variety."

The paper is followed by a discussion.

The effect of certain food accessories on the activity of digestive juices, K. Togami (*Biochem. Ztschr., 9 (1908), No. 5–6, pp. 453–462*).—The tea infusion used hindered the activity of the salivary and pancreatic enzyms and of pepsin in artificial digestion experiments. Coffee infusion made from ordinary coffee, and that with a low caffein content, did not exercise any effect on these digestive enzyms. Chocolate infusion slightly diminished the digestive power of pepsin. From his results the author draws the general conclusion that when of usual strength the materials studied exercise no harmful effect upon digestive ferments. If, however, the infusions are very strong, the reverse may be the case, as was shown by the tests with tea.

A study of the enzyms of the human pancreatic and intestinal juice obtained through a jejunal fistula, J. H. Hoelscher (*Ther. Gaz., 32 (1908), No. 10, pp. 692–703*).—According to the author the experiments which he reported show that the amylolytic ferment present in the digestive juice studied and which changes maltose into glucose is glucase. "It could be shown that part of the sugar formed in the experiments was glucose; this was due to the presence of an active glucase furnished by the succus entericus of the small intestine.

"It could be shown by other experiments that the proteolytic ferment present was trypsin and not pepsin; it acted best in an alkaline, poorer in a neutral, and very poor or not at all in an acid solution. Besides, in one experiment the presence of leucin and tyrosin as the end-product of the proteolytic fermentation was shown. This proved beyond doubt that the proteolytic ferment present was trypsin. Only once did we succeed in demonstrating the presence of lipase; but it is a well-known fact that the latter is a very unstable enzym,

easily destroyed and hard to obtain except by direct watery extracts from fresh pancreatic tissue."

The author studied especially the susceptibility of the enzyms present in the digestive juices to a number of medicinal substances and the results reported have to do particularly with these questions.

Concerning "secretins," O. von Fürth and C. Schwarz (*Arch. Physiol. [Pflüger]*, *124 (1908)*, *No. 9–10, pp. 427–446*).—The authors conclude that "secretin" is a mixture of substances of which cholin is one.

Respired air, W. Weichardt (*Arch. Hyg., 65 (1908)*, *No. 3, pp. 252–274, pls. 2, figs. 4*).—From his studies of respired air the author concludes that it may have toxic properties due to the presence of kenotoxins.

Muscular work and pulse rate, T. A. Auto (*Skand. Arch. Physiol., 21 (1908)*, *No. 2–3, pp. 146–160, figs. 12*).—From experiments with men the author concludes that neither kneading the muscles, passive movements, nor severe rubbing of the skin, increases the pulse rate in any marked degree. The changes in respiratory movements and circulation which attend muscular work are not sufficient to account for the acceleration of the heart beat. The author concludes that the results of his investigations strengthen the theory that this increase noted in muscular work is chiefly due to the excitation of the nerve centers of the heart.

Concerning the body temperature of man, D. Rancken (*Skand. Arch. Physiol., 21 (1908)*, *No. 2–3, pp. 161–236, figs. 23*).—From his investigations the author concludes that muscular work exercises a marked effect on the variations in body temperature. Hot or cold food naturally has an effect on body temperature, but aside from this, the ordinary diet does not affect rectal temperature when no muscular work is performed. The temperature changes which other investigators have attributed to eating food are in the author's opinion due to increased heat production in the muscles, ascribable either to increased muscular work or increased muscular tonus, due to the work of chewing the food and the comfortable feeling which accompanies eating something which is palatable.

Animal heat, S. Tolkowsky (*Ann. Gembloux, 18 (1908)*, *No. 11, pp. 638–652, figs. 2*).—A digest of data on the subject.

ANIMAL PRODUCTION.

The feeding value of cereals as calculated from chemical analyses, J. S. Chamberlain (*U. S. Dept. Agr., Bur. Chem. Bul. 120, pp. 64*).—This bulletin discusses different methods of calculating feeding values and reports results of a chemical study of the feeding value of oats, wheat, barley, and other cereals. Analyses of home and foreign-grown grains, and the production values of these grains as computed from chemical analyses, are presented in tabular form.

Among the terms discussed in the introductory part are: Coefficient of digestibility, metabolizable energy, production values, and nutritive ratio. Explanations are given for expressing the "production value," Kellner's term for the value of the material fed in addition to a basal maintenance ration in three different ways, as follows: (1) Calories per 100 lbs., (2) pounds of flesh gained per 100 lbs., and (3) starch value per 100 lbs.

The production values in calories for the various nutrients correspond to the production of a definite weight of body tissues, and in the investigations reported in this bulletin the value of each nutrient of which the cereal is composed is expressed in terms of pounds of flesh gained per 100 lbs. of feed when

fed to mature cattle. The factors used are those given by Kellner except in the case of sorghum, to which material the recent results of Tangl are deemed more applicable. The term "pounds of flesh gained" is not considered as synonymous with gain in live weight, as the latter includes the increase of water also, but "the two terms are approximately the same and express the increase in flesh or weight as the result of feeding 100 lbs. of food in addition to a basal maintenance ration."

From analyses of several varieties of domestic and foreign-grown oats "it is evident that the characteristic tendency of the oats grown in the United States, when compared with oats grown in Europe, is toward a higher protein content with a correspondingly lower amount of carbohydrate, resulting in a narrow nutritive ratio combined with a slightly lower production value." The differences in production values are not great, the maximum difference being about 0.25 lb. of flesh gain per 100 lb. of grain fed.

"The average production value for five groups of United States oats is 17.87 lbs. of flesh gained, or 77,266 calories, while the average of the three groups of foreign oats is only 18.26 lbs. of flesh gained, or 78,954 calories, a difference of only 0.39 lb. of flesh gained, or 1,688 calories. This difference is not large, especially when it is remembered that the purely domestic oats have a mean production value of 18.11 lbs. of flesh gained, only 0.15 lb. below the foreign average.

"The nutritive ratio, however, shows a very noticeable difference. The nutritive ration of the domestic oats, with one exception, varies from 1 : 4.6 to 1 : 6.6, while that of the foreign is 1 : 7.0 to 1 : 7.3."

Swedish select oats were grown in 20 States. From 4 States the protein was approximately equal to the foreign-grown oats, and only 4 out of the 20 fell below the foreign grown. Foreign-grown barley also was found to be poorer in protein and richer in carbohydrates, higher in productive value and broader in nutritive ratio.

"The maximum protein content was found in the 2 United States samples of Kitzing [barley], namely, total, 15.25 lbs. per 100 lbs., or 10.67 lbs. digestible, the carbohydrate in the same sample being 75.56 lbs. total and 69.51 lbs. digestible. The lowest protein content, on the other hand, was found in the 8 foreign-grown samples, namely, 12.52 lbs. total and 8.76 lbs. digestible, the carbohydrate in the same samples being 78.03 lbs. total and 71.78 lbs. digestible. The production value of the United States Kitzing was 21.03 lbs. of flesh gained or 90,912 calories and of the foreign samples 21.19 lbs. of flesh gained or 91,604 calories, the nutritive ratio being 1 : 7.0 for the domestic and 1 : 8.8 for the foreign.

"With both of these grains this increase in protein is an improvement. It increases the high-protein, muscle-producing value of the oats and raises the intrinsic food value of the barley, so that it becomes more nearly equal to that of wheat. Selection and breeding for high-protein content in feeding barleys is a distinct improvement in their value for this purpose."

Analyses and production values are also given of emmer, einkorn, wheat, barley, proso, sorghum, and maize.

"As feeding grains the cereals may be grouped into three classes typified by our three most common grains, namely, (*a*) oat group, (*b*) wheat group, (*c*) maize group.

"Of these three groups the oat group stands at one end as a typical muscle or energy producing food and the maize group at the other end as fat or heat producing. The wheat group is intermediate between these two.

"In the oat group belong the less common cereals, emmer and einkorn, and in the maize group proso and nonsaccharine sorghum.

"The two cereals emmer (*Triticum dicoccum*) and einkorn (*Triticum monococcum*) belong to the same group as the oats and like it are characterized by high protein and relatively low carbohydrate. They have a lower intrinsic food value than the other grains, but a narrow nutritive ratio and consequently are muscle or energy producers. In food value they are nearly the same as oats, and their cultivation where oats can not be grown is to be advocated.

"The two cereals proso or broom-corn millet (*Panicum miliaceum*) and the nonsaccharine sorghum (*Andropogon sorghum*) belong to the maize group, and though lower in food value than maize itself they equal the oat group. They are of great importance when maize can not be grown and when there is need for a high carbohydrate and heat or fat producing food.

"Barley and rye belong to the wheat group and are nearly equal to it in food value."

Modern views concerning the food requirements of farm animals and the principles of rational feeding, N. Hansson (*Nord. Mejeri Tidn., 23 (1908), Nos. 42, pp. 495–497; 43, pp. 508, 509; 44, pp. 520–522*).—An address which discusses the results of recent studies conducted by Kellner, the Copenhagen Experiment Station and others, of feeding problems and the nutritive effect of different food components. The author has crystallized his deductions into feeding standards showing the amounts of digestible protein and total feed units (1 "feed unit" equaling 0.6 starch value) required per head daily under varying conditions, in the case of dairy cows, fattening steers, young cattle, working oxen and horses, and fattening and breeding swine.

The mineral elements in animal nutrition, E. B. Forbes (*Ohio Sta. Bul. 201, pp. 129–172*).—This is an important summary of available data. The main facts regarding the function of the mineral elements in animal nutrition are presented in such manner as to serve the student of agriculture as an introduction to this important subject.

Commercial feeding stuffs, E. H. Jenkins and J. P. Street (*Connecticut State Sta. Rpt. 1907–8, pt. 10, pp. 717–762*).—The 218 samples of feeding stuffs analyzed under the State law and 55 samples sent by individuals included cotton-seed and linseed meals, wheat bran, middlings, and feeds, maize meal, maize for ensilage, gluten feeds, hominy feed, rye, buckwheat, flax and barley products, distillers' and brewers' grains, spent hops, dried beet pulp, meat scrap, proprietary stock and poultry feeds, mixed feeds, and miscellaneous materials. Nine brands of gluten feed contained artificial coloring matter. The acidity of the gluten feeds is reported as determined with different indicators, the results being lowest with litmus, and considerably higher with phenolphthalein and Toepfer's reagent. Several proprietary feeds were found to contain large quantities of weed seeds, one brand of flax feed, costing $25 per ton, containing 86,000 weed seeds per pound.

Commercial feeding stuffs in 1907–8, J. W. Carson and G. S. Fraps (*Texas Sta. Bul. 117, pp. 5–67*).—This bulletin contains the text of the State feeding stuffs law and reports and discusses the results of the first year's operation. Analyses are given of 1,642 samples of feeding stuffs, which included cotton-seed meal and cakes, wheat bran, shorts and chops, rice polish, bran and hulls, corn chops, crushed ears and bran, Kafir corn chops, milo maize chops, and mixed feeds. A list of the provisional standards and definitions is included.

Concentrated commercial feeding stuffs, A. McGill (*Lab. Inland Rev. Dept. [Canada] Bul. 156, pp. 26*).—This bulletin contains analyses of bran, middlings or shorts, linseed meal, cotton-seed meal, chopped feed, and other concentrated feeding stuffs.

Sugar-producing product (desiccated beet root), G. W. McMullen (*U. S. Patent 898,592, Sept. 15, 1908; Jour. Soc. Chem. Indus., 27 (1908), No. 24, p. 1216*).—A patent has been obtained for a process of drying sugar beets. The beets are so sliced and desiccated as to preserve their sugar content in an uninverted state. The slices are spread in thin layers in a closed chamber in which a reduced pressure is maintained and the water is evaporated at a temperature of about 155° F. The desiccated slices, which should contain less than 30 per cent of moisture, are ground and may be preserved unchanged for an indefinite period.

Steer feeding, J. M. Scott (*Florida Sta. Bul. 96, pp. 29–37, figs. 8*).—In the experiments reported in this bulletin 16 Shorthorn native steers were divided into 4 lots and fed for 84 days. The feeds compared were crab-grass hay, velvet beans, and sorghum silage, which were grown on the station farm and estimated to be worth $4, $6, and $3 per ton, respectively, which is about the actual cost of production. The other feeds were purchased in the market.

The lot fed corn, cotton-seed meal, and crab-grass hay made an average daily gain per head of 2.583 lbs., at a cost of 9.07 cts. per pound, whereas for the lot fed corn, cotton-seed meal, sorghum silage, and cotton-seed hulls the corresponding gain was 2.681 lbs., at a cost of 10.65 cts. per pound, for the lot fed corn, velvet beans in the pod, and cotton-seed hulls 2.922 lbs., at a cost of 7.55 cts. per pound, and for the lot fed cotton-seed meal and cotton-seed hulls 1.848 lbs., at a cost of 12 cts. per pound.

Although all these steers were fed at a loss because of abnormal conditions, the author thinks "the feeding period required to fatten cattle in Florida is shorter than in the Northern States. The average daily gain that may be obtained in Florida by proper methods of feeding is larger than the northern feeder can expect. A combination of corn, velvet beans in the pod, and some roughage(such as cotton-seed hulls, crab-grass hay, or sorghum hay), with a nutritive ratio of 1 : 6 or 1 : 7, will give best results."

Raising calves on skim milk, C. H. Eckles (*Missouri Bd. Agr. Mo. Bul., 6 (1908), No. 6, pp. 3–14, figs. 3*).—A summary of information on calf raising gleaned from various sources and written for the practical farmer.

The cost of raising young stock, F. Dettweiler (*Deut. Landw. Presse, 35 (1908), Nos. 91, pp. 955, 956; 92, pp. 963, 964; 94, pp. 982–984; 95, pp. 993, 994*).—From statistics gathered from a large number of practical breeders it was found that the cost of feeding a heifer the first 12 months varied from 85 to 298.7 marks (about $20 to $70), and the second year from 71 to 255 marks ($17 to $60). The total cost from birth to calving time varied from 165 to 624 marks ($40 to $150).

The preparation of a herd book for cattle, A. König (*Landw. Jahrb. Schweiz, 22 (1908), No. 12, pp. 625–708*).—This is an elaborate plan originated by the author for keeping the pedigrees of live stock.

The sheep industry from the market standpoint, W. C. Coffey (*Illinois Sta. Circ. 125, pp. 16, figs. 3*).—This circular presents data regarding the location and development of the principal sheep markets in this country, the nature of the supply of sheep received at the Chicago market, factors to consider in handling sheep and lambs intended for market, shipping sheep and lambs to market, and the purchasing of feeders and breeding sheep on the open market.

Sheep husbandry in Canada, J. B. Spencer (*Canada Dept. Agr., Branch Live Stock Comr. Bul. 12, pp. 127, pls. 27, figs. 13*).—This is a description of the breeds of sheep and a general treatise on sheep husbandry in Canada.

The raising of sheep and goats for milk production, J. de Castro (*Prog. Agr. y Pecuario, 14 (1908), No. 591, pp. 467–471*).—A general discussion of the subject. Analyses of the milk of goats and ewes are given.

Annual wool review, J. B. McPherson (*Bul. Nat. Assoc. Wool Manfrs., 38 (1908), No. 4, pp. 353–396, chart 1*).—A review of the wool industry for 1908 with much statistical matter. In New Mexico and Arizona the number of sheep fit for shearing increased during the year. The price of wool was 15 per cent lower than in 1907. A storage warehouse was built at Omaha, where 1,000,000 lbs. of wool was stored until the market partially recovered. A movement is on foot to establish a permanent storage warehouse in the Central West, where wool can be stored and sold directly to the manufacturer.

On digestion of meat in the stomach and small intestine of swine, E. Lörsch (*Zur Kenntnis der Verdauung von Fleisch im Magen u. Dünndarme des Schweines. Inaug. Diss., Univ. Leipsic, 1908, pp. 54, fig. 1*).—Horse flesh, from which all fat had been removed, was ground, cooked for 1 hour, and washed until the wash water showed no biuret reaction. Six swine were fed 500 gm. each of this meat, and the protein metabolism was studied by post-mortem examinations of the stomachs and small intestines. In all cases 2 hours after feeding time there was an acid reaction in all parts of the stomach, though from ½ to 1 hour after the feeding period near the opening of the esophagus the reaction was alkalin. Chemical analyses were made of different portions of the stomach. After ½ hour digestion, cleavage products of protein were found in all portions.

The following table shows the cleavage products of the mixed contents in the stomach at different periods:

Protein cleavage products in the stomach of swine.

Hours after feeding period.	Total nitrogen.	Coagulable nitrogen.[a]	Total incoagulable nitrogen.[a]	Syntonin.[a]	Albumoses.[a]	Peptone.[a]	Other incoagulable nitrogenous substances.[a]

[a] Per cent of the total nitrogen. [b] Per cent of the total incoagulable nitrogen.

Syntonin was found in the pylorus as well as in the cardia and fundus. The pig being omnivorous the amount of syntonin found was less than other investi-

gators have found in herbivorous animals and more than in the carnivorous animals. The protoalbumose was much less than the other albumoses, which were less in the pylorus than in other parts, but the difference increased during the process of digestion. Peptone and nitrogenous substances not precipitated by picric and phosphotungstic acids remained fairly constant in all portions. The percentage of acidity was much the highest in the pylorus. In the small intestine the percentage of peptone was much larger than in the stomach.

Food requirements of growing and fattening swine, W. Dietrich (*Illinois Sta. Circ. 126, pp. 18, chart 1*).—This circular presents deductions drawn from experiments in pig feeding now in progress at the Illinois Station. A method of feeding is outlined by which 40 per cent greater gains in live weights were produced than by the use of the Wolff-Lehmann standard.

"It was found that maximum gains are produced at a minimum cost, by starting the pig on approximately 0.6 lb. of digestible crude protein per day per 100 lbs. live weight, increasing the quantity to 0.7 during the first 7 weeks, decreasing to 0.6 the following 4 weeks, and then feeding 0.65 lb. during the last 7 weeks of the growing period. During the first 4 weeks of the fattening stage this is reduced to approximately 0.33 lb., which is fed to the close."

The deposition of fat and lean in hogs, R. R. Dinwiddie and A. K. Short (*Arkansas Sta. Bul. 103, pp. 237–250, figs. 9*).—Comparative tests were made of the lard and bacon types of hogs in the utilization of wide and narrow rations.

In all, 38 pure-bred hogs were fed, the lard type being represented by the Poland-China, Berkshire, Duroc Jersey, and Ohio Improved Chester, and the bacon type by the Yorkshire and Tamworth. The rations fed consisted of corn chops, bran, middlings, blood meal, and tankage, and there were 6 feeding periods of 21 days each. With the lard type of hog 2 lots on a narrow ration with a nutritive ratio of 1:3, made an average daily gain per head of 1.42 and 1.21 lbs., respectively, whereas 2 lots with which there was a wide nutritive ratio, 1:8, made corresponding gains of 1.07 and 0.51 lbs., respectively, and 1 lot with a medium nutritive ratio, 1:5, made an average daily gain of 0.8 lb. per head. On similar rations the average daily gains per head were for 2 lots of the bacon type on a narrow ration 1.54 and 1.29 lbs., respectively, for 2 lots on a wide ration 0.89 and 0.29 lb., respectively, and for 1 lot on a medium ration 0.93 lb. The bacon hogs made more noticeable gains during the first half than in the last half of the test.

"Measured by actual increase in weight and by increase relative to feed consumed, the lard type of hog possesses much the larger capacity for utilizing rations of wide nutritive ratio.

"By the same standard the bacon hogs showed slightly the greater capacity for digesting narrow or proteid rations. . . .

"In both types of hogs the largest increase in weight relative to feed consumed and apparently the fattest hogs resulted from the feeding of the more nitrogenous ration.

"Of all the breeds tested the Tamworth proved to be least adapted for growth on an exclusive corn ration.

"At the close of our feeding experiments all the lard type of hogs both on narrow and wide rations, although varying in weight, were in a finished condition, ready for the butcher. Moreover, the most typical 'fat back' of all was a Berkshire fed on narrow ration. Of the 5 bacon hogs on wide ration 2 only (Yorkshires) were fit for slaughter."

Pork production under North Dakota conditions, W. B. Richards (*North Dakota Sta. Bul. 83, pp. 797–831, figs. 16*).—This bulletin describes the best methods of rearing and feeding swine in North Dakota, the information contained therein being based on results of experiments at this station and on the

experience of some of the best farmers. The topics discussed are the practicability of swine raising in North Dakota, bacon *r.* lard hogs, the selection and methods of handling breeding stock, feeding and management of the young pigs, the use of forage crops, hog fences, finishing for market, sanitation dipping, etc., shelter, and preventive measures concerning hog cholera and swine plague.

Protein digestion in horses. E. ROSENFELD (*Über die Eiweissverdauung im Magen des Pferdes. Inaug. Diss., Univ. Leipsic, 1908, pp. 55, fig. 1*).—The author made post-mortem examinations of the contents of the stomach and small intestines of 9 horses, each of which had been fed 1,500 gm. of oats.

In general, these results agree with those of Grimmer (E. S. R., 18, p. 1069). The pylorus portion contained a larger percentage of water than other parts of the stomach. One-half hour after eating all portions of the stomach were alkalin, and the esophagus end of the stomach remained alkalin for an hour. In one horse the reaction was neutral 3 hours after eating, whereas in all other cases reactions were acid after one-half hour.

The percentage of protein products in the stomach at different periods are given in the following table:

Protein cleavage products in the stomach of horses.

Hours after feeding period.	Total nitrogen.	Soluble nitrogen.[a]	Incoagulable nitrogen.[a]	Syntonin +soluble coagulable nitrogen.[a]	Albumoses.[a]	Peptone.[a]	Other soluble nitrogen.[a]

Three	3.3012	8.02	91.98	40.54	39.00	20.46

[a] Per cent of total nitrogen. [b] Per cent of total incoagulable nitrogen.

At the beginning of the digestive period there were more products of protein hydrolysis in the fundus than in other portions of the stomach, but this difference did not continue for any considerable length of time. Protein digestion was very rapid in the small intestine. Albumoses were there far less in amount than the simpler compounds.

Diastasolin as a nutrient for horses, SCHADE (*Deut. Tierärztl. Wchnschr., 17 (1909), No. 4, pp. 45–48*).—The author added small quantities of diastasolin to the ration of 4 coach horses. At the end of 9 days they had gained an average of 4.6 kg. each in weight, though they had been kept at work. Good results were also obtained by feeding diastasolin to sick horses.

Egg records (*Dept. Agr. and Tech. Instr. Ireland Jour., 9 (1908), No. 1, pp. 121–128*).—Egg-laying statistics gathered from breeders of White and Brown Leghorns, Black Minorcas, Buff and White Orpingtons, White Wyandottes, Plymouth Rocks, Faverolles, Houdans, Light Sussex, and mixed flocks are reported. The best record was made by the Brown Leghorns, which laid an average of 39.6 eggs each from July 1 to September 30. The Houdans laid an average of 21.8, which was the lowest record of any breed.

The egg trade of the United States, M. M. HASTINGS (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 140, pp. 34, figs. 2*).—This is a study of the conditions which surround the production and marketing of eggs, made for the purpose of determining the causes of deterioration in quality and consequent loss. The topics discussed are the importance of the poultry industry, quality in eggs, detrimental changes, methods of marketing and preservation, requisites for the production of good eggs, and how to effect improvement for the benefit of both producer and consumer.

The author states that the enormous waste due to the actual spoiling of eggs is caused by ignorance of the correct method of caring for the product and because the farmer and storekeeper are not financially rewarded for taking greater pains. This latter condition will continue until the present method of bartering eggs for merchandise is discontinued for some plan of buying eggs on a quality basis.

Infection and preservation of eggs, G. H. LAMSON, Jr. (*Connecticut Storrs Sta. Bul. 55, pp. 203–214, figs. 7*).—This bulletin reports bacteriological studies with reference to the cause of decomposition and sources of infection of eggs, the part played by temperature, and precautions to be observed in preserving eggs.

Dissections of hens were made by the author and the ovary and oviduct were examined. "Bacteria [were present] in the oviduct of the hen even in the upper portion, so that an egg may be infected in the earlier stage of its formation, particularly at the time when the white or albumin is secreted. A diseased condition of the ovary of the hen may cause infection of the eggs. Poultrymen, especially those who dress large numbers of fowls, frequently find hens that are so diseased. . . . Unfertile eggs are infected as well as fertile. . . .

"Eggs may be infected after they have been laid, as it is possible for the bacteria to pass through the pores of the shell. Moisture plays a part in such infections, for while the egg is covered with its normal mucilaginous coating and kept in a dry place it is difficult to infect. Infection is not a difficult matter, however, when the egg is moist. Many egg shells are defective, caused by not feeding hens a sufficient amount of shell-forming food. Eggs are liable to be infected soon after they are laid." Nine species of bacteria were found in one nest, hence the author thinks that nesting material is a great source of infection, for if this has been allowed to remain unchanged for a long time it becomes foul and teems with bacteria.

"Whatever the means of infection, it has been found that a larger percentage of the July, August, and early September eggs are infected or contain a greater

number of bacteria (at a time they may be called 'fresh') than the eggs of the other months of the year, particularly when compared with the eggs laid during the months of April, May, and June. This corroborates the opinion of egg packers, who invariably prefer April, May, and June eggs to those produced during the other months of the year. . . .

"The fact that an egg contains bacteria does not mean that it is worthless. The question is mainly whether or not they are present in large numbers, and if present in small numbers, whether or not they are likely to multiply.

"Bacteria which are commonly found in eggs do not multiply at low temperatures. An egg that is kept at 34° F. is safe from decomposition. Repeated experiments have shown that the rapid growth of bacteria does not occur until the temperature is raised over 55°. While there is some growth at temperatures lower than 55°, it is very slow. At the temperature of 98.6° the bacteria in the egg multiply rapidly. In order to demonstrate the rapid multiplication of bacteria resulting in decomposition, a dozen (January) eggs were taken, and in six of them small holes were made and into each egg bacteria from a rotten egg were introduced on a platinum loop. These holes were sealed with wax and the eggs thus infected, together with the six untreated eggs, were placed in an incubator running at a temperature of 110°. In 48 hours the 6 eggs which had been infected were so badly decomposed as to be very offensive and the remaining six showed no changes in them."

Directions are given for using water glass in the preservation of eggs.

Humane slaughtering. Improved foreign methods (*Mo. Cons. and Trade Rpts.* [*U. S.*], *1908, No. 338, pp. 105–118*).—This is a report by American consular officers on the methods of slaughtering animals for food in France, Germany, Italy, Belgium, United Kingdom, Austria, Russia, the Netherlands, British India, China, and Japan. The operations vary widely in cities of the same country, there being apparently no uniform laws, though the cities have regulations and restrictions.

Recent theories and experiments on heredity and inheritance. II. DRINKWATER (*Brit. Med. Jour., 1908, No. 2499, pp. 1538–1541*).—A review of the principal theories that have been propounded.

The possibility of inheritance through the placental circulation instead of through the germ cells, F. T. LEWIS (*Amer. Nat., 42 (1908), No. 494, pp. 134–136*).—Attention is called to the recent work of Theobold Smith and others in the inheritance by mice, guinea pigs, and rabbits of immunity to toxic substances. As this immunity is inherited through the females only it is suggested that immunity and also hemophilia may be caused by a substance in the blood and thus be inherited through the somatic elements. As the next generation only are immune, it is not a case of inheritance of acquired characters as ordinarily understood by biologists.

Recent researches on the determination and heredity of sex, E. B. WILSON (*Science, n. ser., 29 (1909), No. 732, pp. 53–70, figs. 2*).—This is the address of the vice-president of the American Association for the Advancement of Science, at Baltimore, December, 1908.

Sex production is a phenomenon of heredity. Every form of heredity is in a sense a response of the developing organism to external stimuli. Male and female are relative terms and denote tendencies only. The work of earlier investigators on this subject was not of sex determination but rather of suppression of one set of organs. More recent investigation on insects, amphibia, mammals, Bryophyta, and pollen grains of higher plants has led to negative re-

sults. In many organisms the fertilized egg is predetermined as male, female, or hermaphrodite. The sex of the individual is unalterable by external conditions. Double monsters, multiple embryos, and secondary embryos are always the same sex when derived from the same egg. Cytological studies on the dimorphic spermatozoa of insects, myriopods, and arachnids show that spermatozoa which do not contain the accessory chromosome are not functional.

The author points out the difficulties in the way of accepting the Mendelian theories of sex heredity suggested by Castle, Correns, and Bateson, and he proposes the provisional hypothesis that a single X-element (in the simplest cases represented by the accessory chromosome) in itself causes or determines the male tendency, while two such elements in association create, or at least set free, the female tendency. Evidence now indicates that in dioecious organisms sex production is primarily adapted for the production of males and females in equal number.

A new color variety of the guinea pig, W. E. Castle (*Science, n. ser., 28 (1908), No. 712, pp. 250–252*).—The author believes that color inheritance in all its phases seems to conform to Mendel's law of heredity. In guinea pigs there are three different kinds of pigments, black, brown, and yellow. In the wild guinea pig these pigments are so placed on the individual hair as to give it a banded appearance. The banding is inherited as a factor independent of the colors present. Any mating that brings all four factors together will result in a return to the original color of wild forms. If this hypothesis is correct it ought to be possible to produce a color variety of guinea pigs not previously known.

True to this prediction the author obtained a new variety in the following way: "Agouti-colored individuals were crossed with chocolates. The young were all agouti-colored. But when mated with each other these agouti young produced offspring of four sorts, agouti, black, cinnamon-agouti, and chocolate. The cinnamon agoutis are a sharply defined and unmistakable new variety, differing from the wild type in the total absence of black pigment from the eye, the skin of the extremities, and from the hair. . . . We are able to predict the production of new varieties, and to produce them. We must not, of course, in our exuberance, conclude that the powers of the hybridizer know no limits. The result under consideration consists, after all, only in the making of new combinations of unit characters, but it is much to know that these units exist and that all conceivable combinations of them are ordinarily capable of production. This valuable knowledge we owe to the discoverer and to the rediscoverers of Mendel's law."

Inheritance in canaries, C. B. Davenport (*Carnegie Inst. Washington Pub. 95, pp. 26, pls. 3*).—The author bred crested and noncrested canaries of the short or German type to see if the crest was alternative and dominant as in the case of poultry and pigeons, as previously reported (E. S. R., 18, p. 271).

Of 102 offspring of 2 noncrested parents all were noncrested. Crested offspring were obtained from crested parents. Of 66 offspring from 2 heterozygous crested parents, 18 were noncrested and 48 crested. This is very close to the 25 and 75 per cent which theory calls for. A heterozygous parent was crossed with a crested parent and the result was 52 noncrested and 42 crested offspring. The crest is thus found to be dominant in canaries as well as in other birds. The advice of practical men that 2 crested birds should not be mated as they produce baldness is based on an error.

The inheritance of plumage color was studied with green, yellow, lizard, and cinnamon colored canaries. Crosses were also made between the European goldfinch and the yellow canary, with the following results:

"The yellow canary is derived from the original 'green' canary by the loss of black. It carries a mottling factor. Consequently when the yellow canary is crossed with a pigmented canary or with a finch the hybrids are mottled.

"The mottling is not a fixed pattern. The spots vary in position and relative size—they may cover nearly the whole body or they may form a mere 'ticking.' The degree of mottling is inheritable. Ticking behaves as a unit-character.

"Mottling is a heterozygous character and throws mottled, clear yellow, and self-greens.

"The principle of localization of the units of a complex plumage must be recognized. The cap of the Lizard canary, the red face of the goldfinch, the shoulder striping of the green canary are not only unit-characters but they occur only at their proper localities and in their proper forms in the body plumage. In mottled canaries the presence of black on the shoulder means striping, on the wing it means dead black, white-laced remiges, on the mid-breast it means a uniform olive color. The plumage of a yellow canary may be compared with a letter that has been written with invisible ink. Wherever the developer acts (i. e., the black pigment of the green canary is added) that which is written appears with all of its idiosyncrasies."

The influence of the testes upon the secondary sexual characters of fowls, C. E. Walker (*Proc. Roy. Soc. Med. [London], 1 (1908), No. 6, pp. 153–156, figs. 5; abs. in Arch. Rassen u. Gesell. Biol., 5 (1908), No. 4, pp. 565, 566*).—The macerated testes of a cock were strained, mixed with normal salt solution, and subcutaneous injections of ½ cc. made daily on 2 adult laying hens from February 1 to August 30, 1907. From that time until October 4, when the injections were discontinued, the amount of extract was reduced one-half.

A few days after beginning the injections the combs and wattles became brighter in color and grew considerably until the end of June. By October 4 they became bluish, wrinkled, and flabby. There was no noticeable change in the spurs. From the middle of March the hens ceased laying until January, 1908. Though peaceable at the beginning of the experiment they began to attack the cocks a few weeks later. Evidently the testes possess some function which influences or controls the appearance of the secondary sexual characters. The potentiality of differentiation necessary to the production of some at any rate of these characters is present in the cells of the female.

DAIRY FARMING—DAIRYING—AGROTECHNY.

The farm dairy, H. B. Gurler (*Chicago, Ill., 1908, pp. 164, pls. 38, figs. 3*).—This popular work, which treats of the dairy herd, cow stables, rations for dairy cows, silos, handling of milk, butter making, and other dairy matters, is of a practical nature. The author dedicates it "to the boys, hoping that it will help them to see the opportunities in the field of agriculture and especially in dairying, the most profitable branch of agriculture when its possibilities are developed."

The care of milk on the farm, I. P. Whitney (*Washington Sta. Popular Bul. 12, pp. 4*).—This bulletin contains brief notes on the proper care, handling, and cooling of milk on the farm to avoid premature souring or contamination from dirt and bacteria.

The score-card system of dairy inspection, C. B. Lane and G. M. Whitaker (*U. S. Dept. Agr., Bur. Anim. Indus. Circ. 139, pp. 32, dgms. 2, map 1*).—The score-card system of inspecting the milk supply is explained, and its advan-

tages for the inspector, the dairyman, and the consumer are pointed out. An improved form of score card, which was prepared to secure uniformity in dairy inspection, is explained in detail, and directions are given for using the card for scoring dairy farms and city milk plants. A plan for systematizing and simplifying the work for dairy inspection is described. A list of publications on the testing of milk and cream is appended.

Dairy investigations, O. F. Hunziker (*Indiana Sta. Rpt. 1908, pp. 62–69*).—Preliminary results are reported of studies on the moisture content of butter and the factors which control its variation, the influence of the period of lactation on the proteids in milk, the effect of heat on milk albumin, the financial loss to creameries by improperly kept composite samples of cream, and the conditions controlling the percentage of solids in the preparation of condensed milk.

The influence of interrupted milking on the composition of milk, K. Windisch (*Württemb. Wchnbl. Landw., 1908, No. 51, pp. 849–851; Milchw. Zentbl., 4 (1908), No. 12, pp. 535–538*).—Chemical analyses were made and the specific gravity determined in cow's milk when the first and last portions were drawn into separate receptacles.

How many grams of digestible protein are needed to produce one kilogram of cow's milk? J. R. von Marszalkowicz (*Ztschr. Landw. Versuchsw. Österr., 11 (1908), No. 8, pp. 669–700, dgms. 2*).—A critical discussion of the work of Armsby, Jordan, Kellner, Hollmann, and others in cattle feeding. The author thinks that with a ration containing abundant carbohydrates and 600 gm. of protein per 1,000 kg. live weight, a cow requires on an average not more than 37 gm. of digestible protein to produce 1 kg. of milk. In support of this view the experiments of the author are cited.

The variation in the composition of milk, A. Lauder (*Edinb. and East of Scot. Col. Agr. Bul. 15, pp. 35*).—This bulletin contains data as to the yield and composition of the milk of 22 Shorthorn cows which constitute the dairy herd at the Mid-Lothian and Peebles county asylum, Rosslynlee.

The composition of asses' milk, B. Wagner (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 3, pp. 174, 175; abs. in Chem. Zentbl., 1908, II, No. 11, p. 970*).—The author gives analyses of the milk of she-asses at different periods after foaling. On the first day there was 8.116 per cent of fat, on the fifth day 2.587 per cent, and on the thirty-fifth day 1.55 per cent of fat. The milk sugar and other solids remained fairly constant.

The acidity of milk, H. G. Chapman (*Proc. Linn. Soc. N. S. Wales, 33 (1908), pt. 2, pp. 436–443*).—The acidity of fresh milk, according to the author, is not due to lactic acid but to phosphates and caseinogen. The capacity of milk to combine with sodium hydroxid is increased by heating and diminished by dilution.

Investigations on milk serum, A. Burr, F. M. Berberich, and F. Lauterwald (*Milchw. Zentbl., 4 (1908), Nos. 4, pp. 145–156; 5, pp. 210–237; 6, pp. 262–275; Molk. Ztg., 22 (1908), Nos. 15, pp. 401–403; 16, pp. 431, 432*).—Studies were made of fresh milk, skim milk, cream, buttermilk, pasteurized milk, and milk coagulated in various ways. Chemical analyses were made and the specific gravity, percentage of acidity, and other properties were determined. Special attention was given to the specific gravity of the sera of whole milk, skim milk, and buttermilk.

The acetic acid method for coagulating milk is recommended as it is rapid, does not affect the specific gravity of the serum, produces no fermentation, and all of the albumin remains in the serum. Rennet is not a good chemical precipitant for raw milk and much less so for pasteurized milk. The average

results obtained from unpasteurized milk, cream, skim milk, buttermilk, and milk sera are summarized in the following table:

Chemical composition and properties of milk, skim milk, cream, and buttermilk and the sera therefrom.

Number of investigations.	Nature of coagulation.	Specific gravity.	Water.	Nitrogen.	Fat.	Fat-free dry matter.	Degree of acidity (Soxhlet-Henkel).
			Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	
8.....	Milk.....	1.0307	91.04	.....	3.57	8.63	.....
	Whole milk sera:						
8.....	Acetic acid.....	1.0285	93.39	0.37	.24	6.60	26.9
8.....	Spontaneous ...	1.0277	93.65	.98	.05	6.35	24.8
4.....	Rennet.....	1.0278	93.48	1.09	.11	6.51	4.4
	Skim milk sera:						
8.....	Acetic acid.....	1.0284	93.42	.93	.04	6.58	25.7
8.....	Spontaneous ...	1.0276	93.64	.97	.03	6.36	23.7
4.....	Rennet.....	1.0274	93.48	1.11	.09	6.51	4.3

	Buttermilk sera:						
8.....	Spontaneous...	1.0264	93.81	.98	.11	6.18	21.5

The serum from the acetic acid curd contained more fat than when the milk was otherwise coagulated. The acidity of the serum spontaneously coagulated at room temperatures was a little lower than that coagulated in an incubator, but the specific gravity was about the same in both cases.

The specific gravity of pasteurized milk serum was also found to be slightly higher than that of the serum of raw milk, but on allowing it to curdle spontaneously the serum of the pasteurized milk was the lower. Pasteurizing lowered the specific gravity of the serum of cream and of buttermilk. The specific gravity of pure serum from mixed milk is never under 1.0260. The ash content of serum spontaneously curdled varies from 0.75 to 0.8 per cent, a smaller percentage indicating watering.

The use of the refractometer is also of service in detecting watered milk. The refractive power of spontaneously curdled serum should not be less than 8 divisions on a Wollny refractometer. Ten per cent of water will lower it one degree. When the blue solution (copper-glycerin-potash) of Baier and Neumann is added to milk and the power of refraction is under 20 scale divisions the milk has been watered.

Experiments on the germicidal action of cow's milk. P. G. Heinemann and T. H. Glenn (*Jour. Infect. Diseases, 5 (1908), No. 5, pp. 534–541, fig. 1, chart 1*).—The authors studied the bacterial content of milk and milk serum obtained by passing milk through a Berkefeld filter. Some of their conclusions are as follows:

"The decrease of bacteria in fresh cow's milk is more decided if fairly large numbers are inoculated than if small numbers only are present.

"The relative increase of bacteria in milk is more pronounced in milk heated to 75° C. or 100° C. than in raw milk or in milk heated to 56° C.

"Milk inoculated with pure cultures of bacteria seems to restrain to a marked degree the multiplication of these bacteria for several hours at 37° C., and for a somewhat longer period at room temperature, excepting in the case of *Strepto-*

coccus lacticus, which increases from the beginning, although it may be inhibited to some extent.

"Heating milk to 56° C. for 30 minutes does not entirely destroy the power to restrain the multiplication of bacteria; this power is weakened however, and at 75° C. is destroyed completely. This fact together with the fact that milk serum agglutinates some species of bacteria in vitro to a marked degree seems to favor the assumption that agglutinins are in part responsible for the apparent decrease of bacteria in fresh milk, since bactericidal substances are destroyed by heating to 56° C. for 30 minutes.

"The agglutination of certain bacteria in milk serum seems to bear some relation to the apparent decrease in numbers of bacteria observed in fresh milk, but this is probably not the only factor causing such reduction."

The bactericidal property of milk, J. S. Evans and T. A. Cope (*Univ. Penn. Med. Bul., 21 (1908), No. 9, pp. 264–274, fig. 1, charts 8*).—The contradictory conclusions of previous investigators on the subject are reviewed, and it is suggested that the varying results may be due to the variation in methods, as none of these investigators employed absolutely sterile milk. The authors obtained sterile milk by drawing milk from the teat with a cannula connected with rubber tubing to a bottle. The following results were obtained:

"*Streptococcus pyogenes.*—At the end of 4 hours the bacterial content of the unheated milk had decreased 3.5 per cent; that of the milk heated to 55° C., 20 per cent; that of the frozen milk 7 per cent; while the pasteurized and sterilized milks had an increase in their bacterial content of 25 per cent and 10 per cent, respectively, the bouillon control increasing 6 per cent. At the end of 8 hours this wide variation in the percentages of increase disappeared. . . .

"*Staphylococcus aureus.*—At the end of 4 hours the number of bacteria in raw milk had decreased about 20 per cent; the milk heated to 100° C. showed an increase of 100 per cent in bacterial content; in that heated to 68° C. there was an increase of between 10 per cent and 20 per cent; in that heated to 55° C. there was found an increase of 4 per cent; while in that frozen there was an increase of 40 per cent. The bacterial increase in the bouillon control was 1 per cent. . . .

"*Bacillus coli communis.*—At the end of 4 hours this organism decreased 40 per cent in the count in raw sterile milk, while it increased 10 per cent, 25 per cent, 100 per cent, and 2,000 per cent, respectively, in the counts in the milk heated at 55° C., the bouillon control, the milk heated at 68° C., and the milk heated at 100° C. At the end of 8 hours the bacterial content increased rapidly, the raw milk, however, showing the smallest ratio of increase. At the end of 24 hours there was very little difference in the percentages of increase in the various specimens. . . .

"*Bacillus acidi lactici.*—At the end of 4 hours this organism showed an increase of 6 per cent, 55 per cent, 250 per cent, 1,000 per cent, 3,500 per cent, and 2,500 per cent, respectively, in the bacterial content of the raw sterile milk, the frozen milk, the milk heated at 55° C., the milk heated at 68° C., the milk heated at 100° C., and the bouillon control. . . .

"*Bacillus subtilis.*—At the end of 4 hours this organism showed an increase of 5.5 per cent, 2.5 per cent, 20 per cent, 85 per cent, 450 per cent, and 60 per cent, respectively, in the bacterial content of the raw sterile milk, the milk heated at 55° C., the frozen milk, the milk heated at 68° C., the milk heated at 100° C., and the bouillon control."

It would seem from these results that freshly drawn milk possesses a bactericidal activity toward certain micro-organisms and an inhibitory activity toward others. This activity is destroyed at 68° C., and materially impaired at 55° C.

Further trials showed that this bacterial activity varied with different cows. It was also found that "coagulation and acidity of milk do not depend solely upon the bacterial content. They are influenced by natural properties of milk which are soon overshadowed by the metabolic products of bacteria." The authors look upon pasteurized or sterilized milk with disfavor, although realizing that at the present time it is a necessity under certain conditions.

Investigation of pasteurized milk, O. GALVAGNO (*Centbl. Bakt.* [*etc.*], *2. Abt., 21 (1908), No. 20–21, pp. 632–647; abs. in Milchw. Zentbl., 5 (1909), No. 1, pp. 35, 36*).—The work of other investigators concerning the efficiency of pasteurizing as a method of destroying bacteria is reviewed. The author made many tests to determine the value of different reagents for testing milk at different temperatures. Arnold's tincture of guaiac method gave an immediate reaction at 25° C. Above or below that temperature the reaction was slower. Schardinger's methylene blue and formalin method is reliable but depends upon many factors besides temperature. The Neisser-Wechsberg method is reliable but requires a much longer time than the Schardinger method. Storch's paraphenylendiamin method gives an immediate reaction in raw milk and in milk heated to 70°, but is negative at temperatures above 79°. Saul's orthol reaction was immediate up to 70°, was retarded at 74°, and negative at 78°. An amid potassium iodid solution, to which a drop of hydrogen peroxid was added, gave an immediate reaction up to 70°, but at higher temperatures it was retarded, and 2 or more drops of hydrogen peroxid also delayed the reaction. The magnesium sulphate method proved worthless.

These tests were also used in samples that had been kept 6 days, raw milk and milk heated to 65° C. being kept on ice and at ordinary room temperature. The preservation of the sample made little difference in the Storch or the amid potassium iodid-hydrogen peroxid methods. The guaiac reaction was retarded. The Saul method reacted as when the sample was fresh up to the fourth day, after which the reaction was slower. The Schardinger method was unaffected until the third day, when the reaction was retarded in both the milks kept on ice, and accelerated with the milk heated at 65° and kept at room temperature. On the fourth day the reaction was accelerated in all cases except with the raw milk kept on ice. On the fifth day the reaction was the same in all cases as on the fourth day, except that the reaction with the milk heated at 65° was accelerated. On the sixth day in all cases the reaction was accelerated.

On the therapeutic action of fermented milk, C. A. HERTER (*Pop. Sci. Mo., 74 (1909), No. 1, pp. 31–42*).—A critical discussion on the therapeutic value of fermented milks of various kinds, especially milk fermented by *Bacillus bulgaricus*. Many physicians report favorable results from the use of milk that has undergone lactic-acid fermentation, but little is known as to the nature of its action. By some it is thought that the beneficial results are due to the antiputrefactive action of lactic acid. The reduction of the carbohydrates to lactic acid and a change from a food containing a large protein content will decrease the amount of putrefiable material, but accurate data as to any direct action on the part of *B. bulgaricus* is wanting. See also a previous note (E. S. R., 20, p. 496).

The effect of hydrogen peroxid on tuberculous milk, A. MONVOISIN (*Rev. Gén. Lait, 7 (1908), Nos. 4, pp. 73–80; 5, pp. 97–101*).—Guinea pigs were inoculated with milk treated with hydrogen peroxid by the method of Much and Römer (E. S. R., 18, p. 368). The results agreed with those of Bergmann and Hultman, that tuberculous germs are not always killed by sterilizing in this way. Bacilli taken from young cultures were thus destroyed, but from older cultures they were more resistant.

Investigations on the influence of salt on the bacteria, yeasts, and fungi of butter, O. Fettick (*Centbl. Bakt. [etc.], 2. Abt., 22 (1908), No. 1–3, pp. 32–44*).—The initial flora of unsalted butter consist chiefly of bacteria and yeasts, but these begin to decrease in number in about 2 months. At first fungi are present only in small numbers, but gradually increase for several months. In salted butter the fungi disappear in 3 months. The number of bacteria and yeasts begin to diminish in the third month.

The influence of saltpeter on the quality of cheese, A. Wolff and F. M. Berberich (*Molk. Ztg., 22 (1908), No. 52, pp. 1487, 1488*).—Saltpeter is sometimes used to prevent cheese inflation. The authors added 20 gm. of saltpeter to 100 liters of milk. For a time the cheese was normal, but after 6 weeks cracks appeared. The aroma and quality of the cheese was good except a slight yeastlike odor near the cracks. A bacteriological examination of the saltpeter revealed large numbers of cocci and a few yeasts. It is suggested that many common faults of butter and cheese may be due to bacteria contained in the salt. To prevent infection from this source the salt used in the manufacture of dairy products should be bacteriologically as well as chemically pure and should be kept in closed receptacles.

Cracks in Cheddar [cheese] (*N. Y. Produce Rev. and Amer. Cream., 27 (1908), No. 9, pp. 384, 385*).—A symposium on this subject by practical cheese makers. The principal causes of cracking are: (1) too much acid; (2) too dry an atmosphere; (3) drafts blowing directly on the cheese; (4) too much fat in the curd; (5) insufficient pressure; (6) dirty, greasy, or sour hoops and bandages; (7) careless carrying of the cheese to the press; (8) allowing the curd to get too cold; (9) extreme heat in the curing room; and (10) too much or too little salt.

Concerning pear tannin and the changes it undergoes in fruit wine making, W. Kelhofer (*Landw. Jahrb. Schweiz., 22 (1908), No. 7, pp. 343–410, pls. 4, figs. 5, dgm. 1*).—The author reports the results of an extended study of the preparation of pear tannin, its physical and chemical characteristics in comparison with other similar bodies, and the discovery of this tannin in must, with special reference to the making of fruit wine.

Mannitic fermentation in fruit and grape wines, W. Bierberg (*Mitt. Weinbau u. Kellerw., 1908, No. 7, pp. 109–112*).—Mannite occurs in many fruits, but usually does not ferment in temperate climates unless the customary fermentations are checked. It occurs more frequently in overripe fruits containing a small amount of acid. To prevent this undesirable fermentation, fruits containing little acid should be harvested early or mixed with more acid fruit. The customary fermentation may be hastened by adding yeast and by regulating the temperature.

Investigations on wine making with sterilized must, A. Rosenstiehl (*Chem. Ztg., 32 (1908), No. 69, pp. 814, 815*).—The author finds that the characteristics of wine are to a large extent independent of the pure yeasts used in fermentation.

The participation of yeasts and the variety of grapes in the formation of the bouquet of wine, A. Rosenstiehl (*Chem. Ztg., 32 (1908), No. 73, pp. 865, 866; abs. in Ztschr. Angew. Chem., 21 (1908), No. 48, p. 2467*).—The nature of the bouquet depends upon the variety of grape, but its strength and development upon the ferment. Some ferments produce no bouquet, while others possess the power to some extent (anthogenous ferments). Musts contain a substance (anthophor) which varies with the variety of grape. Anthophor exists in the plant in an equal amount whether or not the grapes are ripened in the best situation. The ferment, on the contrary, which develops the anthophor is present only when ripened in the best situation.

With our present knowledge, the best results in practice are obtained by sterilizing the grape juice and fermenting with anthogenous yeasts at as low a temperature as 20° C. if possible.

The oil trade at Marseille (*Chem. and Drug., 73 (1908), No. 1503, p. 770; Jour. Soc. Chem. Indus., 27 (1908), No. 22, p. 1120*).—Marseille now produces an average of 420,000 tons per annum of oil and oil cake from vegetable substances. This output includes oils obtained from the olive, peanut, beechnut, cotton seed, palm, karite, coconut, and castor bean, coco butter, Chinese vegetable lard, and various mixtures sold as salad oils.

Rock salt [in Louisiana], G. D. Harris, C. J. Maury, and L. Reinecke (*Geol. Survey La. Bul. 7, pp. XI+259, pls. 48, figs. 21*).—The investigations reported in this bulletin were made under the direction of the Louisiana Experiment Stations. The report deals with the origin, geological occurrence, and economic importance of rock salt deposits in Louisiana and also contains brief notes and references to all known salt deposits and industries of the world.

VETERINARY MEDICINE.

The systematic relationships of the Coccaceæ with a discussion of the principles of bacterial classification, C. E. A. and Anne R. Winslow (*New York and London, 1908, pp. VIII+300, pl. 1, figs. 3; rev. in Science, n. ser., 29 (1909), No. 740, p. 387*).—This book is stated to be the outgrowth of an attempt to classify certain bacteria of sanitary importance, belonging to the family Coccaceæ. An effort was made to discover natural types among the Coccaceæ by a study of the numerical frequence with which various characters occur. From various sources 500 different strains of Coccaceæ were isolated and submitted to 11 definite and quantitative tests. The results were analyzed with a view to the centers about which each character varied in the series as a whole, and to the general correlation between different characters.

The authors conclude that bacterial groups can be defined, and can only be defined by a study of the numerical frequence of various characters in a large series of cultures. In the Coccaceæ, "two main series, or subfamilies, may be distinguished—one primarily parasitic and the other saprophytic. The groups differ in morphology, staining reactions, cultural characters, and biochemical powers. Within these 2 subfamilies are 8 minor groups which seem to merit generic rank. Each is marked by the correlation of several apparently independent characters, and the eight form, in general, a more or less linear series, connecting such purely parasitic forms as the meningococcus with the saprophytic cocci, so common in the air. Within each genus are included 3 or 4 distinct specific types, each marked by a single peculiarity but sharing the common characters of the genus as a whole. Species and genera alike are connected by numerous intergrading varieties; but the central types in each case are defined by the preponderating frequency of their occurrence."

A key to the genera and species of the Coccaceæ and a bibliography are appended.

Practical bacteriolcgy, blood work, and animal parasitology, E. R. Stitt (*Philadelphia, 1909, pp. XI+294, pls. 4, figs. 82*).—In this manual, part 1 is devoted to bacteriology, part 2 to the study of the blood, part 3 to animal parasitology, and part 4 to clinical bacteriology and animal parasitology of the various body fluids and organs. In an appendix are given methods of preparation of microscopic sections, directions for mounting and preserving animal parasites, the preparation of normal solutions, and data regarding diseases of unknown etiology.

Contribution to the study of the bacterial flora of eggs, A. Chrétien (*Hyg. Viande et Lait, 2 (1908), No. 6, pp. 247–254*).—The author examined spotted eggs and found them to contain bacteria of the genera Pasteurella, Bacterium, Sarcina, and Staphylococcus.

Researches on the pathogenic anaerobes, E. von Hibler (*Untersuchungen über die pathogenen Anaëroben. Jena, 1908, pp. 438, pls. 17, rev. in Brit. Med. Jour., 1909, No. 2514, p. 604*).—This volume deals with 15 species, including the bacillus of symptomatic anthrax, varieties of bacilli of malignant edema, the tetanus bacillus, and bacilli associated with epidemics of meat poisoning. The cultural characters of these various micro-organisms and diagnostic points of difference are considered in the first part of the book. Data regarding the pathogenicity of the anaerobes and the anatomical and histological character of the lesions produced make up the remainder of the volume.

The ultravisible viruses, J. M'Fadyean (*Jour. Compar. Path. and Ther., 21 (1908), Nos. 1, pp. 58–68, fig. 1; 2, pp. 168–175; 3, pp. 232–242*).—The author considers the ultravisible viruses at length. Attention is first called to the fact that the virus of contagious bovine pleuro-pneumonia is on the border limit of visibility, since it can just be made out with a magnification of 2,000 and a brilliant illumination. The mosaic or spotted disease of the tobacco plant appears to have been the first disease whose cause was proved to be of the nature of an ultravisible virus. Foot-and-mouth disease is the first animal disease shown to be due to an ultravisible virus, an account of which discovery was published in 1898. African horse sickness, fowl plague, yellow fever, cattle plague, sheep pox, epithelioma contagiosum of birds, hog cholera, rabies, cow pox, equine pernicious anemia, canine distemper, blue tongue, and leucocythemia in fowls are the other diseases known to be due to ultravisible viruses, and here considered.

Immune sera, C. F. Bolduan (*New York and London, 1908, 3. ed., enl., pp. VIII+176, figs. 10*).—A third and enlarged edition of this work, which is a concise exposition of our present knowledge concerning the constitution and mode of action of antitoxins, agglutinins, hemolysins, bacteriolysins, precipitins, cytotoxins, and opsonins.

Some examples of malignant disease in animals, J. B. Cleland (*Jour. Compar. Path. and Ther., 21 (1908), No. 3, pp. 242–245, fig. 2*).—The author presents an account of cancerous conditions that have been met with during the past 2 years in western Australia, which he considers of interest particularly as showing the widespread distribution of such diseases. These include carcinoma of the breast of a lioness, carcinoma of the udder in a dairy cow, squamous epithelioma of the perinæum of a cow, epithelioma displacing the eye of a horse, epithelioma growing from the conjunctival surface of the lower eyelid of a horse and displacing the globe, alveola sarcoma of the mediastinum in a bullock, and a malignant disease (carcinoma) of the suprarenal gland of a sheep.

Veterinary division, A. Grist (*Dept. Agr. Orange River Colony, Ann. Rpt., 4 (1907–8), pp. 77–90*).—Glanders is reported as greatly decreased in prevalence during the year under report. A single case of pleuro-pneumonia is said to remain from the outbreaks resulting from its introduction in 1907 from Cape Colony. Although East Coast fever has not yet extended to Orange River Colony, its spread is causing the department much anxiety. Hog cholera has not as yet been reported from the colony. Quarter evil is said to be very prevalent during certain portions of the year, and geil-ziekte as prevalent in the spring. Some 7,000 sheep were vaccinated against blue-tongue during the year with Theiler's preventive vaccine with satisfactory results. Other diseases mentioned as having occurred during the year include anthrax, ulcerative

lymphangitis, scabies, ephemeral fever, geel dikkop, white scour in calves, and jag-ziekte.

Experiments regarding the diagnosis of anthrax, G. Mazzini (*Arch. Sci. R. Soc. Accad. Vet. Ital., 5 (1907), No. 7–8; Jour. Trop. Vet. Sci., 3 (1908), No. 2, pp. 207–216*).—The author concludes that "(1) the material should be collected from the animal before advanced putrefaction occurs, preferably not later than 24 hours after death in the summer; (2) the method of Heim, with threads, or that of Fischoeder with 2–3 mm. of blood is the best, because putrefaction is thus arrested or impeded; (3) the cultural test is made by sowing a piece of thread saturated with spleen juice on agar; (4) the biological proof on the guinea pig is less reliable on account of the presence of extraneous organisms; and (5) the failure of both these above tests does not exclude anthrax. Heating of the material to 60° C. must be had recourse to."

Vaccination against symptomatic anthrax, E. Leclainche and H. Vallée (*Rev. Gén. Méd. Vét., 11 (1908), No. 131, pp. 625–635; Jour. Compar. Path. and Ther., 21 (1908), No. 3, pp. 264–269*).—The authors conclude that the method of vaccination against blackleg by the use of pure vaccines meets all the requirements of practice. "In infected areas, the combined use of immunizing serum and of a single vaccine enables the practitioner immediately to check the spread of disease and to vaccinate the contaminated animals without danger, even under conditions where vaccination properly so-called would be dangerous and could only confer protection after considerable delay.

"In noninfected areas, double vaccination with pure liquid vaccines is preferable."

The cause, prevention, and treatment of Mediterranean fever, P. W. Bassett-Smith (*Vet. Jour., 64 (1908), No. 394, pp. 174–178*).—This is a historical résumé of recent work on the disease. The author considers the terms "Malta" and "Mediterranean" fever both wrong and misleading, and prefers the term "undulant" fever to "septicemia of Bruce" as lately used.

Experimental study of the fate of tetanus toxin in the digestive canal, H. Vincent (*Ann. Inst. Pasteur, 22 (1908), No. 4, pp. 341–352; abs. in Bul. Inst. Pasteur, 6 (1908), No. 13, pp. 605–607; Centbl. Bakt. [etc.], 1. Abt. Ref., 42 (1908), No. 11–13, pp. 370, 371; Vet. Rec., 21 (1908), No. 1059, p. 260*).—The author has found that the tetanus toxin is destroyed in vivo in the stomach of the guinea pig in less than 1 hour. In the duodenum and large intestine it is destroyed after 2 or 3 hours. It was found that the gastric, biliary, pancreatic, and enteric juices in vivo destroy the toxicity of the tetanus poison. The author interprets this as a phenomenon of digestion, as he finds that the digestive and antitoxic properties of the gastric and pancreatic ferments vary in very much the same way under similar conditions.

A report on trypanosomiasis of domestic stock in northwestern Rhodesia, R. E. Montgomery and A. Kinghorn (*Ann. Trop. Med. and Par., 2 (1908), No. 2, pp. 97–132, pls. 4, map 1*).—The authors conclude that trypanosomiasis of domestic stock is very prevalent in the northern area of northwestern Rhodesia, and that it is due to *Trypanosoma dimorphon*, *T. vivax*, and a trypanosome morphologically allied to *T. brucei*. While *T. theileri* also occurs it does not appear to cause serious damage. These trypanosomes may be transmitted by *Glossina morsitans*, *Stomoxys calcitrans*, and a species of Lyperosia.

Reports of the "sleeping sickness" expedition to the Zambesi for the years 1907–8, A. Kinghorn and R. E. Montgomery (*Ann. Trop. Med. and Par., 2 (1908), No. 2, pp. 53–76*).—Data on the distribution of tsetse flies are included in this report.

A note on the occurrence of a large trypanosome in the blood of native cattle in South China, C. M. Heanley (*Jour. Compar. Path. and Ther., 21*

(*1908*), *No. 2, pp. 178, 179, figs. 4*).—A trypanosome that corresponds in size with *Trypanosoma theileri*, and also has the long flagellum and acutely pointed posterior extremity of that organism, has been taken from cattle at the cattle depot at Hong-Kong.

A peculiar form of streptotrichosis among cattle, J. D. E. Holmes (*Jour. Trop. Vet. Sci., 3* (*1908*), *No. 3, pp. 289–300, pls. 4, figs. 5*).—The author presents a report of a study made of a disease that appeared among army transport bullocks in Calcutta in 1907. The clinical features of the disease are said to bear a resemblance to equine epizootic lymphangitis.

Redwater in England and its carriers, S. Stockman (*Jour. Compar. Path. and Ther., 21* (*1908*), *No. 3, pp. 225–232; Vet. Jour., 64* (*1908*), *No. 401, pp. 538–548, charts 4; Vet. Rec., 21* (*1908*), *No. 1067, pp. 391–401, charts 4*).—This paper is based upon 3 years' investigations of the disease in Great Britain in collaboration with J. McFadyean, a more complete report of which will be published later.

Contrary to reports previously published in the United Kingdom, the author has found the disease to be inoculable in a way similar to the Texas fever type. Only two species of ticks (*Ixodes ricinus* and *Hæmaphysalis punctata*) have been met with in England on cattle and sheep. Each of these species drops for both molts. *I. ricinus* has been found the most often in redwater pastures. *H. punctata* though much more restricted in its distribution than *I. ricinus* is more common in the southeast of England and has been obtained from redwater farms on which *I. ricinus* could not be found.

The few experiments made with *I. ricinus* failed to show that infection passes through the eggs to the seed ticks. Four experiments made with *H. punctata* in which larvæ were engorged upon infected hosts and placed as nymphs upon susceptible hosts all resulted negatively. Similar results were obtained when the larvæ from an infected female were used. In both of two experiments, however, in which nymphs that had engorged on infected hosts were placed as adults upon susceptible hosts, the disease was produced.

The difficulty in destroying the ticks is shown by the fact that the immature stages require but 3 or 4 days to engorge and drop. This habit of dropping for the molts appears to be favorable, however, in that the ticks are not carried far to infect new territory. The author does not consider the number of ticks found on the animal to have any relation to the severity of the attack but considers such to depend upon the virulence of the Piroplasma. The greater prevalence of the disease from May to August is said to correspond to the period in the year at which adults are most numerous. As a prevention of the disease the author recommends that cattle be kept off infected pastures, that such pastures be well stocked with sheep, and that the sheep be dipped or sprayed at intervals of 10 days, particularly during the season at which the adult ticks are in evidence. This recommendation is based upon the fact that 10 days or more are required for the female ticks to engorge.

Investigations on the nature of hog cholera and methods for its control, Uhlenhuth et al. (*Arb. K. Gsndhtsamt., 27* (*1908*), *No. 3, pp. 425–671; abs. in Centbl. Bakt. [etc.], 1. Abt., Ref., 41* (*1908*), *No. 14–16, p. 480; Bul. Inst. Pasteur, 6* (*1908*), *No. 12, p. 565; Rev. Gén. Méd. Vét., 12* (*1908*), *No. 139–140, p. 414*).—The authors have investigated the disease in Germany and corroborated the results obtained by Dorset, Bolton, and McBryde of this Department, and proved the identity of German "schweinepest" with the English swine fever and American hog cholera. The virus was found to pass through Berkefeld, Pukall, and Heim filters.

The disease can not be produced by the injection of filtrates from cultures of *Bacillus suipestifer*, or by filtrates of serum or organ extracts from healthy

animals. *B. suipestifer* is a saprophyte present in the intestines of healthy swine, having been found in the intestinal contents in 51 of 600 normal hogs examined. It was isolated in 76 of 271 examinations made of animals affected with hog cholera. Swine inoculated with *B. suipestifer* were not immune to hog cholera. The ultravisible virus was present in the blood, bile, and urine, the urine of diseased hogs being highly infectious. It does not appear to occur regularly in the feces, as filtrates from the intestinal contents of 4 affected hogs examined, which exhibited extensive intestinal lesions, were not infectious.

The virus retained its virulence for 23 days when kept in the refrigerator and for 10 weeks when kept at room temperature. In serum it resisted heating 2 hours at 58° C., but was destroyed at the end of 1 hour when exposed to a temperature of 78°. The blood continues virulent after 24 hours of refrigeration at —18°. Twenty-four hours drying of the virus at 27° in blood and serum does not destroy it. The limit of resistance appears to be close to 60°. A 0.1 per cent solution of bicholrid of mercury used in the proportion of 1:2 and a 5 per cent solution of carbolized glycerin used in the proportion of 2:5 did not kill the virus in defibrinated blood after 8 days' contact. In buried organs putrefaction destroys the virus in from 1 to 4 weeks. Horses, cattle, donkeys, goats, dogs, cats, fowls, pigeons, rabbits, guinea pigs, wild and tame rats, and gray and white mice are resistant to the virus. The serum from hyperimmunized hogs showed a strong protective power.

The swine plague ("schweineseuche") bacteria found in the lung lesions in the course of hog cholera are considered as constant but harmless organisms of the respiratory passages of healthy pigs and their pathogenicity as due to the diminished resistance in animals affected with hog cholera.

A bibliographical list is appended.

Suggestions for an organized plan to combat hog cholera. A. D. Melvin (*Wallaces' Farmer, 34 (1909), No. 11, p. 385*).—In order that the possibilities of well-directed work may be brought to the attention of those who may in the future have hog cholera to deal with, the author has outlined the following suggestions for combating the disease through serum immunization as worked out by the Bureau of Animal Industry of this Department.

"The serum should be prepared by the State experiment stations or by live stock sanitary boards which are properly equipped with laboratory facilities, the efficacy of all serum to be determined by the laboratories before distribution.

"The field application of the serum should be in the hands of the State live stock sanitary board or State veterinarian.

"The State should be organized into districts, each in charge of a deputy State veterinarian or a deputy appointed by the live stock sanitary board. These districts should be small enough to permit the deputy to exercise close watch over them.

"The deputy State veterinarian should keep a supply of serum on hand to see that prompt action is taken when infection appears.

"Hog raisers generally throughout the State should be informed when this serum is available for distribution, and if necessary compulsory notification of the presence of disease in a herd should be imposed.

"Upon notification to the deputy in charge of the district or the State live stock sanitary board or State veterinarian that hog cholera has appeared in a certain neighborhood the diseased herd or herds should be immediately quarantined, the premises disinfected as thoroughly as possible, and all hogs on the farm which have been exposed or which are not visibly ill should be treated with the serum alone. All hogs on the farm which have not been exposed should be treated by what is termed the serum-simultaneous method, and of course the prompt burning or burial of dead animals should be enforced. At

the same time all hogs on surrounding farms should be treated by the serum-simultaneous method."

Investigations into the hematogenous nephritis of swine, K. DEGEN (*Untersuchungen über die hämatogene Nephritis des Schweines. Inaug. Diss., Univ. Giessen, 1907; rev. in Berlin. Tierärztl. Wchnschr., 1908, No. 31, p. 548; Vet. Rec., 21 (1908), No. 1048, p. 95*).—The disease is not a specific one due to a single micro-organism but to a polybacterial infection. The author estimates that 5 per cent of all swine slaughtered in Dresden are affected.

Infectious anemia of the horse, M. FRANCIS and R. P. MARSTELLER (*Texas Sta. Bul. 119, pp. 3–19, figs. 8, dgm. 1, charts 5*).—This is a preliminary report on the symptoms and post-mortem examinations of a number of horses and mules affected with an obscure wasting disease prevalent in the flat coastal district of Texas and similar to infectious anemia reported from Nebraska, Minnesota, North Dakota, Manitoba, and other localities. Intermittent fevers and emaciation are the conspicuous symptoms of this disease. The author estimates that 80 per cent of the affected animals die within a few weeks.

Inoculation experiments were conducted with a virus obtained in October, 1907, from a horse (No. 1) at Katy, Harris County, a summary of which is here given in tabular form.

Results of inoculation experiments.

Animal.	Infection.		Effect.	Remarks.
	Source.	Form.		
Horse No. 2..	Horse No. 1.	5 cc. of blood subcutaneously, 5 cc. of blood intravenously.	Chronic type ...	Inoculated Oct. 25, 1907; alive Nov. 18, 1908, though very thin.
Horse No. 3..	Horse No. 2.	2 cc. in bouillon intravenously, 1 cc in bouillon subcutaneously.	Died on 51st day.	Virus lived 48 hours at 37° C. before injection.
Horse No. 4..	Horse No. 3.	10 cc. blood serum	Died on 20th day.	Horse killed to end suffering.
Horse No. 5..	Horse No. 2.	2 cc. of blood subcutaneously.	Died on 25th day.	Acute fatal type.
Horse No. 6..	Horse No. 5.	1 cc. of blood subcutaneously.	Died on 153d day.	Slow chronic type.
Mule No. 7 ..	Horse No. 6.	1 cc. of blood subcutaneously.	Chronic type ...	Remained in good physical condition.
Mule No. 8 ..	Mule No. 7..	4 cc. of blood subcutaneously.	.....	
Mule No. 9 ..	Mule No. 7..	4 cc. filtrate subcutaneously.	Died on 44th day.	
Mule No. 10..	Horse No. 2.	.....	Mild reaction ..	Not susceptible.
Horse No. 11.	Horse No. 2.	2 cc. of blood subcutaneously.	Died on 22d day.	Blood obtained from horse No. 2 12½ months after it was inoculated.

A calf, sheep, goat, and pig were inoculated subcutaneously with 1 cc. of blood taken from horse No. 2, and one of each was also inoculated with a similar amount of blood taken from horse No. 5. None of these was susceptible. A dog inoculated subcutaneously with 1 cc. of blood from horse No. 6 was not susceptible.

The infection is thought to be due to an ultravisible organism which can be conveyed to other horses and mules by subcutaneous and intravenous injections of blood. The blood of animals that survived the first attack and regained much of their lost flesh and spirit is as capable of producing the disease one year after primary infection as during the first sickness. It seems probable that the blood remains virulent during the life of the animal affected. Mule No. 7 while susceptible resisted the infection to such a degree as to continue in good health. "This may make the detection and eradication of the disease a

very difficult matter, as mule No. 7 would to-day pass almost everyone as sound while the blood is still infectious." It has been found that while some mules regain much of their flesh and strength when well fed and not worked, almost every horse dies in spite of the best care and attention.

Immunization against glanders, A. Marxer (*Rev. Gén. Méd. Vét., 12 (1908), No. 133, pp. 1–5; abs. in Jour. Compar. Path. and Ther., 21 (1908), No. 3, pp. 269–271*).—An account is given of experiments conducted in association with E. Levy and F. Blumenthal, based upon the idea that vaccines might be prepared by treating the bacteria with solutions of chemical substances which were indifferent to the bacteria but were capable of changing the osmotic pressure and thus enfeebling the bacteria without killing them, without seriously altering their constitution, or without modifying the antigens which are so important in producing immunity.

Glycerin and urea are said to possess such properties. The attenuation of the virus of glanders in solutions of glycerin and urea is said to be proportional to the temperature and inversely proportional to the density of the emulsion. Experiments were first made with the guinea pig, then with the horse. Emulsions containing urea are most useful, as they can readily be evaporated to dryness and reduced to a powder which keeps for a long time, even at comparatively high temperatures. Complete immunity was produced in horses by a single injection of 600 mg. of dead bacilli or 2 injections of 300 mg. each of dead bacilli with urea. The immunity conferred lasts at least a year.

In practice it is convenient to inject under the skin a dose of 100 mg. of the immunizing powder, followed at intervals of a week by doses of 200 and 250 mg.

The mallein reaction in nonglandered horses, H. J. Südmersen (*Vet. Jour., 64 (1908), No. 394, pp. 197, 198*).—"Immune horses rarely give any rise in temperature (3 cases in 50), and when such a rise does take place the maximum is reached at 12 hours after injection and the temperature rapidly falls and reaches the normal in about 24 hours."

The author's experience with glandered horses has been that the maximum temperature is not reached until the fifteenth hour and the fall is only gradual. "Out of 26 horses with large local reactions, and which were shown to be glandered on post-mortem examination, 19 had considerable increase in temperature (average rise 2.7° F.) while 7 gave very little rise (average 1.1° F.). The local reaction obtained upon immune horses also differs from that of glandered animals."

Preventive vaccination against strangles, F. S. H. Baldrey (*Jour. Compar. Path. and Ther., 21 (1908), No. 2, pp. 158–162*).—"As a result of these experiments it would appear that subcutaneous vaccination with either a broth culture killed under tolnol, or an agar culture in salt solution killed at a temperature of 58° C., will have a very considerable effect in raising an animal's resistance to a streptococcic infection, and is therefore useful as a preventive to the disease. Control animals will show a more or less severe abscess when tested with a nonlethal dose of strangles streptococcus culture, whereas the vaccinated animal will suffer practically no ill effects."

Investigation of an outbreak of horse surra with result of treatment with atoxyl, tartar emetic, mercury, and other drugs, J. D. E. Holmes (*Jour. Trop. Vet. Sci., 3 (1908), No. 2, pp. 157–172, pls. 2*).—The author reports an outbreak of surra in India in 1907 and the results obtained from treatment with atoxyl, mercury, and tartar emetic.

Continuation of experiments on protective inoculation against equine piroplasmosis, A. Theiler (*Jour. Compar. Path. and Ther., 21 (1908), No. 2, pp. 97–148*).—The experiments, which are here reported in detail, have been

continued on a somewhat different line from previous ones, as a result of the observation, made in connection with Texas fever, that the inoculation of cattle with blood of a calf immune from the disease is not so frequently followed by strong reactions and mortality as when the blood is derived from a full-grown animal.

"The inoculation of animals with horse foal blood of the first, second, and third generations caused a mortality of 6 out of 186, or 3 per cent.

"The inoculation of animals with horse foal blood of the fourth, fifth, sixth, seventh, and eighth generations caused a mortality of 1 in 22, or 4.5 per cent.

"The inoculation of animals with donkey foal blood of second to sixth generations caused no mortality amongst 173 animals.

"The reactions caused by injection of horse foal blood were more severe than those given by injection of donkey foal blood.

"No cases of relapses after discharge have occurred, proving that the immunity given by the injection of donkey foal blood is as good as that afforded by horse foal blood.

"For further immunization purposes, therefore, I recommend the passing of blood originating from a natural infection of a donkey with *Piroplasma equi* through donkey foals, and to use 1 cc. blood from the fourth generation and upwards, bearing in mind the precautionary measures mentioned above.

"Finally, all foals kept for tapping purposes, and used in connection with the inoculation, must be kept free from ticks. This precaution has been carried out at this laboratory with all foals used in the experiments, as it stands to reason that a reinfection by means of ticks would increase the virulency of the blood which is to be used as vaccine."

Typhoid fever of the horse—a piroplasmosis, A. Pricolo (*Vet. Jour., 64 (1908), No. 400, pp. 490–494, fig. 1*).—The author presents an account of the disease produced by *Piroplasma equi*. According to the author's experience and to the statistics of the Italian war department, this disease is spread over all Italy, including Sicily and Sardinia, but seems to be localized in centers from which it has little tendency to spread. The disease may be conveyed by injections of blood of diseased horses into healthy susceptible ones.

"The morphological characters of the parasite, its manner of reproduction, transmission of the disease by injection of the blood, clinical features, and post-mortem appearances show that Italian equine piroplasmosis is identical with equine piroplasmosis described by Theiler in South Africa, and generally with all equine piroplasmosis found in Africa and Asia."

A résumé of our knowledge of canine piroplasmosis with an outbreak amongst the hounds of the Madras hunt, H. T. Pease and W. D. Gunn (*Jour. Trop. Vet. Sci., 3 (1908), No. 2, pp. 175–190, pl. 1, charts 4*).—Following a review of the present knowledge of malignant jaundice of dogs the author reports an outbreak of the disease in Madras hounds. Temperature charts are presented.

Acariasis as found in the transport animals employed on field service Barry (*Vet. Jour., 64 (1908), No. 396, pp. 280–294, figs. 8*).—Next to the horse the camel is considered the most important animal of transport affected, acariasis being very prevalent among them. Mules are frequently used on field service, but in the author's opinion are less subject to scabies. The ass, sometimes used for pack purposes, though receiving little or no care is not affected to any extent, and when affected it is usually with the psoroptic acariasis.

On the prophylaxis of trypanosomiasis, with particular reference to the influence of the camel in India, R. E. Montgomery (*Jour. Trop. Vet. Sci., 3 (1908), No. 3, pp. 301–329*).—The author discusses this subject at some length. Attention is called to the fact that the basis of trypanosomiasis prophylaxis is

the prevention or union between the three essential factors—the reservoir, the transmitting agent, and the receptive host, a combination of any two to the absolute exclusion of the third being harmless.

Concerning certain parasitic protozoa observed in Africa, J. E. Dutton, J. L. Todd, and E. N. Tobey (*Pt. 1, Liverpool School Trop. Med. Mem. 21, 1906, pp. 87–97, pls. 2, fig. 1; pt. 2, Ann. Trop. Med. and Par., 1 (1907), No. 3, pp. 287–370, pls. 13, figs. 35*).—Protozoal parasites of mammals, birds, reptiles, amphibians, fishes, and arthropods are here considered.

On some parasites in the museum of the school of tropical medicine, Liverpool, A. Looss (*Ann. Trop. Med. and Par., 1 (1907), No. 1, pp. 123–154, pls. 3*).—Eight species of endoparasites, one of which is new, are considered in this account.

The presence of Spirochæta duttoni in the ova of Ornithodoros moubata, R. M. Carter (*Ann. Trop. Med. and Par., 1 (1907), No. 1, pp. 157–160, pl. 1*).—The author concludes that ticks infected by spirochetes lay infected eggs, that multiplication of the spirochetes probably takes place in the eggs, and that morphological changes in the spirochetes also occur in the eggs.

On the morphology and life history of Spirochæta duttoni, A. Breinl (*Ann. Trop. Med. and Par., 1 (1907), No. 3, pp. 435–438, pl. 1*).—"The life history of the spirochete might be thus summarized: Just before the crisis the spirochetes disintegrate, certain of them coiling up into skeins, the majority of which are phagocytosed by the spleen. Some of them become encysted and break up into very small bodies, out of which the new generation of spirochetes is evolved."

Contribution to the study of the Porocephalus moniliformis, A. Broden and J. Rodhain (*Ann. Trop. Med. and Par., 1 (1908), No. 4, pp. 493–504, pl. 1*).—Observations on the occurrence of this parasite at Leopoldville, in Kongo Free State, are here reported. A description is presented of the larvæ.

RURAL ENGINEERING.

Irrigation in the Sacramento Valley, California, S. Fortier et al. (*U. S. Dept. Agr., Office Expt. Stas. Bul. 207, pp. 99, pl. 1, figs. 24*).—The investigations reported in this bulletin include a study of the present status of irrigation in the Sacramento Valley, its advantages, possibilities, methods, and costs. That this valley has not shared in the wonderful development which has taken place in other fertile valleys of the arid region is believed to be due largely to two conditions which have retarded the introduction of irrigation. First, that the climate permits grain and hay to be grown in the winter months and matured in the spring; and second, that the size of the majority of holdings is large. In 1907 less than 1 per cent of the arable land was irrigated.

Regarding the general development of the valley through irrigation, the authors believe that three operations are involved, namely: (1) Protective works to control floods, estimated to cost $24,000,000; (2) providing a water supply for irrigation, $50,000,000; and (3) preparing the land for irrigation, $35,000,000. In this connection the introductory chapter of the bulletin gives a review of the present agricultural situation, in which are discussed early efforts at development, soil, climate, overflow conditions, etc., and the general status of irrigation development.

The method followed in the investigations was to make detailed studies of representative localities and general observations of the remainder of the territory. The localities selected were the lands irrigated under the Yolo County Consolidated Water System, Yolo County, under the Central Canal in Glenn and Colusa counties, under the Butte County Canal in Butte and Sutter counties,

and along Stony Creek in the vicinity of Orland. The report of these investigations includes a brief description of the chief features, followed by "an investigation of the various subjects pertaining to the use of water in irrigation, embracing the conveyance of water and its delivery to users, character of water rights, and cost of water, seepage, and evaporation losses both in the channels and on the fields, duty of water under main canals and laterals and on individual farms, proper methods of preparing the land, methods of applying water, ascertaining the right time to irrigate, the removal of waste water, irrigated products, etc."

In connection with the investigations along Stony Creek there were conducted eight experiments to determine the amount of water used by farmers under usual conditions. In five of these experiments devoted to alfalfa an area of 67.9 acres yielded under irrigation an average of 5.38 tons per acre for the season at an average cost of $1.78 per ton. The net depth of water applied as averaged for four of these and one other alfalfa experiment was 4.15 feet, this being the difference between the quantity entering the field and that wasted. In an experiment with lemons the net depth applied was 1.76 feet. The results of the experiments led to the conclusion that an unnecessary amount of water was used on the crops, and he gives at the end of the bulletin a few suggestions regarding the economical use of water.

The hydrologic station of Abbeville, P. HOULLIER and H. PELLET (*Bul. Assoc. Chim. Sucr. et Distill., 26 (1908), No. 6, pp. 427–444, figs. 2*).—An account is given of the equipment and work of this station, which is connected with a beet-sugar factory of Abbeville. The station was established to study the relation between rainfall, evaporation, transpiration, and drainage, particularly with reference to the water requirements of the sugar beet. It is equipped with rain gauges, evaporometers, vegetation cases, and other appliances necessary for exact measurements of rainfall, drainage, evaporation, and transpiration. The results of studies during 1906, 1907, and 1908 on evaporation from fallow soil and from soil planted to sugar beets are reported, as well as of a study of the amount of water required for the growth of sugar beets.

Earth roads, A. R. HIRST (*Wis. Geol. and Nat. Hist. Survey Road Pamphlet 1, pp. 32, figs. 13*).—This is the first of a series of pamphlets issued by the Wisconsin Geological and Natural History Survey on the subject of roads. It is intended to give in a brief form the best methods of earth road construction, and to point out how to obtain the best results for the amount expended.

The earth road drag, A. R. HIRST (*Wis. Geol. and Nat. Hist. Survey Road Pamphlet 2, pp. 24, figs. 4*).—The object and benefits of road dragging are discussed here, with an explanation of the proper construction and use of the drag. The material is largely compiled from reports of the Illinois State Highway Commission, and from a bulletin on rural highways issued by the Survey.

Stone and gravel roads, A. R. HIRST (*Wis. Geol. and Nat. Hist. Survey Road Pamphlet 3, pp. 32, figs. 12*).—This is the third of the series noted above and considers briefly the main points to be observed in stone and gravel road construction. There are described and illustrated the approved practices in stone road construction, but it is stated that the bulletin should be considered more in the nature of a preliminary guide to prospective road builders than as a treatise.

Culverts and bridges, A. R. HIRST (*Wis. Geol. and Nat. Hist. Survey Road Pamphlet 4, pp. 54, pl. 1, figs. 15*).—The design and construction of culverts, with particular reference to the materials used, is taken up quite fully in this pamphlet, and directions for making concrete culverts are given in detail.

The subject of bridges is treated in a general way, with illustrations and descriptions of types in use and suggestions to communities regarding the selection of the most suitable kind. The material on bridges, it is stated, is largely taken from a report of the Illinois State Highway Commission.

Implements and machinery at the Smithfield Show (*Impl. and Mach. Rev., 34 (1909), No. 405, pp. 1098–1134, figs. 29*).—In this report there are briefly described several new steam traction and portable explosive engines as well as numerous farm machines and implements.

Trials with seed drills and cultivators, C. V. Birk (*Tidsskr. Landökonomi, 1908, No. 5, pp. 289–298*).—Three 2-row seed drills and 17 different cultivators were included in these trials and were judged by the committee on trials of farm machinery of the Royal Agricultural Society of Denmark.

Water aspirators for homes, T. H. Norton (*Mo. Cons. and Trade Rpts. [U. S.], 1909, No. 3/0, pp. 208–210*).—According to data summarized by the author, an ordinary laboratory suction pump may be used with rubber tubing for dusting and cleaning in the home.

Practical paint tests in 1907, E. F. Ladd (*North Dakota Sta. Bul. 81, pp. 577–714, figs. 11*).—There is given in this bulletin an account of painting tests which were carried out in continuation of work previously reported (E. S. R., 18, p. 209). Tests were made with specially prepared paints furnished by the Paint Manufacturers Association of the United States, and considered to be representative of manufacturers' formulas, and also with commercial white lead submitted by the manufacturers. The paints comprised the whites, warm drabs, and yellows of 18 different formulas.

The paints and leads were applied in various manners to fences made of four types of lumber and so constructed as to give a wide range of conditions.

The substance of the bulletin is made up of detailed reports of these tests, covering formulas, directions for application, and data concerning the areas covered and the weight of paint used. The results are given of examinations which were made of the fences at periods of 6 months and 1 year, and of the condition of the paints after standing for about 8 months in the can.

Tests were also made on a number of houses with practically the same paints as used on the fences, and these are described.

RURAL ECONOMICS.

Report of the Country Life Commission, L. H. Bailey et al. (*U. S. Senate, 60. Cong., 2. Session, Doc. 705, pp. 65*).—This includes a special message from the President of the United States transmitting the report to Congress, and an account of the purpose and methods of the commission in their inquiries into the economic and social conditions surrounding rural life at the present time.

In addition to a general statement, the report discusses the main special deficiencies in country life, as disregard of the inherent rights of land workers, highways, soil depletion and its effects, agricultural labor, health in the open country, and woman's work on the farm. According to the commission, the general corrective forces that should be set in motion are along the line of agricultural or country life surveys, a redirected education, cooperative effort, the country church, and personal ideals and local leadership. The report has also been discussed editorially (E. S. R., 20, p. 601).

Rural conditions in Maine, T. J. Lyons (*Ann. Rpt. Bur. Indus. and Labor Statis. Me., 22 (1908), pp. 84–299*).—This article sets forth the rural conditions in every county and township in the State, the data being compiled by the labor commissioner from the replies to a circular letter of inquiry sent to representative farmers. Special topics also discussed are the agricultural resources of

Maine, abandoned farms, farm labor and immigration with accounts of the Finn colonies near West Paris and in South Thomaston, population of towns and rural districts, farm wages, and loss in rural population.

The average monthly farm wages in Maine in 1907 was $26.14, a gain of 42 per cent since 1887. With regard to the rural population, the decrease "has not been so marked in the last 8 years as is shown by the census figures from 1860 to 1900."

Farming west of the 100th meridian. JAMES WILSON (*Breeder's Gaz., 54 (1908), No. 12, pp. 1215, 1216*).—This is a description by the Secretary of Agriculture of the work of this Department in soil surveys, the introduction and culture of crops, the conservation of soil moisture, and the utilization of the natural resources of the semiarid or dry lands of the Great Plains region.

Agriculture in the Po Valley (*Economist, 68 (1909), No. 3418, p. 455*).—This is a review of S. Pugliese's book on Two Centuries of Agriculture in the Vercellese District of the Po Valley. The book treats of the economic conditions among the laboring classes in the district, system of agriculture practiced, changes in labor conditions during two centuries, systems of land tenure, rents, contracts, prices, and women's wages.

Agriculture in Bavaria according to the latest statistics, ZAHNBRECHER (*Vrtljschr. Bayer. Landw. Rat., 13 (1908), No. 4, pp. 387–397*).—This is a comparative study of the Bavarian census figures of 1882, 1895, and 1907, with special reference to the agricultural population. The percentages of the whole population engaged in agriculture in these years were 50.9, 45.8, and 40.3, respectively. The independent farmers in 1882 numbered 406,007 and in 1907 435,421, a relative decrease, when compared with the increase of population, of 1.4 per cent. The number of farm laborers increased from 1,097,267 in 1882 to 1,257,516 in 1907, a relative increase of 1.3 per cent.

[Land occupation, live stock, and agriculture in New Zealand], E. J. VON DADELSZEN (*New Zeal. Off. Yearbook 1908, pp. 468–495*).—Statistical returns in 1908 are presented and discussed. Of 73,367 holdings, 21,186 ranged from 1 to 10 acres in size, 12,147 from 10 to 50 acres, and 10,098 from 100 to 200 acres, the last alone being a decrease over 1907 (E. S. R., 19, p. 1089).

Crop Reporter (*U. S. Dept. Agr., Bur. Statis. Crop Reporter, 11 (1909), No. 4, pp. 25–28*).—Statistical data on the condition of crops in the United States and foreign countries, the condition and losses of farm animals, and the value and prices of agricultural products are reported.

Scientific investigation and its relation to practical farm work, E. J. JAMES (*Breeder's Gaz., 54 (1908), No. 12, pp. 1191, 1192*).—The importance of science in promoting the progress of agriculture and national welfare by investigations on soils, the culture and adaptation of crops, the prevention of animal diseases, the invention of agricultural machinery, and the use of electricity on farms is discussed in this article.

The problem of farm returns, A. OSTERMAYER (*Wiener Landw. Ztg., 58 (1908), No. 98, pp. 961–964*).—The data as to the returns from 10 different-size farms in the district of Mähren are discussed and compared with similar data from 29 other farms in the same section of country for the purpose of determining the system of farm management that will give the best returns to capital and labor.

The supply of farm labor, G. K. HOLMES (*Ann. Amer. Acad. Polit. and Soc. Sci., 33 (1909), No. 2, pp. 362–372*).—This article is an analysis of the situation concerning the supply and character of farm labor in the United States, with suggestions as to the best means of conserving, increasing, and improving farm labor. These means include retaining the children on the farm, the farmers' institute movement, practical demonstration work among farmers by experts

from this Department and the State experiment stations, the development of agricultural education, and the agencies which are at work to improve the dwellings of country people, their modes of living, their home life, and their social life. These influences, it is believed, "may be depended upon to save to our agriculture all the labor it will need for the maintenance of our national self-sufficiency."

A history of the English agricultural laborer, W. HASBACH (*London, 1908, pp. XVI+470; rev. in Economist, 68 (1909), No. 3412, Sup., pp. V, VI; Jour. Roy. Statis. Soc., 71 (1908), No. 4, pp. 722–725*).—A history of the agrarian problem in England to the year 1907, with particular reference to the development of the agricultural proletariat during the past two centuries.

The breaking of contracts by agricultural laborers, F. MENDELSON (*Landw. Wchnschr. Sachsen, 11 (1909), Nos. 11, pp. 115–117; 12, pp. 127, 128*).—Statistics are presented and discussed regarding the prevalence of contract breaking among different classes of agricultural laborers in Saxony, the data being confined largely to the years 1907 and 1908.

Free agricultural employment agencies in Sweden, W. MÜLLER (*Illus. Landw. Ztg., 28 (1908), No. 93, pp. 799, 800*).—The author describes the operation of the free employment agencies that have been established in ten of the chief cities of Sweden since 1902. Their chief value lies in locating on farms the unemployed in cities, particularly those persons who had left farms to seek employment in the cities. A great number of laborers have already been won back to farm life, and the extension of the agencies throughout Sweden is urged in behalf of agriculture and the national welfare.

State assistance to agriculture in Switzerland, L. VON HENNET (*Mitt. Fachberichterstat. K. K. Ackerb. Min. [Vienna], 1909, No. 4, pp. 25–28; Jour. Bd. Agr. [London], 15 (1909), No. 11, pp. 864, 865*).—The law of 1893 for the promotion of agriculture is discussed. Subsidies under its provision are now granted for the following lines of work: Agricultural instruction, establishments for research and experiments, improvement and insurance of cattle, soil improvement by drainage and irrigation, measures against plant diseases, and insurance against hail, and for agricultural societies and syndicates.

The encouragement of agriculture [in Switzerland]. Mutual aid and agricultural education (*Bul. Mens. Off. Renseig. Agr. [Paris], 8 (1909), No. 1, pp. 55–64*).—Notes are given on the different forces in operation for the promotion of agriculture. These include the state inspection of plants and animals offered for sale, federal and state assistance for various undertakings, and agricultural associations, expositions, legislation, and education.

Data are presented regarding the date of origin, organization, membership, and state financial aid to the more important agricultural societies in Switzerland.

The union of Swiss peasants (*Bul. Mens. Off. Renseig. Agr. [Paris], 7 (1908), No. 12, pp. 1559–1562*).—This society was organized in 1898 and has for its object the furtherance of agricultural interests in Switzerland. In 1907 the organization had more than 98,000 members and published two monthly journals. One of its chief economic inquiries has related to the determination of the profitableness of agriculture in Switzerland, accounts of which have already been noted (E. S. R., 19, p. 691; 20, p. 587).

Concerning the establishment of a central agricultural credit bank, V. CAMANNI (*Bol. Quind. Soc. Agr. Ital., 14 (1909), No. 1, pp. 10–12*).—The author favors the establishment in Italy under state supervision of a central bank serving both public and private ends, but with particular reference to the furnishing of credit to agriculturists.

Report on the working of cooperative credit societies in the Punjab for the year ending June 30, 1908, S. WILBERFORCE (*Rpt. Work. Coop. Credit Soc.*

Punjab, 1908, pp. 14+XI).—The number of rural mutual credit societies increased during the year from 174 to 253 and the surplus was 53,864 rupees (about $17,450), or twice as large as in July, 1907 (E. S. R., 20, p. 390). The rate of interest charged by the societies is less than 10 per cent, while private money lenders charge 25 per cent or more.

AGRICULTURAL EDUCATION.

The college of agriculture and the State. L. H. Bailey ([*Ithaca, N. Y.*], *1909, pp. 36*).—A notable address on the functions of a State agricultural college, delivered during Farmers' Week at Cornell University, February 26, 1909, and intended to be preliminary to a State campaign for rural progress to supplement the work of the National Country Life Commission.

There is presented an analysis of the agencies already at work, the relations of the agricultural to the general educational system, and the relations of the agricultural college to present social problems. The author held that inasmuch as civilization develops out of industries and occupations, and the agricultural colleges represent this civilization, they can not be properly considered as class institutions. The three-fold function of such colleges, the "discovery of fact, teaching it to students, taking it to all the people," was clearly emphasized and elaborated. The suitable training of agricultural teachers was characterized as the "greatest work now before this college." The present support of college education in agriculture in the State of New York was shown to be at the rate of only one sixty-sixth of 1 per cent of the property valuation of the State.

Agriculture in secondary schools, T. F. Hunt (*Ann. Rpt. Penn. Dept. Agr., 13 (1907), pp. 382–395*).—A review is given of progress in introducing agriculture into secondary schools, and attention is called to available literature and other facilities to aid in carrying on such work.

Rural education, A. C. True (*Ann. Rpt. Penn. Dept. Agr., 13 (1907), pp. 231–237*).—Attention is called to the desirability of introducing instruction in agriculture into the rural school curriculum, and examples of successful work along this line are cited.

The education of the farmer, C. De Mar (*Ann. Rpt. Ohio Bd. Agr., 62 (1907), pp. 572–575*).—This paper, read at the farmers' institute held at Newtown, Ohio, December 6, 1907, discusses the value of farmers' institutes, the importance of home industrial training, recreation, and good, business-like farm management.

Domestic science, Alice Penrose (*Ann. Rpt. Ohio Bd. Agr., 62 (1907), pp. 478–481*).—This paper, read at the farmers' institute held at Damascus, Ohio, February 26 and 27, 1908, points out in detail the value for girls of this kind of work in furnishing immediate application in the home for the facts learned in school in the lines of cooking, chemistry, bacteriology, and physiology. These applications are of great service in interesting the mothers as well in the advancement of modern domestic practice.

The nature-study outlook, L. H. Bailey (*Nature-Study Rev., 4 (1908), No. 6, pp. 169–172*).—This informal address considers several important considerations in nature-study work. The author maintains that the ordinary public school seems to lack motive power, being dominated too much by system, regularity, and college ideals, and that "the formal literary college entrance requirement is not an expression of the best activities of living." He believes that while nature-study work should be systematic, definite, and have relation, nevertheless it is easy to make it so formidable as to take the life out of it. "Laboratory teaching may be just as far from life as book teaching is; it all depends on the intention and the mode."

Wanted: A philosophy of nature study. C. H. Robison (*Nature-Study Rev., 4 (1908), No. 7, pp. 206, 207*).—This important theme is treated suggestively rather than elaborately. Emphasis is laid upon the belief that the method of approach must depend on the philosophic basis of our theory "on whether we regard the child as a member of a present and a future society or as an isolated individual, as a social creature, or solely as an intellectual being." The author considers aims and theory as being still in a chaotic state, needing a master's treatment; so that while the "what" is rather definitely understood, the "why" leaves much to be desired, and the "how" must be largely conditional on a clearly worked out rationale. He concludes that much of our present procedure rests on faith rather than on definitely determined psychological results.

The training of teachers of nature study. J. W. Shepherd et al. (*Nature-Study Rev., 4 (1908), No. 6, pp. 173–182, 193–196*).—The first of these papers points out that a large part of elementary science work has been diluted college work, that much of the laboratory work does not raise a personal problem for the individual student, and that the nature-study teacher must come over to the children's standpoint and concern herself with furnishing them rich, vital experiences, rather than developing scientific generalities. To this end the student-teacher should herself have experiences as a student with the same kind of material that the children will use in nature study.

O. P. Dellinger, in discussing the same general subject, holds that the nature-study training course should differentiate nature study from what it is not, make clear the aim of nature study as distinct from that of other related subjects, acquaint the student-teacher with the literature of the subject, give a few type outlines of lessons, and stratify the work for the different grades.

M. A. Bigelow sets forth the belief that nature study should not be limited to any particular phase of the subject, that direct observational study is the essential method, that the study should be made from the standpoint of nature as it touches our daily lives, and that close imitation of the technical science of higher schools is highly undesirable for nature study in the elementary schools.

C. F. Hodge contributes a paper the essence of which appears in the following quotation: "It would be far better if biology teachers in our normal schools be drawn from graduates of our agricultural colleges, or from the ranks of intelligent gardeners and horticulturists, than from those who have had the present biology course in many colleges and have been given no hint that it is not and can not be 'adapted' to the needs of normal-school students and grade pupils. If the colleges are to train normal-school teachers in biology, it is imperative that they supplement their present technical courses by a thorough course in biological nature study."

Nature courses and science courses. W. F. Ganong (*Nature-Study Rev., 4 (1908), No. 8, pp. 242–246*).—This is a reply to a criticism offered by C. F. Hodge on the ordinary courses in secondary science work, as noted above. The author defends them on the ground that they are practicable of educational administration, that the information they impart is worth far more to the majority of students than that offered as substitutes under the name of nature study, and that they give an intellectual training far superior.

Recent aspects of the nature-study movement. E. Davenport (*Nature-Study Rev., 4 (1908), No. 9, pp. 261–264*).—The author points out the advantage of agriculture as nature study in the fact that it utilizes the child's personal desire to produce something, and thus awakens the three strongest impulses to activity—his observing powers, the possibility of exerting controlling influence over natural processes, and the actual production of objects that had no

previous existence as such. He believes that the appeal of agriculture lies in its utility to the race, and that certain phases of agriculture, well taught in a good high school, are a valuable means of education for any man, as well as for the one who is to be a farmer. He suggests, for example, that there is no plant known to botany more significant in its histological and physiological aspects than is Indian corn, which has the added advantage of a deep significance to our social and economic welfare; for "we learn more from inference, even in school, than we do by the direct method."

A school-room study of a robin's nest. JESSIE R. MANN (*Nature-Study Rev., 4 (1908), No. 9, pp. 265–271, fig. 1*).—This study was undertaken as a definite attempt to answer questions raised by the children concerning the number of times a day young birds are fed, whether the father helps in the feeding, what kind of food the parents bring, and how long before the young will fly. Each pupil prepared ruled sheets of paper for the following items: (1) The number of the feeding for that day, (2) time of feeding, (3) the parent bringing the food, (4) the kind of food brought, (5) the nestling fed (numbered 1, 2, or 3 with ink on its bill), and (6) remarks. Complete all-day observations were made for 6 days—for 3 days in succession in the beginning and for the last 3 days before the birds left the nest when 13 days old. Progressive drawings were made of the dorsal view of the young birds, the leg and wing structure compared with the human limbs, the development of feather growth and structure, and sketches of the alimentary canal with a study of its functions.

MISCELLANEOUS.

Twenty-first Annual Report of Arkansas Station, 1908 (*Arkansas Sta. Rpt. 1908, pp. 16*).—This includes the organization list of the station and a report of the acting director, the latter containing an account of the work and publications of the station and a financial statement for the fiscal year ended June 30, 1908.

Twenty-first Annual Report of Indiana Station, 1908 (*Indiana Sta. Rpt. 1908, pp. 97*).—This contains the organization list, reports of the director and heads of departments, the experimental work of which is for the most part noted elsewhere in this issue, a list of the periodicals received by the station, a list of the bulletins and circulars issued by the station to January 1, 1909, and a financial statement as to the Federal and miscellaneous funds for the fiscal year ended June 30, 1908, and as to the State funds for the fiscal year ended September 30, 1908.

Twenty-first Annual Report of Louisiana Stations, 1908 (*Louisiana Stas. Rpt. 1908, pp. 46*).—This contains the organization list, a report of the director and departmental reports on the work of each of the stations and of the State geological survey, lists of available publications and of those issued during the year, a summary of the analytical work on fertilizers, feed stuffs, Paris green, and miscellaneous material, and a financial statement as to the Federal funds for the fiscal year ended June 30, 1908, and as to the State funds for the fiscal year ended November 30, 1908.

A visitor's guide to the more important features of the station's work. F. H. BALLOU (*Ohio Sta. Circ. 85, pp. 5½, figs. 60*).—A revision of a circular previously noted (E. S. R., 18, p. 691).

Accessions to the Department Library, October–December, 1908 (*U. S. Dept. Agr., Library Bul. 70, pp. 61*).

NOTES.

Arkansas University and Station.—The appropriations received from the legislature for the ensuing biennium aggregate $64,900, an increase of $29,700. An appropriation of $8,000 has also been made for farmers' institute work, which has been organized as a department of the college, with G. A. Cole, the former agriculturist, as superintendent.

Dr. R. R. Dinwiddie has retired from active station work, but will continue as consulting pathologist and bacteriologist.

Colorado College.—C. A. Lory, for several years professor of physics and electrical engineering, has been elected president.

Connecticut State Station.—At the request of the Massachusetts authorities, Dr. G. P. Clinton, botanist of the station, has gone to Japan to secure and bring to this country, if possible, a fungus which is parasitic on the gipsy moth.

Clarence Rodman resigned as chemist on May 8, and has been succeeded by R. B. Roe.

Hawaii Federal Station.—The territorial legislature at its recent session made an appropriation to the station of $5,000 annually for the next biennial period, to enable the carrying on of more extensive experiments in forage production, crop rotation, soil studies, and plant diseases. In addition to this sum, about $5,000 annually from funds derived from a territorial income tax is to be at the disposal of the station.

The desirability of improving transportation facilities and marketing methods of Hawaiian agricultural products has become generally recognized in the Territory, and with a view to securing a basis for practical legislation the appointment by the governor of a commission to investigate the matter was authorized. The special agent in charge of the station has been made chairman of this commission, and work has already been begun. Cooperation has been effected with the promotion committee, the chamber of commerce, various associations of growers, and the farmers' institute, and it is expected that financial assistance can be obtained from the legislature upon the formulation of a suitable working plan.

Illinois University and Station.—According to *Illinois Agriculturist*, C. E. Lee, assistant professor of dairy manufactures in the university and assistant chief in dairy manufactures in the station, has accepted the assistant professorship of dairy husbandry at the University of Wisconsin.

Iowa College and Station.—*Science* notes the resignation of E. T. Robbins, assistant animal husbandman, to accept a position on the editorial staff of *The Breeders' Gazette*.

Louisiana Stations.—A substation for rice culture has been established at Crowley, and work began there this spring. Local parties gave 60 acres of land for the use of the station and subscribed $3,500 for buildings. The last legislature authorized the establishment of a rice station, but made no appropriation. It will be maintained for the present out of the fertilizer funds. The Bureau of Plant Industry of this Department will cooperate in the work by stationing a rice specialist there and sending experts from time to time.

Maine University.—Because of the great demand for teachers competent to teach agriculture in secondary schools, the college of agriculture will offer a one-year course in agriculture for teachers, to begin September 15. The course is open to college graduates, to high-school teachers with at least two years' experience, and to normal-school graduates who have had three years' experience in teaching.

Michigan College and Station.—At a recent meeting of the governing board Dr. W. J. Beal was appointed station botanist, this including membership in the station council. Dr. J. B. Dandeno was appointed assistant botanist and a member of the advisory staff.

In connection with the extension work of the college and station an experimental union has been organized. In the spring of 1908, 32 farmers undertook cooperative experiments in alfalfa growing, and during March and April of the present year 93 farmers, 67 of whom had attended the short courses, undertook cooperative work with grains. About 62 bushels of improved seed have been furnished by the college and distributed in 46 counties. Under the arrangement agreed upon, the cooperator pays the freight or express charges and reports results to the college.

Minnesota University and Station.—According to the *Minneapolis Morning Tribune* of May 8, the board of regents has established in the college of agriculture a two-year course in industrial and agricultural education for the preparation of teachers in the agricultural high schools provided for by the recent legislature. A summer school for teachers is being held for three weeks, beginning June 21.

A short course in traction engineering has been offered for the four weeks beginning May 25. The course of study included steam boilers, traction and stationary steam engines, gasoline, kerosene, and denatured alcohol engines, and their operation, repair, etc.

Minnesota Farm Review notes the appropriation by the legislature of $2,000 for tobacco experiments.

Missouri University.—The enrollment in the university courses in animal husbandry is now 456, an increase of 86 per cent in the last three years. A considerable portion of the increase is in the elective courses. In addition, the short course enrollment in animal husbandry courses for the year was 160, as compared with 50 in 1907.

Nebraska University and Station.—Dr. S. Avery, acting chancellor since December, 1908, has been appointed chancellor of the university. Dr. C. E. Bessey, who was dean of the industrial college, which has recently been divided into separate colleges of agriculture and engineering, has been appointed head dean in the university, thereby becoming chairman of the board of deans and acting chancellor in the absence or indisposition of the chancellor. E. A. Burnett and C. R. Richards, formerly associate deans in the industrial college, have been made deans of the colleges of agriculture and engineering, respectively.

The new college of agriculture is to include the university work in general and technical agriculture, forestry, and domestic science. The departments of soils and farming crops have been reorganized into a department of instructional agronomy and farm management and a department of experimental agronomy. These are to be in charge, respectively, of C. W. Pugsley and E. G. Montgomery. The former will also act as soil agronomist in the station. T. A. Kiesselbach has been transferred from instruction work to become assistant in experimental agronomy. P. B. Barker has been appointed adjunct professor of agronomy and assistant in agronomy (soils) in the station.

Other recent appointments include R. E. Stone as assistant professor of agricultural botany and assistant in the station; R. C. Ashby and Ellis Rail as adjunct professors of animal husbandry; R. S. Trumbull as adjunct professor of agricultural chemistry; R. F. Howard as adjunct professor of horticulture, and Erwin Hopt as assistant in field crops at the North Platte substation, and instructor of agronomy in the school of agriculture. Alvin Keyser resigned as professor of soils June 1 to accept the professorship of agronomy in the Colorado College and Station.

Science notes that the regents are taking steps to locate the two additional substations provided for by the legislature; one is contemplated for the sand hill regions of central Nebraska and the other in the irrigated section in the western part of the State.

New Jersey College and Stations.—Daniel W. Horner, John E. Darnell, Samuel B. Ketcham, Abram C. Holdrum, and Henry Bell, of the board of managers of the State Station, and J. B. Drury, of the board of trustees of the college, have resigned and have been succeeded by Alexander P. Owen, of Mickleton, A. Engle Haines, of Medford, Frank E. Bate, of Fishing Creek, Philip Todd, of Peapack, Albert Richards, of Dover, Charles C. Basley, of Maywood, and Edwin Radford, James McCarthy, and Emil Bonnot, of Jersey City.

Dr. B. H. A. Groth, a graduate of Harvard University, was appointed plant physiologist of the college station April 1, for research under the Adams Act. Leon A. Congdon, a graduate of Syracuse University, has been appointed assistant chemist at the State Station in connection with the fertilizer and feedstuffs inspection.

Cornell University.—The legislature has appropriated $175,000 for the maintenance of the college of agriculture, an increase over last year of $25,000.

New York State Station.—In connection with the proposed grape investigations in Chautauqua County, the station has leased a 30-acre farm near Fredonia, where work will be carried on in general vineyard management and the investigation of grape diseases and insects. In the grape disease work the Cornell Station is to cooperate. F. E. Gladwin, previously a nursery inspector under the State department of agriculture, is to be in general charge of the work in Fredonia, and Frederick Z. Hartzell, of Cornell University, has been appointed to carry on the entomological investigations.

W. J. Young, formerly scientific assistant in the Bureau of Chemistry of this Department, has accepted a position as student assistant in horticulture at the station.

North Dakota Station.—A pure-seed law has been enacted by the legislature, under which a seed-inspection laboratory is to be established at the station.

Oregon College.—The college is offering a reading course of five lessons in poultry husbandry. A set of questions accompanies each lesson, and at the end of the course a written examination will be given. Satisfactory completion of the course will count a certain number of points in a poultry contest to begin in the fall, though the taking of the course will not be required of those entering the contest.

Pennsylvania College and Station.—The appropriations by the legislature for the ensuing biennium for the college and station aggregate $525,999.76. Among the items of expenditure authorized are $170,786 for the school of agriculture and the station, $169,050 for the school of engineering, $9,368 for the maintenance of the department of home economics, and $4,000 for the institute of animal nutrition.

Porto Rico Station.—Martin J. Iorns, horticulturist since December, 1906, died in the hospital at San Juan, May 17. Doctor Iorns was born in Louisiana in

1867, and was graduated from Cornell College, Iowa, in 1892. Upon graduation he engaged in civil engineering work and later in teaching, serving as principal of several schools in Iowa and Illinois and as instructor in Cornell College. He took up graduate work at the University of Chicago in 1898, specializing for three years in chemistry, botany, physics, and geology, and serving as laboratory assistant.

In 1900 he was appointed to the chair of science of Fort Worth University, Texas, and also served as lecturer in the medical college. This position he resigned in 1904 to enter the college of agriculture of Cornell University as a candidate for the degree of Ph. D., choosing horticulture as a major subject and physiography and soils as minors. Upon receiving the degree in 1906 he served as assistant on the hydrographic survey of Iowa for the United States Geological Survey until receiving his Porto Rico appointment.

The work of Doctor Iorns in Porto Rico had been attended with much success and his death is a distinct loss to the horticultural interests of the island. He had under way a number of promising investigations which were being pursued with great energy and ability. He was joint author with the former horticulturist of a bulletin recently issued by the station on Pineapple Growing in Porto Rico, a contributor to the newly established *Porto Rico Horticultural News*, and the author of numerous shorter articles. His short career at the station was characterized by an unselfish devotion to duty and a warm-hearted sympathy with the people for whom he was laboring, which won for him the highest commendation.

Rhode Island College.—By a recent act of the general assembly the name of the college has been changed from Rhode Island College of Agriculture and Mechanic Arts to Rhode Island State College. The work on the new dormitory and assembly hall is progressing rapidly, and it is hoped to have the building ready for occupancy in the autumn.

Tennessee Station.—L. R. Neel has been appointed assistant in cooperative experiments at Columbia.

Texas College and Station.—The legislature has passed a bill establishing four new substations, one to be located in the western part of the State, one in the northwestern portion, one in the black-land belt of the north or central portion, and one in the southern or southeastern portion, together with such other substations as the governing board may determine. The sum of $25,000 annually for the biennium beginning September 1 has been appropriated for the establishment and maintenance of these substations.

Work has been begun on the new $35,000 station administration building, and it is expected that this will be completed by September 1. For equipment about $15,000 will be available from the surplus derived from fees collected under the State feeding stuffs inspection law.

The new engineering building, costing $65,000, is to be completed about August 1. The departments of civil, electrical, and architectural engineering are to be quartered in this building.

L. L. McInnis, of the board of directors, has been succeeded by A. R. McCollum, of Waco.

Vermont University and Station.—M. B. Cummings, a graduate of the university in 1901 and at present assistant in horticulture at Cornell University, has been appointed professor of horticulture in the university and horticulturist in the station, vice William Stuart, whose resignation has been previously noted. H. L. Miner, assistant chemist, has resigned to engage in commercial work.

Washington College.—A better-farming special train, sent out March 22–27 through five counties in the eastern part of the State, was visited by nearly

10,000 persons on its trip. W. D. Foster has been promoted to the superintendency of the college farm.

Wisconsin University.—The *Student Farmer* announces that the board of regents has recently established two fellowships at $400 a year and two scholarships at $225 a year for graduate students in agriculture. These are to be open to graduates of colleges of recognized standing and other students with equivalent education, and both men and women are to be eligible.

United States Department of Agriculture.—C. B. Lane, assistant chief of the Dairy Division since 1903, has resigned to accept a position with a large dairy concern in Philadelphia, taking up his new work about June 15.

James B. Rorer, of the fruit disease investigations of the Bureau of Plant Industry, has accepted a two-year appointment as mycologist and pathologist for the Board of Agriculture in Trinidad, and has entered upon his duties.

Dr. C. C. Clark, associate statistician of the Bureau of Statistics, has resigned to become statistician of the International Institute of Agriculture at Rome.

Fourth Graduate School of Agriculture.—The fourth session of the Graduate School of Agriculture is to be held during the summer of 1910 at Ames, Iowa, under the auspices of the State College of Agriculture and Mechanic Arts. The school will, as formerly, be under the general management of the Association of American Agricultural Colleges and Experiment Stations through its committee on graduate study, of which Dr. H. P. Armsby has recently been made chairman. Dr. A. C. True, of this Office, has again consented to serve as dean.

Cuban Experiment Station.—J. T. Crawley resigned as director May 15. The personnel of the station now includes José G. Couret as vice-director and the following chiefs of departments: Agriculture, J. C. Pagliery; animal industry, Emilio L. Luaces; chemistry, Diego V. Tejeda; vegetable pathology, W. T. Horne; and botany, vacant; and twenty-nine assistants. No provision has been made for continuing the horticultural department. It is reported unofficially that Ramón Garcia Osés has been made director of the station.

Agricultural and Educational Meetings.—The twenty-sixth annual convention of the Association of Official Agricultural Chemists is to be held at Denver, Colo., August 26–28, and the meeting of the Association of State and National Food and Dairy Departments is to be at the same place from August 24 to 27. The Society for the Promotion of Agricultural Science is to meet at Portland, Oreg., August 17. The fourth Dry Farming Congress is to meet at Billings, Mont., October 26–28. It is announced that 17 States and 10 foreign countries will be represented by delegates.

The forty-seventh annual convention of the National Education Association is to be held at Denver July 3–9. The programme for the department of rural and agricultural education includes a round table conference on How May the Rural Schools be More Closely Related to the Life and Needs of the People, led by D. J. Crosby, of this Office, and addresses by S. A. Knapp on Agricultural Education for the Rural Districts, E. E. Balcomb on The Type of Farmers' and Teachers' Institutes Used in Oklahoma to Help in Introducing Agriculture and Industrial Work into the Common Schools, H. H. Seerley on National Aid in the Preparation of Teachers of Agriculture for the Public Scools, E. C. Bishop on The Present Status of Agricultural Education in the Public Schools, Josiah Main on Agriculture Correlated with Science Work for High Schools, and Riley O. Johnson on Agriculture for the Elementary Schools. Considerable attention to agricultural education and its interests will also be given in other departments, notably those on normal schools and manual training.

Among the societies to meet with the association are the National Committee on Agricultural Education and the American Home Economics Association.

Secondary Agricultural Schools in Arkansas.—An appropriation of $160,000 has been made by the Arkansas legislature for four secondary agricultural schools. The State is to be divided into four districts and the location of the schools will be determined by their respective governing boards.

Pennsylvania Appropriations for Agricultural Education.—In addition to the very large appropriations for the Pennsylvania College and Station, noted elsewhere in this issue, the legislature appropriated $40,000 for the State Forest Academy at Mount Alto and $25,000 for the National Farm School at Doylestown.

Proposed Agricultural College in Saskatchewan.—It is announced that the recently established University of Saskatchewan is to be organized along lines similar to the state universities of this country, and that it will include a college of agriculture. A site has been selected at Saskatoon, about 250 miles north of the Canadian border of Montana, where a tract of nearly 1,200 acres has been set aside for the college farm and campus. The college is to include departments of animal husbandry and veterinary science, field husbandry and soils, farm mechanics, including carpentry, blacksmithing and farm machinery, dairying, horticulture and tree planting, nature study, including biology and geology, chemistry, physics, mathematics, and English. There will also be an extension department, which will take over the work now carried on by the agricultural societies, under the direction of the superintendent of fairs and institutes.

W. J. Rutherford, deputy commissioner of agriculture of the Province of Saskatchewan, has been appointed dean of the college of agriculture, and John Bracken, superintendent of fairs and institutes, as one of the professors. The organization of the college is to proceed at once under their supervision. Buildings of modern type are to be erected ready for occupancy in the fall of 1910, when it is planned to open the institution to students.

School Gardens for the South.—H. P. Stuckey, of the Georgia Station, began in the March number of the *Southern Ruralist*, a series of articles on School Gardens for the South. Among the topics so far considered are the educational value of the school garden, seed supplies, the kinds of work especially adapted to the different seasons, and suitable laboratory exercises.

Miscellaneous.—The recent death is noted of William H. Council, Ph. D., president of the Agricultural and Mechanical College for Negroes at Normal, Ala., following a long period of ill health.

Dr. Francis Watts, of Antigua, Leeward Islands, has accepted the position of Imperial Commissioner of Agriculture for the West Indies, vice Sir Daniel Morris, whose resignation has been previously noted.

The *Canterbury A. and P. Associations Journal* for April announces the appointment of Robert Alexander as director of the Canterbury Agricultural College, Lincoln, near Christchurch, New Zealand.

A gift of $100,000 has been made to Yale University by Mrs. Morris K. Jessup to establish the Morris K. Jessup chair of agriculture in the forestry school.

The Order of the Red Eagle, third class, has been conferred upon Prof. O. Kellner, director of the Moeckern Experiment Station.

EXPERIMENT STATION RECORD.

VOL. XX. JUNE, 1909. No. 12.

With the present number the abstract portion of the twentieth volume of *Experiment Station Record* is brought to a close. This portion of the volume contains 1,200 pages, of which 1,054 are devoted to abstracts, 76 to editorials and special articles, and the remainder to station and miscellaneous notes. The customary author and subject indexes will be issued separately somewhat later.

The number of abstracts in the volume is 5,336, which is by far larger than in any previous volume, and nearly 700 in excess of the number in Volume XIX. It is estimated that the preparation of this material involved the review of 40 reports of the American experiment stations, 398 station bulletins and circulars, and 232 publications of this Department, together with the examination of fully 20,000 copies of other publications, including periodicals, books, etc., appearing in twelve or more different languages.

The distribution of the abstracts by subjects was as follows: Agricultural chemistry, 469; meteorology—water, 193; soils—fertilizers, 666; agricultural botany, 176; field crops, 306; horticulture, 223; forestry, 222; plant diseases, 259; economic zoology—entomology, 542; foods—human nutrition, 559; animal production, 383; dairy farming—dairying—agrotechny, 304; veterinary medicine, 475; rural engineering, 97; rural economics, 197; agricultural education, 169; and miscellaneous, 96.

The twenty volumes of the Record thus far issued contain about 71,650 titles, besides editorials, special articles, and notes. The station reports abstracted have numbered 868, the station bulletins and circulars 6,912, and the publications of this Department 3,055.

It is of interest to note that of the total number of abstracts about 36,400, or somewhat more than one-half, have appeared in the eight volumes issued since the publication of the first general index. It is hoped to cover this period by a general index to Volumes XIII–XX in the near future.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY.

Principles and practice of agricultural analysis, H. W. Wiley (*Easton, Pa., 1908, vol. 2, 2. ed. rev. and enl., pp. XI+680, pls. 7, figs. 40*).—This is a second revised and enlarged edition of this volume, which deals with fertilizers and insecticides. The preface states that "a great part of the material relating to the occurrence and analysis of ammonia, nitrous and nitric acid printed in the first volume of the first edition of this work has been rewritten and transferred to this volume. . . . All the matter of this volume has been rewritten and brought down to date. New features of moment are those relating to the production of nitric acid for manurial purposes from cyanamid and by direct electric oxidation of the nitrogen of the air. A chapter on the analysis of insecticides has also been added."

Volume 1 of the work has been previously noted (E. S. R., 18, p. 607).

Report of progress in agricultural chemistry in 1907, T. Dietrich et al. (*Jahresber. Agr. Chem., 3. ser., 10 (1907), pp. XXXV+623*).—This volume reviews as usual, by abstract of the more important articles and by title of those of less importance, the published accounts of the work of 1907 in the whole field of agricultural chemistry.

The more important articles on sugar chemistry which have appeared in 1908, E. O. von Lippmann (*Deut. Zuckerindus., 33 (1908), Nos. 28, pp. 600–603; 29, pp. 616–617; 30, pp. 636–638; 34 (1909), Nos. 5, pp. 105–107; 6, pp. 124, 125; 7, pp. 142–144; 8, pp. 161, 162*).—A digest of recent investigations.

The solubility of lime in water, G. T. Moody and L. T. Leyson (*Jour. Chem. Soc. [London], 93 (1908), No. 553, pp. 1767–1772, figs. 2; abs. in Analyst, 34 (1909), No. 395, p. 72; Ztschr. Angew. Chem., 22 (1909), No. 9, p. 397, fig. 1*).—A study of various conditions affecting the solubility of lime in water, which grew out of the observation that the limewater used in volumetric analysis varied very greatly in composition, is reported in this article, and determinations of the exact solubility of lime at temperatures of from 2° to 80° are given.

The decomposition of feldspar by water, W. Funk (*Ztschr. Angew. Chem., 22 (1909), No. 4, pp. 145, 146; abs. in Jour. Soc. Chem. Indus., 28 (1909), No. 4, p. 202; Jour. Chem. Soc. [London], 96 (1909), No. 556, II, p. 146; Bul. Soc. Chim. France, 4. ser., 6 (1909), No. 7, p. 491*).—Tests showing the ease with which a certain portion of the alkali of even the coarser particles of ground feldspar is extracted by water alone are briefly described.

The different forms of nitrogen in proteins, T. B. Osborne, C. S. Leavenworth and C. A. Brautlecht (*Amer. Jour. Physiol., 23 (1908), No. 3, pp. 180–200*).—As the authors point out, with available means it is not yet possible to determine accurately most of the monoamino-acids obtained in the cleavage of proteids, the results obtained by the methods falling considerably below the actual amount of these amino-acids which are produced by hydrolysis.

The results of an extended study of the determination of basic products of proteid decomposition are reported "which have led us to believe that under

suitable conditions a very considerable degree of accuracy can be obtained in determining ammonia, histidin, arginin, and lysin. We also believe that these determinations afford the best means now available for differentiating the many forms of proteins. . . . The data obtained respecting the determination of ammonia make it highly probable that the results are very accurate, and that this ammonia originates from an amid union in the protein molecule."

Determinations of the actual quantities of histidin, arginin, and lysin present in a number of proteids have shown that the amount of nitrogen contained in these bases corresponds closely with that precipitated by phosphotungstic acid.

"In view of the close agreement between the amount of nitrogen precipitated by phosphotungstic acid and the sum of the nitrogen contained in the arginin, histidin, and lysin which the large number of different proteins from many sources yield on hydrolysis, it seems improbable that other basic products than those just named will be found in the future among the decomposition products of the proteins. In respect to accuracy, the determinations of histidin, arginin, and lysin appear to leave little to be desired if the methods of analysis are carefully and properly carried out.

"It was found that for many proteins a much longer hydrolysis was necessary to liberate all of the bases than has been heretofore supposed. Apparently a considerable part of these bases is present in some of the proteins in very difficultly hydrolyzable combinations which require 24 hours, or more, continued boiling with 25 per cent sulphuric acid for their complete dissolution. This condition was found to hold especially for the proteins of leguminous seeds.

"The wide differences between seed proteins in the proportion of nitrogen precipitated by phosphotungstic acid is chiefly caused by differences in the amount of arginin which was obtained from all of them. This forms about 1 per cent of the protein containing the least, and over 14 per cent of those containing the most, basic nitrogen. The amount of histidin which was also obtained from all of the proteins was nearly the same in the majority of the proteins analyzed, that is, about 2.5 per cent. The amounts of lysin found in the several proteins differed considerably, none being present in any of the alcohol soluble proteins, 4 to 5 per cent in most of the leguminous seed proteins, and over 6 per cent in conalbumen from hen's egg.

"The proteins, when arranged in the order of their yield of arginin, fall into three groups: first the oil seeds, then the leguminous seeds, and finally the cereal grains—the only exception being the glutelin of maize, which is one of the least well characterized and studied of all the proteins in the list, and may be a mixture of several different proteins. . . .

"We have in the chemical constitution of these seed proteins an apparent relationship not only to the biological relations of the plants which produced them, but also to the chemical constitution of the seeds themselves."

Products formed by the decomposition of casein, I. W. Bissegger and L. Stegmann (*Ztschr. Physiol. Chem., 58 (1908), No. 2, pp. 147–152; abs. in Jour. Chem. Soc. [London], 96 (1909), No. 555, I, p. 72*).—Details are given for the isolation of a new basic substance obtained from the lysin fraction. When casein is digested with pancreatin and pepsin in the presence of toluene and sodium fluorid, tetra- and penta-methylenediamins can not be isolated.

On the presence of isoleucin in casein, R. Weitzenböck (*Monatsh. Chem., 27 (1906), pp. 831–837; abs. in Milchw. Zentbl., 5 (1909), No. 1, p. 38*).—Among the cleavage products in the hydrolysis of casein, the author found leucin, isoleucin, and phenylalanin in the first fraction when precipitated with phosphotungstic acid. These substances were not obtained in the pure state but were always united with aminovaleric acid.

A note on the constitution of phytin, E. Winterstein (*Ztschr. Physiol. Chem., 58 (1908), No. 2, pp. 118–121*).—Data on the characteristics of phytin are summarized and the question of its constitution is discussed.

The inversion of cane sugar by invertase, II, C. S. Hudson (*Jour. Amer. Chem. Soc., 30 (1908), No. 10, pp. 1564–1583, figs. 3*).—The author points out that the neglect of the mutarotation of the invert sugar in studying the inversion of cane sugar by invertase has led to a series of erroneous conclusions on the laws of the action of this enzym. The investigations which he reports are a critical contribution to the subject in continuation of work previously noted (E. S. R., 20, p. 611).

Gravimetric determination of nitric acid, A. Hes (*Ztschr. Analyt. Chem., 48 (1909), No. 2, pp. 81–98; abs. in Analyst, 34 (1909), No. 396, pp. 114, 115; Ztschr. Angew. Chem., 22 (1909), No. 15, pp. 684, 685; Jour. Chem. Soc. [London], 96 (1909), No. 557, II, p. 265; Chem. Zentbl., 1909, I, No. 7, p. 579*).—A study of the influence of concentration of solution and the presence of various other substances on the accuracy of the determination of nitric acid by means of nitron according to the Busch method (E. S. R., 16, p. 945) is reported.

It was found that this method gives entirely reliable results when used with a 0.1 per cent nitrate solution. With very dilute solutions the nitric acid is not precipitated or only partly precipitated by nitron. Dextrin, gelatin, and perhaps other organic compounds interfere with the crystallization of nitron nitrate. The presence of aluminum sulphate, magnesium sulphate, ammonium sulphate, potassium phosphate, magnesium chlorid, tartaric acid, citric acid, saccharose, and glucose do not interfere with the accurate determination of nitric acid. Higher results are obtained in the presence of oxalic acid. The difference, however, does not correspond to the amount of oxalic acid present, but is very irregular.

Chloric acid is quantitatively precipitated by nitron in the form of nitron chlorate in solutions containing about 0.25 per cent of chloric acid. In solutions which contain both chloric and nitric acids the nitron precipitates both of these acids quantitatively.

Modification of the Kjeldahl method, R. Corradi (*Indus. Quim., 1908, p. 189; abs. in Ann. Chim. Analyt., 14 (1909), No. 1, pp. 29, 30*).—A method specially adapted to the analysis of food materials is described. The nitrogen is determined in the Kjeldahl distillate by decomposition with sodium hypobromite and the measurement of the free nitrogen in a Dupré azotometer.

The determination of potash as potassium molybdic phosphate, A. Schlicht (*Chem. Ztg., 32 (1908), Nos. 93, pp. 1125, 1126; 94, pp. 1138–1140; abs. in Analyst, 34 (1909), No. 394, p. 39; Jour. Chem. Soc. [London], 96 (1909), No. 555, II, p. 94*).—The method proposed is in brief as follows: Mix 0.1 gm. of potassium sulphate free from ammonium salts with 10 cc. of the author's molybdic reagent and evaporate to dryness. Take up with 10 cc. of hot 5 per cent solution of magnesium sulphate, and when cold collect the precipitate on an asbestos filter, wash first with 10 cc. and then with 5 cc. of 5 per cent magnesium sulphate, and then again three times with 5 cc. of 5 per cent ammonium nitrate, finally with alcohol and ether. Dry or ignite and weigh.

The molybdic reagent is prepared as follows: Dissolve 100 gm. of molybdic acid in water, add 250 gm. of crystallized sodium carbonate, evaporate to dryness, and heat the residue for 2 hours at 150°. Dissolve 500 cc. in water. Dissolve 6 gm. of magnesium pyrophosphate in boiling nitrohydrochloric acid and evaporate repeatedly with nitric acid to expel the chlorin. Dissolve the residue in a little water and nitric acid (specific gravity 1.36) and dilute to 500 cc. with acid of the same strength. To this add gradually and with stirring

the molybdic solution and another 500 cc. of water, and filter after standing for 2 hours.

On the quantitative determination of potash, H. Kühl (*Pharm. Zentralhalle, 50 (1909), No. 7, pp. 127–129*).—Methods for the determination of potash in potash salts, sludge, and other organic substances are briefly described.

Determination of insoluble phosphoric acid, F. B. Carpenter (*Jour. Indus. and Engin. Chem., 1 (1909), No. 2, p. 119*).—Attention is called in this article to the difficulty of securing an ammonium citrate of uniform composition by the official methods.

The determination of phosphoric acid in Thomas slag by weighing the yellow ammonium phosphomolybdate precipitate, Z. Románski (*Chem. Ztg., 33 (1909), No. 6, pp. 46, 47, fig. 1; Ztschr. Angew. Chem., 22 (1909), No. 9, p. 400; abs. in Jour. Chem. Soc. [London], 96 (1909), No. 556, II, p. 182; Chem. Zentbl., 1909, I, No. 7, p. 580*).—The author reports tests of a modification of the Lorenz method in which the ordinary Wagner molybdic solution is used for precipitation in presence of a mixture of nitric and sulphuric acids (34 cc. of sulphuric acid of 1.84 sp. gr. in 1 liter of nitric acid of sp. gr. 1.2) and the precipitate is finally washed with benzin (sp. gr. 0.64 to 0.7) instead of ether. The results obtained by this method in a large number of determinations were found to agree quite closely with those obtained by the Wagner molybdic method.

Determination of caustic lime, P. Philossophoff (*Chem. Ztg., 33 (1909), No. 8, pp. 67, 68*).—It is maintained that Pöpel's ammonium chlorid method (E. S. R., 20, p. 703) is inaccurate on account of the fact that calcium carbonate will drive off ammonia from ammonium chlorid in warm solution.

Progress report of the committee on standard methods of chemical analysis of water and sewage, E. B. Phelps et al. (*Amer. Jour. Pub. Hyg., 18 (1908), No. 4, pp. 419–424*).—This is a summary of information secured from replies to a circular of inquiry. It refers to changes suggested in methods of determining turbidity, free ammonia, organic nitrogen, nitrates, copper, hardness, manganese, hydrogen sulphid, free chlorin, alum, sewage sludge, putrescibility in sewage work, filter control, and field assay of water.

The examination of waters in place, H. Klut (*Untersuchung des Wassers an Ort und Stelle. Berlin, 1908, pp. VII+159, figs. 29*).—This is a revision and enlargement of an article first published in *Pharmazeutischen Kalender, 1908*. It gives plain directions for the taking of samples and for quickly testing temperature, turbidity, color, organic matter, smell, taste, nitrous and nitric acids, ammonia compounds, hardness, reaction, bacteriological character, iron, free carbon dioxid, dissolved oxygen, lead, and manganese.

Detection and determination of nitrates and nitrites in water, Tabuteau (*Arch. Méd. Angers, 1908, Sept. 20; abs. in Ann. Chim. Analyt., 14 (1909), No. 1, pp. 17–19*).—Various methods which are available for detecting and determining nitrites and nitrates together and nitrites alone are discussed.

A new method of detecting nitrites in drinking water, A. Rochaix (*Compt. Rend. Soc. Biol. [Paris], 66 (1909), No. 4, pp. 171, 172*).—The method proposed is based upon the blue coloration produced when a solution of tolylene red is added to water containing nitrous acid.

The estimation of urea in urine, S. R. Benedict and F. Gephart (*Jour. Amer. Chem. Soc., 30 (1908), No. 11, pp. 1760–1764*).—In the proposed method of the estimation of urea in urine, 5 cc. of urine and an equal volume of dilute hydrochloric acid (1 volume acid to 4 distilled water) are mixed in a wide test tube with the top covered by folding a piece of lead foil over it, and placed in a small autoclave heated to a temperature of 150° to 155° C. for about 1½ hours.

After cooling, the contents of the test tube are washed into a flask, diluted to about 400 cc., treated with 20 cc. of 10 per cent sodium hydroxid solution, and distilled for about 40 minutes into an excess of standard acid. The residue is determined and the urea nitrogen calculated after subtracting the previously determined ammonia nitrogen.

The author reports determinations which in his opinion show that the method is accurate.

The determination of total sulphur in urine, F. W. Gill and H. S. Grindley (*Jour. Amer. Chem. Soc., 31 (1909), No. 1, pp. 52–59*).—A critical study of the sodium peroxid method for the determination of total sulphur in urine, which according to the authors shows a loss of sulphur when such methods are used "and probably in fact where any alkaline fusion methods are used. . . . Experiments are now being made in this laboratory to determine the nature and extent of the losses, if any, occurring in the determination of sulphur in foods and feces. Results so far obtained show that the determination of the total sulphur in foods and feces by the method of procedure usually employed in the determination of total sulphur in urines gives fusions which more or less frequently evolve hydrogen-sulphid gas upon being acidified."

The identification of horse meat by the biological method, E. Baier and E. Reuchlin (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 9, pp. 513–520*).—On the basis of their investigations the authors conclude that this method is satisfactory for the detection of horse meat in dried sausage.

The identification of horse meat in sausage, A. Beihe (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 9, pp. 521–526*).—According to the author's studies, the chief difficulty in applying the biological method is the preparation of a suitable antiserum.

The accumulation of tyrosin in preserved liver, A. Beihe (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 9, pp. 525, 526*).—The presence of free tyrosin in preserved liver indicates decomposition and goods showing it should not be offered for sale.

The determination of malic acid in food products, H. W. Cowles, Jr. (*Jour. Amer. Chem. Soc., 30 (1908), No. 8, pp. 1285–1288; abs. in Chem. Abs., 3 (1909), No. 1, p. 83*).—A critical study of methods.

The estimation of tartaric acid in the presence of malic and succinic acids, L. Gowing-Scopes (*Analyst, 33 (1908), No. 389, pp. 315–319*).—A critical study of methods.

The determination of boric acid with iodin, M. L. Barthe (*Proc. Verb. Soc. Sci. Phys. et Nat. Bordeaux, 1906–7, pp. 41, 42*).—The author believes that under the usual laboratory conditions it is not possible to determine boric acid satisfactorily with iodin in the presence of glycerin and mannit.

Résumé of the work of the International Commission for Uniform Methods of Sugar Analysis, E. G. Wiechmann (*Internat. Sugar Jour., 11 (1909), No. 123, pp. 124–133*).—A digest of data.

History, manufacture, and analysis of maple products, A. P. Sy (*Jour. Franklin Inst., 166 (1908), pp. 249–280; abs. in Chem. Abs., 2 (1908), No. 24, p. 3376*).—The history of maple sugar making, the botanical classification and distribution of sugar maple, the physiology of sap flow, and other similar matters are discussed and an account of the development of processes for the manufacture of maple products is given. The analysis of maple products is also considered, and experimental work carried on in an attempt to isolate flavoring substances present in maple sap is described.

The lead value of maple products, A. P. Sy (*Jour. Amer. Chem. Soc., 30 (1908), No. 10, pp. 1611–1616; abs. in Chem. Abs., 2 (1908), No. 24, pp. 3376, 3377*).—By lead value is meant the amount of lead in grams found in the pre-

cipitate formed by adding neutral lead acetate to 100 gm. maple sugar or 100 cc. sirup. Investigation showed that concordant results can be obtained if the method is followed closely, and pure and adulterated products are readily differentiated.

The method is as follows: To 50 gm. sugar, or 50 cc. sirup, add 200 cc. water, heat to boiling, add 20 cc. of a 10 per cent solution lead acetate (neutral), cover, heat again to boiling, let stand till cold, filter, and wash with 100 cc. water. Transfer filter and precipitate to a 400 cc. beaker and digest with 15 cc. HNO_3 and 10 cc. HCl until colorless; cool, add 10 cc. H_2SO_4, heat to fumes; cool, add 50 cc. water and 100 alcohol; determine $PbSO_4$, as usual. $PbSO_4 \times 1.366$=lead value, which should be not less than 0.250 and is usually over 0.300 for pure maple products.

The results of determinations made with 80 samples are given. See also a previous note (E. S. R., 18, p. 525).

The colorimetric estimation of benzaldehyde in almond extracts, A. G. Woodman and E. F. Lyford (*Jour. Amer. Chem. Soc., 30 (1908), No. 10, pp. 1607–1611*).—An adaptation of the fuchsin sulphurous-acid method to the estimation of small amounts of benzaldehyde is described.

"A number of test analyses have demonstrated the accuracy of the method and its convenience in the assay of commercial almond extracts. It is probable that it could be applied also to the valuation of almond oils."

The determination of aldehydes in oil of lemon, A. H. Bennett (*Analyst, 34 (1909), No. 394, pp. 14–17*).—A study of methods.

The detection of caramel in vanilla extract, A. G. Woodman and E. H. Newhall (*Tech. Quart., 21 (1908), No. 3, pp. 280–287; Chem. Abs., 3 (1909), No. 1, p. 86*).—Comparative tests of pure and specified vanillas showed that the use of absorptive reagents such as fuller's earth, or the removing of the natural color by selective solvents, is of little value. The best results are obtained with phenylhydrazin and paraldehyde.

A color reaction for mustard, T. Merl (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 9, pp. 526, 527*).—Note on the detection of curcuma and coal-tar dyes in mustard.

A doubtful color reaction, T. Merl (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 9, pp. 528, 529*).—Note on mustard analysis.

Decree relating to methods for analysis of wines, alcohol, brandies, and liqueurs (*Bul. Mens. Off. Renseig. Agr. [Paris], 7 (1908), No. 5, pp. 522, 523*).—Official methods are prescribed for determining the dry extract at 100° of ordinary wines and for the determination of impurities of alcohols, brandies, and liqueurs in accordance with the law of August 1, 1905.

Analysis of milks, G. Hinard (*Analyse des Laits. Paris, [1909], pp. 190, figs. 6*).—This handbook was written for the dairy chemist. Methods for the physical examination and the chemical analysis of normal and adulterated milks are described.

On the testing for ferments, especially in milk, S. Rothenfusser (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 1–2, pp. 63–74*).—The author reviews the various methods which have been proposed for ascertaining whether or not milk has been heated, and classifies them as follows: (1) Those which precipitate casein and fat by various agencies, (2) tests for oxidases, (3) tests for substances which decompose hydrogen peroxid, and (4) tests for reductases. There are also physical methods which are at present of little practical value. The methods included under (2) and (3) are more rapid than the others. Zink and Siegfeld's method of using guaiac is recommended. A modification of the Storch method is outlined, which can be used when various preservatives have been added to the milk.

On milk judging. H. R. CHRISTENSEN (*Tidsskr. Landökonomi, 1908, Nos. 11, pp. 555–560; 13, pp. 690–692*).—This paper contains a discussion of the reductase test as to the purity and keeping quality of milk, originally proposed by Neisser and Wechsberg. The results obtained by Barthel (E. S. R., 20, p. 12) are quoted at length.

A new reaction differentiating raw milk from heated (pasteurized) milk, as well as for the detection of hydrogen peroxid. W. P. WILKINSON and R. C. PETERS (*Jour. Dept. Agr. Victoria, 6 (1908), No. 4, pp. 251–253; Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 3, pp. 172–174; abs. in Rev. Gén. Lait, 7 (1908), No. 7, p. 162*).—This is a critical review of the methods which have been suggested for this purpose.

The authors also give the results of their experiments with benzidin according to the following method: "To 10 cc. of the milk to be tested are added 2 cc. of an alcoholic solution of benzidin, then 2 to 3 drops of glacial acetic acid (just sufficient to cause coagulation of the milk), shake the whole, and finally add 2 cc. of a 3 per cent solution of hydrogen peroxid. If the milk is unboiled or if it has not been heated to above 78° C., an intense blue coloration is immediately produced. Milk which has been heated to above 80° does not show any change by this treatment."

The advantages of using the benzidin test are that the reaction is more reliable than either the guaiac or potassium-iodid test, and more sensitive and intense than the paraphenylendiamin test. The reagent is also cheap and will keep for a long time. "The usefulness of benzidin as a test for unboiled milk may be extended by reversing the reaction and applying it as a very sensitive test for hydrogen peroxid."

The freezing point of milk as affected by the addition of water. P. FISCHER (*Pharm. Ztg., 53 (1908), No. 5, pp. 48, 49*).—The author found the freezing point of 100 samples of milk to vary from −0.54 to −0.58° C. Whenever water was added the freezing point was raised, and he concludes that the freezing point of milk will vary according to the percentage of water added to it.

The freezing point of milk. W. R. G. ATKINS (*Chem. News, 97 (1908), No. 2530, pp. 241, 242; Dairy, 20 (1908), No. 237, p. 238; abs. in Analyst, 33 (1908), No. 388, p. 279*).—The author found the mean freezing point of milk to be −0.55° C. and fairly constant, the variations rarely exceeding 0.03°. If milk is skimmed the specific gravity will be too high, but the freezing point will be unaffected, as fats have no effect on the freezing point. If water is added to bring the specific gravity to the correct value, the freezing point will be nearer that of pure water.

A contrivance for the determination of fat in milk by the Gottlieb-Röse method. E. RIETER (*Schweiz. Wchnschr. Chem. u. Pharm., 44 (1906), No. 12, pp. 170–172, fig. 1; Ann. Chim. Analyt., 14 (1909), No. 2, pp. 54–57, fig. 1*).—This is a description of a tube used in the author's modification of the Gottlieb-Röse method of determining the fat content.

The determination of fat in skim milk. R. LEZÉ (*Ann. Chim. Analyt., 13 (1908), No. 5, pp. 179, 180; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 11, p. 701*).—The author adds ammonia and sodium hydroxid to skim milk, which is then centrifuged and the portion containing the fat tested as in the case of whole milk.

A study of the Lezé process for the analysis of skim milk. R. LEZÉ, BOUTINES, and DUFLOS (*Rev. Gén. Lait, 7 (1909), No. 9, pp. 193–197*).—In order to overcome the variable results obtained in some cases by the Lezé method, noted above, the authors point out the conditions requisite for accurate determinations with this method.

A rapid method for the detection and estimation of formaldehyde in milk, H. S. Shrewsbury and A. W. Knapp (*Analyst, 34 (1909), No. 394, pp. 12–14*).—This is a paper presented at the meeting of the Society of Public Analysts and other Analytical Chemists at London, December 2, 1908.

The reagent used by the authors is made up of 1 cc. of pure nitric acid added to 100 cc. of hydrochloric acid. To 5 cc. of milk in a test tube 10 cc. of the freshly made reagent is added, shaken vigorously, and kept for 10 minutes in a water bath at 50° C. A violet color appears if formaldehyde is present and its intensity indicates the amount.

Disadvantages of potassium bichromate as a preservative, A. Monvoisin (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 25, pp. 1403, 1404; abs. in Jour. Soc. Chem. Indus., 28 (1909), No. 1, p. 36*).—The French law of August 1, 1905, requires that potassium bichromate be added to samples of milk taken for analysis. The author finds that after such addition the Storch test for heated milk can not be used. Potassium bichromate also interferes with the determination of the acidity, the cryoscopic point, the refractive index, and probably also the detection of formaldehyde.

The determination of the moisture content of butter, F. Bengen (*Ztschr. Untersuch. Nahr. u. Genussmtl., 17 (1908), No. 10, pp. 587–594; abs. in Hyg. Rundschau, 19 (1909), No. 1, p. 36*).—From a study of other investigators and his own experience in determining the moisture content of butter by drying in a Soxhlet apparatus, the author concludes that the present methods of determination by drying are not reliable, since some of the fatty acids are volatile and the result will be too high. The indirect method of subtracting the fat plus the solids-not-fat from 100 is recommended.

Studies on fatty acids in butter, R. K. Dons (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 12, pp. 705–725, dgms. 2*).—Continuing the researches previously noted (E. S. R., 19, p. 1111), the author has improved the methods for determining the amount of caproic, lauric, myristic, and other fatty acids of butter, which he describes in this article.

The Müntz-Coudon number in butters from the vicinity of Pavia, N. Monti (*Staz. Sper. Agr. Ital., 41 (1908), No. 5–6, pp. 370–382*).—The author used the Müntz-Coudon modification of the Polenske method in an examination of 76 samples of butter as to adulteration with other fats. A butter having a higher number than 13.36 is deemed free from coconut fat.

Artificial means of increasing the Reichert-Meissl value and saponification value of butter fat, H. Fincke (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 11, pp. 666–673; abs. in Analyst, 34 (1909), No. 395, pp. 50, 51*).—The author describes methods for the determination of acetin and triacetin when it is suspected that oils containing these glycerids have been added to fats for the purpose of imitating butter.

The determination of sugar in molasses feeds by polarization, F. Herles (*Ztschr. Zuckerindus. Böhmen, 32 (1908), No. 11, pp. 626–628*).—The author describes a method of determining the sugar content in molasses feeds which he has successfully used for the past 10 years.

Rapid determination of oil in cotton-seed products, C. H. Herty, F. B. Stem, and M. Orr (*Jour. Indus. and Engin. Chem., 1 (1909), No. 2, pp. 76–81*).—In this article the objections to the usual methods are enumerated and a new method is described, in which the objections are said to be met.

The higher melting point constituents of Japanese fish oil, H. Okada (*Chem. Ztg., 32 (1908), No. 99, pp. 1199–1201, figs. 2; abs. in Analyst, 34 (1909), No. 395, p. 62*).—A fish oil derived from several species of herring was found to have a melting point of 34 to 35° C. The saponification value was 195.9, the

iodin value was 29.7, and the refractometer reading at 41 to 42° C. was 1.4545. The oil was found to contain oleic acid and solid acids which appeared to be a mixture of stearic and isocetic acids.

Detection of savin oil, A. Beythien and P. Atenstädt (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 11, pp. 677–679; abs. in Analyst, 34 (1909), No. 395, pp. 63, 64*).—A note on methods for differentiating between savin oil, juniper oil, and turpentine.

Characteristics of ergot and lycopodium oils and areca-nut fat, A. Ratilje (*Arch. Pharm., 246 (1908), No. 9, pp. 692–709; abs. in Analyst, 34 (1909), No. 395, p. 64*).—Analytical data are given on these oils.

[Miscellaneous analyses], H. E. Annett (*Ann. Rpt. Dept. Agr. Bombay, 1907–8, pp. 27–31*).—This is the annual report of the official chemist and contains analyses of milk, cream, oil seeds, and other agricultural products.

[Miscellaneous analyses], J. Graftiau (*Rap. Lab. Anal. Louvain, 1906, pp. 17; 1907, pp. 16*).—These are the annual reports of the official chemist and contain analyses of fertilizers, feeding stuffs, and agricultural products.

[Miscellaneous analyses], T. F. Sedgwick (*Mem. Dir. Fomento [Peru], 1907–8, vol. 1, pp. 53–101*).—This is the annual report of the sugar cane experiment station for the year ending March 31, 1908. During the year 447 samples of soils, fertilizers, sugars, and other agricultural materials were analyzed.

[Miscellaneous analyses], J. McCrae (*Transvaal Govt. Labs. Ann. Rpt. 1907–8, pp. 5–21*).—This is the annual report of the government analyst and contains analyses of milk, meal, flour, water, and other agricultural materials.

METEOROLOGY—WATER.

Introduction to weather forecasting, W. J. van Bebber (*Anleitung zur Aufstellung von Wettervorhersagen. Brunswick, 1908, 2. rev. ed., pp. VI+38, figs. 16; rev. in Beibl. Ann. Phys., 33 (1909), No. 5, pp. 306, 307*).—A second revised edition of this pamphlet, which contains a brief popular discussion of the subject for the use of schools and farmers.

Constantly appearing secondary maxima and minima in the yearly course of meteorological elements, Van Rijckevorsel (*Konstant auftretende secundäre Maxima und Minima in dem jährlichen Verlauf der meteorologischen Erscheinungen. Rotterdam, 1908, pt. 5, pp. 14, fig. 1, charts 3; rev. in Beibl. Ann. Phys., 33 (1909), No. 5, p. 306*).—Temperature, pressure, and rainfall curves are traced and discussed.

The isothermal layer of the atmosphere and atmospheric radiation, E. Gold (*Proc. Roy. Soc. [London], Ser. A, 82 (1909), No. A551, pp. 43–70*).—The topics treated in this article are the phenomenon of the isothermal layer and the experimental evidence of its existence; the possible temperature distributions in an atmosphere; experimental data on gaseous radiation and absorption; and general expressions for the radiation from the atmosphere and conditions of its equilibrium as applied to an atmosphere of uniform constitution, the earth's atmosphere, taking into account the diminution of water vapor with height, and the day and night temperatures of the earth's surface.

The isothermal layer of the atmosphere, J. I. Craig, W. H. Dines, R. H. Hughes, and E. Gold (*Nature [London], 78 (1908), No. 2031, pp. 550–552; 79 (1909), Nos. 2045, pp. 281, 282; 2047, pp. 340, 341; 80 (1909), No. 2055, p. 68*).—The paper noted above is briefly discussed in this series of articles.

Recent observations in atmospheric electricity, P. H. Dike (*Amer. Jour. Sci., 4. ser., 27 (1909), No. 159, pp. 197–209*).—This is a paper presented before the Philosophical Society of Washington and is a critical review of recent work of investigators in this great field, which is said to be almost entirely neglected in this country.

The origin of atmospheric ozone and the causes of variation of carbon dioxid in the air, H. Henriet and M. Bouyssy (*Ann. Observ. Munic. (Observ. Montsouris) [Paris], 9 (1908), No. 1–2, pp. 167–195*).—This is a detailed account of investigations, a brief report of which has already been noted (E. S. R., 20, p. 422).

Analyses of air, P. Miquel (*Ann. Observ. Munic. (Observ. Montsouris) [Paris], 9 (1908), No. 1–2, pp. 7–28*).—Numerous determinations of ozone and carbon dioxid in the free air and more detailed examinations of the confined air of subways, tunnels, and buildings are reported.

[Meteorological observations in Trinidad], J. H. Hart and H. Millen (*Bot. Dept. Trinidad Ann. Rpt. 1908, pp. 24, 25, 32–37*).—Tables are given which show the monthly and annual rainfall at the Royal Botanic Gardens from 1862 to 1907; mean annual barometric pressure, temperature, and rainfall at the same place, 1888 to 1907; and observations on rainfall during 1907 at 56 stations in Trinidad; besides miscellaneous meteorological observations during that year at various stations in the island. The mean annual rainfall at the botanic gardens, 1862 to 1907, was 72.39 in.; for 20 years, 1888 to 1907, 66.6 in. The mean barometric pressure for the 20 years, 1888 to 1907, was 29.96 in.; the annual temperature 78.50.

The rainfall in Natal, E. Nevill (*Natal Agr. Jour., 11 (1908), No. 12, pp. 1531–1533*).—Attention is called to the fact that there is a distinct 18-year periodical fluctuation in rainfall in Natal, the epochs of heaviest rainfall centering around the years 1855–56, 1873–74, and 1892–93. The indications point to a similar exceptionally heavy rainfall centering around the year 1910–11. The excess of rain is usually spread over a period of about 5 years. These periods of excessive rainfall are attributed to the gradual northerly drift of the great rain belt, the normal position of which is to the southeast of Cape Colony.

It is noted also that these epochs of heavy rainfall coincide "with that of the approach of the node of the moon's orbit to the position of the vernal or spring equinox, when the inclination of the plane of the moon's orbit to the plane of the terrestrial equator reaches its maximum value, as if there were some connection between the two occurrences, and this coincidence points to a possible cause of this 18-year fluctuation in the rainfall. . . . If the great rain belt has any tendency to follow the deformation of the atmosphere under the attraction of the moon, as it should according to theory, then the greatest northerly drift will occur when the moon's node approaches the vernal equinox, and this is exactly what is indicated by the observations. It is to be noted that this is purely a local cause affecting Southeast Africa, and not necessarily holding of any other place. . . .

"It is noteworthy that three 11 or 12 year solar periods of variation in density of rain belt are not very different from two 18-year lunar periods, so that every 35 or 36 years the two should coincide and give rise to a specially heavy excess of rain, similar to that which is recorded by the observations. Thus the excess of rainfall near 1855–56 and 1892–93 was much heavier than that at the intermediate 18-year epoch in 1873–74. If this be so, the coming heavy rains of 1910–11 will not be so heavy as those of either 1855–56 or 1892–93."

Contributions to hydrology, H. Dessoliers (*Contributions Diverses à l'Hydrogeuèse. Algiers, 1908, pp. 168, pls. 4, figs. 4*).—This is a series of articles treating of sources and means of conserving and increasing the water supply.

Underground waters of Georgia, S. W. McCallie (*Geol. Survey Ga. Bul. 15, pp. 370, pls. 29, figs. 5, map 1*).—This report has an introductory chapter on the general conditions controlling the amount of water taken up by soils, discusses briefly the physiography and geology of Georgia, and takes up in detail

the amount, composition and other characteristics of the underground water by geological formations and by counties. The report is in part a revision of a paper on the artesian well system of Georgia, published in 1898.

Dew ponds, G. Hubbard (*Jour. Roy. Soc. Arts, 57 (1909), No. 2937, pp. 330–340*).—The article tells what dew ponds are, explains the conditions essential to their efficient action, and discusses the possibility of their introduction with advantage into arid regions. Accurate data are too limited to draw positive conclusions as to the latter point. See also a previous note (E. S. R., 17, p. 533).

A phase of ground water problems in the West, W. C. Mendenhall (*Econ. Geol., 4 (1909), No. 1, pp. 35–45, figs. 2*).—This article is based upon observations on "the relation of the withdrawals of ground water by artificial means to the recharge from precipitation and run-off" in the San Bernardino Valley, California, "where, during 8 or 9 years past, the total developed waters and the total waters that rise naturally in springs have been measured twice annually. The total water from both these sources, all of which is used for domestic purposes or for irrigation, has increased slowly, although irregularly, to keep pace with the increasing population of the dependent communities, but the most striking fact brought out by the measurements is the general increase in the amount of developed water, accompanying an equally marked general decrease in the natural waters; that is to say, the flow of springs has lessened markedly as the yield of wells has increased. . . .

"Detailed measurements have not been made for other of the many basins that together constitute the valley of southern California, but there is no doubt that were they to be had they would indicate about the same condition that exists in the San Bernardino basin."

The need of "constant records of fluctuations in ground water levels, for comparison with the average rainfall, or the average flow of the supplying stream," is emphasized.

The presence of nitrites and ammonia in drinking water, S. Van Eyk (*Pharm. Weekbl., 45 (1908), No. 41, pp. 1162–1165; abs. in Chem. Abs., 3 (1909), No. 6, p. 682*).—The occurrence of considerable amounts of nitrites in water from a zinc-lined pump is reported. An investigation of the matter indicated that the nitrites were due to the reduction of nitrates by the zinc.

The removal of iron from well water, Peters (*Ztschr. Hyg. u. Infektionskrank., 61 (1908), No. 2, pp. 247–261; abs. in Chem. Abs., 3 (1909), No. 6, p. 682*).—The method proposed is to pour into the well water which has been standing for some time in the open air and has become thoroughly aerated. The iron is precipitated by the oxygen thus introduced and the water may be pumped out and filtered.

The purification of ground waters containing iron and manganese, R. S. Weston (*Proc. Amer. Soc. Civ. Engin., 34 (1908), No. 10, pp. 1324–1393, pls. 3, figs. 8; 35 (1909), No. 2, pp. 150–166, fig. 1; abs. in Engin. Rec., 59 (1909), No. 6, pp. 146–148, fig. 1; Engin. Digest, 5 (1909), No. 3, pp. 251–256*).—This article explains that the method of deferrization which it is advisable to use in any given case depends upon the composition and character of the water. A careful study of the water is therefore a necessary preliminary to the application of efficient methods. Methods which have been employed with success are described. The most important feature of all of these methods is thorough aeration.

Chemical purification of drinking water in the country, J. Laurent (*Jour. Pharm. et Chim., 6. ser., 28 (1908), No. 9, pp. 392, 393; abs. in Rev. Sci. [Paris], 47 (1909), I, No. 5, p. 150*).—Directions are given for the application of a method based upon the use of permanganate of potash and alum followed by the addition of sodium hyposulphite and carbonate.

The recent Parisian experiments on water sterilization by ozone, C. Daage (*Engin. Rec., 59 (1909), No. 7, p. 183*).—Experiments with Siemens-de Frise ozonizers are reported. The treatment was found to be very effective in destroying organisms in the water.

On the sterilization of potable water by means of the mercury vapor lamp, J. Courmont and T. Nogier (*Compt. Rend. Acad. Sci. [Paris], 148 (1909), No. 8, pp. 523, 524*).—Experiments are reported which show that by the use of the Kromayer mercury vapor lamp complete sterilization can be secured in from 1 to 2 minutes, even when the samples are very highly polluted.

Examinations of water, P. Miquel (*Ann. Observ. Munic. (Observ. Montsouris) [Paris], 9 (1908), No. 1–2, pp. 29–62*).—Detailed examinations of potable waters of Paris and environs, sewage and drainage waters, and rain water are reported.

SOILS—FERTILIZERS.

The soil, A. D. Hall (*London, 1908, 2. ed., rev. and enl., pp XV+311, pls. 13, figs. 4*).—This is a second revised and enlarged edition of this work, which is described as an introduction to the scientific study of the growth of crops. The principal changes which have been made are a revision of the method of mechanical analysis of soils, modification of the author's views on the nature of clay and on the absorption of ammonium and other salts by zeolitic silicates in the soil, and enlargement and complete revision of the chapter on the living organisms of the soil, besides numerous minor corrections and modifications.

The genetic classification of soils, N. Tulaikov (*Jour. Agr. Sci., 3 (1908), No. 1, pp. 80–85*).—This is a brief description of the genetic classification of soils as worked out by Dokouchayev and Sibertzev in Russia (E. S. R., 12, pp. 704, 807; 19, p. 314) and partially adopted by Hilgard and Ramann.

In this classification the word soil is taken to mean "the loose surface strata of the earth's crust in which general dynamic processes (weathering, erosion, etc.) have taken place, and are taking place in conjunction with chemico-biological processes." The classification includes 7 types, as follows: Laterite soils, wind-blown loess soils, soils of the dry steppe, black soils (chernozem), gray soils, peat and ashy (podzol) soils, and fenland (tundra) soils. These 7 fundamental groups of soils "are spread over the surface of large continents in zones which coincide with the physico-geographical zones of those continents."

It is stated that notwithstanding the seeming complexity of this classification, "its fundamental feature is the general statement that soil is the product of the conditions of its development, and that the peculiarities of soils are closely interrelated."

Soil investigations, I, K. O. Björlykke (*Tidsskr. Norske Landbr., 15 (1908), No. 11, pp. 496–504*).—A discussion of the principles underlying the problem of soil studies. In this article considerable attention is given to American work in this line, particularly to that of Hilgard.

Biochemical studies in forest soils, R. Albert and A. Luthier (*Jour. Landw., 56 (1908), No. 4, pp. 347–370; abs. in Chem. Zentbl., 1909, I, No. 7, p. 572*).—The studies, which were made with four diluvial forest soils, included determinations by Remy's method of putrefactive capacity under different conditions of season and water supply, nitrifying power by the Buhlert and Fickendey method, fermentative power for soluble carbohydrates by the Remy method, and physical and chemical examinations of the soils. The studies reported are considered preliminary to further investigations and therefore few con-

clusions are drawn. The results in general indicate the usefulness of Remy's methods of study.

A certain parallelism was observed to exist between biological activity and the carbohydrates, lime, mineral matter, and fine particles of the surface soil. The character of the humus appeared to be of more importance than its total amount. Determinations of absorptive power for nitrogen according to Knop's method and of hygroscopicity according to Mitscherlich's method proved of value in judging the character of the soils. Determinations of free acids in humus by Süchting's method were found to be of little value.

Chemico-agricultural study of the soils of Poggiomarino, S. de Grazia (*Ann. R. Scuola Sup. Agr. Portici, 2. ser., 7 (1907), pp. 26*).—Poggiomarino is a district in the province of Naples, its soils being of volcanic origin. The mechanical analysis, litho-mineralogical analysis of the coarse material, physico-chemical analysis (Schloesing), and a brief chemical analysis of soil from seven points in the region are given and discussed at considerable length. In general the soil of the region may be classified as fertile.

A remarkable accumulation of nitrogen, carbon, and humus in a prairie soil, F. J. Alway and C. E. Vail (*Jour. Indus. and Engin. Chem., 1 (1909), No. 2, pp. 74–76*).—Analyses of 2 types of soil, bowlder clay and lacustral clay, from the experimental farm at Indian Head are reported. The samples of lacustral clay were taken from the summits of hummocks which are a characteristic feature of the area under consideration, as well as from rifts between the hummocks. No marked difference was observed in the composition of the till and the soil from the summits of the hummocks. The rifts, however, contained more than twice as much humus (7.18 per cent), humus nitrogen (0.46 per cent), total nitrogen (0.84 per cent), and carbon (10.59 per cent) as the soil from the tops of the hummocks.

Soil acidity in its relation to lack of available phosphates, C. W. Stoddart (*Jour. Indus. and Engin. Chem., 1 (1909), No. 2, pp. 69–74; abs. in Jour. Soc. Chem. Indus., 28 (1909), No. 6, p. 320*).—In a previous paper (E. S. R., 18, p. 1024; 19, p. 17) it was shown that acid soils are as a rule in need of phosphates.

Further study of typical acid and neutral soils, more particularly the relation of phosphoric acid to humus, showed that the phosphoric acid content of the humus was about the same in both acid and nonacid soils. The acid soils contained a higher percentage of total phosphoric acid in combination with iron and aluminum and less in combination with calcium than the nonacid soils.

Some of the results obtained indicate that the phosphorus of humus may not be available to plants. Fifth-normal nitric acid was found to be an excellent indicator of soil needs with respect to phosphates, due to the fact that it determines with accuracy the amount of calcium phosphate in soils. The general conclusion is reached that as far as Wisconsin soils are concerned, when the percentage of phosphoric acid soluble in fifth-normal nitric acid falls below 0.015 the soils will respond to phosphate fertilizer.

The problem of our unproductive lands, T. Cherry (*Jour. Dept. Agr. Victoria, 7 (1909), No. 1, pp. 18–25*).—The lands referred to include "first approximately 4 million acres of the inferior and poor parts of the Mallee; second, at least double that area of hilly country forming the main part of the Great Dividing Range and its northern and southern spurs; and third, perhaps million acres of the sandy land along the coast. The total area is at least one-fourth of the entire extent of Victoria."

The composition of the soil of these areas as compared with that of other parts of Victoria is shown in the following table:

Results of analyses of Victorian soils.

	Nitrogen.	Phosphoric acid.	Potash.
	Per cent.	*Per cent.*	*Per cent.*
Rich western district land	0.250	0.150	0.300
Average northern wheat land	.110	.065	.300
Average coastal plain land	0.040– .350	0.010– .100	0.010– .150
Average hill soils	.025– .150	.040– .080	.100– .300
Average Mallee soils	.025– .200	.005– .100	.200–1.000

One prominent physical characteristic of these soils is the very slight difference between surface soil and subsoil. Potash is as a rule very abundant in the soils and nitrogen is generally fairly abundant, but phosphoric acid is deficient. Lime is a prominent constituent, in many cases running as high as 10 to 25 per cent. Practical trials indicate that the use of manure and phosphates and thorough cultivation are among the most efficient means of improving these soils.

On the effect of various mulching materials on the productiveness of soils. CLAUSEN (*Illus. Landw. Ztg., 28 (1908), No. 99, p. 846; abs. in Chem. Abs., 3 (1909), No. 6, p. 684*).—Comparative tests of sand, peat, and sawdust are reported. It was found that the use of an amount of peat corresponding to only 1.6 per cent of the amount of soil increased the yield about 25 per cent.

Fixation of free nitrogen, nitrification, etc., A. KOCH (*Jahresber. Gärungs-Organismen, 16 (1905), pp. 352–389*).—This is a review of investigations reported during 1905 on fixation of free nitrogen, denitrification, nitrification, and related subjects, more particularly fermentative changes occurring in manure.

Contribution to the knowledge of the chemical processes involved in the assimilation of free nitrogen by Azotobacter and Radiobacter, J. STOKLASA ET AL. (*Centbl. Bakt. [etc.], 2 Abt., 21 (1908), Nos. 15–16, pp. 484–509; 20–21, pp. 620–632, pls. 3; abs. in Jour. Chem. Soc. [London], 94 (1908), Nos. 552, II, p. 880; 533, II, p. 975; Jour. Soc. Chem. Indus., 27 (1908), No. 23, p. 1167*).—This article discusses the morphology and biology of *Bacillus radiobacter* in the light of recent investigations, and reports investigations on the isolation of this organism and to test the behavior of Azotobacter and Radiobacter in mixed and pure cultures; the rate of nitrogen fixation of mixed and pure cultures of the 2 organisms; the influence of different kinds of carbohydrates on nitrogen fixation; the behavior of the organisms in the presence of sodium nitrate; the consumption of carbohydrates in the assimilation of free nitrogen by *Azotobacter chroococcum;* the intensity of respiration of *A. chroococcum;* chemical processes involved in the breaking down of glucose and mannite by the respiration enzym of Azotobacter; the metabolism balance of *A. chroococcum*, Beijerinck; production of hydrogen in the metabolic processes of *A. chroococcum*, B.; behavior of phosphorus of various phosphatic nutrients in the Azotobacter mass; nuclein in the bacterial mass of *A. chroococcum* and in the organism itself; and chemical analysis of the bacterial mass of *A. chroococcum* B.

It is shown that these organisms are widely distributed in nature and are especially abundant in soils having vigorous growth of blue-green algæ. They do not occur, however, in high-lying soils of the Alps. Radiobacter has only a slight power of fixing nitrogen as compared with Azotobacter, and the fixing

power of the latter is but slightly increased by symbiosis with Radiobacter. Of the sugars tested as sources of carbonaceous food of the organisms, l-arabinose gave the best results, and rhamnose the poorest. With dextrose 99 to 224 gm. of sugar was converted into carbon dioxid for every gram of nitrogen fixed. The results obtained with the various sugars suggest that the furfuroids of the soil are the best source of food for Azotobacter. Nitrate of soda inhibited nitrogen fixation, but apparently was not as good a food as free nitrogen. It was found that nitrite and ammonia were invariably formed when nitrate of soda was used in the culture medium. Radiobacter was shown to be a powerful denitrifier, liberating free nitrogen from nitrate and exhibiting intense respiration.

Analysis of the bacterial mass produced in the cultures showed ash 8.6 per cent, phosphoric acid 4.9 per cent, potash 2.4 per cent, and nitrogen 11.3 per cent.

Nitrogen and nitragin, A. J. Ewart (*Jour. Dept. Agr. Victoria, 7 (1909), No. 1, pp. 36–39*).—This article discusses briefly the nature and use of commercial cultures of organisms which assimilate free nitrogen, and explains the conditions under which such cultures are likely to be beneficial. The general conclusion is that in the present state of knowledge of the subject the use of these cultures is not to be recommended except under "very special conditions." "The net result of the activity of soil bacteria in rich, well-manured soils is to produce a loss rather than a gain of nitrogen, and hence no advantage is to be expected by the addition of cultures of any kind of bacterium to such soils."

The inoculation of leguminous crops, F. J. Chittenden (*Jour. Roy. Hort. Soc. [London], 34 (1908), No. 2, pp. 231–254, pl. 1, fig. 1; 34 (1909), No. 3, pp. 491–499*).—In experiments at Wisley Garden in 1908 with peas treated with the inoculating material prepared by Professor Bottomley of Kings College, it was found in one series of experiments that "7 out of the 12 plats on which inoculated seed was sown gave smaller crops than the corresponding uninoculated plats, and one gave an equal crop. . . . The crop from the inoculated seed was not better in any way than that from the uninoculated, nor did it reach maturity earlier." In a second series of experiments "only 7 out of 24 rows of inoculated seed gave a greater yield than the uninoculated, one gave an equal yield, and 16 gave a smaller."

Watering peas with the inoculating material gave like results.

The general conclusion drawn is that the inoculation of leguminous crops with the material used is not likely to prove beneficial in ordinary garden soils.

Experiments on the value of nitro-bacterine, C. T. Gimingham (*Gard. Chron., 3. ser., 45 (1909), No. 1152, pp. 59, 60*).—Experiments with peas on very poor and on well manured garden soil at the Southeastern Agricultural College, Wye, are reported. "There was no evidence of any kind to show that the slightest benefit had been obtained by the use of 'nitro-bacterine' on either type of soil."

Experiments on the value of nitro-bacterine, F. Keeble (*Gard. Chron., 3. ser., 45 (1909), Nos. 1150, pp. 20, 21; 1151, pp. 35, 36*).—The results obtained by Chittenden (noted above) are discussed, and experiments of a similar character made on the grounds of the botanical laboratory of University College, Reading, are reported.

It was found in these experiments that the increase of yield from inoculated seed was so small that it did not represent a sufficient increase of profit to make the use of nitro-bacterine on ordinary garden soils of practical value. To this extent the results confirm those reported by Chittenden, but they do not confirm the conclusion that inoculation generally decreases the yield.

Experiments on the value of nitro-bacterine, F. J. Chittenden (*Gard. Chron., 3. ser., 45 (1909), No. 1153, pp. 68, 69*).—Attention is called to certain errors which occurred in a previous report tending to exaggerate the reduction in yield from inoculated seed.

Nitro-bacterine, G. Henslow (*Gard. Chron., 3. ser., 45 (1909), No. 1154, p. 92*).—Beneficial results from watering scarlet runner beans with culture solutions of the "nitro-bacterine" are reported.

Experiments with nitro-bacterine, W. B. Bottomley (*Gard. Chron., 3. ser., 45 (1909), Nos. 1154, pp. 91, 92; 1156 p. 114*).—Referring to experiments at Wisley, Wye, and Reading, noted above, the author calls attention to conditions of soil and fertilizing in those experiments which in his judgment account for the unfavorable results obtained.

Investigations on lime nitrogen and nitrogen lime, A. Sabaschnikoff (*Mitt. Landw. Inst. Leipzig, 1908, No. 9, pp. 77–123; abs. in Chem. Ztg., 33 (1909), No. 43–44, Repert., p. 202*).—Previous investigations on this subject are reviewed and laboratory investigations on decomposition in soil and fertilizer experiments in the field are reported, as well as investigations on the character and work of the bacteria which cause decomposition of lime nitrogen. Among the more important results obtained were the following:

It was again shown that a culture medium consisting of soil extract, 0.5 per cent of acid potassium phosphate, 0.1 per cent of asparagin, and 0.1 per cent of grape sugar furnishes a very good medium for decomposition experiments with lime nitrogen and nitrogen lime. Formation of ammonia occurs in media which do not contain asparagin and grape sugar, but the formation in this case is very slow. Heating the lime nitrogen solution produced no injurious effect, but to a certain extent promoted the formation of ammonia. Neither on heating nor on standing was dicyandiamid formed in lime nitrogen solutions. The substance produced by heating is very easily decomposed. It is apparently an isomer of dicyandiamid.

Carbon dioxid does not cause the formation of dicyandiamid. It does not retard, but to some extent promotes the cleavage of cyanamid. Calcium cyanamid solutions which had not been heated were decomposed by pure cultures of bacteria only when absorbent substances were present. This fact is of great importance with respect to the action of lime nitrogen and nitrogen lime on soils of low absorptive capacity, and the mixing of these substances with compost appears to be advisable in such cases.

The intensity of the cleavage of cyanamid varied widely in the same soil in the course of the year, depending more upon the time of the year than upon the weather. The nitrogen of lime nitrogen and nitrogen lime was converted in like amount into ammonia and its decomposition was brought about by the same bacteria. Among the very active organisms in the cleavage of cyanamid was *Bacterium erythrogenes*, which also is active in the cleavage of urea.

The chemical changes in lime nitrogen when used as a fertilizer, H. Kappen (*Centbl. Bakt. [etc.], 2. Abt., 22 (1908), No. 7–10, pp. 281–298; abs. in Chem. Zentbl., 1909, I, No. 4, pp. 310, 311*).—This is a further contribution to a controversy with Löhnis on this subject (E. S. R., 20, p. 123).

The decomposition of lime nitrogen, III, F. Löhnis and R. Moll (*Centbl. Bakt. [etc.], 22 (1908), No. 7–10, pp. 254–281; abs. in Chem. Zentbl., 1909, I, No. 4, p. 310*).—This article reviews previous observations and hypotheses relating to the decomposition of lime nitrogen, referring more particularly to the work of Kappen (E. S. R., 18, p. 1028) and reports further studies by the authors on the hydration of cyanamid, the influence of the soil on the decomposi-

tion of lime nitrogen, the formation and decomposition of dicyandiamid, and the relation of bacteria to the decomposition of lime nitrogen.

The authors conclude from their investigations that the decomposition of lime nitrogen in the soil takes place in the following way: By solution the calcium cyanamid is converted into calcium dicyandiamid $(CN.NH)_2Ca$. On standing of the solution, or more quickly under the influence of heat or the absorptive power of the soil particles, the lime of the cyanamid is set free. The cyanamid under the action of weak acids (carbon dioxid) or heating in the presence of basic substances (caustic lime) is converted into ammonium cyanate and finally into urea, the latter being converted into ammonium carbonate by the action of bacteria.

As Ulpiani found, there is no direct bacterial action on cyanamid. Bacteria do not attack dicyandiamid either in dilute or concentrated solution. In experiments on the decomposition of lime nitrogen in which soil is used it makes no difference whether the solution is heated or not.

Is dicyandiamid a poison for field crops? O. Loew (*Chem. Ztg., 33 (1909), No. 3, pp. 21, 22; abs. in Jour. Chem. Soc. [London], 96 (1909), No. 556, II, p. 177; Chem. Zentbl. 1909, I, No. 9, p. 785; Chem. Abs., 3 (1909), No. 10, p. 1197*).—Pot experiments with barley on humus garden soil, comparing dicyandiamid (0.75 gm. to 3.5 kg. of soil) on sterilized and unsterilized soil, ammonium sulphate, and no nitrogenous fertilizer, are reported.

The results showed that on sterilized soil dicyandiamid gave the same yield as ammonium sulphate. On unsterilized soil the growth of the plants was seriously interfered with as a result, in the author's opinion, of the formation of injurious compounds from the dicyandiamid through the action of the bacteria. It was noticed in the case both of sterilized and unsterilized soil that the use of dicyandiamid resulted in a drying up of the tips of the leaves of the barley, a result attributed to the excessive accumulation of the dicyandiamid in that part of the plant.

The structural formula of the dicyandiamid is discussed.

An observation on calcium cyanamid, J. Aeby (*Chem. Ztg., 33 (1909), No. 17, p. 145; abs. in Ztschr. Angew. Chem., 22 (1909), No. 15, p. 687*).—It is reported that a loss of 1.1 per cent due to the formation of acetylene was observed in a lot of calcium cyanamid left exposed to damp air on the wharves at Antwerp. This is attributed to excess of calcium carbid in the material resulting from imperfect methods of manufacture, and it is suggested that a guaranty of the content of this substance should be required in case of calcium cyanamid intended for extended transportation.

The assimilation of potash by plants, W. Krüger (*Ztschr. Ver. Deut. Zuckerindus., 1908, No. 631, II, pp. 739–750; Jahrb. Deut. Landw. Gesell., 23 (1908), No. 4, pp. 633–649; abs. in Chem. Abs., 3 (1909), No. 3, p. 350*).—Fertilizer experiments with sugar beets, rye grass, chicory, barley, rye, peas, potatoes, and other plants are reported, and the factors influencing the assimilation of potash are discussed. These are variety of plant, character and quality of soil, fertilizer, weather, etc., and the micro-organisms of the soil. Attention is called to the importance of the return of fertilizing constituents from the plant to the soil during the period of growth. The effect of good fertilization in offsetting injury from nematodes is emphasized. Lack of potash in the culture of sugar beets was not shown until the reserve of potash in the root had been consumed, when further development was checked.

Phonolith, so-called potash silicate, as a fertilizer, P. Wagner (*Mitt. Deut. Landw. Gesell., 24 (1909), No. 2, pp. 19, 20*).—Comparative tests of this material and of sulphate of potash on grass and tomatoes on sandy soils are reported, the results showing that the rock meal furnished so little assimilable

potash that the potash-hunger of the plants was not satisfied. Apparently the potash of this material was very resistant to the solvent action of acids, soils, and plant roots.

On the fertilizing value of the phosphoric acid of vivianite, O. Böttcher (*Deut. Landw. Presse, 36 (1909), No. 7, p. 61; abs. in Chem. Ztg., 33 (1909), No. 25, Repert., p. 118*).—An impure vivianite derived from swamp deposits containing 15.02 per cent of phosphoric acid and 18.1 per cent of water was compared with superphosphate in pot experiments with oats. Taking the efficiency of superphosphate as 100, that of the vivianite was 22 to 30. The phosphoric acid is slowly available and the material has some fertilizing value, but not sufficient to pay for long transportation or much handling.

The phosphorites of Gafsa, Tebessa, and Cape Leuca, R. Rossi (*Ann. R. Scuola Sup. Agr. Portici, 2. ser., 7 (1907), pp. 16*).—The physical characteristics of phosphorite from these places are given, as well as a description of the preparation of the samples, processes of analysis, and tables showing the results of the analyses.

The average percentages of calcium phosphate shown by the analyses were: Gafsa phosphorite 56.48, Tebessa phosphorite 43.53, and Cape Leuca phosphorite 17.31. The percentages of calcium carbonate in the phosphates were high, being 15.56 in case of Gafsa phosphorite, 36.39 in Tebessa phosphorite, and 70.73 in Cape Leuca phosphorite.

Namban Creek phosphatic deposits, E. A. Mann et al. (*Jour. Dept. Agr. West. Aust., 17 (1908), Nos. 5, pp. 805–810; 6, pp. 980–982*).—Deposits of phosphatic guano occurring in caves in this district are described and analyses are reported showing phosphate of lime varying from 26.6 to 45.25 per cent, and nitrogen from 0.2 to 1.65 per cent. The larger proportion of the phosphoric acid was found to be soluble in citrate solution.

Phosphatic and gypsum deposits, A. Despeissis (*Jour. Dept. Agr. West. Aust., 17 (1908), No. 6, pp. 906, 907*).—Statistics of the consumption of fertilizers in Western Australia are given, with notes on deposits of phosphate and gypsum which have been discovered in that colony. It is stated that 16,486 tons of fertilizers were imported into Western Australia during the half year ended June 30, 1908. The occurrence of extensive deposits of both phosphate and gypsum is reported.

The present status of the nitrate industry of Chile, Gerlach (*Ztschr. Agrarpolitik, 7 (1909), No. 1, pp. 10–18*).—This article discusses the present and probable future supply of nitrate and the present business problems and organization of the industry.

The Chilean nitrate fields (*Mark Lane Express, 100 (1909), No. 4036, p. 119*).—Reference is here made to the report of the Chilean government inspector of nitrate, which states that the minimum stock in sight is 220,000,000 tons and that there is no danger of a failure of supply for a century at least.

Analyses of fertilizers, R. E. Rose (*Fla. Quart. Bul. Dept. Agr., 19 (1909), No. 1, pp. 1–6, 12–27, 31–35, 46–80, 133–161*).—The results of inspection of fertilizers during the year 1908 are reported, with the laws providing for this work and the rules and regulations adopted under the laws, and suggestions regarding the purchase and use of fertilizers. It is stated that inspection tags covering 133,224 tons of commercial fertilizers were sold during the year. This represents an increase of 8,618 tons.

Comparing the economy of high-grade and low-grade fertilizers, it is stated that "the high-grade fertilizers, for but little more than a third advance in price over the cost of the low-class goods, furnish two-thirds more plant food and five-sixths more commercial value." Those who require low-grade goods

are advised to purchase the necessary materials and have them mixed and bagged at the factory.

Commercial fertilizers. T. L. CALVERT (*Off. Rpt. Sec. Ohio Bd. Agr. on Com. Ferts., 1908, pp. 86*).—This is a report in the usual form on inspection of fertilizers licensed and analyzed in Ohio during the year 1908. The report also contains notes on trade values of fertilizer ingredients during the year and the text of the new fertilizer law which went into effect November 1, 1908.

AGRICULTURAL BOTANY.

Linnaeus's lectures on the cultivation of plants, M. B. SWEDERUS (*Uppsala Univ. Aarsskr. 1907, Linnéfest Skr. 1, pp. VIII+107*).—This is a translation into German of a series of lectures on the cultivation of plants that are supposed to have been delivered by Linnaeus at the University of Upsala about 1759. The manuscript was found in St. Petersburg a few years ago.

The weeds and suspected poisonous plants of Queensland, F. M. BAILEY (*Brisbane, 1906, pp. 245, figs. 408*).—Brief botanical descriptions are given of the orders, genera, and species of weeds and suspected poisonous plants of Queensland. In each instance the locality is named from whence the specimens were obtained and notes are given regarding their economic, noxious, medicinal, and other properties. With a few exceptions, a portion of each plant is illustrated.

Triple hybrids, H. DE VRIES (*Bot. Gaz., 47 (1909), No. 1, pp. 1–8*).—An account is given of studies of evening primrose hybrids in which the possibilities of so combining the species as to form triple and even quadruple hybrids are described. The author states that twin hybrids are produced when the pollen of *Œnothera lamarckiana* or of one of its derivatives is crossed with the European subspecies of *Œ. biennis* or of *Œ. muricata*. Triple hybrids may be produced by combining one of these with species such as *Œ. lata* and *Œ. scintillans*. The segregation of characters in the progeny is discussed.

The chemistry of plants, G. ANDRÉ (*Chimie Végétale. Paris, 1909, pp. XII+560, figs. 14*).—This is issued as a portion of Encyclopédie Agricole, published under the direction of G. Wery. While essentially an elementary work, the author designed this treatise for those who want to gain something more than a superficial knowledge of the processes of plant nutrition.

Chapters are given on the essential elements, structures, and function of vegetable material in general, after which the function of chlorophyll, formation of intermediate ternary compounds, assimilation and elaboration of nitrogen, chlorophyll and other plant pigments, germination, respiration, mineral composition, the forms under which various mineral substances are found in plants, and the rôle of water in the plant kingdom are discussed.

While the treatment is popular in its nature, the author has incorporated the results of many recent investigations and states the more recent theories on plant life and processes.

The bio-chemistry of animals and plants, O. ROSENHEIM (*Sci. Prog. Twentieth Cent., 2 (1908), No. 8, pp. 676–699; 3 (1908), No. 9, pp. 106–123*).—This is a summary giving the present status of the bio-chemistry of plants and animals, the first part of the paper being devoted to a discussion of the nitrogen cycle, including nitrification, denitrification, and nitrogen fixation, the synthesis of proteids, and the history, occurrence, properties, classification, etc., of proteids. In the second portion of the paper the significance of proteids in the plant is discussed, and the occurrence and function of a number of other compounds, such as phytotoxins, toxolecithides, lipoids, inosite, organic phosphoric

acids, etc., are described. The author concludes with a discussion of chlorophyll and its relation to hemoglobin.

Some problems and results of a study of the mechanics of plant anatomy, E. Küster (*Prog. Bot., 2 (1908), No. 4, pp. 455–558, figs. 24*).—The author discusses some of the problems of cell and tissue development in plants, the paper being based upon lectures given at the University of Halle in 1907. The literature of the subject is quite extensively reviewed.

The effects of variations in the inorganic salts and the reactivity of the external medium upon the nutrition, growth, and cell division in plants and animals, B. Moore, H. E. Roaf, and R. E. Knowles (*Bio-Chem. Jour., 3 (1908), No. 6–8, pp. 279–312, pls. 4*).—The results of experiments with acid and alkaline salts on the growth, cell division, etc., of various plants, and their effects on certain animals are described. The inorganic salts used were sodium hydrate, hydrochloric acid, potassium hydrate, sodium carbonate and bicarbonate, monosodium phosphate, and disodium phosphate. The plants experimented with were hyacinths and onions, the various solutions being made up on the basis of gram-molecular strengths.

Marked effects were produced upon the dividing cells of plant rootlets by small variations in the alkalinity or acidity of the medium. The range of ionic concentrations compatible with plant growth was a very narrow one. Short of the lethal dose there was found a marked stimulation by the alkali which was not found with the acid. The kation present appeared to have a specific effect, and potassium was more stimulating than sodium to both rootlets and foliage leaves. The phosphatic anion had a special effect upon the flower, causing an increase in size at optimum strength. At higher concentrations, irregular inflorescences with packed florets on dwarfed stalks were obtained.

The cytological effects of the different inorganic salts were studied, and there was found to be an absence or depression of nuclear division with the acid, and a thickening of cell walls. With the alkalis there was an increase in nuclear division, changes in chromosomes, and the cell outlines became obscured.

Both acid and alkaline phosphates at optimum concentrations caused increased growth in amphibia. In the case of the alkaline salts, higher concentrations resulted in death, preceded by a stage of hyper-excitability.

The effect on mammals showed that either alkaline or acid phosphates in the proportion of 0.26 to 0.38 gm. per kilogram of body weight caused an increased metabolism with diminishing body weight, and finally death.

The distribution of the indispensable inorganic nutrients in bean seedlings, II, L. von Portheim and M. Samec (*Flora, 99 (1909), No. 3, pp. 260–276*).—In a previous publication (E. S. R., 19, p. 426), the distribution of the more essential inorganic substances in bean seedlings when grown in Knop's solution with and without lime was shown. In the present paper an account is given of the distribution of these same compounds in bean seedlings with reference to the calcium and magnesium ratios. Analyses are reported showing the dry weight; ash; percentage of lime, magnesia, potash, phosphoric acid, sulphuric acid, chlorin, and iron oxid in the ash; and the weight of lime, magnesia, potash, and phosphoric acid in the ash of 250 of the seedlings. The data are grouped to show the amount of these different compounds in seedlings grown in distilled water and in normal solutions of the nitrates of lime and magnesia and various mixtures of these compounds.

The plants became diseased when grown in distilled water and in the solutions containing magnesium nitrate, the roots being stunted, browned, and often rotten. A mixture of the two compounds in the nutrient solution resulted in an increase in the amount of magnesia taken up and a reduction in the proportion

of lime. The slight increase in the magnesia content in the plants grown in the solutions containing lime and magnesia is believed to be due to the protective or neutralizing action of the lime.

The phosphorus nutrition of plants, Cavalier and Artus (*Trav. Sci. Univ. Rennes, 6 (1907), No. 1, pp. 132–139*).—A study was made of the availability of different sources of phosphorus for the nutrition of maize grown in sand and watered with nutrient solutions that varied only in the phosphorus compound employed.

In the cultures, which were maintained for 92 days, the same amount of phosphorus was added to each, the calculated quantity being 2.14 gm. The various sources of phosphorus were sodium orthophosphate, pyrophosphate, metaphosphate, and phosphite as inorganic compounds, and potassium monoethylphosphate, sodium diethylphosphate, triethylphosphate, and monoallylphosphate, and calcium glycerophosphate as organic compounds. The latter is said to be a commercial preparation, while for the others the author made and purified his own compounds. At the end of the experiment, the total weight, ash, phosphorus content, etc., for the different plants were determined.

All the treated plants were better developed than the checks, except in the lot where the glycerophosphate was used. This substance, or impurities which it contained, proved injurious to all the plants, greatly reducing their development. There was little or no difference in the proportion of phosphorus in the dry matter of the different lots of plants, but where an actual increase in phosphorus was noted, it was accompanied by an increased growth of the plants, hence by greater dry weight.

The experiments show that plants are not necessarily restricted to the orthophosphoric acid salts for their phosphorus supplies, but that maize is capable of taking phosphorus from a number of other organic and inorganic compounds.

Phosphorus and the formation of amino acids by the higher plants, F. Scurti (*Gaz. Chim. Ital., 38 (1908), II, No. 2, pp. 272–275*).—According to the author, a correlation exists between the presence of phosphorus and the formation of proteids in the higher plants. This correlation is not limited to the proteid nitrogenous bodies, but also pertains to the amino acid group of compounds, and probably plays an important rôle in the synthesis of all albuminoid substances in plants.

The decomposition of sugar during the processes of respiration, P. B. Jensen (*Ber. Deut. Bot. Gesell., 26a (1908), No. 9, pp. 666, 667*).—The author states that the decomposition of sugar during alcoholic fermentation is not a single process but involves two stages. The intermediary product is said to be dioxyacetone. In the process of decomposition the dextrose is broken down into dioxyacetone, which may further change into carbon dioxid and alcohol, or, by the addition of oxygen through the action of oxydase, into carbon dioxid and water.

On the "strength" and development of the grain of wheat, W. E. Brenchley (*Ann. Bot. [London], 23 (1909), No. 89, pp. 117–139, pls. 2, figs. 5*).—This investigation was inaugurated with a view to determining the question of the "strength" of wheat from a biological standpoint. The term "strength," according to the author, is by no means exactly defined, but for the purpose of his investigation it is taken to indicate the capacity of wheat to produce a large, well-piled loaf of bread.

In the author's summary it is stated that no cytological differences can be observed between wheat grains of different varieties, grown under similar conditions, which produce flour of varying strengths, nor are there any differences indicative of strength to be found in the developing grains of one variety of wheat grown in the same field, under similar soil and climatic conditions, but

subject to radical differences in manuring. The reputed difference in strength between grains of the same variety grown under identical conditions, but cut green and dead ripe, is not associated with any significant cytological change.

Examination of the different grades of flour obtained during the various processes of roller milling shows that the cells of the aleurone layer very rarely get into the flour, but remain attached to the bran. The endosperm of the seed during its development arises in the first place by free cell formation, but after about a week wall formation begins, starting from the periphery of the embryo sac and proceeding inward. The peripheral layer is marked off about two weeks after pollination, and develops into the aleurone layer. The deposition of starch grains begins in the middle of the flanks of the endosperm at the lower end of the grain and proceeds upward and outward. Reserve nitrogenous materials enter at the same time as the starch. During the process of ripening a disorganization of the endosperm nuclei takes place, caused by the increasing pressure of the surrounding food stuffs. The nuclei lose their nucleoli, become deformed, and finally appear as a fine network spread out between the intruding starch grains.

A study of the development of the embryo was made, and it was found to be normal, but a fifth lateral rootlet is said to be formed in addition to the two pairs of laterals usually described.

The presence of amylase in old seeds, Brocq-Rousseu and E. Gain (*Compt. Rend. Acad. Sci. [Paris], 148 (1909), No. 6, pp. 359–361*).—In previous accounts (E. S. R., 20, p. 130), the authors have shown that the duration of diastases in seeds is limited. In the present report the results are given of a study of wheat taken from museum specimens that are known to be 50 years old.

In this investigation dextrinase and amylase were found present and still capable of transforming starch into sugar. The experiments did not permit of definite conclusions as to whether the diastatic action was retained with its initial power for the entire period. They confirmed the conclusion, however, that the power of germination in seeds is not entirely due to the action of certain diatases, as the seeds in no case would germinate although the diastase was present.

The presence of oxydases in india rubber, D. Spence (*Bio-Chem. Jour., 3 (1908), Nos. 4, pp. 165–181; 6–8, pp. 351, 352*).—A study has been made of the latex of Para rubber trees and also of fresh latex from *Funtumia elastica*, from which the author is able to show the presence of oxydases in the latex. He believes that the darkening in color of raw rubber is due to an oxydase which is associated with the protein or the so-called insoluble constituent of the rubber. Further experiments are to be carried on to determine how far the oxydase is responsible for certain other changes occurring in raw rubber, such as decomposition, oxidation, and the like.

The second paper reports an examination of 4 separate samples of latex from *Hevea brasiliensis*, Para rubber, in each of which was found evidence of the presence of an oxidizing enzym, the chemical properties of which have not yet been studied.

The author suggests that the caoutchouc is probably a reserve food material for the plant, and that to account for its formation and subsequent decomposition the presence of oxidizing enzyms must be considered.

Relation of plant growth and vegetation forms to climatic conditions, J. J. Thornber (*Plant World, 12 (1909), No. 1, pp. 1–7*).—An account is given of studies on the relation of plant growth to climatic conditions in different parts of Arizona, particular attention being given to winter and summer annuals. The author claims that on account of temperature conditions, it is impossi-

ble to grow successfully during the winter months the annual summer flowering plants which do not survive the intense heat of the summer, or to grow during the summer months the annual flowering plants generally referred to as winter-growing species. This also holds true for vegetables.

Plant culture in diffused daylight, A. BURGERSTEIN (*Verhandl. K. K. Zool. Bot. Gesell. Wien, 58 (1908), No. 6–7, pp. 322–329*).—Experiments are reported on the growth of about 20 species of ornamental plants in diffused light and in beds so situated as to receive direct sunlight for a few hours in the morning and evening and diffused light during midday.

Almost without exception the growth of the stalks, leaves, flowers, and seed capsules was greatest in what is termed the mixed light. The plants remained green for a longer period, and flowered more abundantly. The dry weight of the plants which received the early and late sunlight was from 1.4 to 11.2 times as great as that of similar species grown in diffused light. Similar conditions were noted for flower and seed production.

The influence of light on the development of fruits and seeds, W. LUBIMENKO (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 24, pp. 1326–1328*).—Studies by the author have shown that while a certain amount of illumination is absolutely essential during the early stages for the formation of fruit, after a fruit has passed a short stage of development it is possible to complete its development in greatly reduced light. If self-pollinated plants are inclosed before the pollination of their flowers in black or white bags fastened to the plants, in general but very few normal fruits will be formed, due to the insufficient illumination. In one instance 30 heads of wheat were inclosed in black sacks before the pollination of the flowers and only 3 to 5 grains were produced to the head, while heads in the same stage of growth inclosed in white bags gave from 16 to 25 grains per head. Similar results were obtained with peas.

Studies made with a considerable number of plants show that there is an optimum for the illumination required for the development of dry matter in fruits and that this optimum corresponds to a somewhat attenuated illumination. The maximum dry weight of seeds and pericarp of a number of fruits, such as currants, cherries, apples, pears, etc., corresponds to illumination slightly less than the maximum of light. It is shown also that the acidity of the fruit diminishes with the illumination. In the majority of cases fruit inclosed in sacks was less acid than that maturing in the open. On the contrary, the material reduced by Fehling's solution was greater in those fruits which were inclosed in sacks and less in those ripening normally.

The influence of radium rays on a few life processes of plants, C. S. GAGER (*Pop. Sci. Mo., 74 (1909), No. 3, pp. 222–232, figs. 13*).—This paper is a nontechnical account of some of the more striking results described in the author's memoir on the effects of the rays of radium on plants (E. S. R., 20, p. 929).

The author summarizes his investigations, stating that radium acts as a stimulus to the various physiological processes of plants. If the strength of the radium, the duration of exposure, and other conditions are suitable, the response is an excitation of function, but if the radium is too strong and the exposure too prolonged, the result is a retardation, or a complete inhibition of function, or even the death of the plant. There were found to be differences in sensitiveness between individuals, and also between different species and different tissues.

Electroculture, J. B. MARTIN (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 29 (1908), No. 41, pp. 439–442*).—An account is given of some experiments carried on by Lieutenant Basty for the past 7 years in the vicinity of Tours,

France, to determine the effect of electricity applied before germination and during the various stages of development of plants on the earliness, abundance, and quality of fruit. The plants experimented with were potatoes, sainfoin, white mustard, spinach, beets, hemp, flax, barley, and wheat.

The experiments show that there is an evident stimulating action of atmospheric, dynamic, and static electricity on the growth of plants, practically all of the plants being more vigorous, blooming earlier, and giving a larger yield of leaf, stem, tuber, or other part compared.

Comparisons of the beginning of development of perennial and annual plants, G. ANDRÉ (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 26, pp. 1485–1487*).—A study was made of the walnut and horse-chestnut in the first year or two of growth and comparisons made with the dry material in annual plants.

In the annual plant the dry material in the young root is relatively high, representing about one-tenth of the total weight of the plant. This weight diminishes toward the end of the period of growth, when it does not represent more than 3 to 5 per cent of the total dry weight of the plant. In the case of the perennial plants the weight of the root is relatively low and is much less than with similar annual plants.

A study of the distribution of the mineral matter at different periods of growth showed that in annual plants it amounted to about one-seventh of the weight of the plant at the beginning of vegetative growth, and by the time of flowering to about one-fifteenth. With the walnuts and horse-chestnuts the proportionate weights were from about one-fiftieth to one-thirtieth.

Studies were also made of the distribution of phosphoric acid in the roots. The content was found to be relatively high at all periods of growth, but the proportionate amount was somewhat less in the walnut than in the horse-chestnut. The phosphoric acid continues to be taken up from the soil through the roots and supplied to the stem up to the end of active growth, when part of it is returned from the leaves before their fall. This translocation occurs in annual plants at the end of their period of growth.

Perennial plants during the first and second years of their growth behave very similarly to annual plants up to the time of their flowering. The absolute weight, however, of the roots of perennial plants is considerably greater than that of the annuals, and the reserve mineral materials are greater, particularly in the roots, where phosphoric acid among the mineral elements is stored for use in later stages of growth.

The perennation of the clover dodder (Cuscuta epithymum), F. C. STEWART and G. T. FRENCH (*Torreya, 9 (1909), No. 2, pp. 29, 30*).—Most botanical writers are stated to have considered the species of Cuscuta as annuals, although as long ago as 1868 Kühn claimed that clover dodder lived over winter on clover and alfalfa plants in Germany. This statement has been questioned by a number of investigators and confirmed by others, but apparently until quite recently there was no published record of any dodder living over winter in the United States.

The authors' investigations during the past 3 years have indicated that clover dodder lives over winter in New York alfalfa fields, hibernating on the crowns of alfalfa, red clover, and certain weeds, among them the fleabane (*Erigeron annuus*) and yellow trefoil (*Medicago lupulina*). It has also been found passing the winter on dandelion. The fleabane and the yellow trefoil are generally classed as annuals, but they are regularly biennial in New York.

Experiments have shown that it is quite possible, by placing the dodder-infested crowns of plants in a moist chamber for a few days, to secure an abundant growth, indicating that the plant passes the winter in a viable state. It appears probable that this is the principal method by which it is propagated.

On the parasitism of Siphonostegia, S. KUSANO (*Bul. Col. Agr. Tokyo Imp. Univ., 8 (1908), No. 1, pp. 51–57, figs. 5*).—The author has been carrying on studies on Japanese phanerogamic parasites, and in this paper gives an account of *S. chinensis*, which appears to be a hemiparasite. It is a herbaceous plant common in grassy fields of Japan. A detailed account is given of its anatomical structure.

Studies on Æginetia indica, S. KUSANO (*Bul. Col. Agr. Tokyo Imp. Univ., 8 (1908), No. 1, pp. 59–78, pl. 1*).—This paper gives an account of some of the facts in the life history of *Æ. indica*, a phanerogamic parasite common in Japan, where it occurs on certain species of monocotyledonous plants. Experiments have shown that the seed of the parasite will not germinate unless it has the stimulus of the roots of other plants. The stimulation may be induced by the presence of the roots of a great many plants, but its parasitism is limited to certain species of Cyperaceæ, grasses, ginger, cannas, etc.

FIELD CROPS.

Report on the agricultural and botanical departments, Barbados, D. MORRIS (*Imp. Dept. Agr. West Indies, Rpt. Agr. and Bot. Depts. Barbados, 1898–1907, pp. 37, figs. 14, dgms. 2*).—This report covers the period 1898–1907, and includes a review of the sugar-cane experiments since 1884. The work with cotton, bananas, and other crops is also noted.

Since 1898, when the Imperial Department of Agriculture was established, about 30,000 canes have been raised from seed. In 1904 work was begun which resulted in securing 5 hybrid sugar canes through artificial cross-pollination. The raising of seedling canes resistant to disease and yielding a large amount of sugar is also one of the principal lines of work. The history of these experiments is given in full and the results secured each season are briefly summarized. During recent years a number of canes are being tested which seem to give even better results than B. 147 and B. 208, which have given very satisfactory yields. Among these canes are B. 1753, B. 3390, B. 3412, B. 3675, B. 3696, B. 3747, B. 6204, and B. 6450.

The results of fertilizer experiments with sugar cane are summarized for the past 13 years. In the nitrogen series the most satisfactory yields were obtained where 60 lbs. of nitrogen as sulphate of ammonia was applied in June, in addition to 80 lbs. of assimilable phosphates, and 60 lbs. of potash as sulphate of potash, the average yield being 7,911 lbs. of saccharose per acre.

In the superphosphate series of experiments the best results were secured on the plat which received only nitrogen and potash. In the basic slag series of plats the best result for 12 years was obtained on the plat which received 100 lbs. of phosphate as basic slag, the yield being 8,446 lbs. of saccharose per acre as compared with 8,406 lbs. on the check plat.

The best result in the potash series was obtained on the plat which received 80 lbs. of potash as sulphate of potash, in addition to 15 lbs. of nitrogen as sulphate of ammonia in January and 45 lbs. in June, and 80 lbs. of phosphate as superphosphate of lime applied in January. The average yield in this series was 7,739 lbs. of saccharose per acre.

Tillage experiments showed a difference of 2½ tons of canes per acre between the best and the poorest plat. The most favorable results were secured from close subsoiling, digging the cane holes, manuring, and cultivating in the usual manner, and the least favorable results were secured on the plats ridged with a disk plow, turning under farmyard manure 8 in. deep, planting the canes in rows at the bottom of the furrows, and cultivating.

The cotton industry in Barbados is described and the results of fertilizer experiments are reported. In determining the quantity of nitrogen needed to produce the best results it was found that the most satisfactory yields were secured when nitrogen as sulphate of ammonia was applied at the rate of 30 lbs. per acre, the increased yield amounting to 279 lbs. of seed cotton. In the phosphoric acid series 40 lbs. of phosphoric acid as superphosphate of lime produced the best effects, the increase in seed cotton being 281 lbs. per acre. The most satisfactory returns in the potash series were secured where 20 lbs. of potash as sulphate of potash was used. In these tests the increase of seed cotton per acre amounted to 196 lbs.

Nitrogen fertilizer experiments on meadows, Bachmann (*Landw. Wchnbl. Schles. Holst., 59 (1909), No. 2, pp. 22–24*).—Cooperative tests are reported in which sulphate of ammonia, nitrate of soda, and nitrogen lime were compared. In one experiment the plats were 0.05 hectare (about $\frac{1}{8}$ acre) in size and each received 25 kg. each of Thomas slag and kainit. The nitrogen was applied in 10 kg. of sulphate of ammonia and 10 kg. of nitrogen lime, each substance containing 20 per cent of nitrogen.

In 1907 the average yield of hay from one cutting on the plat receiving no fertilizer whatever was 62.5 kg., and on the plat treated only with Thomas slag and kainit 86.5 kg. The plat receiving one-fourth of the sulphate of ammonia in the spring and three-fourths in the fall gave 110.5 kg. of hay, the plat receiving the entire application of sulphate in April 133.5 kg., the one receiving the sulphate in two applications in spring 176 kg., and the plat treated with the nitrogen lime in one application early in April 165 kg. In 1908 the yields of hay on these plats without further fertilization were 125.5, 161, 183.5, 189, 203, and 207.5 kg. respectively.

The results of a second and a third experiment show that nitrate of soda given in two applications in the spring gave the best yields of hay, being followed by sulphate of ammonia and nitrogen lime, each given in a single application in the spring.

Manurial experiments on grass land, 1908, J. Percival (*Univ. Col. Reading, Dept. Agr. and Hort. Bul. 4, pp. 27*).—The cooperative fertilizer experiments on grass land were conducted at 13 centers. Nitrogen, phosphoric acid, and potash were applied in different combinations, the applications consisting of 1 cwt. of nitrate of soda, 5 cwt. of basic slag, and 3 cwt. of kainit per acre, with the exception that in the complete application only 2 cwt. of kainit was used. Barnyard manure was applied at the rate of 16 loads per acre.

The increase in crop as due apparently to the different fertilizer treatments was as follows: Nitrate of soda alone, 5 cwt.; kainit alone, 5 cwt.; slag alone, 10 cwt.; the complete fertilizer application, 15.25 cwt.; barnyard manure, 13.75 cwt.; slag and kainit together, 10.25 cwt.; slag and nitrate of soda, 12.75 cwt.; and nitrate and kainit together, 11.25 cwt. The herbage grown with the commercial fertilizer was of a much better quality than that produced with barnyard manure.

It was observed that soils containing less than 0.025 to 0.030 per cent of available phosphoric acid generally responded freely to the use of a phosphatic fertilizer such as slag or superphosphate. Soils containing less than 0.010 per cent of available potash gave increased yields and improved quality of grass when kainit or sulphate of potash were used.

Rotation experiment, R. B. Greig (*Aberdeen and No. of Scot. Col. Agr. Bul. 10, pp. 11–16*).—The rotation consisted of turnips, barley, and hay, and the standard application of fertilizers per acre comprised 20 lbs. of nitrogen, 100 lbs. of phosphoric acid, and 40 lbs. of potash. The results showed that super-

phosphate gave a profit of 20s. per acre, basic slag 17s. 3d., and ground Florida phosphate 5s. 9d., and the use of bone meal a loss of 27s. 3d. per acre. When these fertilizers were applied with barnyard manure they all gave a profit, the largest £4 2s. 7d. per acre over the unmanured plat being secured from ground Florida phosphate.

The utilization of straw, A. Grégoire (*Rev. Écon. Internat., 6 (1909), I, No. 2, pp. 438–448*).—The value of straw for litter, manure, and feeding is pointed out, and a résumé of experiments on the effect of straw in barnyard manure and on the preparation of straw for feeding purposes is presented.

Southern crops, edited by G. F. Hunnicutt (*Atlanta, Ga., 1908, pp. 245, figs. 10*).—This book treats of the culture of cotton, cereals, hay, forage and root crops, and also of several of the most common vegetables.

Cotton production in Egypt, F. C. Roux (*Rev. Écon. Internat., 6 (1909) I, No. 2, pp. 303–339*).—This article discusses the history of cotton culture in Egypt, the progress in its cultivation, and the systems of irrigation and drainage in use, and presents statistics on the production and commerce.

International Cotton Congress, Paris, 1908 (*Off. Rpt. Internat. Cotton Cong., 5 (1908), pp. 341*).—This is the official report of the Fifth International Cotton Congress held in Paris, June 1–3, 1908. The proceedings have a bearing on the various phases of the cotton industry, including statistics with reference to production and commerce, and papers on cotton growing in the United States, the Congo Free State, the French and German colonies, Asia Minor, and the Eritrean colony of Italy. Copies of the statistics issued by the International Federation of Master Cotton Spinners' and Manufacturers' Associations in regard to the consumption of cotton and stocks of cotton in spinners' hands are given in an appendix.

Potato variety tests by the German experiment station for potato culture, C. von Eckenbrecher (*Ztschr. Spiritusindus., 1909, Sup., pp. 3–56; abs. in Deut. Landw. Presse, 36 (1909), Nos. 15, pp. 159, 160; 16, p. 174*).—Cooperative tests were conducted in 1908 in 27 different localities of Germany with 20 varieties of potatoes, and the results secured in each individual test are reported in tabular form and described.

According to starch content the leading varieties were Agraria, Erste von Nassenheide, and Prof. Wohltmann, with 21.5, 21.3, and 21 per cent of starch, respectively. The leading varieties in productiveness and their yields were as follows: Hassia, 27,640 kg.; Alma, 25,010 kg.; and Fürstenkrone, 24,910 kg. per hectare. Arranged according to starch production, Prof. Wohltmann stood first with a yield of 5,180 kg., Böhms Erfolg second with 5,060 kg., and Switez third with 4,920 kg. per hectare.

Notes on the composition, disease resistance, keeping quality, and value for different uses of the varieties are given, and all results are tabulated in detail. Bojar, Switez, Brocken, Bohun, Böhms Erfolg, Erste von Nassenheide, and Prof. Wohltmann showed the highest keeping quality, and Alma, Bojar, Böhms Erfolg, Richter Imperator, and Brocken are considered the best varieties for eating purposes.

Potato variety tests conducted by F. Heine at Hadmersleben, 1908, W. Oetken (*Ztschr. Spiritusindus., 1909, Sup., pp. 57–66*).—In 1908, 129 varieties of potatoes were grown and yielded on an average 28,640 kg. of tubers per hectare (about 25,500 lbs. per acre), containing 17.90 per cent of starch and producing an absolute average yield per hectare of 5,126 kg. (4,562 lbs. per acre).

The beet-sugar industry, A. Blue (*Census and Statis. [Canada] Bul. 9, pp. 75, figs. 3*).—This bulletin describes the present development of the beet-sugar

industry in Canada, outlines its possibilities, and presents statistics with reference to sugar production, consumption, and commerce.

Tobacco, J. G. SMITH (*Honolulu Chamber Com. Ann., 1908, pp. 123, 124*).—The possibilities of tobacco culture in Hawaii are briefly discussed. It is stated that in 1908 about 65 acres were grown. It is estimated that the planting for 1909 will be from 300 to 500 acres and that the output for the next 3 years will be about 5,000 bales.

Notes on tobacco, J. VAN LEENHOFF (*Transvaal Dept. Agr., Farmers' Bul. 2, pp. 9, figs. 7*).—General notes on tobacco soils and seed-bed management are presented.

How to produce bright tobaccos, J. VAN LEENHOFF (*Transvaal Dept. Agr., Farmers' Bul. 10, pp. 16, figs. 4, dgm. 1*).—General directions for growing this type of tobacco and for curing it are given.

Report on turnip experiment, 1907, R. B. GREIG (*Aberdeen and No. of Scot. Col. Agr. Bul. 10, pp. 1–10*).—Nitrate of lime and calcium cyanamid were practically as effective as sulphate of ammonia. The cyanamid was applied with the seed and appeared to have no detrimental effect. Not taking the residual value into account, 5 cwt. of superphosphate was applied at a loss as compared with 2½ cwt. The results with high-grade and low-grade slag showed but little difference.

On the inheritance of strength in wheat, R. H. BIFFEN (*Jour. Agr. Sci., 3 (1908), No. 1, pp. 86–101, dgm. 1*).—The statement is made in this article that Red Fife after having been grown in England for 6 years is still equal in strength to the same variety grown in Canada. Culture tests have shown that in some localities this variety produces better crops than the common English sorts, while in others its yields are not profitable. It has also been brought out that the straw is not as strong as desirable. These facts have led to attempts to originate varieties having the productivity of common English wheats combined with the strength of the Red Fife.

Varieties with soft starchy grains were crossed with the Red Fife, which produces hard and translucent kernels. Among soft varieties, Rough Chaff and Rivet when grown on poor soil have rarely produced translucent grains, while in Squarehead Master, Browick, Standup, and others opaque and translucent grains have often been found in one and the same head when the varieties were grown on poor soil. In the experiments referred to, Red Fife was used more than any other variety as a strong parent, but a considerable number of varieties of Russian and Canadian wheats were also included.

The F. 1 generation of plants raised from the hybrid grains produced a grain of undoubted strength, but no indications of segregation into strong and weak grains could be detected at this stage. The F. 2 generation was grown under uniform soil conditions and each plant harvested separately. The grain types were sorted out, and in the cases examined the segregation into strong and weak types was perfectly obvious. On attempting, however, to count out the types represented in the F. 2 generation it was found that some crosses gave simple Mendelian ratios, while others could not be sorted with any accuracy. In one cross between Rough Chaff and Fife wheat 4 types of grain were present, strong red, strong white, weak red, and weak white. In the first 100 samples the proportions of these were 58 : 16 : : 18 : 8, and in the second, 59 : 18 : : 16 : 7, showing a reasonably near approach to the 9 : 3 : : 3 : 1 ratio expected when the characters redness and whiteness and strength and weakness are concerned. On the other hand, the F. 2 generation of a cross between Red Lammas and Red Fife contained plants with obviously strong and weak grains, but between the extremes there was a long series of plants which could not be classified with any certainty.

From 30 to 40 plants were raised from individuals of the F. 2 generation, these being selected for the most part for recessive chaff and color characters. The grain characters of parent and progeny were as follows: The F. 2 generation plants of Rough Chaff crossed with Fife, which were used in the test, represented 50 strong and 12 weak plants, and the types of the F. 3 generation showed 16 strong, 34 mixed, and 12 weak plants. In the case of the hybrid between Lammas and Red Fife the F. 2 generation plants sown represented 50 strong, 20 mixed, and 10 weak individuals, while the types of the F. 3 plants showed 50 strong, 3 strong and 17 mixed as corresponding to the 20 mixed in the F. 2 plants, and 10 weak individuals. It is pointed out that in the first case strength is dominant to lack of strength and that the heterozygotes are indistinguishable from the dominant homozygotes, but that in the second case the domination is not so sharply marked and the heterozygous individuals can be distinguished with a certain degree of accuracy. These examples were typical of some 30 others, but in most of them it was not considered necessary to determine whether the recessive lack of strength was pure from the moment of its appearance in the F. 2 generation. Forty of 66 strong cultures proved homozygous in all respects. The grain of the F. 3 generation was planted and the result demonstrated the value of Mendelian methods, for in this F. 4 generation the types appeared perfectly fixed.

The milling of these grains showed that they were strong wheats, and this character was so prominent that the miller without knowing the origin of the grain he was grinding noted that it ground like Manitoban wheat. Later, baking tests also confirmed the conclusion that strength and lack of strength segregate from one another in the F. 2 generation in the same manner as the morphological characters already examined.

In another experiment of this kind, a cross between Polish wheat (*Triticum polonicum*) and Rivet wheat (*T. turgidum*) was studied. The grain of the Polish wheat is brittle, translucent, and white in color, and has an average nitrogen content of 2.2 per cent, while the Rivet wheat is a typical starchy red wheat with a soft, mellow endosperm and an average nitrogen content of about 1.6 per cent. In the F. 1 generation the grain was uniformly brittle, translucent, and red. In the following generation the expected segregation into red and white, translucent and starchy grains occurred, but the mode was not as simple as in certain of the crosses referred to above. When the endosperm characters were taken into consideration it was found that many plants produced grain which could not satisfactorily be placed in either the starchy or the translucent class. The results of a further examination showed that the distribution of the nitrogen content is not affected by the shape of the glumes. It is stated that the failure to give sharp segregation into two or more groups in the F. 2 generation is not uncommon in crosses between cereals. In the F. 3 generation it was shown that all plants selected on the basis of short or long glume character bred true to these characters, and that when they were chosen from the intermediate series they proved heterozygous. The author points out that an analysis of the F. 3 generation is required to unravel the mode of segregation, when it will be found that the heterozygotes can be at once distinguished from the homozygotes and that they occur in the ordinary Mendelian proportions.

The analysis of the F. 2 generation showed that the grains with a translucent endosperm were high, and those with a mellow, starchy endosperm low in nitrogen. Grains flecked with starchy patches generally showed an intermediate nitrogen content, but the percentages varied widely. A slightly flecked sample, for instance, did not always show a higher content than one in which the grains were starchy. The plants producing translucent grain were considered to be

homozygous with regard to high nitrogen content and those with mellow grain were considered to be pure with respect to low nitrogen content. Analyses made of such bulk samples gave an average content of 2.4 and 1.6 per cent of nitrogen, respectively. The remaining samples were mixtures of translucent, starchy, and flecked grains, the last type being the most abundant. The occurrence in one F. 3 bunch of grain resembling each of the parental forms is taken as showing that the F. 2 plant from which it was descended was heterozygous in its endosperm characters. The total nitrogen contents of the majority of such F. 2 plants fell within the limits of 1.7 to 2.1 per cent. Thus, the nitrogen content from 1.3 to 1.6 or from 2.3 to 2.6 marked approximately the pure low or pure high types distinguishable from the heterozygotes by analyses only. The total number of plants with low nitrogen content was 26, 63 were apparently heterozygotes, and 21 were high in nitrogen.

The baking properties of a number of hybrid wheats, as determined by other investigators, are discussed, and the results taken in all are believed to indicate that the problem of breeding strong wheats suitable for English conditions offers no special difficulties. It is also believed that high yielding capacity and strength can be obtained in combination in the same variety, although it still remains to be determined whether high and low yielding capacity segregates at the F. 2 stage.

HORTICULTURE.

The scientific aspects of Luther Burbank's work, D. S. Jordan and V. L. Kellogg (*San Francisco, 1909, pp. XIV+115, pls. 14, figs. 20*).—This work comprises a paper entitled Some Experiments of Luther Burbank (E. S. R., 16, p. 773), by D. S. Jordan, and one entitled Scientific Aspects of Luther Burbank's Work, by V. L. Kellogg. These papers were originally published in *Popular Science Monthly*, and are here reprinted in book form with the view of acquainting general readers with the scientific character and value of Burbank's work.

Vegetable growing in Cuba, C. F. Austin and E. W. Halstead (*Estac. Cent. Agron. Cuba Bul. 13, pp. 44, pls. 6*).—This bulletin reports the practical results secured by the station during the past 3 years in growing and marketing various kinds of garden vegetables. Brief descriptions are given of the different varieties grown, including statements relative to their adaptability to the soil and climatic conditions of Cuba.

The home garden, E. E. Rexford (*Philadelphia and London, 1909, pp. 198, pls. 8*).—This is a popular work on vegetable and small-fruit growing for the use of the amateur gardener.

Report of the government horticultural experimental fields in South Holland for 1908, C. H. Claassen et al. (*Verslag Rijkstuinbouwproefvelden Zuid-Holland, 1908, pp. 120*).—Data are given for 161 cooperative cultural, variety, fertilizer, and spraying experiments with fruits and vegetables conducted at various localities in South Holland in 1908, under the direction of the professor of horticulture at Boskoop. Several experiments are also reported in which fruit grown in paper sacks was compared with fruit grown without such protection.

Contribution to the physiology of the graft. Influence of the stock on the scion, G. Rivière and G. Bailhache (*Jour. Soc. Nat. Hort. France, 4. ser., 10 (1909), Feb., pp. 133–135*).—Analytical data secured in 1908 are given of the must of grapes of *Chasselas musqué* grown upon its own roots and upon 10 different stocks, which appear to show, as the authors previously found in investigations with apples and pears (E. S. R., 19, p. 539), that the stock has a

decided influence in either enhancing or detracting from certain characteristics of the scion, which in this instance is indicated by variations in the sugar and acid content of the must.

New experiments in fertilizing grapes, J. Stoklasa (*Wiener Landw. Ztg., 59 (1909), No. 18, p. 182, figs. 3*).—In fertilizer experiments with grapes conducted at the Agricultural Physiological Experiment Station, at Prague, Bohemia, the plat manured with a combination of superphosphate and kainit gave larger yields of fruit and a higher sugar content in the must than the unfertilized plat. A complete fertilizer, composed of superphosphate, kainit, and ammonium sulphate, gave still better results.

The history of viticulture with special reference to the Rhenish Palatinate, F. Bassermann-Jordan (*Geschichte des Weinbaus unter besonderer Berücksichtigung der Bayerischen Rheinpfalz. Frankfort-on-the-Main, 1907, vols. 1, pp. 350, pls. 10, figs. 66; 2, pp. 351–690, pls. 7, figs. 45; 3, pp. 691–962, pls. 4, figs. 27*).—This extensive work may well be considered an encyclopedia of German viticulture.

Part 1 contains a general historical account of grape growing in Germany from the earliest period to the present time. Part 2 consists of a detailed historical study of grape growing and wine making. Part 3 discusses the various obstacles which have confronted German viticulture, of which the chief is shown to have been man by means of war, abuse of taxation, cultural restrictions, wine falsification, etc. Part 4 treats of the history of wine utensils, and of different kinds of wine, and contains a considerable amount of data relative to the cost of production, wages, yields, and returns in different periods. In part 5 the author has brought together and arranged in chronological order a vast number of more or less brief notes gleaned from documents of various kinds on wine growing, meteorological data, and wine prices covering a period of several centuries. Part 6 deals with the statistics of the wine trade and wine consumption. Part 7 concludes the work with an extensive bibliography of viticultural literature.

Date varieties for the Southwest, J. E. Coit (*Pacific Rural Press, 77 (1909), No. 11, pp. 201, 210, figs. 2*).—Descriptions are given of 3 Arizona-grown seedling dates which appear to be sufficiently valuable to warrant further propagation.

Scheme for the classification of the races of olives grown in southern Italy, M. Marinucci (*Schema di Sistemazione delle Razze d'Olivo Coltivate nell' Italia Meridionale. Naples, 1908, pp. 18*).—The author presents a system for classifying olives according to the shape of the fruit in which they are grouped under 5 main types: Fusiform, circular oblong, elliptical oblong, elliptical, and obovate. They are again subdivided into regular obtuse and acute, and irregular obtuse and acute. In the final subdivision they are classified as pure-bred and mongrel.

The coffee tree, E. P. Dieseldorff (*Der Kaffeebaum. Berlin, [1909], pp. 36, fig. 1*).—This pamphlet contains practical notes on coffee culture in northern Guatemala.

The mangoes of Bhagalpur, E. J. Woodhouse (*Dept. Agr. Bengal, Quart. Jour., 2 (1909), No. 3, pp. 168–187*).—Horticultural descriptions are given of a large number of varieties of mangoes, including those commonly found in the market at Bhagalpur as well as several received from the Sabour Experimental Farm. The characteristic shapes of the different varieties described are indicated by outline drawings.

The book of the pansy, viola, and violet, H. H. Crane (*New York and London, 1907, pp. VIII+106, pls. 15, figs. 1*).—This popular work treats in

detail of the methods of growing various kinds of pansies and violets, both for general purposes and for exhibition.

Classified list of daffodil names, 1908 (*London: Roy. Hort. Soc., 1908, pp. 51*).—This consists of an alphabetical list of all known daffodils, prepared by the Royal Horticultural Society of London. The different varieties are placed in one of 7 arbitrary divisions, based principally on measurements, as follows: Long trumpets, short trumpets, large cups, small cups, flat cups, doubles, and bunch-flowered. This system of classification is commended for trial for garden and show purposes.

The encyclopedia of gardening, T. W. SANDERS (*London [1909], 13. ed., pp. XV+466*).—This work consists of a dictionary of plants generally cultivated in gardens. It gives in alphabetical sequence the culture and propagation of hardy and half-hardy plants, trees and shrubs, orchids, ferns, fruits, vegetables, hothouse and greenhouse plants, etc., including the specific and common names. The present edition has been revised and brought up to date relative to cultural methods, varieties, nomenclature, etc.

Garden design—comparative, historical, and ethical, T. H. MAWSON (*Jour. Roy. Hort. Soc. [London], 34 (1909), No. 3, pp. 361–372, 378–383, figs. 6*).—This consists of two lectures on the above subject delivered before the Royal Horticultural Society in September, 1908.

The practice of garden design, T. H. MAWSON (*Jour. Roy. Hort. Soc. [London], 34 (1909), No. 3, pp. 384–393, figs. 2*).—The third lecture on the series noted above, in which the author offers several suggestions on the practical development of garden design.

The Royal Botanic Gardens, Kew, W. J. BEAN (*New York, Paris, London, Toronto, and Melbourne, 1908, pp. XX+222, pls. 60*).—This work contains a historical account of the Kew Botanic Gardens, together with a discussion of its aims, its work, and the leading principles on which it is conducted. Part 1 deals with the origin and development of the Royal gardens. Succeeding portions of the work discuss in detail English landscape gardening at Kew, Kew in its scientific aspects, plant collections (tropical and warm temperate), and the hardy plant collections. The work is well illustrated by reproductions in color and half-tone photographic plates.

A park system for the city of Cincinnati, G. E. KESSLER (*Cincinnati: Board of Public Service, 1907, pp. 54; pls. 15, figs. 6, maps 8*).—This consists of a comprehensive plan for parks and parkways in Cincinnati, prepared by the author at the instance of the Cincinnati Park Commission. Maps and illustrations are given showing the proposed park system as a whole and the treatment of various sections.

FORESTRY.

Trees, H. M. WARD (*Cambridge, 1908, vol. 4, pp. 161, pl. 1, figs. 147*).—This is the fourth volume of a series by the author, which was designed as a handbook of forest botany for the woodlands and the laboratory. Its publication was interrupted by the death of the author. The present volume treats of fruits, the previous ones treating of buds, leaves, flowers, and inflorescences (E. S. R., 17, p. 255).

The trees of Great Britain and Ireland, H. J. ELWES and A. HENRY (*Edinburgh, 1909, vol. 4, pp. VIII+713–1000, pls. 64*).—This is volume 4 of an extensive treatise which is being issued on the trees either native to or cultivated in Great Britain and Ireland (E. S. R., 20, p. 340). The volume, like the previous volumes, is divided into 2 parts.

In part 1 the varieties and species of the following genera are considered relative to their history, botany, distribution, cultural requirements, uses of the timber, etc.: Abies, Pseudotsuga, Castanea, Fraxinus, Zelkova, Celtis, Alnus, Betula, and Diospyros. Descriptions are also given of specimen trees growing in Great Britain. Part 2 is made up of illustrations and botanical drawings of the trees discussed in part 1.

Woods and forests in Jamaica, W. Fawcett (*West India Com. Circ., 23 (1908), Nos. 265, pp. 561–562; 266, p. 586; 267, pp. 609–610; 24 (1909), Nos. 268, p. 11; 269, pp. 36, 37; 270, pp. 58, 59; 271, p. 82; 272, p. 106*).—The author briefly discusses the important features involved in the management and exploitation of forests, and gives a reference list of some of the more important native timbers of Jamaica as well as such foreign timbers as might be grown to advantage. Each species of wood is briefly described relative to its distinguishing characteristics, economic value, and uses.

Micrography of the woods of Javanese trees, J. W. Moll and H. H. Janssonius (*Mikrographie des Holzes der auf Java vorkommenden Baumarten. Leyden, 1906, vol. 1, pt. 1, pp. 368, figs. 44; 1908, vol 1, pt. 2, pp. 369–568, figs. 30; vol. 2, pp. 160, figs. 21*).—The authors have conducted since 1903 an extensive investigation relative to the wood anatomy of Javanese species of trees. In the 2 volumes thus far published descriptions are given of the wood anatomy of some 230 species. Under each description is given the important literature of the species, notes on the material used in the study and its preparation, the reagents employed, and a detailed micrographical description of the wood and its component elements. Figures are given showing the sections of all dissimilar woods. Introductory chapters in volume 1 discuss the methods employed in the investigation, the preparation of the material, the nomenclature used, etc.

The pines of Mexico, G. R. Shaw (*Boston, 1909, pp. 29, pls. 22, map 1*).—This paper, which is the first of a series of publications of the Arnold Arboretum, consists of a systematic classification, botanical descriptions and drawings of the Mexican species of pines. The paper is based upon specimens collected by representatives of this Department and of the National Museum, and submitted to the author for identification, together with personal studies of these pines in their native country. Reference is given to the literature on the various species as well as to the different collectors and the specimen numbers in the National Museum. The author finds that numerous forms previously described as distinct species are but several varieties of a few species.

Monterey pine, F. Albert (*El Pino de Monterei, Pinus insignus o mejor Pinus radiata. Santiago de Chile: Min. Indus., 1908, pp. 26, figs. 19; An. Agron. [Santiago de Chile], 3 (1908), No. 2–3, pp. 376–399, figs. 19*).—A monograph on this species of pine with special reference to its culture in Chile. A list is given of its common names and synonyms, and the species is discussed relative to its botany, habitat, range, geographical distribution, the timber and its uses, climatic and soil requirements, methods of propagation, and silvicultural treatment.

Canary Islands pine, F. Albert (*El Pino Tea de las Canarias o Pinus Canariensis. Santiago de Chile: Min. Indus., 1908, pp. 36, figs. 14; An. Agron. [Santiago de Chile], 3 (1908), No. 2–3, pp. 333–366, figs. 14*).—A monograph on this species of pine similar to the one noted above.

Sand-binding plants, V. S. Iyer (*Indian Forester, 35 (1909), No. 2, pp. 82–97*).—The author gives a brief survey of attempts made in different countries and at different times to bind drifting sand, discusses climatic and other influences affecting plant growth in sandy regions, and describes several

peculiarities of root systems, stems, leaves, flowers, etc., of sand-binding and other maritime plants. A list is also given of typical sand-binding plants.

Timber, J. R. Baterden (*London, 1908, pp. 351, figs. 54*).—A practical work consisting of descriptive notes on the economic timbers of various countries, together with a discussion of subjects of importance to the timber industry, including the causes of decay and destruction, seasoning and impregnation, defects in timber, strength and testing, and "figure" in timber. The work is based upon the author's personal experience, supplemented by information secured from various authentic sources. A bibliography is appended.

Planting and care of a forest of evergreens, A. Knechtel (*Dept. Int. Canada, Forestry Branch Bul. 2, pp. 8, figs. 3*).—A brief, popular bulletin on this subject which discusses the collection of seed, nursery practices, planting operations, thinnings, and the final cut.

The new planting method in forests, M. Kozesnik (*Die neue Pflanzungs-Methode im Walde. Vienna, 1908, 3. ed., pp. 19, figs. 6*).—This is the revised edition of a short paper on this subject which was first published several years ago, and in which the author recommends and describes in detail a method of planting young trees which closely corresponds to the careful methods employed by private gardeners in setting out plants.

Forest valuation and forest statics, H. Stoetzer (*Waldwertrechnung und Forstliche Statik. Frankfort-on-the-Main, 1908, 4. ed., pp. VIII+248*).—This is a manual of forest valuation and statics. In the introduction consideration is given to the importance, historical development, and literature of these subjects. Part 1 contains a general discussion of worth and price and treats in detail of the fundamental principles, execution, and application of forest valuation. Part 2 discusses forest statics relative to methods of estimating and their application.

Is permanent forestry justified from a financial point of view? K. Fredenberg (*K. Landtbr. Akad. Handl. och Tidskr., 47 (1908), No. 5–6, pp. 289–311*).—The results obtained in the management of a number of Swedish crown forests are given with the view of supporting an affirmative answer to the above question.

Report of the Pennsylvania Department of Forestry for the year 1907 (*Rpt. Penn. Dept. Forestry, 1907, pp. 197, pls. 19*).—This report includes a statement of the general operations of the department of forestry and of specific forest administration by foresters and other officers of the department, together with several papers dealing with practical phases of forestry.

Report of the superintendent of forestry, R. H. Campbell (*Dept. Int. Canada, Ann. Rpt., 1908, pt. 7, pp. 46, pls. 12*).—In addition to a general report of forest operations of the forestry branch of the Canadian Department of the Interior for the year 1907–8, reports are given by the officials in charge of the different divisions of the work.

The Dominion forest reserves, A. Knechtel (*Dept. Int. Canada, Forestry Branch Bul. 3, pp. 19, pls. 4*).—This bulletin contains a general account of the Dominion forest reserves relative to their purpose and administration. The following phases are discussed: Location and area, dates of formation, grazing on forest reserves, protection against fire, reforesting, removal of squatters, marking reserve boundaries, forest survey, kinds of timber, timber estimates, removal of timber, and the reserves as pleasure resorts.

Report of the Rocky Mountains Park of Canada, H. Douglas and N. B. Sanson (*Dept. Int. Canada, Ann. Rpt., 1908, pt. 5, pp. 26, pls. 27*).—This report embraces the annual reports of the superintendent of the Rocky Mountains Park, Yoho Park, and Glacier Park reserves, and of the curator of the museum, for the fiscal year ended March 31, 1908. The meteorological data for the year,

and numerous plates illustrating plant life and various scenes in the parks are appended.

Report on the reforestation of waste lands in southern Ontario, 1908, E. J. Zavitz (*Toronto: Ontario Dept. Agr., 1909, pp. 28, figs. 21*).—In this report the author describes and gives maps of the various districts of southern Ontario, discusses the present condition of the waste lands, and presents figures to show the financial possibility of artificially reforesting these lands at a profit. The conclusion is reached that on large areas where no seed trees of commercial species exist, it will be impossible to obtain satisfactory new natural growth within a reasonable time, and the policy of putting these lands under forest management is advocated.

Report of the superintendent of forestry, R. S. Hosmer (*Rpt. Bd. Comrs. Agr. and Forestry, Hawaii, 5 (1908), pp. 11–55*).—This is the customary annual report of the division of forestry. It discusses the present status of the forest reserves, the progress made in forest extension, miscellaneous forest work, the present status of rubber in Hawaii, and results of rubber tapping tests, which have been noted from another source (E. S. R., 20, p. 844). Reports of the district foresters and the forest fire service are also included, together with a summary of recommendations for further development of the work.

Report of the forest nurseryman, D. Haughs (*Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 5 (1908), pp. 56–62*).—A progress report on the work at the government nursery, the forestry experiment station at Makiki, the Nuuanu Station, and the Tantalus Forest, including a statement as to advice and assistance rendered for the year ended December 31, 1908.

Annual report of the director of forestry of the Philippine Islands for the period July 1, 1907, to June 30, 1908, G. P. Ahern (*Ann. Rpt. Dir. Forestry P. I., 1908, pp. 26*).—A progress report on the work conducted during the year by the divisions of administration and investigation, including a discussion of new legislation and miscellaneous matters pertaining to the Philippine forest service. The appendix contains tabular data relative to licenses, registration of woodlands, utilization of forest products, timber cut by leading licensees, important timbers by species, imports and exports, revenues, and expenses.

Para rubber cultivation, C. Mathieu (*Culture du Caoutchouc de Para. Paris, 1909, pp. II+201, figs. 46*).—This work, which is offered as a manual of rubber cultivation in Malaysia, is printed both in English and in French. Part 1 deals with the problems which confront the prospective settler, such as the selection and acquirement of land, location and construction of dwelling houses and other buildings, methods of living, the labor question, etc. Part 2 discusses rubber culture in detail, including the preparation of the land, nursery practices, planting operations, manuring, pruning and subsequent care, collecting latex, and preparation of rubber for market. Estimates are given relative to yields, expenditures, and returns.

Distribution of [Guayule] rubber in different parts of the shrub, T. Whittelsey (*Jour. Indus. and Engin. Chem., 1 (1909), No. 4, pp. 247–249, dgms. 2*).—Analytical methods and data are given of an investigation relative to the distribution of Guayule rubber in different parts of the plant.

In a previous paper on this subject (E. S. R., 17, p. 257), Endlich reported that the ratio of the rubber found in the bark to that found in the wood is approximately 7 : 2. The data secured from the present investigation indicate that the trunk wood contains no rubber, although it does contain a small percentage of a rubber-like resin which might be mistaken for rubber when the extraction is made directly with tetrachlorid. Analyses of the whole plant

gave 9.5 per cent pure rubber on a water-free basis, or, taking the mill weight of the material as a basis, 8 per cent. Inspection of the material prepared for analysis showed that the trunks were made up of 46.4 per cent bark and 53.6 per cent wood. Determinations made of 2 whole plants gave 54.6 and 57.8 per cent of bark, respectively.

[Rubber tapping experiments and mechanical tests of several Surinam woods], W. A. VAN ASBECK (*Dept. Landb. Suriname Bul. 15, pp. 17*).—This bulletin contains the results of tapping experiments conducted with *Hevea guyanensis* in 1908, including analyses of samples of the rubber, and notes on their valuation by different commercial firms. Data are also given on mechanical tests made with 5 Surinam woods.

The direct utilization of latex in the industries, L. MORISSE (*Le Latex: Son Utilisation directe dans l'Industrie. Paris, 1908, pp. 684, figs. 17*).—This work is offered as a résumé of the present state of our knowledge relative to latex. It consists of an exposition of the advantages of the author's secret process of coagulating latex, whereby the coagulated latex may be used directly for manufacturing purposes without first being converted into crude rubber. All of the author's early and recent papers on the subject of harvesting and coagulation of latex are included, together with the reports of the purely scientific latex investigations made by the author's two principal collaborators, V. Henri and G. Vernet.

DISEASES OF PLANTS.

A method of checking parasitic diseases in plants, M. C. POTTER (*Jour. Agr. Sci., 3 (1908), No. 1, pp. 102–107*).—The author has previously shown (E. S. R., 13, p. 467) that the organism causing the white rot of turnips owes its power to the fact that it secretes an enzym which acts upon the cellulose, dissolving the middle lamella and effecting the disintegration of the cell wall, while at the same time it produces a toxin fatal to the protoplasm of its host cell. Subsequent studies with this organism (*Pseudomonas destructans*) have showed that it is possible that the toxin may be one of the waste products of bacterial metabolism.

In a series of investigations, the author grew the organism in cultures, and after considerable growth was made he sterilized the media, filtered it, and steamed it, thus destroying the enzyms and all organisms present. Turnips were then inoculated with the organism causing the white rot, and the prepared toxic solution was employed to determine whether it would check the rot after it had once become well advanced. Cultures were allowed to develop for several days, after which the toxic solution was placed on one half of an inoculated turnip, the other half remaining as a control. On the half receiving the toxic substance the growth of the organism ceased. Where weaker solutions were used the bacteria were found to be unable to grow in the solutions and they prevented further extension of the rot. The toxic solution prepared from the turnip was found not to be necessarily destructive of other organisms.

Some investigations were conducted to determine whether this curative principle would apply in other directions, and cultures were made of *Penicillium italicum* and *P. oliraceum*, which cause the rapid rotting of oranges and lemons. These fungi were grown in sterilized orange juice, and after preparation of the toxic substance a number of oranges were inoculated with the fungus. A few days later, when the characteristic color of the rot had appeared, the oranges were treated with the toxic solution and no further decay was noticed.

8880—No. 12—09——4

Mucor cultures. D. R. Sumstine (*Science, n. ser., 29 (1909), No. 737, p. 267*).—A study is reported of the common mold (*Mucor stolonifer*) made to determine the development or nondevelopment of zygospores. In all, about 2,000 cultures were examined and not a single zygospore found.

Cultures were made on different media and placed under conditions where oxygen was wanting, to determine the necessity for oxygen in the growth of zygospores, but no zygospores were obtained.

Further studies on anthracnoses. C. L. Shear and Anna K. Wood (*Abs. in Science, n. ser., 29 (1909), No. 737, pp. 272, 273*).—In continuation of previous studies (E. S. R., 18, p. 1141) 23 forms of Colletotrichum and Gloeosporium have been studied from different species of plants. Cultures have been made, the fungi compared, and cross inoculation experiments carried on, but no morphological characters have been found to be sufficiently constant to justify the segregation of species except perhaps in the case of the cotton anthracnose. The characters of *Gloeosporium* (*Glomerella*) *rufomaculans* represent fairly well the essential characters of all.

Cross inoculations from forms on fruits seem to indicate that the fungus may soon adapt itself to a different host and after a few generations develop almost as readily on one fruit as on another. All the so-called species are believed to be slightly specialized physiological forms of one omnivorous species.

Cultures of Uredineæ in 1908. J. C. Arthur (*Abs. in Science, n. ser., 29 (1909), No. 737, p. 270*).—An account is given of the tenth consecutive season's cultures of various species of rusts made from the resting as well as the summer spores. Among the various facts presented, the author states that for the first time in America the early or brown rust of rye was grown on *Anchusa* sp., being sown early in July. A similar rust on wheat failed to germinate so soon after maturity, seeming to settle the identity of the so-called *Puccinia dispersa* of Europe and America. Trials with the rust of timothy (*P. phleipratensis*) failed to infect barberry plants, in this respect agreeing with European studies.

During the season's investigation considerable information was added regarding the life history of species of Gymnosporangium, and the life cycle was demonstrated for one species from the Southern States, one from the Northern States, and one from west of the Rocky Mountains.

Notes on Sclerospora graminicola. G. B. Traverso (*Nuovo Giorn. Bot. Ital., n. ser., 14 (1907), No. 4, pp. 575–578*).—A study was made of *S. graminicola*, a common parasite of *Setaria italica*. As a result of inoculation and other experiments, the author concludes that the form commonly occurring on the Italian millet is quite distinct from the species, and he describes it as *S. graminicola setariæ-italicæ*.

A leaf blight of beans. T. Ferraris (*Riv. Patol. Veg., 3 (1909), No. 16, pp. 241–244*).—A description is given of a disease of beans in which the leaves become dried and blackened. The cause was found to be the fungus *Alternaria brassicæ phascoli*, and the disease is said to have occurred rather widely in Italy during 1908 and to have caused considerable loss. A wet spring followed by high temperatures in June and July is said to favor the development of the fungus. For the prevention of its attack spraying with Bordeaux mixture or soda Bordeaux mixture is recommended.

Artificial cultures of Phytophthora with special reference to oospores. G. P. Clinton (*Abs. in Science, n. ser., 29 (1909), No. 737, pp. 271, 272*).—In a previous report (E. S. R., 18, p. 48) the author gave the results of investigations with species of Phytophthora. In the present account he gives notes on the absence of oospores from potato mildew and their presence in other species of Phytophthora, due possibly to distinct sexual mycelia. This is indicated by observations that the antheridia and oogonia of the other two species (*P. phasc-*

oli and *P. thalictri*) are borne on separate mycelial threads. During the investigations the author cultivated pure growths of the Lima bean mildew and found that in mixed cultures oospores were always produced. Cultures are now being carried on to obtain mycelia from single spores, and if the theory of sexual mycelia is correct, these should produce no oospores.

Studies of the potato fungus (Phytophthora infestans), L. R. Jones and N. J. Giddings (*Abs. in Science, n. ser., 29 (1909), No. 737, p. 271*).—The authors state that pure cultures of the potato-rot fungus have been maintained for 4 years in the laboratories of the station. Sealed gelatin cultures have been maintained for 7 months, remaining alive but slow in starting growth.

Some noteworthy morphological characters have been observed, among them haustoria-like branches in potato tissue, the abundance of cell partitions in old cultures, an apparent differentiation into two strains, one exceeding the other in vegetative vigor, and oogonia-like bodies produced sparingly on certain media and frequently on others.

It was found that infection normally occurs through the eyes of the tubers before digging and in storage, but occasionally through wounds or lenticels. Wide differences were found between different varieties as to the ease of leaf infection and subsequent rate of spread, which leads to the conclusion that the disease resistance of the leaves may reside in the mesophyll as well as in the epidermal tissues.

Similar differences occur in the rate of development upon sterile blocks cut from the interior of the potato tubers, and these differences are not due to the acid reaction of the cell sap.

A disease of tomatoes, V. Vera (*Prog. Agr. y Pecuario, 15 (1909), No. 613, pp. 64–66, fig. 1*).—An account is given of a disease of tomatoes due to the fungus *Septoria lycopersici*. The effect of the disease on the different parts of the plant is noted with suggestions for its control. It is stated that the form present in Europe differs from that originally described as coming from Argentina and that the former is probably *S. lycopersici europeæ*.

Studies of two species of Glœosporium, E. Lasnier (*Bul. Trimest. Soc. Mycol. France, 24 (1908), No. 1, pp. 17–43, pls. 3*).—Studies were made of *G. cattleyæ* found on the leaves of certain species of Cattleya, and of *G. musarum* on banana fruits.

The morphological and biological characters of each fungus are described, and the author concludes that they are both saprophytes. The perfect form of neither species has been recognized. The characteristics, as shown in culture media, are described at length. The species occurring on orchids somewhat resembles that described by Cooke and Massee under the name *G. vanillæ*. That occurring on the banana is strictly saprophytic, attacking the fruits only after they have attained complete maturity.

Investigations on the development of Glœosporium nervisequum, A. Guilliermond (*Rev. Gén. Bot., 20 (1908), Nos. 238, pp. 385–400, pls. 3, figs. 5; 239, pp. 429–440, figs. 5; 240, pp. 449–460, pls. 6*).—A detailed study is given of the sycamore anthracnose, *G. nervisequum* or *Gnomonia veneta*, as its perfect form is known. The fungus was carefully isolated and cultivated in a number of media, but in none of them was the author able to recognize the yeast forms described by Viala and Pacottet (E. S. R., 18, p. 347). The author thinks that probably these authors had impure cultures and that the yeast and cyst forms were due to the development of some other organism. In other respects the general features of development agree.

Experiences on the control of grape downy mildew in 1908, G. Chappaz (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 30 (1909), No. 10, pp. 285–289*).—The results of spraying experiments with different fungicides for the control of

mildew in 1908 are described. These experiments were carried on in a field connected with the departmental laboratory at Châlons-sur-Marne, and the meteorological conditions are said to have been exceptionally favorable during the summer for the development of the mildew. After describing the meteorological conditions for the summer of 1908, the experiments are outlined.

In these 8 lots of vines were given different treatments. The fungicides used were neutral copper acetate and ammonia; copper acetate and liquid polysulphids; copper acetate and solid polysulphids; Burgundy mixture, sulphur, and ammonia; and some trade fungicides, the bases of which were chlorate of copper and sulphur, and bisulphite of copper and formalin. Another plat received sodium chlorate as a fungicide. Where no form of sulphur was added to the fungicide the vines received during the summer 2 or 3 applications of sublimed sulphur. In addition to the above fungicides, a test was made of a solution of sea salt, but this proved of no value as a fungicide.

In comparing the different treatments, it was found that the mixtures of neutral copper acetate and polysulphids gave the best results. In comparing the simple with the compound mixtures, the advantage was in favor of those fungicides which were compounded, receiving sulphur or polysulphids.

The mildews of the grape, I. B. P. Evans (*Transvaal Agr. Jour.*, 7 (*1909*), *No. 26, pp. 213–217, pls. 2*).—Descriptions are given of the downy mildew (*Plasmopara viticola*) and the powdery mildew of the grape (*Uncinula spiralis*), and for their control it is recommended that Bordeaux mixture be used for the downy mildew and sulphur for the powdery mildew.

Note on the European apple-tree canker fungus, I. B. P. Evans (*Transvaal Agr. Jour.*, 7 (*1909*), *No. 26, p. 217*).—A brief note is given on the occurrence of the apple-tree canker fungus (*Nectria ditissima*) in southern Africa.

Diseases of the olive, L. Navarro and E. Noriega (*Prog. Agr. y Pecuario, 15 (1909), Nos. 611, pp. 31–33, figs. 3; 612, pp. 47–49, figs. 2*).—An account is given of some new and little known fungus and insect injuries of the olive that have been observed by the authors in Seville, Spain. Among the principal fungi noted are *Glœosporium olivarum*, *Macrophoma dalmatica*, and *Cycloconium oleaginum*. In addition there are notes on the tuberculosis of the olive, the olive fly (*Dacus oleæ*) and *Diplosis oleisuga*.

The injurious action of calcium cyanamid on olive trees, F. Francolini (*Italia Agr., 1909, No. 1, pp. 12–14, pl. 1; abs. in Rir. Patol. Veg., 3 (1909), No. 17, p. 268*).—The results of 3 years' experiments are given showing the effect of calcium cyanamid on olive trees.

In 1906 one lot of trees was fertilized with 2 kg. of Thomas slag, 2 kg. of land plaster, and 1 kg. of calcium cyanamid. The check lot received 1 kg. of nitrate of soda as the source of nitrogen, and the same amounts of the other fertilizers as were given the test trees. Similar comparisons were made between nitrate of soda and calcium cyanamid in 1907 and 1908.

In every case the calcium cyanamid proved injurious to the trees, the injury being characterized by a browning of the foliage, the change of color progressing from the tip of the leaf toward its base. Later the trees lost considerable of their foliage and a large proportion of the fruit dropped from the trees. In clay soils and those rich in humus, the injury was not as pronounced as where the trees were grown in volcanic soils, which were poor in clay and lime.

A bacterial disease of the peach, J. B. Rorer (*Mycologia, 1 (1909), No. 1, pp. 23–27*).—According to the author, during the past 5 or 6 years peach growers in various sections of the country have called attention to a shot-hole disease of peaches which in wet seasons has caused a great deal of premature defoliation.

This was believed to be of bacterial origin and was so reported by Clinton in 1903 (E. S. R., 16, p. 624). The disease was again noticed in 1905, and in 1906, 1907, and 1908 the author undertook a detailed study of it throughout the South and Middle West. In these sections it proved to be the commonest shot-hole disease of peach leaves, the Cercospora leaf spot being but rarely met with. Numerous investigations showed that the disease was of bacterial origin. A bacterial disease of peach twigs and of the fruit was also found, and it seems probable that they, as well as the leaf spot, are caused by the same organism.

During the summer of 1907 a series of successful inoculation experiments with the organism was made. There appears to be but little doubt that the organism causing the leaf spot is the same as that described by Smith as *Bacterium pruni*, the cause of the bacterial black spot of plums and a plum leaf spot (E. S. R., 17, 157).

As the fruit spot was not discovered until toward the close of the peach season, little work has been done upon it.

The immunity of Coffea congensis to Hemileia vastatrix. M. Dubard (*Journ. Agr. Trop., 8 (1908), No. 96, pp. 363, 364*).—A description is given of the variety *chaloti* of *C. congensis*, which is grown at the experiment station at Tamatave, Madagascar, and which has proved to be decidedly resistant to attacks of *H. vastatrix*. This variety seems to have originated from seed that has been under observation for a number of years in Madagascar, the original coming from the Kongo region of Africa. The variety seems not only more immune, but is of decidedly better quality than the Liberian coffee, and it is believed that it can still be improved by breeding experiments.

Witches' broom disease of cacao. C. J. J. van Hall and A. W. Drost (*Rec. Trav. Bot. Néerland., 4 (1908), No. 4, pp. 243–319, pls. 17; Jour. Bd. Agr. Brit. Guiana, 2 (1909), No. 3, pp. 126–132; Roy. Bot. Gard. Kew, Bul. Misc. Inform., 1909, No. 5, pp. 223, 224*).—A study on the origin, nature, and treatment of the witches' broom disease of cacao as it occurs in Surinam is reported.

The symptoms of the disease are summarized, from which it appears that the witches' brooms are hypertrophied branches, considerably thickened at the base, with rough surfaces. They are further distinguished by the leaves being small and stunted. Another form of the disease is characterized by the hardening of the pods, a symptom not originally associated with this disease, but usually attributed to the fungus *Phytophthora omnivora*. The third manifestation of the disease is what is designated as "star flowers." These are borne on fruit branches which present the same pathological symptoms as the witches' brooms, but they appear as an agglomeration of a large number of flowers, having among them vegetative branches transformed into small witches' brooms. They seldom give rise to ripe pods.

The disease, according to the authors, has been found to be due to the fungus *Colletotrichum luxificum*, a description of which is given.

The effects of the disease are chiefly shown in the reduction of the crop, and for its prevention severe pruning, after which the trees are to be sprayed with Bordeaux mixture, is recommended. The pruning in some of the experiments amounted to practically the cutting away of the entire top of the tree, after which all the diseased material was burned. This drastic treatment resulted in the practical loss of the crop for a year or two, but the tree recovered, and in a few years had grown well-developed tops.

So far as the authors' investigations go, other species of trees are not subject to the attack of this species of Colletotrichum, as has been currently reported.

Root rot. A. Despeissis (*Journ. Dept. Agr. West. Aust., 17 (1908), No. 1, pp. 534–540, pls. 2*).—According to the author, considerable trouble is reported in different parts of West Australia, due to the root rot of various orchard and

other trees. Investigation showed that most of it is caused by various species of mushrooms, the one most particularly concerned being the honey agaric (*Agaricus melleus*).

For the prevention of injury, the clearing of lands, in which all roots and stumps should be removed, and the draining and cultivation of the newly cleared lands are recommended. When trees are found slightly affected they can be protected to some extent by uncovering the roots, removing the diseased portions, and spraying the sound parts with fungicides.

Observations on the relation of wound parasites to the heartwood of the affected tree, P. Spaulding (*Abs. in Science, n. ser., 29 (1909), No. 737, p. 272*).—While studying various wood-rotting fungi, the author has noted an apparent relation between the wound parasites and the heartwood of diseased trees. A striking instance of this was that of *Fomes ribis* occurring on sassafras trees. In every case examined this fungus was found attacking the trees only in wounds where the heartwood was exposed by some injury. *F. igniarius*, studied upon the beech, was found to occur in a similar manner. Hundreds of blazed beech trees have been examined, but in not a single instance was the fungus found growing where the wound only extended into the sapwood. On the other hand, it was constantly found in wounds extending into the heartwood. The fungus *Polystictus versicolor* on catalpa and *F. fraxinophilus* on the white ash can be traced to the heartwood through dead stubs or wounds. In a similar way von Schrenk has called attention to the fact that *F. rimosus*, which attacks the heartwood of black locust, enters either through the dead stubs or through insect burrows.

These investigations seem to indicate that the heartwood must be exposed before these fungi are capable of attacking the hosts.

Rusts on the leaves of bamboos, S. Kusano (*Bul. Col. Agr. Tokyo Imp. Univ., 8 (1908), No. 1, pp. 37–50, pl. 1, fig. 1*).—A description is given of 5 species of Puccinia known to occur on bamboos in Japan, the species being *P. phyllostachydis*, *P. sasæ*, *P. kusanoi*, *P. kusanoi azuma*, and *P. longicornis*. Notes are included on the distribution, economic relationship, and some of the biological characters of the different species.

A new disease of oaks, A. Fiori (*Bul. R. Soc. Toscana Ort., 3. ser., 13 (1908), No. 9, pp. 266–268*).—A description is given of the mildew of oaks, which was very prevalent in the oidium stage in Europe during 1908. The author thinks that it is probably *Microsphæra quercina*, although the fruiting stage has not been found.

Oak mildew in the southwest of France, Gard (*Jour. Bot. [Paris], 21 (1908), No. 10, pp. 253–256*).—An account is given of the occurrence of mildew on oak trees in the southwest of France during the summer and autumn of 1908. The species *Quercus tozza* seemed most susceptible, although others were subject to attack. The most injury was done on the young trees, particularly where they were grown as coppice. The season seemed to have been especially favorable to the development of mildews, as the author reports mildews abundant on a number of other species of plants.

Biology of the chrysanthemum rust, S. Kusano (*Bul. Col. Agr. Tokyo Imp. Univ., 8 (1908), No. 1, pp. 27–36, fig. 1*).—A study has been made of the rusts which are known to attack various species of chrysanthemums in Japan, particular attention being paid to the black rust (*Puccinia chrysanthemi*), the white rust (*P. horiana*), and the brown rust (*Uredo autumnalis*).

The author states that there is some question as to the specific name of the first species as well as the host plants attacked. The white rust is of comparatively recent scientific knowledge, although it is said to have been known by gardeners for a considerable time. It proves very destructive, particularly on

some forms of chrysanthemums, and is much more injurious than the black rust because of its attacking the host plants while quite young and also on account of its rapid propagation. The repeated use of Bordeaux mixture is said to be very effective in preventing this rust.

All of the rusts mentioned occur on the wild chrysanthemum (*Chrysanthemum decaisneanum*). They also have a tendency to occur on *C. sinense*, although in some parts of Japan there seems to be more or less specialization regarding their hosts.

A bacterial gall of the daisy and its relation to gall formations on other plants, C. O. Townsend (*Abs. in Science, n. ser., 29 (1909), No. 737, p. 273*).—Investigations on the galls occurring on the Paris daisy have been carried on for some time by the author. After repeated efforts an organism was isolated, which has the ability to induce the formation of new galls upon healthy plants when inoculated into the stems and branches or even into the leaves of healthy daisy plants.

This organism will also produce galls upon a large number of other plants, including the tomato, potato, tobacco, sugar beet, hop, carnation, grape, raspberry, peach, and apple. The work has led to the isolation of pathogenic organisms from the galls of peach, the hard gall of apple, hairy root of apple, hop, rose, and chestnut. The organisms obtained from these galls are cross inoculable and are very similar if not identical in size, shape, structure, and habits of growth with the organism from the daisy gall.

These investigations, the author claims, leave no doubt regarding the cause of the crown gall of the peach as well as of some of the gall formations upon the apple and other economic plants.

Leaf spot of Odontoglossum, M. C. Potter (*Gard. Chron., 3. ser., 45 (1909), No. 1158, pp. 145, 146, figs. 4*).—The attention of the author has been directed to numerous black spots occurring on the lower surface of the leaves of *O. uroskinneri*. The spots are found chiefly on the older leaves, the younger ones being almost, if not entirely, unaffected.

Transverse sections through the region of the spots show an accumulation of a brown mucilaginous or gummy substance beneath the epidermis. In the initial stages this substance is present only in the respiratory cavities of the stomata, from which it exudes into the stomatal openings. In more advanced stages it collects in large masses, spreading through the hypodermal cells into the internal tissues of the leaves.

This leaf spot disease is said to differ in many respects from the common leaf spot of orchids, which is characterized by the plasmolysis of the cells.

No fungus has been found associated with this leaf spot, but numerous bacteria are present in the affected tissues. Thus far all attempts to induce the disease upon healthy plants by inoculation with bacteria have proved unsuccessful, but the author believes that bacteria play an important part in the development of the disease, particularly in the formation of the gum. It is thought that unsuitable cultural conditions are also largely responsible for the initial occurrence of the disease.

The transmissibility of the cause of olive tuberculosis to the oleander, L. Savastano (*Bol. Arbor. Ital., 4 (1908), No. 2, pp. 86, 87*).—As a result of inoculation experiments with pure cultures of the organism causing olive tuberculosis and of the insertion of fragments of olive tubercles into healthy oleander trees, the author states that the bacterial disease of the olive can not be transmitted to the oleander, as claimed by C. O. Smith (E. S. R., 18, p. 453).

Report of the Phytopathological Institute of Wageningen for 1907, J. Ritzema Bos (*Meded. Rijks Hoogere Land, Tuin en Boschbouwsch., 1908, No. 1, pp. 33–137*).—A description is given of the organization of the institute for the

study of plant diseases and reports made on a number of investigations. The diseases are grouped into nonparasitic, those due to plant parasites, those caused by insects, and those the causes of which are not definitely known.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Economic zoology, H. OSBORN (*New York, 1908, pp. XV+490, figs. 269*).—An introductory text-book in zoology, with special reference to its applications in agriculture, commerce, and medicine.

A German-French glossary of anatomical and zoological terms, R. BLANCHARD (*Glossaire Allemand-Français des Termes d'Anatomie et de Zoologie. Paris, 1908. pp. VII+298*).—In this glossary the French equivalents with family, order, or class to which the species belong are given for the German names of animals.

Catalogue of the type-specimens of mammals in the United States National Museum, including the Biological Survey collection, M. W. LYON, Jr., and W. H. OSGOOD (*U. S. Nat. Mus. Bul. 62, pp. X+325*).—This catalogue includes all type-specimens of mammals known to be in the U. S. National Museum on July 1, 1908. A total of 1,405 type-specimens are here included, of which 692 are in the collection of the Division of Mammals and 713 in the Biological Survey collection. A list is appended of 26 type-specimens that should be in the National Museum collection but of which no part can now be found.

The fauna of Mayfield's cave, A. M. BANTA (*Carnegie Inst. Washington Pub. 67, pp. 114, pl. 1, figs. 13, map 1; abs. in Science, n. ser., 29 (1908), No. 743, pp. 503, 504*).—This cave, located in Monroe County, Ind., was visited by the author on an average of once a week during some 26 months, covering different seasons of the years 1903, 1904, and 1905. The collections made are here recorded under the headings of Mammalia, Pisces, Insecta, Myriopoda, Arachnida, Crustacea, Annelida, Mollusca, and Turbellaria. Of 138 species known to exist in Indiana caves, 110 are recorded from Mayfield's cave. Descriptions by C. F. Adams of 2 new species of fungus flies (*Mycetophila analis* and *M. incerta*) are included. A bibliographic list is given of more than 130 works and papers consulted.

Annual report of the chief inspector of rabbits, A. CRAWFORD (*Jour. Dept. Agr. West. Aust., 17 (1908), No. 6, pp. 935–939*).—The total length of rabbit-proof fence erected is said to be 2,023 miles with about 10 miles in the course of erection. Details are given of the work of the year.

Plague among the ground squirrels of California, W. B. WHERRY (*Jour. Infect. Diseases, 5 (1908), No. 5, pp. 485–506, pl. 1, map 1*).—The fact that a number of ground squirrels (*Otospermophilus beecheyi*) have been proved to be infected with *Bacillus pestis* in two widely separated sections of the State of California is considered as the most serious feature of the plague situation in this country. The Norway rat (*Mus norvegicus*) was the principal species of rodent caught in traps set well within the burrows of the ground squirrel by employed trappers. The relation between squirrel plague and the origin of certain human cases is said to have been demonstrated. Pathological and bacteriological features of the squirrel plague are here discussed.

Experiments on the use of Bacillus pestiscaviæ as a rat virus, W. B. WHERRY (*Jour. Infect. Diseases, 5 (1908), No. 5, pp. 519–553*).—In a study made of this species it was found that when ingested by young rats (*Mus norvegicus*) and mice (*M. musculus*) it is acutely pathogenic. A large percentage of adult rats are naturally immune to the infection through the gastrointestinal canal or when infected they subsequently recover.

Outbreak of illness caused by vermin-destroying virus, W. Collingridge (*Pub. Health [London], 22 (1908), No. 3, pp. 94–96*).—An outbreak of illness was traced to the virus that had been used for the destruction of rodents.

The birds of Tierra del Fuego, R. Crawshay (*London, 1907, pp. XL+158, pls. 44, fig. 1, map 1*).—Six months were spent by the author in the investigations here reported. In the preface the author briefly considers the flora and fauna including the mammals, fishes, spiders, insects, etc. Birds are the most important fauna of all, although the majority are only summer visitors. Thirteen orders and 79 species of birds are considered.

Nests of the barred owl, red-shouldered hawk, and barn owl on Staten Island, in 1907, J. Chapin (*Proc. Staten Isl. Assoc. Arts and Sci., 2 (1907–8), No. 1, pp. 3–8*).—Notes are given on the habits of *Syrnium varium*, *Buteo lineatus*, and *Strix pratincola*.

The food of some British birds, R. Newstead (*Jour. Bd. Agr. [London], 15 (1908), No. 9, Sup., pp. VIII+87*).—A memoir based upon 871 post-mortem examinations of the stomach contents and the pellets or castings of 128 species of British birds.

"We find that insects occurred in about 41 per cent of the total number of post-mortem records and pellets. If we eliminate the finches, the hawks and owls, ducks, geese, divers and the oceanic birds from this total, we find that the insects forming the whole or part of the dietary of the remaining birds amounts to between 70 and 75 per cent; and it is important to note that those insects which are included in the injurious group vastly outnumber those which may be considered beneficial, and are almost twice as numerous as the beneficial and the innoxious groups combined."

Philippine ornithological literature, I, R. C. McGregor (*Philippine Jour. Sci., A. Gen. Sci., 3 (1908), No. 4, pp. 285–292*).—This list of 50 titles is said to be the first of a series of papers having for its final object a complete bibliography of Philippine ornithology.

Notes on a collection of birds from Siquijor, Philippine Islands, R. C. McGregor (*Philippine Jour. Sci., A. Gen. Sci., 3 (1908), No. 4, pp. 275–281*).—A list with notes on species of birds collected from Siquijor, a coral rock island with an area of about 235 sq. km. (about 91 sq. miles) which lies in close proximity to the large island of Negros.

Priority and practical entomology, H. M. Lefroy (*Jour. Econ. Biol., 3 (1908), No. 4, pp. 105–112*).—The author here reviews many of the changes which have been made in the names of insects of economic importance and suggests methods by which the names of the more important insects could be standardized.

Insects: The rôle they play in the transmission of disease, H. Albert (*Bien. Rpt. Bd. Health Iowa, 14 (1908), pp. 136–144*).—A general discussion of insect transmission of disease.

How best to control and eradicate insect enemies and pests, F. Whiteside (*Bien. Rpt. Mont. Bd. Hort., 5 (1907–8), pp. 24–63, figs. 18*).—An account is given of the more important insect enemies and diseases of fruits with methods of control. A spray calendar is appended.

New pests we should guard against, E. M. Ehrhorn (*Cal. Fruit Grower, 38 (1908), No. 1066, pp. 10–13*).—Among the insects which have not yet been introduced into California and which are to be guarded against, the author mentions the terrapin scale or peach lecanium (*Eulecanium nigrofasciatum*), scurvy bark louse, the West Indian peach scale (*Aulacaspis pentagona*), maple scale (*Phenacoccus acericola*), pear tree psylla (*Psylla pyricola*), cigar case bearer (*Coleophora fletcherella*), the bud moth (*Tmetocera ocellana*), Japanese apple fruit borer (*Laverna herellera*), pear fruit borer (*Nephopteryx rubri-*

zonella), gipsy moth, brown-tail moth, squash borer (*Melittia satyriniformis*), peach root borer (*Sanninoidea exitiosa*), fall webworm, bagworm, and peach sawfly (*Pamphilius persicum*).

A preliminary bulletin on some economic insects and plant diseases of Indiana, B. W. Douglass (*Indianapolis, Ind., 1907, pp. 28, figs. 8*).—A brief account of the more important insects and plant diseases including methods of treatment.

The principal insects injurious to horticulture during 1906–7, M. H. Swenk (*Bul. Nebr. State Hort. Soc., No. 19, pp. 24, figs. 31*).—In this bulletin, which forms part 1 of the report of the State entomologist, the author considers the insects which have been actively injurious to horticulture in Nebraska during the 2 years ended April 1, 1908. These are the codling moth, lesser apple worm, leaf crumpler (*Mineola indiginella*), white-marked tussock-moth (*Homerocampa leucostigma*), apple-tree tent-caterpillar, yellow-necked apple-tree caterpillar (*Datana ministra*), pear slug (*Eriocampoides limacina*), rose slug (*Monostegia rosæ*), leaf-cutter bees (*Megachile* spp.), buffalo tree-hopper (*Ceresa bubalus*), snowy tree cricket (*Œcanthus niveus*), plum curculio, and plum gouger.

Scale insects injurious in Nebraska during 1906–7, H. S. Smith (*Bul. Nebr. State Hort. Soc., No. 20, pp. 16, figs. 6*).—This bulletin forms part 2 of the report of the State entomologist.

While the San José scale does not occur in Nebraska, several other species are a source of injury. The oyster-shell scale was the cause of considerable injury to apple trees during the 2 years under report. The scurfy scale is not as common as *Lepidosaphes ulmi* and rarely does much injury. The elm-tree white-scale (*Chionaspis americana*) occasionally becomes injurious to the common elm. The pine leaf scale (*C. pinifoliæ*) is said to be a very common species of both native and cultivated conifers. The cottonwood scale (*C. ortholobis*) has been quite abundant in eastern Nebraska for several years on young poplars, cottonwood, and willow. The cottony maple scale has not been sufficiently abundant during the past 2 years to cause much injury. During the summer of 1907 the western cottony grass scale (*Eriopeltis coloradensis*) became prevalent on wild wheat grass in the southwestern portion of the State. Several parasites of this scale have been bred by the author from the egg sacs, the most common being the dipterous parasite, *Leucopis nigricornis*.

Injurious insects and other animals observed in Ireland during the year 1907, G. H. Carpenter (*Econ. Proc. Roy. Dublin Soc., 1 (1908), No. 15, pp. 559–588, pls. 6, figs. 10*).—Insects of the year are reported under the following headings: Parasites of domestic animals, corn insects, clover, cabbage, and mangold insects, potato and parsnip insects, tobacco insects, orchard insects, hawthorn insects, and forest insects.

Insect investigations in Mexico, A. Koebele (*Hawaii. Planters' Mo., 27 (1908), No. 12, pp. 507–513*).—This is an account of investigations made in Mexico by the author.

The moth borer (*Diatræa saccharalis*) is said to be widely distributed in the country. It is stated that 50 per cent of the eggs deposited are destroyed by a parasite (*Trichogramma pretiosa*). While the pest does not occur in Hawaii, it seems quite probable that it will be sooner or later introduced, as it is a species widely distributed.

The large Mexican sugar-cane leaf-hopper (*Cyrtodisca major*) is said to be injurious in the State of Morelos. The Mexican sugar-cane hopper (*Cyrtodisca* sp.) is widely distributed, breeding throughout the year. Its eggs are destroyed to a large extent by fungus diseases and parasites. Other injurious

insects commonly found in cane fields include an earwig (*Sphingolabis forniata*), the chinch bug (*Blissus leucopterus*), and jassid and fulgorid leaf hoppers.

Report of the entomologist and vegetable pathologist. H. Tryon (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1907–8, pp. 84–92*).—A brief account is given of the more important insects, insectivorous birds, and plant diseases of the year. These are grouped under insects affecting agricultural crops, useful insects, insects and ticks affecting stock, human ecto-parasites, diseases of agricultural crops, and diseases of horticultural crops. An account is also given of the inspection and disinfection of plants exported and imported during the year.

Annual report of the assistant entomologist. L. J. Newman (*Jour. Dept. Agr. West. Aust., 17 (1908), No. 6, pp. 940–944*).—An account is given of work with parasites of the fruit fly, cabbage aphis, scales, etc., and with lady beetles. The prevalence of and injury by the more important insect pests are briefly considered.

Insects and other Arthropoda collected in the Congo Free State. R. Newstead, J. E. Dutton, and J. L. Todd (*Ann. Trop. Med. and Par., 1 (1907), No. 1, pp. 3–113, pls. 6, figs. 21, maps 2*).—Insects of the families Culicidæ, Chironomidæ, Psychodidæ, Simulidæ, Tabanidæ, Sarcophagidæ, Muscidæ (particularly tsetse flies), Hippoboscidæ, Pulicidæ, Cimicidæ, and several families of the Acarina, including Ixodidæ, are included in this account.

A guide to the study of Australian butterflies. W. J. Rainbow (*Melbourne, 1907, pp. 272, pls. 7, figs. 262*).—A small guide intended for beginners.

Notes on the life histories of certain wood-boring lepidoptera. F. X. Williams (*Ent. News, 20 (1909), No. 2, pp. 58–62, pl. 1*).—The species here noted are *Vespamima sequoiæ*, *Sesia mellinipennis*, *S. polygoni*, and *Pterophorus baccharides*.

Notes on the study of some Iowa Catocalæ. R. R. Rowley (*Ent. News, 20 (1909), No. 1, pp. 12–18*).—Notes on food plants are included in this account.

The fauna of British India, including Ceylon and Burma. Coleoptera (*London, 1906, vol. 1, pp. XVIII+329, figs. 107; 1908, vol. 2, pp. XX+534, pls. 2, figs. 172*).—Volume 1 on the Cerambycidæ is by C. J. Gahan and volume 2 on the Chrysomelidæ is by M. Jacoby.

The distribution of the North American species of Phytonomus. R. L. Webster (*Ent. News, 20 (1909), No. 2, pp. 80–82*).—A brief account of the distribution of the weevils belonging to the genus Phytonomus.

Notes on Tenthredinoidea, with description of new species, II, III, IV, V. S. A. Rohwer (*Canad. Ent., 41 (1909), Nos. 1, pp. 9–21; 3, pp. 88–92; 4, pp. 106–112; 5, pp. 145–149*).—In these papers species and varieties from Colorado, California, Nebraska, Nevada, New Mexico, Kansas, and the District of Columbia are described as new. The new genus Protemphytus is also erected.

A note on the habits of Aphilanthops. C. N. Ainslie (*Canad. Ent., 41 (1909), No. 3, pp. 99, 100*).—The author reports observing the wasp *Aphilanthops taurulus* capture and carry away *Pogonomyrmex barbatus* at Albuquerque, New Mexico.

Notes on some Chalcidoidea. J. C. Crawford (*Canad. Ent., 41 (1909), No. 3, pp. 98, 99*).—*Megorismus fletcheri* bred from *Nectarophora pisi* at Ottawa, Canada, is described as new. The new genus Hemadas is erected of which *Megorismus nubilipennis* is designated as the type species. A table is given for the separation of the various genera of the tribe.

Two new seed-infesting chalcis flies. C. R. Crosby (*Canad. Ent., 41 (1909), No. 2, pp. 50–55, figs. 2*).—*Prodecatoma phytophaga*, reared from the seeds of the Virginia creeper (*Parthenocissus quinquefolia*), and *Eurytoma rhois*, reared

from seeds of the sumac (*Rhus hirta*), which were collected at Ithaca and Taughannock Falls, N. Y., are described as new to science.

A key to the species of Prospaltella, with table of hosts, and descriptions of four new species. L. O. HOWARD (*Ann. Ent. Soc. Amer., 1 (1908), No. 4, pp. 281–284*).—The species *Prospaltella quercicola* reared from *Aleyrodes gelatinosus*, *P. koebelei* from *Aspidiotus longispina*, *P. citrella* from *Aleyrodes coronatus*, and *P. brunnea* from a species of Aleyrodes are described as new to science.

Comparative ethology of the European and North American ants. W. M. WHEELER (*Jour. Psychol. u. Neurol., 13 (1908), pp. 404–435, pls. 2, figs. 6*).—The author first considers the composition of the European and North American ant fauna. For America north of Mexico 450 species, subspecies, and varieties belonging to 63 genera and subgenera are said to have been listed by the author. As a number of forms remain to be described, it is estimated that the total number will exceed 500. It is considered certain that the North American ant fauna is more than twice as rich as that of Europe. Fossil ants, the nidification of the European and North American ants, the parasitic ants of Europe, and Myrmecophiles are considered at some length.

Honey ants, with a revision of the American Myrmecocysti. W. M. WHEELER (*Bul. Amer. Mus. Nat. Hist., 24 (1908), pp. 345–397, figs. 28*).—To this account is appended a bibliographical list of 49 titles.

The ants of Casco Bay, Maine, with observations on two races of Formica sanguinea Latreille. W. M. WHEELER (*Bul. Amer. Mus. Nat. Hist., 24 (1908), pp. 619–645*).—Data are included on the habits of some of the species here listed.

The ants of Texas, New Mexico, and Arizona, I. W. M. WHEELER (*Bul. Amer. Mus. Nat. Hist., 24 (1908), pp. 399–485, pls. 2*).—One hundred and one species, subspecies, or varieties are here considered.

The ants of Porto Rico and the Virgin Islands. W. M. WHEELER (*Bul. Amer. Mus. Nat. Hist., 24 (1908), pp. 117–158, pls. 2, figs. 4*).—"Of the 65 species, subspecies, and varieties of these insects recorded, 12 have been found only in St. Thomas, 4 only on Culebra, and 21 only on Porto Rico; 11 are common to Culebra and Porto Rico, 5 to St. Thomas and Porto Rico, and 12 occur on all three of the islands."

The ants of Jamaica. W. M. WHEELER (*Bul. Amer. Mus. Nat. Hist., 24 (1908), pp. 159–163*).—"Of the 40 enumerated forms, 9, or nearly 25 per cent, are well-known cosmopolites, and nearly half of the remainder are widely distributed through the West Indies and adjacent South and Central American countries."

The fauna of British India, including Ceylon and Burma. Rhynchota. W. L. DISTANT (*London, 1908, vol. 4, pp. XV+501, figs. 282*).—This, the fourth volume of the Rhynchota, deals with the Membracidæ, Cercopidæ, and Jassidæ. In the appendix are included such species of the Pentatomidæ, Coreidæ, and Berytidæ as have been added to the Indian fauna since the publication in 1902 of volume 1 of the Rhynchota.

A catalogue of the hemiptera of Fiji. G. W. KIRKALDY (*Proc. Linn. Soc. N. S. Wales, 33 (1908), pt. 2, pp. 345–391, pl. 1, figs. 5*).—This list, based mainly upon collections from 3 islands, increases the number of known Fijian hemiptera from the previous total of 40 species to 202 species. Notes are included on the food plants of some of the species.

Life histories of some Philippine Cassididæ. W. SCHULTZE (*Philippine Jour. Sci., A. Gen. Sci., 3 (1908), No. 4, pp. 261–271, pls. 6*).—Life-history notes are given on the species *Prioptera sinuata*, *P. schultzei*, *Aspidomorpha miliaris*, *Cassida picifrons*, *Metriona trivittata*, and *Lacoptera philippinensis*. The *M.*

trivittata larvæ were often found infested by a fly and pupæ of *A. miliaris* by a chalcidid. The eggs of but one species, *L. philippinensis*, were found parasitized.

Studies on Aphididæ, I. J. J. Davis (*Ann. Ent. Soc. Amer., 1 (1908), No. 4, pp. 251–264, pls. 3*).—Studies of the habits, with descriptions of the life stages of *Myzus ribagni*, the barberry plant louse (*Rhopalosiphum berberidis*), the yellow clover plant louse (*Callipterus trifolii*), and the red clover aphis (*Aphis bakeri*).

Phyllaphis coweni, C. P. Gillette (*Canad. Ent., 41 (1909), No. 2, pp. 41–45, fig. 1*).—Notes are given upon the life history of this species of plant louse. Bearberry (*Arctostaphylos uva-ursi*) is said to be the host plant.

The Lecanium of Robinia, P. Marchal (*Compt. Rend. Soc. Biol. [Paris], 65 (1908), No. 24, pp. 2–5*).—After considering the origin of the locust scale (*Lecanium robiniarum*), the author presents the details of a breeding experiment, in which he shows this scale to be a variety of *L. corni*. For this variety he proposes the name *L. corni robiniarum*.

On Thysanoptera, II. J. Franklin (*Ent. News, 20 (1909), No. 5, pp. 228–231*).—The genus Aleurodothrips is erected for the species *Cryptothrips fasciapennis*. This species has been found feeding upon the eggs, larvæ, and pupæ of the citrus white fly (*Aleyrodes citri*).

A report on the species of Siphonaptera found within the boundaries of the city and county of San Francisco, Cal., C. Fox (*Ent. News, 20 (1909), No. 1, pp. 10, 11*).—Seventeen species, representing 9 genera, were recognized among some 17,000 specimens collected.

Revision of the noncombed eyed Siphonaptera, K. Jordan and N. C. Rothschild (*Parasitology, 1 (1908), No. 1, pp. 1–100, pls. 7*).—A bibliography is appended to this revision.

Two little-known aphids on Carex sp., C. P. Gillette (*Ent. News, 20 (1909), No. 3, pp. 119–121, pl. 1*).—The author reports the collection of an alate viviparous female of *Brachycolus ballii* from Carex and presents a description of it. *Callipterus flabellus* was taken in large numbers from a small species of Carex. Descriptions of adult apterous viviparous and winged females are accompanied by illustrations.

The preparatory stages of Euchloe sara, K. R. Coolidge and E. J. Newcomer (*Canad. Ent., 41 (1909), No. 2, pp. 45–47*).—Notes are given upon the life history and habits of this species, which occurs in California on species of Brassica and other Cruciferæ.

Weevils and other insects affecting grains and cereal products, R. Ramírez (*Estac. Agr. Cent. [Mexico] Circ. 5, pp. 5, pls. 6*).—A general account of these insects.

Notes on Contarinia sorghicola, G. W. Herrick (*Ent. News, 20 (1909), No. 3, pp. 116–118, pl. 1*).—This cecidomyid is reported as the source of widespread injury to the seed of Kafir corn and sorghum in Texas. Parasites of the species *Aprostocetus diplosidis* were bred in large numbers from it. The pest is difficult to control. It is suggested that the parasites may increase sufficiently as the season advances to enable a late crop of Kafir corn to mature its seed.

Poisoned bait remedy [for cutworms], C. W. Mally (*Agr. Jour. Cape Good Hope, 33 (1908), No. 5, pp. 628–635, figs. 3*).—The remedy here described consists of cutting up any available green stuff as lucern, barley, forage, cabbage or rape leaves, young succulent weeds, etc., into lengths of about ½ in. moistening with poisoned sweet and scattering broadcast in cabbage, tomato, tobacco, and other infested fields. A mixture of arsenite of soda, 1 lb., molasses or brown sugar, 8 lbs., and water, 10 gal., has been used in which to moisten the green stuff. Ants, and a bacterial disease are mentioned as enemies of cutworms.

Preliminary report upon experiments with powdered arsenate of lead as a boll weevil poison, W. NEWELL and T. C. BARBER (*Crop Pest Com. La. Circ. 23, pp. 9–10, figs. 3*).—The authors first present a brief review of the use of Paris green in combating the boll weevil. At their request one firm attempted and, after some experimentation, succeeded in the spring of 1908 in producing a powdered arsenate of lead. Experiments carried out with this insecticide are reported in which it was found to be twice as effective as Paris green, and that if applied to cotton just before the first squares form 70 per cent of the boll weevils then present would be killed. Conclusions as to the probable profit following such application should be drawn with caution, since all the boll weevils are not out of hibernation when the squares first appear. For the destruction of the cotton caterpillar or leaf worm in midsummer, powdered arsenate of lead is preferred to Paris green since it is equally as effective, is noninjurious to the cotton plant, and is cheaper. Powdered arsenate of lead is also considered a better application for the bollworm than is Paris green.

Destroying the boll weevils before they enter hibernation, W. NEWELL (*Crop Pest Com. La. Circ. 24, pp. 41–48*).—Attention is called to the importance of fall destruction of cotton stalks. Early and complete destruction is shown to be a necessary precedent to the successful use of powdered arsenate of lead the following spring.

What constitutes a perfect stand of cotton when fighting the boll weevil? W. NEWELL (*Crop Pest Com. La. Circ. 25, pp. 15*).—In sections infested by the boll weevil, cotton bolls are not made after August 15 (and oftentimes none after August 1) and therefore each plant requires only enough growing room in which to produce bolls up to the date of maximum infestation, about August 15. Having in mind these facts, the author conducted experiments to determine what constitutes a perfect stand, by this being meant the number of plants on any given area which will give the greatest yield per acre. A summary of the comparative production of widely spaced and closely spaced cotton is presented in the following table:

Comparative production of cotton in wide rows, in narrow rows, and in rows of medium width.

Experiment.	Yield of seed cotton per acre.		
	Widely spaced.	Closely spaced.	Medium distance.
	Pounds.	*Pounds.*	*Pounds.*
Mansfield, 1907	734	947	892
Mansfield, 1908	838	1,341	993
Mansura, 1908	474	627	392
Bayou Pierre, 1908	380	636	553
Average yield, all experiments	607	889	708

These experiments were conducted on such a variety of soils and under such a variety of conditions that the results are considered trustworthy.

"From our own experience we are inclined to believe that spacing about as follows will give the maximum yields per acre under ordinary conditions:

"On poor upland soil, rows 3 ft. apart, plants 10 in. apart in the row. On rich upland or good prairie soils, rows 3 ft. apart, plants 12 in. apart in the drill. For worn, or very sandy bottom lands, rows 3½ ft. apart, plants 12 in. apart in the drill. On bottom lands of medium fertility, well drained, rows 4 ft. apart, plants 15 in. apart in the drill."

Maize stalk borer (Sesamia fusca). C. W. Mally (*Agr. Jour. Cape Good Hope, 33 (1908), No. 5, pp. 616–624, figs. 2*).—A general account is given of this pest, including methods of control.

Insect enemies of cotton. F. Sherman, Jr. (*Bul. N. C. Dept. Agr., 29 (1908), No. 6, pp. 54, figs. 24*).—This is an account of the more important cotton insects, their biology, injury, and remedies. The author considers $2,000,000 a conservative estimate of the injury annually done to cotton in North Carolina by insects.

Cutworms are the source of considerable injury, particularly in the Piedmont counties. Of 7 species reared to maturity, 4 are reported as having reached the moth stage in spring, and 2 in fall, while 1 was observed in summer only. Injury by the cotton leaf-louse (*Aphis gossypii*) is said to be rather general throughout the cotton-growing regions of the State. *Aphis maidiradicis* has been reported from several counties as the source of injury.

The cowpea pod weevil (*Chalcodermus æneus*) was reported in 1907 from several counties as injurious to cotton. The new cotton beetle (*Lupcrodes brunneus*) has been the source of considerable damage to blooms and squares. The cotton red spider (*Tetranychus gloveri*) has been at times a source of injury, principally in a belt about two counties wide extending across the State from north to south. The cotton worm (*Alabama argillacea*) has not often been destructive in the State. The bollworm while not considered a serious enemy of cotton in North Carolina does some damage every year. The boll weevil is not as yet known to occur in the State. Several cotton insects of lesser importance are also considered.

Notophallus hæmatopus attacking peas in France. P. Marchal (*Bul. Soc. Ent. France, 1908, No. 3, pp. 41, 42*).—This acarid is described as causing considerable injury to peas near Gien in central France.

Further biological notes on the Colorado potato beetle (Leptinotarsa decemlineata), including observations on the number of generations and length of the period of oviposition. A. A. Girault (*Ann. Ent. Soc. Amer., 1 (1908), No. 2, pp. 155–178*).—A continuation in 1907 at New Richmond, Ohio, of observations made during 1906 in Georgia, previously noted (E. S. R., 19, p. 159).

Contribution to the study of the sugar-cane borers. N. Lévy (*Bol. Min. Fomento [Peru], Dir. Fomento, 6 (1908), No. 7, pp. 1–4*).—The species *Diatræa striatalis* and *Sesamia nonagrioides* var. *albiciliata* are here considered.

Paper on the frog hopper. J. J. McLeod (*Proc. Agr. Soc. Trinidad and Tobago, 8 (1908), No. 12, pp. 552–556*).—An account is given of part of the life history of a Trinidad species of cercopid, which the author considers the principal cause of the injury and disease of sugar cane throughout the island. As a remedy it is recommended that the fields be burned over as soon as the canes are cut and that badly infested fields be allowed to lie fallow for at least a year.

Insects injurious to tobacco. G. E. Anastasia (*Bol. Tec. Coltiv. Tabacchi [Scafati], 7 (1908), No. 2, pp. 107–114, pl. 1*).—In this article the author considers the Thysanoptera or thrips known to injure tobacco, the nature of their injury, natural enemies, and methods of control.

A new vegetable pest—the tomato weevil. C. French, Jr. (*Jour. Dept. Agr. Victoria, 6 (1908), No. 12, pp. 754, 755*).—*Desiantha nobica*, a species of weevil recently described as new, is reported to have fed upon and destroyed great numbers of tomato and other garden plants.

The Japanese Coccidæ. T. D. A. Cockerell (*Canad. Ent., 41 (1909), No. 2, pp. 55, 56*).—Notes on a number of species.

The San José scale (Aspidiotus perniciosus) and methods of treatment. A. E. Stene (*Ann. Rpt. Bd. Agr. R. I., 23 (1907), App., pp. 1–91, pls. 19, figs.*

30).—A general account of this insect including its natural enemies and methods of control.

The fruit-infesting forms of the dipterous genus Rhagoletis, with one new species, J. M. Aldrich (*Canad. Ent., 41 (1909), No. 2, pp. 69–73, fig. 1*).—Notes and a table are given for the separation of the species of this genus of fruit flies.

Annual report of the chief orchard inspector, T. Hooper (*Jour. Dept. Agr. West. Aust., 17 (1908), No. 6, pp. 933–935*).—A remarkable reduction from that of the previous year is reported in the quantity of fruit destroyed by the fruit fly. The use of kerosene for the destruction of these flies is considered as a valuable discovery, as many flies have been destroyed by it. A brief account is given of the more important orchard insects of the year.

Observations on the oviposition of Œcanthus quadripunctatis Beutenmüller, J. P. Jensen (*Ent. News, 20 (1909), No. 1, pp. 25–28, pl. 1*).—Injury to blackberry and raspberry canes is said to be due to *O. quadripunctatis* and not to *O. niveus*.

The woolly aphis of the apple tree, J. R. Inda (*Estac. Agr. Cent. [Mexico], Circ. 2, pp. 6, pl. 1*).—This is a general account including remedies for *Schizoneura lanigera*.

The apple blossom weevil, W. E. Collinge (*Jour. Bd. Agr. [London], 15 (1908), No. 9, pp. 674–678*).—An account of the life history and bionomics and of preventive and remedial measures for *Anthonomus pomorum*.

[The olive fly and methods of control] (*Ann. Agr. [Italy], 1908, No. 256, pp. 34–79*).—In the proceedings of the annual meeting of the Consultative Commission of Olive Culture and Oil Manufacture, reports are given by Profs. Berlese, Silvestri, and others on investigations of the value of parasites, sweetened arsenicals, etc., in combating the olive fly and *Lecanium oleæ*.

Some new and undescribed insect pests affecting cocoa in West Africa, W. M. Graham (*Jour. Econ. Biol., 3 (1908), No. 4, pp. 113–117, pls. 2, fig. 1*).—A capsid belonging to an undetermined genus, *Chryphalus horridus*, and *Ceratitis anonæ* are described as new to science.

On a new species of Kermes destructive to oak trees in North India, E. E. Green (*Ent. Mo. Mag., 2. ser., 20 (1909), No. 229, pp. 10–12, figs. 4*).—The species here described (*Kermes himalayensis*) is reported as killing oaks (*Quercus incana*) over a considerable area.

The large larch sawfly, C. G. Hewitt (*Jour. Bd. Agr. [London], 15 (1908), No. 9, pp. 649–660, pl. 1, map 1*).—The author here considers the life history of *Nematus erichsonii*, the nature and effects of its attack, its occurrence, natural enemies, and remedial and preventive measures. Birds and the field vole (*Microtus [Arvicola] agrestis*) are reported to be the most important factors in the natural control of this pest. In two lots of cocoons examined, 3.4 and 9.5 per cent, respectively, were found parasitized by the ichneumon *Mesoleius audicus*.

The Monterey pine resin midge (Cecidomyia resinicoloides n. sp.), F. X. Williams (*Ent. News, 20 (1909), No. 1, pp. 1–8, pl. 1*).—The author here presents an account of the life history and habits of a species new to science.

Biological studies on bark beetles, C. Hennings (*Naturw. Ztschr. Forst u. Landw., 5 (1907), Nos. 1, pp. 66–75; 2, pp. 97–125; 12, pp. 602–608, fig. 1; 6 (1908), No. 9, pp. 469–486, fig. 1*).—In part 1 of this report the biology of *Tomicus typographus* is considered. In part 2, *Ips typographus*, *I. sexdentatus*, and *Myelophilus piniperda* are briefly considered. Part 3 has been previously noted (E. S. R., 20, p. 559). Part 4 is devoted to a discussion of the life histories and feeding habits of bark beetles.

The fumigation of nursery stock, B. W. Douglass (*Ind. State Ent. Bul. 2, pp. 9, figs. 3*).—During the summer of 1907 over 30 nurseries in Indiana were found infested with the San José scale. The author describes a fumigation house of concrete that was built for a nursery man at a total cost of less than $100. Photographs are given of the house while under construction and after completion.

Attention is called to the fact that the formula given for fumigation is based upon the chemically pure potassium cyanid and not upon the commercial brand, which averages less than 50 per cent pure. Examinations made of samples of potassium cyanid obtained from nurseries over the State where fumigation is carried on show that as a rule the article sold by the average druggist is of the commercial grade.

Directions are given by the author for the fumigation of stock and by W. C. Reed for the fumigation of buds and scions.

Descriptions of some new species and a new genus of American mosquitoes, H. G. Dyar and F. Knab (*Smithsn. Misc. Collect., 52, No. 1813, pp. 253–266, fig. 1*).—The genus Dianamesus based upon the new species *D. spanius* which was collected in the Canal Zone, Panama, is described as new to science. Thirty-five species belonging to the genera Aedes, Bancroftia, Culex, Deinocerites, Wyeomyia, and Limatus are also described as new.

Mosquito comment, H. G. Dyar and F. Knab (*Canad. Ent., 41 (1909), No. 3, pp. 101, 102*).—*Culex trachycampa* from the Canal Zone, Panama, and *Aedes sansoni* from Banff, Alberta, Canada, are described as new.

On the larval and pupal stages of Anopheles maculipennis, A. E. Mms (*Pt. 1, Jour. Hyg. [Cambridge], 7 (1907), No. 2, pp. 291–318, pls. 2; pt. 2, Parasitology, 1 (1908), No. 2, pp. 103–133, pls. 2*).—The author presents a detailed description of the internal structure of the larva and pupa of this mosquito. A bibliography is appended to each part.

Biology of Philippine Culicidæ, C. S. Banks (*Philippine Jour. Sci., A. Gen. Sci., 3 (1908), No. 4, pp. 235–258, pls. 10*).—Studies were made on the life history and habits of *Worcesteria grata, Desvoidya jolonsis, Stegomyia persistans, S. samarensis, Hulecatomyia pseudotæniata*, the filaria mosquito (*Culex fatigans*), *Banksinella lutcolateralis, Mansonia annulifera*, and *M. uniformis*. The larvæ of *W. grata* are said to destroy enormous numbers of those of other species. It is the author's opinion that *Mansonia uniformis* plays a rôle in the transmission of dengue fever as important as does *Culex fatigans*.

New Philippine mosquitoes, C. S. Ludlow (*Canad. Ent., 41 (1909), No. 3, p. 97*).—A new species of mosquito collected at Parang, Mindanao, P. I., is described as *Oculiomyia fulleri*.

Millions and mosquitoes, H. A. Ballou (*Imp. Dept. Agr. West Indies Pamphlet 55, 1908, pp. 16, fig. 1; West Indian Bul., 9 (1909), No. 4, pp. 382–390, figs. 4*).—An account is given of a species of small fish (*Girardinus pœciloides*), commonly known as million, which largely assists in keeping some species of mosquitoes in check through feeding upon the eggs, larvæ, and pupæ. This fish has recently been introduced into St. Kitts-Nevis, Antigua, Jamaica, St. Vincent, St. Lucia, and Guayaquil, and also into British Guiana, Colon, and Bolivar.

A note upon the possibility of the mosquito acting in the transmission of leprosy, W. R. Brinckerhoff (*Washington, D. C.: Pub. Health and Mar. Hosp. Serv. U. S., 1908, pp. 22–24*).—The author has found *Culex pipiens* to defecate during the process of blood sucking in a way very similar to *Myzomyia ludlowii* as observed by Banks. Such a habit makes it mechanically possible for mosquitoes to carry lepra bacilli from lepers to well persons and highly

probable that if so carried the bacilli will be rubbed into the skin of the person bitten.

Bibliography on flies and mosquitoes as carriers of disease, W. P. Gerhard (*Ent. News, 20 (1909), Nos. 2, pp. 84–89; 5, pp. 207–211*).—One hundred and nine titles are listed.

A preliminary account of the biting flies of India, H. M. Lefroy (*Agr. Research Inst. Pusa [India] Bul. 7, 1907, pp. III+45+II, pls. 4, figs. 32*).—In this preliminary account the author considers briefly the classification, life histories, and habits of the blood-sucking flies.

A new species of Ceratophyllus, C. Fox (*Ent. News, 20 (1909), No. 3, pp. 107–110, figs. 3*).—A new species of flea taken from *Microtus californicus* and also from the nest of a wood rat (*Neotoma* sp.) is here described as *C. multidentatus*.

The tumbu-fly (Cordylobia anthropophaga), E. E. Austen (*Jour. Roy. Army Med. Corps, 10 (1908), No. 1, pp. 18–24, figs. 2*).—An account of the life history and habits of a fly found in Central and South Africa which in the maggot stage burrows beneath the skin of human beings, monkeys, dogs, and other animals.

Description of two new species of African ticks, G. Neumann (*Ann. Trop. Med. and Par., 1 (1907), No. 1, pp. 115–120, figs. 4*).—*Rhipicephalus duttoni* taken from a bovine at Zambie and *R. longus* from a bovine at Kasongo are here described as new.

The structure and biology of Hæmaphysalis punctata, I, G. H. F. Nuttall, W. F. Cooper, and L. E. Robinson (*Parasitology, 1 (1908), No. 2, pp. 152–181, pls. 5, figs. 9*).—An account is given of this European species which is widely distributed, though never very numerous. The great majority of these ticks received by the authors were taken from sheep, though specimens were also received that had been taken from goats and ferrets.

Experimental studies on the transmission of recurrent fever by ticks, B. Möllers (*Ztschr. Hyg. u. Infectionskrank., 58 (1908), No. 2, pp. 277–286; abs. in Bul. Inst. Pasteur, 6 (1908), No. 21, p. 964*).—Experiments conducted with *Ornithodoros moubata* brought back by Koch from German East Africa are reported. The author presents data on the life history and habits of this tick and reports experiments in which recurrent fever was transmitted to monkeys. Larvæ from infected females were found to transmit the disease.

Spirochetosis transmitted in Tunis by Argas persicus, B. Galli-Valerio (*Centbl. Bakt. [etc.], 1. Abt., Orig., 47 (1908), No. 4, pp. 494, 495.*)—The author has demonstrated the occurrence of *Spirochæta gallinarum* in Tunis and that *A. persicus* is the active agent in its transmission.

Mycetozoan endoparasites of insects. I, Sporomyxa scauri, n. g. and n. sp., L. Léger (*Arch. Protistenk., 12 (1908), No. 1–2, pp. 109–130, figs. 3*).—The species here reported is a parasite of the tenebrionid beetle *Scaurus tristis*. The specimens studied came from Algeria, particularly the province of Oran, where this parasite appears to be widely distributed. As a result of infestation the reproductive organs of the host are said to be destroyed.

The house cockroach, J. R. Inda (*Estac. Agr. Cent. [Mexico] Bol. 7, pp. 16, pl. 1*).—*Ectobia germanica* is the species here considered.

Descriptions and records of bees, T. D. A. Cockerell (*Ann. and Mag. Nat. Hist., 8. ser., 2 (1908), No. 10, pp. 323–334*).—A list of fossil Bombiform bees, a general scheme of relationships, and a description of a new fossil species are given. Records of bees collected in Colorado, descriptions of several new species, and a table for the separation of bees in the Foxii group of Nomia follow.

Report of State inspector of apiaries, M. E. Darby (*Missouri Bd. Agr. Mo. Bul., 6 (1908), No. 11, pp. 3–13, figs. 6*).—During the season of 1908, 340 apiaries and 5,155 colonies were inspected, of which 166 apiaries and 469 colonies were found diseased. A brief account is given of foul brood and other bee diseases.

The hive and honey bee, L. L. Langstroth, rev. by C. Dadant (*Hamilton, Ill., 1908, pp. X+575, pls. 28, figs. 229*).—A second revision of this work.

A guide to the culture of mulberry trees and to the commercial raising of silkworms, J. Bolle (*Anleitung zur Kultur des Maulbeerbaumes und zur Rationellen Aufzucht der Seidenraupe. Görz, 1908, pp. VII+107, pls. 2, figs. 112*).—In part 1 the author considers the culture of mulberry trees, their enemies, diseases, etc. In part 2 a detailed account is given of the methods of rearing silkworms, nature and treatment of the diseases affecting them, etc.

Inheritance in silkworms, I, V. L. Kellogg (*Leland Stanford Jr. Univ. Pubs., Univ. Ser., 1908, No. 1, pp. 89, pls. 4, figs. 2*).—This is said to be a first contribution of data and results derived from a general study of silkworm inheritance.

FOODS—HUMAN NUTRITION.

On the presence of tin in certain canned foods (*Local Govt. Bd. [Gt. Brit.], Med. Dept., Rpts. Insp. Foods, 1908, No. 7, pp. 30*).—This document consists of two parts, namely, a report of investigations and a discussion.

General observations on the inquiry, by G. S. Buchanan (pp. 1–4).—The investigations reported in the following paper are briefly summarized and discussed.

On the presence of tin in certain canned foods, together with some investigations on the toxicology of tin, by S. B. Schryver (pp. 5–30).—The author reports the examination for tin of a large number of samples of canned goods, in many cases five to seven years old. A colorimetric and gravimetric method were used for the estimation of tin, the former depending upon the purple color reaction obtained by the use of dinitro-diphenylamine-sulphoxid with stannous chlorid in the presence of an excess of hydrochloric acid. Under the experimental conditions described 0.25 grain of tin per pound of sample gave a marked color.

The procedure in the gravimetric method employed was for the most part similar to that used for the colorimetric estimation. "The organic matter was destroyed by a mixture of potassium sulphate and sulphuric acid, and the tin precipitated from the diluted solution as sulphid. This was converted into oxid, which was weighed as such instead of being estimated colorimetrically."

As regards the results obtained, "the meat foods, as a class, appeared to have taken up into their substance a comparatively small proportion of tin, even after six years or more. Often the quantity of tin present in these meats has been less than 0.5 gr. per pound; in only one instance (canned tripe) did it reach 2 gr. per pound. Meat extracts of similar age, however, had absorbed a considerably greater proportion of tin, and the same in a less degree was the case with meat essences.

"Only one of the three samples of canned soup of 6 to 8 years old contained tin in large quantities; in this instance the soup no doubt contained fruit acid derived from tomatoes. Canned lobster of 6 to 8 years of age had absorbed as much as 2.39 gr. of tin to the pound. . . .

"The two samples of canned vegetables (parsnips and carrots, 6 to 8 years) showed 1.5 and 2.19 gr. of tin per pound respectively. Canned jams and puddings containing fruit, of the same age, took up considerably more tin than the

meat foods; the apple and plum puddings and a sample of apricot jam contained about 3 grains of tin to the pound. No samples of the canned fruits most commonly consumed in this country (pears, apricots, pineapple, etc.) were included . . . [in the samples examined.] It was satisfactory to find that the highest amount of tin present in samples of canned pears, apricots, and peaches, obtained from a London importer, who specially selected them as old stock and stated them to be between 1 and 2 years old, was not more than 1.03 gr. per pound."

As the author notes, his investigations brought out a fact which he had observed before with meat extracts, namely, "that the tin after solution in the liquid contents of the can, becomes in course of time absorbed in or chemically combined with the solid contents (meat, fruit, etc.) in such a way that the latter contain relatively larger quantities than the liquid itself.

"Other examinations tended to emphasize the important part which may be played by unsatisfactory soldering in connection with high degrees of contamination; . . . It is evident that the presence of solder in the contents of the can may cause very pronounced solution of tin; no doubt owing to electrolytic action. It is possible that unsatisfactory tin plate (e. g., cans which have been so thinly coated on the interior that the underlying metal is at points practically exposed to the action of the contained liquid) may also tend to affect the extent of solution of tin by means of electrolytic action."

In pharmacological studies of which the author himself was the subject tin in the form of a double tartrate with sodium was taken during three weeks. Urine and feces were collected and examined.

"In the one experiment on a human being, the excretion of tin kept pace for a fortnight with the intake, when the latter did not exceed 2 gr. daily. With an increase of dose in the third week, there was some evidence of a cumulative action. . . . There was in all cases relatively small amount of absorption from the alimentary tract, as indicated by the small amounts of metal excreted in the urine. When tin enters the system by a channel other than the alimentary tract, the metal is excreted (at any rate in the case of dogs) in larger quantities in the urine than in the feces. . . .

The data presented . . . "do not indicate much probability of serious risk of chronic poisoning by the absorption of nonirritant compounds of tin as a result of a diet which consists largely of canned foods and is continued over considerable periods of time."

The work of other investigators is summarized and discussed in connection with the experimental data reported and a bibliography is appended to the paper.

The deterioration and commercial preservation of flesh foods. I, General introduction and experiments on frozen beef. W. D. Richardson and E. Schierbel (*Jour. Amer. Chem. Soc., 30 (1908), No. 10, pp. 1515–1564*).—The general subject of deterioration of meat is discussed and results of experiments reported on the physical and chemical changes which take place when meat is kept in cold storage.

The physical changes in frozen beef may be due to desiccation or to pressure produced by the expansion of water during the freezing process and particularly to the fact that water freezes outside the cell walls. Another physical effect in meat under conditions of storage lies in the contraction of the insoluble tissue elements which takes place even when the moisture remains constant. The temperature at which meat becomes solid depends upon phenomena connected with the lowering of the freezing point of water by the presence of soluble solids and similar constituents.

The evidence from both cultural and microscopic examinations of frozen beef led to the conclusion that bacteria are not capable of penetrating it in this con-

dition. In the chemical work on frozen meat it was the authors' purpose to show whether or not there was a progressive change in the constituents of the meat such as would result in an increase of its soluble constituents and ammoniacal nitrogen. The figures for fresh and frozen samples are very similar, and the variations did not tend definitely in one direction. The authors believe that whenever decomposition of meat occurs to any noticeable extent volatile basic substances are formed, increasing with the degree of decomposition, chief of which is NH_3 derived from NH_4 salts.

From their experiments they conclude that no decomposition is shown by the values obtained for ammonia nitrogen and hence that no bacterial decomposition occurred in the stored meat. Frozen beef stored 610 days was in their opinion not different in flavor from fresh beef. The general conclusion is reached that cold storage below — 9° is an adequate and satisfactory method for the preservation of beef for at least 554 days.

Refrigeration and the preservation of meat, U. Ferretti (*I Frigoriferi e la Conservazione delle Carni. Rome, [1908], pp. 26, figs. 21*).—This article contains a summary and discussion of refrigeration and cold storage with special reference to meat and the use of cold storage meat in the diet.

Food products at the First International Cold Storage Congress, H. Bouvier (*Rev. Sci. [Paris], 5. ser., 10 (1908), No. 26, pp. 804–808*).—A report of proceedings of the First International Cold Storage Congress, Paris, October, 1908, with special reference to the question of preservation of food.

The preserving of fruits, vegetables, and meat, Rosa Albert (*Das Konservieren von Obst, Gemüse und Fleisch. Hanover, 1907, pp. VIII+93, figs. 11*).—This is a second edition of a work on the preserving of foods and is based on the practical experience of the author.

The temperature attained in sterilizing preserved vegetables and fruits, J. Kochs and R. Weinhausen (*Ber. K. Gärt. Lehranst. Dahlem. 1906–7, pp. 146–161; Pure Products, 4 (1908), Nos. 11, pp. 517–522; 12, pp. 565–571*).—In confirmation of the work of other observers, it was noted that the diffusion of heat in sterilizing canned goods is dependent upon the manner in which the contents are packed. The more solidly the material is packed, and the less fluid in the can, the greater the difficulty with which the heat will penetrate. The results obtained are not regarded as definite enough for final deductions.

In tests with glass and earthenware jars satisfactory results were obtained. Since heating canned goods in a water bath does not make it certain that all of the micro-organisms are killed, the authors believe that fractionated sterilization is sometimes desirable. The great importance of cleanliness in canning is insisted upon.

The manufacture of preserved vegetables, J. Ott (*Die Fabrikation der Gemüsekonserven. Leipsic, 1909, pp. VIII+143, figs. 24*).—A general treatise on the canning of vegetables on a commercial scale.

Preserved fruits in Europe, H. L. Washington and R. P. Skinner (*Daily Cons. and Trade Rpts. [U. S.], 1909, Nos. 3399, pp. 1–4; 3414, pp. 1–8*).—These consular reports describe French methods of preparing candied fruits and chestnuts.

Canning and preserving, E. K. Ellsworth (*Bur. of the Census [U. S.], Manfrs. 1905, pt. 3, pp. 389–429*).—Noted from another source (E. S. R., 19, p. 166).

Slaughtering and meat packing (*Bur. of the Census [U. S.], Manfrs. 1905, pt. 3, pp. 457–491*).—Noted from another source (E. S. R., 20, p. 63).

The examination of sausage, E. Roth (*Schweiz. Wchnschr. Chem. u. Pharm., 47 (1909), No. 7, pp. 93–96*).—Analytical data are reported and discussed. The

author concludes that on the fat-free basis sausage should not contain more than 75 per cent water.

Spectroscopic properties of yolk of egg, L. Lewin, A. Miethe and E. Stenger (*Arch. Physiol. [Pflüger], 124 (1908), pp. 585–590; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 554, II, 1054*).—Attempts are being made to establish relationships between the coloring matters of egg yolk and blood on account of the close morphological relation of these materials. Spectroscopic analysis showed that the yellow coloring matter in the yolk gave characteristic bands and it is therefore concluded that it is possible to detect the adulteration of egg yolk by spectroscopic measurements.

The nutritive value and digestibility of raw and soft boiled hens' eggs, S. Aufrecht and F. Simon (*Deut. Med. Wchnschr., 34 (1908), No. 53, pp. 2308–2310*).—From the results of a single digestion experiment with a healthy man, in which raw and soft boiled eggs were eaten in comparison with meat as a part of a simple mixed diet, the authors conclude that the raw eggs have the higher digestibility and nutritive value.

Desiccated milk, W. M. Booth (*Spice Mill, 31 (1908), No. 10, pp. 620–623*).—A brief description is given of the method of manufacture of several sorts of commercial powdered milk goods and analytical data are summarized regarding the composition of such materials. As the author points out, powdered milks are made to contain varying amounts of fat by the removal of more or less cream before evaporation.

Notes on investigations on the nutritive value of plant amids, E. Schulze (*Ztschr. Physiol. Chem., 57 (1908), No. 1–2, pp. 67–73*).—A critical discussion of recently published work on this subject.

Starch, R. H. Merriam (*Bur. of the Census [U. S.], Manfrs. 1905, pt. 3, pp. 381–388*).—Noted from another source (E. S. R., 20, p. 64).

On some vegetable fats native to Sarawak, J. Hewitt (*Agr. Bul. Straits and Fed. Malay States, 6 (1908), No. 5, pp. 173–175*).—A number of oil bearing seeds are described which are important sources of culinary fats used by Malays. Some information is also given regarding the character of the oils and methods of preparation.

Befri seed, W. H. Michael (*Mo. Cons. and Trade Rpts. [U. S.], 1908, No. 338, p. 125*).—Some information is given regarding the composition and use as food in India of the seed of a leguminous plant called befri (*Indigofera glandulosa*).

Sensitiveness to light of white animals fed buckwheat, W. Öhmke (*Zentbl. Physiol., 22 (1908), No. 22, pp. 685, 686*).—It has been observed that white or partially white animals fed buckwheat, when exposed to light, suffer from skin disease, and the author made experiments with small animals to obtain additional data on this subject. It was found that the skin affection followed eating either buckwheat grain or hull, but that the effects were not noted if the animals were kept in the dark. The alcoholic extract of buckwheat produced the same effects while the extracted grain did not do so. The alcoholic extract was fluorescent and the author suggests a possible connection between buckwheat disease, fagopyrismus, and this property, in line with results of other investigators. [This work is of interest in view of the widespread belief that eating buckwheat causes rash and other skin troubles.]

Pellagra, a précis, C. H. Lavinder (*Washington: Pub. Health and Mar. Hosp. Serv. U. S., 1908, pp. 22, pl. 1*).—This digest of data regarding the occurrence, symptoms, and treatment of pellagra, a disease most prevalent in northern and central Italy and in Roumania and commonly attributed to eating spoiled Indian corn, is of interest in connection with the preparation and use

of corn as food, especially since "there has appeared in the Southern States a disease which is possibly true pellagra. . . .

"The culture of maize in the United States has been practiced since before the discovery of America, and it has always been a staple article of diet over a large area of territory, yet, with the exception of a few sporadic cases in Mexico and Central America, the North American continent has been singularly free from the disease. This has been attributed by writers on pellagra to a climate well adapted to growing maize, and probably to better general hygienic conditions among the poorer rural classes."

As regards the prophylaxis treatment of the disease, "this may be summed up briefly—cease using spoiled maize as food. This seems simple enough, but in reality is often difficult of accomplishment for many obvious reasons. In individual cases it may often be easy, but to apply it to a large area of territory is another matter. The only apparent methods would seem to be: (1) Avoid alterations in maize and consequent feeding on a toxic substance; (2) replace maize with some other cereal and cease using all food and drink derived from maize [where the disease exists].

"Many and various attempts have been made in Italy to do the former by the establishment of drying ovens, economical kitchens, pellagrous hospitals, etc., but such efforts have not met with great success. As for the latter, at present the difficulties seem almost insuperable."

Corn oil in the treatment of pulmonary tuberculosis, J. Ritter (*Jour. Amer. Med. Assoc., 51 (1908), No. 1, pp. 39, 40*).—In this discussion of the use of corn oil in the treatment of tuberculosis the author presents data on its manufacture and general food value. In his opinion corn oil is an economical and useful food fat.

Aboriginal methods of preparing corn for food by the American Indians of Arizona and New Mexico, E. Krulish (*Dietet. and Hyg. Gaz., 25 (1909), No. 1, pp. 55–57*).—On the basis of personal knowledge the author discusses the methods followed in making corn bread and other corn food dishes and beverages.

Some useful maize dishes (*Natal Agr. Jour., 11 (1908), Nos. 10, pp. 1297–1303; 11, pp. 1446–1455*).—A collection of recipes for Indian corn dishes.

Rice, cleaning and polishing, H. McK. Fulgham (*Bur. of the Census [U. S.], Manfrs. 1905, pt. 3, pp. 431–442*).—Noted from another source (E. S. R., 19, p. 166).

Flour and grist mill products, E. K. Ellsworth (*Bur. of the Census [U. S.], Manfrs. 1905, pt. 3, pp. 341–379*).—Noted from another source (E. S. R., 20, p. 64).

Milling of wheats, J. C. Brunnich (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1907–8, pp. 67, 72–77*).—As part of the work of the agricultural chemist milling tests of a large number of varieties of wheat were made and reported. The author notes that in the case of some of the flours gluten could not be obtained in the usual manner, by washing, as it crumbled into small pieces. This the author attributes to previous treatment of the flour with sulphur fumes.

Hungarian wheat and Hungarian flour, T. Kosutány (*Der Ungarische Weizen und das Ungarische Mehl. Budapest, 1907, pp. 356, figs. 60, map 1*).—An exhaustive summary and digest of data on Hungarian wheat and flour. The author subdivides his volume into three divisions, namely, (1) wheat from the standpoint of chemistry, plant physiology, physical and agricultural value, (2) flour, and (3) bread.

The theory and practice of testing flour, Cornelia Kennedy (*Pure Products, 5 (1909), No. 3, pp. 127–135*).—The author summarizes and describes the

methods of testing the quality of flour employed by millers, including determinations of moisture, ash, acids, total nitrogen and gliadin, baking tests, absorption and expansion tests, and determinations of wet and dry gluten.

"These are the principal tests, technical and chemical, generally used in testing flour. No single test has yet been found which can be used to the exclusion of other tests nor can any hard and fast rule be laid down as to what constitutes a flour of high baking qualities. By making these tests day in and day out records accumulate which are invaluable as guides in the testing and making of flour."

Defense of the bleaching of flour, B. S. Elliott (*Amer. Hay, Flour, and Feed Jour., 14 (1909), No. 2, pp. 27–29*).—A summary of data presented in a hearing before the Secretary of Agriculture, with reference to the legal status of flour bleaching.

Air bleaching of flour in the doughing state, C. Cristadoro (*Amer. Miller, 36 (1908), No. 8, pp. 619, 620*).—According to the author, white bread can be made from yellowish durum flours by so controlling the fermentation of the dough that the bread is thoroughly aerated.

Fungus and bacterial growth on stored flour, H. G. Bell (*Amer. Miller, 37 (1909), No. 4, pp. 280, 281, fig. 1*).—As the author points out, the chief destructive agencies in stored flour are fungi and bacteria. "The fungi or molds readily break down the starches of the flour, setting free organic acids and causing the flour to go sour. The bacterial forms, on the other hand, are all liquefying, or decomposing, in nature, and cause the rapid destruction of the flour."

In a comparison of patent flour and baker's flour of good grades stored under the same conditions a greater number of both bacteria and molds were found in the baker's flour than in the patent grade. "This is probably due to the finer separations made in the process of separating the high-grade flour. Without doubt, these molds and bacteria have much to do with the deterioration of flours in storage. Probably the molds cause the rapid increase in acid, which reacts upon the gluten of the flour. Some of the liquefying bacteria probably react upon this same element, the gluten of the flour, causing the value of the material stored to deteriorate very rapidly."

As protection against the growth of these low forms of life the author suggests storage in well-lighted rooms.

The water content of bread, O. Mezger (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 7, pp. 395–397*).—Determinations of the water content of black bread and white bread are reported which were undertaken in a comparison of actual conditions with the food-law requirements. The results show, according to the author, that in many cases the crumb of freshly baked bread does not show the qualities which might be expected from a determination of its water content.

Concerning the potato content of bread, J. Tóth (*Chem. Ztg., 32 (1908), pp. 685, 686; abs. in Chem. Abs., 2 (1908), No. 20, p. 2831*).—No differences in protein content were noted in bread made from wheat, rye, a mixture of wheat and rye, and wheat and potato in equal parts. The potato bread, however, gave a smaller and moister loaf. The ash of the potato flour contained considerably less phosphoric acid than the wheat or rye flour.

Sophisticated zwieback, E. Glaser (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 8, pp. 469–473*).—One of the samples of zweiback described showed green patches due to the use of artificially colored caraway seeds and the other showed brown spots due to rancid oil from aniseed added to the dough. Suitable packages for marketing zweiback, and similar questions were discussed.

The iron and phosphorus content of vegetables, E. Haensel (*Biochem. Ztschr., 16 (1909), No. 1, pp. 9–19*).—Determinations of total ash, phosphoric acid, and iron oxid in a large number of samples of vegetables, fruits, and nuts are reported. In 3 sorts of edible fungi, peanuts, and Brazil nuts lecithin was determined and in the case of the fungi the nitrogen also.

In connection with this work the author studied the amount of iron removed in cooking spinach and lettuce. In one test with spinach 0.17 per cent iron oxid was found in the material extracted in cooking and 0.73 per cent in the material not dissolved. In the second test the values were 0.15 and 0.66 per cent. When lettuce was cooked in a similar way 0.35 per cent iron was found in the extracted material and 0.84 per cent in the insoluble portion in one test and 0.39 and 0.85 per cent, respectively, in the second test. As the author notes, these results show that all the iron contained in such foods is not utilized if the water in which they are cooked is thrown away.

Beans containing hydrocyanic acid, L. Guignard (*Rec. Actes Off. et Doc. Hyg. Pub., Trav. Cons. Sup. Hyg. Pub. France, 36 (1906), pp. 594–632*).—A summary of extended investigations of beans of different sorts.

The author concludes that all varieties of *Phascolus lunatus*, both wild and cultivated, contain the hydrocyanic acid compound and the ferment which liberates the hydrocyanic acid when the grain, crushed or ground, is mixed with water and the temperature is not great enough to destroy the ferment. In order that beans may be free from hydrocyanic acid it is essential that cooking be long continued.

In an appendix a method of determining hydrocyanic acid is proposed.

Canned vegetables containing copper, G. Graff (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 8, pp. 459–468*).—The author concludes that copper salts are not native bodies and that their use should be restricted. The article contains data regarding the extent of the greening of vegetables with copper salts in Germany and methods for detecting copper.

The rapid change in composition of certain tropical fruits during ripening, H. C. Prinsen Geerligs (*K. Akad. Wetensch. Amsterdam Proc. Sect. Sci., 11 (1908), pp. 74–84; abs. in Jour. Chem. Soc. [London], 94 (1908), No. 553, II, p. 977*).—Mangoes, bananas, tamarinds, and sapodillas, the fruits included in this investigation, are commonly gathered in an immature state; within a few days they become tender and palatable, and in a few days more they become overripe, soft, and unpalatable. Experiments with bananas showed that during the ripening process there is an evolution of carbon dioxid and water, and a considerable conversion of starch into sugar. Oxygen is necessary for the ripening process, and bananas will keep their starch intact if surrounded with an atmosphere of nitrogen. The author therefore considers that sugar production is a vital process, although he succeeded in showing the presence of an enzym capable of decomposing starch.

The results obtained with the mango were similar to those obtained with the banana. In the case of the sapodilla, however, the amount of sugar before and after ripening remains unaltered, and the change appears to be chiefly a softening of the hard pectin, and a deposition of tannin and gutta-percha from the juice as insoluble substances.

A sweetmeat from bananas, R. J. Totten (*Mo. Cons. and Trade Rpts. [U. S.], 1909, No. 341, p. 76*).—The author describes a method of making a crystallized fruit sweetmeat by drying bananas in sugar.

Sulphured fruit, H. Lührig (*Pharm. Zentralhalle, 49 (1908), No. 42, pp. 851–854*).—The author examined different portions of packages of sulphured fruits to determine whether the sulphur content was uniform, a matter of importance in the examination of such goods in connection with food inspection.

According to his results the middle portion contained more sulphur than either the upper or lower layer. It was also found that the length of time the goods were kept affected the quantity of the sulphur, much smaller amounts being found after storage for about 9 months.

[Wholesomeness of sulphured fruits], A. J. Atkins (*Cal. Fruit Grower, 39 (1909), No. 1073, pp. 3, 11, fig. 1*).—A popular description of a test in which a considerable quantity of sulphured fruit was included in the diet. From general considerations of weight and opinions of the subjects the author believes no harmful results were induced. Some determinations of the sulphurous acid in the cooked fruit are reported.

Vegetables and fruit as articles of diet and remedial agents, A. Brass (*Schr. Volksw. Ver. Obst u. Gemüseverwert. Deut., 1908, No. 3, pp. 14*).—A popular discussion of the subject.

Viscosity of cane-sugar molasses, H. C. Prinsen Geerligs (*Internat. Sugar Jour., 10 (1908), No. 120, pp. 584–592*).—The investigations reported and discussed led to the conclusion that concentration and temperature are the principal factors which determine the viscosity of molasses, and that the gum content, the presence of decomposition products of reducing sugar and other deposits, and the presence of fine grains of sugar, are secondary factors. Molasses which is satisfactory from the standpoint of viscosity may be obtained "by taking care not to drive the concentration of the last massecuites too far, or, in case they have become too much concentrated, to dilute them with dilute molasses in a judicious manner and this until the sugar-salt combination . . . has attained its own full-water content."

Maple sirup, A. Thurston (*Merck's Rpt., 18 (1909), No. 3, pp. 60, 61*).—The author reports results obtained in the examination of 33 samples of pure maple sirup and 3 samples of adulterated goods and outlines the methods followed.

The honey produced by sugar-fed bees, Neubauer (*Rheinische Bienenztg., 59 (1908), pp. 110–113; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 17 (1909), No. 1, p. 58*).—The author does not consider that such goods can properly be called honey.

Concerning rose apple jam, O. Mezger and K. Fuchs (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 7, pp. 390–395, figs. 4*).—A microscopical and chemical study of rose hips and jam made from them. This material is commonly homemade but has some commercial importance in Germany.

Ice cream, A. McGill (*Lab. Inland Rev. Dept. Canada Bul. 162, pp. 14*).—Of 80 samples of ice cream received in such condition that the fat content could be studied one-half contained over 14 per cent and one-half less than 14 per cent of this constituent. Of the last-mentioned group 12 samples contained less than 10 per cent fat. Gelatin was found in 73 of the samples examined and starch in 27. In some cases the starch was present in small quantities and "may be due to the freezing apparatus, or other container, having previously been used for a starch containing product."

Most of the samples were uncolored. Of those which were colored only two contained coal-tar dyes.

Composition of oriental foodstuffs: Bosa, halva, and locoum, N. Petkoff (*Ztschr. Öffentl. Chem., 14 (1908), No. 11, pp. 205–208*).—The first of these products is a nonalcoholic beverage and the remaining two a sort of confection. Analyses of a number of samples of each are reported.

Cider, A. McGill (*Lab. Inland Rev. Dept. Canada Bul. 169, pp. 19*).—The results of an examination of a large number of samples of cider are reported. Although the author considers some of them suspicious, he believes that more work is needed before a definite pronouncement can be made as to the specific character of cider and the extent of its variations.

Native wines, A. McGill (*Lab. Inland Rev. Dept. Canada Bul. 160, pp. 23*).—Analyses of a large number of samples of native wines are reported and discussed.

Swiss wine statistics (*Landw. Jahrb. Schweiz, 22 (1908), No. 11, pp. 601–623*).—A summary of statistics of the wine produced in Switzerland in 1907.

A study of certain genuine wines from the province of Florence, R. Salvadori and A. Mazzaron (*Gaz. Chim. Ital., 38 (1908), I, pp. 54–63, figs. 2*).—Analyses of 15 samples of red wine and 3 samples of white wine are included in this report.

Composition of Mâconnais-Beaujolais wine, G. Paturel (*Prog. Agr. et. Vit. (Ed. l'Est-Centre), 30 (1909), No. 5, pp. 147–153*).—Samples of 49 wines were analyzed.

Analyses of musts and wines from vines sprayed with arsenic compounds, A. Szameitat (*Ber. K. Lehranst. Wein, Obst u. Gartenbau Geisenheim, 1907, pp. 176–179*).—The analyses in most cases showed only a slight trace of arsenic.

The occurrence of arsenic in German wines, A. Szameitat (*Ber. K. Lehranst. Wein, Obst u. Gartenbau Geisenheim, 1907, pp. 180–185*).—Of 38 samples analyzed 24 showed small amounts of arsenic, the source of which was not identified.

Investigation of musts and wines from vines infested with Peronospora (*Ber. K. Lehranst. Wein, Obst u. Gartenbau Geisenheim, 1907, pp. 191–204*).—The fermentation of the musts and composition of the wine were found to be entirely normal, and the conclusion is reached that the so-called peronospora taste noticeable in some wines must be due to faulty fermentation, incorrect cellar treatment, or some other similar cause.

Olive oil for protecting wine, U. Rossi-Ferrini (*Rivista, 4. ser., 14 (1908), No. 17, pp. 392–395*).—Spoiling of wine owing to the rancidity of olive oil floated on top to protect it is discussed.

Effects of coffee and objections to the use of chicory, R. Grimshaw (*Brit. Food Jour., 11 (1909), No. 121, p. 3*).—Data on the effects of coffee and chicory are summarized from which the following statements are quoted:

"The organic constituents of roasted chicory mainly consist of sugar, with caramel, inulin, and albumin. With the caramel there are also other organic coloring matters; and the tinctorial power being very great, this is a principal reason for the employment of chicory as an addition to coffee, very slight quantities thereof sufficing to make true coffee infusion appear very dark brown, hence apparently very strong. Digestion is more impeded by chicory than by coffee. The constant use of extract of chicory as a drink may cause injury to the system by reason of the great quantity of potash salts which it contains, and it exhibits no compensating advantages in the way of nourishment or stimulating and exhilarating effects on the system."

Concerning the quality of tea, C. Hartwich and P. A. Du Pasquier (*Apoth. Ztg., 24 (1909), No. 14, pp. 130, 131*).—A number of analyses are reported and discussed with reference to judging the quality of tea.

Concerning coco, K. Farnsteiner (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 11, pp. 625–647*).—A study of the effects of the different methods of treating coco to increase its solubility.

The microscopical examination of chocolate and powdered coco, E. Collin (*Ann. Chim. Analyt., 13 (1908), No. 12, pp. 471–478, fig. 1*).—With a view to facilitating the examination of coco and chocolate the author reports the results of a microscopical study of the histological elements of these materials.

Pepper adulterated with vetch seeds, Fleury (*Trav. Sci. Univ. Rennes, 6 (1907), pp. 140–142*).—A sample of unground black pepper examined was

found to contain 30 per cent of vetch seed treated with some solution which had given a spicy taste and caused a wrinkled appearance.

Ground pepper. A. McGill (*Lab. Inland Rev. Dept. Canada Bul. 165, pp. 33*).—Of the 298 samples of pepper examined 216 were considered genuine, 13 doubtful, and 69 adulterated.

"It appears that the chief centers of adulteration of pepper are in and about Montreal, although Winnipeg is becoming too prominent in this regard."

Oil of lemon. A. McGill (*Lab. Inland Rev. Dept. Canada Bul. 154, pp. 11*).—Analyses are reported of 45 samples of lemon oil collected in Canada. Definite conclusions are not drawn from the work.

Concerning canarium oil. K. Wedemeyer (*Seifensieder Ztg., 34 (1907), p. 26; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 17 (1909), No. 1, pp. 57, 58*).—A study of the physical and chemical characteristics of canarium or Java almond oil. This oil, as stated, is used as a high grade culinary fat and also as an adulterant for almond oil. When thus used it may be detected by means of its iodin number.

Concerning Liebig's meat extract. R. Engeland (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 11, pp. 658–664*).—The investigations reported were undertaken with a view to simplifying the technique of investigations reported earlier (E. S. R., 18, p. 563).

Are yeast extracts justifiable as substitutes for extract of meat? A. Gamgee (*Brit. Med. Jour., 1908, No. 2486, pp. 449–453*).—From a digest of data on the subject the author concludes that yeast extracts should not thus be used. The dietetic value of such materials is also considered.

Purin metabolism and yeast extracts (*Brit. Med. Jour., 1908, No. 2486, pp. 518–520*).—An editorial discussion of the question considered in the above article.

Food extracts made from yeast. A. C. Chapman (*Brit. Med. Jour., 1908, No. 2502, pp. 1741–1743*).—The author does not agree with the conclusions advanced by Gamgee, as noted above.

Diastase ferments. W. A. Puckner (*Jour. Amer. Med. Assoc., 51 (1908), No. 2, pp. 140–142*).—Results are reported which were obtained in the examination of the diastatic power of a number of samples of commercial diastase and recommendations made for the testing of such goods.

The factors and cost of board on Minnesota farms. T. P. Cooper (*Jour. Home Econ., 1 (1909), No. 1, pp. 43–51*).—Data regarding the cost of board on farms in selected regions in Minnesota are summarized and the factors which influence the cost of board are discussed. On an average the cost of farm board per man for the years 1905, 1906, and 1907 was $12.07 per month or 40 cts. per day. The average annual consumption of farm produce per man on a number of Minnesota farms was calculated.

[Standards of living of Mexican labor in the United States]. V. S. Clark (*Bur. Labor [U. S.] Bul. 78, pp. 466–522*).—This forms a part of an extended discussion of the general subject of Mexican labor in the United States and previously noted (E. S. R., 20, p. 991). Information regarding home life and standards of living is given, as well as general information regarding food and diet. According to the author, it is the general opinion that the Mexican immigrants have a better and more varied diet in the United States than at home.

French school cantines. L. Goldschmidt (*Daily Cons. and Trade Rpts. [U. S.], 1909, No. 3384, p. 13*).—A brief note on the dinners served to school children at Nantes, France.

The diet of the Chinese. Matignon (*Rev. Hyg. et Pol. Sanit., 31 (1909), No. 2, pp. 120–125*).—The food habits of the Chinese in North China are discussed, animal and vegetable foods described, and general data summarized.

Prices and wages in India (*Calcutta, India: Govt., 1908, pp. 226*).—A collection of statistics of wages and wholesale and retail prices of foodstuffs in India for periods of years up to 1907 or 1908.

Manual for the subsistence department, United States Army (*War Dept. [U. S.], Off. Com. Gen. Doc. 321, pp. 142, fig. 1*).—Subsistence stores, ration issues, subsistence property including kitchen cars, and other related subjects, are considered in this manual revised to September 1, 1908, and prepared under the direction of the Commissary-General of the U. S. Army.

U. S. Navy cookbook (*Annapolis, Md., 1908, pp. 62*).—Recipes and directions are given for the preparation of a large number of food materials in quantities sufficient for a mess of 100 men. The cookbook was prepared by the direction of the Bureau of Navigation at the School for Cooks and Bakers at the U. S. Naval Training Station, Newport, R. I.

The baking trade, G. Wolf (*Bäckerei. Hanover, 1907, pp. 147, figs. 71*).—A handbook designed for the instruction of bakers and students of milling and also for self-instruction. The three sections into which the book is divided include raw materials, bread, and bakery equipment, machines and ovens.

Plain cookery. Catharine A. Mulligan (*Winthrop Norm. and Indus. Col. S. C. Bul., 1 (1907), No. 1, pp. 54, figs. 7*).—Detailed directions are given for the preparation of vegetables, eggs, meats, poultry, and other foods, and some general principles of cookery are discussed.

Large meals for little money, Florence K. Johnson (*New York, 1909, pp. 36*).—This pamphlet is designed for use in university extension work, and in a series of twelve lessons gives directions for cooking simple dishes. Bills of fare for inexpensive meals and similar data are also included.

Treatise on food and nutrition under normal and pathological conditions, II, E. Maurel (*Traité de l'Alimentation et de la Nutrition à l'État Normal et Pathologique. Paris, 1908, pp. 680; rev. in Rev. Gén. Sci., 19 (1908), No. 14, p. 589*).—In this volume the author considers especially the rations suitable for growth, maintenance of the adult, food requirements in old age, and similar topics.

A system of diet and dietetics, G. A. Sutherland (*London, 1908, pp. 906; rev. in Brit. Med. Jour., 1909, No. 2513, Epit., pp. 537–539*).—This volume contains articles by different authors on a variety of topics concerned with diet in health and disease. Among others are a paper on the Evolution of Diet by H. Campbell, on the Physiology of Digestion by E. I. Spriggs, on Diet in Old Age by H. Campbell, and on Diet in Hot Climates by Sir P. Manson.

Criteria and standards in infant feeding, T. G. Allen (*Jour. Amer. Med. Assoc., 51 (1908), No. 20, pp. 1687–1691*).—The author discusses infant feeding in relation to protein and energy quotients and suggests that these values be used as a basis for determining infant diet.

Chemistry in its relation to food, J. F. Snell (*Jour. Soc. Chem. Indus., 28 (1909), No. 2, pp. 49–53, dgms. 2*).—The principal subjects included in this discussion are the determination of the relative value of foods, the elucidation of processes of digestion, the hygienic preservation of food, and the detection of adulterants.

The influence of feeding on the chemical composition of the animal body, L. B. Mendel (*Biochem. Ztschr., 11 (1908), No. 4, pp. 281–293*).—A summary of investigations carried on under the author's direction which have been previously published in full (E. S. R., 20, pp. 265, 266, 267).

The resorption of protein, K. von Körösy (*Ztschr. Physiol. Chem., 57, (1908), No. 3–4, pp. 267–287*).—The author's investigations, in his opinion, strongly substantiate the theory that resorbed protein becomes a part of the proteid material of the blood.

Further experiments on the utilization in the animal body of protein cleavage products, E. Abderhalden and J. Olinger (*Ztschr. Physiol. Chem., 57 (1908), No. 1–2, pp. 74–79*).—Meat protein cleavage products gave satisfactory results in feeding experiments with a dog. Casein cleavage products were not so satisfactory.

The behavior of carnitin in animal metabolism, R. Engeland (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 11, pp. 664–666*).—In experiments with dogs it was found that carnitin was completely broken down in the body. Some of the data reported indicate that carnitin may not be entirely harmless. Experiments with Herbivora (a rabbit) did not lead to conclusive results.

The digestibility of fat in the animal body, III, S. Levites (*Ztschr. Physiol. Chem., 57 (1908), No. 1–2, pp. 46–48*).—A note on the determination of glycerin in feces in connection with the author's work on the digestion of fat (E. S. R., 20, p. 663).

The functions of the liver in relation to the metabolism of fats, J. B. Leathes (*Lancet [London], 1909, I, No. 9, pp. 593–599*).—Results of the author's investigations and the work of other observers are summarized and discussed in this theoretical consideration of the metabolism of fat.

The author believes that "it is a fair hypothesis to make the starting point for work that the liver stands in a different relation to circulating fat [i. e., fat absorbed from the intestine and consigned into the systemic circulation] from the other organs of the body. Its work is to take up this fat and bring about certain changes in it [designated desaturation of the acids], the result of which is to make this material available for the use of the organs in which its potential energy is required." Reasons are given for the belief that the change referred to is at any rate in part a desaturation of the fatty acids.

"There is another difference between what may be called organized fat—the fat, that is, in the cells of the heart, muscles, kidneys, etc.—and the unorganized merely stored fat of the adipose tissue. The latter is the unaltered fat of the individual's food; it has its iodin value determined by that of the fat which has been absorbed, but it also contains no phosphorus. The fat in the liver and the other organs of the body, the organized fat, is very largely composed of phosphatid lipoid substances. Of these we know more or less dimly of a considerable number, more or less definitely, of one lecithin. . . . It has also been repeatedly noted that the fatty acids which can be obtained by saponification of lecithin or other phosphatid lipoid substances are more unsaturated than those from adipose tissue.

"It may therefore be that the work of the liver consists in the conversion of food fat into organized fat and that the desaturation of fatty acids is a change which occurs after that conversion has taken place; a change that is, therefore, removed from our ken so long as our knowledge of the nature and constitution of these lipoid molecules is as meagre as it is at present."

The probable importance of octohydroxy-arachidic acid in the metabolism of fat is discussed.

A preliminary note on the examination of fat in the liver in health and disease, E. L. Kennaway and J. B. Leathes (*Lancet [London], 1909, I, No. 2, pp. 95–98*).—Pig, goat, dog, and human liver were included in this study of liver fat.

Animal fat and the petroleum ether extract of the liver, Y. Nukada (*Biochem. Ztschr., 14 (1908), No. 5–6, pp. 419–429*).—According to the author about 0.4 to 0.7 per cent of the fat of flesh consists of a mixture of the lower water soluble and volatile fatty acids. The amount increases with the length of time the fat is kept. Such fat when fresh contains only small amounts of material

with free hydroxyl groups. On storage the amount of such material increases. On saponification, such fat and liver extract both yield cholesterin, the yield from liver fat being considerably the greater.

The behavior of certain indigestible carbohydrates in the digestive tract, L. B. MENDEL (*Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, n. ser., 3 (1908), No. 17, pp. 641–654*).—A digest of data on insoluble carbohydrates, particularly those of marine algæ, and a summary of digestion experiments carried on in the author's laboratory with such foods in comparison with raw Italian chestnuts. See also a previous note (E. S. R., 18, p. 1068).

The possible advantage of these algæ carbohydrates as laxatives and other questions are considered.

An improved respiration apparatus of the Regnault and Reiset type, N. ZUNTZ and C. OPPENHEIMER (*Biochem. Ztschr., 14 (1908), No. 5–6, pp. 361–368, pl. 1*).—The respiration apparatus described is so arranged that it is immersed in water during experimental periods. The authors claim greater convenience of operation and the elimination of parts which are easily broken. With this form of apparatus it is not necessary to use mercury, and this also is considered an advantage.

Adjusting and testing the modified Regnault and Reiset respiration apparatus devised by Zuntz and Oppenheimer, A. SCHLOSSMANN and H. MURSCHHAUSER (*Biochem. Ztschr., 14 (1908), No. 5–6, pp. 369–384, figs. 3*).—According to the results of check experiments in which alcohol was burned in the respiration chamber the instrument gives very accurate results. Similar accuracy was obtained in an experiment with a dog which is also recorded.

Respiratory exchange of an infant as shown by experiments with the Zuntz and Oppenheimer respiration apparatus, A. SCHLOSSMANN, C. OPPENHEIMER, and H. MURSCHHAUSER (*Biochem. Ztschr., 14 (1908), No. 5–6, pp. 385–406*).—Using the respiration apparatus described above, experiments with a nursing infant are reported. Considering the average of six 8-hour periods, the oxygen consumption was 0.731 gm. per kilogram of body weight and the carbon dioxid production 0.913 gm., and the respiratory quotient 0.911. The average weight of the child was 5.79 kg. Determinations are also reported with infants asleep for different periods after feeding.

The transformation of energy in the muscles when work is performed, M. F. MAIGNON (*Ann. Soc. Agr. Sci. et. Indus. Lyon, 1907, pp. 145–161*).—A mathematical discussion of food energetics.

The effects of muscular work upon the excretion of endogenous purins, E. L. KENNAWAY (*Jour. Physiol., 38 (1908), No. 1, pp. 1–25*).—Quotations from the author's summary of his extended investigations follow:

"During unaccustomed muscular exercise, the output of uric acid is diminished, while that of the purin bases is increased; the total output of purin compounds does not differ greatly from the normal amount. Such exercise is followed by a greatly increased excretion of uric acid.

"If a certain amount of a certain form of work be performed on a series of occasions, the changes observed show a progressive diminution in amount. . . .

"Salicylic acid and muscular work can produce their characteristic effects upon the output of uric acid simultaneously without any apparent modification, and the amount excreted under these conditions is extremely large. These facts are most readily explained by supposing that muscular work leads to an increased formation of uric acid.

"The increase of purin bases and decrease of uric acid in the urine during muscular work appear to be due to defective oxidation of purin compounds. It was not found possible to produce evidence of a definite increase in these oxidative processes by inhalation of oxygen.

"The total amount of purin compounds excreted is a more constant quantity, both from day to day and at periods separated by intervals of months, than is the output of uric acid.

"The output of purin bases exhibits variations, corresponding to different portions of the day, which are very similar to those exhibited by the uric acid output.

"The amount of uric acid excreted tends to vary inversely, and that of the purin bases to vary directly, with the volume of urine."

Principles of general metabolism of matter and energy, II, O. KRUMMACHER (*Ergeb. Physiol., 7 (1908), pp. 444–446*).—A critical summary and digest of data on the metabolism of matter and energy.

International catalogue of scientific literature. Q—Physiology (*Internat. Cat. Sci. Lit., 6 (1909), pt. 1, pp. VIII+832; 6 (1908), pt. 2, pp. 936*).—The bibliography of physiology, including experimental psychology, pharmacology, and experimental pathology, previously noted (E. S. R., 19, p. 463), is continued in this volume, which contains material received between May, 1906, and August, 1907. Part 1 is the author catalogue and part 2 the subject catalogue.

ANIMAL PRODUCTION.

Reports to the evolution committee, W. BATESON ET AL. (*Rpts. to Evolution Com. Roy. Soc. [London], 1908, No. 4, pp. 60, figs. 3*).—This report is in continuance of previous work on the physiology of heredity. Investigations on poultry and sweet peas are reported by W. Bateson and R. C. Punnett, and on stocks by Miss E. R. Saunders and H. B. Killby; a preliminary account of the inheritance of coat color in mice by Miss F. M. Durham; on sex inheritance in the moth *Abraxas grossulariata* and its variety, *A. grossulariata* var. *lacticolor* by L. Doncaster; a note on the inheritance of sex in canaries by Miss Durham and Miss D. C. E. Marryat; and a corrigenda to report 3 on the factors which produce hoariness.

The work reported on poultry deals chiefly with the factors which influence the inheritance of (a) comb structure, and (b) white plumage. The study of comb inheritance has involved over 12,500 birds, and the results of this and previous work are presented in tabular form. "The rose comb is in reality a single comb modified by the presence of a 'rose' factor. The omission of this factor enables the single comb to appear. The same considerations apply to the pea comb, which is single plus a pea factor. The true allelomorphic pair in each case is the presence of a given factor which is dominant to the absence of that factor. . . . As the acceptance of the 'presence and absence' hypothesis seems to demand some general expression for such interrelation between factors belonging to distinct allelomorphic pairs, we propose the terms 'epistatic' and 'hypostatic.' For example, the combless, the single-combed, and the rose-comed conditions may, in the light of our present knowledge, be regarded as forming a cumulative series and we should speak of the factor for single as being dominant to the combless condition but hypostatic to the rose factor, and similarly the rose factor may be referred to as epistatic to the single."

A walnut comb is one in which both the rose factor and the pea factor are present, and such a comb may be either homozygous or heterozygous for one or both of these factors.

In the studies of white plumage there are two distinct classes of white fowl: (a) Those in which white is dominant to color, and (b) those in which white is recessive to color. The recessive whites are of at least three kinds, namely, the white birds which have arisen in the course of these experiments, the white of the silky fowl, and the white of the rose-comb bantams.

The results of the experiments in sex inheritance with canaries and the moth *A. grossulariata* are closely parallel, the females considered to be heterozygous in sex, femaleness being deemed dominant, and the male as homozygous in the absence of femaleness. The black-eye character of canaries is a dominant and the pink-eye character a recessive. "Whatever may be the truth regarding the transmission of sex, there is no escape from the remarkable conclusion that just as the normal females of the moth *A. grossulariata* are in reality hybrids in the lacticolor character, so the ordinary black-eyed hen canaries are hybrids in the pink-eye character."

The heredity of sex, R. C. PUNNETT and W. BATESON (*Science, n. ser., 27 (1908), No. 698, pp. 785–787*).—In this article Mendelian theories of sex are discussed. The authors believe that the sex determinants behave as Mendelian allelomorphs, females being dominant, that female individuals are heterozygous in respect to sex, and males homozygous, and that at least in some cases when two dominant factors coexist there is a repulsion between them such that each gamete takes one or other of these two factors, not both.

Secondary sexual characters, R. MÜLLER (*Das Problem der Sekundären Geschlechtsmerkmale und die Tierzucht. Stuttgart. 1908. pp. 89*).—This is an expansion of two lectures, in which the differences between the sexes in animals are discussed.

Recessive characters, C. B. DAVENPORT (*Science, n. ser., 28 (1908), No. 725, p. 729*).—A cow without a trace of body hairs gave birth to a calf with the ordinary hairy coat. "This result indicates that the presence of the hairy follicles is dominant over their absence. This adds another case to the law that the presence of a quality is dominant over its absence or that a retrogressive or retarded condition is recessive to the more developed conditions."

Degeneration, albinism, and inbreeding, C. B. DAVENPORT (*Science, n. ser., 28 (1908), No. 718, pp. 454, 455*).—The author enunciates certain principles which aid in understanding the reason for the degeneration which sometimes follows the practice of inbreeding. "When the two parents have any organ or quality A in two conditions, A+ and A—, of which the former is a highly developed or progressive condition, the latter a poorly developed or even absent condition, the former condition will regularly dominate over the latter. . . . When both parents have an organ in a low condition of development it will be so also in all of their children. This principle explains the persisting or increasing degeneration in the descendants of two degenerate parents."

Another class of degeneration is albinism, which is not a sport but a necessary, predictable result of certain combinations of gametes. "The only part that inbreeding plays is to make more probable the necessary combination of gametes. The degeneration in this case follows from the union of two negative factors in dihybrids, and this is a common cause of degeneration."

Breeding experiments with rats, T. H. MORGAN (*Amer. Nat., 43 (1909), No. 507, pp. 182–185*).—This is a report of some experiments in crossing rats to determine how far the Mendelian lines of discontinuous inheritance apply to wild varieties and species. In crosses of the black rat with the gray roof rat black is dominant to gray, whichever way the cross is made. All attempts thus far to cross the black rat or the roof rat with the Norway rat have failed.

The chondriosomes as bearers of the hereditary qualities, F. MEVES (*Arch. Mikros. Anat. u. Entwicklungsgeschichte, 72 (1908), No. 4, pp. 816–867, pls. 4; abs. in Amer. Nat., 43 (1909), No. 507, pp. 190–192*).—The author finds a large number of independent structures in the cytoplasm of the chick embryo at about the third day of incubation, which he calls "chondriosomes." He thinks that

these are the bearers of the hereditary qualities of the cytoplasm as chromosomes are the bearers of the hereditary qualities of the nucleus.

The inheritance of hyperdactylism in poultry, D. Barfurth (*Arch. Entwickl. Mech. Organ., 26 (1908), No. 4, pp. 631–649*).—Seven hyperdactyl Orpington hens were mated to a normal male of the same breed. Of 152 chickens which resulted 80, or 52.6 per cent, had the normal number of toes. Instances of hyperdactylism noted by other observers are cited.

Spurious allelomorphism [in poultry], W. J. Spillman (*Amer. Nat., 42 (1908), No. 501, pp. 610–615*).—Black Langshan males were mated with Barred Plymouth Rock females. In the progeny, all the females were black and all the males barred. The author also calls attention to several cases reported by other observers.

Yearbook of scientific and practical animal breeding, R. Müller (*Jahrb. Wiss. u. Prakt. Tierzucht, 3 (1908), pp. LLIV+227*).—The larger part of this report is occupied with critical reviews of literature relating to the anatomy, physiology, psychology, biology, geographical distribution, hygiene, feeding, breeding, and the history of domesticated breeds. There are original articles on the acclimatization of domesticated animals, a mutation in the Fjell breed of cattle, the "polled" character of cattle, and the influences that affect the length of the pregnant period of domesticated animals. From data collected on the last-named subject, P. Sabatini concludes that in horses, cattle, and sheep the length of pregnancy is shorter with twins, with the first born, with a female fetus, and in the early maturing breeds than with single births, males, the second or later births, or in the late-maturing breeds. These results do not appear to hold true in the case of swine.

The principles of animal nutrition, H. P. Armsby (*New York, 1908, 3. ed. rev., pp. VII+614*).—This is the third revised edition of this work (E. S. R., 14, p. 896).

The rate of growth of the egg yolk in the chick, and the significance of white and yellow yolk in the ova of vertebrates, O. Riddle (*Science, n. ser., 27 (1908), No. 703, p. 945*).—The author has employed a method discovered by Daddi in 1896, by which the rate of growth of the egg yolk of the chick may be easily measured. "If the fat stain Sudan III be fed to laying hens at intervals of one, two, or more days, the stain can be found later in the form of concentric red rings in all of the rapidly growing ova. The actual rate of growth varies widely from 0 to 2 mm., but one day of growth normally includes a layer of white yolk and a layer of yellow yolk. It is probable that the layer of white yolk represents the part which is grown during the later hours of the night, and that the yellow yolk is yolk of more rapid growth produced during the remainder of the day."

Sudan III deposited on the egg and transmitted to the chick, S. H. and Susanna P. Gage (*Science, n. ser., 28 (1908), No. 719, pp. 494, 495*).—The authors repeated the experiments of Riddle (noted above) and summarize the work on the subject as follows:

"The specific fat stain, Sudan III, colors the fat laid down in the living hen and in the fatty portions of the yolk while the feeding experiments are in progress, and thus serves to give exact data concerning the time and amount of deposit.

"The eggs so colored hatch, and the chick utilizing the yolk as food produces fat in its own body colored as in the adult, showing in the most striking manner the transmission of a specific and unusual or foreign substance from the mother to the egg, and from the egg to the offspring, and thereby marking the transmission of the actual substance of the egg, and indirectly of the mother, to the offspring.

"The precision of the method and its striking results apparently open to biologists a field which has lain dormant since its discovery by Daddi 12 years ago, that is, the possibility of following with great exactness at least one of the processes of nutrition."

Comparative investigations on the effect of proteid and nonproteid nitrogen on (the) gain in weight of ruminants, J. Just (*Landw. Vers. Stat., 69 (1908), No. 5–6, pp. 393–460*).—For these experiments 7 months old lambs were fed a basal ration low in protein, which consisted of meadow hay, starch meal, and sugar. For supplementary rations gluten meal was alternated with molasses chips, malt sprout extract, potato chips, and grass extract.

There was but little difference between the protein digestion coefficient of the supplementary feeds, except that with potato flakes it was somewhat lower and with grass extract it was considerably lower than with the other feeds. In general the results of these experiments agreed with those of Friedlaender (E. S. R., 20, p. 70) that amids are not of equal value with true protein.

On the influence of food fat on the body fat of swine, with special reference to the final location of phytosterin, J. König and J. Schluckebier (*Ztschr. Untersuch. Nahr. u. Genussmtl., 15 (1908), No. 11, pp. 641–661; abs. in Chem. Zentbl., 1908, II, No. 5, p. 427*).—From their original investigations the authors found that fat in cotton-seed meal and sesame meal was well utilized by young animals. The nonsaponifiable fats may be resorbed as body fats. Coloring matters in cotton-seed meal and sesame meal may be detected in the body fat of swine, though when fed to cows they could not be detected in milk fat. The body fats seem to retain the same chemical and physical properties that they have in the feed. As animals grow older the melting point of the body fat is raised and the corresponding iodin number falls. Leaf fat has a high melting point and a low iodin number. Phytosterin and cholesterin appear partially as koprosterin in the feces, though a part is unchanged. Relatively more nonsaponifiable fat is found in the feces than is contained in the food fat. After a long feeding with plant fats only cholesterin appears in the body in organic fats. Organs like the brain and liver though rich in cholesterin are not rich in phytosterin.

These experiments confirm the results of other investigators (E. S. R., 16, p. 18) that the phytosterin and phytosterin-acetate test of Bömer is a reliable method of detecting plant fats in animal fats.

Daily rations approximately balanced for different animals per 1,000 lbs. live weight, W. H. Dalrymple (*Ann. Rpt. Agr. and Indus. Statis. Bd. Agr. and Immigr. [La.], 1908, pp. 5–8*).—This presents sample rations for horses, mules, oxen, and dairy cattle, in which cotton-seed meal, molasses, and other by-products can be utilized.

Commercial feeding stuffs of Pennsylvania in 1907, F. D. Fuller (*Penn. Dept. Agr. Bul. 167, pp. 7–97*).—This is the annual report of the chemical and microscopical work performed by the division of chemistry in the examination of commercial feeding stuffs, and contains descriptions, analyses, and the comparative cost of feeds.

"Of the 560 samples collected, 498 were examined chemically and microscopically. Fifty-eight samples contained less protein than guaranteed by the manufacturers, and 37 samples were deficient in fat. . . . Practically all of the molasses feeds found upon the market contained a large proportion of weed seeds, and many of them were adulterated with rice hulls. Money which was formerly spent in purchasing low grade oat feeds is apparently being put into feeding stuffs of standard quality, and, therefore, we do not find as much oat feed in Pennsylvania as in former years." The most serious adulteration was

the use of ground rice hulls, which are useless as a feed, to adulterate molasses grains and other dairy feeds. "The poor quality of cotton-seed meal was due largely to weather conditions through the growing season, making it more difficult for mills to separate the hulls from the seed."

Analyses were also made of linseed meal, distillers' grains, brewers' grains, malt sprouts, gluten feed, wheat flour, bran and middlings, mixed feeds, animal by-products, and proprietary feeds of various kinds.

The artificial drying of moist feeding stuffs and their agricultural significance, D. MEYER (*Die Künstliche Trocknung der Wasserreichen Futtermittel. Hanover, 1908, pp. VI+130, figs. 26, dgms. 2*).—This work describes methods and apparatus used in drying beet chips, turnip tops, potatoes, brewers' grains, and distillers' slops. The nutritive value of these feeding stuffs for different kinds of live stock is also briefly treated in a popular manner.

Corn grits and corn meal as brewing adjuncts, J. L. WILLS (*Brewers' Jour., 33 (1908), No. 2, pp. 51–55, figs. 3*).—The author discusses the adaptability of the corn kernel to replace rice as a starch adjunct. Only No. 2 white corn with degerminated kernel can be used for this purpose. The finished product consists of hard white, angular fragments known as corn grits, and approaches rice in composition.

The composition of brewers' and distillers' grains, T. W. FAGAN and C. ALLAN (*Edinb. and East of Scot. Col. Agr. Bul. 16, pp. 21*).—The percentage of fat and nitrogeneous matter was found to vary to only a slightly greater extent in distillers' grains than in brewers' grains. "As far as the chemical analyses of the two grains is concerned there does not seem to be the difference in composition that would be expected when the prices of the two feeding stuffs are taken into consideration."

The nutritive value of grape marc, J. FABRE (*Ann. École Nat. Agr. Montpellier, n. scr., 8 (1909), No. 3, pp. 219–228*).—This is a report of analyses and of digestion coefficients of grape marc. The percentage of digestibility in horses was found to be as follows: Dry matter 28.5, protein 21.5, fat 50.4, nitrogen-free extract 34.5, fiber 20.3, and ash 29.0. In sheep the digestion coefficients were for dry matter 33.6, protein 15.9, fat 49.3, nitrogen-free extract 36.9, fiber 26.4, and ash 50.1 per cent.

The occurrence of cyanogenetic glucosids in feeding stuffs, T. A. HENRY and S. J. M. AULD (*Jour. Soc. Chem. Indus., 27 (1908), No. 9, pp. 428–433, dgm. 1*).—It has been previously noted that a number of plants used for feeding stuffs contain cyanogenetic glucosids and a glucosidolytic enzym. When these two products are brought into contact by placing them in water hydrocyanic acid is produced as a result of the decomposition of the glucosid. The author describes a method for determining the hydrocyanic-acid content and discusses the possibility of poisoning stock by feeding plants in which hydrocyanic acid is liable to be produced. If the enzyms in the plant are destroyed by heating there is less danger of poisoning.

Farm stock, C. W. BURKETT (*New York, 1909, pp. IX+358, pl. 1, figs. 113*).—This is a practical treatise on horses, cattle, sheep, and swine, including their breeding, feeding, care, and management in health and disease. "It is an everyday handbook of live stock and contains the best ideas gathered from the various authorities and the experience of a score of practical men in all departments of live-stock production."

The meat industry in Hungary, L. M. DOUGLAS (*Meat Trades' Jour., 28 (1908), No. 1072, pp. 564, 565, figs. 3; Vet. Jour., 64 (1908), No. 402, pp. 595–599, pls. 3*).—The information contained in this brief popular account of animal production and dairying in Hungary was obtained from a personal visit.

Horse breeding is a great industry and over $5,000,000 worth of horses are exported annually. Native Hungarian cattle constitute about 22 per cent of the total number of cattle, the rest being mainly breeds imported from Switzerland. Until recently but little attention had been paid to butter making, and hog fat is used largely to take the place of butter. The number of swine in the country is about 5,000,000. These for the most part consist of the Mangalicza breed, a coarse, long-haired beast with about 5 in. of fat along the back. Recently Yorkshires have been introduced. The system of meat inspection is very complete and up-to-date abattoirs exist throughout the country.

Cattle raising, F. Dettweiler (*Die Aufsucht des Rindes. Berlin, 1908, pp. 235*).—This is a treatise for the practical breeder. There are brief accounts of the origin of domesticated cattle and of the factors which influence inheritance. The main part of the book is devoted to the care and management of the growing animal. In an appendix of 61 pages data are given as to the cost of raising young stock of the different breeds.

The history of cattle breeding at Einsiedeln, P. O. Ringholz (*Landw. Jahrb. Schweiz, 22 (1908), No. 8, pp. 413–508, pls. 4, figs. 2*).—A contribution to the history of the Brown Swiss cattle from the ninth century to the present time. It contains much general information on the agriculture of Switzerland of the period, as well as an account of the improvement and importance of the Brown Swiss breed.

The spotted cattle of southern Moravia, M. Nitsche (*Österr. Molk. Ztg., 16 (1909), Nos. 1, pp. 1–3; 2, pp. 17–19; 3, pp. 31–33; 4, pp. 45–47*).—This is an abstract of a work by L. Adametz on the spotted cattle of this region. The variations in color, conformation, and economic qualities of these cattle are described. The methods of feeding are also noted.

Aberdeen-Angus cattle, A. Pulling (*London, 1908, pp. 150*).—This contains an account of the leading families of this breed, with a few notes as to why certain families have become fashionable.

On the protein minimum for growing wethers, T. Katayama (*Landw. Vers. Stat., 69 (1908), No. 5–6, pp. 321–341*).—From digestion experiments with 4-year-old wethers, the author concludes that leaving out of consideration the growth of wool, 0.41 kg. per 1,000 kg. live weight is the minimum protein requirement for wethers. The rations in these experiments consisted of hay, straw, sugar, starch, and aleuronat.

Fertility in Scottish sheep, F. H. A. Marshall (*Trans. Highland and Agr. Soc. Scot., 5. ser., 20 (1908), pp. 139–151*).—From a study of data collected from the lambing returns of 1905, 1906, and 1907 it appears that some form of flushing or extra feeding immediately preceding the lambing period increases the percentage of fertility.

Unique experiment in sheep breeding, J. B. Spencer (*Farmer's Advocate, 43 (1908), No. 846, p. 1883*).—Selection experiments made by A. G. Bell to ascertain whether extra nipples could be so developed as to become functional, and whether sheep with four functional nipples were more prolific than other sheep, are reported. In the original flock those that bore twins constituted 24 per cent of the normally nippled and 43 per cent of the abnormally nippled ewes. After several years of selection most of the ewes born possessed four functional mammæ, and some had from 5 to 8 nipples. The multi-nippled sheep have not proved to be more fertile than the others. Twin lambs though smaller at birth often overtake single lambs by autumn.

Caracul sheep, A. Pirocchi (*Bol. Uffic. Min. Agr., Indus. e Com. [Rome], 7 (1908), IV, No. 4, pp. 407–420*).—In this article the author describes the characteristics of these sheep and their geographical distribution. He thinks

that they should be imported to Italy for experimentation in acclimatization and crossing.

Origin of the Australian Merino (*Queensland Country Life, Spec. No., 1908, Dec., pp. 17, 18*).—This outlines the history of Merino sheep in Australia since their first introduction into that country in 1787.

Australian sheep, J. P. Bray (*Daily Cons. and Trade Rpts. [U. S.], 1909, No. 3401, pp. 5, 6*).—This is a statistical review of the sheep industry of Australia by the consul-general at Sydney.

Steamed v. dried potatoes as a feed for swine, M. Schmoeger (*Landw. Vers. Stat., 69 (1908), No. 5–6, pp. 359–391*).—In these experiments with swine the basal ration consisted of split peas, fish meal, and skim milk. When steamed potatoes were added to the basal ration the daily gain was 0.584 kg. (about 1.28 lbs.) per head, at a cost of 0.5267 mark per kilogram (about 5.7 cts. per pound). With potato flakes as a supplement the corresponding gain was 0.563 kg., at a cost of 0.547 mark per kilogram; with softened potato chips 0.519 kg., at a cost of 0.594 mark; and with steamed potato chips 0.647 kg., at a cost of 0.5778 mark.

The horse in history, B. Tozer (*London, 1908, pp. XX+304, pls. 25*).—This book traces "the progress of the horse from very early times down to the present day, mainly from the standpoint of the effect its development had upon the advancement of the human race."

Army remounts, M. A. O'Callaghan (*Agr. Gaz. N. S. Wales, 20 (1909), No. 2, pp. 99–110, figs. 15*).—Descriptions of types of horses required for remounts in the English army.

Age of trotting horse sires, F. R. Marshall (*Amer. Nat., 43 (1909), No. 505, pp. 50–53*).—The author discusses Redfield's dynamic theory of development, and takes the view that as the average age of sires of 2.10 trotting horses is about the same as that of the first thousand in the index digest, the records reveal no superiority of the old sire over the younger one.

Southern poultry guide or forty years with poultry, C. Husselman (*Richmond, Va., 1908, pp. 119, pl. 1, figs. 20*).—This is a practical treatise on the care and management of poultry, which is written more particularly for the people of the South who are engaged in this industry.

Poultry and eggs for market and export, D. D. Hyde (*New Zeal. Dept. Agr. [Pamphlet], 1908, pp. 51, pls. 8, figs. 28*).—This pamphlet is intended as a handy guide to practical methods of poultry keeping in New Zealand.

Poultry and eggs, F. R. Mowrer and R. P. Skinner (*Daily Cons. and Trade Rpts. [U. S.], 1909, No. 3400, pp. 8–12*).—The consul-general at Copenhagen reports that the growing demands of British markets have stimulated poultry raising in Denmark. Danish eggs to the value of $8,800,000 are annually consumed in England.

The consul-general at Hamburg reports that Germany imports about 3,500,000,000 eggs, principally from Russia, Asia Minor, and Egypt, and thinks that America could participate in this trade. Methods of preparing eggs for export are described.

The Buff Orpington duck, A. G. Goodacre (*Rel. Poultry Jour., 16 (1909), No. 1, pp. 12, 75, fig. 1*).—This article describes the characteristics of a new breed of ducks which originated in England a few years ago.

The care and breeding of rabbits, P. Mahlich (*Kaninchenzucht und Kaninchenhaltung. Hanover, 1908, pp. 68, figs. 11*).—This book contains brief descriptions of the different breeds of rabbits, with notes on their feeding, care, and management.

DAIRY FARMING—DAIRYING—AGROTECHNY.

Investigations on the influence of feed on the milk secretion of cows, A. BUSCHMANN (*Landw. Jahrb., 37 (1908), No. 6, pp. 899–959*).—This is a series of studies on the effect of feeding sunflower cake, coconut cake, wheat bran, and cotton-seed cake on the yield of milk and the characteristics of butter fat.

In the first experiment, with 18 cows, when coconut cake was replaced by sunflower cake the quantity of milk and the percentage of fat decreased, the saponification number of the butter fat was lowered, and the iodin number raised. In another experiment 4 cows were fed for three periods. In the first period while sunflower cake was the supplementary feed the percentage of fat in the milk was 3.01. In the second period when sunflower cake was replaced by coconut cake the percentage of fat was 3.13. In the third period the ration was the same as in the first and the fat decreased to 3 per cent.

In another experiment with three groups of 7 cows, when sunflower cake was replaced by coconut cake the yield of milk and the percentage of fat increased. When replaced by wheat bran there was a decrease in quantity and quality of milk. When cotton-seed cake was substituted for sunflower cake there was a correlation between the saponification and iodin values of the feed and of the butter fat, but no correlation of melting points. Nine out of 10 cows showed an increase in the quality of the milk when cotton seed was substituted for sunflower cake. Compared with coconut cake the cotton seed decreased the yield of milk but increased the percentage of fat.

A further study was made of the effect of feed on the properties of butter fat. When the cotton seed replaced sunflower cake the Reichert-Meissl number, saponification number, and melting point were raised, but the iodin number was lowered. The author concludes that a part of the fat of the food must be absorbed as such, but that the fat of the milk is affected by influences yet unknown. The quality of the butter apparently depends more upon the character of the food than on the amount of volatile fatty acids that it contains.

The protein requirement for milch cows, P. DERWA (*Rev. Gén. Agron., n. ser., 3 (1908), No. 11, pp. 455–458*).—From experiments in feeding 8 cows on rations containing different amounts of protein, the author concludes that a ration should contain 1 gm. of digestible protein for each kilogram of live weight plus 50 gm. for each liter of milk produced.

A local cow census (*Hoard's Dairyman, 40 (1909), No. 5, pp. 146, 147*).—The cost of feeding and the income from 50 herds of cows belonging to patrons of the creamery at Barron, Wis., for the year 1908 is presented in tabular form and the results discussed. The average number of cows in a herd was 10.6, the average cost of feed per cow $28.76, the average cash return from the creamery per cow $37.23, the average yield of butter fat per cow 139.5 lbs., the average price of butter fat 26.4 cts. per pound, the average cost of butter fat 21.6 cts. per pound, and the average value of butter fat per $1 of feed $1.35. The best herd showed a profit of $37.72 per cow and the poorest herd an average loss of $15.63 per cow.

[The cost of transporting a quart of milk], W. A. GRAUSTEIN (*New England Farmer, 88 (1909), No. 10, p. 3*).—According to a milk contractor's estimate the average cost of transporting milk within the radius of 100 miles of Boston is 1.19 cts. per quart.

The business of dairying, C. B. LANE (*New York and London, 1909, pp. XII+234, pl. 1, figs. 46, dgms. 2*).—The information contained in this book has been obtained largely from the author's experience and has been prepared for

the use of dairy students, purchasers and handlers of milk, and all who make dairying a business. After a short introduction on the farmer as a business man, the work is divided into six parts as follows: The soil, crops, the dairy herd, feeds and feeding, products, and sales. Considerable space is given to presenting forms and methods of keeping accurate accounts of expenditures and receipts in each line of work undertaken on the dairy farm.

Works on the science and practice of dairying during the first half of 1908, R. W. RAUDNITZ (*Separate from Monatsschr. Kinderheilk., 7 (1908), No. 7, pp. 46*).—This is a critical review of the literature on dairying published during this period.

Report of the dairy and cold storage commissioner, J. A. RUDDICK (*Rpt. Dairy and Cold Storage Comr. Canada, 1908, pp. 160, pls. 15*).—This report contains statistical matter on the progress of dairying, records of cow-testing associations, and an account of a visit to Great Britain and Holland.

Dairy production, 1907, A. BLUE (*Census and Statis. [Canada] Bul. 7, pp. IX+14+X*).—The statistics in this bulletin are compiled from the returns of 3,516 butter and cheese factories and 7 factories producing condensed milk and cream.

The value of the products of these factories is increasing annually, yet the dairying season of 1907 was not a good one owing to the prevailing drought in some localities. The text of the bulletin is also printed in French.

The past, the present, and the future of the dairy industry in the province of Quebec, J. C. CHAPAIS (*Rpt. Dairymen's Assoc. Prov. Quebec, 25 (1906), App., pp. 3–39, figs. 56*).—This is a lecture before the twenty-fifth annual convention of the dairymen's association, February, 1906.

Dairying in Denmark, 1907, B. BÖGGILD (*Tidsskr. Landökonomi, 1908, No. 4, pp. 225–243*).—The annual report of the professor of dairying in the Royal Veterinary and Agricultural College at Copenhagen.

Dairying in Norway prior to 1905, S. J. BENTERUD, J. GRUDE, and E. E. WOLD (*Mejeridriften i Norge indtil Aaret 1905. Christiania, 1908, pp. 234; rev. in Mælkeritid., 21 (1908), No. 49, pp. 969–976*).—An historical sketch of the Norwegian dairying industry, its development and present conditions.

Swedish dairying, A. OESTERGREN (*Nord. Mejeri Tidn., 23 (1908), Nos. 46, pp. 543–545; 47, pp. 555–556*).—An address delivered before the Swedish Dairy Instructors' Association. Statistics of the present conditions of the Swedish dairying industry and its progress during the past 15 years are given, with suggestions as to its future development. It is shown that there were 1,575 creameries in Sweden in 1905; these were supplied in the aggregate with 918,094,785 kg. (about 242,377,000 gals.) of milk from 1,763,857 milch cows. The average amount of milk handled per creamery daily is 1,335 kg. (about 352 gals.), ranging from 232 to 5,560 kg. Of the number of creameries given 470 were cooperative. The total number of patrons of the creameries was 70,647.

New Zealand dairy produce on the British market, D. CUDDIE (*New Zeal. Dept. Agr., Dairy Div. Bul. 12, pp. 45*).—This is a report of a visit to Great Britain, Denmark, Canada, and the United States with the view to obtain information that would be of value to New Zealand dairymen.

Biological and biochemical studies of milk, C. J. KONING (*Biologische und Biochemische Studien über Milch. Leipsic, 1908, No. 2, pp. 98, charts 2*).—This has been reported from another source (E. S. R., 19, pp. 371, 372).

Essentials of milk hygiene, C. O. JENSEN, trans. and amplified by L. PEARSON (*Philadelphia and London, 1909, 2. ed. rev., pp. X+291, figs. 24*).—This is the second edition of a work previously noted (E. S. R., 19, p. 275). "A few corrections and changes have been made in the text and new matter has been

added to give in detail what may be regarded as the official method for the examination of milk for bacteria and cells."

Milk as affected by stable practices and subsequent handling, M. H. Reynolds (*Amer. Vet. Rev., 32 (1908), No. 6, pp. 690–709, figs. 3, dgms. 3*).—This is a paper read before the American Veterinary Medical Association at its forty-fourth annual meeting and previously reported (E. S. R., 19, p. 199).

The influence of the sugars on the secretion of milk, G. Piantoni (*Arch. Farmacol. Sper. e Sci. Aff., 7 (1908), Nos. 7, pp. 329–336; 8–9, pp. 337–364*).—Hypodermic injections of disaccharids administered to a goat produced effects that varied with the amount injected. A small dose increased the amount of milk secreted without altering the proportion of its constituents. Larger doses diminished the quantity of milk and the percentage of milk sugar, and decreased slightly the percentage of fat, but increased the flow of urine which showed traces of sugar. Monosaccharids produce similar effects provided double the quantity is used. The sugar contained in the urine of the goat is lactose, which conforms with the assertion of Porcher.

On the variability of milk, G. von Wendt (*Skand. Arch. Physiol., 21 (1908), No. 2–3, pp. 89–145; Mitt. Landw. Inst. Leipzig, 1908, No. 9, pp. 127–179*).—Various salts were added to the rations of milch cows and their effect upon the chemical composition of the milk was studied. Some of the author's conclusions are as follows:

Common salt, carbonate of lime, sodium phosphate, magnesium bromid, and calcium glycero-phosphate appeared to have no influence on the composition of milk. Acid calcium phosphate appears sometimes to influence favorably the amount of fat and to increase the relative amount of original calcium. The percentage of albumin does not increase toward the end of the lactation period. Phosphorus, total nitrogen, and casein are the least variable, while chlorin, potassium, and albumin are the most variable of milk constituents.

The effect of rutting on the composition of cow's milk, O. Mezger (*Ztschr. Untersuch. Nahr. u. Genussmtl., 16 (1908), No. 5, pp. 273–281*).—The author made chemical analyses of the milk of seven cows during the rutting period and found that such variations as occur are largely due to the individuality of the cows. In no case did the amount of fat-free dry matter vary to any extent.

On the composition of cow's milk of different breeds, with special reference to the lime and phosphoric acid content, T. Katayama (*Landw. Vers. Stat., 69 (1908), No. 5–6, pp. 342–358*).—Analyses were made of milk from cattle of Roumania, Ceylon, Korea, Africa, and different German breeds, and from the buffalo. There was a great variation between individuals of the same breed, but in the same individual the lime and phosphoric acid content varied but little from time to time. The lime content varied from 0.143 per cent in the East Prussian Holland breed to 0.227 in the black and white East Frisian. The phosphoric acid varied from 1.53 per cent in the buffalo to 0.299 in the Korean cattle.

On the variations of the globules of milk, G. Alessi and E. Carapelle (*Rev. Hyg. et Méd. Infant., 7 (1908), No. 4, pp. 309–329, pls. 3*).—A microscopic examination was made of milk from the goat, dog, guinea pig, and cow, as well as of human milk. The globules varied much in form and in size under normal as well as abnormal conditions. In some cases the fatty substance did not appear to fill the entire globule, while in other cases the presence of a viscous material caused the globules to form clusters. Pathological conditions cause many changes in the form and character of the globules.

Investigations on the viscosity and surface tension of milk, B. Kobler (*Arch. Physiol. [Pflüger], 125 (1908), No. 1–2, pp. 1–72, figs. 5; abs. in Rev.*

Gén. Lait, 7 (1909), No. 10, pp. 234–236).—According to the author both the surface tension and capillarity in milk are constant for a given animal under ordinary conditions, but are influenced by the character of the feed and other factors. The viscosity of milk depends upon the chemical composition and a number of physical properties. During the gestation period the viscosity gradually increases but rapidly diminishes a few days after calving.

The application of new physico-chemical methods of milk investigation from the socio-medical and physiological standpoint, H. Zanger (*Schweiz. Arch. Tierheilk., 50 (1908), No. 5, pp. 247–267; abs. in Milchw. Zentbl., 5 (1909), No. 2, pp. 86, 87*).—This article discusses the methods of determining physical constants previously reported by Schnorf (E. S. R., 16, p. 1016), and in the article noted above. Their importance for detecting adulterated and pathological milks is pointed out. The conclusions reached are based on the examination by the author and his assistant of 10,000 samples of milk.

Investigations on the rennet coagulation of milk, W. Van Dam (*Rev. Gén. Lait, 7 (1908), Nos. 6, pp. 121–129; 7, pp. 145–155; 8, pp. 169–178; Ztschr. Physiol. Chem., 58 (1909), No. 4, pp. 295–330, dgms. 3*).—Investigations were undertaken to discover the cause of variation in the coagulability of milk. By diluting milk with water or by adding a soluble citrate the time of coagulation was lengthened. The addition of a soluble oxalate rendered the milk incoagulable. On the other hand, the addition of calcium chlorid hastened coagulation. The author concludes that the time of coagulation is inversely proportional to the concentration of hydrogen in the milk.

The effect of some normal elements of milk on its coagulation with rennet, C. Gerber (*Compt. Rend. Soc. Biol. [Paris], 65 (1908), No. 26, pp. 182–184*).—The addition of lacto-casein and lactose retarded coagulation. Adding sodium chlorid and potassium chlorid in either small or large quantities hastened coagulation, but in medium quantities retarded it.

Further contributions to the theory of the coagulation of milk by rennet, G. Wernicken (*Ztschr. Biol., 52 (1908), No. 1–3, pp. 47–71, dgms. 16*).—After a study of the optical properties of milk and casein and their ability to combine with hydrochloric acid and alkali, both before and after adding rennet, the author does not agree with Laqueur that casein splits into paracasein and milk albumin. On the contrary, his results agree with Petry and Spiro (E. S. R., 18, p. 475).

Microscopical studies of the colostrum of cow's milk, P. Schulz (*Ztschr. Fleisch. u. Milchhyg., 19 (1908), No. 2, pp. 55–61; 19 (1909), No. 4, pp. 132–145; abs. in Rev. Gén. Lait, 7 (1909) No. 9, p. 210; Molk. Ztg. [Hildesheim], 23 (1909), No. 5, p. 110; N. Y. Produce Rev. and Amer. Cream., 27 (1909), No. 16, p. 654*).—The author reviews the literature on this subject and gives the results of his own investigations. Some of his conclusions are as follows:

The colostrum bodies disappear from the third to the eleventh day after calving, the length of time which they remain being independent of breed, yield of milk, age of the cow, nature of the feed, or the length of the dry period. During the first lactation period they remain longer than in the succeeding periods. They persist longer if the milking is imperfect or the secretion of milk is interfered with in any way. Occasionally they may persist in some cows during the entire lactation period.

Analyses of colostrum, M. Siegfeld (*Molk. Ztg., 22 (1908), No. 45, p. 1293; abs. in Milchw. Zentbl., 5 (1909), No. 1, pp. 37, 38*).—These analyses show a great range in chemical composition. The variations are due to the individuality of the cow and the length of time between calving and the milking period. The specific gravity varied from 1.031 to 1.083, the percentage of fat from 4.7 to 12, the protein from 5.42 to 23.75, and the carbohydrates from 1.60 to 3.50.

The proteolytic enzym of human milk, A. E. Austin (*Jour. Med. Research, 19 (1908), No. 2, pp. 309–319*).—Samples of milk from 21 persons at different periods of lactation were examined to determine why breast milk often disagrees with the healthy infant. No enzyms were found by Volhard's method, employed for trypsin. A modification of Rietschel's method was employed for the determination of rest nitrogen (nonprotein nitrogen). The results were variable and inexplicable.

"Before the subject here treated can be fully settled we must know more of the character of this rest nitrogen, and the most attractive feature is the possibility of the presence of amino acids." As a test for amino acid a combination of Ackermann and Levene's method was employed. No free glycocol, alamin, nor leucin were found. The results are summarized as follows:

"There is no evidence of autodigestion of human milk, at least under the conditions pertaining to such digestions in organ tissues.

"The digestive disturbances of infants fed on human milk can have no relation to such an enzym, as the milk of both healthy and sick women was examined.

"The rest nitrogen is still a riddle, though if amino acids compose a part of it they are remnants of a synthesis to protein, and not products of digestion of milk protein."

On the nucleon content of human milk, A. Valenti (*Arch. Farmacol. Sper. e Sci. Aff., 7 (1908), No. 10, pp. 447–459, charts 2; abs. in Chem. Zentbl., 1909, I, No. 2, p. 93*).—The author found that the average percentage of nucleon in human milk with three subjects tested three times a month was 0.1302, 0.1339, and 0.1305, respectively, and appeared to vary inversely with the amount of milk. The maximum amount of nucleon was in the first two or three months of lactation.

On milk secretion and the microscopical testing of milk, W. Winkler (*Ztschr. Landw. Versuchsw. Österr., 11 (1908), No. 6, pp. 562–630, pls. 4; abs. in Fühling's Landw. Ztg., 57 (1908), No. 19, p. 672*).—The results of a microscopical study of milk and the tissues of the mammary glands are reported and the work of other investigators is reviewed.

The author could distinguish four different cellular layers in the sections of the alveolus, as follows: (1) The membrana propia, described by Fürstenberg, which is composed of connective tissue; (2) a layer of muscular fibers that can contract the alveolus and force out the secretion; (3) a merismatic layer wherein nuclear division is very active during the lactation period; and (4) a layer of secretory epithelial cells.

The author believes that fat globules have a firm membrane, and that the "lactokonien" of Kreidl are granules of casein. Rancid milk may sometimes be caused by irregular-shaped fat globules formed in the udder. Leucocytes and lymphocytes are seldom found in milk. A distinction should be made between leucocytes and epithelial cells of milk.

Slimy milk, L. Eberlein (*Pure Products, 4 (1908), No. 11, pp. 494–499*).—This is a review of bacteriological investigations on the causes of slimy and colored milk.

Fermentations of milk and cheese. A. Koch (*Jahresber. Gärungs-Organismen, 16 (1905), pp. 259–351*).—A review of the articles on this subject for 1905.

On lactic-acid fermentation in milk, M. W. Beijerinck (*K. Akad. Wetensch. Amsterdam, Proc. Sect. Sci., 10 (1907), pt. 1, pp. 17–34*).—This is mainly a discussion of the properties of different types of lactic-acid bacteria.

Lactic acid as an agent to reduce intestinal putrefaction, P. G. Heinemann (*Jour. Amer. Med. Assoc., 52 (1909), No. 5, pp. 372–376*).—The work of Metchnikoff and other observers is reviewed. The author's investigations with steril-

ized milk, self-coagulated milk, and the commercial preparations known as lactobacilline, fermenlactyl, kefilac, yoghourt, and latone led him to think, that so far as the therapeutic effect is concerned, there is yet no convincing evidence that sour milk prepared with commercial cultures is preferable to naturally soured milk. Yeasts were present in all but one of the commercial preparations.

Colloidal cream and process of making the same. L. M. Rousseau (*French Patent 392,253, Sept. 20, 1907; Jour. Soc. Chem. Indus., 27 (1908), No. 24, p. 1218*).—This is a patented process by which a colloidal preparation of casein containing 66 per cent of water is obtained by subjecting skim milk to centrifugal action. A sufficient amount of this preparation is added to fresh cream to make the total amount of casein in the product equal to one-fourth of the weight of the fat. The mixture is then heated to about 65°, homogenized under a pressure of 150 to 300 kg., and then sterilized.

The preservative action of boric acid in butter. M. A. O'Callaghan (*Agr. Gaz. N. S. Wales, 19 (1908), No. 12, pp. 1033–1035; 20 (1909), No. 2, pp. 148, 149*).—Experiments were undertaken to determine the proper quantity of boric acid to add to butter for preservative purposes without injuring the flavor or other qualities.

Ninety lbs. of butter was divided into three portions. To the first portion was added 3 per cent of salt; to the second, 3 per cent of salt and 0.25 per cent of a preservative consisting mainly of boric acid; and to the third portion, 3 per cent of salt and the preservative at the rate of 0.5 per cent. The butter was then worked in the ordinary manner.

At the end of 3 months the third portion would just pass for a first quality of frozen butter as regards flavor. The second portion showed evidences of decomposition, while the first portion was distinctly third class in flavor. Chemical analyses showed that about one-half of the boric acid was lost in working. A repetition of the experiment gave similar results.

[The effect of cold storage on the changes in butter]. L. A. Rogers (*Ice and Refrig., 36 (1909), No. 1, pp. 9–11, charts 3*).—This is a lecture before the eighteenth annual convention of the American Warehousemen's Association, held at Washington, D. C., December, 1908. According to the author's experiments so far it would seem that the condition of butter, after remaining in cold storage, is much more dependent on the methods of manufacture than on the storage temperature.

Butter. A. McGill (*Lab. Inland Rev. Dept. Canada Bul. 170, pp. 19*).—This bulletin reports the analyses of 295 samples of butter.

A study of Argentine butters. P. Lavenir (*Crón. Agr. [Argentina], 2 (1908), No. 7–9, pp. 103–107*).—The physical and chemical properties of 8 samples of butter are determined and presented in tabular form.

Danish butter exports, 1907–8. B. Böggild (*Tidsskr. Landökonomi, 1908, No. 13, pp. 649–659*).—This is the usual annual review of the conditions of the Danish butter trade published by the author.

The imports of butter during the year ending September 30, 1908, were 31,192,000 Danish pounds, 21,000,000 of which came from Russia (largely Finland). The net exports amounted to 169,700,000 lbs., an increase of 8,600,000 lbs. over the exports of the preceding year, and the gross exports to 200,800,000 lbs. Of this quantity 183,970,000 lbs. went to England, an increase of a little over 6,000,000 lbs. over the figure for the preceding year. The domestic production of oleomargarine was 54,220,000 lbs. and the imports 6,570,000 lbs., making a total of 60,790,000 lbs. of oleomargarine consumed in Denmark during the year.

The average price received for the butter during the year was about 103 öre per pound (25.1 cts. per pound avoirdupois), an increase of about 6¼ öre (1.7 cts.) over the average price received during 1906 7.

Denmark's butter exports during the last 25 years, B. Bøggild (*Ugeskr. Landm., 53 (1908), No. 4, pp. 47–49*).—A review of the development of the industry since 1882, with statistics.

Refrigeration and Siberian butter (*Milch Ztg., 37 (1908), No. 45, p. 533*).—This is an account of the recent growth of the dairy industry in Siberia, which is already a successful competitor with Denmark and Holland in the London butter market. At the present time 36,000,000 kg. (about 8,182 tons) of butter are sent annually from Siberia to London and the amount is constantly increasing, this being due to improved methods, cheap transportation, and refrigeration.

The science and practice of cheese making, L. L. Van Slyke and C. A. Publow (*New York, 1909, pp. XVI+383, pl. 1, figs. 55*).—This work is intended as a text-book for students and as a reference book for the practical cheese maker. A large amount of space is devoted to Cheddar cheese making. The work is divided into five parts, viz, the manufacture of American Cheddar cheese, defects of American Cheddar cheese, the science of cheese making, methods of making different varieties of cheese, and methods of testing, factory organization and literature.

Cheese making, J. W. Decker, edited by F. W. Woll (*Madison, Wis., 1909, rev. ed., pp. 211, pl. 1, figs. 93*).—This is a fifth edition of this work. Among the new subjects discussed are the cold-curing and paraffining of Cheddar cheese, the use of the acidimeter, Hart's test for casein in milk, a synopsis of defects in American Cheddar cheese, and the manufacture of Camembert, Gouda, Italian, potted, sage and other kinds of fancy cheese.

Cheese, A. McGill (*Lab. Inland Rev. Dept. Canada Bul. 171, pp. 21*).—Analytical data regarding 237 samples of cheese are reported. Seventy-four per cent of the samples contained from 44 to 48 per cent of fat.

Some analyses of cream cheese, C. H. Cribb (*Analyst, 34 (1909), No. 395, pp. 45–48*).—The fat from 28 samples of cream cheese ranged from 0.63 to 75.6 per cent, though all but four samples were apparently made from whole milk or from a mixture of cream and milk.

The fat in cheese, G. Cornalba (*Indus. Latt. e Zootec., 7 (1909), No. 2, pp. 23, 24*).—Analyses of 31 samples of different kinds of Italian cheese are reported. The percentage of water ranged from 16.6 to 60, the fat from 8.2 to 41.5, and the protein from 16.3 to 50.9.

The fat content of Edam cheese, L. Müller (*Molk. Ztg., 22 (1908), No. 35, pp. 997–999*).—This is a discussion of the factors which influence the fat content of cheese and the methods of estimating it. Analyses of Edam and Limburger cheeses are also reported.

The cheese industry of Normandy, Beau (*Indus. Lait., [Paris], 33 (1908), No. 36, pp. 651–656*).—This is a discussion of the adaptability of the fertile soil in the Auge Valley. The cattle are chiefly of the Normandy breed. The principal dairy product is Camembert cheese, which had its origin in this region, having been first made in 1791.

The cheese industry in the Rhine Province (*Dept. Landb., Nijv. en Handel, Verslag. en Meded. Dir. Landb. [Netherlands], 1908, No. 6, pp. 85–102*).—A general survey of the growth of the cheese industry in that region since 1825.

Casein and its applications, F. W. Richardson (*Jour. Soc. Dyers and Colourists, 25 (1909), No. 1, pp. 4–8; abs. in Jour. Soc. Chem. Indus., 28 (1909),*

No. 3, p. 137).—In this article the methods of using casein for sizing cotton warps, for dressing for cotton and linen fabrics, and for waterproofing are discussed. Casein may also replace albumin in calico printing. Mention is made of the production of a noninflammable photographic film from casein and the possibility of its employment to "animalize" cotton so that it may dye like wool.

The characteristics of red currant seed oil, R. Kržizan (*Chem. Rev. Fett u. Harz Indus., 16 (1909), No. 1, pp. 1–3; abs. in Jour. Soc. Chem. Indus., 28 (1909), No. 2, p. 97; Analyst, 34 (1909), No. 396, p. 101*).—"The air-dried seeds of Italian and Bohemian red currants yielded on extraction with petroleum spirit 16 and 18.5 per cent of oil, respectively. In each case the oil was of an orange-yellow color and had an odor resembling that of linseed oil. In the film test the oils dried in 3 to 4 days, yielding an elastic skin." Other values of these oils are also given.

Oil from "Carapa guyanensis" (Carapa procera, DC.), J. Lewkowitsch (*Analyst, 34 (1909), No. 394, pp. 10, 11; abs. in Jour. Soc. Chem. Indus., 28 (1909), No. 3, p. 150*).—Physical and chemical properties of this oil are given.

The rate of fermentation of ciders and perries, B. T. P. Barker (*Jour. Agr. Sci., 3 (1908), No. 1, pp. 1–21*).—A study was made of the influence of various factors on the rate of fermentation. The main factor appears to be the amount of nitrogenous matter present in the juice which is assimilable by the yeast. The variety of fruit, state of ripeness, aeration of the juice, and temperature also have some influence, but the kind of yeast and the chemical constituents in the juice other than nitrogenous compounds do not appear to be influential factors. A certain measure of control over the rate of fermentation can be exercised by the cider maker.

Acetic aldehyde in wine, its origin, and its significance, A. Trillat (*Ann. Inst. Pasteur, 22 (1908), Nos. 9, pp. 704–719; 10, pp. 753–762; 11, pp. 876–895; Bul. Assoc. Chim. Sucr. et Distill., 26 (1909), No. 8, pp. 654–690*).—The author reviews the work of other investigators, and describes in detail his own experiments concerning the various factors which influence the amount of acetic aldehyde in wines and brandies. Acetic aldehyde is formed by the oxidation of alcohol under the influence of the air and participates more or less in all the principal modifications which take place in wine.

Malic acid in wine making. Malo-lactic fermentations, W. Mestrezat (*Jour. Pharm. et Chim., 6. ser., 28 (1908), No. 1, pp. 13–20*).—After reviewing the work on this subject the author maintains that a malo-lactic fermentation does not necessarily take place because of the disappearance of malic acid.

Report of the Swiss experiment station for horticulture and wine making at Wädenswil for 1905–6, H. Müller-Thurgau (*Landw. Jahrb. Schweiz, 22 (1908), No. 14, pp. 745–920, figs. 10*).—This is the annual report of work done at this station on the diseases of fruits, variety tests of grapes, wine fermentation, tests of different kinds of yeasts, and related topics.

Agricultural and industrial distillation, E. Boullanger (*Industries de Fermentation Distillerie Agricole et Industrielle. Paris, 1909, pp. XI+554, figs. 107*).—This work treats of the distillation of industrial alcohol, brandies, and rums both from the practical and theoretical standpoint. The principal topics treated are the properties and uses of alcohol, methods of determining the chemical composition of beets, molasses, fruits, and other materials used in distilling, the methods of preparing and fermenting different musts, the distillation and rectification of alcohol, and the composition and utilization of by-products of distilleries. There is some statistical informaton on the alcohol industry and also a chapter on alcoholometry.

VETERINARY MEDICINE.

Veterinary materia medica and therapeutics, K. Winslow (*New York, 1908, 6. ed., rev. and enl., pp. VIII+859*).—A sixth revised edition of this work of which that part of the text treating of the physiological action of drugs has been almost completely rewritten on the basis of recent pharmacological investigations.

Further studies upon anaphylaxis, M. J. Rosenau and J. F. Anderson (*Pub. Health and Mar. Hosp. Serv. U. S., Hyg. Lab. Bul. 45, pp. 65; abs. in Jour. Med. Research, 19 (1908), No. 1, pp. 37–66; Bul. Inst. Pasteur, 6 (1908), No. 18, pp. 827–829*).—"The period of incubation of serum anaphylaxis is about 7 days in guinea pigs sensitized in the brain and about 9 days in guinea pigs sensitized subcutaneously. It also appears that the sensitization comes on somewhat gradually. . . . The sensitizing principle is gradually influenced by heat. It disappears almost entirely when horse serum is heated to 100° C. for 1 hour. . . . The toxic principle in horse serum is gradually destroyed by heat. . . . The toxicity of horse serum does not appear to diminish with the age of the serum. . . .

"The specific nature of anaphylaxis is further shown by various experiments. . . . A substance known as 'anaphylactin' is present in the blood serum of sensitized guinea pigs. This substance is not present during the period of incubation. We have been unable to demonstrate the presence of anaphylactin in the blood serum of man, the monkey, and the cat. . . . We believe that these morphological alterations do not explain the mechanism of anaphylaxis. It is probable that the mechanism will not be unraveled until further light is shed upon the chemistry of protein metabolism. . . . The repeated injection of small amounts of horse serum sensitizes guinea pigs. Repeated injections of large amounts render guinea pigs partially immune. . . . We suggest a possible relation between the toxemias of pregnancy and anaphylaxis."

Investigations of the leucocytes and lymphoid tissue of invertebrates, M. Kollmann (*Ann. Sci. Nat. Zool., 9. ser., 8 (1908), No. 1–4, pp. 1–6*).—The investigations are reported in three parts. Part 1 is devoted to a review of the literature and to important questions of technique. In part 2 details are given of the results of studies in the various groups while in part 3 is found a synthetic review of the investigation and the conclusions therefrom. A bibliographical list is given.

Further notes on rat leprosy and on the fate of human and rat lepra bacilli in flies, W. B. Wherry (*Jour. Infec. Diseases, 5 (1908), No. 5, pp. 507–514*).—While engaged in plague work in California the author made careful search for leprosy in rats in view of the possibility of blood-sucking insects playing some rôle in the transmission of the disease. Out of 9,361 rats dissected during a period of 4 months in the summer of 1908, 20 were found infected with leprosy. There is said to be no evidence, however, that human leprosy and rat leprosy are identical or that human beings need fear infection from leper rats.

Experiments were made in which flies in the larval and adult stages were fed upon the carcass of a leper rat. Both stages were found to ingest the bacilli in enormous numbers. The bacilli did not appear to multiply in the flies (*Calliphora vomitoria, Lucilia cæsar,* and *Musca domestica*) as they were clear of bacilli in less than 48 hours.

Larvæ of *C. vomitoria* heavily infested did not appear to be capable of developing further than the nymphal stage. "A fly caught on the face of a human leper was found to be infested with leper-like bacilli. These were few in num-

ber at the beginning of the observation, but on the third day more than 1,152 were present in each speck deposited. Only one bacillus was found between the third and sixth day and the acid-proof bacilli were not infective when injected into the subcutaneous tissue of a guinea pig."

The etiology and diagnosis of hydrophobia, Anna W. Williams and May M. Lowden (*Ann. Rpt. Dept. Health City of New York, 1906, vol. 2, pp. 635–671*).—Some of the conclusions drawn by the authors following the investigation here reported are:

"The smear method of examining the Negri bodies is superior to any other method so far published. . . .

"The Negri bodies as shown by the smears as well as by the sections are specific to hydrophobia.

"Numerous 'bodies' are found in fixed virus. 'Bodies' are found before the beginning of visible symptoms—i. e., on the fourth day in fixed virus, on the seventh day in street virus, and evidence is given that they may be found early enough to account for the appearance of infectivity in the host tissues. Forms similar in structure and staining qualities to the others, but just within the limits of visible structure at 1,500 diameter magnification have been seen. Such tiny forms, considering the evidence they give of plasticity, might be able to pass the coarser Berkefeld filters.

"The Negri bodies are organisms belonging to the class Protozoa. The reasons for this conclusion are: (a) They have a definite characteristic morphology; (b) this morphology is constantly cyclic, i. e., certain forms always predominate in certain stages of the disease, and a definite series of forms indicating growth and multiplication can be demonstrated; (c) the structure and staining qualities as shown especially by the smear method of examination resemble that of certain known Protozoa, notably of those belonging to the suborder Microsporidia. The proof that the 'Negri bodies' are living organisms is sufficient proof that they are the cause of hydrophobia."

The prevalence of hydrophobia in the Philippine Islands, F. W. Dudley (*Jour. Amer. Med. Assoc., 51 (1908), No. 25, pp. 2143–2149*).—In response to circulars mailed by the author, cases which largely occurred between October 1, 1902, and February 28, 1907, were reported as follows: In 253 dogs, 3 cats, 1 carabao, 1 cow, 4 horses, 2 pigs, 3 rats, and 1 monkey. Thirty-nine provinces were shown to have been infected by the disease, 16 having escaped according to reports. The author considers the disease sufficiently prevalent to warrant the Government in providing means for the Pasteur treatment.

Transmission of rabies to mice by ingestion, P. Remlinger (*Compt. Rend. Soc. Biol. [Paris], 65 (1908), No. 30, pp. 385, 386*).—Experiments indicate that mice can contract rabies not only when bit by an affected dog or cat but also when they eat virulent parts of an animal dead from the disease.

Experiments on the production of antirabic serum, D. W. Poor and P. J. Friedman (*Ann. Rpt. Dept. Health City of New York, 1906, vol. 2, pp. 682–692*).—The following conclusions have been drawn from the experiments reported:

"It is possible to produce a strong immune serum against rabic virus, in rabbits, sheep, dogs, and horses.

"For the production of such a serum a long course of treatment is necessary.

"This serum when fresh prolongs the incubation of rabies when injected into test animals a short time after infection."

Note on the investigation of cattle disease in the Protectorate of Sierra Leone, F. Harvey (*Jour. Roy. Army Med. Corps, 10 (1908), No. 1, pp. 41–44, map 1; abs. in Bul. Inst. Pasteur, 6 (1908), No. 19, p. 883*).—An account of a trypanosomiasis that is apparently fatal to cattle, horses, dogs, goats, and prob-

ably mules, sheep, and other domestic animals. A description is given of the species, which Mesnil considers as probably *Trypanosoma dimorphon*.

Notes on the duration and course of camel surra, H. T. Pease and S. H. Gaiger (*Jour. Trop. Vet. Sci., 3 (1908), No. 4, pp. 427–433*).—The percentage of camels that recover from surra seems to be low. They appear to be in an intermediate stage of tolerance and it is possible that they are gradually acquiring an immunity similar to that of Indian cattle.

Natural canine surra, S. H. Gaiger (*Jour. Trop. Vet. Sci., 3 (1908), No. 4, pp. 443–451, charts 11*).—Examinations made by the author in India of the blood of several hundred dogs resulted in the finding of but one case of natural surra. A report is presented of the symptoms in this dog and in other animals, including the horse, dog, rabbit, guinea pig, and white mouse, inoculated subcutaneously with blood from the natural case. These inoculations are said to show that the dog was probably infected from the horse.

"In the Punjab we have to deal with only one type of trypanosome but with two strains, a camel strain and an equine strain, which can not be distinguished morphologically, but can be distinguished by the virulence of the disease they produce in animals experimentally inoculated or naturally infected. By a series of inoculations one strain may take on the characters of the other. The 'camel surra' trypanosome by passage through several horses comes up to the standard of virulence of what might be called the 'horse surra' trypanosome."

Treatment of surra by atoxyl and orpiment, J. D. E. Holmes (*Jour. Trop. Vet. Sci., 3 (1908), No. 4, pp. 434–442*).—In the experiments here recorded the results obtained by Laveran and Thiroux (E. S. R., 20, p. 579) from the use of atoxyl in subcutaneous injections alternated with trisulphid of arsenic by mouth were confirmed. The horse, guinea pig, and rabbit were used in these experiments.

"Solutions of atoxyl up to 15 per cent can be given intravenously and subcutaneously without injury to the tissue. In our experiments we found that the lower dilutions were preferable, as they were absorbed more readily and caused less irritation at the seat of inoculation. For horses, a 4 per cent solution and for small animals, a 1 per cent solution was adopted. The horse can tolerate 5.5 gm. of atoxyl per 500 lbs. body weight, administered intravenously. Subcutaneously somewhat less than double this amount can be administered without any toxic effect. In the guinea pig 0.06 gm. per 500 gm. body weight is the maximum amount which can be injected subcutaneously with safety. In the treatment of surra with atoxyl it is not necessary to use large doses. About a quarter of the toxic amount is sufficient."

The relation of human and bovine tuberculosis, R. Koch (*Tuberculosis, 7 (1908), No. 11, pp. 491–505; Jour. Compar. Path. and Ther., 21 (1908), No. 4, pp. 303–308*).—This is a paper presented at the International Congress on Tuberculosis held in Washington, D. C., in 1908.

Attention having been called by Dr. Theobald Smith to certain differences between the tubercle bacilli found in man and cattle, experiments were conducted in cooperation with Schütz. The conclusions arrived at are similar to those presented at the British Congress on Tuberculosis in 1901, viz: "The tubercle bacilli of human tuberculosis are different from those of bovine tuberculosis. Human beings may be infected by bovine tubercle bacilli, but serious diseases from this cause occur very rarely. Preventive measures against tuberculosis should therefore be directed primarily against the propagation of human tubercle bacilli." It is stated that there are many possible sources of error in the work and that it is only when such have been excluded that the results can be accepted as conclusive.

Infection of dogs with human and bovine types of the tubercle bacillus, C. Titze and O. Weidanz (*Tuberkulose Arb. K. Gsudhtsamt., 1908, No. 9, pp. 79–92; abs. in Bul. Inst. Pasteur, 6 (1908), No. 22, p. 1006*).—The authors first consider the statistics relating to the frequency of the disease and review the literature on the subject. From inoculation experiments it is concluded that dogs are very resistant to both the human and bovine types of the bacillus, whatever the manner of introduction. This appears to be a natural immunity possessed even by young dogs. Tuberculous dogs were found to react to tuberculin. A bibliography is appended.

Tuberculosis of parrots and canaries, A. Weber, C. Titze, and O. Weidanz (*Tuberkulose Arb. K. Gsudhtsamt., 1908, No. 9, pp. 59–78; abs. in Bul. Inst., Pasteur, 6 (1908), No. 22, pp. 1004, 1005*).—Parrots were infected in various ways with the bovine, human, and fowl types of the tubercle bacillus. While they were susceptible to the 3 types, the bovine type was most virulent and the fowl type the least so.

Experiments are also reported in which the 3 types were ingested by canaries. The fowl type was found to be the most virulent.

The ophthalmic reaction to tuberculin, Le D. Bailliart (*Jour. Compar. Path. and Ther., 21 (1908), No. 4, pp. 308–321*).—This is a report presented on behalf of the Société de Pathologie Comparée to the International Congress on Tuberculosis held at Washington, D. C., in 1908. The following are the conclusions arrived at:

"The ophthalmic test is a method of diagnosis which is, in general, without danger when applied to eyes that are quite free from any tuberculous lesions. It is sometimes followed by slight and temporary ill effects. The reaction is not always proportionate to the extent of the lesions. It is often absent in the last stages of the disease. It is sometimes followed by systemic disturbance, which is always inconsiderable and lasts only for a short time. Very often the reaction is doubtful. In bovines, because of the difficulties of examination, doubtful cases should be considered negative. . . .

"In bovines the ophthalmic test alone is a very untrustworthy method, and can not pretend to replace the ordinary subcutaneous injection. The secondary ocular reaction gives results which are far superior. In the vast majority of cases the two processes, simple subcutaneous injection and the combined ophthalmic reaction, give the same results.

"Exceptionally, a tuberculous animal does not react to this second ocular test. More frequently one gets a positive ophthalmic reaction in a nontuberculous animal. Although the combined ophthalmic reaction can not replace the subcutaneous injection of tuberculin as a means of diagnosis, it remains a useful method, far more simple, and of genuine utility in certain circumstances."

Five years' experience of protective inoculation against tuberculosis in cattle by von Behring's method, Strelinger (*Berlin. Tierärztl. Wchnschr., 1908, No. 22, pp. 385–388; abs. in Jour. Compar. Path. and Ther., 21 (1908), No. 3, pp. 220–225*).—The author reports inoculation experiments conducted at Sávár, Hungary, in which von Behring's directions were punctiliously observed. Attention is called to the importance of choosing only quite young and healthy animals.

"Our experience shows that bovovaccination is capable of conferring marked protection against infection for a period of 5½ years, the percentage of 5½-year-old animals protected by bovovaccination, and which reacted when afterwards submitted to tuberculin, only numbering 10 per cent, whilst before the introduction of protective inoculation 50 per cent of 2-year-old artificially reared animals reacted to tuberculin.

"When we further consider that such good results can also be obtained on farms in which the inoculated calves are constantly kept together with highly tuberculous cows, it is plain that protective inoculation can be carried out with good results under ordinary agricultural conditions, and it seems justifiable to conclude that the power of resistance against tuberculous infection conferred on animals by bovovaccination, having already lasted over 5 years, will probably prove to continue for some years longer.

"Taking everything into consideration, I consider it absolutely superfluous to repeat the protective inoculation every year, as has recently been suggested. According to my view, inoculation should not be repeated even once, on account of the possibility of infection through the milk.

"Instead of repeating the inoculation, I would recommend that, as far as economically possible, suitable hygienic measures should be adopted."

It is pointed out that the danger of animals from tubercle-free farms from becoming infected if removed to other centers obtains under the methods of Bang and Ostertag. It is therefore of great importance that cattle not only be protected from tuberculosis infection, but also that an active resistance be conferred. The author considers a combination of Ostertag's method with von Behring's bovovaccination as the remedy sought for. The following are considered the most important points in such a combined method:

"The most important condition, in my estimation, is that the bovovaccination should be carried out with the most scrupulous care and exactly in accordance with von Behring's directions.

"The method of testing, by tuberculin, the adult animals protected by von Behring's method should be discontinued, and only employed in special cases. For it should be substituted exact clinical tests of the whole number of animals at fixed intervals.

"The tuberculin testing of the calves recommended by Ostertag can in the combined method be discontinued, inasmuch as the bovovaccine injections exhibit an action similar to tuberculin. (I may add that we have often noted that calves which react typically during the protective inoculation have later proved to be infected.)

"By combining the two methods, the artificial rearing of the calves, as recommended by Ostertag, could be discontinued, for our experiments have shown that calves develop just as well under ordinary agricultural conditions as those reared artificially, provided they have been protectively inoculated in early life. This appears to me an advantage of the combined method which should not be overlooked, because in agricultural practice artificial rearing is often difficult to carry out."

The vaccination of cattle against tuberculosis, T. Smith (*Jour. Med. Research, 18 (1908), No. 3, pp. 451–485; abs. in Bul. Inst. Pasteur, 6 (1908), No. 23, p. 1038*).—"Vaccination of calves with the human type of the tubercle bacillus is harmless. Cases in which injuries are said to have resulted from it may have been due to other concomitant affections, among which pneumonia is probably the most common. Persons trying vaccination should first assure themselves that the culture they intend to use belongs to the human and not to the bovine type of the bacillus.

"Vaccination with the human type of bacillus leads to a relatively high resistance to fatal doses of the bovine bacillus.

"Vaccination with a carefully tested, attenuated bovine bacillus may be as efficacious, even in a single injection, as the double vaccination with human bacilli. Such vaccination may be less dangerous to man than when human bacilli are used.

"The immunity conferred by vaccination, as hitherto practiced, does not appear to be satisfactory as regards degree or duration. More evidence is needed with regard to these points. The herds of large public institutions are well adapted to decide these questions if vaccination is thoroughly applied, and the animals supervised by properly trained men.

"Insufficient immunity following vaccination may prove dangerous in giving rise to mild cases, after ordinary exposure in infected herds, which tend to discharge tubercle bacilli from small foci in the lungs.

"The immunity acquired by two vaccinations with human bacilli should be fortified by a subsequent injection of attenuated bovine bacilli.

"Investigations should be made looking toward the selection, by the injection of attenuated bovine bacilli, of races or breeds of cattle which possess naturally a high degree of resistance to tuberculosis. The capacity of different breeds to acquire a high degree of immunity should also be investigated.

"The survival of human and bovine bacilli in the lungs and udders of calves vaccinated intravenously with them should be more definitely determined.

"Vaccines may be easily and cheaply prepared in the form of suspensions in fluids ready for injection. The length of time during which suspensions maintain their highest efficiency remains to be determined."

The vaccination of cattle against tuberculosis, J. F. Heymans (*Arch. Internat. Pharmacod. et Thér., 17 (1907), No. 1–2, pp. 133–146; 18 (1908), No. 3–4, pp. 179–203*).—Details of investigations previously noted (E. S. R., 20, p. 877).

Phagocytic immunity, J. C. Meakins (*Jour. Expt. Med., 11 (1909), No. 1, pp. 100–117, charts 6*).—From the experiments here described it is concluded that animals immunized with living tubercle bacilli may develop phagocytic immunity of a high degree and that such immunity may help to protect the animal from a lethal dose of virulent tubercle bacilli.

Further filtration experiments with virus of cattle plague, E. H. Ruediger (*Philippine Jour. Sci., B. Med. Sci., 3 (1908), No. 4, pp. 319–321, charts 11*).—A continuation of investigations in which experiments with peritoneal fluids (E. S. R., 20, p. 790) were repeated. The author concludes that peritoneal fluid retains its virulence on being passed through Berkefeld filters marked V, N, or W, but is harmless after having been passed through a Chamberland filter marked B.

Tick fever, or redwater, S. Dodd (*Dept. Agr. and Stock, Vet. Dir., Queensland, Bul. 2, 1908; Queensland Agr. Jour., 21 (1908), Nos. 5, pp. 245–251; 6, pp. 308–317, fig. 1; abs. in Vet. Rec., 21 (1909), No. 1069, p. 438*).—An account of the history, causation, symptoms, post-mortem appearance, and preventive and curative treatment of this disease, including the life history of *Margaropus (Rhipicephalus) australis*. Preventive inoculation and eradication of the ticks are considered at length.

Report on methods adopted for the eradication of cattle ticks in the United States of America, S. Dodd (*Queensland Agr. Jour., 21 (1908), No. 1, pp. 47–51*).—A summary is given of the work that has been carried on in this country up to the end of 1907.

Contributions to a biological study of Bacillus vitulisepticus and to the immunization of calves against septicemic pneumonia, H. Schirop (*Centbl. Bakt. [etc.], 1. Abt., Orig., 47 (1908), No. 3, pp. 307–342; abs. in Bul. Inst. Pasteur, 6 (1908), No. 20 pp. 917, 918*).—After studying *Bacillus vitulisepticus* in different media and its pathogenic power for different species of animals, the author conducted immunization experiments. He concludes that there are many races of the bacillus since the monovalent serum protects animals against the race used in preparing the serum but only rarely against others.

The etiology of white scour in calves, C. Titze and A. Weichel (*Berlin. Tierärztl. Wchnschr., 1908, No. 26, pp. 457, 458; abs. in Jour. Compar. Path. and Ther., 21 (1908), No. 3, pp. 271–273*).—In corroboration of the work of Jensen and others, the authors have found that feeding with small quantities of cultures of various kinds of bacilli produces a severe diarrhea in young calves which often ends in death. In a spontaneous outbreak of white scour, in which 5 out of 20 calves died, the authors accidentally obtained from the intestinal contents the so-called bacillus of hog cholera. The same bacillus was also found in the dung of healthy horses. In another enzootic of white scour investigated, *Bacillus enteritidis* appeared to be the cause of the diarrhea.

In order to determine the relationship that obtains between the individual varieties of typhoid bacilli found in white scour and to determine whether or not the meat poisoning bacilli play an important part, the authors examined 200 different varieties of white-scour organisms which had been isolated during numerous outbreaks of white scour occurring over almost the whole of Prussia. These were named according to their morphological and biological properties and their agglutinative effects. Of the organisms found, 151 specimens appeared to be the common *B. coli*, 28 the paracolon bacillus of Jensen, 14 the pseudocolon bacillus of Poels, 2 the *B. proteus*, and 1 the *Bacterium acidi lactici*, while 4 varieties could not be determined because they arrived in an impure state.

The authors consider it possible that the cause of white scour and of pneumonia of calves is of the nature of an ultravisible virus.

Diarrhea in calves, E. L. Vallejo (*Estac. Agr. Cent. [Mexico] Circ. 9, pp. 6*).—A general account of the disease.

A new Indian tick, Ornithodoros lahoriensis, L. G. Neumann (*Jour. Trop. Vet. Sci., 3 (1908), No. 4, pp. 462–467, figs. 4*).—This tick, taken upon sheep in India and reported to transmit a disease of sheep, is here described as new. According to the natives the tick appears to infest old sheepfolds, living in cracks and crevices and attacking sheep in November and December and the winter months. While the exact nature of the disease has not yet been determined it is said to be a pernicious anemia.

Infectious mastitis of the goat, W. R. L. Best (*Philippine Agr. Rev. [English Ed.], 1 (1908), No. 8, pp. 335–337*).—A general account of the symptoms and nature of this disease with prophylactic measures and remedial treatment.

Swine plague, W. Jowett (*Jour. Compar. Path. and Ther., 21 (1908), No. 4, pp. 321–324*).—The author here records an observation in which swine plague occurred unaccompanied by post-mortem lesions that resembled hog cholera. It is said that while hog cholera was quite prevalent in Cape Colony in 1904 it has apparently been stamped out. Post-mortem findings are reported in detail.

Cure of a stallion suffering from dourine by means of atoxyl at the remount depot at Constantine, M. Moxod (*Bul. Soc. Cent. Méd. Vét., 85 (1908), No. 12, pp. 303–309, chart 1; Jour. Trop. Vet. Sci., 3 (1908), No. 4, pp. 456–461*).—The author considers that it would be imprudent to conclude from a single case that atoxyl is a specific against dourine. The action of the drug, however, is said to have been well marked, though the usefulness of this stallion as a sire still remains to be determined. Given in progressive and intermittent doses atoxyl is borne well by the horse. The dog is said to be an uncertain test animal in this disease.

The agglutination test as applied to the diagnosis of glanders, K. R. Collins (*Am. Rpt. Dept. Health City of New York, 1906, vol. 2, pp. 693–704*).—This is a preliminary summary of investigations conducted, from which it is concluded that at present the value of the test lies in its use as an indicator for the mallein test. A later report has already been noted (E. S. R., 20, p. 879).

What should each dog owner know? T. Ritt (*Was muss jeder Hundebesitzer wissen? Stuttgart, 1908, pp. VIII+112, pl. 1, figs. 21*).—The aim of this work is to inform dog owners concerning their duties in order to prevent dogs from spreading diseases and parasites injurious to man and domesticated animals. Instructions are given concerning the care and management of dogs, with brief descriptions of diseases which may be transmitted by them. There is also a digest of the laws and police ordinances relating to dogs in Germany, Austria, and Switzerland.

A contribution to the study of follicular mange in the dog, N. Almond (*Vet. Rec., 21 (1909), No. 1069, pp. 428–430*).—A 2.5 per cent solution of zinc chlorid in water has been used with success by the author in treating this disease in dogs. Applications were made with a sponge at night and in the morning.

Contributions to the morphology and life history of Piroplasma canis, A. Breinl and E. Hindle (*Ann. Trop. Med. and Par., 2 (1908), No. 3, pp. 233–248, pls. 4; abs. in Bul. Inst. Pasteur, 6 (1908), No. 20, pp. 909, 910, figs. 5*).—The studies here reported were made with a strain sufficiently virulent to kill all the dogs infected. In regard to the flagellate forms the authors report as follows: "Very rarely true small flagellate forms were seen, especially in blood from the lung; but we were never able to trace the origin of the single flagellum. . . . We have been able to trace the development of large biflagellate forms from the normal intracellular parasite. . . . These observations appear to point to the fact that the biflagellate forms of *P. canis* represent a very transient stage in its life history."

The development of Piroplasma canis in culture, G. H. F. Nuttall and G. S. Graham-Smith (*Parasitology, 1 (1908), No. 3, pp. 243–260, pl. 1, fig. 1*).—The details are presented of studies made by the authors of the development of *P. canis* in vitro.

The mode of multiplication of Piroplasma bovis, P. pitheci in the circulating blood compared with that of P. canis, with notes on other species of Piroplasma, G. H. F. Nuttall and G. S. Graham-Smith (*Parasitology, 1 (1908), No. 2, pp. 134–142, pl. 1, dgms. 4; abs. in Bul. Inst. Pasteur, 6 (1908), No. 20, pp. 910, 911*).—"In stained preparations *P. canis*, *P. bovis*, and *P. pitheci* may be distinguished from other intracorpuscular parasites by the presence of intracorpuscular pyriform bodies, usually occurring in pairs and less commonly in fours, eights, and sixteens. These pyriform bodies show a dense mass of chromatin near the pointed end and a loose mass, often connected with the dense mass, situated toward the blunt end. In suitable preparations peculiar dividing forms, most typically represented by trilobed forms or more or less pyriform bodies joined to a single smaller rounded or elongated mass of protoplasm, may be seen.

"In the absence of observations on the living parasite we consider that these points may be taken as characteristic of the genus Piroplasma.

"In spite of the fact that dividing forms have not yet been found and that the secondary mass of chromatin has not yet been observed *P. muris* may perhaps be included in this genus.

"*P. quadrigeminum*, an intracorpuscular parasite recently observed by Nicolle in a small North African rodent (*Ctenodactylus gundi*), apparently divides in a totally different manner, and shows a peculiar disposition of the chromatin. No loose chromatin has been observed. Until further observations have been made this parasite can not be included among the true Piroplasma.

"Further observations are needed before the position of the other so-called Piroplasma can be determined."

Observations on the piroplasmosis of cattle in Indo-China, and proof of piroplasmosis among buffaloes. H. Schein (*Ann. Inst. Pasteur, 22 (1908), No. 12, pp. 1005–1011, figs 17, dym. 1*).—The author has studied the forms of piroplasma found in the blood of cattle in Indo-China, and here presents the results of several observations in detail. The bigeminal pear-shaped form was less frequently met with than the bacillary and ovoid forms. The pear-shaped form only appears at the height of the disease, namely, from the seventh to the tenth day after inoculation. Occasionally animals were met with which only showed the bacillary form.

In buffaloes examined the ovoid form was more frequently found than the bacillary, while the pear-shaped form was not discovered.

A new microbe pathogenic in cats. Z. Skrzynski (*Ann. Inst. Pasteur, 22 (1908), No. 8, pp. 682–688; abs. in Bul. Inst. Pasteur, 6 (1908), No. 20, p. 916*).—A new microbe that belongs to the *Bacillus coli* group was isolated from a disease epizootic in cats.

Investigations of epithelioma contagiosum of fowls. B. Lipschütz (*Centbl. Bakt. [etc.], 1 Abt., Orig., 46 (1908), No. 7, pp. 609–622; abs. in Bul. Inst. Pasteur, 6 (1908), No. 16, pp. 745, 746*).—This is a contribution from the Pasteur Institute at Paris, in which the author reports microscopical studies, culture and immunization experiments, and investigations made of the influence of substances on the virus.

The micrococci are stained by the methods of Löffler and Giemsa and feebly by Ziehl's stain. A 10 per cent solution of atoxyl did not attenuate the virus in vitro. Exposed to a 1 per cent solution of saponin for 1 hour the virus was not affected, but after 24 hours it appeared attenuated. A 10 per cent solution of sodium taurochlorate destroyed the virulence of the virus (in a concentrated medium) in 2 hours. The virus was not cultivated artificially. It was found present in the internal organs and also within the brain of diseased and recovered pigeons.

Culture in vitro of the fowl plague virus. E. Marchoux (*Compt. Rend. Acad. Sci. [Paris], 147 (1908), No. 6, pp. 357–359; abs. in Bul. Inst. Pasteur, 6 (1908), No. 20, p. 904*).—The author has obtained 10 transplantations in which one-fifth of 1 cc. of the virus was sufficiently virulent to kill a fowl in 2 days.

Spirochetosis of fowls in South Oran. Transmission of this disease by Argas persicus. E. Brumpt and Foley (*Compt. Rend. Soc. Biol. [Paris], 65 (1908), No. 26, pp. 132–134; abs. in Bul. Inst. Pasteur, 6 (1908), No. 21, pp. 964, 965*).—Experiments are here reported which show the incubation period of spirochetosis of fowls to be about 6½ days, and that at Beni-Ounif about 1 in every 6 of the Argasids are infected. The spirochætes transmitted by *A. persicus* are identical with the *Spirochæta gallinarum* discovered by Marchoux and Salimbeni in Brazil.

The air-sac mite. L. V. Nathan (*Jour. Dept. Agr. West. Aust., 17 (1908), No. 5, pp. 853–856, fig. 1*).—The author reports this mite (*Cytodites nudus*) as the source of a disease that is "decimating the poultry yards of the gold fields" in western Australia. He has also observed the disease in birds in South Australia.

Epizootic pneumo-pericarditis in the turkey. W. Jowett (*Jour. Compar. Path. and Ther., 21 (1908), No. 4, pp. 324–330, figs. 2; Agr. Jour. Cape Good Hope, 34 (1909), No. 1, pp. 42–45*).—This disease, said to have been first described by M'Fadyean in England, is reported by the writer as having occurred in a large flock near Capetown, South Africa. Inoculations and post-mortem examinations are reported and the causal organism is described. In the out-

break reported fowls, geese, and pigeons were in close contact with diseased turkeys but were not affected.

Notes on ostrich parasites, W. ROBERTSON (*Agr. Jour. Cape Good Hope, 33 (1908), No. 5, pp. 583–588, figs. 6*).—The ostrich tapeworm (*Tænia struthionis*) and the wireworm (*Strongylus douglasii*) are here described. A species closely related to the guinea worm of man is also mentioned.

The cestodes of birds, O. FUHRMANN (*Zool. Jahrb., 1908, Sup. 10, No. 1, pp. 232*).—A monograph based upon museum and private European collections. From 544 species of birds 495 cestode parasites are recorded. These parasites are shown to be of great importance in zoogeographic investigations. In the faunistic section a list is given of the hosts, with their distribution and cestode parasites.

An alphabetical index is given of the families, genera, and species. The last 20 pages are devoted to a bibliography.

Note on the behavior of Spirochætæ in Acanthia lectularia, G. H. F. NUTTALL (*Parasitology, 1 (1908), No. 2, pp. 143–151*).—The experiments reported "show that *Spirochæta duttoni* retains its virulence after a sojourn of 5 or more days in the intestine of *Acanthia lectularia* when the insect is maintained at a temperature of 12° C. Living (motile) spirochetes were observed in the gut-contents of the bugs up to 6 days at 12°, but only up to 6 hours at 20 to 24°. The observations made at various temperatures appear to indicate that the spirochetes are simply digested by the bug and that their more rapid disappearance from the insect's gut at higher temperatures is dependent upon the insect's digesting its food more rapidly when kept warm. . . . Although the bug is not the true host of *S. duttoni* it is conceivable that it may serve as a mechanical carrier of the parasite. . . .

"The foregoing experiments, whilst not sufficiently numerous to permit of any final conclusions, appear to indicate that *S. obermeieri* may die out more rapidly than *S. duttoni* in the gut of the bug. It is possible that the bugs digested their food more rapidly owing to their being more hungry than the lot used for experiments with *S. duttoni*.

"It has been demonstrated by one experiment that *A. lectularia* fed on an infected mouse and immediately afterwards upon a healthy mouse is capable of transmitting the spirochete."

Leucocytozoon musculi, a parasitic protozoon from the blood of white mice, ANNIE PORTER (*Proc. Zool. Soc. London, 1908, III, pp. 703–716, pl. 1, fig. 1*).—Studies of a microscopic organism found in the leucocytes of mice. This the author considers the first recorded from the mouse.

A monozoic cestode-like blood parasite (Saguinicola armata and inermis), MARIANNE PLEHN (*Zool. Anz., 33 (1908), No. 13, pp. 427–440, figs. 6*).—This parasite occurs in the blood system of Cyprinid fishes.

Helminthological technique, M. LANGERON (*Arch. Par., 12 (1908), No. 1, pp. 150–154; abs. in Jour. Trop. Vet. Sci., 3 (1908), No. 4, pp. 495–498*).—Directions are given for the fixing, staining, mounting, and preservation of cestodes, trematodes, and nematodes, and the eggs of these parasites. The formulas of the reagents used are included.

RURAL ENGINEERING.

Irrigated lands of United States, Canada, and Mexico, C. R. PRICE (*Los Angeles, Cal., 1908, pp. 71, figs. 17, maps 4*).—This is a compilation of data concerning public and private irrigation enterprises with descriptions of the irrigated lands and the surrounding conditions. Its aim is stated to be to furnish comprehensive information to "expert, engineer, colonist, or homeseeker." In

the pamphlet is a synopsis of the Federal laws relating to the preemption of lands and it includes information published by the Department of the Interior of interest to colonist or homeseeker.

[Irrigation investigations in California], F. W. Roeding (*Rpt. State Engin. Cal., 1907–8, pp. 153–156*).—A brief review of the cooperative work of the irrigation investigations of this Office and the State of California.

[Irrigation in Madras Presidency], P. F. Martin (*Engineer [London], 107 (1909), No. 2770, 109, 110*).—An account is given of the projects being undertaken by the British Government, in one of which it is proposed to erect the largest dam in the world. The proposed works are described, with figures as to drainage areas, reservoir capacities, dimensions of structures, and estimates of cost.

Mechanical irrigation stations on the Nile, J. B. Van Brussel (*Engin. Mag., 36 (1909), No. 5, pp. 749–764, figs. 17*).—In this article there is described a plant located at Wadi-Kom-Ombo in upper Egypt, which will make use of part of the additional water of the Nile stored up by the Assuan Barrage. The area to be irrigated covers 150,000 acres of land where the crops will be absolutely dependent on the pumps. Reliability was therefore a prime consideration, and the pumps had to be of the centrifugal type because of the large amount of silt in the water of the Nile.

The mechanical equipment comprises centrifugal pumps with 2-meter suction pipes, operated by horizontal 4-cylinder, triple-expansion engines, and also a steel canal 5,200 feet long, nearly semicircular in cross section. By the use of a fuel economizer an increase in efficiency of 5 per cent will be obtained. Further data regarding the pumps and engines and the methods employed in the construction of the canal are given in the article.

Tidal power, W. C. Hornsnaill (*Engineer [London], 107 (1909), Nos. 2774, pp. 214–226, figs. 7; 2775, pp. 233, 234, figs. 3*).—In the first of these articles the writer considers the factors involved in utilizing tidal power, with a mathematical discussion as to the amount of power available from a given rise and fall and as to the efficiency of tide mills, with examples of developments.

A discussion of the economy of tidal power as compared with that of steam or gas is given in the second article, showing it to be too low to compete with them at the present value of coal.

Third Biennial Report State Engineer, North Dakota (*Bien. Rpt. State Engin. N. Dak., 3 (1907–8), pp. 77, pls. 3, dgm. 1*).—In this are contained reports of drainage projects, preliminary surveys of irrigation projects, accounts of hydrographic surveys of several important rivers of the State, with data and a discussion of the relation between rainfall and stream flow in the State. There is also an account of the progress being made under the various irrigation projects being carried on.

Peat levees, N. Ellery (*Rpt. State Engin. Cal., 1907–8, pp. 88–92*).—The writer makes recommendations as to construction and maintenance of peat levees. Among the recommendations are planting willows on the berm and up the outside slope, as it is believed that by doing this the roots will interlace the soil so as to give it increased resistance to water pressure.

The automatic water finder (*Impl. and Mach. Rev., 34 (1908), No. 406, p. 1238, fig. 1*).—The instrument here described is reported to have been successfully used for locating underground water courses. It is stated that the operation of the instrument is based upon the measurement of electric currents constantly flowing between the earth and atmosphere. These are strongest in the vicinity of subterranean flowing waters, the strength being indicated by the deflection of a needle.

Road improvement in the United States (*Good Roads Mag., n. ser., 10 (1909), No. 3, pp. 85–91, figs. 7.*)—This is a compilation of brief reports submitted from about one-half of the States, showing the progress made during 1908 and the prospects for 1909.

Superheated-steam plowing machine (*Maschinen Ztg., 6 (1908), No. 23, pp. 267–270, figs. 5*).—This is a description of a plowing machine using superheated steam, which is meeting with considerable success in Germany. Greater power with less water and coal consumption than with the ordinary steam engine is claimed for it. By an attachment so placed that the hottest gases as they leave the fire box pass through the tubes a superheat of 300° C. is obtained. The arrangement of the pipes and connections is explained and illustrated in the article.

In addition to the superheating arrangement this locomotive embodies many other novel features.

New milking machine systems, R. Georgs (*Maschinen Ztg., 7 (1909), No. 3, pp. 26–31, figs. 3*).—The evolution of the milking machine and the difficulties encountered in its practical application are discussed briefly. There follows a description of the principles and construction of two new types of machines, with an account of experience with them.

Machine milking and its practical application, G. Ellbrecht (*Mælkeritid., 21 (1908), No. 50, pp. 996–1004*).—A general discussion of the subject, with descriptions of a number of milking machines, among them being several new types.

Milking machines (*Norsk Landmandsblad, 27 (1908), No. 41, pp. 503–506, figs. 3*).—Special mention is made of two Swedish machines, with illustrations of both in operation.

Ventilation of poultry houses, K. J. J. Mackenzie and E. J. Russell (*Trans. Highland and Agr. Soc. Scot., 5. ser., 20 (1908), pp. 87–100, figs. 3*).—Experiments with different types of poultry houses showed that in the presence of 6 to 8 parts of carbonic acid per 10,000 volumes of air the birds were apparently healthy. Nine volumes is believed to be the maximum content that a poultry house should contain. In order that this degree of purity may be obtained each bird must be allowed 40 cu. ft. of air per hour. In building a poultry house each bird should be allowed 10 cu. ft. of space and there should be top ventilation.

RURAL ECONOMICS.

Cyclopedia of American agriculture. Farm and community, L. H. Bailey et al. (*New York, 1909, vol. 4, pp. XIV+650, pls. 25, figs. 163*).—This is the last of the series of volumes devoted to agriculture in the United States and Canada, the other volumes having been previously noted (E. S. R., 20, p. 778).

This volume contains 10 chapters which treat, respectively, of the agricultural wealth of North America, the historical evolution of North American agriculture, including a list of current agricultural periodicals, phases of the agricultural shift, the natural resources of agriculture, land and labor, business organization in agriculture, social and service associations, education by means of agriculture, governmental and legal aid and control, and biographies of persons who have aided in the development of agriculture in North America.

The articles under the different chapters have been prepared by specialists, and particular attention is given to the bearing of the agricultural industry on the economic and social welfare of communities. Bibliographies are appended to many of the articles.

The influence of immigration on agricultural development, J. L. COULTER (*Ann. Amer. Acad. Polit. and Soc. Sci., 33 (1909), No. 2, pp. 373–379*).—This article discusses the advantages, both to agricultural wealth production and to the economic welfare of the laborers, of the proper location of farm immigrants in parts of the country which conform as nearly as possible in physical environment, agricultural methods, and crops produced to their native lands. The results of such settlements by Swiss, Bohemians, Poles, Russians, Italians, etc., in different parts of the country are briefly discussed with reference to agriculture as a whole, to such particular branches of the industry as cheese making, and to the farm labor problem in the United States.

The Italian as an agricultural laborer, A. PECORINI (*Ann. Amer. Acad. Polit. and Soc. Sci., 33 (1909), No. 2, pp. 380–390*).—This article presents data on the number of Italians and the branches of the agricultural industry in which they are engaged in New York, Connecticut, Massachusetts, New Jersey, Pennsylvania, North and South Carolina, Ohio, Louisiana, Arkansas, Alabama, Texas, and California. Truck farming and the raising of cotton, sugar cane, tobacco, rice, and fruits are their principal lines of work. The best results are said to be attained when the Italian owns his land or is a tenant, "but decidedly he is not adapted to be exploited as a day laborer under the peonage system."

The Jewish Agricultural and Industrial Aid Society, A. JARETZKI ET AL. (*Jewish Agr. and Indus. Aid Soc. Ann. Rpt. 1908, pp. 58*).—This is the annual report for the year 1908. The purpose of this society is to assist, encourage, and instruct Jewish farmers engaged in agriculture. At the close of the year there were 2,409 farmers occupying 2,164 farms, and this is believed to represent only about 50 per cent of the number of Jewish farmers in the United States. The loans granted and the educational and other features of the society for encouraging agriculture are presented in detail.

Concerning settlements of farm laborers in East Prussia (*Illus. Landw. Ztg., 29 (1909), No. 10, pp. 82, 83*).—This article discusses the purposes of agricultural labor settlements and the conditions which lead to success. Among the latter are mentioned the profitableness of agriculture, the fertility of the land, and the capability of the farm laborer. The development of the laborer into an independent farmer, it is believed, rests upon the last factor more than on any other, and it is thought that this has not been sufficiently considered by those who have advocated the establishment of small holdings as a solution of the agricultural labor problem in Prussia.

Concerning settlements of farm laborers, DAVERHUTH ET AL. (*Illus. Landw. Ztg., 29 (1909), No. 14, pp. 123, 124*).—These two articles discuss the ineffectiveness of land settlements to solve the farm labor problem in Germany. The authors contend from observations and experience that the regular farm hand on the average farm is better off than the small holder in agricultural colonies working for himself.

The land and the landless, G. CADBURY, Jr., and T. BRYAN (*London, 1908, pp. VIII+182, dgms. 2*).—This is a history of the agrarian problem in England with particular reference to the economic and social status of farmers and farm laborers, in which it is suggested "that the rural problem will not be solved by settling a large number of men on small farms, but that it is also necessary to set up in rural England such conditions of life and industry as shall make small farms permanently possible." The conditions which will make for success are, the authors believe, to increase the size of small holdings to from 20 to 60 acres, a sound system of furnishing capital, cooperation among

farmers, subsidiary industries to small holdings, afforestation, and a graded and better system of agricultural education.

An extensive bibliography is appended.

Small holdings and the law of April 10, 1908 (*Jour. Agr. Prat., n. ser., 17 (1909), No. 7, p. 202*).—A brief discussion of the chief features of the law (E. S. R., 20, p. 191), which provides for the use of government funds not exceeding 100,000,000 francs (about $20,000,000) at 2 per cent interest, in its bearing on the economic and social welfare of the owners of small farms in France.

Provisions of cottages and allotments in France (*Jour. Bd. Agr. [London], 15 (1909), No. 11, pp. 863, 864*).—Notes are given on the more important features of the law of April 10, 1908, relating to government assistance to farm laborers for the purchase, improvement, control, and disposition of small holdings.

A small holders' Utopia, H. Beaumont (*Farm and Garden, 10 (1909), Nos. 489, p. 134; 490, p. 151*).—This is a brief history of the South Lincolnshire Small Holdings Association since 1886. Some of the features of the work which have proved successful are common pasturage, the erection of cottages, and copartnership farms. The beneficial results on the economic and social welfare of the tenants and their families are particularly emphasized.

Cooperative societies for the purchase of farming requisites (*Jour. Bd. Agr. [London], 15 (1909), No. 12, pp. 917–924; Country Life [London], 25 (1909), No. 637, p. 398*).—An account of the organization, objects, membership, and business transactions of cooperative societies in Great Britain.

Report of the Irish Agricultural Organization Society, Limited, H. Plunkett and R. A. Anderson (*Rpt. Irish Agr. Organ. Soc. 1908, pp. 105*).—Detailed statistical data and discussions of the work of the affiliated cooperative organizations for the year ended June 30, 1908, are given. The societies numbered 941, as compared with 873 in 1907 (E. S. R., 20, p. 289), of which 299 were cooperative creameries, 270 mutual credit societies, and 174 agricultural organizations.

Statistics of agricultural associations in 1907 (*Bul. Admin. Agr. [Brussels], 2 (1909), No. 2, pp. 15–64, maps 4*).—Complete returns of agricultural cooperative associations in Belgium on December 31, 1907, are reported, discussed, and illustrated.

The societies are grouped into agricultural business associations of various kinds, numbering 1,271; organizations for the purchase of seeds, fertilizers, feeding stuffs, and machinery, which numbered 1,024; societies for the sale of milk and the manufacture and sale of butter and cheese, numbering 497 in active operation; agricultural credit societies, which numbered 543, and societies insuring live stock, of which there were 1,023.

Agricultural associations in Portugal, L. de Castro (*Bul. Soc. Nat. Agr. France, 68 (1908), No. 10, pp. 782–788*).—Data are presented regarding the population and agricultural conditions of Portugal (E. S. R., 20, p. 587), and a brief history is given of agricultural cooperative associations from 1297 to the present time. Portugal has only about 100 associations, but government interest in them is shown by the fact that the parliament recently passed a law authorizing the use of 25,000,000 francs (about $5,000,000) for the promotion of agricultural credit.

Danish agriculture in 1908, H. Hertel (*Tidsskr. Landökonomi, 1909, No. 1, pp. 1–42*).—This is the annual summary of the general conditions of Danish agriculture for the year 1908.

Norwegian agriculture in 1908 (*Norsk Landmandsblad, 28 (1909), No. 1, pp. 1–10*).—A general survey.

AGRICULTURAL EDUCATION.

The farmer's chance to grow intellectually in his business, J. W. Cook (*Ann. Rpt. Ill. Farmers' Inst., 13 (1908), pp. 234–245*).—The central thought of this address is that scientific interest is the characteristic of the age and that the farmer is at the center of "the scientific situation." Only work is educative, and the farmer's work is more educative than that of any other industrial laborer because of its freedom from meaningless repetition. The farm must become a school if its resources are to be transmitted unimpaired to later generations. "Education for social efficiency is the modern watchword."

Studies in the history of modern education, C. O. Hoyt (*New York, Boston, Chicago, 1908, pp. 223, pls. 7, maps 3, figs. 2*).—This book presents certain fundamental facts in the history of education, with suggestions for their discussion, questions to invite thought and encourage research, and directions for assisting such research. It is preeminently designed as a college text, but contains a good bibliography of reference works for the general reader. The chapter headings name the representative educators and the epochs for which each stands. The term agricultural education does not appear in the index of the volume, nor is it mentioned in the single reference made to industrial training. Nor is allusion made to the American system of land-grant colleges.

Education, F. A. Nicholson (*Note on Agriculture in Japan. Madras, 1907, pp. 77–91*).—This article, which forms a part of a treatise previously noted (E. S. R., 20, p. 892), includes brief accounts of and statistical data concerning science and agriculture in primary schools in Japan, supplementary (continuation) schools, regular agricultural schools, higher agricultural education, education in forestry, farm schools, private schools, itinerant teaching, support of schools, and results and cost of ordinary agricultural education.

The beginnings of college history, M. F. Dickinson (*Boston, 1908, pp. 17*).—This address, delivered on the occasion of the fortieth anniversary of the founding of the Massachusetts Agricultural College, presents a very interesting review of the movements which led to the establishment of that institution.

The educational organization of nature study, Mary P. Anderson (*Jour. N. Y. Bot. Gard., 10 (1909), No. 111, pp. 56–63*).—Attention is called to the modern viewpoint as to the proper subject-matter for nature-study work, i. e., its relation to the life of the child.

The June-bug is not studied merely as an example of the beetles, but is approached through the fat white grub that is responsible for the patches of dead grass in our lawn. The star-fish no longer gets its interest for the child as a classic example of the radiates, but from the fact that it also eats oysters. The child is not ready for the scientific classification attempted in early nature-study programmes; he is the center of his own universe, which must be explored in gradually-widening circles.

The author suggests home and its immediate surroundings, home geography, and industrial geography, as the important centers of activity for the first 5 grades.

Nature study by grades, H. H. Cummings (*New York, Cincinnati, Chicago, 1908, pp. 180, figs. 44*).—This book is the outgrowth of a series of exercises prepared for training teachers in the Utah State Normal School, but is applicable to general nature study. An important feature is the graded arrangement of topics (for the first three grades) on a plan which insures against useless repetition.

An elementary study of corn, V. M. Shoesmith (*Agr. Col. Ext. Bul. [Ohio State Univ.], 4 (1909), No. 8, pp. 16, figs. 13*).—The writer has included in this

bulletin data for a serviceable public school manual on the selection and study of seed-corn.

The house fly as a carrier of disease, W. L. Underwood (*Hampton Leaflets, n. ser., 5 (1909), No. 3, pp. 8, figs. 2*).—This leaflet deals with the house fly as a carrier of disease. It contains a reproduction of a fly's footprints on a plate of jelly as shown by the colonies of bacteria which developed from them in 12 hours.

Illinois Arbor and Bird Days, F. G. Blair (*Springfield, Ill.: Dept. Pub. Instr., 1909, pp. 95, figs. 64*).—This bulletin is unusually well illustrated with half-tone engravings of fruit and flowering trees, vines, palms, ferns, house and garden plants, and all the common birds of the State. The economic value of birds is fully explained, and a chapter is given to the propagation and distribution of game birds by the State.

Wisconsin Arbor and Bird Day annual, 1909, O. S. Rice (*Madison, Wis.: State Supt. of Pub. Instr., 1909, pp. 120, pls. 6, figs. 14*).—In addition to other matter, this contains 6 colored plates illustrating the rose-breasted grosbeak, black and white creeping warbler, American sparrow hawk, barn swallow, screech owl, and horned lark.

Elements of Philippine Agriculture, E. B. Copeland (*Yonkers-on-Hudson, N. Y., and Manila, 1908, pp. XV+192, figs. 126*).—This text on elementary agriculture, designed for the island schools, deals with the subject from the standpoint of the native agricultural soils, plants, and insects, but includes maize and several other crops that are common to America. Among those peculiar to the region may be mentioned the jack-fruit, papaya, taro, ampalaya, abacá, mangosteen, atis, and chico. The book includes directions for school gardens, experiments, plant records, and the use of tools, and is illustrated to show the contrast between primitive Philippine implements and methods and the most modern developments, such as the steam plow and grain thrasher.

A practical arithmetic, F. L. Stevens, T. Butler, and Mrs. F. L. Stevens (*New York, 1908, pp. IX+386*).—This arithmetic is distinguished by the large proportion of agricultural problems, these forming probably 75 per cent of the whole number given. They convey, mostly by implication, a large amount of information on seed selection, judicious use of fertilizers, balancing of animal rations, crop rotation, prevention or treatment of plant diseases, conservation of soil moisture and soil fertility, prevention of insect injury, methods of harvesting, dairying and herd improvement, poultry culture, good roads, etc.

MISCELLANEOUS.

The importance of scientific experimentation in agriculture, J. Schroeder (*7. Cong. Rural An. [Uruguay], 1908, pp. 31–60, figs. 7*).—A paper presented at the Seventh Annual Rural Congress of Uruguay. Some of the beneficial results secured from systematic agricultural experimentation in other countries are pointed out and a plea is made for the development of such work in Uruguay.

Preliminary report of the Territorial Conservation Commission of Hawaii (*Hawaii. Forester and Agr., 5 (1908), No. 12, pp. 334–347*).—This report includes a summary of data as to the nature and present condition of the natural resources of the Territory, with recommendations as to their development and use.

Conservation of Hawaii's natural resources (*Honolulu: Bd. Comrs. Agr. and Forestry, 1909, pp. 21*).—This consists of the addresses before the Territorial legislature March 1, 1909, by the governor and his conferees who attended the governors' conference with the President in Washington, D. C., in May, 1908, and by others

Twenty months of the administration of the minister of agriculture, E. R. MEXIA (*Veinte Meses de Administración en el Ministerio de Agricultura. Buenos Ayres, 1908, pp. 297*).—This is a report of the minister of agriculture of Argentina for the 20 months ending with October, 1907.

Report of the department of agriculture of Finland, 1905 (*Landtbr. Styr. Meddel, 1907, No. 55, pp. X+218*).—The usual reports on the agricultural conditions of the year are given, together with data as to the work of the various agricultural, educational, and research institutions for the advancement of agriculture.

Report of the department of agriculture of Sweden, 1906, M. VON FEILITZEN ET AL. (*K. Landtbr. Styr. Underdåniga Ber. 1906, pp. [VI]+504+VII*).—The report contains the usual accounts of the various agencies for the promotion of Swedish agriculture, with reports of the work of the agricultural and other schools, and the chemical and seed control stations during the year.

Report of the Third Scandinavian Agricultural Congress, Christiania, 1907, H. TVETER (*Beretning om den 3 die Nordiske Landbrugskongres i Kristiania 1907. Christiania, 1908, vols. 1, pp. 170; 2, pp. 674*).—Volume 1 contains the transactions of the congress, with reports of the discussions following the reading of the papers, which are given in full in volume 2.

The agricultural service and laboratories of Indo-China (*Bul. Écon. Indo-Chine, n. scr., 11 (1908), No. 70, pp. 1–33*).—A detailed description of the organization and work of the Indo-China agricultural service, including the Bureau of Agriculture, inspection and control work, and experiment stations.

The work of the minister of agriculture, industry, and commerce through the public library, V. STRINGHER (*L'Opera del Ministero d'Agricoltura, Industria e Commercio per le Biblioteche Popolari. Rome: Govt., 1909, pp. 45; Bol. Uffic. Min. Agr., Indus. e Com. [Rome], 7 (1908), VI, No. 7–8, pp. 721–760*).—An address presented at the First National Public Library Congress, held at Rome, December 6–9, 1908. An account of the organization of agricultural circulating libraries is presented, together with the regulations adopted and catalogues of the books sent out by the various organizations engaged in this work.

The traveling instructor in agriculture and the public library, E. FILENI (*Bol. Quind. Soc. Agr. Ital., 14 (1909), No. 3, pp. 101–107*).—An address delivered at the above congress in which the use of circulating libraries in extension work is discussed.

General index to volumes 26–40 of Centralblatt für Bakteriologie, Parasitenkunde und Infektionskrankheiten, Erste Abteilung: Medizinisch-hygienische Bakteriologie und tierische Parasitenkunde, G. LINDAU (*Jena, 1908, pp. 429*).—This contains an author index, a subject index, and an index of illustrations to these volumes.

General index to volumes 11–20 of Centralblatt für Bakteriologie, Parasitenkunde und Infektionskrankheiten, Zweite Abteilung: Allegemeine, landwirtschaftlich-technologische Bakteriologie, Gärungsphysiologie und Pflanzenpathologie, K. TAUTZ (*Jena, 1908, pp. 246*).—This contains an author index, a subject index, and an index of illustrations to these volumes.

NOTES.

Connecticut State Station.—Dr. E. M. East, who has been in charge of the work in plant breeding, has accepted an assistant professorship in Harvard University, where his time will be exclusively occupied in research in plant breeding. His resignation takes effect September 1.

Idaho University and Station.—E. E. Elliott, dean of the college of agriculture, has been appointed director of the station.

Maryland Station.—C. W. Melick has resigned as dairy husbandman to accept a position as bacteriologist with a dairy concern in Omaha, Nebr., his resignation becoming effective September 1. A. L. Stabler, a 1909 graduate of the college, has been appointed assistant in animal husbandry in connection with the investigations with hogs and sheep.

New Mexico College and Station.—J. H. Squires, Ph. D., who has been engaged in graduate work at Cornell University for the past two years, has been appointed associate professor of agriculture, and will enter upon his duties at once. He will also be connected with the station.

Cornell University and Station.—Dean Bailey has been given leave of absence for the ensuing academic year, during which time Dr. H. J. Webber will serve as acting dean and director. G. W. Cavanaugh, H. H. Whetzel, E. O. Fippin, G. F. Warren, W. A. Stocking, jr., and G. N. Lauman have been promoted from assistant professorships to professorships. Other recent appointments include as assistant professors, G. W. Herrick, recently of the Texas College and Station, in economic entomology, C. R. Crosby in entomological investigations, A. W. Gilbert, Ph. D. (Cornell, 1909), and H. H. Love in plant breeding investigations, Donald Reddick in plant pathology, J. G. Needham in limnology and general biology, H. E. Ross in dairy industry, and H. W. Riley in farm mechanics; as instructor, K. C. Livermore in farm crops; and as assistants, F. S. Harris in soil technology, Robert Matheson in entomology, W. S. Lyon in poultry investigations, A. T. Moir in poultry husbandry, and L. B. Cook in dairy industry.

A series of farm barns and greenhouses is being erected.

Office of Experiment Stations.—L. W. Fetzer, Ph. D., assistant chemist of the Maryland Station, has accepted a position on the editorial staff of *Experiment Station Record*, to have charge of the work in agricultural chemistry. He will enter upon his new duties about September 1. J. M. Stedman, entomologist of the Missouri University and Station, has been appointed assistant farmers' institute specialist beginning May 21. F. W. Howe, instructor in agriculture at the Michigan College and of long experience as teacher and principal of public schools in Michigan, has been appointed assistant in agricultural education, and has entered upon his duties.

The Automobile in Agriculture.—It is announced in *La Moto-Culture*, a new monthly journal devoted to the agricultural motor and its applications, that the First International Congress of the Agricultural Automobile and the Application of Mechanical Motors in Agriculture will be held at Amiens, France, July 22 and 23, 1909, in connection with the Second International Exposition of the Agricultural Automobile and the Agricultural Motor. The address of the general secretary is 166 Boulevard de Magenta, Paris.

INDEX OF NAMES.

INDEX OF SUBJECTS.

NOTE.—The abbreviations "Ala. College," "Conn. State," "Mass.," etc., after entries refer to the publications of the respective experiment stations; "Alaska," "Hawaii," and "P. R." to those of the experiment stations in Alaska, Hawaii, and Porto Rico; "Can." to those of the experiment stations in Canada, and "U. S. D. A." to those of this Department.

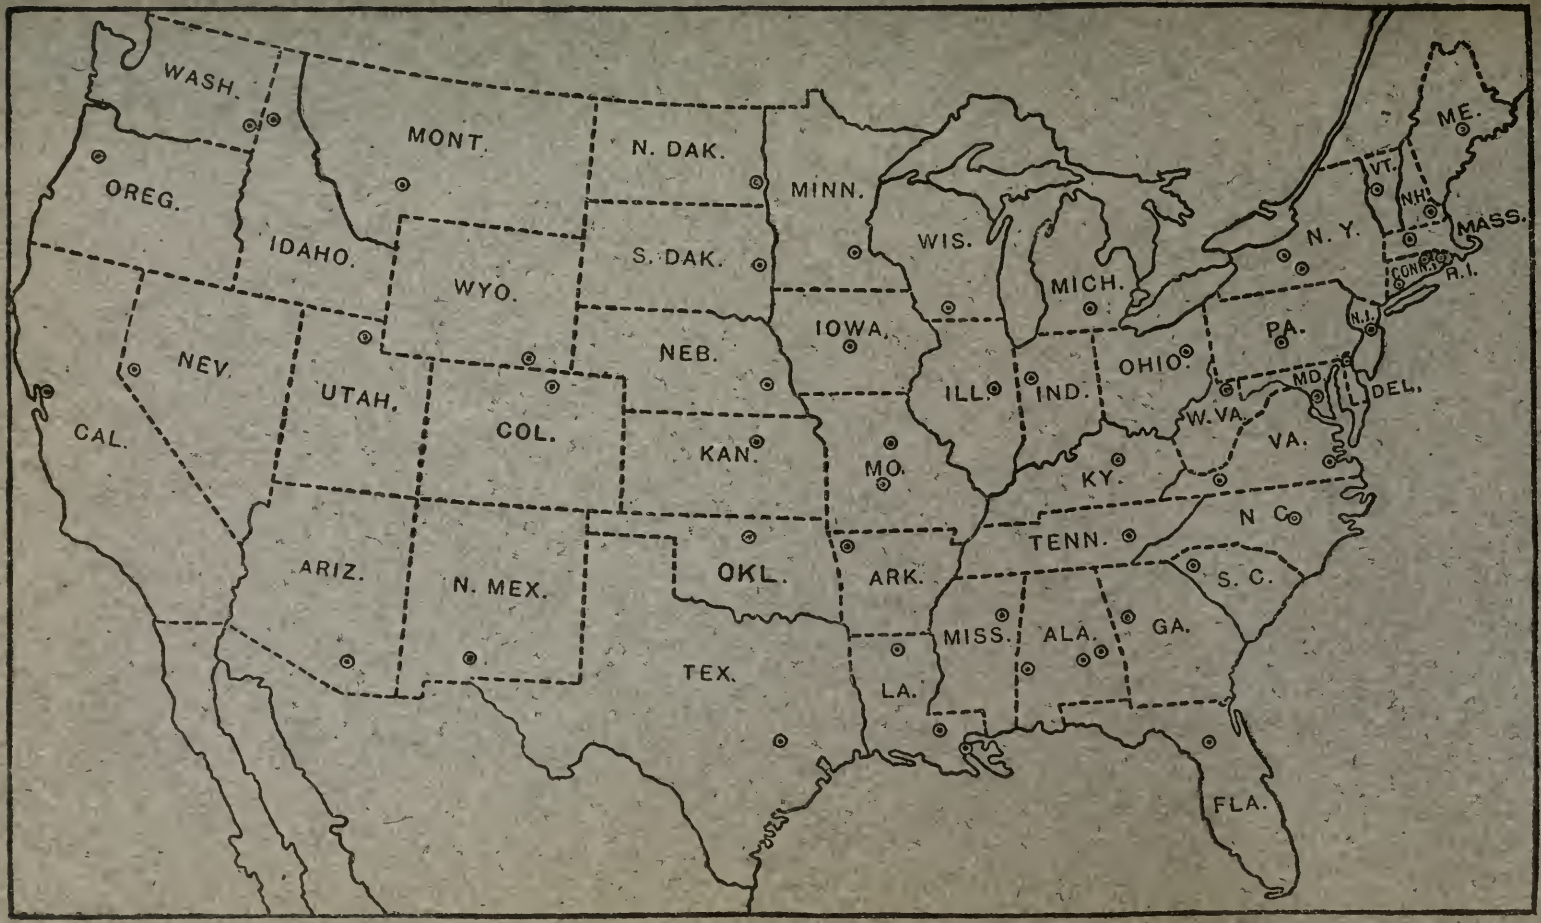
BULLETINS OF THE OFFICE OF EXPERIMENT STATIONS.

Experiment Station Record, Vols. I–XIX, with indexes; Vol. XX, Nos. 1–6.

Bulletins.—Nos. 1, Organization and History of the Stations; 2, Digest of Reports of the Stations, 1888; 3, Meeting of Horticulturists, 1889; 4, List of Station Horticulturists; 5, 12, 13, 19, 23, 27, 39, 47, 59, 74, 88, 111, 122, 137, 151, 161, 176, 197, 206, Organization Lists of Stations and Colleges; 6, List of Station Botanists; 7, 16, 20, 24, 30, 41, 49, 65, 76, 99, 115, 123, 142, 153, 164, 184, 196, Proceedings of Association of Colleges and Stations; 8, 22, 106, Investigations at Rothamsted; 9, Fermentations of Milk; 10, Meteorological Work for Agricultural Institutions; 11, A Compilation of Analyses of American Feeding Stuffs; 14, Convention of National League for Good Roads; 15, Handbook of Experiment Station Work; 17, Suggestions for Food Laboratories; 18, Assimilation of Nitrogen by Mustard; 25, Dairy Bacteriology; 26, Experiment Stations—Their Objects and Work; 28, Composition of American Food Materials; 29, 53, 89, 187, Nutrition Investigations, University of Tennessee; 31, Dietary Studies, University of Missouri, 1895; 33, The Cotton Plant; 35, Nutrition Investigations in New Jersey; 36, Irrigation in Connecticut and New Jersey; 37, Dietary Studies, Maine State College; 38, 71, Dietary Studies of Negroes in Alabama and Eastern Virginia; 40, 54, Dietary Studies in New Mexico; 42, Cotton Culture in Egypt; 43, Losses in Boiling Vegetables, and the Composition and Digestibility of Potatoes and Eggs; 44, 45, 63, 69, 169, 117, 121, 136, 175, Metabolism Experiments; 46, 116, Dietary Studies in New York City; 48, 62, 82, 94, Reports to Congress on Agriculture in Alaska; 50, 61, 83, 93, Reports on the Work and Expenditures of the Agricultural Experiment Stations; 51, 64, 78, 97, 114, 128, Statistics of Colleges and Stations; 52, Nutrition Investigations in Pittsburg, Pa., 1894–1896; 55, Dietary Studies in Chicago; 57, Varieties of Corn; 58, Water Rights on the Missouri River and Tributaries; 60, Laws for Acquiring Titles to Water from the Missouri River and Tributaries; 66, Physiological Effect of Creatin and Creatinin; 67, 85, 101, 120, 143, 156, Studies on Bread and Bread Making; 68, Some Chinese Vegetable Food Materials and Their Value; 70, Water-Right Problems of Bear River; 72, Farmers' Reading Courses; 73, Irrigation in the Rocky Mountain States; 77, Digestibility of American Feeding Stuffs; 79, Farmers' Institutes—History and Status; 80, Experiment Stations in the United States; 81, Irrigation in Wyoming and its Relation to Ownership and Distribution; 84, Nutrition Investigations, California Experiment Station; 86, Use of Water in Irrigation; 87, Irrigation in New Jersey; 90, Irrigation in Hawaii; 91, Nutrition Investigations, University of Illinois, North Dakota Agricultural College, and Lake Erie College, Ohio; 92, Reservoir System of the Cache la Poudre Valley; 95, Report on the Agricultural Resources and Capabilities of Hawaii; 96, Irrigation Laws of the Northwest Territories; 98, The Effect of Muscular Work on Food Consumption, Digestion, and Metabolism of Bicyclers; 100, Report of Irrigation Investigations in California; 102, 141, 162, Cooking of Meats; 103, Evolution of Reaping Machines; 104, 119, 133, 158, Reports of Irrigation Investigations, 1900, 1901, 1902, 1904; 105, Irrigation in the United States; 107, 132, Fruit and Chinese Dietaries in California; 108, Irrigation Practice Among Fruit Growers on the Pacific Coast; 110, 120, 138, 154, 165, 182, 199, Proceedings of Farmers' Institute Workers; 112, Agricultural Experiment Stations in Foreign Countries; 113, Irrigation of Rice in the United States; 118, Irrigation from Big Thompson River; 124, Report of Irrigation Investigations in Utah; 125, A Digest of Recent Experimenta on Horse Feeding; 127, Instruction in Agronomy at Some Agricultural Colleges; 129, Dietary Studies in Boston, Springfield, Philadelphia, and Chicago; 130, Egyptian Irrigation; 131, Plans of Structures in Use on Irrigation Canals in the United States; 134, Storage of Water on Cache la Poudre and Big Thompson Rivers; 135, Legislation Relating to Farmers' Institutes; 139, Special and Short Courses in Agricultural Colleges; 140, Acquirement of Water Rights in the Arkansas Valley in Colorado; 144, 190, Irrigation in Northern Italy; 145, Preparing Land for Irrigation and Methods of Applying Water; 146, Current Wheels—Their Use in Lifting Water for Irrigation; 147, Report on Drainage Investigations, 1903; 148, Report on Irrigation Investigations in Humid Sections of the United States; 149, Studies of the Food of Maine Lumbermen; 150, Dietary Studies at the Government Hospital for the Insane, Washington, D. C.; 152, Dietary Studies with Harvard University Students; 155, Agricultural Instruction for Adults in the British Empire; 157, Water Rights on Interstate Streams; 159, A Digest of Japanese Investigations on the Nutrition of Man; 160, School Gardens; 163, Agricultural Instruction for Adults in Continental Countries; 166, Course in Cheese Making for Movable Schools of Agriculture; 167, Irrigation in the North Atlantic States; 168, The State Engineer and His Relation to Irrigation; 169, 170, 171, Reports of Agricultural Investigations in Alaska, Hawaii, and Porto Rico, 1905; 172, Irrigation in Montana; 173, Corn-Harvesting Machinery; 174, History of Farmers' Institutes in the United States; 177, Evaporation Losses in Irrigation and Water Requirements of Crops; 178, Course in Fruit Growing for Movable Schools of Agriculture; 179, Small Reservoirs in Wyoming, Montana, and South Dakota; 180, Publications of the Agricultural Experiment Stations in the United States; 181, Mechanical Tests of Pumping Plants in California; 183, Mechanical Tests of Pumps and Pumping Plants Used for Irrigation and Drainage in Louisiana; 185, Iron in Food and Its Functions in Nutrition; 186, Exercises in Elementary Agriculture—Plant Production; 188, Irrigation in the Yakima Valley, Washington; 189, Report on Drainage of Eastern North Dakota; 191, Tests of Internal-Combustion Engines on Alcohol Fuel; 192, Irrigation and Drainage Laws of Italy; 193, Studies of the Effect of Different Methods of Cooking upon the Thoroughness and Ease of Digestion of Meat, University of Illinois; 194, A Review of Investigations in Soil Bacteriology; 195, Simple Exercises Illustrating Some Applications of Chemistry to Agriculture; 198, Prevention of Injury by Floods in the Neosho Valley, Kansas; 200, Course in Cereal Foods and Their Preparation for Movable Schools of Agriculture; 201, Cost of Pumping from Wells for the Irrigation of Rice in Louisiana and Arkansas; 202, Digestibility of Starch of Different Sorts as Affected by Cooking; 203, Distribution of Water in the Soil in Furrow Irrigation; 204, School Gardening and Nature Study in English Rural Schools and in London; 205, Irrigation in Wyoming; 207, Irrigation in the Sacramento Valley, California.



THE AGRICULTURAL EXPERIMENT STATIONS OF THE UNITED STATES
